NSFOCUS Firewall Series

NF Command Reference

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

About the NSFOCUS firewall series command references

The NSFOCUS firewall series command references describe the commands and command syntax options available for the NSFOCUS firewall series.

Applicable hardware and software versions

To obtain software version information for a device, use the **`display version`** command in any view on the device. The command references use the R8560P28 versions as examples to illustrate feature commands. For information about feature changes in other software versions, see the release notes for your device.

Contents

Table 1 lists features included in each command reference. Support for the features depends on the device model.

Table 1 Command reference content

Command reference	Content
Fundamentals Command Reference	Covers the commands for using the CLI and logging in to and setting up a firewall. This command reference includes: • CLI (command privilege settings and CLI management commands) • RBAC • Login management (including login methods and login user access control) • License management • Device management • FTP and TFTP • File system management • Configuration file management • Software upgrade • ISSU • Automatic configuration • Tcl • Python
Virtual Technologies Command Reference	Covers the commands for configuring virtual technologies features. .This command reference includes: • IRF • Context • Reth interface and redundancy group
Security Command Reference	Covers security feature commands. Available security features include identity authentication (AAA and PKI), access security (portal), secure management (SSH), and attack protection (ARP attack protection, uRPF, and attack detection and prevention). This command reference includes: • Security zone • Security policy • ASPF

Command reference	Content
	• Session management • Object group • IP source guard • AAA • 802.1X • User identification • Password control • Portal • MAC authentication • IPoE • Public key management • PKI • SSH • SSL • Connection limit • Attack detection and prevention • Server connection detection • ARP attack protection • ND attack defense • uRPF • IP-MAC binding • APR • Keychain • Crypto engine • MAC learning through a Layer 3 device • SMS
DPI Command Reference	Covers the commands for configuring deep packet inspection (DPI). This command reference includes: • DPI engine • IPS • URL filtering • Data filtering • File filtering • Anti-virus • Data analysis center • Proxy policy
NAT Command Reference	Covers the commands for configuring NAT features. This command reference includes: • NAT • NAT66 • AFT
VPN Command Reference	Covers the commands of multiple VPN technologies. This command reference includes: • SSL VPN • IPsec, • ADVPN • Tunneling • GRE • L2TP
Internet Access Behavior	Covers the Internet access behavior management commands. This

Command reference	Content
Management Command Reference	command reference includes: • Bandwidth management • Application audit and management • NetShare control
Load Balancing Command Reference	Covers the commands for configuring load balancing.
High Availability Command Reference	Covers high availability commands for managing failure detection and failover.
Interface Command Reference	Covers the interface management commands. This command reference includes: • Bulk interface • Ethernet interface • Loopback, null, and inloopback interfaces
Layer 2—LAN Switching Command Reference	Covers the commands for configuring Layer 2 technologies and features in a LAN switched network. This command reference includes: • MAC address table • Ethernet link aggregation • VLAN • VLAN termination • Spanning tree • LLDP • Layer 2 forwarding
Layer 2—WAN Access Command Reference	Covers the Layer 2 WAN access commands. This command reference includes: • PPP • Mobile communication modem
Layer 3—IP Services Command Reference	Covers the commands for configuring and managing IP addressing (including static and dynamic IPv4 and IPv6 address assignment), network performance optimization, ARP, and interoperation between IPv4 and IPv6. This command reference includes: • IP addressing • IP forwarding basics • Fast forwarding • ARP (including proxy ARP) • IPv6 basics • IPv6 fast forwarding • DHCP • DHCPv6 • DNS • IP performance optimization • Multi-CPU packet distribution • Adjacency table • Web caching
Layer 3—IP Routing Command Reference	Covers the commands for configuring routes for IPv4 and IPv6 networks of different sizes, route filtering, route control, and policy based routing. This command reference includes: • Basic IP routing • Static routing • IPv6 static routing • RIP

Command reference	Content
	• RIPng • OSPF • OSPFv3 • IS-IS • BGP • Policy-based routing • IPv6 policy-based routing • Routing policy • Guard route • RIR
ACL and QoS Command Reference	Covers the commands for classifying traffic with ACLs, and allocating network resources and managing congestions with QoS technologies to improve network performance and network use efficiency. This command reference includes: • ACL • QoS (including QoS policy and traffic policing) • Time range
IP Multicast Command Reference	Covers the commands for Layer 3 multicast protocols. This command reference includes: • Multicast routing and forwarding • IGMP • PIM • IPv6 multicast routing and forwarding • MLD
Network Management and Monitoring Command Reference	Covers the commands that help you manage and monitor your network, for example, manage system events, collect traffic statistics, sample packets, assess network performance, and test network connectivity. This command reference includes: • Information center • Flow log • Fast log output • NetStream • Cloud connection • Mirroring • Packet capture • NQA • Track • BFD • Monitor Link • Smart Link • Interface backup • Interface collaboration • System maintenance and debugging • NTP • EAA • Process monitoring and maintenance • NETCONF • SNMP • RMON • Event MIB • CWMP

Command reference	Content
	• Process placement
VPN Instance Command Reference	Covers the commands for configuring VPN instances.
VXLAN Command Reference	Covers the commands for configuring VXLANs.
Service Chain Command Reference	Covers the commands for configuring *Service Chain*.

NSFOCUS Firewall Series

NF Fundamentals Command Reference

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

This command reference describes commands that help you get started with the device. It includes the commands for the following features and tasks:

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Basic CLI commands

alias

Use **alias** to configure a command alias.

Use **undo alias** to delete a command alias.

Syntax

alias *alias command*

undo alias *alias*

Default

The device has a set of system-defined command aliases, as listed in Table 1.

Table 1 System-defined command aliases

Command alias	Command or command keyword
access-list	**acl**
end	**return**
erase	**delete**
exit	**quit**
hostname	**sysname**
logging	**info-center**
no	**undo**
show	**display**
write	**save**

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

alias: Specifies an alias, a case-sensitive string of 1 to 20 characters. An alias cannot be **alias** or contain spaces.

command: Specifies a command string. Make sure the command string meets the syntax requirements.

Usage guidelines

System-defined command aliases cannot be deleted.

You can configure one or more aliases for a command or the starting keywords of commands. Then, you can use the aliases to execute the command or commands. If the command or commands have **undo** forms, you can also use the aliases to execute the **undo** command or commands.

For example, if you configure the alias **shiprt** for **display ip routing-table**, you can enter **shiprt** to execute the **display ip routing-table** command. If you configure the alias **ship** for **display ip**, you can use **ship** to execute all commands that start with **display ip**:

- Enter **ship routing-table** to execute the **display ip routing-table** command.
- Enter **ship interface** to execute the **display ip interface** command.

The command string can include up to nine parameters. Each parameter starts with the dollar sign ($) and a sequence number in the range of 1 to 9. For example, you can configure the alias **shinc** for the **display ip $1 | include $2** command. Then, to execute the **display ip routing-table | include Static** command, you only need to enter **shinc routing-table Static**. To execute the **display ip interface | include GigabitEthernet1/0/1** command, you only need to enter **shinc interface GigabitEthernet1/0/1**.

Examples

Configure **shiprt** as the alias for the **display ip routing-table** command and verify the configuration.

```
<Sysname> system-view
[Sysname] alias shiprt display ip routing-table
[Sysname] shiprt
Destinations : 13        Routes : 13
Destination/Mask   Proto   Pre Cost        NextHop         Interface
0.0.0.0/32         Direct  0   0           127.0.0.1       InLoop0
3.3.3.3/32         Static  60  0           192.168.1.62    GE1/0/1
127.0.0.0/8        Direct  0   0           127.0.0.1       InLoop0
127.0.0.0/32       Direct  0   0           127.0.0.1       InLoop0
127.0.0.1/32       Direct  0   0           127.0.0.1       InLoop0
127.255.255.255/32 Direct  0   0           127.0.0.1       InLoop0
169.254.0.0/24     Direct  0   0           169.254.0.188   GE1/0/1
169.254.0.0/32     Direct  0   0           169.254.0.188   GE1/0/1
169.254.0.188/32   Direct  0   0           127.0.0.1       InLoop0
169.254.0.255/32   Direct  0   0           169.254.0.188   GE1/0/1
224.0.0.0/4        Direct  0   0           0.0.0.0         NULL0
224.0.0.0/24       Direct  0   0           0.0.0.0         NULL0
255.255.255.255/32 Direct  0   0           127.0.0.1       InLoop0
```

Configure **shinc** as the alias for **display ip $1 | include $2**.

```
[Sysname] alias shinc display ip $1 | include $2
```

Use alias **shinc** to display all static routes.

```
[Sysname] shinc routing-table Static
3.3.3.3/32         Static  60  0           192.168.1.62     GE1/0/1
```

Related commands

display alias

display | { begin | exclude | include }

Use **display |** { **begin** | **exclude** | **include** } to filter the output from a **display** command with a regular expression.

Syntax

display *command* **|** { **begin** | **exclude** | **include** } *regular-expression*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

command: Specifies the keywords and arguments of a **display** command. To display available keywords and arguments, enter **display ?**.

begin: Displays the first line matching the specified regular expression and all subsequent lines.

exclude: Displays all lines not matching the specified regular expression.

include: Displays all lines matching the specified regular expression.

regular-expression: Specifies a regular expression, a case-sensitive string of 1 to 256 characters.

Usage guidelines

Use the **|** { **begin** | **exclude** | **include** } *regular-expression* option with a **display** command to filter the command output. For more information about regular expressions, see *Fundamentals Configuration Guide*.

Examples

Display the lines that contain **vlan** in the running configuration.

```
<Sysname> display current-configuration | include vlan
vlan 1
vlan 999
 port access vlan 999
```

display | by-linenum

Use **display | by-linenum** to number each output line for a **display** command.

Syntax

display *command* **| by-linenum**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

command: Specifies the keywords and arguments of a **display** command. To display available keywords and arguments, enter **display ?**.

Usage guidelines

By numbering each output line from a **display** command, you can easily identify the lines of interest.

Each line number is displayed as a 5-character string and might be followed by a colon (:) or hyphen (-). If you specify both **| by-linenum** and **| begin** *regular-expression* for a **display** command, a hyphen is displayed for all lines that do not match the regular expression.

Examples

Display VLAN 999 settings, with each output line identified by a number.

```
<Sysname> display vlan 999 | by-linenum
    1:  VLAN ID: 999
    2:  VLAN type: Static
    3:  Route interface: Configured
    4:  IPv4 address: 192.168.2.1
    5:  IPv4 subnet mask: 255.255.255.0
    6:  Description: For LAN Access
    7:  Name: VLAN 0999
    8:  Tagged ports:   None
    9:  Untagged ports:
   10:     GigabitEthernet1/0/1
   11:
```

Display the first line that begins with **user-group** in the running configuration and all of the following lines.

```
<Sysname> display current-configuration | by-linenum begin user-group
  114:  user-group system
  115-  #
  116-  return
```

display >

Use **display >** to save the output from a **display** command to a separate file.

Syntax

display *command* **>** *filename*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

command: Specifies the keywords and arguments of a **display** command. To display available keywords and arguments, enter **display ?**.

filename: Specifies the name of the file that is used to save the output, a string of 1 to 63 characters.

Usage guidelines

The **display** commands show the configuration, statistics, and states of the device. You can use the **display >** command to save the output to a file.

If the specified file does not exist, the system creates the file and saves the output to the file. If the file already exists, the system overwrites the file.

Examples

Save VLAN 1 settings to a separate file named **vlan.txt**.

```
<Sysname> display vlan 1 > vlan.txt
```

Check the content of the **vlan.txt** file.

```
<Sysname> more vlan.txt
VLAN ID: 1
 VLAN type: Static
 Route interface: Not configured
 Description: VLAN 0001
 Name: VLAN 0001
 Tagged ports:   None
 Untagged ports:
    GigabitEthernet1/0/2
```

display >>

Use **display >>** to append the output from a **display** command to the end of a file.

Syntax

display *command* **>>** *filename*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

command: Specifies the keywords and arguments of a **display** command. To display available keywords and arguments, enter **display ?**.

filename: Specifies the name of the file that is used to save the output, a string of 1 to 63 characters.

Usage guidelines

The **display** commands show the configuration, statistics, and states of the device. You can use **display >>** to save the output to a file.

If the specified file does not exist, the system creates the file and saves the output to the file. If the file already exists, the system appends the output to the end of the file.

Examples

Append the VLAN 999 settings to the end of the **vlan.txt** file.

```
<Sysname> display vlan 999 >> vlan.txt
<Sysname>
```

Check the content of the **vlan.txt** file.

```
<Sysname> more vlan.txt
VLAN ID: 1
 VLAN type: Static
 Route interface: Not configured
 Description: VLAN 0001
 Name: VLAN 0001
 Tagged ports:   None
 Untagged ports:
    GigabitEthernet1/0/2

 VLAN ID: 999
 VLAN type: Static
 Route interface: Configured
 IPv4 address: 192.168.2.1
 IPv4 subnet mask: 255.255.255.0
 Description: For LAN Access
 Name: VLAN 0999
 Tagged ports:   None
 Untagged ports:
    GigabitEthernet1/0/2
```

display alias

Use **display alias** to display command aliases.

Syntax

display alias [*alias*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

alias: Specifies a command alias. If you do not specify this argument, the command displays all command aliases.

Examples

Display all command aliases.

```
<Sysname> display alias
Index     Alias               Command key
1         access-list         acl
2         end                 return
3         erase               delete
4         exit                quit
5         hostname            sysname
6         logging             info-center
7         no                  undo
8         shinc               display $1 | include $2
9         show                display
10        sirt                display ip routing-table
11        write               save
```

Display the command alias **shinc**.

```
<Sysname> display alias shinc
Alias               Command key
shinc               display ip $1 | include $2
```

Related commands

alias

display history-command

Use **display history-command** to display all commands that are saved in the command history buffer for the current CLI session.

Syntax

display history-command

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Usage guidelines

The system automatically saves commands you have successfully executed to the command history buffer for the current CLI session. You can view them and execute them again.

By default, the system can save up to 10 commands in the buffer. You can use the **history-command max-size** command to change the buffer size. To buffer a new command when the buffer is full, the system deletes the oldest command entry in the buffer.

All commands in the command history buffer for the current CLI session will be cleared when you log out.

Examples

Display all commands saved in the command history buffer for the current CLI session.

```
<Sysname> display history-command
  system-view
  vlan 2
  quit
```

Related commands

history-command max-size

display history-command all

Use **display history-command all** to display all commands that are saved in the command history buffer for all CLI sessions.

Syntax

display history-command all

Views

Any view

Predefined user roles

network-admin

context-admin

Usage guidelines

The system automatically saves commands successfully executed by users to the command history buffer for all CLI sessions. Users can view them but cannot recall them from the buffer.

Up to 1024 commands can be saved in the command history buffer. To buffer a new command when the buffer is full, the system deletes the oldest command entry in the buffer.

A user logout does not cause the system to delete commands from the history buffer for all CLI sessions.

Examples

Display all commands saved in the command history buffer for all CLI sessions.

```
<Sysname> display history-command all
  Date       Time     Terminal   Ip              User
  03/16/2017 20:03:33 vty0       192.168.1.26    **
  Cmd:dis his all

  03/16/2017 20:03:29 vty0       192.168.1.26    **
  Cmd:sys
```

Table 2 Command output

Field	Description
Date	Date when the command was executed.
Time	Time when the command was executed.
Terminal	User line used by the user.

Field	Description
Ip	IP address of the terminal used by the user.
User	Username used by the user if the user login authentication mode is **scheme**. If the login authentication mode is **none** or **password**, this field displays ******.
Cmd	Command string entered by the user.

Related commands

`display history-command`

display hotkey

Use **`display hotkey`** to display hotkey information.

Syntax

`display hotkey`

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display hotkey information.

```
<Sysname> display hotkey
----------------- Hotkeys -----------------
           -Defined command hotkeys-
CTRL_G display current-configuration
CTRL_L display ip routing-table
CTRL_O undo debugging all
           -Undefined command hotkeys-
CTRL_T NULL
CTRL_U NULL
           -System-reserved hotkeys-
CTRL_A  Move the cursor to the beginning of the line.
CTRL_B  Move the cursor one character to the left.
CTRL_C  Stop the current command.
CTRL_D  Erase the character at the cursor.
CTRL_E  Move the cursor to the end of the line.
CTRL_F  Move the cursor one character to the right.
CTRL_H  Erase the character to the left of the cursor.
CTRL_K  Abort the connection request.
CTRL_N  Display the next command in the history buffer.
CTRL_P  Display the previous command in the history buffer.
CTRL_R  Redisplay the current line.
```

```
CTRL_V  Paste text from the clipboard.
CTRL_W  Delete the word to the left of the cursor.
CTRL_X  Delete all characters from the beginning of the line to the cursor.
CTRL_Y  Delete all characters from the cursor to the end of the line.
CTRL_Z  Return to the User View.
CTRL_]  Kill incoming connection or redirect connection.
ESC_B   Move the cursor back one word.
ESC_D   Delete all characters from the cursor to the end of the word.
ESC_F   Move the cursor forward one word.
ESC_N   Move the cursor down a line.
ESC_P   Move the cursor up a line.
ESC_<   Move the cursor to the beginning of the clipboard.
ESC_>   Move the cursor to the end of the clipboard.
```

Table 3 Command output

Field	Description
CTRL_]	Terminates the current connection.
ESC_D	Deletes all characters from the cursor to the end of the word.
ESC_N	Moves the cursor down a line.
ESC_P	Moves the cursor up a line.
ESC_<	Moves the cursor to the beginning of the clipboard.
ESC_>	Moves the cursor to the end of the clipboard.

Related commands

hotkey

hotkey

Use **hotkey** to assign a command to a configurable command hotkey.

Use **undo hotkey** to restore the default.

Syntax

hotkey { **ctrl_g** | **ctrl_l** | **ctrl_o** | **ctrl_t** | **ctrl_u** } *command*

undo hotkey { **ctrl_g** | **ctrl_l** | **ctrl_o** | **ctrl_t** | **ctrl_u** }

Default

- **Ctrl+G**: **display current-configuration** (display the running configuration).
- **Ctrl+L**: **display ip routing-table** (display the IPv4 routing table information).
- **Ctrl+O**: **undo debugging all** (disable all debugging functions).
- **Ctrl+T**: No command is assigned to this hotkey.
- **Ctrl+U**: No command is assigned to this hotkey.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ctrl_g: Assigns a command to **Ctrl+G**.

ctrl_l: Assigns a command to **Ctrl+L**.

ctrl_o: Assigns a command to **Ctrl+O**.

ctrl_t: Assigns a command to **Ctrl+T**.

ctrl_u: Assigns a command to **Ctrl+U**.

command: Specifies the command to be assigned to the hotkey.

Usage guidelines

The system defines some hotkeys and provides five configurable command hotkeys. Pressing a command hotkey executes the command assigned to the hotkey.

To display system-defined and configurable hotkeys, use the **display hotkey** command.

Examples

Assign the **display tcp statistics** command to hotkey **Ctrl+T**.

```
<Sysname> system-view
[Sysname] hotkey ctrl_t display tcp statistics
```

Related commands

display hotkey

quit

Use **quit** to return to the upper-level view.

Syntax

quit

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Usage guidelines

Executing this command in user view disconnects you from the device.

Examples

Return from GigabitEthernet 1/0/1 interface view to system view and then to user view.

```
[Sysname-GigabitEthernet1/0/1] quit
[Sysname] quit
<Sysname>
```

repeat

Use **repeat** to repeat commands in the command history buffer for the current CLI session.

Syntax

repeat [*number*] [**count** *times*] [**delay** *seconds*]

Views

Any view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the number of the most recently executed commands in the command history buffer for the current CLI session that you want to execute. The value range is 1 to 10. The default is 1.

count *times*: Specifies the number of times that you want to execute the commands. The value range is 0 to 4294967295. The default is 0. If you do not specify this option, the system keeps executing the commands until you press the escape key to terminate the execution.

delay *seconds*: Specifies the time (in seconds) for the system to wait before executing the commands again. The value range is 0 to 4294967295. The default is 1.

Usage guidelines

To repeat a command, first enter the view for the command. To repeat multiple commands, first enter the view for the first command.

The **repeat** command executes commands in the order they were executed.

The system waits for your interaction when it repeats an interactive command.

Examples

Configure the system to execute the two most recently executed commands (**display cpu-usage** and **display clock**) three times at an interval of 10 seconds.

```
<Sysname> repeat 2 count 3 delay 10
<Sysname> display cpu
Unit CPU usage:
      33% in last 5 seconds
      32% in last 1 minute
      33% in last 5 minutes

<Sysname> display clock
07:02:18 UTC Thu 06/19/2017
<Sysname> display cpu-usage
Unit CPU usage:
      33% in last 5 seconds
      32% in last 1 minute
      33% in last 5 minutes

<Sysname> display clock
07:02:28 UTC Thu 06/19/2017
```

```
<Sysname> display cpu-usage
Unit CPU usage:
      33% in last 5 seconds
      32% in last 1 minute
      33% in last 5 minutes

<Sysname> display clock
07:02:38 UTC Thu 06/19/2017
```

Related commands

`display history-command`

`escape-key`

`history-command max-size`

return

Use **`return`** to return to user view from any other view except Tcl configuration view and Python shell view.

Syntax

`return`

Views

Any view except user view, Tcl configuration view, and Python shell view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Usage guidelines

In any view except user view, Tcl configuration view, and Python shell view, pressing **Ctrl+Z** has the same effect as the **`return`** command.

To return to user view from Tcl configuration view, use the **`tclquit`** command.

To return to user view from Python shell view, use the **`exit()`** command.

Examples

Return to user view from GigabitEthernet 1/0/1 interface view.

```
[Sysname-GigabitEthernet1/0/1] return
<Sysname>
```

screen-length disable

Use **`screen-length disable`** to disable pausing between screens of output for the current CLI session.

Use **`undo screen-length disable`** to enable pausing between screens of output for the current CLI session.

Syntax

screen-length disable

undo screen-length disable

Default

The default depends on the configuration of the **screen-length** command in user line view.

The following are the default settings for the **screen-length** command:

- Pausing between screens of output.
- Displaying up to 24 lines on a screen.

Views

User view

Predefined user roles

network-admin

context-admin

Usage guidelines

If you disable pausing between screens of output, all output is displayed. The screen is refreshed continuously until the final screen is displayed.

This command takes effect only for the current CLI session. When you are logged out, the default is restored.

Examples

Disable pausing between screens of output for the current CLI session.

```
<Sysname> screen-length disable
```

Related commands

screen-length

system-view

Use **system-view** to enter system view from user view.

Syntax

system-view

Views

User view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Enter system view from user view.

```
<Sysname> system-view
System View: return to User View with Ctrl+Z.
[Sysname]
```

Contents

RBAC commands

description

Use **description** to configure a description for a user role for easy identification.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

A user role does not have a description.

Views

User role view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 128 characters.

Examples

Configure the description as **labVIP** for user role **role1**.

```
<Sysname> system-view
[Sysname] role name role1
[Sysname-role-role1] description labVIP
```

Related commands

display role

role

display role

Use **display role** to display user role information.

Syntax

display role [**name** *role-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

name *role-name*: Specifies a user role name, a case-sensitive string of 1 to 63 characters. If you do not specify a user role name, the command displays information about all user roles, including the predefined user roles.

Examples

Display information about user role **123**.

```
<Sysname> display role name 123
Description: 123
  VLAN policy: Permit (default)
  Interface policy: Permit (default)
  VPN instance policy: Permit (default)
  Security zone policy: Permit (default)
```

Display information about all user roles.

```
<Sysname> display role
Role: network-admin
  Description: Predefined network admin role has access to all commands on the device
  VLAN policy: Permit (default)
  Interface policy: Permit (default)

Table 1 Command output

Field	Description
Role	User role name. Predefined user role names: • network-admin. • network-operator. • context-admin. • context-operator. • level-*n* (where *n* represents an integer in the range of 0 to 15). • security-audit. • guest-manager. • system-admin. • security-admin. • audit-admin.
Description	User role description.
VLAN policy	VLAN policy of the user role: • **Deny**—Denies access to any VLANs except for permitted VLANs. • **Permit (default)**—Default VLAN policy, which enables the user role to access all VLANs.
Permitted VLANs	VLANs accessible to the user role.
Interface policy	Interface policy of the user role: • **Deny**—Denies access to any interfaces except for permitted interfaces. • **Permit (default)**—Default interface policy, which enables the user role to access all interfaces.
Permitted interfaces	Interfaces accessible to the user role.
VPN instance policy	VPN instance policy of the user role: • **Deny**—Denies access to any VPN instances except for permitted VPN instances. • **Permit (default)**—Default VPN instance policy, which enables the user role to access all VPN instances.
Permitted VPN instances	VPN instances accessible to the user role.
Security zone policy	Security zone policy of the user role: • **Deny**—Denies access to any security zones except for permitted security zones. • **Permit (default)**—Default security zone policy, which enables the user role to access all security zones.
Permitted security zones	Security zones accessible to the user role.
Rule	User role rule number. Predefined user role rules are identified by sys-*n*, where *n* represents an integer.
Perm	Access control type: • **Permit**—User role has access to the items in the **Entity** field. • **Deny**—User role does not have access to the items in the **Entity** field.

Field	Description
Type	Controlled type: • **R**—Read-only. • **W**—Write. • **X**—Execute.
Scope	Rule control scope: • **command**—Controls access to the command or commands, as specified in the **Entity** field. • **feature**—Controls access to the commands of the feature, as specified in the **Entity** field. • **feature-group**—Controls access to the commands of the features in the feature group, as specified in the **Entity** field. • **web-menu**—Controls access to Web menus. • **xml-element**—Controls access to XML elements. • **oid**—Controls access to MIB nodes.
Entity	Command string, feature name, feature group, Web menu, XML element, or OID specified in the user role rule: • An en dash (–) represents any feature. • An asterisk (*) represents zero or more characters.

Related commands

role

display role feature

Use **display role feature** to display features available in the system.

Syntax

display role feature [**name** *feature-name* | **verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

name *feature-name*: Specifies a feature by feature name. The *feature-name* argument represents the feature name, and all letters must be in lower case.

verbose: Displays the commands of each feature.

Usage guidelines

If you do not specify any parameters, the command displays only the list of features available in the system.

Examples

Display the list of feature names.

```
<Sysname> display role feature
```

```
Feature: device          (Device configuration related commands)
Feature: interface       (Interface related commands)
Feature: lconn           (Lconn related commands)
Feature: syslog          (Syslog related commands)
...
```

Display the commands of each feature.

```
<Sysname> display role feature verbose

```

Table 2 Command output (display role feature name aaa)

Field	Description
Feature	Displays the name and brief function description of the feature.
system-view ; domain *	All commands that start with the **domain** keyword in system view, and all commands in ISP domain view.
system-view ; header *	All commands that start with the **header** keyword in system view.
system-view ; aaa *	All commands that start with the **aaa** keyword in system view.
display domain *	All commands that start with the **display domain** keywords in user view.
system-view ; user-group *	All commands that start with the **user-group** keyword in system view, and all commands in user group view.

Field	Description
system-view ; local-user *	All commands that start with the **local-user** keyword in system view, and all commands in local user view.
display local-user *	All commands that start with the **display local-user** keywords in user view.
display user-group *	All commands that start with the **display user-group** keywords in user view.
display debugging local-server	All commands that start with the **display debugging local-server** keywords in user view.
debugging local-server *	All commands that start with the **debugging local-server** keywords in user view.
super *	All commands that start with the **super** keyword in user view.
display password-control *	All commands that start with the **display password-control** keywords in user view.
reset password-control *	All commands that start with the **reset password-control** keywords in user view.
system-view ; password-control *	All commands that start with the **password-control** keyword in system view.
(W)	Command type is Write. A write command configures the system.
(R)	Command type is Read. A read command displays configuration or maintenance information.
(X)	Command type is Execute. An execute command executes a specific function.

Related commands

feature

display role feature-group

Use **display role feature-group** to display feature group information.

Syntax

display role feature-group [**name** *feature-group-name*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

name *feature-group-name*: Specifies a feature group. The *feature-group-name* argument represents the feature group name, a case-sensitive string of 1 to 31 characters. If you do not specify a feature group, the command displays information about all feature groups.

verbose: Displays the commands of each feature in feature groups. If you do not specify this keyword, the command displays only the feature lists of feature groups.

Usage guidelines

Feature groups **L2** and **L3** are predefined feature groups.

Examples

Display the feature lists of feature groups.

```
<Sysname> display role feature-group
Feature group: L2
Feature: igmp-snooping   (IGMP-Snooping related commands)
Feature: mld-snooping    (MLD-Snooping related commands)
Feature: lacp            (LACP related commands)
Feature: stp             (STP related commands)
Feature: lldp            (LLDP related commands)
Feature: dldp            (DLDP related commands)
Feature: smart-link      (Smart-link related commands)
Feature: monitor-link    (Monitor-link related commands)
Feature: loopbk-detect   (Loopback-detection related commands)
Feature: vlan            (Virtual LAN related commands)
Feature: evb             (EVB related commands)
Feature: ptp             (PTP related commands)
Feature: ofp             (OFP related commands)
Feature: port-security   (Port-security related commands)

Feature group: L3
Feature: route           (Route management related commands)
Feature: usr             (Unicast static route related commands)
Feature: ospf            (Open Shortest Path First protocol related commands)
Feature: rip             (Routing Information Protocol related commands)
Feature: isis            (ISIS protocol related commands)
Feature: bgp             (Border Gateway Protocol related commands)
Feature: l3vpn           (Layer 3 Virtual Private Network related commands)
Feature: route-policy    (Routing Policy related commands)
Feature: multicast       (Multicast related commands)
Feature: pim             (Protocol Independent Multicast related commands)
Feature: igmp            (Internet Group Management Protocol related commands)
Feature: mld             (Multicast Listener Discovery related commands)
Feature: rir             (RIR related commands)

Feature group: security-features
```

Display the commands in each feature group. For more information about the wildcards and marks used in the command list, see Table 2.

```
<Sysname> display role feature-group verbose
Feature group: L2
Feature: igmp-snooping   (IGMP-Snooping related commands)
  display l2-multicast *    (R)
  system-view ; probe ; display system internal l2-multicast *    (R)
  reset l2-multicast *    (W)
```

```

```

Display the feature list of the **L3** feature group.

```
<Sysname> display role feature-group name L3
Feature group: L3
Feature: route           (Route management related commands)
Feature: usr             (Unicast static route related commands)
Feature: ospf            (Open Shortest Path First protocol related commands)
Feature: rip             (Routing Information Protocol related commands)
Feature: isis            (ISIS protocol related commands)
Feature: bgp             (Border Gateway Protocol related commands)
Feature: l3vpn           (Layer 3 Virtual Private Network related commands)
Feature: route-policy    (Routing Policy related commands)
Feature: multicast       (Multicast related commands)
```

```
Feature: pim             (Protocol Independent Multicast related commands)
Feature: igmp            (Internet Group Management Protocol related commands)
Feature: mld             (Multicast Listener Discovery related commands)
Feature: rir             (RIR related commands)
```

Related commands

feature

role feature-group

feature

Use **feature** to add a feature to a feature group.

Use **undo feature** to remove a feature from a feature group.

Syntax

feature *feature-name*

undo feature *feature-name*

Default

A user-defined feature group does not have any features.

Views

Feature group view

Predefined user roles

network-admin

context-admin

Parameters

feature-name: Specifies a feature name. You must enter the feature name in lower case.

Usage guidelines

Repeat the **feature** command to add multiple features to a feature group.

Examples

Add the AAA and ACL features to feature group **security-features**.

```
<Sysname> system-view
[Sysname] role feature-group name security-features
[Sysname-featuregrp-security-features] feature aaa
[Sysname-featuregrp-security-features] feature acl
```

Related commands

display role feature

display role feature-group

role feature-group

interface policy deny

Use **interface policy deny** to enter user role interface policy view.

Use **undo interface policy deny** to restore the default.

Syntax

interface policy deny

undo interface policy deny

Default

A user role has access to all interfaces.

Views

User role view

Predefined user roles

network-admin

context-admin

Usage guidelines

CAUTION:

This command denies a user role access to any interfaces if you do not specify accessible interfaces by using the **permit interface** command. To configure an interface, make sure the interface is permitted by the user role interface policy in use.

To limit the scope of interfaces accessible to a user role, perform the following tasks:

1. Use **interface policy deny** to enter user role interface policy view and deny the user role access to any interfaces.
2. Use **permit interface** to specify accessible interfaces.

You can perform the following tasks on an accessible interface:

- Create, remove, or configure the interface.
- Enter interface view.
- Specify the interface in feature commands.

The create and remove operations are available only for logical interfaces.

Any change to a user role interface policy takes effect only on users who log in with the user role after the change.

Examples

Enter user role interface policy view of **role1**, and deny **role1** to access any interfaces.

```
<Sysname> system-view
[Sysname] role name role1
[Sysname-role-role1] interface policy deny
[Sysname-role-role1-ifpolicy] quit
```

Enter user role interface policy view of **role1**, and permit **role1** to access only interfaces GigabitEthernet 1/0/1 to GigabitEthernet 1/0/2.

```
<Sysname> system-view
[Sysname] role name role1
[Sysname-role-role1] interface policy deny
[Sysname-role-role1-ifpolicy] permit interface gigabitethernet 1/0/1 to gigabitethernet
1/0/2
```

Related commands

display role

permit interface

role

permit interface

Use **permit interface** to configure a list of interfaces accessible to a user role.

Use **undo permit interface** to disable the access of a user role to specific interfaces.

Syntax

permit interface *interface-list*

undo permit interface [*interface-list*]

Default

No permitted interfaces are configured in user role interface policy view.

Views

User role interface policy view

Predefined user roles

network-admin

context-admin

Parameters

interface-list: Specifies a space-separated list of up to 10 interface items. Each interface item specifies one interface in the *interface-type interface-number* form or a range of interfaces in the *interface-type interface-number* **to** *interface-type interface-number* form. If you specify an interface range, the end interface must meet the following requirements:

- Be the same type as the start interface.
- Have a higher interface number than the start interface.

Usage guidelines

To permit a user role to access an interface after you use the **interface policy deny** command, you must add the interface to the permitted interface list of the policy. With the user role, you can perform the following tasks to the interfaces in the permitted interface list:

- Create, remove, or configure the interfaces.
- Enter the interface views.
- Specify the interfaces in feature commands.

The create and remove operations are available only for logical interfaces.

You can repeat the **permit interface** command to add multiple permitted interfaces to a user role interface policy.

The **undo permit interface** command removes the entire list of permitted interfaces if you do not specify an interface.

Any change to a user role interface policy takes effect only on users who log in with the user role after the change.

Examples

1. Configure user role **role1**:

Permit user role **role1** to execute all commands available in interface view.

```
<Sysname> system-view
[Sysname] role name role1
```

```
[Sysname-role-role1] rule 1 permit command system-view ; interface *
```

Permit the user role to execute all commands available in VLAN view.

```
[Sysname-role-role1] rule 2 permit command system-view ; vlan *
```

Permit the user role to access only GigabitEthernet 1/0/1.

```
[Sysname-role-role1] interface policy deny
[Sysname-role-role1-ifpolicy] permit interface gigabitethernet 1/0/1
[Sysname-role-role1-ifpolicy] quit
[Sysname-role-role1] quit
```

2. Verify that you cannot use user role **role1** to work on any interfaces except for GigabitEthernet 1/0/1:

Verify that you can enter GigabitEthernet 1/0/1 interface view.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] quit
```

Verify that you can assign GigabitEthernet 1/0/1 to VLAN 10. In this example, the user role can access all VLANs because the default VLAN policy of the user role is used.

```
[Sysname] vlan 10
[Sysname-vlan10] port gigabitethernet 1/0/1
[Sysname-vlan10] quit
```

Verify that you cannot enter interface view of GigabitEthernet 1/0/2.

```
[Sysname] interface gigabitethernet 1/0/2
Permission denied.
```

role

permit security-zone

Use **permit security-zone** to configure a list of security zones accessible to a user role.

Use **undo permit security-zone** to remove the permission for a user role to access specific security zones.

Syntax

permit security-zone *security-zone-name*&<1-10>

undo permit security-zone [*security-zone-name*&<1-10>]

Default

No permitted security zones are configured in user role security zone policy view.

Views

User role security zone policy view

Predefined user roles

network-admin

context-admin

Parameters

security-zone-name&<1-10>: Specifies a space-separated list of up to 10 security zone names. Each name is a case-sensitive string of 1 to 31 characters.

Usage guidelines

To permit a user role to access a security zone after you use the **security-zone policy deny** command, you must add the security zone to the permitted security zone list of the policy. With the user role, you can perform the following tasks on the security zones in the permitted security zone list:

- Create, remove, or configure the security zones.
- Enter the security zone views.
- Specify the security zones in feature commands.

You can repeat the **permit security-zone** command to add multiple permitted security zones to a user role security zone policy.

The **undo permit security-zone** command removes the entire list of permitted security zones if you do not specify a security zone.

Any change to a user role security zone policy takes effect only on users who log in with the user role after the change.

Examples

1. Configure user role **role1**:

Permit user role **role1** to execute all commands available in system view.

```
<Sysname> system-view
[Sysname] role name role1
[Sysname-role-role1] rule 1 permit command system-view ; *
```

Permit the user role to access security zones **trust** and **abc**.

```
[Sysname-role-role1] security-zone policy deny
[Sysname-role-role1-zonepolicy] permit security-zone trust abc
[Sysname-role-role1-zonepolicy] quit
[Sysname-role-role1] quit
```

2. Verify that you cannot use user role **role1** to work on any security zones except for security zones **trust** and **abc**:

Verify that you can create security zone **abc** and enter security zone view.

```
[Sysname] security-zone name abc
[Sysname-security-zone-abc] quit
```

Verify that you can create a zone pair with source security zone **trust** and destination zone **abc**.

```
[Sysname] zone-pair security source trust destination abc
[Sysname-zone-pair-security-Trust-abc] quit
```

Verify that you cannot create security zone **local** or enter security zone view.

```
[Sysname] security-zone name local
Permission denied.
```

Related commands

display role

role

security-zone policy deny

permit vlan

Use **permit vlan** to configure a list of VLANs accessible to a user role.

Use **undo permit vlan** to remove the permission for a user role to access specific VLANs.

Syntax

permit vlan *vlan-id-list*

undo permit vlan [*vlan-id-list*]

Default

No permitted VLANs are configured in user role VLAN policy view.

Views

User role VLAN policy view

Predefined user roles

network-admin

context-admin

Parameters

vlan-id-list: Specifies a space-separated list of up to 10 VLAN items. Each VLAN item specifies a VLAN by VLAN ID or specifies a range of VLANs in the form of *vlan-id1* **to** *vlan-id2*. The value range for the VLAN IDs is 1 to 4094. If you specify a VLAN range, the value for the *vlan-id2* argument must be greater than the value for the *vlan-id1* argument.

Usage guidelines

To permit a user role to access a VLAN after you use the **vlan policy deny** command, you must add the VLAN to the permitted VLAN list of the policy. With the user role, you can perform the following tasks on the VLANs in the permitted VLAN list:

- Create, remove, or configure the VLANs.
- Enter the VLAN views.
- Specify the VLANs in feature commands.

You can repeat the **permit vlan** command to add multiple permitted VLANs to a user role VLAN policy.

The **undo permit vlan** command removes the entire list of permitted VLANs if you do not specify a VLAN.

Any change to a user role VLAN policy takes effect only on users who log in with the user role after the change.

By default, all access ports belong to VLAN 1. To assign an access port to any other VLAN by using the **port access vlan** command, make sure you have a user role that can access both VLAN 1 and the new VLAN.

Examples

1. Configure user role **role1**:

Permit user role **role1** to execute all commands available in interface view and VLAN view.

```
<Sysname> system-view
[Sysname] role name role1
[Sysname-role-role1] rule 1 permit command system-view ; interface *
[Sysname-role-role1] rule 2 permit command system-view ; vlan *
```

Permit user role **role1** to access VLANs 1, 2, 4, and 50 to 100.

```
[Sysname-role-role1] vlan policy deny
[Sysname-role-role1-vlanpolicy] permit vlan 1 2 4 50 to 100
[Sysname-role-role1-vlanpolicy] quit
[Sysname-role-role1] quit
```

2. Verify that you cannot use user role **role1** to work on any VLANs except for VLANs 1, 2, 4, and 50 to 100:

   # Verify that you can create VLAN 100 and enter VLAN view.

   ```
   [Sysname] vlan 100
   [Sysname-vlan100] quit
   ```

   # Verify that you can add GigabitEthernet 1/0/1 to VLAN 100 as an access port.

   ```
   [Sysname] interface gigabitethernet 1/0/1
   [Sysname-GigabitEthernet1/0/1] port access vlan 100
   [Sysname-GigabitEthernet1/0/1] quit
   ```

   # Verify that you cannot create VLAN 101 or enter VLAN view.

   ```
   [Sysname] vlan 101
   Permission denied.
   ```

permit vpn-instance

Use **permit vpn-instance** to configure a list of MPLS L3VPN instances accessible to a user role.

Use **undo permit vpn-instance** to disable the access of a user role to specific MPLS L3VPN instances.

Syntax

permit vpn-instance *vpn-instance-name*&<1-10>

undo permit vpn-instance [*vpn-instance-name*&<1-10>]

Default

No permitted VPN instances are configured in user role VPN instance policy.

Views

User role VPN instance policy view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance-name&<1-10>: Specifies a space-separated list of up to 10 MPLS L3VPN instance names. Each name is a case-sensitive string of 1 to 31 characters.

Usage guidelines

To permit a user role to access a VPN instance after you use the **vpn-instance policy deny** command, you must add the VPN instance to the permitted VPN instance list of the policy. With the user role, you can perform the following tasks on the VPN instances in the permitted VPN instance list:

- Create, remove, or configure the VPN instances.
- Enter the VPN instance views.

- Specify the VPN instances in feature commands.

You can repeat the **permit vpn-instance** command to add multiple permitted VPN instances to a user role VPN instance policy.

The **undo permit vpn-instance** command removes the entire list of permitted VPN instances if you do not specify a VPN instance.

Any change to a user role VPN instance policy takes effect only on users who log in with the user role after the change.

Examples

1. Configure user role **role1**:

Permit the user role to execute all commands available in system view and in the child views of system view.

```
<Sysname> system-view
[Sysname] role name role1
[Sysname-role-role1] rule 1 permit command system-view ; *
```

Permit the user role to access VPN instance **vpn1**.

```
[Sysname-role-role1] vpn policy deny
[Sysname-role-role1-vpnpolicy] permit vpn-instance vpn1
[Sysname-role-role1-vpnpolicy] quit
[Sysname-role-role1] quit
```

2. Verify that you cannot use user role **role1** to work on any VPN instances except for **vpn1**:

Verify that you can enter the view of **vpn1**.

```
[Sysname] ip vpn-instance vpn1
[Sysname-vpn-instance-vpn1] quit
```

Verify that you can specify the primary accounting server at 10.110.1.2 in VPN instance **vpn1** for RADIUS scheme **radius1**.

```
[Sysname] radius scheme radius1
[Sysname-radius-radius1] primary accounting 10.110.1.2 vpn-instance vpn1
[Sysname-radius-radius1] quit
```

Verify that you cannot create VPN instance **vpn2** or enter VPN instance view.

```
[Sysname] ip vpn-instance vpn2
Permission denied.
```

Related commands

display role

role

vpn-instance policy deny

role

Use **role** to create a user role and enter its view, or enter the view of an existing user role.

Use **undo role** to delete a user role.

Syntax

role name *role-name*

undo role name *role-name*

Default

The system has the following predefined user roles: network-admin, network-operator, context-admin, context-operator, level-*n* (where *n* represents an integer in the range of 0 to 15), guest-manager, security-audit, system-admin, security-admin, and audit-admin.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

name *role-name*: Specifies a username. The *role-name* argument is a case-sensitive string of 1 to 63 characters.

Usage guidelines

You can create a maximum of 64 user roles in addition to the predefined user roles.

You cannot delete the predefined user roles or change the permissions assigned to network-admin, network-operator, context-admin, context-operator, level-15, guest-manager, security-audit, system-admin, security-admin, or audit-admin.

The access permissions of the level-0 to level-14 user roles can be modified through user role rules and resource access policies. However, you cannot make changes on the predefined access permissions of these user roles. For example, you cannot change the access permission of these user roles to the **display history-command all** command.

Examples

Create user role **role1** and enter its view.

```
<Sysname> system-view
[Sysname] role name role1
[Sysname-role-role1]
```

Related commands

display role

interface policy deny

rule

vlan policy deny

vpn-instance policy deny

role default-role enable

Use **role default-role enable** to enable the default user role feature for remote AAA users.

Use **undo role default-role enable** to restore the default.

Syntax

role default-role enable [*role-name*]

undo role default-role enable

Default

The default user role feature is disabled. AAA users who do not have a user role cannot log in to the device.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

role-name: Specifies a user role by its name for the default user role. The user role must already exist. The argument is a case-sensitive string of 1 to 63 characters.

Usage guidelines

The default user role feature assigns the default user role to AAA-authenticated users if the authentication server (local or remote) does not assign any user roles to the users. These users are allowed to access the system with the default user role.

For local authorization, this command is required if you do not use the **authorization-attribute user role** command to assign user roles to local users.

If AAA users have been assigned user roles, they log in with the user roles.

If you do not specify the *role-name* argument, the following default user role settings apply:

- For login to the default context, the default user role is network-operator.
- For login to a non-default context, the default user role is context-operator.

Examples

Enable the default user role feature.

```
<Sysname> system-view
[Sysname] role default-role enable
```

Related commands

role

role feature-group

Use **role feature-group** to create a user role feature group and enter its view, or enter the view of an existing user role feature group.

Use **undo role feature-group** to delete a user role feature group.

Syntax

role feature-group name *feature-group-name*

undo role feature-group name *feature-group-name*

Default

Two user role feature groups **L2** and **L3** exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

name *feature-group-name*: Specifies a feature group name. The *feature-group-name* argument is a case-sensitive string of 1 to 31 characters.

Usage guidelines

The **L2** feature group includes all Layer 2 feature commands, and the **L3** feature group includes all Layer 3 feature commands. These predefined feature groups are not user configurable.

In addition to the predefined feature groups **L2** and **L3**, you can create a maximum of 64 user role feature groups.

Examples

Create feature group **security-features** and enter its view.

```
<Sysname> system-view
[Sysname] role feature-group name security-features
[Sysname-featuregrp-security-features]
```

Related commands

display role feature

display role feature-group

feature

rule

Use **rule** to create or change a user role rule.

Use **undo rule** to delete user role rules.

Syntax

rule *number* { **deny** | **permit** } { **command** *command-string* | { **execute** | **read** | **write** } * { **feature** [*feature-name*] | **feature-group** *feature-group-name* | **oid** *oid-string* | **web-menu** [*web-string*] | **xml-element** [*xml-string*] } }

undo rule { *number* | **all** }

Default

A user-defined user role does not have any rules and cannot access any resources.

Views

User role view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies a rule number in the range of 1 to 256.

deny: Denies access to the specified commands, Web menus, XML elements, or MIB nodes.

permit: Permits access to the specified commands, Web menus, XML elements, or MIB nodes.

command *command-string*: Specifies a command string. The command string can represent a command or a group of commands. The *command-string* argument is a case-sensitive string of 1 to 128 characters, including the wildcard asterisk (*), the delimiters space and tab, and all printable characters. If the command string includes a left bracket ([) or right bracket (]), you must add a back

slash (\) as the escape character before the left or right bracket. For example, to specify the **statistics[ifindex="*"]** command, you must enter **statistics\[ifindex="*"\]** for the *command-string* argument.

execute: Specifies the execute commands, Web menus, XML elements, or MIB nodes to execute a specific function or program. The **ping** command is an example of execute commands.

read: Specifies the read commands, Web menus, XML elements, or MIB nodes to display configuration or maintenance information. The **display**, **dir**, **more**, and **pwd** commands are examples of read commands.

write: Specifies the write commands, Web menus, XML elements, or MIB nodes to configure the system. The **ssh server enable** command is an example of write commands.

feature [*feature-name*]: Specifies one or all features. The *feature-name* argument is a case-sensitive character string. If you do not specify a feature name, you specify all the features in the system.

feature-group *feature-group-name*: Specifies a user-defined or predefined feature group. The *feature-group-name* argument represents the feature group name, a case-sensitive string of 1 to 31 characters. If the feature group has not been created, the rule takes effect after the group is created. To display the feature groups that have been created, use the **display role feature-group** command.

oid *oid-string*: Specifies an OID of a MIB node. The *oid-string* argument represents the OID, a case-insensitive string of 1 to 255 characters. The OID is a dotted numeric string that uniquely identifies the path from the root node to this node. For example, 1.3.6.1.4.1.25506.8.35.14.19.1.1.

web-menu [*web-string*]: Specifies a Web menu. The *web-string* argument represents the ID path of the Web menu, a case-insensitive string of 1 to 255 characters. Use the forward slash (/) to separate ID items, for example, M_DEVICE/I_BASIC_INFO/I_reboot. If you do not specify a Web menu, the rule applies to all Web items. To verify the ID path of a Web menu, use the **display web menu** command.

xml-element [*xml-string*]: Specifies an XML element. The *xml-string* argument represents the XPath of the XML element, a case-insensitive string of 1 to 255 characters. Use the forward slash (/) to separate Xpath items, for example, Interfaces/Index/Name. If you do not specify an XML element, the rule applies to all XML elements.

all: Specifies all the user role rules.

Usage guidelines

You can define the following types of rules for different access control granularities:

- **Command rule**—Controls access to a command or a set of commands that match a regular expression.
- **Feature rule**—Controls access to the commands of a feature by command type.
- **Feature group rule**—Controls access to the commands of a group of features by command type.
- **Web menu rule**—Controls access to Web menus by menu type.
- **XML element rule**—Controls access to XML elements by element type.
- **OID rule**—Controls access to the specified MIB node and its child nodes by node type.

A user role can access the set of permitted resources specified in the user role rules. User role rules include predefined (identified by sys-n) and user-defined user role rules.

You can configure a maximum of 256 user-defined rules for a user role. The total number of user-defined user role rules cannot exceed 1024.

Any rule modification, addition, or removal for a user role takes effect only on the users who log in with the user role after the change.

Access to the file system commands is controlled by both the file system command rules and the file system feature rule.

A command with output redirection to the file system is permitted only when the command type write is assigned to the file system feature.

The following guidelines apply to non-OID rules:

- If two user-defined rules of the same type conflict, the rule with the higher ID takes effect. For example, a user role can use the **tracert** command but not the **ping** command if the user role contains rules configured by using the following commands:
  - **rule** *1* **permit command** *ping*
  - **rule** *2* **permit command** *tracert*
  - **rule** *3* **deny command** *ping*
- If a predefined user role rule and a user-defined user role rule conflict, the user-defined user role rule takes effect.

The following guidelines apply to OID rules:

- The system compares an OID with the OIDs specified in rules, and it uses the longest match principle to select a rule for the OID. For example, a user role cannot access the MIB node with OID 1.3.6.1.4.1.25506.141.3.0.1 if the user role contains rules configured by using the following commands:
  - **rule** *1* **permit read write oid** *1.3.6*
  - **rule** *2* **deny read write oid** *1.3.6.1.4.1*
  - **rule** *3* **permit read write oid** *1.3.6.1.4*
- If the same OID is specified in multiple rules, the rule with the higher ID takes effect. For example, a user role can access the MIB node with OID 1.3.6.1.4.1.25506.141.3.0.1 if the user role contains rules configured by using the following commands:
  - **rule** *1* **permit read write oid** *1.3.6*
  - **rule** *2* **deny read write oid** *1.3.6.1.4.1*
  - **rule** *3* **permit read write oid** *1.3.6.1.4.1*

When you specify a command string, follow the guidelines in Table 3.

Table 3 Command string configuration rules

Rule	Guidelines
Semicolon (;) is the delimiter.	Use a semicolon to separate the command of each view that you must enter before you access a command or a set of commands. However, do not use a semicolon to separate commands available in user view or any view, for example, **display** and **dir**. Each semicolon-separated segment must have a minimum of one printable character. To specify the commands in a view but not the commands in the view's subviews, use a semicolon as the last printable character in the last segment. To specify the commands in a view and the view's subviews, the last printable character in the last segment must not be a semicolon. For example, you must enter system view before you enter interface view. To specify all commands starting with the **ip** keyword in any interface view, you must use the "system ; interface * ; ip * ;" command string. For another example, the "system ; radius scheme * ;" command string represents all commands that start with the **radius scheme** keywords in system view. The "system ; radius scheme *" command string represents all commands that start with the **radius scheme** keywords in system view and all commands in RADIUS scheme view.

Rule	Guidelines
Asterisk (*) is the wildcard.	An asterisk represents zero or multiple characters. In a non-last segment, you can use an asterisk only at the end of the segment. In the last segment, you can use an asterisk in any position of the segment. If the asterisk appears at the beginning, you cannot specify a printable character behind the asterisk. For example, the "system ; *" command string represents all commands available in system view and all subviews of the system view. The "debugging * event" command string represents all event debugging commands available in user view.
Keyword abbreviation is allowed.	You can specify a keyword by entering the first few characters of the keyword. Any command that starts with this character string matches the rule. For example, "**rule 1 deny command display arp source** *" denies access to the **display arp source-mac interface** and **display arp source-suppression** commands.
To control the access to a command, you must specify the command immediately after the view that has the command.	To control access to a command, you must specify the command immediately behind the view to which the command is assigned. The rules that control command access for any subview do not apply to the command. For example, the "rule 1 deny command system ; interface * ; *" command string disables access to any command that is assigned to interface view. However, you can still execute the **acl advanced** command in interface view, because this command is assigned to system view rather than interface view. To disable access to this command, use "rule 1 deny command system ; acl *;".
Do not include the vertical bar (|), greater-than sign (>), or double greater-than sign (>>) when you specify **display** commands in a user role command rule.	The system does not treat the redirect signs and the parameters that follow the signs as part of command lines. However, in user role command rules, these redirect signs and parameters are handled as part of command lines. As a result, no rule that includes any of these signs can find a match. For example, "rule 1 permit command display debugging > log" can never find a match. This is because the system has a **display debugging** command but not a **display debugging > log** command.

Examples

Permit user role **role1** to execute the **display acl** command.

```
<Sysname> system-view
[Sysname] role name role1
[Sysname-role-role1] rule 1 permit command display acl
```

Permit user role **role1** to execute all commands that start with the **display** keyword.

```
[Sysname-role-role1] rule 2 permit command display *
```

Permit user role **role1** to execute the **radius scheme aaa** command in system view and use all commands assigned to RADIUS scheme view.

```
[Sysname-role-role1] rule 3 permit command system ; radius scheme aaa
```

Deny the access of **role1** to the read or write commands of any features.

```
[Sysname-role-role1] rule 4 deny read write feature
```

Deny the access of **role1** to the read commands of the **aaa** feature.

```
[Sysname-role-role1] rule 5 deny read feature aaa
```

Permit **role1** to access all read, write, and execute commands of feature group **security-features**.

```
[Sysname-role-role1] rule 6 permit read write execute feature-group security-features
```

Permit **role1** to access all read and write MIB nodes starting from the node with OID 1.1.2.

```
[Sysname-role-role1] rule 7 permit read write oid 1.1.2
```

Related commands

role

security-zone policy deny

Use **security-zone policy deny** to enter user role security zone policy view.

Use **undo security-zone policy deny** to restore the default.

Syntax

security-zone policy deny

undo security-zone policy deny

Default

A user role has access to all security zones.

Views

User role view

Predefined user roles

network-admin

context-admin

Usage guidelines

CAUTION:

This command denies a user role access to any security zones if you do not specify accessible security zones by using the **permit security-zone** command. To configure a security zone, make sure the security zone is permitted by the user role security zone policy in use.

To limit the scope of security zones accessible to a user role, perform the following tasks:

1. Use **security-zone policy deny** to enter user role security zone policy view and deny the user role access to any security zones.
2. Use **permit security-zone** to specify accessible security zones.

You can perform the following tasks on an accessible security zone:

- Create, remove, or configure the security zone.
- Enter security zone view.
- Specify the security zone in feature commands.

Any change to a user role security zone policy takes effect only on users who log in with the user role after the change.

Examples

Enter user role security zone policy view of **role1**, and deny the access of **role1** to any security zones.

```
<Sysname> system-view
[Sysname] role name role1
[Sysname-role-role1] security-zone policy deny
[Sysname-role-role1-zonepolicy] quit
```

Enter user role security zone policy view of **role1**, and deny the access of **role1** to any security zones except for security zones **trust** and **abc**.

```
<Sysname> system-view
[Sysname] role name role1
[Sysname-role-role1] security-zone policy deny
[Sysname-role-role1-zonepolicy] permit security-zone trust abc
```

permit security-zone

role

super

Use **super** to obtain another user role without reconnecting to the device.

Syntax

super [*role-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

role-name: Specifies a user role, a case-sensitive string of 1 to 63 characters. The user role must exist in the system and cannot be security-audit or guest-manager. If you do not specify a user role, you obtain the default target user role which is set by using the **super default role** command.

Usage guidelines

The obtained user role is a temporary user role, because this command is effective only on the current login. The next time you are logged in with the user account, the original user role settings take effect.

To enable a user to obtain another user role without reconnecting to the device, you must configure user role authentication.

Enter the username (if any) and password within 60 seconds after you enter the **super** command. If you fail to do so, the command will time out. To obtain the role, you will need to re-execute the command.

- If no local password is configured in the local password authentication (**local**), a console user can obtain the user role by either entering a string or not entering anything.
- If no local password is configured in the local-then-remote authentication (**local scheme**), a console or VTY user performs remote authentication.

Examples

Obtain the user role network-operator.

```
<Sysname> super network-operator
Password:
User privilege role is network-operator, and only those commands that authorized to the role can be used.
```

Related commands

authentication super (*Security Command Reference*)

super authentication-mode

super password

super authentication-mode

Use **super authentication-mode** to set an authentication mode for temporary user role authorization.

Use **undo super authentication-mode** to restore the default.

Syntax

super authentication-mode { **local** | **scheme** } *

undo super authentication-mode

Default

Local password authentication applies.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

local: Enables local password authentication.

scheme: Enables remote AAA authentication.

Usage guidelines

For local password authentication, use the **super password** command to set a password.

For remote AAA authentication, set the username and password on the RADIUS or HWTACACS server.

If you specify both **local** and **scheme** keywords, the keyword first entered in the command takes precedence.

- **scheme local**—Enables remote-then-local authentication mode. The device first performs AAA authentication to obtain a temporary user role. Local password authentication is performed if the remote HWTACACS or RADIUS server does not respond, or if the AAA configuration on the device is invalid.
- **local scheme**—Enables local-then-remote authentication mode. The device first performs local password authentication. If no password is configured for the user role, the device performs remote authentication for VTY users.A console user can obtain another user role by either entering a string or not entering anything.

For more information about AAA, see *Security Configuration Guide*.

Examples

Enable local-only authentication for temporary user role authorization.

```
<Sysname> system-view
[Sysname] super authentication-mode local
```

Enable remote-then-local authentication for temporary user role authorization.

```
<Sysname> system-view
[Sysname] super authentication-mode scheme local
```

Related commands

authentication super (*Security Command Reference*)

super password

super default role

Use **super default role** to specify the default target user role for temporary user role authorization.

Use **undo super default role** to restore the default.

Syntax

super default role *role-name*

undo super default role

Default

If you log in to the default context, the default target user role is network-admin.

If you log in to a non-default context, the default target user role is context-admin.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

role-name: Specifies the name of the default target user role, a case-sensitive string of 1 to 63 characters. The user role must exist in the system and cannot be security-audit or guest-manager.

Usage guidelines

The default target user role is applied to the **super** or **super password** command when you do not specify a user role for the command.

Examples

Specify **network-operator** as the default target user role for temporary user role authorization.

```
<Sysname> system-view
[Sysname] super default role network-operator
```

Related commands

super

super password

super password

Use **super password** to set a password for a user role.

Use **undo super password** to delete the password for a user role.

Syntax

super password [**role** *role-name*] [{ **hash** | **simple** } *string*]

undo super password [**role** *role-name*]

Default

No password is set for a user role.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

role *role-name*: Specifies a user role, a case-sensitive string of 1 to 63 characters. The user role must exist in the system and cannot be security-audit or guest-manager. If you do not specify a user role, the command sets a password for the default target user role which is set by using the **super default role** command.

hash: Specifies a password in hashed form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in hashed form.

string: Specifies the password. The plaintext form of the password is a case-sensitive string of 1 to 63 characters. The hashed form of the password is a case-sensitive string of 1 to 110 characters.

Usage guidelines

If you do not specify any parameters, you specify a plaintext password in the interactive mode.

Set a password if you configure local password authentication for temporary user role authorization.

It is a good practice to specify different passwords for different user roles.

When the global password control feature is enabled, the device maintains a history of super passwords, which are stored in hashed form.

Use the following guidelines when you change the authentication password for a user role when the global password control feature is enabled:

- If you set the new password in plaintext form, you must make sure the password is different from the current one and those stored in the history super password records.
- If you set the new password in hashed form, the system does not compare the new super password with the current one or the history super password records. The password can be the same as the current one or a history password retained by the device.

Examples

Set the password to **123456TESTplat&!** in plaintext form for user role network-operator.

```
<Sysname> system-view
[Sysname] super password role network-operator simple 123456TESTplat&!
```

Set the password to **123456TESTplat&!** in the interactive mode for user role network-operator.

```
<Sysname> system-view
[Sysname] super password role network-operator
Password:
Confirm :
Updating user information. Please wait......
```

Related commands

super authentication-mode

super default role

super use-login-username

Use **super use-login-username** to enable the device to automatically obtain the login username when a login user requests temporary user role authorization from a remote authentication server.

Use **undo super use-login-username** to restore the default.

Syntax

super use-login-username

undo super use-login-username

Default

The device prompts for a username when a login user requests temporary user role authorization from a remote authentication server.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command is applicable only to the login from a user line that uses scheme authentication, which requires a username for login.

If the user was logged in from a user line that uses password authentication or no authentication, the device cannot obtain the login username. The request for temporary user role authorization from a remote authentication server will fail.

This command does not take effect on local password authentication for temporary user role authorization.

Examples

Enable the device to automatically obtain the login username when a login user requests temporary user role authorization from a remote authentication server.

```
<Sysname> system-view
[Sysname] super use-login-username
```

Related commands

authentication super (*Security Command Reference*)

super authentication-mode

super password

vlan policy deny

Use **vlan policy deny** to enter user role VLAN policy view.

Use **undo vlan policy deny** to restore the default.

Syntax

vlan policy deny

undo vlan policy deny

Default

A user role has access to all VLANs.

Views

User role view

Predefined user roles

network-admin

context-admin

Usage guidelines

CAUTION:

This command denies a user role access to any VLANs if you do not specify accessible VLANs by using the **permit vlan** command. To configure a VLAN, make sure the VLAN is permitted by the user role VLAN policy in use.

To limit the scope of VLANs accessible to a user role, perform the following tasks:

1. Use **vlan policy deny** to enter user role VLAN policy view and deny the user role access to any VLANs.
2. Use **permit vlan** to specify accessible VLANs.

You can perform the following tasks on an accessible VLAN:

- Create, remove, or configure the VLAN.
- Enter VLAN view.
- Specify the VLAN in feature commands.

Any change to a user role VLAN policy takes effect only on users who log in with the user role after the change.

Examples

Enter user role VLAN policy view of **role1**, and deny the access of **role1** to any VLANs.

```
<Sysname> system-view
[Sysname] role name role1
[Sysname-role-role1] vlan policy deny
[Sysname-role-role1-vlanpolicy] quit
```

Enter user role VLAN policy view of **role1**, and deny the access of **role1** to any VLANs except for VLANs 50 to 100.

```
<Sysname> system-view
[Sysname] role name role1
[Sysname-role-role1] vlan policy deny
[Sysname-role-role1-vlanpolicy] permit vlan 50 to 100
```

Login management commands

Some login management commands are available in both user line view and user line class view. For these commands, the device uses the following rules to determine the settings to be activated:

- A setting in user line view applies only to the user line. A setting in user line class view applies to all user lines of the class.
- A non-default setting in either view takes precedence over a default setting in the other view. A non-default setting in user line view takes precedence over a non-default setting in user line class view.
- A setting in user line class view takes effect on login sessions that are established after the setting is configured.

activation-key

Use **activation-key** to set the terminal session activation key. Pressing this shortcut key starts a terminal session.

Use **undo activation-key** to restore the default.

Syntax

activation-key *key-string*

undo activation-key

Default

The terminal session activation key is **Enter**.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Parameters

key-string: Specifies a shortcut key. It can be a character (case sensitive), or an ASCII code value in the range of 0 to 127. For example, if you use **activation-key 1**, the shortcut key is **Ctrl+A**. If you use **activation-key a**, the shortcut key is **a**. For information about ASCII code values of individual characters, see the standard ASCII code chart. For information about ASCII code values of combined keys that use the **Ctrl** key, see Table 1.

Usage guidelines

This command is not supported in VTY line view or VTY line class view.

This command takes effect immediately.

This command is available in both user line view and user line class view. A non-default setting in either view takes precedence over a default setting in the other view. A non-default setting in user line view takes precedence over a non-default setting in user line class view.

You can use only the specified terminal session activation key to start a terminal session. To display the current terminal session activation key, use the **display current-configuration | include activation-key** command.

Table 1 ASCII code values for combined keys that use the Ctrl key

Combined key	ASCII code value
Ctrl+A	1
Ctrl+B	2
Ctrl+C	3
Ctrl+D	4
Ctrl+E	5
Ctrl+F	6
Ctrl+G	7
Ctrl+H	8
Ctrl+I	9
Ctrl+J	10
Ctrl+K	11
Ctrl+L	12
Ctrl+M	13
Ctrl+N	14
Ctrl+O	15
Ctrl+P	16
Ctrl+Q	17
Ctrl+R	18
Ctrl+S	19
Ctrl+T	20
Ctrl+U	21
Ctrl+V	22
Ctrl+W	23
Ctrl+X	24
Ctrl+Y	25
Ctrl+Z	26

Examples

Configure character **s** as the terminal session activation key for console line 0.

```
<Sysname> system-view
[Sysname] line console 0
[Sysname-line-console0] activation-key s
```

To verify the configuration:

1. Exit the console session.

   ```
   [Sysname-line-console0] return
   <Sysname> quit
   ```

2. Log in again through the console line.

The following message appears:

```
Press ENTER to get started.
```

3. Press **Enter**.

   Pressing **Enter** does not start a session.

4. Press **s**.

   A terminal session is started.

```
<Sysname>
```

authentication-mode

Use **authentication-mode** to set the authentication mode for a user line.

Use **undo authentication-mode** to restore the default.

Syntax

authentication-mode { **none** | **password** | **scheme** }

undo authentication-mode

Default

The authentication mode is **scheme** for the VTY and console lines.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Parameters

none: Disables authentication.

password: Performs local password authentication.

scheme: Performs AAA authentication. For more information about AAA, see *Security Configuration Guide*.

Usage guidelines

CAUTION:

- When authentication is disabled, users can login without authentication. For security purpose, disable authentication with caution.
- When you enable password authentication, you must also configure an authentication password for the line or line class. If no authentication password is configured, you cannot log in to the device through the line or line class at the next time.
- When you enable scheme authentication, make sure an authentication user account is available. If no authentication user account is available, you cannot log in to the device through the line or line class at the next time.

Only users assigned the network-admin, context-admin, or level-15 user role can execute this command. Other users cannot execute this command, even if they are granted the right to execute this command.

In VTY line view, this command is associated with the **protocol inbound** command.

- If the settings of the two commands in VTY line view are both the default settings, the settings for the commands in VTY line class view take effect.
- If the settings of the two commands in VTY line view are both non-default settings, the non-default settings in VTY line view take effect.
- If only one command has a non-default setting in VTY line view, the other command uses the default setting, regardless of the setting in VTY line class view.

An authentication mode change does not take effect on the current session. It takes effect on subsequent login sessions.

Examples

Enable the **none** authentication mode for VTY line 0.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] authentication-mode none
```

Enable password authentication for VTY line 0 and set the password to **hello12345**.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] authentication-mode password
[Sysname-line-vty0] set authentication password simple hello12345
```

Enable scheme authentication for VTY line 0. Configure local user **test** and set the password to **hello12345**. Assign the Telnet service and the user role network-admin to the user.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] authentication-mode scheme
[Sysname-line-vty0] quit
[Sysname] local-user test
[Sysname-luser-manage-test] password simple hello12345
[Sysname-luser-manage-test] service-type telnet
[Sysname-luser-manage-test] authorization-attribute user-role network-admin
```

Related commands

set authentication password

auto-execute command

Use **auto-execute command** to specify the command to be automatically executed for a login user.

Use **undo auto-execute command** to restore the default.

Syntax

auto-execute command *command*

undo auto-execute command

Default

No command is specified to be automatically executed for a login user.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Parameters

command: Specifies the command to be automatically executed.

Usage guidelines

CAUTION:

After using this command for a user line, you might be unable to access the CLI through the user line. Make sure you can access the CLI through a different user line before you use this command and save the configuration.

The device will automatically execute the specified command when a user logs in through the user line, and close the user connection after the command is executed.

This command is not supported in console line view or console line class view.

This command is available in both user line view and user line class view. A non-default setting in either view takes precedence over a default setting in the other view. A non-default setting in user line view takes precedence over a non-default setting in user line class view.

A configuration change made by this command does not take effect on the current session. It takes effect on subsequent login sessions.

Examples

Configure the device to automatically execute the **`telnet 192.168.1.41`** command when a user logs in through VTY line 0.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] auto-execute command telnet 192.168.1.41
This action will lead to configuration failure through line-vty0. Are you sure?
[Y/N]:y
[Sysname-line-vty0]
```

To verify the configuration, Telnet to the device (192.168.1.40).

The device automatically Telnets to 192.168.1.41. The following output is displayed on the configuration terminal:

```
C:\> telnet 192.168.1.40
******************************************************************************
* Copyright (c) 2004-2017 NSFOCUS. All rights reserved.                      *
* Without the owner's prior written consent,                                 *
* no decompiling or reverse-engineering shall be allowed.                    *
******************************************************************************

<Sysname>
Trying 192.168.1.41 ...
Press CTRL+K to abort
Connected to 192.168.1.41 ...
******************************************************************************
* Copyright (c) 2004-2017 NSFOCUS. All rights reserved.                      *
* Without the owner's prior written consent,                                 *
* no decompiling or reverse-engineering shall be allowed.                    *
```

```
**************************************************************************
<Sysname.41>
```

This operation is the same as directly logging in to the device at 192.168.1.41 through Telnet. When you close the Telnet connection to 192.168.1.41, the Telnet connection to 192.168.1.40 is closed at the same time.

command accounting

Use **command accounting** to enable command accounting.

Use **undo command accounting** to disable command accounting.

Syntax

command accounting

undo command accounting

Default

Command accounting is disabled. The accounting server does not record executed commands.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Usage guidelines

When command accounting is enabled but command authorization is not, every executed command is recorded on the HWTACACS server. When both command accounting and command authorization are enabled, only authorized commands that are executed are recorded on the HWTACACS server.

Invalid commands are not recorded.

A configuration change made by this command does not take effect on the current session. It takes effect on subsequent login sessions.

After you use the **command accounting** command in user line class view, you cannot use the **undo command accounting** command in any user line views in the class.

Examples

Enable command accounting for VTY line 0.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] command accounting
```

Related commands

accounting command (*Security Command Reference*)

command authorization

command authorization

Use **command authorization** to enable command authorization.

Use **undo command authorization** to disable command authorization.

Syntax

command authorization

undo command authorization

Default

Command authorization is disabled. Logged-in users can execute commands without authorization.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Usage guidelines

When command authorization is enabled, commands available for a user vary by the user's login authentication mode.

- If authentication is disabled or password authentication is enabled, command authorization does not take effect, and the user cannot use any commands.
- If scheme authentication is enabled, commands available for a user vary by the user's access authentication method.
  - If local authentication is used, the device uses the user roles assigned to the user to perform command authorization.
  - If remote authentication is used, the remote authorization server performs command authorization to determine whether a command entered by a login user is permitted. If remote authorization fails, the device uses the user roles of a local user with the same name as the login user to determine whether the command can be used. If the authorization also fails, the login user cannot use the command.

Command authorization configuration changes in user line class view do not take effect on the current session. The changes take effect only on subsequent login sessions. Command authorization configuration changes in user line view take effect immediately on all users that access the user line.

If you use the **command authorization** command in user line class view, command authorization is enabled for all user lines in the class. You cannot use the **undo command authorization** command in the view of a user line in the class.

Examples

Enable command authorization for VTY line 0.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] command authorization
```

Related commands

authorization command (*Security Command Reference*)

databits

Use **databits** to specify the number of data bits for a character.

Use **undo databits** to restore the default.

Syntax

databits { | **7** | **8** }

undo databits

Default

Eight data bits are used for a character.

Views

User line view

Predefined user roles

network-admin

context-admin

Parameters

7: Uses seven data bits for a character.

8: Uses eight data bits for a character.

Usage guidelines

This command is not supported in VTY line class view.

This setting must be the same as the setting on the configuration terminal.

Examples

Set the number of data bits for a character to 7.

```
<Sysname> system-view
[Sysname] line console 0
[Sysname-line-console0] databits 7
```

display ip http

Use **display ip http** to display HTTP service configuration and status information.

Syntax

display ip http

Views

Any view

Predefined user roles

context-operator

Examples

Display HTTP service configuration and status information. In this example, a Layer 2 ACL is applied to the HTTP service.

```
<Sysname> display ip http
HTTP port: 80
ACL: 4444 (Layer 2)
Operation status: Enabled
```

Display HTTP service configuration and status information. In this example, an IPv4 basic ACL and an IPv6 basic ACL are applied to the HTTP service.

```
<Sysname> display ip http
HTTP port: 80
IPv4 ACL: 2222 (basic)
IPv6 ACL: 2333 (basic)
Operation status: Enabled
```

Table 2 Command output

Field	Description
HTTP port	HTTP service port number.
ACL/IPv4 ACL/IPv6 ACL	Number or name of the Layer 2, IPv4, or IPv6 ACL used to control HTTP access. If no ACL is used, this field displays **0**. The ACL type is enclosed into a pair of parentheses. Available ACL types: • **basic**—Basic ACL. • **advanced**—Advanced ACL. • **Layer 2—**Layer 2 ACL.
Operation status	Whether the HTTP service is enabled.

Examples

Display HTTPS service configuration and status information. In this example, a Layer 2 ACL is applied to the HTTPS service.

```
<Sysname> display ip https
HTTPS port: 443
SSL server policy: test
Certificate access-control-policy: Not configured
ACL: 4444 (layer 2)
Operation status: Enabled
```

Display HTTPS service configuration and status information. In this example, an IPv4 basic ACL and an IPv6 basic ACL are applied to the HTTPS service.

```
<Sysname> display ip https
HTTPS port: 443
SSL server policy: test
Certificate access-control-policy: Not configured
IPv4 ACL: 2222 (basic)
IPv6 ACL: 2333 (basic)
Operation status: Enabled
```

Table 3 Command output

Field	Description
HTTPS port	HTTPS service port number.
SSL server policy	SSL server policy applied to the HTTPS service. If no SSL server policy is applied, this field displays **Not configured**.
Certificate access-control-policy	Certificate-based access control policy used to control client access rights. If no certificate-based access control policy is used, this field displays **Not configured**.
ACL/IPv4 ACL/IPv6 ACL	Number or name of the Layer 2, IPv4, or IPv6 ACL used to control HTTPS access. If no ACL is used, this field displays **0**. The ACL type is enclosed into a pair of parentheses. Available ACL types: • **basic**—Basic ACL. • **advanced**—Advanced ACL. • **Layer 2**—Layer 2 ACL.
Operation status	Whether the HTTPS service is enabled.

display line

Use **display line** to display user line information.

Syntax

display line [*number1* | { **console** | **vty** } *number2*] [**summary**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

number1: Specifies the absolute number of a user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

console: Specifies the console line.

vty: Specifies the VTY line.

number2: Specifies the relative number of a user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

summary: Displays summary information about user lines. If you do not specify this keyword, the command displays detailed information.

Examples

Display information about user line 0.

```
<Sysname> display line 0
  Idx  Type     Tx/Rx      Modem Auth  Int        Location
+ 0    CON 0    9600       -     N     -           1/0

  +    : Line is active.
  F    : Line is active and in async mode.
  Idx  : Absolute index of line.
  Type : Type and relative index of line.
  Auth : Login authentication mode.
  Int  : Physical port of the line.
  A    : Authentication use AAA.
  N    : No authentication is required.
  P    : Password authentication.
```

Table 4 Command output

Field	Description
Modem	Whether the modem allows calling in or out. By default, this attribute is not configured and this field displays a hyphen (-). This field is not supported in the current software version.
Int	Physical port for the line. If there is no physical port for the line or the port is a console port, this field displays a hyphen (-).
Location	Physical position of the line, in the form of *slot number*/*CPU number*.

Display summary information about all user lines.

```
<Sysname> display line summary
  Line type : [CON]
            0:XX
  Line type : [VTY]
            2:UUUX XXXX XXXX XXXX
           18:XXXX XXXX XXXX XXXX
           34:XXXX XXXX XXXX XXXX
           50:XXXX XXXX XXXX XXXX

   3 lines used.      (U)
  63 lines not used.  (X)
```

Table 5 Command output

Fields	Description
Line type	Type of the user line: • **CON**—Console line. • **VTY**—VTY line.
number:*status*	*number*: Absolute number of the first user line in the user line class. *status*: User line status. **X** is for unused and **U** is for used.

display telnet client

Use **display telnet client** to display the packet source setting for the Telnet client.

Syntax

display telnet client

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Usage guidelines

This command displays the source IPv4 address or source interface specified for the Telnet client to use in outgoing Telnet packets, depending on the **telnet client source** command.

Examples

Display the packet source setting for the Telnet client.

```
<Sysname> display telnet client
 The source IP address is 1.1.1.1.
```

Related commands

telnet client source

display user-interface

Use **display user-interface** to display user line information.

Syntax

display user-interface [*number1* | { **console** | **vty** } *number2*] [**summary**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

number1: Specifies the absolute number of a user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

console: Specifies the console line.

vty: Specifies the VTY line.

number2: Specifies the relative number of a user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

summary: Displays summary information about user lines. If you do not specify this keyword, the detailed information is displayed.

Usage guidelines

This command is an older version reserved for backward compatibility purposes. It has the same functionality and output as the **display line** command. As a best practice, use the **display line** command.

Examples

Display information about user line 0.

```
<Sysname> display user-interface 0
  Idx  Type     Tx/Rx      Modem Auth  Int        Location
+ 0    CON 0    9600       -     N     -          1/0

  +    : Line is active.
  F    : Line is active and in async mode.
  Idx  : Absolute index of line.
  Type : Type and relative index of line.
  Auth : Login authentication mode.
  Int  : Physical port of the line.
  A    : Authentication use AAA.
  N    : No authentication is required.
  P    : Password authentication.
```

Table 6 Command output

Field	Description
Modem	Whether the modem allows calling in or out. By default, this attribute is not configured and this field displays a hyphen (-). This field is not supported in the current software version.
Int	Physical port for the line. If there is no physical port for the line or the port is a console port, this field displays a hyphen (-).
Location	Physical position of the line, in the form of *slot number*/*CPU number*.

Display summary information about all user lines.

```
<Sysname> display user-interface summary
  Line type : [CON]
            0:XX
  Line type : [VTY]
            2:UUUX XXXX XXXX XXXX
           18:XXXX XXXX XXXX XXXX
           34:XXXX XXXX XXXX XXXX
           50:XXXX XXXX XXXX XXXX
```

Table 7 Command output

Fields	Description
Line type	Type of the user line: • **CON**—Console line. • **VTY**—VTY line.
number:*status*	*number*: Absolute number of the first user line in the user line class. *status*: User line status. **X** is for unused and **U** is for used.

display users

Use **display users** to display online CLI users.

Syntax

display users [**all**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

all: Displays all user lines supported by the device.

Examples

Display online user information.

```
<Sysname> display users
  Idx  Line     Idle       Time              Pid     Type
+ 10   VTY 0    00:00:00   Jan 01 00:33:10   484     TEL
  12   VTY 2    00:06:22   Jan 01 00:33:22   495     TEL

Following are more details.
VTY 0   :
        Location: 192.168.1.107
VTY 2   :
        Location: 192.168.1.134
 +    : Current operation user.
 F    : Current operation user works in async mode.
```

Table 8 Command output

Field	Description
Idx	Absolute number of the user line.
Line	Type and relative number of the user line.
Idle	Time elapsed after the user's most recent input, in the *hh*:*mm*:*ss* format.
Time	Login time of the user.
Pid	Process ID of the user session.
Type	User type: • **TEL**—Telnet user. • **SSH**—SSH user. • **Switchto User**—User who logged in by using the **`switchto context`** command. • For a user who logged in through the console port, this field does not display anything.
+	User line you are using.
User name	Username used by the user. This field is displayed only if the user provided a username and password for authentication at login.
Location	IP address of the user.

display web menu

Use **`display web menu`** to display Web interface navigation tree information.

Syntax

`display web menu` [**`chinese`**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

chinese: Displays information about the Chinese Web interface navigation tree. If you do not specify this keyword, the command displays information about the English Web interface navigation tree.

Usage guidelines

This command displays all options on the Web interface navigation tree.

Examples

Display Web interface navigation tree information.

```
<Sysname> display web menu
  .
  |--Dashboard: ID = dashboard
  |    |--Operation Monitor: ID = m_dashboard
  |    |--Traffic Monitor: ID = m_flowdetection
  |    |--Threat Monitor: ID = m_threatdetection
  |    |--Filtering Monitor: ID = m_urldetection
  |    |--LoadBalance Monitor: ID = m_loadbalancedash
  |    |--User-Defined Monitor: ID = m_definedboard
  |    `--Interface Information: ID = m_ifinfopanel
  |--Monitor: ID = m_monitor
  |    |--Application Analysis Center: ID = m_cdas
  |    |--Security Logs: ID = m_atklog
  |    |    |--Blacklist Logs: ID = m_blacklistlog
  |    |    |--Single-Packet Attack Logs: ID = m_singleatk
  |    |    |--Scanning Attack Logs: ID = m_scanatk
  |    |    |--Flood Attack Logs: ID = m_floodatk
  |    |    |--Threat Logs: ID = m_threatlog
  |    |    |--URL Filtering Logs: ID = m_urllog
  |    |    |--File Filtering Logs: ID = m_filefilterlog
  |    |    |--Security Policy Logs: ID = m_zonepairlog
  |    |    |--Sandbox Logs: ID = m_aptlog
  |    |    |--NAT Logs: ID = m_natflowlog
  |    |    |--SSL VPN User Access Logs: ID = m_sslvpnuserlog
---- More ----
```

display web users

Use **display web users** to display online Web users.

Syntax

display web users

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display online Web users.

```
<Sysname> display web users
UserID          Name            Type   Language JobCount LoginTime LastOperation
AB2039483271293 Administrator   HTTP   Chinese     3     12:00:23  14:10:05
F09382BA2014AC8 user            HTTPS  English     1     13:05:00  14:11:00
```

Table 9 Command output

Field	Description
UserID	ID used to uniquely identify the online Web user.
JobCount	Number of connections established by the user.

escape-key

Use **escape-key** to set the escape key.

Use **undo escape-key** to disable the escape key.

Syntax

escape-key { *key-string* | **default** }

undo escape-key

Default

The escape key is **Ctrl+C**.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Parameters

key-string: Specifies a shortcut key. It can be a character (case sensitive, except for **d** and **D**), or an ASCII code value in the range of 0 to 127. For example, if you use **escape-key 1**, the shortcut key is **Ctrl+A**. If you use **escape-key a**, the shortcut key is **a**. If you specify the character **d** or **D** for this argument, the actual shortcut key is **Ctrl+C**. To use **d** or **D** as the shortcut key, you must specify the ASCII code value of the character for this argument. For information about ASCII code values of individual characters, see the standard ASCII code chart. For information about ASCII code values of combined keys that use the **Ctrl** key, see Table 1.

default: Restores the default escape key **Ctrl+C**.

Usage guidelines

You can press the escape key to abort a command that is being executed, for example, a **ping** or **tracert** command. Whether a command can be aborted by **Ctrl+C** by default depends on the

software implementation of the command. For more information, see the usage guidelines for the command.

As a best practice, use a key sequence as the escape key. If you define a single character as the escape key, pressing the key while a command is being executed stops the command. If no command is being executed, pressing the key enters the character as a common character. If you Telnet from the device to a remote device, pressing the key enters the character as a common character on the remote device. The key acts as the escape key on the remote device only when the following conditions are met:

- You define the same character as the escape key on the remote device.
- You press the key while a command is being executed on the remote device.

The **undo escape-key** command disables the current escape key. After you execute this **undo** command, no escape key is available.

This command is available in both user line view and user line class view. A non-default setting in either view takes precedence over a default setting in the other view. A non-default setting in user line view takes precedence over a non-default setting in user line class view.

The setting in user line view takes effect immediately on the current session. The setting in user line class view takes effect on login sessions that are established after the setting is configured.

To display the current escape key, use the **display current-configuration | include escape-key** command.

Examples

Configure character **a** as the escape key for VTY line 0.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] escape-key a
```

To verify the configuration:

1. Ping IP address 192.168.1.49, specifying the **-c** keyword to set the number of ICMP echo request packets to 20.

   ```
   Ping 192.168.1.49 (192.168.1.49): 56 data bytes, press 'a' to break
   56 bytes from 192.168.1.49: icmp_seq=0 ttl=255 time=1.000 ms
   56 bytes from 192.168.1.49: icmp_seq=1 ttl=255 time=0.000 ms
   ```

2. Press **a**.

   The system aborts the command and returns to user view.

   ```
   --- Ping statistics for 192.168.1.49 ---
   20 packet(s) transmitted, 20 packet(s) received, 0.0% packet loss
   round-trip min/avg/max/std-dev = 0.000/0.200/1.000/0.400 ms
   <Sysname>
   ```

flow-control

Use **flow-control** to configure the flow control mode.

Use **undo flow-control** to restore the default.

Syntax

flow-control { **hardware** | **none** | **software** }

undo flow-control

Default

Flow control is disabled.

Views

User line view

Predefined user roles

network-admin

context-admin

Parameters

hardware: Performs hardware flow control.

none: Disables flow control.

software: Performs software flow control.

Usage guidelines

This command is not supported in VTY line view.

The device supports flow control in both the inbound and outbound directions.

- For flow control in the inbound direction, the local device listens to flow control information from the remote device.
- For flow control in the outbound direction, the local device sends flow control information to the remote device.

The flow control setting takes effect in both directions.

To communicate, two devices must operate in the same flow control mode.

Examples

Configure software flow control in the inbound and outbound directions for console line 0.

```
<Sysname> system-view
[Sysname] line console 0
[Sysname-line-console0] flow-control software
```

free line

Use **free line** to release a user line.

Syntax

free line { *number1* | { **console** | **vty** } *number2* }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

number1: Specifies the absolute number of a user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

console: Specifies the console line.

vty: Specifies the VTY line.

number2: Specifies the relative number of a user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

Usage guidelines

This command does not release the line you are using.

Examples

Release VTY line 1.

```
<Sysname> free line vty 1
Are you sure to free line vty1? [Y/N]:y
 [OK]
```

free user-interface

Use **free user-interface** to release a user line.

Syntax

free user-interface { *number1* | { **console** | **vty** } *number2* }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

number1: Specifies the absolute number of a user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

console: Specifies the console line.

vty: Specifies the VTY line.

number2: Specifies the relative number of a user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

Usage guidelines

This command does not release the line you are using.

This command is an older version reserved for backward compatibility purposes. It has the same functionality and output as the **free line** command. As a best practice, use the **free line** command.

Examples

Release VTY line 1.

```
<Sysname> free user-interface vty 1
Are you sure to free line vty1? [Y/N]:y
 [OK]
```

free web users

Use **free web users** to log off online Web users.

Syntax

free web users { **all** | **user-id** *user-id* | **user-name** *user-name* }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

all: Specifies all Web users.

user-id *user-id*: Specifies a Web user by the ID, a hexadecimal number of 15 digits. The system assigns each Web user a unique ID at login to identify the user.

user-name: Specifies a Web user by the username, a case-sensitive string of 1 to 255 characters.

Examples

Log off all online Web users.

```
<Sysname> free web users all
```

Related commands

display web users

history-command max-size

Use **history-command max-size** to set the size of the command history buffer for a user line.

Use **undo history-command max-size** to restore the default.

Syntax

history-command max-size *size-value*

undo history-command max-size

Default

The command history buffer for a user line stores up to 10 history commands.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Parameters

size-value: Specifies the maximum number of history commands the buffer can store, in the range of 0 to 256.

Usage guidelines

Each user line uses a separate command history buffer to store commands successfully executed by its user. The buffer size determines how many history commands the buffer can store.

To display history commands in the buffer for your session, press the up or down arrow key, or execute the **display history-command** command. For more information about the command history buffer, see *Fundamentals Configuration Guide*.

Terminating a CLI session clears the commands in the command history buffer.

The setting in user line view takes effect immediately on the current session. The setting in user line class view takes effect on login sessions that are established after the setting is configured.

Examples

Set the command history buffer size to 20 for VTY line 0.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] history-command max-size 20
```

http method

Use **http method** to specify the HTTP methods to be added to the reply to an OPTIONS request.

Use **undo http method** to remove the HTTP methods to be added to the reply to an OPTIONS request.

Syntax

http method { **delete** | **get** | **head** | **options** | **post** | **put** } *

undo http method { **delete** | **get** | **head** | **options** | **post** | **put** } *

Default

No HTTP methods are specified.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

delete: Specifies the DELETE method.

get: Specifies the GET method.

head: Specifies the HEAD method.

options: Specifies the OPTIONS method.

post: Specifies the POST method.

put: Specifies the PUT method.

Usage guidelines

An HTTP client sends an OPTIONS request to the device to obtain the HTTP methods supported by the device. The device identifies whether the requested URL resources have a service that has registered for the OPTIONS method.

- If yes, the service responds to the OPTIONS request.
- If not, the device identifies whether the **options** keyword is specified for this command.
  - If yes, the device uses the settings for this command to generate and return a reply to the OPTIONS request.
  - If not, the device returns the **405 Method Not Allowed** message.

This command does not affect HTTP requests except for OPTIONS requests.

Examples

Specify GET, HEAD, POST, and OPTIONS methods as the HTTP methods to be added to the reply to an OPTIONS request.

```
<Sysname> system-view
[Sysname] http method get head post options
```

idle-timeout

Use **idle-timeout** to set the CLI connection idle-timeout timer.

Use **undo idle-timeout** to restore the default.

Syntax

idle-timeout *minutes* [*seconds*]

undo idle-timeout

Default

The CLI connection idle-timeout timer is 10 minutes.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Parameters

minutes: Specifies the number of minutes, in the range of 0 to 35791.

seconds: Specifies the number of seconds, in the range of 0 to 59. The default is 0 seconds.

Usage guidelines

The system automatically terminates a user connection if no information interaction occurs on the connection within the idle-timeout interval.

To disable the idle-timeout feature, execute the **idle-timeout 0** command.

This command is available in both user line view and user line class view. A non-default setting in either view takes precedence over a default setting in the other view. A non-default setting in user line view takes precedence over a non-default setting in user line class view.

The setting in user line view takes effect immediately on the current session. The setting in user line class view takes effect on login sessions that are established after the setting is configured.

Examples

Set the CLI connection idle-timeout timer to 1 minute and 30 seconds for VTY line 0.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] idle-timeout 1 30
```

ip http acl

Use **ip http acl** to apply an ACL to the HTTP service.

Use **undo ip http acl** to restore the default.

Syntax

ip http acl [**ipv6**] [**advanced**] { *acl-number* | **name** *acl-name* }

ip http acl mac { *acl-number* | **name** *acl-name* }

undo ip http acl [**ipv6**]

undo ip http acl mac

Default

No ACL is applied to the HTTP service.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies an IPv6 ACL. If you do not specify this keyword, the command applies an IPv4 ACL to the HTTP service.

advanced: Specifies an advanced ACL. If you do not specify this keyword, the command applies a basic ACL to the HTTP service.

mac: Specifies a Layer 2 ACL.

acl-number: Specifies an ACL number in the range of 2000 to 4999.

- 2000 to 2999 for a basic ACL.
- 3000 to 3999 for an advanced ACL.
- 4000 to 4999 for a Layer 2 ACL.

name *acl-name*: Specifies an ACL by its name. The *acl-name* argument is a case-insensitive string of 1 to 63 characters. It must start with an English letter and to avoid confusion, it cannot be **all**. The specified ACL takes effect only when the ACL exists.

Usage guidelines

To specify an IPv4 basic ACL, do not specify the **advanced** or **ipv6** keyword. To specify an IPv6 basic ACL, specify the **ipv6** keyword without the **advanced** keyword.

In an advanced ACL applied to the HTTP service, only the following match criteria take effect:

- Source and destination IP addresses.
- Source and destination ports.
- Transport layer protocol.

In a Layer 2 ACL applied to the HTTP service, only the source MAC address match criterion takes effect.

When no ACL is applied to the HTTP service or the applied ACL does not exist or does not have rules, all clients can access the device through HTTP. To control HTTP access, specify an ACL that exists and has rules so only clients permitted by the ACL can access the device through HTTP.

You can apply one IPv4 basic ACL and one IPv6 basic ACL to the HTTP service, or apply one IPv4 advanced ACL and one IPv6 advanced ACL to the HTTP service. If you execute this command multiple times for the same type of ACLs, the most recent configuration takes effect.

If a VPN instance is specified in an ACL rule, the rule applies only to the packets of the VPN instance. If no VPN instance is specified in an ACL rule, the rule applies only to the packets on the public network.

For more information about ACLs, see *ACL and QoS Configuration Guide.*

Examples

Use IPv4 basic ACL 2001 to allow only users from 10.10.0.0/16 to access the device through HTTP.

```
<Sysname> system-view
[Sysname] acl basic 2001
[Sysname-acl-ipv4-basic-2001] rule permit source 10.10.0.0 0.0.255.255
[Sysname-acl-ipv4-basic-2001] quit
[Sysname] ip http acl 2001
```

Related commands

`acl` (*ACL and QoS Command Reference*)

ip http enable

Use **`ip http enable`** to enable the HTTP service.

Use **`undo ip http enable`** to disable the HTTP service.

Syntax

`ip http enable`

`undo ip http enable`

Default

The HTTP service is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

To allow users to access the device through HTTP, you must enable the HTTP service.

To improve device security, the system automatically enables the HTTPS service when you enable the HTTP service. When the HTTP service is enabled, you cannot disable the HTTPS service.

Examples

Enable the HTTP service.

```
<Sysname> system-view
[Sysname] ip http enable
```

Related commands

`ip https enable`

ip http port

Use **`ip http port`** to specify the HTTP service port number.

Use **undo ip http port** to restore the default.

Syntax

ip http port *port-number*

undo ip http port

Default

The HTTP service port number is 80.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

port-number: Specifies a port number in the range of 1 to 65535.

Usage guidelines

When the HTTP service is enabled, changing the HTTP service port number re-enables the HTTP service and closes all HTTP connections. To log in again, users must enter the new URL in the Web browser's address bar.

Examples

Set the HTTP service port number to 80.

```
<Sysname> system-view
[Sysname] ip http port 80
```

ip https acl

Use **ip https acl** to apply an ACL to the HTTPS service.

Use **undo ip https acl** to restore the default.

Syntax

ip https acl [**ipv6**] [**advanced**] { *acl-number* | **name** *acl-name* }

ip https acl mac { *acl-number* | **name** *acl-name* }

undo ip https acl [**ipv6**]

undo ip https acl mac

Default

No ACL is applied to the HTTPS service.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies an IPv6 ACL. If you do not specify this keyword, the command applies an IPv4 ACL to the HTTPS service.

advanced: Specifies an advanced ACL. If you do not specify this keyword, the command applies a basic ACL to the HTTPS service.

mac: Specifies a Layer 2 ACL.

acl-number: Specifies an ACL number in the range of 2000 to 4999.

- 2000 to 2999 for a basic ACL.
- 3000 to 3999 for an advanced ACL.
- 4000 to 4999 for a Layer 2 ACL.

name *acl-name*: Specifies an ACL by its name. The *acl-name* argument is a case-insensitive string of 1 to 63 characters. It must start with an English letter and to avoid confusion, it cannot be **all**. The specified ACL takes effect only when the ACL exists.

Usage guidelines

To specify an IPv4 basic ACL, do not specify the **advanced** or **ipv6** keyword. To specify an IPv6 basic ACL, specify the **ipv6** keyword without the **advanced** keyword.

In an advanced ACL applied to the HTTPS service, only the following match criteria take effect:

- Source and destination IP addresses.
- Source and destination ports.
- Transport layer protocol.

In a Layer 2 ACL applied to the HTTPS service, only the source MAC address match criterion takes effect.

When no ACL is applied to the HTTPS service or the applied ACL does not exist or does not have rules, all clients can access the device through HTTPS. To control HTTPS access, specify an ACL that exists and has rules so only clients permitted by the ACL can access the device through HTTPS.

Because the device always uses HTTPS to transfer Web login requests, the ACL applied to the HTTPS service controls both HTTPS and HTTP logins. To access the device, HTTP clients must be permitted by the following ACLs:

- ACL applied to the HTTP service.
- ACL applied to the HTTPS service.

You can apply one IPv4 basic ACL and one IPv6 basic ACL to the HTTPS service, or apply one IPv4 advanced ACL and one IPv6 advanced ACL to the HTTPS service. If you execute this command multiple times for the same type of ACLs, the most recent configuration takes effect.

If a VPN instance is specified in an ACL rule, the rule applies only to the packets of the VPN instance. If no VPN instance is specified in an ACL rule, the rule applies only to the packets on the public network.

For more information about ACLs, see *ACL and QoS Configuration Guide.*

Examples

Use IPv4 basic ACL 2001 to allow only users from 10.10.0.0/16 to access the device through HTTPS or HTTP.

```
<Sysname> system-view
[Sysname] acl basic 2001
[Sysname-acl-ipv4-basic-2001] rule permit source 10.10.0.0 0.0.255.255
[Sysname-acl-ipv4-basic-2001] quit
[Sysname] ip https acl 2001
```

Related commands

acl (*ACL and QoS Command Reference*)

ip https certificate access-control-policy

Use **ip https certificate access-control-policy** to apply a certificate-based access control policy to control HTTPS access.

Use **undo ip https certificate access-control-policy** to restore the default.

Syntax

ip https certificate access-control-policy *policy-name*

undo ip https certificate access-control-policy

Default

No certificate-based access control policy is applied for HTTPS access control.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies a certificate-based access control policy by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

For more information about the certificate-based access control policy, see PKI configuration in *Security Configuration Guide*.

Examples

Use certificate-based access control policy **myacl** to control HTTPS access.

```
<Sysname> system-view
[Sysname] ip https certificate access-control-policy myacl
```

Related commands

pki certificate access-control-policy (*Security Command Reference*)

ip https enable

Use **ip https enable** to enable the HTTPS service.

Use **undo ip https enable** to disable the HTTPS service.

Syntax

ip https enable

undo ip https enable

Default

The HTTPS service is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

To allow users to access the device through HTTPS, you must enable the HTTPS service.

Enabling the HTTPS service triggers the SSL handshake negotiation process.

- If the device has a local certificate, the SSL handshake negotiation succeeds and the HTTPS service starts up.
- If the device does not have a local certificate, the certificate application process starts. Because the certificate application process takes a long time, the SSL handshake negotiation might fail and the HTTPS service might not be started. To solve the problem, execute this command again until the HTTPS service is enabled.

Examples

Enable the HTTPS service.

```
<Sysname> system-view
[Sysname] ip https enable
```

Related commands

ip https certificate access-control-policy

ip https ssl-server-policy

ip https port

Use **ip https port** to specify the HTTPS service port number.

Use **undo ip https port** to restore the default.

Syntax

ip https port *port-number*

undo ip https port

Default

The HTTPS service port number is 443.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

port-number: Specifies a port number in the range of 1 to 65535.

Usage guidelines

When the HTTPS service is enabled, changing the HTTPS service port number re-enables the HTTPS service and closes all HTTPS and HTTP connections. To log in again, users must enter the new URL in the Web browser's address bar.

Examples

Set the HTTPS service port number to 8080.

```
<Sysname> system-view
[Sysname] ip https port 8080
```

ip https ssl-server-policy

Use **ip https ssl-server-policy** to apply an SSL server policy to control HTTPS access.

Use **undo ip https ssl-server-policy** to restore the default.

Syntax

ip https ssl-server-policy *policy-name*

undo ip https ssl-server-policy

Default

No SSL server policy is applied. The HTTPS service uses a self-signed certificate.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies an SSL server policy name, a string of 1 to 31 characters.

Usage guidelines

If the HTTP service and HTTPS service are enabled, changes to the applied SSL server policy do not take effect. For the changes to take effect, you must disable HTTP and HTTPS, and then apply the policy and enable HTTP and HTTPS again.

To restore the default, you must disable HTTP and HTTPS, execute the **undo ip https ssl-server-policy** command, and then enable HTTP and HTTPS again.

Examples

Apply SSL server policy **myssl** to the HTTPS service.

```
<Sysname> system-view
[Sysname] ip https ssl-server-policy myssl
```

Related commands

ssl server-policy (*Security Command Reference*)

line

Use **line** to enter one or multiple user line views.

Syntax

line { *first-number1* [*last-number1*] | { **console** | **vty** } *first-number2* [*last-number2*] }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

first-number1: Specifies the absolute number of the first user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

last-number1: Specifies the absolute number of the last user line. To view the value range for this argument, enter a question mark (?) in the place of this argument. This number must be greater than *first-number1*.

console: Specifies the console line.

vty: Specifies the VTY line.

first-number2: Specifies the relative number of the first user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

last-number2: Specifies the relative number of the last user line. To view the value range for this argument, enter a question mark (?) in the place of this argument. This number must be greater than *first-number2*.

Examples

Enter the view of VTY line 0.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0]
```

Enter the views of VTY lines 0 to 63.

```
<Sysname> system-view
[Sysname] line vty 0 63
[Sysname-line-vty0-63]
```

Related commands

line class

line class

Use **line class** to enter user line class view.

Syntax

line class { **console** | **vty** }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

console: Specifies the console line class view.

vty: Specifies the VTY line class view.

Usage guidelines

To configure the same settings for all user lines of a line class, use this command to enter the user line class view.

In user line class view, you can execute the following commands:

- **activation-key**
- **auto-execute command**
- **authentication-mode**
- **command accounting**
- **command authorization**
- **escape-key**
- **history-command max-size**
- **idle-timeout**
- **protocol inbound**
- **screen-length**
- **set authentication password**
- **shell**
- **terminal type**
- **user-role**

For commands that are available in both user line view and user line class view, the device uses the following rules to determine the settings to use:

- A setting in user line view applies only to the user line. A setting in user line class view applies to all user lines of the class.
- A non-default setting in either view takes precedence over a default setting in the other view. A non-default setting in user line view takes precedence over a non-default setting in user line class view.
- A setting in user line class view does not take effect on current online users. It takes effect only on new login users.

Examples

Set the CLI connection idle-timeout timer to 15 minutes in VTY line class view.

```
<Sysname> system-view
[Sysname] line class vty
[Sysname-line-class-vty] idle-timeout 15
```

In console line class view, configure the character **s** as the terminal session activation key.

```
<Sysname> system-view
[Sysname] line class console
[Sysname-line-class-console] activation-key s
[Sysname-line-class-console] quit
```

In the view of console line 0, restore the default terminal session activation key.

```
[Sysname] line console 0
[Sysname-line-console0] undo activation-key
```

Alternatively, you can use the following command:

```
[Sysname-line-console0] activation-key 13
```

To verify the configuration:

1. Exit the session on console line 0.
   ```
   [Sysname-line-console0] return
   <Sysname> quit
   ```
2. Log in again through the user line.
   The following message appears:
   ```
   Press ENTER to get started.
   ```
3. Press **Enter**.
   Pressing **Enter** does not start a session.
4. Enter **s**.
   A terminal session is started.
   ```
   <Sysname>
   ```

Related commands

line

lock

Use **lock** to lock the current user line and set the password for unlocking the line.

Syntax

lock

Default

The system does not lock any user lines.

Views

User view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command locks the current user line to prevent unauthorized users from using the line. You must set the password for unlocking the line as prompted. The user line is locked after you enter the password and confirm the password.

To unlock the user line, press **Enter** and enter the password you set.

Examples

Lock the current user line and set the password for unlocking the line.

```
<Sysname> lock
Please input password<1 to 16> to lock current line:
Password:
Again:

                    locked !
```

// The user line is locked. To unlock it, press **Enter** and enter the password:

```
Password:
<Sysname>
```

lock reauthentication

Use **lock reauthentication** to lock the current user line and enable unlocking authentication.

Syntax

lock reauthentication

Default

The system does not lock any user lines or initiate reauthentication.

Views

Any view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command locks the current user line. To unlock the user line, you must press **Enter** and provide the login password to pass reauthentication. If you have changed the login password after login, you must provide the new password. If no login password is set, the system unlocks the user line after you press **Enter**.

Examples

Lock the current user line and enable unlocking authentication.

```
<Sysname> lock reauthentication

Please press Enter to unlock the screen.
```

// The user line is locked. To unlock it, press **Enter** and enter the login password:

```
Password:

<Sysname>
```

Related commands

lock-key

lock-key

Use **lock-key** to set the user line locking key. Pressing this shortcut key locks the current user line and enables unlocking authentication.

Use **undo lock-key** to restore the default.

Syntax

lock-key *key-string*

undo lock-key

Default

No user line locking key is set.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Parameters

key-string: Specifies a shortcut key. It can be a character (case sensitive), or an ASCII code value in the range of 0 to 127. For example, if you use **lock-key 1**, the shortcut key is **Ctrl+A**. If you use **lock-key a**, the shortcut key is **a**. For information about ASCII code values of individual characters, see the standard ASCII code chart. For information about ASCII code values of combined keys that use the **Ctrl** key, see Table 1.

Usage guidelines

As a best practice, specify a combined key as the user line locking key. If you specify a single character as the key, the character acts only as the user line locking key. You cannot type the character for any commands, keywords, or arguments.

Pressing the user line locking key is equivalent to executing the **lock reauthentication** command.

This command takes effect immediately.

To display the current user line locking key, use the **display current-configuration | include lock-key** command.

Examples

Set the user line locking key to **Ctrl+A** for VTY line 0.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] lock-key 1
[Sysname-line-vty0] quit
```

To verify the configuration:

1. Press **Ctrl+A**.

```
[Sysname]

Please press Enter to unlock the screen.
```

2. Press **Enter** and enter the login password.

```
Password:

[Sysname]
```

Related commands

lock reauthentication

parity

Use **parity** to specify the parity.

Use **undo parity** to restore the default.

Syntax

parity { **even** | **mark** | **none** | **odd** | **space** }

undo parity

Default

The setting is **none**. No parity is used.

Views

User line view

Predefined user roles

network-admin

context-admin

Parameters

even: Uses even parity.

mark: Uses mark parity.

none: Uses no parity.

odd: Uses odd parity.

space: Uses space parity.

Usage guidelines

This command is not supported in VTY line view.

The configuration terminal and the device must use the same parity.

Examples

Configure console line 0 to use odd parity.

```
<Sysname> system-view
[Sysname] line console 0
[Sysname-line-console0] parity odd
```

protocol inbound

Use **protocol inbound** to specify the supported protocols.

Use **undo protocol inbound** to restore the default.

Syntax

protocol inbound { **all** | **ssh** | **telnet** }

undo protocol inbound

Default

All of the protocols are supported.

Views

VTY line view

VTY line class view

Predefined user roles

network-admin

context-admin

Parameters

all: Supports both Telnet and SSH.

ssh: Supports SSH only.

telnet: Supports Telnet only.

Usage guidelines

Only users assigned the network-admin, context-admin, or level-15 user role can execute this command. Other users cannot execute this command, even if they are granted the right to execute this command.

A configuration change in user line view does not take effect on the current session. It takes effect on subsequent login sessions.

Before configuring a user line to support SSH, set the authentication mode to **scheme** for the user line.

In VTY line view, this command is associated with the **authentication-mode** command. If you specify a non-default value for one of the two commands, the other command uses the default setting, regardless of the setting in VTY line class view.

- If the settings of the two commands in VTY line view are both the default settings, the settings for the commands in VTY line class view take effect.
- If the settings of the two commands in VTY line view are both non-default settings, the non-default settings in VTY line view take effect.
- If only one command has a non-default setting in VTY line view, the other command uses the default setting, regardless of the setting in VTY line class view.

Examples

Enable user lines VTY 0 through VTY 4 to support only SSH.

```
<Sysname> system-view
[Sysname] line vty 0 4
[Sysname-line-vty0-4] authentication-mode scheme
[Sysname-line-vty0-4] protocol inbound ssh
```

Enable SSH support and set the authentication mode to scheme in VTY line class view. Enable user lines VTY 0 through VTY 4 to support all protocols and disable authentication for the user lines.

```
<Sysname> system-view
[Sysname] line class vty
[Sysname-line-class-vty] authentication-mode scheme
[Sysname-line-class-vty] protocol inbound ssh
[Sysname-line-class-vty] line vty 0 4
[Sysname-line-vty0-4] authentication-mode none
```

To verify the configuration:

1. Telnet to the device.

```
<Client> telnet 192.168.1.241
Trying 192.168.1.241 ...
Press CTRL+K to abort
Connected to 192.168.1.241 ...

******************************************************************************

******************************************************************************

<Server>
```

You are logged in without authentication.

2. Display online CLI user information.

```
<Server> display users
  Idx  Line     Idle       Time              Pid     Type
+ 50   VTY 0    00:00:00   Jan 17 15:29:27   189     TEL

Following are more details.
VTY 0   :
        Location: 192.168.1.186
 +    : Current operation user.
 F    : Current operation user works in async mode.
```

The output shows that you are using VTY 0. The configuration in user line view is effective.

[Sysname] restful https port 1000
```

restful https ssl-server-policy

Use **restful https ssl-server-policy** to apply an SSL server policy to the RESTful access over HTTPS service.

Use **undo restful https ssl-server-policy** to restore the default.

Syntax

restful https ssl-server-policy *policy-name*

undo restful https ssl-server-policy

Default

No SSL server policy is applied to the RESTful access over HTTPS service.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies an SSL server policy name, a string of 1 to 31 characters.

Usage guidelines

The RESTful access over HTTPS service will use the SSL server policy to enhance service security. For more information about SSL server policies, see SSL configuration in *Security Configuration Guide*.

You can use this command only when RESTful access over HTTPS is disabled.

This command takes effect after you enable RESTful access over HTTPS.

If you execute this command multiple times, the most recent configuration takes effect.

After the RESTful access over HTTPS service is enabled, changes to the applied SSL server policy take effect only on HTTPS connections established after the changes. These changes do not take effect on existing HTTPS connections.

Examples

Apply SSL server policy **myssl** to the RESTful access over HTTPS service.

```
<Sysname> system-view
[Sysname] restful https ssl-server-policy myssl
```

Related commands

restful https enable

ssl server-policy (*Security Command Reference*)

screen-length

Use **screen-length** to set the maximum number of lines of command output to send to the terminal at a time when the screen pausing feature is enabled.

Use **undo screen-length** to restore the default.

Syntax

screen-length *screen-length*

undo screen-length

Default

A maximum of 24 lines are sent.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Parameters

screen-length: Specifies the maximum number of lines to send, in the range of 0 to 512. To send command output without pausing, set the number to 0 or execute the **screen-length disable** command.

Usage guidelines

The number of lines that can be displayed on the terminal screen is restricted by both this setting and the display specification of the terminal. For example, if this setting is 40, the device sends 40 lines to the terminal at a time. If the terminal display specification is 24 lines, only the last 24 lines are displayed on the terminal screen. To view the previous 16 lines, you must press **PgUp**.

To continue to display command output after a pause, press the space bar.

By default, pausing between screens of output is enabled.

This command is available in both user line view and user line class view. A non-default setting in either view takes precedence over a default setting in the other view. A non-default setting in user line view takes precedence over a non-default setting in user line class view.

The setting in user line view takes effect immediately on the current session. The setting in user line class view takes effect on login sessions that are established after the setting is configured.

Examples

Set the maximum number of lines to send at a time to 30 for VTY line 0.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] screen-length 30
```

Related commands

screen-length disable

send

Use **send** to send messages to online login users.

Syntax

send { **all** | *number1* | { **console** | **vty** } *number2* }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

all: Specifies all user lines.

number1: Specifies the absolute number of a user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

console: Specifies the console line.

vty: Specifies the VTY line.

number2: Specifies the relative number of a user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

Usage guidelines

You can use this command to send notifications to online users before performing an operation that might affect other online users, for example, before rebooting the device.

To end a message, press **Enter**. To abort the send operation, press **Ctrl+C**.

Examples

Send a notification to the user on VTY 1.

```
<Sysname> send vty 1
Input message, end with Enter; abort with CTRL+C:
Your attention, please. I will reboot the system in 3 minutes.
Send message? [Y/N]:y
```

The message should appear on the user's terminal screen as follows:

```
[Sysname]

***
***
***Message from vty0 to vty1
***
Your attention, please. I will reboot the system in 3 minutes.
```

set authentication password

Use **set authentication password** to set the password for local password authentication.

Use **undo set authentication password** to restore the default.

Syntax

set authentication password { **hash** | **simple** } *string*

undo set authentication password

Default

No password is set for local password authentication.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Parameters

hash: Specifies a password in hashed form.

simple: Sets a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in hashed form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 4 to 16 characters and must contain a minimum of two character types. Its hashed form is a case-sensitive string of 1 to 110 characters.

Usage guidelines

Only users assigned the network-admin, context-admin, or level-15 user role can execute this command. Other users cannot execute this command, even if they are granted the right to execute this command.

This command is available in both user line view and user line class view. A non-default setting in either view takes precedence over a default setting in the other view. A non-default setting in user line view takes precedence over a non-default setting in user line class view.

A password change does not take effect on the current session. It takes effect on subsequent login sessions.

Examples

Set the password to **hello12345** for local password authentication on VTY line 0.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] authentication-mode password
[Sysname-line-vty0] set authentication password simple hello12345
```

Related commands

authentication-mode

shell

Use **shell** to enable the terminal service for user lines.

Use **undo shell** to disable the terminal service for user lines.

Syntax

shell

undo shell

Default

The terminal service is enabled on all user lines.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Usage guidelines

The **undo shell** command is not supported in console line view or console line class view.

You cannot disable the terminal service on the user line you are using.

When the device acts as a Telnet or SSH server, you cannot use the **undo shell** command.

If the **undo shell** command is used in user line class view, you cannot use the **shell** command in the view of a user line in the class.

Examples

Disable the terminal service for VTY lines VTY 0 through 4 so no user can log in to the device through the user lines.

```
<Sysname> system-view
[Sysname] line vty 0 4
[Sysname-line-vty0-4] undo shell
Disable ui-vty0-4 , are you sure? [Y/N]:y
[Sysname-line-vty0-4]
```

speed

Use **speed** to set the transmission rate (also called the baud rate) on a user line.

Use **undo speed** to restore the default.

Syntax

speed *speed-value*

undo speed

Default

The transmission rate is 9600 bps on a user line.

Views

User line view

Predefined user roles

network-admin

context-admin

Parameters

speed-value: Specifies the transmission rate in bps. Supported transmission rates depend on the network environment. The transmission rates for asynchronous serial interfaces might include:

- 300 bps.
- 600 bps.
- 1200 bps.
- 2400 bps.
- 4800 bps.
- 9600 bps.
- 19200 bps.
- 38400 bps.
- 57600 bps.
- 115200 bps.

Usage guidelines

This command is not supported in VTY line view.

The configuration terminal and the device must be configured with the same transmission rate to communicate.

Examples

Set the transmission rate to 19200 bps for console line 0.

```
<Sysname> system-view
[Sysname] line console 0
[Sysname-line-console0] speed 19200
```

stopbits

Use **stopbits** to specify the number of stop bits for a character.

Use **undo stopbits** to restore the default.

Syntax

stopbits { **1** | **1.5** | **2** }

undo stopbits

Default

One stop bit is used.

Views

User line view

Predefined user roles

network-admin

context-admin

Parameters

1: Uses one stop bit.

1.5: Uses one and a half stop bits. The device does not support using one and a half stop bits. If you specify this keyword, two stop bits are used.

2: Uses two stop bits.

Usage guidelines

This command is not supported in VTY line view.

The configuration terminal and the device must use the same number of stop bits to communicate.

Examples

Set the number of stop bits to 1 for console line 0.

```
<Sysname> system-view
[Sysname] line console 0
[Sysname-line-console0] stopbits 1
```

telnet

Use **telnet** to Telnet to a host in an IPv4 network.

Syntax

telnet *remote-host* [*service-port*] [**vpn-instance** *vpn-instance-name*] [**source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] [**dscp** *dscp-value*] [**escape** *character*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

remote-host: Specifies the IPv4 address or host name of a remote host. A host name can be a case-insensitive string of 1 to 253 characters. Valid characters include letters, digits, hyphens (-), underscores (_), and dots (.).

service-port: Specifies the TCP port number for the Telnet service on the remote host. The value range is 0 to 65535 and the default is 23.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the remote host belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the remote host belongs to the public network, do not specify this option.

source: Specifies a source IPv4 address or source interface for outgoing Telnet packets. If you do not specify this option, the device uses the primary IPv4 address of the output interface for the route to the server as the source address.

interface *interface-type interface-number*: Specifies the source interface. The primary IPv4 address of the interface will be used as the source IPv4 address for outgoing Telnet packets.

ip *ip-address*: Specifies the source IPv4 address for outgoing Telnet packets.

dscp *dscp-value*: Specifies a DSCP value for outgoing Telnet packets. The value range is 0 to 63. The default is 48.

escape *character*: Specifies an escape character. You can use the escape character together with a dot (.) as the escape key to terminate the current Telnet connection and return to the upper level connection. The value for the *character* argument is case sensitive and must be different from the login username. As a best practice, specify a tilde (~) for the *character* argument.

Usage guidelines

Methods for terminating Telnet connections include:

- Pressing **Ctrl+K**—Terminates all Telnet connections. You can use this method in any scenarios unless you configure an escape character. After you configure an escape character, pressing **Ctrl+K** does not terminate Telnet connections.
- Executing the **quit** command—Terminates the current Telnet connection and returns to the upper level connection. This method is not available when the Telnet server reboots or fails.
- Using the escape key—Terminates the current Telnet connection and returns to the upper level connection. You can use this method in any scenarios.

To use the escape key to terminate the current Telnet connection, enter the escape character and a dot in a new line. If you enter any other characters or perform any other operations (for example, pressing the backspace key) before entering the escape character, the escape character does not take effect.

The source address or interface specified by this command is applied only to the Telnet connection that is being established.

Examples

Telnet to host 1.1.1.2, using 1.1.1.1 as the source IP address for outgoing Telnet packets.

```
<Sysname> telnet 1.1.1.2 source ip 1.1.1.1
```

Related commands

telnet client source

telnet client source

Use **telnet client source** to specify a source IPv4 address or source interface for the Telnet client to use for outgoing Telnet packets.

Use **undo telnet client source** to restore the default.

Syntax

telnet client source { **interface** *interface-type interface-number* | **ip** *ip-address* }

undo telnet client source

Default

No source IPv4 address or source interface is specified. The Telnet client uses the primary IPv4 address of the output interface for the route to the server as the source IPv4 address.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies a source interface. The primary IPv4 address of the interface will be used as the source IPv4 address for outgoing Telnet packets.

ip *ip-address*: Specifies a source IPv4 address.

Usage guidelines

The setting configured by this command applies to all Telnet connections but has a lower precedence than the source setting specified for the **telnet** command.

Examples

Set the source IPv4 address to 1.1.1.1 for outgoing Telnet packets.

```
<Sysname> system-view
[Sysname] telnet client source ip 1.1.1.1
```

Related commands

display telnet client

telnet ipv6

Use **telnet ipv6** to Telnet to a host in an IPv6 network.

Syntax

telnet ipv6 *remote-host* [**-i** *interface-type interface-number*] [*port-number*] [**vpn-instance** *vpn-instance-name*] [**source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] [**dscp** *dscp-value*] [**escape** *character*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

remote-host: Specifies the IPv6 address or host name of a remote host. A host name can be a case-insensitive string of 1 to 253 characters. Valid characters include letters, digits, hyphens (-), underscores (_), and dots (.).

-i *interface-type interface-number*: Specifies the interface for sending Telnet packets. This option is required when the remote host address is a link-local address. When the server address is a global unicast address, you cannot specify this option.

port-number: Specifies the TCP port number for the Telnet service on the remote host. The value range is 0 to 65535 and the default is 23.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the remote host belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the remote host belongs to the public network, do not specify this option.

source: Specifies a source IPv6 address or source interface for outgoing Telnet packets. If you do not specify this option, the device uses the primary IPv6 address of the output interface for the route to the server as the source address.

interface *interface-type interface-number*: Specifies the source interface. The primary IPv6 address of the interface will be used as the source IPv6 address for outgoing Telnet packets.

ipv6 *ipv6-address*: Specifies the source IPv6 address for outgoing Telnet packets.

dscp *dscp-value*: Specifies a DSCP value for outgoing Telnet packets. The value range is 0 to 63. The default is 48.

escape *character*: Specifies an escape character. You can use the escape character together with a dot (.) as the escape key to terminate the current Telnet connection and return to the upper level connection. The value for the *character* argument is case sensitive and must be different from the login username. As a best practice, specify a tilde (~) for the *character* argument.

Usage guidelines

Methods for terminating Telnet connections include:

- Pressing **Ctrl+K**—Terminates all Telnet connections. You can use this method in any scenarios unless you configure an escape character. After you configure an escape character, pressing **Ctrl+K** does not terminate Telnet connections.
- Executing the **quit** command—Terminates the current Telnet connection and returns to the upper level connection. This method is not available when the Telnet server reboots or fails.
- Using the escape key—Terminates the current Telnet connection and returns to the upper level connection. You can use this method in any scenarios.

To use the escape key to terminate the current Telnet connection, enter the escape character and a dot in a new line. If you enter any other characters or perform any other operations (for example, pressing the backspace key) before entering the escape character, the escape character does not take effect.

Examples

Telnet to the host at 5000::1.

```
<Sysname> telnet ipv6 5000::1
```

Telnet to the host at 2000::1. Use 1000::1 as the source address for outgoing Telnet packets.

```
<Sysname> telnet ipv6 2000::1 source ipv6 1000::1
```

telnet server acl

Use **telnet server acl** to apply an ACL to filter Telnet logins.

Use **undo telnet server acl** to restore the default.

Syntax

telnet server acl [**mac**] *acl-number*

undo telnet server acl

Default

No ACL is used to filter Telnet logins.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

mac: Specifies a Layer 2 ACL. To specify an ACL of a different type, do not specify this keyword.

acl-number: Specifies an ACL by its number. If you specify the **mac** keyword, the value range of this argument is 4000 to 4999. If you do not specify the **mac** keyword, the value range of this argument is 2000 to 3999.

Usage guidelines

When no ACL is applied to the Telnet service, all users can Telnet to the device. To control Telnet logins, specify an ACL that exists and has rules so only users permitted by the ACL can Telnet to the device. If you specify an ACL that does not exist or does not have rules, no users can Telnet to the device.

If a VPN instance is specified in an ACL rule, the rule applies only to the packets of the VPN instance. If no VPN instance is specified in an ACL rule, the rule applies only to the packets on the public network.

For more information about ACLs, see *ACL and QoS Configuration Guide*.

If you execute this command multiple times, the most recent configuration takes effect.

This command does not take effect on existing Telnet connections.

Examples

Permit only the user at 1.1.1.1 to Telnet to the device.

```
<Sysname> system-view
[Sysname] acl basic 2001
[Sysname-acl-ipv4-basic-2001] rule permit source 1.1.1.1 0
[Sysname-acl-ipv4-basic-2001] quit
[Sysname] telnet server acl 2001
```

telnet server acl-deny-log enable

Use **telnet server acl-deny-log enable** to enable logging for Telnet login attempts that are denied by the Telnet login control ACL.

Use **undo telnet server acl-deny-log enable** to disable logging for Telnet login attempts that are denied by the Telnet login control ACL.

Syntax

telnet server acl-deny-log enable

undo telnet server acl-deny-log enable

Default

Logging is disabled for Telnet login attempts that are denied by the Telnet login control ACL.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Only clients permitted by the Telnet login control ACL can Telnet to the device. This logging feature generates log messages for Telnet login attempts that are denied by the Telnet login control ACL.

For information about log message output, see the information center in *Network Management and Monitoring Configuration Guide*. For information about configuring a Telnet login control ACL, see the **telnet server acl** or **telnet server ipv6 acl** command.

Examples

Enable logging for Telnet login attempts that are denied by the Telnet login control ACL.

```
<Sysname> system-view
[Sysname] telnet server acl-deny-log enable
```

Related commands

telnet server acl

telnet server ipv6 acl

telnet server dscp

Use **telnet server dscp** to specify the DSCP value for IPv4 to use for Telnet packets sent to a Telnet client.

Use **undo telnet server dscp** to restore the default.

Syntax

telnet server dscp *dscp-value*

undo telnet server dscp

Default

IPv4 uses the DSCP value 48 for Telnet packets sent to a Telnet client.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Specifies a DSCP value in the range of 0 to 63.

Usage guidelines

The DSCP value is carried in the ToS field of an IPv4 packet to indicate the packet transmission priority.

Examples

Set the DSCP value for IPv4 to use for outgoing Telnet packets to 30 on a Telnet server.

```
<Sysname> system-view
[Sysname] telnet server dscp 30
```

telnet server enable

Use **telnet server enable** to enable the Telnet server.

Use **undo telnet server enable** to disable the Telnet server.

Syntax

telnet server enable

undo telnet server enable

Default

The Telnet server is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Users can Telnet to the device only when the Telnet server is enabled.

Examples

Enable the Telnet server.

```
<Sysname> system-view
[Sysname] telnet server enable
```

telnet server ipv6 acl

Use **telnet server ipv6 acl** to apply an IPv6 ACL to filter IPv6 Telnet logins.

Use **undo telnet server ipv6 acl** to restore the default.

Syntax

telnet server ipv6 acl { **ipv6** | **mac** } *acl-number*

undo telnet server ipv6 acl

Default

No IPv6 ACL is used to filter IPv6 Telnet logins.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies an IPv6 ACL.

mac: Specifies a Layer 2 ACL. To specify an ACL of a different type, do not specify this keyword.

acl-number: Specifies an ACL by its number. If you specify the **ipv6** keyword, the value range of this argument is 2000 to 3999. If you specify the **mac** keyword, the value range of this argument is 4000 to 4999.

Usage guidelines

When no ACL is applied to the Telnet service, all users can Telnet to the device. To control Telnet logins, specify an ACL that exists and has rules so only users permitted by the ACL can Telnet to the device. If you specify an ACL that does not exist or does not have rules, no users can Telnet to the device.

If a VPN instance is specified in an ACL rule, the rule applies only to the packets of the VPN instance. If no VPN instance is specified in an ACL rule, the rule applies only to the packets on the public network.

For more information about ACLs, see *ACL and QoS Configuration Guide*.

If you execute this command multiple times, the most recent configuration takes effect.

This command does not take effect on existing Telnet connections.

Examples

Permit only the user at 2000::1 to Telnet to the device.

```
<Sysname> system-view
[Sysname] acl ipv6 basic 2001
[Sysname-acl6-ipv6-basic-2001] rule permit source 2000::1 128
[Sysname-acl6-ipv6-basic-2001] quit
[Sysname] telnet server ipv6 acl ipv6 2001
```

telnet server ipv6 dscp

Use **telnet server ipv6 dscp** to specify the DSCP value for IPv6 to use for Telnet packets sent to a Telnet client.

Use **undo telnet server ipv6 dscp** to restore the default.

Syntax

telnet server ipv6 dscp *dscp-value*

undo telnet server ipv6 dscp

Default

IPv6 uses the DSCP value 48 for Telnet packets sent to a Telnet client.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Specifies a DSCP value in the range of 0 to 63.

Usage guidelines

The DSCP value is carried in the Traffic class field of an IPv6 packet to indicate the packet transmission priority.

Examples

Set the DSCP value for IPv6 to use for outgoing Telnet packets to 30 on a Telnet server.

```
<Sysname> system-view
[Sysname] telnet server ipv6 dscp 30
```

telnet server ipv6 port

Use **telnet server ipv6 port** to specify the IPv6 Telnet service port number.

Use **undo telnet server ipv6 port** to restore the default.

Syntax

telnet server ipv6 port *port-number*

undo telnet server ipv6 port

Default

The IPv6 Telnet service port number is 23.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

port-number: Specifies a port number. The value can be 23 or in the range of 1025 to 65535.

Usage guidelines

This command terminates all existing Telnet connections to the IPv6 Telnet server. To use the Telnet service, users must reestablish Telnet connections.

Examples

Set the IPv6 Telnet service port number to 1026.

```
<Sysname> system-view
[Sysname] telnet server ipv6 port 1026
```

telnet server port

Use **telnet server port** to specify the IPv4 Telnet service port number.

Use **undo telnet server port** to restore the default.

Syntax

telnet server port *port-number*

undo telnet server port

Default

The IPv4 Telnet service port number is 23.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

port-number: Specifies a port number. The value can be 23 or in the range of 1025 to 65535.

Usage guidelines

This command terminates all existing Telnet connections to the IPv4 Telnet server. To use the Telnet service, users must reestablish Telnet connections.

Examples

Set the IPv4 Telnet service port number to 1025.

```
<Sysname> system-view
[Sysname] telnet server port 1025
```

terminal type

Use **terminal type** to specify the terminal display type.

Use **undo terminal type** to restore the default.

Syntax

terminal type { **ansi** | **vt100** }

undo terminal type

Default

The terminal display type is ANSI.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Parameters

ansi: Specifies the ANSI type.

vt100: Specifies the VT100 type.

Usage guidelines

The device supports two terminal display types: ANSI and VT100. As a best practice, specify the VT100 type on both the device and the configuration terminal. If either side uses the ANSI type, a display problem might occur when a command line has more than 80 characters. For example, a cursor positioning error might occur.

This command is available in both user line view and user line class view. A non-default setting in either view takes precedence over a default setting in the other view. A non-default setting in user line view takes precedence over a non-default setting in user line class view.

A terminal display type change does not take effect on the current session. It takes effect on subsequent login sessions.

Examples

Set the terminal display type to VT100.

```
<Sysname> system-view
[Sysname] line vty 0
[Sysname-line-vty0] terminal type vt100
```

user-interface

Use **user-interface** to enter one or multiple user line views.

Syntax

user-interface { *first-number1* [*last-number1*] | { **console** | **vty** } *first-number2* [*last-number2*] }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

first-number1: Specifies the absolute number of the first user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

last-number1: Specifies the absolute number of the last user line. To view the value range for this argument, enter a question mark (?) in the place of this argument. This number must be greater than *first-number1*.

console: Specifies the console line.

vty: Specifies the VTY line.

first-number2: Specifies the relative number of the first user line. To view the value range for this argument, enter a question mark (?) in the place of this argument.

last-number2: Specifies the relative number of the last user line. To view the value range for this argument, enter a question mark (?) in the place of this argument. This number must be greater than *first-number2*.

Usage guidelines

This command is an older version reserved for backward compatibility purposes. It has the same functionality and output as the **line** command. As a best practice, use the **line** command.

To configure settings for a single user line, use this command to enter the user line view.

To configure the same settings for multiple user lines, use this command to enter multiple user line views.

Examples

Enter the view of console line 0.

```
<Sysname> system-view
[Sysname] user-interface console 0
[Sysname-line-console0]
```

Enter the views of VTY lines 0 to 4.

```
<Sysname> system-view
[Sysname] user-interface vty 0 4
```

```
[Sysname-line-vty0-4]
```

Related commands

user-interface class

user-interface class

Use **user-interface class** to enter user line class view.

Syntax

user-interface class { **console** | **vty** }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

console: Specifies the console line class view.

vty: Specifies the VTY line class view.

Usage guidelines

This command is an older version reserved for backward compatibility purposes. It has the same functionality and output as the **line class** command. As a best practice, use the **line class** command.

To configure the same settings for all user lines of a line class, you can use this command to enter the user line class view.

The following commands are available in user line class view:

- **activation-key**
- **auto-execute command**
- **authentication-mode**
- **command accounting**
- **command authorization**
- **escape-key**
- **history-command max-size**
- **idle-timeout**
- **protocol inbound**
- **screen-length**
- **set authentication password**
- **shell**
- **terminal type**
- **user-role**

For commands that are available in both user line view and user line class view, the device uses the following rules to determine the settings to use:

- A setting in user line view applies only to the user line. A setting in user line class view applies to all user lines of the class.
- A non-default setting in either view takes precedence over a default setting in the other view. A non-default setting in user line view takes precedence over a non-default setting in user line class view.
- A setting in user line class view does not take effect on current online users. It takes effect only on new login users.

Examples

Set the CLI connection idle-timeout timer to 15 minutes in VTY line class view.

```
<Sysname> system-view
[Sysname] user-interface class vty
[Sysname-line-class-vty] idle-timeout 15
```

In console line class view, configure character **s** as the terminal session activation key.

```
<Sysname> system-view
[Sysname] user-interface class console
[Sysname-line-class-console] activation-key s
[Sysname-line-class-console] quit
```

In the view of console line 0, restore the default terminal session activation key.

```
[Sysname] user-interface console 0
[Sysname-line-console0] undo activation-key
```

Alternatively, you can use the following command:

```
[Sysname-line-console0] activation-key 13
```

To verify the configuration:

1. Exit the session on console line 0.

   ```
   [Sysname-line-console0] return
   <Sysname> quit
   ```

2. Log in again through the console line.

   The following message appears:

   ```
   Press ENTER to get started.
   ```

3. Press **Enter**.

   Pressing **Enter** does not start a session.

4. Enter **s**.

   A terminal session is started.

   ```
   <Sysname>
   ```

Related commands

user-interface

user-role

Use **user-role** to assign a user role to a user line. The device assigns the user role to a user of the line when the user logs in.

Use **undo user-role** to remove a user role or restore the default.

Syntax

user-role *role-name*

undo user-role [*role-name*]

Default

A console user of the default context is assigned the **network-admin** user role. Other users on the default context are assigned the **network-operator** user role. A user on a non-default context is assigned the **context-operator** user role.

Views

User line view

User line class view

Predefined user roles

network-admin

context-admin

Parameters

role-name: Specifies a user role name, a case-sensitive string of 1 to 63 characters. The user role can be user-defined or predefined. Available predefined user roles include network-admin, network-operator, context-admin, context-operator,and level-0 to level-15. The predefined security-audit and guest-manager user roles are not supported in user line view or user line class view. If you do not specify this argument, the **undo user-role** command restores the default user roles.

Usage guidelines

Only users assigned the network-admin, context-admin, or level-15 user role can execute this command. Other users cannot execute this command, even if they are granted the right to execute this command.

This command is available in both user line view and user line class view. A non-default setting in either view takes precedence over a default setting in the other view. A non-default setting in user line view takes precedence over a non-default setting in user line class view.

A user role change does not take effect on the current session. It takes effect on subsequent login sessions.

You can assign up to 64 user roles to a user line.

For more information about user roles, see RBAC configuration in *Fundamentals Configuration Guide*.

Examples

Assign user role network-admin to VTY line 0 to 63.

```
<Sysname> system-view
[Sysname] line vty 0 63
[Sysname-line-vty0-63] user-role network-admin
```

web captcha

Use **web captcha** to specify a fixed verification code for Web login.

Use **undo web captcha** to restore the default.

Syntax

web captcha *verification-code*

undo web captcha

Default

No fixed verification code is specified for Web login. A Web user must enter the verification code displayed on the login page.

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

verification-code: Specifies the fixed verification code, a case-sensitive 4-character string.

Usage guidelines

In test environments where a script is used for Web function tests, you can configure a fixed verification code to improve test efficiency.

For Web access security purposes, do not use this feature in production environments.

If you execute the **web captcha** command multiple times, the most recent configuration takes effect.

This command is not saved to the configuration file and will not take effect after a reboot.

Examples

Set the fixed verification code to **test** for Web login.

```
<Sysname> web captcha test
```

web https-authorization mode

Use **web https-authorization mode** to set the authentication and authorization mode for HTTPS login.

Use **undo web https-authorization mode** to restore the default.

Syntax

web https-authorization mode { **auto** | **certificate** | **certificate-manual** | **manual** }

undo web https-authorization mode

Default

Manual mode is used for HTTPS login authentication and authorization.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

auto: Requires the user to provide a username and password or a certificate for authentication and authorization

certificate: Requires the user to provide a certificate for authentication and authorization.

certificate-manual: Requires the user to provide a username and password as well as a certificate for authentication and authorization.

manual: Requires the user to provide a username and password for authentication and authorization.

Usage guidelines

For a user to use a certificate for HTTPS login authentication and authorization, perform the following tasks:

- Apply an SSL server policy to the HTTPS service and enable client authentication in the policy so the SSL server performs certificate-based authentication.
- Specify the certificate field to be used as the username for certificate-based authentication, and create a local user that uses the same username.

During HTTPS connection establishment, a user must select the correct certificate.

Examples

Set the HTTPS login authentication and authorization mode to **certificate**.

```
<Sysname> system-view
[Sysname] web https-authorization mode certificate
```

Related commands

web https-authorization username

web https-authorization username

Use **web https-authorization username** to specify the certificate field to be used as the username for certificate-based authentication.

Use **undo web https-authorization username** to restore the default.

Syntax

web https-authorization username { **cn** | **email-prefix** | **oid** *oid-value* }

undo web https-authorization username

Default

The CN field in the certificate is used as the username for certificate-based authentication.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

cn: Uses the CN field in the certificate as the username.

email-prefix: Uses the string before the @ sign in the emailAddress field of the certificate as the username.

oid *oid-value*: Uses the field corresponding to an OID as the username. The *oid-value* argument is a dotted decimal string of 1 to 255 characters.

Usage guidelines

This command is required when the authentication and authorization mode for HTTPS login is certificate or auto.

Examples

Specify the field corresponding to an OID as the username for certificate-based authentication.

```
<Sysname> system-view
[Sysname] web https-authorization username oid 1.2.840.113549.1.9.1
```

Related commands

web https-authorization mode

web idle-timeout

Use **web idle-timeout** to set the Web connection idle-timeout timer.

Use **undo web idle-timeout** to restore the default.

Syntax

web idle-timeout *idle-time*

undo web idle-timeout

Default

The Web connection idle-timeout timer is 10 minutes.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

idle-time: Specifies the Web connection idle-timeout timer in minutes. The value range is 1 to 999.

Usage guidelines

The system automatically terminates a Web user connection if no mouse or keyboard operation occurs within the idle-timeout interval.

This command takes effect immediately on current Web connections.

Examples

Set the Web connection idle-timeout timer to 100 minutes.

```
<Sysname> system-view
[Sysname] web idle-timeout 100
```

Contents

License management commands

All commands in this chapter are supported only on the default context. Features licensed to the default context are also licensed to non-default contexts. For information about contexts, see *Virtual Technologies Configuration Guide*.

display license

Use **display license** to display detailed license information.

Syntax

display license [**activation-file**] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

activation-file: Displays license information about activation files.

slot *slot-number*: Specifies the member ID of an IRF member device. If no member device is specified, this command displays license information for all IRF member devices.

Usage guidelines

If you do not specify any parameters, this command displays detailed information about all licenses.

Examples

Display detailed information about all licenses.

```
<Sysname> display license
Slot 1:
flash:/license/NGFirewall20171114195245137 53.ak
Feature: IPS
Product Description: Trial IPS License, 30 Days
Registered at: 2017-11-14 20:07:06
License Type: Trial (date restricted)
Trial Validity Period: 2017-11-14 to 2017-12-14
Current State: Expired
```

Table 1 Command output

Field	Description
Feature	Feature name.
Product Description	License description.
Registered at	Time when the license was installed.
License Type	License type by validity period:

Field	Description
	• **NA**—The system cannot obtain the license type. • **Permanent**—Purchased license that never expires and is always valid. • **Days restricted**—Purchased license that is valid for a period of days, for example, 30 days. • **Trial (days restricted)**—Free trial license that is valid for a period of days.
Time Left (days)	Remaining days of the license. This field is available for a purchased license.
Trial Time Left (days)	Remaining days of the trial period. This field is available for a trial license.

Current State	State of the license:
	• **In use**—The license is being used.
	• **Usable**—The license is available for use.
	  ○ If multiple days-restricted licenses for one feature are installed, only one license is in **In use** state and the rest licenses are in **Usable** state.
	  ○ A date restricted license is in this state if its start date is not reached.
	• **Expired**—The license has expired.
	• **Uninstalled**—The license has been uninstalled.
	• **Unusable**—The license cannot be used.
	• **Invalid**—The license is invalid and cannot be used.

Uninstall Key	This field is available for licenses that have been uninstalled.
Uninstall Date	Date when the activation file was uninstalled.

display license device-id

Use **`display license device-id`** to display SN and DID information.

Syntax

`display license device-id slot` *`slot-number`*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`slot` *`slot-number`*: Specifies the member ID of an IRF member device.

Usage guidelines

When you register a license for a device, you must provide its unique SN and DID.

The DID changes each time you use the **`license compress`** command to compress the license storage. Use the **`display license device-id`** command to identify the up-to-date DID each time you register licenses.

Examples

Display the SN and DID for the specified slot.

```
<Sysname> display license device-id slot 1
```

```
SN: 210235A1FXH164000026
Device ID: flash:/license/210235A1FXH164000026.did
```

display license feature

Use **display license feature** to display brief license information for features.

Syntax

display license feature

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display brief feature license information.

```
<Sysname> display license feature
Slot 1:
Total: 32  Usage: 0
Feature                        Licensed        State
ACG                            N               -
AV                             N               -
IPRPT                          N               -
IPS                            N               -
SSLVPN                         N               -
UFLT                           N               -
```

Table 2 Command output

Field	Description
Total	Total number of licenses that can be installed.
Usage	Number of licenses stored in the license storage.
Feature	Feature that must be licensed before being used.
Licensed	Licensing state of the feature: • **N**—Not licensed. • **Y**—Licensed.
State	License type by purchasing state: • **Formal**—Purchased license. • **Trial**—Trial license. • **Pre-licensed**—Preinstalled license. If the feature is not licensed, this field displays a hyphen (-). To use the feature, you must install a valid license file.

license activation-file install

Use **license activation-file install** to install an activation file.

Syntax

license activation-file install *license-file* **slot** *slot-number*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

license-file: Specifies the path of an activation file, a case-sensitive string of 1 to 127 characters. The activation file must be valid and stored on the device.

slot *slot-number*: Specifies the member ID of an IRF member device.

Usage guidelines

To install a license activation file successfully, make sure the SN and DID used for registering the feature license matches the current SN and DID of the device.

Activation files are device locked. A licensed feature can run on the IRF member device where its activation file is installed even after the member device is moved from one IRF fabric to another IRF fabric.

Examples

Install activation file package 20170101.tar.

```
<Sysname> system-view
[Sysname] license activation-file install flash:/license/20170101.tar
This operation might take some time. Do not perform any other operations until the operation
is completed or a failure message is displayed. Please wait...
Decompress......Done.
Begain to install test01.ak …Done.
Begain to install test02.ak …Done.
Begain to install test03.ak …Done.

Total Num:3
Success Num:3
Failed Num:0
```

Install activation file 20170811.ak to the specified slot.

```
<Sysname> system-view
[Sysname] license activation-file install flash:/license/20170811.ak slot 1
This operation might take some time. Do not perform any other operations until the operation
is completed or a failure message is displayed. Please wait...Done.
```

Related commands

display license

display license device-id

license activation-file uninstall

license compress

Use **license compress** to compress the license storage.

Syntax

license compress slot *slot-number*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies the member ID of an IRF member device.

Usage guidelines

The license storage is limited. You can execute this command to clear expired licenses and uninstalled licenses from the license storage.

If uninstalled licenses or expired licenses exist on the device, the compression operation will make the DID or DID file change. Before performing a compression, make sure all licenses registered with the old DID or DID file have been installed. You will be unable to install such licenses after the compression.

Examples

Compress the license storage on the specified slot.

```
<Sysname> system-view
[Sysname] license compress slot 1
This command will delete all data relevant to uninstalled and expired keys/licenses,
including Uninstall keys, and create a new device ID for activation keys/files. Make sure
you have saved the Uninstall keys so you can apply for a new activation key/file for the
unexpired licenses that were covered by the uninstalled activation keys/files.
Are you sure you want to continue? [Y/N]: Y
This operation might take some time. Do not perform any other operations until the operation
is completed or a failure message is displayed. Please wait...Done.
```

Contents

Device management commands

clock datetime

Use **clock datetime** to set the system time.

Syntax

clock datetime *time date*

Default

The system time is Coordinated Universal Time (UTC) 00:00:00 01/01/2011.

Views

User view

Predefined user roles

network-admin

Parameters

time: Specifies a time in the *hh:mm:ss* format. The value range for *hh* is 0 to 23. The value range for *mm* is 0 to 59. The value range for *ss* is 0 to 59. The leading zero in a segment can be omitted. If the seconds segment is 0 (*hh*:*mm*:00), you can omit it. If both the minutes and seconds segments are 0 (*hh*:00:00), you can omit both of the segments. For example, to specify 08:00:00, you can enter 8.

date: Specifies a date in the *MM/DD/YYYY* or *YYYY/MM/DD* format. The value range for *YYYY* is 2000 to 2035. The value range for *MM* is 1 to 12. The value range for *DD* varies by month.

Usage guidelines

CAUTION:

This command changes the system time, which affects the execution of system time-related features (for example, scheduled tasks) and collaborative operations of the device with other devices (for example, log reporting and statistics collection). Before executing this command, make sure you fully understand its impact on your live network.

This command is supported only on the default context.

Correct system time is essential to network management and communication. You must configure the system time correctly before you run the device on the network.

For the device to use the local system time, execute the **clock protocol none** command and this command in turn. The specified system time takes effect immediately. Then, the device uses the clock signals generated by its built-in crystal oscillator to maintain the system time.

Examples

Set the system time to 08:08:08 01/01/2015.

```
<Sysname> clock datetime 8:8:8 1/1/2015
```

Set the system time to 08:10:00 01/01/2015.

```
<Sysname> clock datetime 8:10 2015/1/1
```

Related commands

clock protocol

clock summer-time

clock timezone

display clock

clock protocol

Use **clock protocol** to specify the method for obtaining the system time.

Use **undo clock protocol** to restore the default.

Syntax

clock protocol { **none** | **ntp context** *context-id* }

undo clock protocol

Default

The device uses the system time set by using the **clock datetime** command.

Views

System view

Predefined user roles

network-admin

Parameters

none: Uses the system time set by using the **clock datetime** command.

ntp: Uses NTP to obtain the UTC time periodically. You must configure NTP correctly. For more information about NTP and NTP configuration, see *Network Management and Monitoring Configuration Guide*.

context *context-id*: Specifies a context. For more information about context and the value range for the context ID, see *Virtual Technologies Command Reference*.

The following compatibility matrixes show the support of hardware platforms for the **context** *context-id* option:

Models	Parameter compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080	Yes
NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	No

Usage guidelines

This command is supported only on the default context.

Correct system time is essential to network management and communication. You must configure the system time correctly before you run the device on the network.

- If you execute the **clock protocol none** command, you can use the **clock datetime** command to configure the system time. The device then uses the clock signals generated by its built-in crystal oscillator to maintain the system time.
- If you execute the **clock protocol ntp** command, the device obtains the UTC time through GNSS or NTP periodically. After obtaining the UTC time, the device uses the UTC time, time zone, and daylight saving time to calculate the system time. If the GNSS or NTP signals are lost, the device uses the clock signals generated by its built-in crystal oscillator to maintain the system time. After the GNSS or NTP signals recover, the device obtains the UTC time again from the signals.

If you execute this command multiple times, the most recent configuration takes effect.

All contexts on the device use the same system time. After obtaining the system time from a context, the device automatically synchronizes the system time to the other contexts.

Examples

Configure the device to use the local UTC time.

```
<Sysname> system-view
[Sysname] clock protocol none
```

clock summer-time

Use **clock summer-time** to set the daylight saving time.

Use **undo clock summer-time** to restore the default.

Syntax

clock summer-time *name* *start-time* *start-date* *end-time* *end-date* *add-time*

undo clock summer-time

Default

The daylight saving time is not set.

Views

System view

Predefined user roles

network-admin

Parameters

name: Specifies a name for the daylight saving time schedule, a case-sensitive string of 1 to 32 characters.

start-time: Specifies the start time in the *hh:mm:ss* format. The value range for *hh* is 0 to 23. The value range for *mm* is 0 to 59. The value range for *ss* is 0 to 59. The leading zero in a segment can be omitted. If the seconds segment is 0 (*hh*:*mm*:00), you can omit it. If both the minutes and seconds segments are 0 (*hh*:00:00), you can omit both of the segments. For example, to specify 08:00:00, you can enter 8.

start-date: Specifies the start date in one of the following formats:

- *MM/DD*. The value range for *MM* is 1 to 12. The value range for *DD* varies by month.
- *month week day*, where:
  - *month*—Takes **January**, **February**, **March**, **April**, **May**, **June**, **July**, **August**, **September**, **October**, **November** or **December**.
  - *week*—Represents week of the month. It takes **first**, **second**, **third**, **fourth**, **fifth**, or **last**.
  - *day*—Takes **Sunday**, **Monday**, **Tuesday**, **Wednesday**, **Thursday**, **Friday**, or **Saturday**.

end-time: Specifies the end time in the *hh:mm:ss* format. The value range for *hh* is 0 to 23. The value range for *mm* is 0 to 59. The value range for *ss* is 0 to 59. The leading zero in a segment can be omitted. If the seconds segment is 0 (*hh*:*mm*:00), you can omit it. If both the minutes and seconds segments are 0 (*hh*:00:00), you can omit both of the segments. For example, to specify 08:00:00, you can enter 8.

end-date: Specifies the end date in one of the following formats:

- *MM/DD*. The value range for *MM* is 1 to 12. The value range for *DD* varies by month.
- *month week day*, where:

- *month*—Takes **January**, **February**, **March**, **April**, **May**, **June**, **July**, **August**, **September**, **October**, **November** or **December**.
- *week*—Represents week of the month. It takes **first**, **second**, **third**, **fourth**, **fifth**, or **last**.
- *day*—Takes **Sunday**, **Monday**, **Tuesday**, **Wednesday**, **Thursday**, **Friday**, or **Saturday**.

add-time: Specifies the time to be added to the standard time, in the *hh:mm:ss* format. The value range for *hh* is 0 to 23. The value range for *mm* is 0 to 59. The value range for *ss* is 0 to 59. The leading zero in a segment can be omitted. If the seconds segment is 0 (*hh*:*mm*:00), you can omit it. If both the minutes and seconds segments are 0 (*hh*:00:00), you can omit both of the segments. For example, to specify 08:00:00, you can enter 8.

Usage guidelines

This command is supported only on the default context.

Correct system time is essential to network management and communication. You must configure the system time correctly before you run the device on the network.

After you set the daylight saving time, the device recalculates the system time. To view the system time, use the **display clock** command.

Make sure all devices on the network are using the same daylight saving time as the local time.

Examples

Set the system time ahead 1 hour for the period between 06:00:00 on 08/01 and 06:00:00 on 09/01.

```
<Sysname> system-view
[Sysname] clock summer-time PDT 6 08/01 6 09/01 1
```

Related commands

clock datetime

clock timezone

display clock

clock timezone

Use **clock timezone** to set the time zone.

Use **undo clock timezone** to restore the default.

Syntax

clock timezone *zone-name* { **add** | **minus** } *zone-offset*

undo clock timezone

Default

The UTC time zone is used.

Views

System view

Predefined user roles

network-admin

Parameters

zone-name: Specifies a time zone by its name, a case-sensitive string of 1 to 32 characters.

add: Adds an offset to the UTC time.

minus: Decreases the UTC time by an offset.

zone-offset: Specifies an offset to the UTC time, in the *hh:mm:ss* format. The value range for *hh* is 0 to 23. The value range for *mm* is 0 to 59. The value range for *ss* is 0 to 59. The leading zero in a segment can be omitted. If the seconds segment is 0 (*hh*:*mm*:00), you can omit it. If both the minutes and seconds segments are 0 (*hh*:00:00), you can omit both of the segments. For example, to specify 08:00:00, you can enter 8.

Usage guidelines

This command is supported only on the default context.

Correct system time is essential to network management and communication. You must configure the system time correctly before you run the device on the network.

After you set the time zone, the device recalculates the system time. To view the system time, use the **display clock** command.

Make sure all devices on the network are using the same time zone as the local time.

Examples

Set the name of the time zone to **Z5**, and add 5 hours to the UTC time.

```
<Sysname> system-view
[Sysname] clock timezone Z5 add 5
```

Related commands

clock datetime

clock summer-time

display clock

command

Use **command** to assign a command to a job.

Use **undo command** to revoke a command.

Syntax

command *id command*

undo command *id*

Default

No command is assigned to a job.

Views

Job view

Predefined user roles

network-admin

context-admin

Parameters

id: Specifies an ID for the command, in the range of 0 to 4294967295. A command ID uniquely identifies a command in a job. Commands in a job are executed in ascending order of their command IDs.

command: Specifies the command to be assigned to the job.

Usage guidelines

To assign a command (command A) to a job, you must first assign the job the command or commands for entering the view of command A.

If you specify the ID of an existing command for another command, the existing command is replaced.

Make sure all commands in a schedule are compliant to the command syntax. The system does not examine the syntax when you assign a command to a job.

If a command requires a yes or no answer, the system always assumes that a **Y** or **Yes** is entered. If a command requires a character string input, the system assumes that either the default character string (if any) or a null string is entered.

A job cannot contain the **telnet**, **ftp**, **ssh2**, or **monitor process** command.

Examples

Assign commands to the **backupconfig** job to back up the **startup.cfg** file to the TFTP server at 192.168.100.11.

```
<Sysname> system-view
[Sysname] scheduler job backupconfig
[Sysname-job-backupconfig] command 2 tftp 192.168.100.11 put flash:/startup.cfg
backup.cfg
```

Assign commands to the **shutdownGE** job to shut down GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] scheduler job shutdownGE
[Sysname-job-shutdownGE] command 1 system-view
[Sysname-job-shutdownGE] command 2 interface gigabitethernet 1/0/1
[Sysname-job-shutdownGE] command 3 shutdown
```

Related commands

```

display alarm

Use **display alarm** to display alarm information.

Syntax

display alarm [**slot** *slot-number*]

The following compatibility matrix shows the support of hardware platforms for this command:

Models	Command compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080,	Yes
NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	No

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays alarm information for all IRF member devices.

Usage guidelines

This command is supported only on the default context.

Examples

Display alarm information.

```
<Sysname> display alarm
Slot CPU Level   Info
1    0   ERROR   faulty
```

Table 1 Command output

Field	Description
Slot	Slot that generated the alarm. If the alarm was generated by the frame, this field displays a hyphen (-).
Level	Alarm severity. Possible values include **ERROR**, **WARNING**, **NOTICE**, and **INFO**, in descending order.

Field	Description
Info	Detailed alarm information: • **faulty**—The slot is starting up or faulty. • **Fan** *n* **is absent**—The specified fan is absent. • **Power** *n* **is absent**—The specified power supply is absent. • **Power** *n* **is faulty**—The specified power supply is faulty. • **The temperature of sensor** *n* **exceeds the lower limit**—The temperature of the specified sensor is lower than the low-temperature threshold. • **The temperature of sensor** *n* **exceeds the upper limit**—The temperature of the specified sensor is higher than the high-temperature warning threshold.

Parameters

control-plane: Displays CPU usage statistics for the control plane. If you do not specify this keyword or the **data-plane** keyword, the command displays the total CPU usage statistics.

data-plane: Displays CPU usage statistics for the data plane. If you do not specify this keyword or the **control-plane** keyword, the command displays the total CPU usage statistics.

summary: Displays CPU usage statistics in table form. If you do not specify this keyword, the command displays CPU usage statistics in text form.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays CPU usage statistics for all member devices.

cpu *cpu-number*: Specifies a CPU by its number.

core { *core-number* | **all** }: Displays CPU core usage statistics. If you specify a CPU core by its number, this command displays usage statistics for the CPU core. If you specify the **all** keyword, this command displays average usage statistics for all CPU cores.

Usage guidelines

Executing this command on a context displays the current CPU usage statistics for the context.

If two hyphens (--) are displayed for the CPU usage during the most recent 5-second, 1-minute, and 5-minute intervals, the command might fail to obtain data from the database on the device. Try the command later.

Examples

Display the current CPU usage statistics in text form.

```
<Sysname> display cpu-usage
Slot 1 CPU 0 CPU usage:
       1% in last 5 seconds
       1% in last 1 minute
       1% in last 5 minutes
```

Display the current CPU usage statistics in table form.

```
<Sysname> display cpu-usage
Slot CPU        Last 5 sec        Last 1 min        Last 5 min
1    0          17%               29%               28%
```

Table 2 Command output

Field	Description
x% in last 5 seconds Last 5 sec	Average CPU usage during the most recent 5-second interval.
y% in last 1 minute Last 1 min	Average CPU usage during the most recent 1-minute interval.
z% in last 5 minutes Last 5 min	Average CPU usage during the most recent 5-minute interval.

display cpu-usage configuration

Use **display cpu-usage configuration** to display CPU usage monitoring settings.

Syntax

display cpu-usage configuration [**slot** *slot-number* [**cpu** *cpu-number*]]

Views

Any view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays the CPU usage monitoring settings for the master device.

cpu *cpu-number*: Specifies a CPU by its number.

Usage guidelines

Executing this command on a context displays CPU usage monitoring settings for the context.

Examples

Display the CPU usage monitoring settings.

```
<Sysname> display cpu-usage configuration
CPU usage monitor is enabled.
Current monitor interval is 60 seconds.
Current monitor threshold is 70%.
Current monitor recovery threshold is 30%.
Current statistics-interval is 60 seconds for the following cores: 0 to 1.
```

Table 3 Command output

Field	Description
CPU usage monitor is *xxx*.	Whether CPU usage tracking is enabled.
Current monitor interval is *xxx*.	Sampling interval for CPU usage tracking.
Current monitor threshold is *xxx*.	CPU usage threshold.
Current monitor recovery threshold is *xxx*.	CPU usage recovery threshold.
Current statistics-interval is *xxx* seconds for the following cores	CPU core usage statistics interval.

Related commands

monitor cpu-usage enable

monitor cpu-usage interval

monitor cpu-usage threshold

display cpu-usage history

Use **display cpu-usage history** to display the historical CPU usage statistics in a coordinate system.

Syntax

display cpu-usage history [**job** *job-id*] [**slot** *slot-number* [**cpu** *cpu-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

job *job-id*: Specifies a process by its ID. The value range for *job-id* is 1 to 2147483647. If you do not specify a process, this command displays the statistics for the entire system's CPU usage (the

total CPU usage of all processes). To view the IDs and names of the running processes, use the **display process** command. For more information, see *Network Management and Monitoring Configuration Guide*.

slot *slot-number*: Specifies an IRF member device by its member ID. If you specify a process but do not specify a member device, this command displays the statistics for the process on the master device. If you do not specify any options, this command displays the statistics for all processes on all member devices.

cpu *cpu-number*: Specifies a CPU by its number. If you specify a process but do not specify a CPU, this command displays the statistics for the default CPU. If you do not specify a process or CPU, this command displays the historical statistics for all CPUs.

Usage guidelines

After CPU usage monitoring is enabled, the system regularly samples CPU usage and saves the samples to the history record buffer. This command displays the most recent 60 samples in a coordinate system as follows:

The vertical axis represents the CPU usage. If a statistic is not a multiple of the usage step, it is rounded up or down to the closest multiple of the usage step. For example, if the CPU usage step is 5%, the statistic 53% is rounded up to 55%, and the statistic 52% is rounded down to 50%.

The horizontal axis represents the time.

Pound signs (#) indicate the CPU usage. The value on the vertical axis for the topmost pound sign at a specific time represents the CPU usage at that time.

Executing this command on a context displays the historical CPU usage statistics for the context.

Examples

Display the historical CPU usage statistics.

```
<Sysname> display cpu-usage history
100%|
 95%|
 90%|
 85%|
 80%|
 75%|
 70%|
 65%|
 60%|
 55%|
 50%|
 45%|
 40%|
 35%|
 30%|
 25%|
 20%|
 15%|             #
 10%|            ###  #
  5%|           ########
    ------------------------------------------------------------
              10        20        30        40        50        60  (minutes)
                      cpu-usage (Slot 1 CPU 0) last 60 minutes (SYSTEM)
```

The output shows the following items:

- Process name. The name **SYSTEM** represents the entire system.
- CPU that is holding the process: CPU 0 in slot 1.
- Historical CPU usage statistics for the entire system during the last 60 minutes.
  - **12 minutes ago**—Approximately 5%.
  - **13 minutes ago**—Approximately 10%.
  - **14 minutes ago**—Approximately 15%.
  - **15 minutes ago**—Approximately 10%.
  - **16 and 17 minutes ago**—Approximately 5%.
  - **18 minutes ago**—Approximately 10%.
  - **19 minutes ago**—Approximately 5%.
  - **Other time**—2% or lower.

display device

Use **`display device`** to display device information.

Syntax

`display device` [**`harddisk`** | **`usb`**] [**`slot`** *`slot-number`* [**`subslot`** *`subslot-number`*] | **`verbose`**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`harddisk`: Displays hard disk information.

The following compatibility matrix shows the support of hardware platforms for this keyword:

Models	Parameter compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

`usb`: Displays USB interface information.

`slot` *`slot-number`*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information for all member devices.

subslot *subslot-number*: Specifies an interface module by the number of its slot marked on the device panel. If you do not specify an interface module, this command does not display information about interface modules.

verbose: Displays detailed information. If you do not specify this keyword, this command displays brief information.

Usage guidelines

If you do not specify the **harddisk** or **usb** keyword, this command displays information about member devices.

This command displays information about the physical device, whether you execute it on the default context or a non-default context.

Examples

Display device information.

```
<Sysname> display device
Slot.No   Cpu.Id   Brd Type     Brd Status    Subslot    Sft Ver    Patch Ver
1         0        NFNX3HDB680  Normal        0          9524P07    None
```

Table 4 Command output

Field	Description
Brd Type	Device type.
Brd Status	Role of the device in an IRF fabric: • **Normal**—The member device is operating correctly. • **Fault**—The member device is not operating correctly. • **Absent**—The slot is not installed with a member device.
Sft Ver	Software version of the device.
Patch Ver	Most recently released patch image version that is running on the device. If no patch image is installed, this field displays **None**. If both incremental and non-incremental patch images are running on the device, this field displays the most recently released incremental patch image version. For more information about patch image types, see software upgrade in *Fundamentals Configuration Guide*.

display device manuinfo

Use **display device manuinfo** to display electronic label information for the device.

Syntax

display device manuinfo [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays electronic label information for all member devices.

Usage guidelines

An electronic label contains the permanent configuration information, including the hardware serial number, manufacturing date, MAC address, and vendor name. The data is written to the storage component during hardware debugging or testing. This command displays only part of the electronic label information.

This command is supported only on the default context.

Examples

Display electronic label information for the device.

```
<Sysname> display device manuinfo
 Slot 1 CPU 0:
 DEVICE_NAME           : NFNX3-HDB680
 DEVICE_SERIAL_NUMBER  : 210235A1VNH164000026
 MAC_ADDRESS           : 487A-DA95-91BB
 MANUFACTURING_DATE    : 2016-04-29
 VENDOR_NAME           : NSFOCUS
```

display diagnostic-information

Use **display diagnostic-information** to display or save operating information for features and hardware modules.

Syntax

display diagnostic-information [**hardware** | **infrastructure** | **l2** | **l3** | **service**] [**key-info**] [*filename*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

hardware: Specifies hardware-related operating information.

infrastructure: Specifies operating information for the fundamental features.

l2: Specifies operating information for the Layer 2 features.

l3: Specifies operating information for the Layer 3 features.

service: Specifies operating information for Layer 4 and upper-layer features.

key-info: Displays or saves only critical operating information. The device might have a large amount of operating information if an exception occurs or after the device runs for a long period of time. Specifying this keyword reduces the command execution time and helps you focus on critical operating information. If you do not specify this keyword, the command displays or saves both critical and non-critical operating information.

filename: Saves the information to a file. The *filename* argument must use the **.tar.gz** extension. If you do not specify this argument, the command prompts you to choose whether to save the information to a file or display the information.

Usage guidelines

You can use one of the following methods to collect operating statistics for diagnostics and troubleshooting:

- Use separate **display** commands to collect operating information feature by feature or module by module.
- Use the **display diagnostic-information** command to collect operating information for multiple or all features and hardware modules.

To save storage space, this command automatically compresses the information before saving the information to a file. To view the file content:

1. Use the **tar extract** command to extract the file.
2. Use the **gunzip** command to decompress the extracted file.
3. Use the **more** command to view the content of the decompressed file.

If you abort the **display diagnostic-information** command, the **gunzip** command might not be able to decompress the extracted file. To decompress the extracted file, export the extracted file to a PC that is running Linux, and use the **gunzip -c** command.

If you do not specify a file name for the command, the system prompts you to choose whether to display or save the information. If you choose to save the information, the system automatically assigns a file name and displays the file name in brackets. For file name uniqueness, the file name includes the device name and the current system time. If the device name contains any of the following special characters, the system uses an underscore (_) to replace each special character: forward slashes (/), backward slashes (\), colons (:), asterisks (*), question marks (?), less than signs (<), greater than signs (>), pipeline signs (|), and quotation marks ("). For example, device name **A/B** will change to **A_B** in the file name, as in **flash:/diag_A_B_20160101-000438.tar.gz**.

If you do not specify any feature parameters, this command displays or saves the operating information for all features and modules.

This command does not support the |, **>**, and **>>** options.

While the device is executing this command, do not execute any other commands. Executing other commands might affect the collected operating information.

Examples

Display the operating information for all features and modules.

```
<Sysname> display diagnostic-information
Save or display diagnostic information (Y=save, N=display)? [Y/N]:n
================================================
  ===============display clock===============
14:03:55 UTC Thu 01/05/2015
================================================
  ===============display version===============
...
```

Save the operating information to the default file.

```
<Sysname> display diagnostic-information
Save or display diagnostic information (Y=save, N=display)? [Y/N]:y
Please input the file name(*.tar.gz)[flash:/diag_Sysname_20160101-024601.tar.gz]:
Diagnostic information is outputting to flash:/diag_Sysname_20160101-024601.tar.gz.
Please wait...
```

```
Save successfully.
```

Press **Enter** when the system prompts you to enter the file name.

Save the operating information for all features and modules to file **test.tar.gz**.

```
<Sysname> display diagnostic-information test.tar.gz
Diagnostic information is outputting to flash:/test.tar.gz.
Please wait...
Save successfully.
```

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays temperature information for all member devices.

This command is supported only on the default context.

Examples

Display information about all temperature sensors on the device.

```
<Sysname> display environment
 System Temperature information (degree centigrade):
-------------------------------------------------------------------------------
---
```

```
 Slot     Sensor   Temperature LowerLimit Warning-UpperLimit  Alarm-UpperLimit
Shutdown-UpperLimit
1      inflow  1      33          -2             52               60               NA
1      outflow 1      37          0              55               65               NA
1      hotspot 1      45          0              70               78               NA
```

Table 5 Command output

Field	Description
System Temperature information (degree centigrade)	Temperature information (°C).
sensor	Temperature sensor: • **hotspot**—Hotspot sensor. • **inflow**—Air inlet sensor. • **outflow**—Air outlet sensor.
Slot	Sensor position.
Temperature	Current temperature.
LowerLimit	Low-temperature threshold. If the device does not support this field, this field displays **NA**.
Warning-UpperLimit	High-temperature warning threshold. If the device does not support this field, this field displays **NA**.
Alarm-UpperLimit	High-temperature alarming threshold. If the device does not support this field, this field displays **NA**.
Shutdown-UpperLimit	High-temperature shutdown temperature threshold. When the sensor temperature reaches the limit, the system shuts down automatically. If the device does not support this field, this field displays **NA**.

display fan

Use **`display fan`** to display fan tray operating status information.

Syntax

`display fan` [**`slot`** *`slot-number`* [*`fan-id`*]]

display memory [**summary**] [**slot** *slot-number* [**cpu** *cpu-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

summary: Displays brief information about memory usage. If you do not specify this keyword, the command displays detailed information about memory usage.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays memory usage for all member devices.

cpu *cpu-number*: Specifies a CPU by its number.

Usage guidelines

Executing this command on a context displays memory usage information for the context.

If two hyphens (--) are displayed for all the fields in a line of the command output, the command might fail to obtain data from the database on the device. Try the command later.

Examples

Display detailed memory usage information.

```
<Sysname> display memory
Memory statistics are measured in KB:
Slot 1:
             Total      Used      Free    Shared   Buffers    Cached   FreeRatio
Mem:        984560    456128    528432         0         4     45616       53.7%
-/+ Buffers/Cache:    410508    574052
Swap:            0         0         0
```

Display brief memory usage information.

```
<Sysname> display memory summary
Memory statistics are measured in KB:
Slot CPU        Total      Used      Free  Buffers    Caches FreeRatio
   1   0       984560    456128    528432        4     45616     53.7%
```

Table 7 Command output

Field	Description
Mem	Memory usage information.
Total	Total size of the physical memory space that can be allocated. The memory space is virtually divided into two parts. Part 1 is solely used for kernel code, kernel management, and ISSU functions. Part 2 can be allocated and used for such tasks as running service modules and storing files. The size of part 2 equals the total size minus the size of part 1.
Used	Used physical memory.
Free	Free physical memory.
Shared	Physical memory shared by processes. If this field is not supported, two hyphens (--) are displayed.
Buffers	Physical memory used for buffers. If this field is not supported, two hyphens (--) are displayed.
Cached Caches	Physical memory used for caches. If this field is not supported, two hyphens (--) are displayed.
FreeRatio	Free memory ratio.
-/+ Buffers/Cache	-/+ Buffers/Cache:used = Mem:Used – Mem:Buffers – Mem:Cached, which indicates the physical memory used by applications. -/+ Buffers/Cache:free = Mem:Free + Mem:Buffers + Mem:Cached, which indicates

Field	Description
	the physical memory available for applications.
Swap	Memory space for swapping.

display memory-threshold

display power

Use **display power** to display power supply information.

Syntax

display power [**slot** *slot-number* [*power-id*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays power supply information for all member devices.

power-id: Specifies a power supply by its ID. If you do not specify a power supply, this command displays information about all power supplies at the specified position.

The following compatibility matrixes show the value ranges for the power supply ID:

Models	Value range
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	0 to 1
NFNX3-HDB680, NFNX3-HDB1080	0

Usage guidelines

This command is supported only on the default context.

Examples

Display brief power supply information.

```
<Sysname> display power
Slot  1 Power  0     Status: Absent
Slot  1 Power  1     Status: Normal
```

Table 8 Command output

Field	Description
Status	Power supply status: • **Absent**—The slot is not installed with a power supply. • **Faulty**—The power supply is faulty. • **Normal**—The power supply is operating correctly. • **NotSupport**—The power supply is not supported.

display scheduler job

Use **display scheduler job** to display job configuration information.

Syntax

display scheduler job [*job-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

job-name: Specifies a job by its name, a case-sensitive string of 1 to 47 characters. If you do not specify a job, this command displays configuration information for all jobs.

Examples

Display configuration information for all jobs.

```
<Sysname> display scheduler job
Job name: saveconfig
 copy startup.cfg backup.cfg

Job name: backupconfig

Job name: creat-VLAN100
 system-view
 vlan 100
```

// The output shows that the device has three jobs: the first has one command, the second does not have any commands, and the third has two commands. Jobs are separated by blank lines.

display scheduler logfile

Use **display scheduler logfile** to display job execution log information.

Syntax

display scheduler logfile

context-operator

Examples

Display the automatic reboot schedule.

```
<Sysname> display scheduler reboot
System will reboot at 16:32:00 05/23/2015 (in 1 hours and 39 minutes).
```

Related commands

scheduler reboot at

scheduler reboot delay

display scheduler schedule

Use **display scheduler schedule** to display schedule information.

Syntax

display scheduler schedule [*schedule-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

schedule-name: Specifies a schedule by its name, a case-sensitive string of 1 to 47 characters. If you do not specify a schedule, this command displays information about all schedules.

Examples

Display information about all schedules.

```
<Sysname> display scheduler schedule
Schedule name        : shutdown
Schedule type        : Run once after 0 hours 2 minutes
Start time           : Tue Dec 27 10:44:42 2015
Last execution time  : Tue Dec 27 10:44:42 2015
Last completion time : Tue Dec 27 10:44:47 2015
Execution counts     : 1
------------------------------------------------------------------------
```

```
Job name                                 Last execution status
shutdown                                 Successful
```

Table 10 Command output

Field	Description
Schedule type	Execution time setting of the schedule. If no execution time is specified, this field is not displayed.
Start time	Time to execute the schedule for the first time. If no execution time is specified, this field is not displayed.
Last execution time	Last time when the schedule was executed. If no execution time is specified, this field is not displayed. If the schedule has never been executed, "Yet to be executed" is displayed for this field.
Last completion time	Last time when the schedule was completed. If no execution time is specified, this field is not displayed.
Execution counts	Number of times the schedule has been executed. If the schedule has never been executed, this field is not displayed.
Job name	Name of a job under the schedule.
Last execution status	Result of the most recent execution: • **Successful**. • **Failed**. • **Waiting**—The device is executing the schedule and the job is waiting to be executed. • **In process**—The job is being executed. • **-NA-**—The execution time has not arrived yet. To view information about whether the commands in the job has been executed and the execution results, execute the **`display scheduler logfile`** command.

display system stable state

Use **`display system stable state`** to display system stability and status information.

Syntax

`display system stable state`

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Usage guidelines

Before performing an ISSU or a switchover, execute this command multiple times to identify whether the system is operating stably. If the value of the **System State** field is not **Stable**, you cannot perform an ISSU. If the value of the **Redundancy Stable** field is not **Stable**, you cannot perform a switchover.

The device startup process takes some time. If the values of the status fields do not change to **Stable**, execute this command multiple times to identify the member devices that are not in **Stable** state. You can also use other commands to identify the faulty components. For example:

- Use the **display device** command to identify the device operating status.
- Use the **display ha service-group** command to display the status of HA service groups and identify the groups in batch backup state.
- Use the **display system internal process state** command in probe view to display service operating status.

Examples

Display system stability and status information.

```
<Sysname> display system stable state
System state    : Stable
Redundancy state: No redundance
  Slot   CPU   Role      State
 1      0     Active    Stable
```

Table 11 Command output

Field	Description
System state	System status: • **Stable**—The system is operating stably. • **Not ready**—The system is not operating stably. You cannot perform an ISSU when the system is in this state.
Redundancy state	System redundancy status: • **Stable**—Member devices are operating stably. You can perform a switchover. • **No redundance**—The system has only one member device. You cannot perform a switchover. • **Not ready**—The system is not operating stably. You cannot perform a switchover.
Role	Role of the member device in the system: • **Active**—The member device is the master. • **Standby**—The member device is a subordinate member.
State	Member device status: • **Stable**—The member device is operating stably. • **Board inserted**—The member device has just been installed. • **Kernel initiating**—Member device kernel is being initialized. • **Service starting**—Services are starting on the member device. • **Service stopping**—Services are stopping on the member device. • **HA Batch backup**—An HA batch backup is going on. • **Interface data batch backup**—An interface data batch backup is in progress. • **Service module data batch backup**—A service module data batch backup is in process.
*	The object is not operating stably.

display transceiver alarm

Use **display transceiver alarm** to display transceiver alarms.

Syntax

display transceiver alarm { controller [*controller-type controller-number* **] | interface [** *interface-type interface-number* **] }**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

controller [*controller-type controller-number* **]**: Specifies a controller by its type and number. If no controller is specified, this command displays the alarms present on all controllers.

The following compatibility matrixes show the support of hardware platforms for the **controller [** *controller-type controller-number* **]** option:

Models	Parameter compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No
NFNX3-HDB680, NFNX3-HDB1080	Yes

interface [*interface-type interface-number* **]**: Specifies an interface by its type and number. If no interface is specified, this command displays the alarms present on every transceiver module.

Usage guidelines

Table 12 shows the common transceiver alarm components. If no error occurs, "None" is displayed.

Table 12 Common transceiver alarm components

Field	Description
power	Optical power
RX	Receive
Temp	Temperature
TX	Transmit

Examples

Display the alarms present on the transceiver module in interface GigabitEthernet1/0/1.

```
<Sysname> display transceiver alarm interface gigabitethernet 1/0/1
GigabitEthernet1/0/1 transceiver current alarm information:
  RX loss of signal
```

```
RX power low
```

Table 13 Command output

Field	Description
transceiver current alarm information	Alarms present on the transceiver module.
RX loss of signal	Received signals are lost.
RX power low	Received power is low.

display transceiver diagnosis

Use **display transceiver diagnosis** to display the current values of the digital diagnosis parameters of transceiver modules.

Syntax

display transceiver diagnosis { **controller** [*controller-type controller-number*] | **interface** [*interface-type interface-number*] }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

controller [*controller-type controller-number*] : Specifies a controller by its type and number. If no controller is specified, this command displays the current values of the digital diagnosis parameters on all controllers.

The following compatibility matrixes show the support of hardware platforms for the **controller** [*controller-type controller-number*] option:

Models	Parameter compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No
NFNX3-HDB680, NFNX3-HDB1080	Yes

interface [*interface-type interface-number*]: Specifies an interface by its type and number. If no interface is specified, this command displays the current values of the digital diagnosis parameters on all interfaces.

Examples

Display the current values of the digital diagnosis parameters on the transceiver module in interface GigabitEthernet1/0/1.

```
<Sysname> display transceiver diagnosis interface gigabitethernet 1/0/1
```

```
GigabitEthernet1/0/1 transceiver diagnostic information:
  Current diagnostic parameters:
    Temp(°C)  Voltage(V)  Bias(mA)  RX power(dBm)  TX power(dBm)
    36        3.31        6.13      -35.64          -5.19
  Alarm thresholds:
            Temp(°C)   Voltage(V)  Bias(mA)  RX power(dBM)  TX power(dBM)
    High    50         3.55        1.44      -10.00         5.00
    Low     30         3.01        1.01      -30.00         0.00
```

Table 14 Command output

Field	Description
transceiver diagnostic information	Digital diagnosis information for the transceiver module in the interface.
Temp.(°C)	Temperature in °C, accurate to 1°C.
Voltage(V)	Voltage in V, accurate to 0.01 V.
Bias(mA)	Bias current in mA, accurate to 0.01 mA.
RX power(dBm)	Receive power in dBm, accurate to 0.01 dBm.
TX power(dBm)	Transmit power in dBm, accurate to 0.01 dBm.

display transceiver interface

Use **display transceiver interface** to display the key parameters of transceiver modules.

Syntax

display transceiver interface [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays the key parameters of every transceiver module.

Examples

Display the key parameters of the transceiver module in interface GigabitEthernet1/0/1.

```
<Sysname> display transceiver interface gigabitethernet 1/0/1
GigabitEthernet 1/0/1 transceiver information:
  Transceiver Type              : 1000_BASE_SX_SFP
  Connector Type                : LC
  Wavelength(nm)                : 850
  Transfer Distance(m)          : 550(50um),270(62.5um)
  Digital Diagnostic Monitoring : YES
  Vendor Name                   : NSFOCUS
```

```
Ordering Name                : SFP-GE-SX-MM850
```

Table 15 Command output

Field	Description
Wavelength(nm)	Central wavelength of the laser in nm. For a fiber transceiver module that supports multiple wavelengths, for example, the 10GBASE-LX4 transceiver module, this field displays all the wavelengths, separating the values by commas (,). For a copper module, this field displays **N/A**.
Transfer Distance(m)	Transmission distance, in km (for single-mode modules) or in m (for other modules). For a module that supports multiple transmission media, this field displays all the transmission distances, separating the values by commas (,). Each transmission distance is followed by the medium name in parentheses. • **9um**—9/125um single-mode optical fiber. • **50um**—50/125um OM2 multi-mode optical fiber. • **62.5um**—62.5/125um OM1 multi-mode optical fiber. • **CX4**—CX4 cables. • **OM3**—50um OM3 multi-mode optical fiber. • **OM4**—50um OM4 multi-mode optical fiber. • **OM5**—50um OM5 multi-mode optical fiber. • **STACK**—Stack cables. • **TP**—Twisted pairs.
Digital Diagnostic Monitoring	Whether digital diagnosis is supported: • **YES**—Digital diagnosis is supported. • **NO**—Digital diagnosis is not supported.

display transceiver manuinfo

Use **display transceiver manuinfo** to display electronic label information for transceiver modules.

Syntax

display transceiver manuinfo { **controller** [*controller-type controller-number*] | **interface** [*interface-type interface-number*] }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

controller [*controller-type controller-number*] : Specifies a controller by its type and number. If no controller is specified, this command displays the electronic label information for the transceiver modules in all controllers.

The following compatibility matrixes show the support of hardware platforms for the **controller** [*controller-type controller-number*] option:

Models	Parameter compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No
NFNX3-HDB680, NFNX3-HDB1080	Yes

interface [*interface-type interface-number*]: Specifies an interface by its type and number. If no interface is specified, this command displays electronic label information for the transceiver modules in all interfaces.

Examples

Display electronic label information for the transceiver module in interface GigabitEthernet1/0/1.

```
<Sysname> display transceiver manuinfo interface gigabitethernet 1/0/1
GigabitEthernet1/0/1 transceiver manufacture information:
  Manu. Serial Number  : 213410A0000054000251
  Manufacturing Date   : 2017-09-01
  Vendor Name          : NSFOCUS
```

display version

Use **display version** to display system version information.

Syntax

display version

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display system version information.

```
<Sysname> display version
NSFOCUS NF Software, Version 7.1.064, Ess 9333P07

...
```

Table 16 Command output

Field	Description
Last reboot reason	Reason for the last reboot: • **User reboot**—The reboot was manually initiated from a user interface, such as the CLI or SNMP. • **Cold reboot**—The reboot was caused by a power cycle. • **Kernel abnormality reboot**—The reboot was caused by kernel exceptions. • **DeadLoop reboot**—The reboot was caused by a kernel thread dead loop. • **DEV HandShake reboot**—The reboot was caused by a device management handshake failure. • **SlaveSwitch reboot**—The reboot was caused by a master/subordinate switchover. • **IRF Merge reboot**—The reboot was caused by an IRF merge. • **Auto Update reboot**—The reboot was caused by an automatic software upgrade. • **Memory exhaust reboot**—The reboot was caused by a card-memory-exhausted event.

display version-update-record

Use **display version-update-record** to display startup software image upgrade records.

Syntax

display version-update-record

Views

Any view

Predefined user roles

network-admin

network-operator

Usage guidelines

This command is supported only on the default context.

The device records its current startup software version information whenever it starts up, and records all software version update information. Such information can survive reboots.

Examples

Display the startup software image upgrade records.

```
<Sysname> display version-update-record
Record 1  (updated on Apr 18 2015 at 06:23:54):
 *Name        : boot-test.bin
  Version     : 7.1.070 Test 0001
  Compile time: Mar 25 2015 15:52:43

 *Name        : system-test.bin
  Version     : 7.1.070 Test 0001
  Compile time: Mar 25 2015 15:52:43
```

Table 17 Command output

Field	Description
Record *n*	Number of the startup software image upgrade record. Record 1 is the most recent record.
Name	Software image file name.
*	The software image version changed during the upgrade.

Related commands

reset version-update-record

header

Use **header** to configure a banner.

Use **undo header** to delete a banner.

Syntax

header { **legal** | **login** | **motd** | **shell** } *text*

undo header { **legal** | **login** | **motd** | **shell** }

Default

The device does not have banners.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

legal: Configures the banner to be displayed before a user inputs the username and password to access the CLI.

login: Configures the banner to be displayed before password or scheme authentication is performed for a login user.

motd: Configures the greeting banner to be displayed before the legal banner appears.

shell: Configures the banner to be displayed before a user accesses user view.

text: Specifies the banner message. You can enter the banner message on the same line as the keywords or on different lines. For more information, see device management in *Fundamentals Configuration Guide*.

Examples

Configure the legal banner.

```
<Sysname> system-view
[Sysname] header legal
Please input banner content, and quit with the character '%'.
Welcome to use the legal banner%
```

job

Use **job** to assign a job to a schedule.

Use **undo job** to revoke a job.

Syntax

job *job-name*

undo job *job-name*

Default

No job is assigned to a schedule.

Views

Schedule view

Predefined user roles

network-admin

context-admin

Parameters

job-name: Specifies the job name, a case-sensitive string of 1 to 47 characters.

Usage guidelines

You can assign multiple jobs to a schedule. The jobs in a schedule are executed concurrently.

The jobs to be assigned to a schedule must already exist. To create a job, use the **scheduler job** command.

Examples

Assign job **save-job** to schedule **saveconfig**.

```
<Sysname> system-view
[Sysname] scheduler schedule saveconfig
[Sysname-schedule-saveconfig] job save-job
```

Related commands

scheduler job

scheduler schedule

locator blink

Use **locator blink** *blink-time* to start LED flashing to locate devices.

Use **locator blink stop** to stop LED flashing.

Syntax

locator [**slot** *slot-number*] **blink** *blink-time*

locator [**slot** *slot-number*] **blink stop**

Views

User view

Predefined user roles

network-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, the command applies to all member devices.

blink-time: Specifies the flash duration in seconds. The value range is 5 to 120.

stop: Stops flashing.

Usage guidelines

This command is supported only on the default context.

The device provides a LED for device locating. The **locator blink** *blink-time* command flashes the specified LEDs quickly for a period of time unless you execute the **locator blink stop** command. You can observe the LEDs to locate the devices.

Examples

Start LED flashing to locate devices.

```
<Sysname> locator blink 30
```

Stop LED flashing.

```
<Sysname> locator blink stop
```

memory-threshold

Use **memory-threshold** to set free-memory thresholds.

Use **undo memory-threshold** to restore the default.

Syntax

memory-threshold [**slot** *slot-number* [**cpu** *cpu-number*]] [**ratio**] **minor** *minor-value* **severe** *severe-value* **critical** *critical-value* **normal** *normal-value*

undo memory-threshold [**slot** *slot-number* [**cpu** *cpu-number*]]

Default

The default settings vary by device model. To view the default settings, use the **undo memory-threshold** command to restore the default settings and then execute the **display memory-threshold** command.

Views

System view

Predefined user roles

network-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command sets free-memory thresholds for the master device.

cpu *cpu-number*: Specifies a CPU by its number.

ratio: Specifies free-memory thresholds in percentage. If you do not specify this keyword, the command sets free-memory thresholds in MB.

minor *minor-value*: Specifies the minor alarm threshold. To view the value range for this threshold, enter a question mark (?) in the place of the *minor-value* argument. Setting this threshold to 0 disables the minor alarm feature.

severe *severe-value*: Specifies the severe alarm threshold. To view the value range for this threshold, enter a question mark (?) in the place of the *severe-value* argument. Setting this threshold to 0 disables the severe alarm feature.

critical *critical-value*: Specifies the critical alarm threshold. To view the value range for this threshold, enter a question mark (?) in the place of the *critical-value* argument. Setting this threshold to 0 disables the critical alarm feature.

normal *normal-value*: Specifies the normal state threshold. To view the value range for this threshold, enter a question mark (?) in the place of the *normal-value* argument.

Usage guidelines

This command is supported only on the default context.

To ensure correct operation and improve memory efficiency, the system monitors the amount of free memory space in real time. If the amount of free memory space decreases to or below the minor, severe, or critical alarm threshold, the system issues an alarm to affected service modules or processes.

The early warning feature warns you of an approaching insufficient-memory condition.

If a memory alarm occurs, delete unused configuration items or disable some features to increase the free memory space. Because the memory space is insufficient, some configuration items might not be able to be deleted.

For more information about the thresholds, see device management in *Fundamentals Configuration Guide*.

Examples

Set the minor alarm, severe alarm, critical alarm, and normal state thresholds to 64 MB, 48 MB, 32 MB, and 96 MB, respectively.

```
<Sysname> system-view
[Sysname] memory-threshold minor 64 severe 48 critical 32 normal 96
```

Related commands

display memory-threshold

memory-threshold usage

Use **memory-threshold usage** to set the memory usage threshold.

Use **undo memory-threshold usage** to restore the default.

Syntax

memory-threshold [**slot** *slot-number* [**cpu** *cpu-number*]] **usage** *memory-threshold*

undo memory-threshold [**slot** *slot-number* [**cpu** *cpu-number*]] **usage**

Default

Models	Default
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280	90%
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	95%

Views

System view

Predefined user roles

network-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command sets the memory usage threshold for the master device.

cpu *cpu-number*: Specifies a CPU by its number.

memory-threshold: Specifies the memory usage threshold in percentage. The value range is 0 to 100.

Usage guidelines

This command is supported only on the default context.

The device samples memory usage at 1-minute intervals. If the sample is equal to or greater than the memory usage threshold, the device sends a trap.

Examples

Set the memory usage threshold to 80%.

```
<Sysname> system-view
[Sysname] memory-threshold usage 80
```

Related commands

display memory-threshold

monitor cpu-usage enable

Use **monitor cpu-usage enable** to enable CPU usage monitoring.

Use **undo monitor cpu-usage enable** to disable CPU usage monitoring.

Syntax

monitor cpu-usage enable [**slot** *slot-number* [**cpu** *cpu-number*]]

undo monitor cpu-usage enable [**slot** *slot-number* [**cpu** *cpu-number*]]

Default

CPU usage monitoring is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command enables CPU usage monitoring for the master device.

cpu *cpu-number*: Specifies a CPU by its number.

Usage guidelines

After CPU usage monitoring is enabled, the system samples and saves CPU usage at the interval specified by the **monitor cpu-usage interval** command. You can use the **display cpu-usage history** command to view recent CPU usage.

Examples

Enable CPU usage monitoring.

```
<Sysname> system-view
[Sysname] monitor cpu-usage enable
```

Related commands

display cpu-usage configuration

display cpu-usage history

monitor cpu-usage interval

monitor cpu-usage interval

Use **monitor cpu-usage interval** to set the sampling interval for CPU usage monitoring.

Syntax

monitor cpu-usage interval *interval* [**slot** *slot-number* [**cpu** *cpu-number*]]

Default

The system samples CPU usage every 1 minute.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the sampling interval for CPU usage monitoring. Valid values include **5Sec** (5 seconds), **1Min** (1 minute), and **5Min** (5 minutes), case insensitive.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command sets the interval for the master device.

cpu *cpu-number*: Specifies a CPU by its number.

Usage guidelines

After CPU usage monitoring is enabled, the system samples and saves CPU usage at the specified interval. You can use the **display cpu-usage history** command to view recent CPU usage.

Examples

Set the sampling interval for CPU usage monitoring to 5 seconds.

```
<Sysname> system-view
[Sysname] monitor cpu-usage interval 5Sec
```

Related commands

display cpu-usage configuration

display cpu-usage history

monitor cpu-usage enable

monitor cpu-usage logging

Use **monitor cpu-usage logging** to enable periodic CPU usage logging.

Use **undo monitor cpu-usage logging** to disable periodic CPU usage logging.

Syntax

monitor cpu-usage logging slot *slot-number* **cpu** *cpu-number* **interval** *interval-time*

undo monitor cpu-usage logging slot *slot-number* **cpu** *cpu-number*

Default

Periodic CPU usage logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID.

cpu *cpu-number*: Specifies a CPU by its number.

interval *interval-time*: Specifies the logging interval in seconds, a multiple of five in the range of 5 to 300.

Examples

Enable periodic CPU usage logging for CPU 0 on slot 1 and set the logging interval to 5 seconds.

```
<Sysname> system-view
[Sysname] monitor cpu-usage logging slot 1 cpu 0 interval 5
```

monitor cpu-usage statistics-interval core

Use **monitor cpu-usage statistics-interval core** to set CPU core usage statistics intervals.

Use **undo monitor cpu-usage statistics-interval core** to restore the default.

Syntax

monitor cpu-usage statistics-interval *interval* **slot** *slot-number* **cpu** *cpu-number* **core** *core-id-list*

undo monitor cpu-usage statistics-interval slot *slot-number* **cpu** *cpu-number* **core** *core-id-list*

Default

The CPU core usage statistics interval is 60 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the CPU core usage statistics interval in seconds. The value range for this argument is 10 to 3600. As a best practice, set this argument to a multiple of the sampling interval, which is fixed at 5 seconds. If you do not do so, the actual statistics interval is the biggest multiple of the sampling interval that is smaller than the setting. For example, if you set this argument to 12 seconds, the actual statistics interval is 10 seconds.

slot *slot-number*: Specifies an IRF member device by its member ID.

cpu *cpu-number*: Specifies a CPU by its number.

core *core-id-list*: Specifies a space-separated list of up to 10 CPU core items. Each item specifies a CPU core or a range of CPU cores in the form of *core-id1* [**to** *core-id2*]. The value for *core-id2* must be greater than or equal to the value for *core-id1*.

Usage guidelines

The device samples CPU core usage at 5-second intervals and calculates the average value during each CPU core usage statistics interval. If the value during an interval is greater than the CPU core usage threshold, the device issues an alarm and logs the event.

Examples

Set the usage statistics interval to 60 seconds for a CPU core.

```
<Sysname> system-view
[Sysname] monitor cpu-usage statistics-interval 60 slot 1 cpu 0 core 0
```

Related commands

monitor cpu-usage threshold core

monitor resend cpu-usage core-interval

monitor cpu-usage threshold

Use **monitor cpu-usage threshold** to set CPU usage alarm thresholds.

Use **undo monitor cpu-usage threshold** to restore the default.

Syntax

monitor cpu-usage threshold *severe-threshold* **recovery-threshold** *recovery-threshold* [**slot** *slot-number* [**cpu** *cpu-number*]]

undo monitor cpu-usage threshold recovery-threshold [**slot** *slot-number* [**cpu** *cpu-number*]]

Default

The CPU usage alarm threshold is 70%. The CPU usage recovery threshold is 30%.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

severe-threshold: Specifies the severe CPU usage alarm threshold in percentage. The value range for this argument is 2 to 100.

recovery-threshold *recovery-threshold*: Specifies the CPU usage recovery threshold in percentage. The value range for this argument is 0 to the minor CPU usage alarm threshold minus 1.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command sets the CPU usage threshold for the master device.

cpu *cpu-number*: Specifies a CPU by its number.

Usage guidelines

CAUTION:

If you set the severe CPU usage alarm threshold to a too low value, the device will reach the threshold easily. Normal services will be affected.

The device samples CPU usage at 1-minute intervals. If the sample is greater than the CPU usage threshold, the device sends a trap.

Examples

Set the CPU usage alarm threshold to 90% and the CPU usage recovery threshold to 70%.

```
<Sysname> system-view
[Sysname] monitor cpu-usage threshold 90 recovery-threshold 70
```

Related commands

display cpu-usage configuration

monitor memory-usage logging

Use **monitor memory-usage logging** to enable periodic memory usage logging.

Use **undo monitor memory-usage logging** to disable periodic memory usage logging.

Syntax

monitor memory-usage logging slot *slot-number* **cpu** *cpu-number* **interval** *interval-time*

undo monitor memory-usage logging slot *slot-number* **cpu** *cpu-number*

Default

Periodic memory usage logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID.

cpu *cpu-number*: Specifies a CPU by its number.

interval *interval-time*: Specifies the logging interval in seconds, a multiple of five in the range of 5 to 300.

Examples

Enable periodic memory usage logging for CPU 0 on slot 1 and set the logging interval to 5 seconds.

```
<Sysname> system-view
[Sysname] monitor memory-usage logging slot 1 cpu 0 interval 5
```

monitor resend cpu-usage core-interval

Use **monitor resend cpu-usage core-interval** to set CPU core alarm resending intervals.

Use **undo monitor resend cpu-usage core-interval** to restore the default.

Syntax

monitor resend cpu-usage core-interval *core-interval* [**slot** *slot-number* [**cpu** *cpu-number*]]

undo monitor resend cpu-usage core-interval [**slot** *slot-number* [**cpu** *cpu-number*]]

Default

The CPU core alarm resending interval is 300 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

core-interval: Specifies the CPU core alarm resending interval in seconds, a multiple of 5 in the range of 10 to 3600.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command sets the CPU core alarm resending interval for the master device.

cpu *cpu-number*: Specifies a CPU by its number.

Examples

Set the CPU core alarm resending interval to 60 seconds.

```
<Sysname> system-view
[Sysname] monitor resend cpu-usage core-interval 60
```

monitor resource-usage { bridge-aggregation | route-aggregation } threshold

Use **monitor resource-usage { bridge-aggregation | route-aggregation } threshold** to set aggregate interface usage thresholds.

Use **undo monitor resource-usage { bridge-aggregation | route-aggregation } threshold** to restore the default.

Syntax

monitor resource-usage { bridge-aggregation | route-aggregation } threshold *threshold-value*

undo monitor resource-usage { bridge-aggregation | route-aggregation } threshold

Default

No aggregate interface usage thresholds are set. The aggregate interface usage alarm feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

bridge-aggregation: Sets the Layer 2 aggregate interface usage threshold.

route-aggregation: Sets the Layer 3 aggregate interface usage threshold.

threshold-value: Specifies the aggregate interface usage threshold in the range of 1 to 4294967295.

Usage guidelines

When the number of created Layer 2 or Layer 3 aggregate interfaces reaches the threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 3-hour intervals.

Examples

Set the Layer 2 aggregate interface usage threshold to 100.

```
<Sysname> system-view
[Sysname] monitor resource-usage bridge-aggregation threshold 100
```

Set the Layer 3 aggregate interface usage threshold to 150.

```
<Sysname> system-view
[Sysname] monitor resource-usage route-aggregation threshold 150
```

monitor resource-usage bandwidth inbound threshold

Use **monitor resource-usage bandwidth inbound threshold** to set the total inbound bandwidth usage threshold.

Use **undo monitor resource-usage bandwidth inbound threshold** to restore the default.

Syntax

monitor resource-usage bandwidth inbound threshold *threshold-value* [**duration** *duration-value*]

undo monitor resource-usage bandwidth inbound threshold

Default

The total inbound bandwidth usage threshold is not set. The bandwidth usage alarm feature is disabled.

Views

System view

Predefined user roles

network-admin

Parameters

threshold-value: Specify the total inbound bandwidth usage threshold in Mbps. The value range for this argument is 1 to 4294967295.

duration *duration-value*: Specify the high-usage duration criterion in seconds, a multiple of five in the range of 5 to 300. The default value is 300.

Usage guidelines

This command is supported only on the default context.

If the total inbound traffic remains greater than or equal to the total inbound bandwidth usage threshold for the specified duration, the device sends an alarm. If the alarm state persists, the device resends the alarm at 5-second intervals.

Examples

Set the total inbound bandwidth usage threshold to 1024 Mbps and set the high-usage duration criterion to 60 seconds.

```
<Sysname> system-view
[Sysname] monitor resource-usage bandwidth inbound threshold 1024 duration 60
```

monitor resource-usage context threshold

Use **monitor resource-usage context threshold** to set the global context usage threshold.

Use **undo monitor resource-usage context threshold** to restore the default.

Syntax

monitor resource-usage context threshold *threshold-value*

undo monitor resource-usage context threshold

Default

The global context usage threshold is not set. The context usage alarm feature is disabled.

Views

System view

Predefined user roles

network-admin

Parameters

threshold-value: Specifies the global context usage threshold in the range of 1 to 4294967295.

Usage guidelines

This command is supported only on the default context.

When the number of created contexts on the device reaches the threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 6-hour intervals.

Examples

Set the global context usage threshold to 16.

```
<Sysname> system-view
[Sysname] monitor resource-usage context threshold 16
```

monitor resource-usage nat threshold

Use **monitor resource-usage nat threshold** to set the NAT mapping threshold.

Use **undo monitor resource-usage nat threshold** to restore the default.

Syntax

monitor resource-usage nat threshold *threshold-value*

undo monitor resource-usage nat threshold

Default

The NAT mapping threshold is not set. The NAT mapping alarm feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the NAT mapping threshold in the range of 1 to 4294967295.

Usage guidelines

When the number of NAT mappings reaches the threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 3-hour intervals.

In the current software version, this feature counts only static NAT mappings and effective NAT server mappings. To display the status of NAT server mappings, execute the **display nat server** command.

Examples

Set the NAT mapping threshold to 300.

```
<Sysname> system-view
[Sysname] monitor resource-usage nat threshold 300
```

Related commands

display nat server (*Layer 3—IP Services Command Reference*)

monitor resource-usage security-policy threshold

Use **monitor resource-usage security-policy** { **ip** | **ipv6** } **threshold** to set security policy rule usage thresholds.

Use **undo monitor resource-usage security-policy** { **ip** | **ipv6** } **threshold** to restore the default.

Syntax

monitor resource-usage security-policy { **ip** | **ipv6** } **threshold** *threshold-value*

undo monitor resource-usage security-policy { **ip** | **ipv6** } **threshold**

Default

No security policy rule thresholds are set. The security policy rule alarm feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ip: Sets the IPv4 security policy rule threshold.

ipv6: Sets the IPv6 security policy rule threshold.

threshold-value: Specifies the security policy rule threshold in the range of 1 to 4294967295.

Usage guidelines

When the number of created security policy rules reaches the threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 6-hour intervals.

Examples

Set the IPv4 security policy rule threshold to 500.

```
<Sysname> system-view
[Sysname] monitor resource-usage security-policy ip threshold 500
```

Set the IPv6 security policy rule threshold to 500.

```
<Sysname> system-view
[Sysname] monitor resource-usage security-policy ipv6 threshold 500
```

monitor resource-usage session-count threshold

Use **monitor resource-usage session-count threshold** to set session usage thresholds.

Use **undo monitor resource-usage session-count threshold** to restore the default.

Syntax

monitor resource-usage session-count [**slot** *slot-number*] **threshold** *threshold-value*

undo monitor resource-usage session-count [**slot** *slot-number*] **threshold**

Default

No session usage thresholds are set. The session usage alarm feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command sets the session usage threshold for the master device.

threshold-value: Specifies the session threshold in the range of 1 to 4294967295.

Usage guidelines

When the number of sessions reaches the threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 10-minute intervals.

Examples

Set the session usage threshold to 100000.

```
<Sysname> system-view
[Sysname] monitor resource-usage session-count threshold 100000
```

monitor resource-usage session-rate threshold

Use **monitor resource-usage session-rate threshold** to set session establishment rate thresholds.

Use **undo monitor resource-usage session-rate threshold** to restore the default.

Syntax

monitor resource-usage session-rate [**slot** *slot-number*] **threshold** *threshold-value*

undo monitor resource-usage session-rate [**slot** *slot-number*] **threshold**

Default

No session establishment rate thresholds are set. The session establishment rate alarm feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command sets the session establishment rate threshold for the master device.

threshold-value: Specifies the session establishment rate threshold in the range of 1 to 4294967295.

Usage guidelines

When the session establishment rate reaches the threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 10-minute intervals.

Examples

Set the session establishment rate threshold to 500.

```
<Sysname> system-view
[Sysname] monitor resource-usage session-rate threshold 500
```

password-recovery enable

Use **password-recovery enable** to enable password recovery capability.

Use **undo password-recovery enable** to disable password recovery capability.

Syntax

password-recovery enable

undo password-recovery enable

Default

Password recovery capability is enabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

This command is supported only on the default context.

Password recovery capability controls console user access to the device configuration and SDRAM from BootWare menus.

If password recovery capability is enabled, a console user can access the device configuration without authentication to configure new passwords.

If password recovery capability is disabled, console users must restore the factory-default configuration before they can configure new passwords. Restoring the factory-default configuration deletes the next-startup configuration files.

To enhance system security, disable password recovery capability.

To access the device configuration without authentication, you must connect to the master device and access the BootWare menu while the master device is starting up.

Availability of BootWare menu options depends on the password recovery capability setting. For more information, see the release notes.

Examples

Disable password recovery capability.

```
<Sysname> system-view
[Sysname] undo password-recovery enable
```

reboot

Use **reboot** to reboot the device.

Syntax

reboot [**slot** *slot-number*] [**force**]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify an IRF member device, the command reboots all IRF member devices.

force: Reboots the device immediately without performing software or hard disk check. If this keyword is not specified, the system first identifies whether the reboot might result in data loss or a system failure. For example, the system identifies whether the main system software image file exists and whether a write operation is in progress on a storage medium. If the reboot might cause problems, the system does not reboot the device.

Usage guidelines

CAUTION:

- A reboot might interrupt network services.
- Use the **force** keyword only when the device fails or a **reboot** command without the **force** keyword cannot perform a reboot correctly. A **reboot** command with the **force** keyword might result in file system corruption because it does not perform data protection.

If the main startup software images are corrupt or missing, you must re-specify a set of main startup software images before executing the **reboot** command.

For data security, the device does not reboot if you reboot the device while the device is performing file operations.

If the IRF fabric has only one member device, rebooting the member device reboots the entire IRF fabric. If the IRF fabric has a subordinate member and the member is operating correctly, rebooting the master triggers a master/subordinate switchover.

To ensure correct operation of the IRF fabric and member devices, do not trigger a switchover by rebooting the master if no subordinate member devices are in **Stable** state. To view the status of subordinate member devices, execute the **display system stable state** command.

Examples

Reboot the device. Save the running configuration at prompt.

```
<Sysname> reboot
Start to check configuration with next startup configuration file, please
wait.........DONE!
Current configuration will be lost after the reboot, save current configuration? [Y/N]:y
Please input the file name(*.cfg)[flash:/startup.cfg]
(To leave the existing filename unchanged, press the enter key):
flash:/startup.cfg exists, overwrite? [Y/N]:y
Validating file. Please wait...
Configuration is saved to mainboard device successfully.
This command will reboot the device. Continue? [Y/N]:y
Now rebooting, please wait...
```

Reboot the device immediately without performing software check.

```
<Sysname> reboot force
A forced reboot might cause the storage medium to be corrupted. Continue? [Y/N]:y
Now rebooting, please wait...
```

restore factory-default

Use **restore factory-default** to restore the factory-default configuration for the device.

Syntax

restore factory-default

Views

User view

Predefined user roles

network-admin

Usage guidelines

CAUTION:

This command restores the device to the factory default settings. Before using this command, make sure you fully understand its impact on your live network.

This command is supported only on the default context.

Use this command only when you cannot troubleshoot the device by using other methods, or you want to use the device in a different scenario.

Examples

Restore the factory-default configuration for the device.

```
<Sysname> restore factory-default
This command will restore the system to the factory default configuration and clear the operation data, and forcibly reboot the system. Continue [Y/N]:y
Restoring the factory default configuration. This process might take a few minutes. Please wait....Done.
The system is rebooting...
```

Related commands

reboot

scheduler job

Use **scheduler job** to create a job and enter its view, or enter the view of an existing job.

Use **undo scheduler job** to delete a job.

Syntax

scheduler job *job-name*

undo scheduler job *job-name*

Default

No job exists.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

job-name: Specifies the job name, a case-sensitive string of 1 to 47 characters.

Usage guidelines

A job can be referenced by multiple schedules. In job view, you can assign commands to the job.

Examples

Create a job named **backupconfig** and enter job view.

```
<Sysname> system-view
[Sysname] scheduler job backupconfig
[Sysname-job-backupconfig]
```

Related commands

command

scheduler schedule

scheduler logfile size

Use **scheduler logfile size** to set the size of the job execution log file.

Syntax

scheduler logfile size *value*

Default

The size of the job execution log file is 16 KB.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies the size of the job execution log file, in KB. The value range is 16 to 1024.

Usage guidelines

The job execution log file stores the execution information of jobs. If the file is full, old records are deleted to make room for new records. If the size of the log information to be written to the file is greater than the file size, the excessive information is not written to the file.

Examples

Set the size of the job execution log file to 32 KB.

```
<Sysname> system-view
[Sysname] scheduler logfile size 32
```

Related commands

display scheduler logfile

scheduler reboot at

Use **scheduler reboot at** to specify the reboot date and time.

Use **undo scheduler reboot** to delete the reboot schedule configuration.

Syntax

scheduler reboot at *time* [*date*]

undo scheduler reboot

Default

No reboot date or time is specified.

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the reboot time in the *hh:mm* format. The value range for *hh* is 0 to 23. The value range for *mm* is 0 to 59.

date: Specifies the reboot date in the *MM/DD/YYYY* or *YYYY/MM/DD* format. The value range for *YYYY* is 2000 to 2035. The value range for *MM* is 1 to 12. The value range for *DD* varies by month.

Usage guidelines

CAUTION:
This command enables the device to reboot at a scheduled time, which causes service interruption. Before using this command, make sure you fully understand its impact on your live network.

When the *date* argument is not specified, the system uses the following rules to determine the reboot time:

- If the reboot time is later than the current time, a reboot occurs at the reboot time of the current day.
- If the reboot time is earlier than the current time, a reboot occurs at the reboot time the next day.

The device supports only one device reboot schedule. If you execute both the **scheduler reboot delay** and **scheduler reboot at** commands or execute one of the commands multiple times, the most recent configuration takes effect.

For data security, the system does not reboot at the reboot time if a file operation is being performed.

Examples

Configure the device to reboot at 12:00 p.m. This example assumes that the current time is 11:43 a.m. on June 6, 2015.

```
<Sysname> scheduler reboot at 12:00
Reboot system at 12:00:00 06/06/2015 (in 0 hours and 16 minutes). Confirm? [Y/N]:
```

Related commands

scheduler reboot delay

Syntax

scheduler reboot delay *time*

undo scheduler reboot

Default

No reboot delay time is specified.

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the reboot delay time in the *hh:mm* or *mm* format. This argument can contain up to six characters. When in the *hh:mm* format, *mm* must be in the range of 0 to 59.

Usage guidelines

CAUTION:

This command enables the device to reboot at a scheduled time, which causes service interruption. Before using this command, make sure you fully understand its impact on your live network.

The device supports only one device reboot schedule. If you execute both the **scheduler reboot delay** and **schedule reboot at** commands or execute one of the commands multiple times, the most recent configuration takes effect.

For data security, the system does not reboot at the reboot time if a file operation is being performed.

Examples

Configure the device to reboot after 88 minutes. This example assumes that the current time is 11:48 a.m. on June 6, 2015.

```
<Sysname> scheduler reboot delay 88
Reboot system at 13:16 06/06/2015(in 1 hours and 28 minutes). Confirm? [Y/N]:
```

scheduler schedule

Use **scheduler schedule** to create a schedule and enter its view, or enter the view of an existing schedule.

Use **undo scheduler schedule** to delete a schedule.

Syntax

scheduler schedule *schedule-name*

undo scheduler schedule *schedule-name*

Default

No schedule exists.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

schedule-name: Specifies the schedule name, a case-sensitive string of 1 to 47 characters.

Usage guidelines

You can configure a schedule to have the device automatically run a command or a set of commands without administrative interference.

To configure a schedule:

1. Use the **scheduler job** command to create a job and enter job view.
2. Use the **command** command to assign commands to the job.

3. Use the **scheduler schedule** command to create a schedule and enter schedule view.
4. Use the **job** command to assign the job to the schedule. You can assign multiple jobs to a schedule. The jobs must already exist.
5. Use the **user-role** command to assign user roles to the schedule. You can assign up to 64 user roles to a schedule.
6. Use the **time at**, **time once**, or **time repeating** command to specify an execution time for the schedule. You can specify only one execution time for a schedule.

Examples

Create a schedule named **saveconfig**.

```
<Sysname> system-view
[Sysname] scheduler schedule saveconfig
```

shutdown-interval

Use **shutdown-interval** to set the port status detection timer.

Use **undo shutdown-interval** to restore the default.

Syntax

shutdown-interval *interval*

undo shutdown-interval

Default

The port status detection timer setting is 30 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the port status detection timer value in seconds. The value range is 0 to 300. To disable port status detection, set this argument to 0.

Usage guidelines

The device starts a port status detection timer when a port is shut down by a protocol. Once the timer expires, the device brings up the port so the port status reflects the port's physical status.

If you change the timer setting during port detection, the device compares the new setting (T1) with the time that elapsed since the port was shut down (T).

If T < T1, the port will be brought up after T1 – T seconds.

If T ≥ T1, the port is brought up immediately.

For example, the timer setting is 30 seconds. If you change it to 10 seconds 2 seconds after the port is shut down, the port will come up 8 seconds later. If you change the timer setting to 2 seconds 10 seconds after the port is shut down, the port comes up immediately.

Examples

Set the port status detection timer to 100 seconds.

```
<Sysname> system-view
[Sysname] shutdown-interval 100
```

sysid

Use **sysid** to set the system ID.

Use **undo sysid** to restore the default.

Syntax

sysid *system-id*

undo sysid

Default

The device does not have a system ID.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

system-id: Specifies the system ID for the device. You can use this argument to indicate the position or functionality of the device or any other information.

Examples

Set the system ID of the device to **position-hall**.

```
<Sysname> system-view
[Sysname] sysid positon-hall
```

sysname

Use **sysname** to set the device name.

Use **undo sysname** to restore the default.

Syntax

sysname *sysname*

undo sysname

Default

The device name is NSFOCUS.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

sysname: Specifies a name for the device, a string of 1 to 64 characters.

Usage guidelines

A device name identifies a device in a network and is used in CLI view prompts. For example, if the device name is **Sysname**, the user view prompt is <Sysname>.

Examples

Set the name of the device to **R2000**.

```
<Sysname> system-view
[Sysname] sysname R2000
[R2000]
```

temperature-limit

Use **temperature-limit** to set the temperature alarm thresholds.

Use **undo temperature-limit** to restore the default.

Syntax

temperature-limit slot *slot-number* { **hotspot** | **inflow** | **outflow** } *sensor-number lowlimit warninglimit* [*alarmlimit*]

undo temperature-limit slot *slot-number* { **hotspot** | **inflow** | **outflow** } *sensor-number*

The following compatibility matrixes show the support of hardware platforms for this command:

Models	Command compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480,	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Default

The defaults vary by temperature sensor model. To view the defaults, execute the **undo temperature-limit** and **display environment** commands in turn.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID.

hotspot: Configures temperature alarm thresholds for hotspot sensors. A hotspot sensor is typically near the chip that generates a great amount of heat and used to monitor the chip.

The following compatibility matrixes show the support of hardware platforms for the **hotspot** keyword:

Models	Parameter compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080	Yes
NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	No

inflow: Configures temperature alarm thresholds for inlet sensors. An inlet sensor is near the air inlet and used for monitoring ambient temperature.

outflow: Configures temperature alarm thresholds for outlet sensors. An outlet sensor is near the air outlet for monitoring device temperature.

sensor-number: Specifies a sensor by its number. To view the value range, enter a question mark (?) in the place of this argument.

lowlimit: Specifies the low-temperature threshold in Celsius degrees. The value range varies by temperature sensor. To view the value range, enter a question mark (?) in the place of this argument.

warninglimit: Specifies the high-temperature warning threshold in Celsius degrees. This threshold must be greater than the low-temperature threshold. To view the value range, enter a question mark (?) in the place of this argument.

alarmlimit: Specifies the high-temperature alarming threshold in Celsius degrees. This threshold must be greater than the warning threshold. To view the value range, enter a question mark (?) in the place of this argument.

Usage guidelines

This command is supported only on the default context.

When the device temperature drops below the low-temperature threshold or reaches the high-temperature warning or alarming threshold, the device performs the following operations:

- Sends log messages and traps.
- Sets LEDs on the device panel.

Examples

Set temperature alarm thresholds for hotspot sensor 1 in a slot.

```
<Sysname> system-view

time at

Use **time at** to specify an execution date and time for a non-periodic schedule.

Use **undo time** to delete the execution date and time configuration for a non-periodic schedule.

Syntax

time at *time date*

undo time

Default

No execution time or date is specified for a non-periodic schedule.

Views

Schedule view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the schedule execution time in the *hh:mm* format. The value range for *hh* is 0 to 23. The value range for *mm* is 0 to 59.

date: Specifies the schedule execution date in the *MM/DD/YYYY* or *YYYY/MM/DD* format. The value range for *YYYY* is 2000 to 2035. The value range for *MM* is 1 to 12. The value range for *DD* varies by month.

Usage guidelines

The specified time (date plus time) must be later than the current system time.

The **time at** command, the **time once** command, and the **time repeating** command overwrite one another. The most recently executed command takes effect.

Examples

Configure the device to execute schedule **saveconfig** at 01:01 a.m. on May 11, 2015.

```
<Sysname> system-view
[Sysname] scheduler schedule saveconfig
[Sysname-schedule-saveconfig] time at 1:1 2015/05/11
```

Related commands

scheduler schedule

time once

Use **time once** to specify one or more execution days and the execution time for a non-periodic schedule.

Use **undo time** to delete the execution day and time configuration for a non-periodic schedule.

Syntax

time once at *time* [**month-date** *month-day* | **week-day** *week-day*&<1-7>]

time once delay *time*

undo time

Default

No execution time or day is specified for a non-periodic schedule.

Views

Schedule view

Predefined user roles

network-admin

context-admin

Parameters

at *time*: Specifies the execution time in the *hh:mm* format. The value range for *hh* is 0 to 23. The value range for *mm* is 0 to 59.

month-date *month-day*: Specifies a day in the current month, in the range of 1 to 31. If you specify a day that does not exist in the current month, the configuration takes effect on that day in the next month.

week-day *week-day*&<1-7>: Specifies a space-separated list of up to seven week days for the schedule. Valid week day values include **Mon**, **Tue**, **Wed**, **Thu**, **Fri**, **Sat**, and **Sun**.

delay *time*: Specifies the delay time for executing the schedule, in the *hh:mm* or *mm* format. This argument can have up to six characters. When in the *hh:mm* format, *mm* must be in the range of 0 to 59.

Usage guidelines

If the specified time has already occurred, the schedule will be executed at the specified time the following day.

If the day in the month has already occurred, the schedule will be executed at the specified day in the following month.

If the specified day in a week has already occurred, the schedule will be executed at the specified day in the following week.

The **time at** command, the **time once** command, and the **time repeating** command overwrite one another. The most recently executed command takes effect.

Examples

Configure the device to execute schedule **saveconfig** once at 15:00.

```
<Sysname> system-view
[Sysname] scheduler schedule saveconfig
[Sysname-schedule-saveconfig] time once at 15:00
Schedule starts at 15:00 5/11/2011.
```

Configure the device to execute schedule **saveconfig** once at 15:00 on the coming 15th day in a month.

```
<Sysname> system-view
[Sysname] scheduler schedule saveconfig
[Sysname-schedule-saveconfig] time once at 15:00 month-date 15
```

Configure the device to execute schedule **saveconfig** at 12:00 p.m. on the coming Monday and Friday.

```
<Sysname> system-view
[Sysname] scheduler schedule saveconfig
[Sysname-schedule-saveconfig] time once at 12:00 week-day mon fri
```

Configure the device to execute schedule **saveconfig** after 10 minutes.

```
<Sysname> system-view
[Sysname] scheduler schedule saveconfig
[Sysname-schedule-saveconfig] time once delay 10
```

Related commands

scheduler schedule

time repeating

Use **time repeating** to specify an execution time table for a periodic schedule.

Use **undo time** to delete the execution time table configuration for a periodic schedule.

Syntax

time repeating [**at** *time* [*date*]] **interval** *interval*

time repeating at *time* [**month-date** [*month-day* | **last**] | **week-day** *week-day*&<1-7>]

undo time

Default

No execution time table is specified for a periodic schedule.

Views

Schedule view

Predefined user roles

network-admin

context-admin

Parameters

at *time*: Specifies the execution time in the *hh:mm* format. The value range for *hh* is 0 to 23. The value range for *mm* is 0 to 59. If you do not specify this option, the current system time is used as the execution time.

date: Specifies the start date for the periodic schedule, in the *MM/DD/YYYY* or *YYYY/MM/DD* format. The value range for *YYYY* is 2000 to 2035. The value range for *MM* is 1 to 12. The value range for *DD* varies by month. If you do not specify this argument, the execution start date is the first day when the specified time arrives.

interval *interval*: Specifies the execution time interval in the *hh:mm or mm* format. This argument can have up to six characters. When in the *hh:mm* format, *mm* must be in the range of 0 to 59. When in the *mm* format, this argument must be equal to or greater than 1 minute.

month-date [*month-day* | **last**]: Specifies a day in a month, in the range 1 to 31. The **last** keyword indicates the last day of a month. If you specify a day that does not exist in a month, the configuration takes effect on that day in the next month.

week-day *week-day*&<1-7>: Specifies a space-separated list of up to seven week days for the schedule. Valid week day values include **Mon**, **Tue**, **Wed**, **Thu**, **Fri**, **Sat**, and **Sun**.

Usage guidelines

The **time repeating** [**at** *time* [*date*]] **interval** *interval* command configures the device to execute a schedule at intervals from the specified time on.

The **time repeating at** *time* [**month-date** [*month-day* | **last**] | **week-day** *week-day*&<1-7>] command configures the device to execute a schedule at the specified time on every specified day in a month or week.

The **time at** command, the **time once** command, and the **time repeating** command overwrite one another, whichever is executed most recently takes effect.

Examples

Configure the device to execute schedule **saveconfig** once an hour from 8:00 a.m. on.

```
<Sysname> system-view
[Sysname] scheduler schedule saveconfig
[Sysname-schedule-saveconfig] time repeating at 8:00 interval 60
```

Configure the device to execute schedule **saveconfig** at 12:00 p.m. every day.

```
<Sysname> system-view
```

```
[Sysname] scheduler schedule saveconfig
[Sysname-schedule-saveconfig] time repeating at 12:00
```

Configure the device to execute schedule **saveconfig** at 8:00 a.m. on the 5th of every month.

```
<Sysname> system-view
[Sysname] scheduler schedule saveconfig
[Sysname-schedule-saveconfig] time repeating at 8:00 month-date 5
```

Configure the device to execute schedule **saveconfig** at 8:00 a.m. on the last day of every month.

```
<Sysname> system-view
[Sysname] scheduler schedule saveconfig
[Sysname-schedule-saveconfig] time repeating at 8:00 month-date last
```

Configure the device to execute schedule **saveconfig** at 8:00 a.m. every Friday and Saturday.

```
<Sysname> system-view
[Sysname] scheduler schedule saveconfig
[Sysname-schedule-saveconfig] time repeating at 8:00 week-day fri sat
```

Related commands

scheduler schedule

usb disable

Use **usb disable** to disable USB interfaces.

Use **undo usb disable** to enable USB interfaces.

Syntax

usb disable

undo usb disable

Default

All USB interfaces are enabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

This command is supported only on the default context.

You can use USB interfaces to upload or download files or to connect a 3G modem. By default, all USB interfaces are enabled.

Before executing this command, use the **umount** command to unmount all USB file systems.

Examples

Enable USB interfaces.

```
<Sysname> system-view
[Sysname] undo usb disable
```

user-role

Use **user-role** to assign user roles to a schedule.

Use **undo user-role** to remove user roles from a schedule.

Syntax

user-role *role-name*

undo user-role *role-name*

Default

A schedule has the user roles of the schedule creator.

Views

Schedule view

Predefined user roles

network-admin

context-admin

Parameters

role-name: Specifies a user role name, a case-sensitive string of 1 to 63 characters. The user role can be user-defined or predefined. Predefined user roles include network-admin, network-operator, context-admin, context-operator, and level-0 to level-15.

Usage guidelines

A schedule must have one or more user roles. A command in a schedule can be executed if it is permitted by one or more user roles of the schedule. For more information about user roles, see the RBAC configuration in *Fundamentals Configuration Guide*.

A schedule can have a maximum of 64 user roles. After the limit is reached, you cannot assign additional user roles to the schedule.

Examples

Assign user role **rolename** to schedule **test**.

```
<Sysname> system-view
[Sysname] scheduler schedule test
[Sysname-schedule-test] user-role rolename
```

Parameters

ipv6-address: Specifies the source IPv6 address of an FTP connection. To view the source IPv6 addresses of FTP connections, execute the **display ftp-user** command.

port *port*: Specifies the source port of an FTP connection. To view the source ports of FTP connections, execute the **display ftp-user** command.

Examples

Release the FTP connections established from IPv6 address 2000::154.

```
<Sysname> free ftp user-ip ipv6 2000::154
Are you sure to free FTP connection? [Y/N]:y
<Sysname>
```

ftp server acl

Use **ftp server acl** to apply an ACL to control IPv4 FTP clients' access to the FTP server.

Use **undo ftp server acl** to restore the default.

Syntax

ftp server acl { *advanced-acl-number* | *basic-acl-number* | **mac** *mac-acl-number* }

undo ftp server acl

Default

No ACL is used to control IPv4 FTP clients' access to the FTP server.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

advanced-acl-number: Specifies the number of an IPv4 advanced ACL, in the range of 3000 to 3999.

basic-acl-number: Specifies the number of an IPv4 basic ACL, in the range of 2000 to 2999.

mac *mac-acl-number*: Specifies the number of a Layer 2 ACL, in the range of 4000 to 4999.

Usage guidelines

When no ACL is applied, all IPv4 FTP clients can access the FTP server. To control FTP access, specify an ACL that exists and has rules so only IPv4 FTP clients permitted by the ACL can access the FTP server. If you specify an ACL that does not exist or does not have rules, no IPv4 FTP clients can access the FTP server.

If a VPN instance is specified in an ACL rule, the ACL rule applies only to the packets of the VPN instance. If no VPN instance is specified in an ACL rule, the ACL rule applies only to the packets on the public network.

The ACL takes effect only for FTP connections to be established. It does not impact existing FTP connections.

If you execute this command multiple times, the most recent configuration takes effect.

For more information about ACLs, see *ACL and QoS Configuration Guide.*

Examples

Use ACL 2001 to allow only client 1.1.1.1 to access the FTP server.

```
<Sysname> system-view
[Sysname] acl basic 2001
[Sysname-acl-ipv4-basic-2001] rule 0 permit source 1.1.1.1 0
[Sysname-acl-ipv4-basic-2001] rule 1 deny source any
[Sysname-acl-ipv4-basic-2001] quit
[Sysname] ftp server acl 2001
```

ftp server acl ipv6

Use **ftp server acl** to apply an ACL to control IPv6 FTP clients' access to the FTP server.

Use **undo ftp server acl** to restore the default.

Syntax

ftp server acl ipv6 { *advanced-acl-number* | *basic-acl-number* | **mac** *mac-acl-number* }

undo ftp server acl ipv6

Default

No ACL is used to control IPv6 FTP clients' access to the FTP server.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

advanced-acl-number: Specifies the number of an IPv6 advanced ACL, in the range of 3000 to 3999.

basic-acl-number: Specifies the number of an IPv6 basic ACL, in the range of 2000 to 2999.

mac *mac-acl-number*: Specifies the number of a Layer 2 ACL, in the range of 4000 to 4999.

Usage guidelines

When no ACL is applied, all IPv6 FTP clients can access the FTP server. To control FTP access, specify an ACL that exists and has rules so only IPv6 FTP clients permitted by the ACL can access the FTP server. If you specify an ACL that does not exist or does not have rules, no IPv6 FTP clients can access the FTP server.

If a VPN instance is specified in an ACL rule, the ACL rule applies only to the packets of the VPN instance. If no VPN instance is specified in an ACL rule, the ACL rule applies only to the packets on the public network.

The ACL takes effect only for FTP connections to be established. It does not impact existing FTP connections.

If you execute this command multiple times, the most recent configuration takes effect.

For more information about ACLs, see *ACL and QoS Configuration Guide.*

Examples

Use ACL 2001 to allow only IPv6 client 1:1::1:1/64 to access the FTP server.

```
<Sysname> system-view
[Sysname] acl ipv6 basic 2001
[Sysname-acl-ipv6-basic-2001] rule 0 permit source 1:1::1:1 64
[Sysname-acl-ipv6-basic-2001] rule 1 deny source any
[Sysname-acl-ipv6-basic-2001] quit
[Sysname] ftp server acl ipv6 2001
```

ftp server acl-deny-log enable

Use **ftp server acl-deny-log enable** to enable logging for FTP login attempts that are denied by the FTP login control ACL.

Use **undo ftp server acl-deny-log enable** to disable logging for FTP login attempts that are denied by the FTP login control ACL.

Syntax

ftp server acl-deny-log enable

undo ftp server acl-deny-log enable

Default

Logging is disabled for FTP login attempts that are denied by the FTP login control ACL.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Only clients permitted by the FTP login control ACL can use FTP to access the device. This logging feature generates log messages for FTP login attempts that are denied by the FTP login control ACL.

For information about log message output, see the information center in *Network Management and Monitoring Configuration Guide*. For information about configuring an FTP login control ACL, see the **ftp server acl** or **ftp server acl ipv6** command.

Examples

Enable logging for FTP login attempts that are denied by the FTP login control ACL.

```
<Sysname> system-view
[Sysname] FTP server acl-deny-log enable
```

Related commands

- **ftp server acl ipv6**

ftp server dscp

Use **ftp server dscp** to set the DSCP value for IPv4 to use for FTP packets sent to an FTP client.

Use **undo ftp server dscp** to restore the default.

Syntax

ftp server dscp *dscp-value*

undo ftp server dscp

Default

IPv4 uses the DSCP value 0 for FTP packets sent to an FTP client.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Specifies a DSCP value in the range of 0 to 63.

Usage guidelines

The DSCP value is carried in the ToS field of an IP packet to indicate the transmission priority of the packet.

Examples

Set the DSCP value for IPv4 to use for outgoing FTP packets to 30 on an FTP server.

```
<Sysname> system-view
[Sysname] ftp server dscp 30
```

ftp server enable

Use **ftp server enable** to enable the FTP server.

Use **undo ftp server enable** to disable the FTP server.

Syntax

ftp server enable

undo ftp server enable

Default

The FTP server is disabled.

Views

System view

Predefined user roles

network-admin

Examples

Enable the FTP server.

```
<Sysname> system-view
[Sysname] ftp server enable
```

ftp server ipv6 dscp

Use **ftp server ipv6 dscp** to set the DSCP value for IPv6 to use for FTP packets sent to an FTP client.

Use **undo ftp server ipv6 dscp** to restore the default.

Syntax

ftp server ipv6 dscp *dscp-value*

undo ftp server ipv6 dscp

Default

IPv6 uses the DSCP value 0 for FTP packets sent to an FTP client.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Specifies a DSCP value in the range of 0 to 63.

Usage guidelines

The DSCP value is carried in the Traffic class field of an IPv6 packet to indicate the transmission priority of the packet.

Examples

Set the DSCP value for IPv6 to use for outgoing FTP packets to 30 on an FTP server.

```
<Sysname> system-view
[Sysname] ftp server ipv6 dscp 30
```

ftp server ssl-server-policy

Use **ftp server ssl-server-policy** to associate an SSL server policy with the FTP server.

Use **undo ftp server ssl-server-policy** to restore the default.

Syntax

ftp server ssl-server-policy *policy-name*

undo ftp server ssl-server-policy

Default

No SSL server policy is associated with the FTP server.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies an SSL server policy by its name, a string of 1 to 31 characters.

Usage guidelines

After you associate an SSL server policy with the device, a client that supports SFTP will establish a secure connection to the device to ensure data security.

Examples

Associate SSL server policy **myssl** with the FTP server.

```
<Sysname> system-view
[Sysname] ftp server ssl-server-policy myssl
```

Related commands

ftp server enable

ssl server-policy (*Security Command Reference*)

ftp timeout

Use **ftp timeout** to set the FTP connection idle-timeout timer.

Use **undo ftp timeout** to restore the default.

Syntax

ftp timeout *minute*

undo ftp timeout

Default

The FTP connection idle-timeout timer is 30 minutes.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

Minute: Specifies a time interval in the range of 1 to 35791 minutes.

Usage guidelines

If no data transfer occurs on an FTP connection within the idle-timeout interval, the FTP server closes the FTP connection to release resources.

Examples

Set the FTP connection idle-timeout timer to 36 minutes.

```
<Sysname> system-view
[Sysname] ftp timeout 36
```

FTP client commands

For FTP users to execute FTP client configuration commands, you must configure authorization settings for users on the FTP server. Authorized operations include viewing the files in the working directory, reading/downloading/uploading/renaming/removing files, and creating directories.

The FTP client commands in this section are supported by the device, but whether they can be executed successfully depends on the FTP server.

The output in the examples of this section varies by FTP server type.

?

Use **?** to display all commands supported by an FTP client.

Use **?** *command-name* to display the help information for a command.

Syntax

? [*command-name*]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

command-name: Specifies a command supported by the FTP client.

Usage guidelines

In FTP client view, entering **?** is the same as executing the **help** command.

Examples

Display all commands supported by the FTP client.

```
ftp> ?
Commands may be abbreviated.  Commands are:

append          delete          ls              quit            rmdir
ascii           debug           mkdir           reget           status
binary          dir             newer           rstatus         system
bye             disconnect      open            rhelp           user
cd              get             passive         rename          verbose
cdup            help            put             reset           ?
close           lcd             pwd             restart
```

Display the help information for the **dir** command.

```
ftp> ? dir
dir              list contents of remote directory

help

append

Use **append** to add the content of a file on the FTP client to a file on the FTP server.

Syntax

append *localfile* [*remotefile*]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

localfile: Specifies a file on the FTP client.

remotefile: Specifies a file on the FTP server.

Usage guidelines

You can perform this operation only after you log in to the FTP server.

Examples

Append the content of the local **a.txt** file to the **b.txt** file on the FTP server.

```
ftp> append a.txt b.txt
local: a.txt remote: b.txt
150 Connecting to port 50190
226 File successfully transferred
1657 bytes sent in 0.000736 seconds (2.15 Mbyte/s)
```

ascii

Use **ascii** to set the file transfer mode to ASCII.

Syntax

ascii

Default

The file transfer mode is binary.

Views

FTP client view

Predefined user roles

network-admin

context-admin

Usage guidelines

You can perform this operation only after you log in to the FTP server.

FTP transfers files in either of the following modes:

- **Binary mode**—Transfers non-text files.
- **ASCII mode**—Transfers text files.

When the device acts as the FTP server, the transfer mode is determined by the FTP client. When the device acts as the FTP client, you can set the transfer mode. The transfer mode is binary by default.

Examples

Set the file transfer mode to ASCII.

```
ftp> ascii
200 TYPE is now ASCII
```

Related commands

Related commands

quit

cd

Use **cd** to change the current working directory to another directory on the FTP server.

Syntax

cd { *directory* | **..** | **/** }

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

directory: Specifies the target directory. If the target directory does not exist, the **cd** command does not change the current working directory.

..: Specifies the upper directory. Executing the **cd ..** command is the same as executing the **cdup** command. If the current working directory is the FTP root directory, the **cd ..** command does not change the current working directory.

/: Specifies the FTP root directory.

Usage guidelines

You can perform this operation only after you log in to the FTP server.

The directory that can be accessed must be authorized by the FTP server.

Examples

Change the working directory to the **logfile** subdirectory of the current directory.

```
ftp> cd logfile
250 OK. Current directory is /logfile
```

Change the working directory to the **folder** subdirectory of the FTP root directory.

```
ftp> cd /folder
250 OK. Current directory is /folder
```

Change the working directory to the upper directory of the current directory.

```
ftp> cd ..
250 OK. Current directory is /
```

Change the working directory to the FTP root directory.

```
ftp> cd /
250 OK. Current directory is /
```

Related commands

cdup

pwd

cdup

Use **cdup** to enter the upper directory of the FTP server.

Syntax

cdup

Views

FTP client view

Predefined user roles

network-admin

context-admin

Usage guidelines

You can perform this operation only after you log in to the FTP server.

This command does not change the working directory if the current directory is the FTP root directory.

Examples

Change the working directory to the upper directory.

```
ftp> pwd
257 "/ftp/subdir" is your current location
ftp> cdup
250 OK. Current directory is /ftp
ftp> pwd
257 "/ftp" is your current location
```

Related commands

cd

pwd

close

Use **close** to terminate the connection to the FTP server without exiting FTP client view.

Syntax

close

Views

FTP client view

Predefined user roles

context-admin

Usage guidelines

You can perform this operation only after you log in to the FTP server.

Examples

Terminate the connection to the FTP server without exiting the FTP client view.

```
ftp> close
221-Goodbye. You uploaded 0 and downloaded 0 kbytes.
221 Logout.
ftp>
```

Related commands

disconnect

debug

Use **debug** to enable or disable FTP client debugging.

Syntax

debug

Default

FTP client debugging is disabled.

Views

FTP client view

Predefined user roles

network-admin

context-admin

Usage guidelines

When FTP client debugging is enabled, executing this command disables FTP client debugging.

When FTP client debugging is disabled, executing this command enables FTP client debugging.

Examples

Enable and then disable FTP client debugging.

```
ftp> debug
Debugging on (debug=1).
ftp> debug
Debugging off (debug=0).
```

delete

Use **delete** to permanently delete a file from the FTP server.

Syntax

delete *remotefile*

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

remotefile: Specifies a file on the FTP server.

Usage guidelines

CAUTION:

Permanently delete a file from the FTP server with caution. When you permanently delete a file from the FTP server, make sure the file is no longer in use.

You can perform this operation only after you log in to the FTP server.

To perform this operation, you must have delete permission on the FTP server.

Examples

Delete the **b.txt** file.

```
ftp> delete b.txt
250 Deleted b.txt
```

dir

Use **dir** to display or save detailed information about files and directories on the FTP server.

Syntax

dir [*remotefile* [*localfile*]]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

remotefile: Specifies a file or directory on the FTP server.

localfile: Specifies the name of the local file used to save the displayed information.

Usage guidelines

You can perform this operation only after you log in to the FTP server.

To display detailed information about the files and subdirectories in the working directory on the FTP server, use the **dir** command.

To display detailed information about a file or directory on the FTP server, use the **dir** *remotefile* command.

To save detailed information about a file or directory on the FTP server to a local file, use the **dir** *remotefile localfile* command.

In FTP client view, executing the **dir** command is the same as executing the **ls** command.

Examples

Display detailed information about the files and subdirectories in the working directory on the FTP server.

```
ftp> dir
150 Connecting to port 50201
```

```

ftp

Use **ftp** to log in to an IPv4 FTP server and enter FTP client view.

Syntax

ftp [*ftp-server* [*service-port*] [**vpn-instance** *vpn-instance-name*] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ip** *source-ip-address* }]] *

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

ftp-server: Specifies the IPv4 address or host name of an FTP server. A host name can be a case-insensitive string of 1 to 253 characters. Valid characters for a host name include letters, digits, hyphens (-), underscores (_), and dots (.).

service-port: Specifies the TCP port number of the FTP server, in the range of 0 to 65535. The default is 21.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the FTP server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the FTP server belongs to the public network, do not specify this option.

dscp *dscp-value*: Specifies the DSCP value for IPv4 to use in outgoing FTP packets to indicate the packet transmission priority. The value range is 0 to 63. The default is 0.

source { **interface** *interface-type interface-number* | **ip** *source-ip-address* }: Specifies the source address used to establish the FTP connection.

- **interface** *interface-type interface-number*: Specifies an interface by its type and number. The device will use the interface's primary IPv4 address as the source address. To establish the FTP connection successfully, make sure the interface is up and has the primary IPv4 address configured.
- **ip** *source-ip-address*: Specifies an IPv4 address. To establish the FTP connection successfully, make sure this address is the IPv4 address of an interface in up state on the device.

Usage guidelines

This command is only applicable to IPv4 networks.

If no parameters are specified, this command enters the FTP client view without logging in to an FTP server.

If the server parameters are specified, you are prompted to enter the username and password for logging in to the FTP server.

Examples

Log in to FTP server 192.168.0.211. Use 192.168.0.212 as the source IPv4 address for outgoing FTP packets.

```
<Sysname> ftp 192.168.0.211 source ip 192.168.0.212
Press CTRL+C to abort.
Connected to 192.168.0.211 (192.168.0.211).
220 WFTPD 2.0 service (by Texas Imperial Software) ready for new user

```

ftp client ipv6 source

Use **ftp client ipv6 source** to specify the source IPv6 address for FTP packets sent to an IPv6 FTP server.

Use **undo ftp client ipv6 source** to restore the default.

Syntax

ftp client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *source-ipv6-address* }

undo ftp client ipv6 source

Default

No source address is specified for FTP packets sent to an IPv6 FTP server. The device selects a source IPv6 address as defined in RFC 3484.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. The device will use the interface's IPv6 address as the source address. For successful FTP packet transmission, make sure the interface is up and is configured with an IPv6 address.

ipv6 *source-ipv6-address*: Specifies an IPv6 address. For successful FTP packet transmission, make sure this address is the IPv6 address of an interface in up state on the device.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

The source address specified with the **ftp ipv6** command takes precedence over the source address specified with the **ftp client ipv6 source** command.

The source address specified with the **ftp client ipv6 source** command applies to all FTP connections. The source address specified with the **ftp ipv6** command applies only to the FTP connection that is being established.

Examples

Specify the source IPv6 address of 2000::1 for FTP packets sent to an IPv6 FTP server.

```
<Sysname> system–view
[Sysname] ftp client ipv6 source ipv6 2000::1
```

Related commands

ftp ipv6

ftp client source

Use **ftp client source** to specify the source IPv4 address for FTP packets sent to an IPv4 FTP server.

Use **undo ftp client source** to restore the default.

Syntax

ftp client source { **interface** *interface-type interface-number* | **ip** *source-ip-address* }

undo ftp client source

Default

No source IPv4 address is specified for FTP packets sent to an IPv4 FTP server. The device uses the primary IPv4 address of the output interface for the route to the server as the source address.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. The device will use the interface's primary IPv4 address as the source address. For successful FTP packet transmission, make sure the interface is up and has the primary IPv4 address configured.

ip *source-ip-address*: Specifies an IPv4 address. For successful FTP packet transmission, make sure this address is the IPv4 address of an interface in up state on the device.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

The source address specified with the **ftp** command takes precedence over the source address specified with the **ftp client source** command.

The source address specified with the **ftp client source** command applies to all FTP connections. The source address specified with the **ftp** command applies only to the FTP connection that is being established.

Examples

Specify the source IPv4 address of 192.168.20.222 for FTP packets sent to an IPv4 FTP server.

```
<Sysname> system-view
[Sysname] ftp client source ip 192.168.20.222
```

Parameters

ftp-server: Specifies the IPv6 address or host name of an FTP server. A host name can be a case-insensitive string of 1 to 253 characters. Valid characters for a host name include letters, digits, hyphens (-), underscores (_), and dots (.).

service-port: Specifies the TCP port number of the FTP server, in the range of 0 to 65535. The default is 21.

dscp *dscp-value*: Specifies the DSCP value for IPv6 to use in outgoing FTP packets to indicate the packet transmission priority. The value range is 0 to 63. The default is 0.

source { **ipv6** *source-ipv6-address* | **interface** *interface-type interface-number* }: Specifies the source address used to establish the FTP connection.

- **interface** *interface-type interface-number*: Specifies an interface by its type and number. This option can be used only when the FTP server address is a link local address and the specified output interface has a link local address. For information about link local addresses, see IPv6 basics in *Layer 3—IP Services Configuration Guide*.
- **ipv6** *source-ipv6-address*: Specifies an IPv6 address. To establish the FTP connection successfully, make sure this address is the IPv6 address of an interface in up state on the device.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the FTP server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the FTP server belongs to the public network, do not specify this option.

-i *interface-type interface-number*: Specifies an output interface by its type and number. This option can be used only when the FTP server address is a link local address and the specified output interface has a link local address.

Usage guidelines

This command is only applicable to IPv6 networks.

If no parameters are specified, this command enters the FTP client view.

If the FTP server parameters are specified, you are prompted to enter the username and password for logging in to the FTP server.

Examples

Log in to FTP server 2000::154.

```
<Sysname>ftp ipv6 2000::154
Press CTRL+C to abort.
Connected to 2000::154 (2000::154).
220 FTP service ready.
User (2000::154): root
331 Password required for root.
Password:
230 User logged in
Remote system type is NSFOCUS
```

get

Use **get** to download a file from the FTP server and save the file.

Syntax

get *remotefile* [*localfile*]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

remotefile: Specifies the file to be downloaded.

localfile: Specifies a name for the downloaded file. If you do not specify this argument, the system uses the name of the source file.

Usage guidelines

You can perform this operation only after you log in to the FTP server.

To save the downloaded file to the working directory accessed by the **ftp** command, perform one of the following tasks:

- Execute the command without specifying the *localfile* argument.

- Specify a file name without any path information for the *localfile* argument, for example, a.cfg.

To save the downloaded file to some other directory, you must specify a fully qualified file name for the *localfile* argument, for example, flash:/subdirectory/a.cfg.

Examples

Download the **a.txt** file and save it as **b.txt** in the working directory accessed by the **ftp** command.

```
ftp> get a.txt b.txt
local: b.txt remote: a.txt
150 Connecting to port 47457
226 File successfully transferred
1569 bytes received in 0.00527 seconds (290.6 kbyte/s)
```

Download the **a.txt** file to the **test** directory in the working directory accessed by the **ftp** command.

```
ftp> get a.txt flash:/test/b.txt
local: flash:/test/b.txt remote: a.txt
150 Connecting to port 47457
226 File successfully transferred
1569 bytes received in 0.00527 seconds (290.6 kbyte/s)
```

Download the **a.txt** file to the root directory of the flash memory on a member device. Save the file as **c.txt**.

```
ftp> get a.txt slot1#flash:/c.txt
local: slot1#flash:/c.txt remote: a.txt
150 Connecting to port 47460
226 File successfully transferred
1569 bytes received in 0.0564 seconds (27.2 kbyte/s)
```

Related commands

?

lcd

Use **lcd** to display or change the local working directory of the FTP client.

Syntax

lcd [*directory* | **/**]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

directory: Changes the local working directory of the FTP client to the specified local directory. There must be a slash sign (/) before the name of the storage medium, for example, /flash:/logfile.

/: Changes the local working directory of the FTP client to the local root directory.

Usage guidelines

To display the local working directory of the FTP client, do not specify the *directory* or **/** argument.

Examples

Display the local working directory.

```
ftp> lcd
Local directory now /flash:
```

Change the local working directory to **flash:/logfile**.

```
ftp> lcd /flash:/logfile
Local directory now /flash:/logfile
```

ls

Use **ls** to display or save detailed information about files and directories on the FTP server.

Syntax

ls [*remotefile* [*localfile*]]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

remotefile: Specifies a file or directory on the FTP server.

localfile: Specifies the name of the local file used to save the displayed information.

Usage guidelines

You can perform this operation only after you log in to the FTP server.

To display detailed information about the files and subdirectories in the working directory on the FTP server, use the **ls** command.

To display detailed information about a file or directory on the FTP server, use the **ls** *remotefile* command.

To save detailed information about a file or directory on the FTP server to a local file, use the **ls** *remotefile localfile* command.

In FTP client view, executing the **ls** command is the same as executing the **dir** command.

Examples

Display detailed information about the files and subdirectories in the working directory on the FTP server.

```
ftp> ls
150 Connecting to port 50201
-rwxr-xr-x    1 0          0               1481 Jul  7 15:36 a.txt

```

Related commands

dir

mkdir

Use **mkdir** to create a subdirectory in the current directory on the FTP server.

Syntax

mkdir *directory*

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

directory: Specifies the name for the directory to be created.

Usage guidelines

You can perform this operation only after you log in to the FTP server.

You must have permission to perform this operation on the FTP server.

Examples

Create a subdirectory named **newdir** in the current directory of the FTP server.

```
ftp> mkdir newdir
257 "newdir" : The directory was successfully created
```

newer

Use **newer** to update a local file by using a file on the FTP server.

Syntax

newer *remotefile* [*localfile*]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

remotefile: Specifies a file on the FTP server.

localfile: Specifies the local file to be updated.

Usage guidelines

You can perform this operation only after you log in to the FTP server.

If the local file does not exist, this command downloads the file from the FTP server and saves it locally.

If the file on the FTP server is not newer than the local file, this command does not update the local file.

Examples

Update the local file with the **a.txt** file on the FTP server.

```
ftp> newer a.txt
local: a.txt remote: a.txt
150 Connecting to port 63513
226 File successfully transferred
1573 bytes received in 0.0293 seconds (52.3 kbyte/s)
```

open

Use **open** to log in to an FTP server from FTP client view.

Syntax

open *server-address* [*service-port*]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

server-address: Specifies the IPv4 address, IPv6 address, or host name of the FTP server.

service-port: Specifies the TCP port number of the FTP server, in the range of 0 to 65535. The default is 21.

Usage guidelines

After you issue this command, the system will prompt you to enter the username and password.

After you log in to one FTP server, you must disconnect from the server before you can use the **open** command to log in to another server.

Examples

In FTP client view, log in to FTP server 192.168.40.7.

```
<Sysname>ftp
ftp> open 192.168.40.7
Press CTRL+C to abort.
Connected to 192.168.40.7 (192.168.40.7).
220 FTP service ready.
User (192.168.40.7:(none)): root
331 Password required for root.
Password:
230 User logged in.
Remote system type is NSFOCUS.
```

```
ftp>
```

passive

Use **passive** to change the FTP operation mode.

Syntax

passive

Default

The FTP operation mode is passive.

Views

FTP client view

Predefined user roles

network-admin

context-admin

Usage guidelines

FTP can operate in either of the following modes:

- **Active mode**—The FTP server initiates the TCP connection.
- **Passive mode**—The FTP client initiates the TCP connection.

When the FTP operation mode is passive, executing this command changes the mode to active.

When the FTP operation mode is active, executing this command changes the mode to passive.

This command is typically used together with a firewall to control FTP session establishment between private network users and public network users.

Examples

Change the FTP operation mode to passive.

```
ftp> passive
Passive mode on.
ftp> passive
Passive mode off.
```

put

Use **put** to upload a file from the FTP client to the FTP server.

Syntax

put *localfile* [*remotefile*]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

localfile: Specifies the local file to be uploaded.

remotefile: Specifies the name of the file for saving the uploaded file on the FTP server.

Usage guidelines

You can perform this operation only after you log in to the FTP server.

To upload a file in the current working directory, specify a file name without the path for the *localfile* argument, for example, a.cfg.

To upload a file in some other directory, specify a fully qualified file name for the *localfile* argument, for example, flash:/subdirectory/a.cfg.

Examples

Upload the **a.txt** file from the local working directory to the FTP server. Save the file as **b.txt**.

```
ftp> put a.txt b.txt
local: a.txt remote: b.txt
150 Connecting to port 47461
226 File successfully transferred
1569 bytes sent in 0.000671 seconds (2.23 Mbyte/s)
```

Upload the **a.txt** file from the **test** directory of the local working directory to the FTP server. Save the file as **b.txt**.

```
ftp> put flash:/test/a.txt b.txt
local: flash:/test/a.txt remote: b.txt
150 Connecting to port 47461
226 File successfully transferred
1569 bytes sent in 0.000671 seconds (2.23 Mbyte/s)
```

Upload file **a.txt** from the **test** directory of the storage medium on a member device. Save the file as **b.txt** on the FTP server.

```
ftp> put slot2#flash:/test/a.txt b.txt
local: slot2#flash:/test/a.txt remote: b.txt
150 Connecting to port 47461
226 File successfully transferred
1569 bytes sent in 0.000671 seconds (2.23 Mbyte/s)
```

Related commands

get

pwd

Use **pwd** to display the currently accessed directory on the FTP server.

Syntax

pwd

network-operator

context-admin

context-operator

Parameters

remotefile: Specifies a file on the FTP server.

localfile: Specifies a local file.

Usage guidelines

You can perform this operation only after you log in to the FTP server.

If a file download is not completed due to network or storage space problems, use this command to get the part that has not been downloaded yet.

Examples

Get the part of the **s.bin** file that has not been downloaded yet.

```
ftp> reget s.bin
local: s.bin remote: s.bin
350 Restarting at 1749706
150-Connecting to port 47429
150 38143.3 kbytes to download
226 File successfully transferred
39058742 bytes received in 66.2 seconds (576.1 kbyte/s)
```

rename

Use **rename** to rename a file.

Syntax

rename [*oldfilename* [*newfilename*]]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

oldfilename: Specifies the original file name.

newfilename: Specifies the new file name.

Usage guidelines

You can perform this operation only after you log in to the FTP server.

Examples

Rename the **a.txt** file as **b.txt**.

- Method 1:

  ```
  ftp> rename
  (from-name) a.txt
  (to-name) b.txt
  350 RNFR accepted - file exists, ready for destination
  250 File successfully renamed or moved
  ```

- Method 2:

  ```
  ftp> rename a.txt
  (to-name) b.txt
  350 RNFR accepted - file exists, ready for destination
  250 File successfully renamed or moved
  ```

- Method 3:

```
ftp> rename a.txt b.txt
350 RNFR accepted - file exists, ready for destination
250 File successfully renamed or moved
```

reset

Use **reset** to clear the reply information received from the FTP server in the buffer.

Syntax

reset

Views

Examples

Clear the reply information received from the FTP server.

```
ftp> reset
```

restart

Use **restart** to specify the file retransmission offset.

Syntax

restart *marker*

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

marker: Specifies the retransmission offset, in bytes.

Usage guidelines

Use this command to continue with a file retransmission. The file retransmission starts from the (offset+1)th byte.

You can perform this operation only after you log in to the FTP server.

Support for this command depends on the FTP server.

Examples

Set retransmission offset to 2 bytes and retransmit the **h.c** file. The file has 82 bytes in total.

```
ftp> restart 2
restarting at 2. execute get, put or append to initiate transfer
ftp> put h.c h.c
local: h.c remote: h.c
350 Restart position accepted (2).
```

```
150 Ok to send data.
226 File receive OK.
80 bytes sent in 0.000445 seconds (175.6 kbyte/s)
ftp> dir
150 Here comes the directory listing.
-rw-r--r--    1 0        0              82 Jul 18 02:58 h.c
```

rhelp

Use **rhelp** to display the FTP commands supported by the FTP server.

Use **rhelp** *protocol-command* to display the help information for an FTP command supported by the FTP server.

Syntax

rhelp [*protocol-command*]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

protocol-command: Specifies an FTP command.

Usage guidelines

You can perform this operation only after you log in to the FTP server.

Examples

Display the FTP-related commands supported by the FTP server.

```
ftp> rhelp
214-The following FTP commands are recognized
 USER PASS NOOP QUIT SYST TYPE
 HELP CWD  XCWD PWD  CDUP XCUP
 XPWD LIST NLST MLSD PORT EPRT
 PASV EPSV REST RETR STOR APPE
 DELE MKD  XMKD RMD  XRMD ABOR
 SIZE RNFR RNTO
214 UNIX Type: L8
```

Table 3 Command output

Field	Description
USER	Username.
PASS	Password.
NOOP	Null operation.
SYST	System parameters.
TYPE	Request type.
CWD	Changes the current working directory.

Field	Description
XCWD	Extended command with the meaning of CWD.
PWD	Prints the working directory.
CDUP	Changes the directory to the upper directory.
XCUP	Extended command with the meaning of CDUP.
XPWD	Extended command with the meaning of PWD.
LIST	Lists files.
NLST	Lists brief file description.
MLSD	Lists file content.
PORT	Active mode (IPv4).
EPRT	Active mode (IPv6).
PASV	Passive mode (IPv4).
EPSV	Passive mode (IPv6).
REST	Restarts.
RETR	Downloads files.
STOR	Uploads files.
APPE	Appends uploading.
DELE	Deletes files.
MKD	Creates folders.
XMKD	Extended command with the meaning of MKD.
RMD	Deletes folders.
XRMD	Extended command with the meaning of RMD.
ABOR	Aborts the transmission.
SIZE	Size of the transmission file.
RNFR	Original name.
RNTO	New name.

rmdir

Use **`rmdir`** to permanently delete a directory from the FTP server.

Syntax

`rmdir` *`directory`*

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

directory: Specifies a directory on the FTP server.

Usage guidelines

CAUTION:

Permanently delete a directory from the FTP server with caution. When you permanently delete a directory from the FTP server, make sure the directory is no longer in use.

You can perform this operation only after you log in to the FTP server.

To perform this operation, you must have delete permission on the FTP server.

Delete all files and subdirectories in a directory before you delete the directory. For more information about how to delete files, see the **delete** command.

The **rmdir** command does not delete the files of the specified directory from the recycle bin.

Examples

Delete empty directory **subdir1**.

```
ftp>rmdir subdir1
250 The directory was successfully removed
```

Related commands

delete

rstatus

Use **rstatus** to display FTP server status information.

Use **rstatus** *remotefile* to display detailed information about a directory or file on the FTP server.

Syntax

rstatus [*remotefile*]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

remotefile: Specifies a directory or file on the FTP server.

Usage guidelines

You can perform this operation only after you log in to the FTP server.

Support for this command depends on the FTP server.

Examples

Display FTP server status information.

```
ftp> rstatus
211-FTP server status:
     Connected to 192.168.20.177
     Logged in as root
```

```
     TYPE: ASCII
     No session bandwidth limit
     Session timeout in seconds is 300
     Control connection is plain text
     Data connections will be plain text
     At session startup, client count was 1
     vsFTPd 2.0.6 - secure, fast, stable
211 End of status
```

Table 4 Command output

Filed	Description
211-FTP server status:	Beginning of the display of FTP server status, where 211 specifies the FTP command.
Connected to 192.168.20.177	IP address of the FTP client.
Logged in as root	Login username root.
TYPE: ASCII	File transfer mode ASCII.
Session timeout in seconds is 300	FTP connection idle-timeout interval is 300 seconds.
Control connection is plain text	Control connection type is plain text.
Data connections will be plain text	Data connection type is plain text.
At session startup, client count was 1	FTP connection number is 1.
vsFTPd 2.0.6 - secure, fast, stable	FTP version is 2.0.6.
211 End of status	End of the display of FTP server status.

Display the file **a.txt**.

```
ftp> rstatus a.txt
213-Status follows:
-rw-r--r--    1 0        0             80 Jul 18 02:58 a.txt
213 End of status
```

Table 5 Command output

Field	Description
213-Status follows:	Beginning of the display of the file, where 213 specifies the FTP command.
-rw-r--r--	The first bit specifies the file type. • **-**—Common. • **B**—Block. • **c**—Character. • **d**—Directory. • **l**—Symbol connection file. • **p**—Pipe. • **s**—socket. The second bit through the tenth bit are divided into three groups. Each group contains three characters, representing the access permission of the owner, group, and other users. • **-**—No permission. • **r**—Read permission. • **w**—Write permission. • **x**—Execution permission.

Field	Description
1	Number of connections.
0	Name of the file owner.
0	Group number of the file owner.
80	File size, in bytes.
Jul 18 02:58	Date and time when the file was most recently modified.
a.txt	File name.
213 End of status	End of the display of the file information.

status

Use **status** to display FTP status information.

Syntax

status

Views

FTP client view

Predefined user roles

network-admin

context-admin

Examples

Display FTP status information.

```
ftp> status
Connected to 192.168.1.56.
No proxy connection.
Not using any security mechanism.
Mode: stream; Type: ascii; Form: non-print; Structure: file
Verbose: on; Bell: off; Prompting: on; Globbing: off
Store unique: off; Receive unique: off
Case: off; CR stripping: on
Ntrans: off
Nmap: off
Hash mark printing: off; Use of PORT cmds: on
```

Table 6 Command output

Field	Description
Connected to 192.168.1.56.	IP address of the FTP server that is connected to the FTP client.
Verbose: on; Bell: off; Prompting: on; Globbing: off	Displays debugging information.
Store unique: off; Receive unique: off	The name of the file on the FTP server is unique and the name of the local file is unique.
Case: off; CR stripping: on	Does not support obtaining multiple files once and deletes "\r" when downloading text files.

Field	Description
Ntrans: off	Does not use the input-output transmission table.
Nmap: off	The file name does not use the input-to-output mapping template.
Hash mark printing: off; Use of PORT cmds: on	Does not end with a pound sign (#) and uses "PORT" data transmission.

system

Use **system** to display the system information of the FTP server.

Syntax

system

Views

FTP client view

Predefined user roles

network-admin

context-admin

Usage guidelines

You can perform this operation only after you log in to the FTP server.

Examples

Display the system information of the FTP server.

```
ftp> system
215 UNIX Type: L8
```

user

Use **user** to initiate an FTP authentication on the current FTP connection.

Syntax

user *username* [*password*]

Views

FTP client view

Predefined user roles

network-admin

context-admin

Parameters

username: Specifies the username.

password: Specifies the password.

Usage guidelines

If you tried to access an FTP server but failed to pass the authentication when the device acts as an FTP client, use this command to try again before the connection to the FTP server expires.

Make sure the specified username and password have been configured on the FTP server. If the username or password is not configured, this command fails and the FTP connection is closed.

Examples

After a login failure, log in again to the FTP server before the connection expires.

- Method 1:

```
ftp> user ftp hello12345
331 Password required for ftp.
230 User logged in.
```

- Method 2:

```
ftp> user ftp
331 Password required for ftp.
Password:
230 User logged in.
```

verbose

Use **verbose** to enable or disable the device to display detailed information about FTP operations.

Syntax

verbose

Default

The device displays detailed information about FTP operations.

Views

FTP client view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command affects only the current FTP session.

Examples

Disable the device from displaying detailed information about FTP operations.

```
ftp> verbose
Verbose mode off.
```

Execute the **get** command.

```
ftp> get a.cfg 1.cfg
```

Enable the device to display detailed information about FTP operations.

```
ftp> verbose
Verbose mode on.
```

Execute the **get** command.

```
ftp> get a.cfg 2.cfg
227 Entering Passive Mode (192,168,1,58,68,14)
150-Accepted data connection
150 The computer is your friend. Trust the computer
226 File successfully transferred
```

```
3796 bytes received in 0.00762 seconds (486.5 kbyte/s)
```

TFTP commands

TFTP server commands

tftp server enable

Use **tftp server enable** to enable the TFTP server.

Use **undo tftp server enable** to disable the TFTP server.

Syntax

tftp server enable

undo tftp server enable

Default

The TFTP server is disabled.

Views

System view

Examples

Enable the TFTP server.

```
<Sysname> system-view
[Sysname] tftp server enable
```

Related commands

tftp server work-directory

tftp server work-directory

Use **tftp server work-directory** to set the TFTP server working directory.

Use **undo tftp server work-directory** to restore the default.

Syntax

tftp server work-directory *directory*

undo tftp server work-directory

Default

The TFTP server working directory is the root directory of the default file system.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

directory: Specifies a directory on the TFTP server. It must be the absolute path of an existing directory, a case-insensitive string of 1 to 255 characters.

Usage guidelines

TFTP clients have read and write rights to all files and directories in the TFTP server working directory.

Examples

Set the TFTP server working directory to **flash:/tftp**.

```
<Sysname> system-view
[Sysname] tftp server work-directory flash:/tftp
```

Related commands

tftp server enable

TFTP client commands

tftp

Use **tftp** to download a file from a TFTP server or upload a file to a TFTP server in an IPv4 network.

Syntax

tftp *tftp-server* { **get** | **put** | **sget** } *source-filename* [*destination-filename*] [**vpn-instance** *vpn-instance-name*] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ip** *source-ip-address* }] *

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

tftp-server: Specifies the IPv4 address or host name of a TFTP server. The host name can be a case-insensitive string of 1 to 253 characters and can contain only letters, digits, hyphens (-), underscores (_), and dots (.).

get: Downloads a file and writes the file directly to the destination folder. If the destination folder already has a file with the same name, the system deletes the existing file before starting the download operation. The existing file is permanently deleted even if the download operation fails.

put: Uploads a file.

sget: Downloads a file and saves the file to memory before writing it to the destination folder. The system starts to write the file to the destination folder only after the file is downloaded and saved to memory successfully. If the destination folder already has a file with the same name, the system overwrites the existing file. If the download or save-to-memory operation fails, the existing file in the destination folder is not overwritten.

source-filename: Specifies the source file name, a case-insensitive string of 1 to 1 to 255 characters.

destination-filename: Specifies the destination file name, a case-insensitive string of 1 to 255 characters. If this argument is not specified, the file uses the source file name.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the TFTP server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the TFTP server belongs to the public network, do not specify this option.

dscp *dscp-value*: Specifies the DSCP value for IPv4 to use for outgoing TFTP packets to indicate the packet transmission priority. The value range is 0 to 63. The default is 0.

source { **interface** *interface-type interface-number* | **ip** *source-ip-address* }: Specifies the source address for outgoing TFTP packets. If you do not specify this option, the device uses the primary IPv4 address of the output interface for the route to the TFTP server as the source address.

- **interface** *interface-type interface-number*: Specifies an interface by its type and number. The device will use the interface's primary IPv4 address as the source IPv4 address. For successful TFTP packet transmission, make sure the interface is up and has the primary IPv4 address configured.
- **ip** *source-ip-address*: Specifies an IPv4 address. For successful TFTP packet transmission, make sure this address is the IPv4 address of an interface in up state on the device.

Usage guidelines

The source address specified with the **tftp** command takes precedence over the source address specified with the **tftp client source** command.

The source address specified with the **tftp client source** command applies to all TFTP connections. The source address specified with the **tftp** command applies only to the current TFTP connection.

Examples

Download the **new.bin** file from TFTP server 192.168.1.1 and save the file as **new.bin**.

```
<Sysname> tftp 192.168.1.1 get new.bin
Press CTRL+C to abort.
   % Total    % Received % Xferd  Average Speed   Time    Time     Time   Current
                                  Dload  Upload   Total   Spent    Left   Speed
100 13.9M  100 13.9M    0     0  1206k      0  0:00:11  0:00:11  --:--:-- 1206k
Writing file...Done.
<Sysname>
```

Table 7 Command output

Field	Description
%	Percentage of file transmission progress.
Total	Size of files to be transmitted, in bytes.
%	Percentage of received file size to total file size.
Received	Received file size, in bytes.
%	Percentage of sent file size to total file size.
Xferd	Sent file size, in bytes.
Average Dload	Average download speed, in bps.
Speed Upload	Average upload speed, in bps.

Field	Description
Writing file…	The system was writing the downloaded file to the storage medium. This field is displayed only when the **get** or **sget** keyword is specified. If the operation succeeded, this command displays **Done** at the end of this field. If the operation failed, this command displays **Failed**.

Related commands

tftp client source

tftp client ipv6 source

Use **tftp client ipv6 source** to specify the source IPv6 address for TFTP packets sent to an IPv6 TFTP server.

Use **undo tftp client ipv6 source** to restore the default.

Syntax

tftp client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *source-ipv6-address* }

undo tftp client ipv6 source

Default

No source address is specified for TFTP packets sent to an IPv6 TFTP server. The device selects a source IPv6 address as defined in RFC 3484.

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

tftp-server: Specifies the IPv6 address or host name of a TFTP server. The host name can be a case-insensitive string of 1 to 253 characters and can contain only letters, digits, hyphens (-), underscores (_), and dots (.).

-i *interface-type interface-number*: Specifies an output interface by its type and number. This option can be used only when the TFTP server address is a link local address and the specified output interface has a link local address. For information about link local addresses, see IPv6 basics in *Layer 3—IP Services Configuration Guide*.

get: Downloads a file and writes the file directly to the destination folder. If the destination folder already has a file with the same name, the system deletes the existing file before starting the download operation. The existing file is permanently deleted even if the download operation fails.

put: Uploads a file.

sget: Downloads a file and saves the file to memory before writing it to the destination folder. The system starts to write the file to the destination folder only after the file is downloaded and saved to memory successfully. If the destination folder already has a file using the same name, the system overwrites the existing file. If the download or save-to-memory operation fails, the existing file in the destination folder is not overwritten.

source-filename: Specifies the source file name, a case-insensitive string of 1 to 255 characters.

destination-filename: Specifies the destination file name, a case-insensitive string of 1 to 255 characters. If this argument is not specified, the file uses the source file name.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the TFTP server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the TFTP server belongs to the public network, do not specify this option.

dscp *dscp-value*: Specifies the DSCP value for IPv6 to use in outgoing TFTP packets to indicate the packet transmission priority. The value range is 0 to 63. The default is 0.

source { **interface** *interface-type interface-number* | **ipv6** *source-ipv6-address* }: Specifies the source address for outgoing TFTP packets. If you do not specify this option, the device selects a source IPv6 address as defined in RFC 3484.

- **interface** *interface-type interface-number*: Specifies an interface by its type and number. The device will use the interface's IPv6 address as the source IPv6 address. For

successful TFTP packet transmission, make sure the interface is up and is configured with an IPv6 address.

- **ipv6** *source-ipv6-address*: Specifies an IPv6 address. For successful TFTP packet transmission, make sure this address is the IPv6 address of an interface in up state on the device.

Usage guidelines

The source address specified with the **tftp ipv6** command takes precedence over the source address specified with the **tftp client ipv6 source** command.

The source address specified with the **tftp client ipv6 source** command applies to all TFTP connections. The source address specified with the **tftp ipv6** command applies only to the current TFTP connection.

Examples

Download the **new.bin** file from TFTP server 2001::1 and save the file as **new.bin**.

```
<Sysname> tftp ipv6 2001::1 get new.bin new.bin
Press CTRL+C to abort.
   % Total    % Received % Xferd  Average Speed   Time    Time     Time   Current

```

For more information about the command output, see Table 7.

tftp-server acl

Use **tftp-server acl** to use an ACL to control the device's access to TFTP servers in an IPv4 network.

Use **undo tftp-server acl** to restore the default.

Syntax

tftp-server acl *acl-number*

undo tftp-server acl

Default

No ACL is used to control the device's access to TFTP servers.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

acl-number: Specifies the number of a basic ACL, in the range of 2000 to 2999.

Usage guidelines

You can use an ACL to deny or permit the device's access to specific TFTP servers.

If the ACL does not exist or does not have rules, the device can access all TFTP servers in the network.

If a VPN instance is specified in an ACL rule, the ACL rule applies only to the packets of the VPN instance. If no VPN instance is specified in an ACL rule, the ACL rule applies only to the packets on the public network.

Examples

Allow the device to access only TFTP server 1.1.1.1.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule permit source 1.1.1.1 0
[Sysname-acl-ipv4-basic-2000] quit
[Sysname] tftp-server acl 2000
```

tftp-server ipv6 acl

Use **tftp-server ipv6 acl** to use an ACL to control the device's access to TFTP servers in an IPv6 network.

Use **undo tftp-server ipv6 acl** to restore the default.

Syntax

tftp-server ipv6 acl *ipv6-acl-number*

undo tftp-server ipv6 acl

Default

No ACL is used to control the device's access to TFTP servers.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-acl-number: Specifies the number of a basic ACL, in the range of 2000 to 2999.

Usage guidelines

You can use an ACL to deny or permit the device's access to specific TFTP servers.

If the ACL does not exist or does not have rules, the device can access all TFTP servers in the network.

If a VPN instance is specified in an ACL rule, the ACL rule applies only to the packets of the VPN instance. If no VPN instance is specified in an ACL rule, the ACL rule applies only to the packets on the public network.

Examples

Allow the device to access only TFTP server 2001::1.

```
<Sysname> System-view
[Sysname] acl ipv6 basic 2001
[Sysname-acl-ipv6-basic-2001] rule permit source 2001::1/128
[Sysname-acl-ipv6-basic-2001] quit
[Sysname] tftp-server ipv6 acl 2001
```

Contents

File system management commands

IMPORTANT:

- Before managing storage media, file systems, directories, and files, make sure you know the possible impact.
- A file or directory whose name starts with a dot character (.) is a hidden file or directory. To prevent the system from hiding a file or directory, make sure the file or directory name does not start with a dot character.
- Some system files and directories are hidden. For correct system operation and full functionality, do not modify or delete hidden files or directories.

File system names, directory names, and file names must be compliant with the naming conventions. For more information about the naming conventions and the methods for specifying the names, see file system management in *Fundamentals Configuration Guide*.

Before you use the **copy**, **delete**, **fixdisk**, **format**, **gunzip**, **gzip**, **mkdir**, **move**, **rename**, **rmdir**, or **undelete** command on a file system, make sure the file system is not write protected.

You cannot access a storage medium that is being partitioned, or a file system that is being formatted or repaired. To access the file system, wait for the ongoing operation to be completed and then use one of the following methods:

- Use the absolute path to specify a file or directory. For example, use the **dir flash:/** command to display the files and directories in the **flash:** file system.
- Use the **cd** command to change the working directory to the root directory of the file system before accessing a file or directory in the file system. For example, to display the files and directories in the root directory of the **flash:** file system, perform the following tasks:
  a. Use the **cd flash:/** command to change the working directory to the root directory of the file system.
  b. Execute the **dir** command.

cd

Use **cd** to change the working directory.

Syntax

cd { *directory* | **..** }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

directory: Specifies the destination directory.

..: Specifies the parent directory. If the working directory is the root directory, an error message appears when you execute the **cd ..** command. No online help information is available for this keyword.

Examples

Access the **test** directory after logging in to the device.

```
<Sysname> cd test
```

Change to the parent directory.

```
<Sysname> cd ..
```

copy

Use **copy** to copy a file.

Syntax

copy *source-file* { *dest-file* | *dest-directory* } [**vpn-instance** *vpn-instance-name*] [**source interface** *interface-type interface-number*] [**append**]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

source-file: Specifies the name or URL of the file to be copied. If the file resides on a remote file server rather than on the device, specify the URL of the file. Whether a URL is case sensitive depends on the server.

dest-file: Specifies the name or URL for the destination file. To copy the source file to a remote file server, specify a URL. Whether a URL is case sensitive depends on the server.

dest-directory: Specifies the destination directory or URL. To copy the source file to a remote file server, specify a URL. The device copies the source file to the destination location and saves the file with its original file name. Whether a URL is case sensitive depends on the server.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the destination remote file server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the server belongs to the public network, do not specify this option.

source interface *interface-type interface-number*: Specifies the source interface used to connect to the server. After you specify the source interface, the device uses the primary IP address of the source interface as the source IP address for outgoing packets. If you do not specify this option, the device uses the outgoing interface as the source interface.

append: Saves the content that has been correctly transmitted when a transmission failure or interruption occurs, and continues to copy the missing part when the command is executed again. If you do not specify this keyword and a transmission failure or interruption occurs, the device discards the content that has been correctly transmitted. This keyword is supported only when you copy a file from or to an FTP or HTTP file server.

Usage guidelines

You can use the **copy** command to perform the following tasks:

- Copy a local file and save it locally.
- Copy a local file and save it to an FTP, TFTP, or HTTP server.
- Copy a file from an FTP, TFTP, or HTTP server and save it locally.

To specify a file or directory, use the following guidelines:

Location	Name format	Remarks
On the device	Use the file name guidelines in *Fundamentals Configuration Guide*.	N/A
On an FTP server	Enter the URL in the format of **ftp://***FTP username*[**:***password*]*@server address*[**:***port number*]**/***file path*[**/***file name*].	The username and password must be the same as the username and password configured on the FTP server. If the server authenticates users only by the username, you are not required to enter the password. For example, to use the username a and password 1 and specify the startup.cfg file in the authorized working directory on the FTP server 1.1.1.1, enter ftp://a:1@1.1.1.1/startup.cfg.
On a TFTP server	Enter the URL in the format of **tftp://***server address*[**:***port number*]**/***file path*[**/***file name*].	For example, to specify the startup.cfg file in the working directory on TFTP server 1.1.1.1, enter the URL tftp://1.1.1.1/startup.cfg.
On an HTTP server	Enter the URL in the format of **http://**[*HTTP username*[**:***password*]@]*server address*[**:***port number*]**/***filepath*[**/***file name*].	The username and password in the URL must be the same as the username and password configured on the server. If only the username is required for authentication, you do not need to enter the password. If authentication is not required, you do not need to enter the username or password. For example, the **startup.cfg** file is saved in the authorized directory on the HTTP server at 1.1.1.1. The HTTP account username and password are **a** and **1**, respectively. To copy the file, enter the URL http://a:1@1.1.1.1/startup.cfg. If authentication is not required, enter the URL http://1.1.1.1/startup.cfg.

To specify an IPv6 address, enclose the IPv6 address in square brackets ([ ]), for example, ftp://test:test@[2001::1]:21/test.cfg.

Examples

Copy the **test.cfg** file in the current directory and save it to the current directory as **testbackup.cfg**.

```
<Sysname> copy test.cfg testbackup.cfg
Copy flash:/test.cfg to flash:/testbackup.cfg? [Y/N]:y
Copying file flash:/test.cfg to flash:/testbackup.cfg...Done.
```

Copy the **1.cfg** file in the **flash:/test** directory and save it to the **testbackup** directory of a USB file system as **1backup.cfg**.

```
<Sysname> copy flash:/test/1.cfg usba0:/testbackup/1backup.cfg
Copy flash:/test/1.cfg to usba0:/testbackup/1backup.cfg? [Y/N]:y
Copying file flash:/test/1.cfg to usba0:/testbackup/1backup.cfg...Done.
```

Copy the **test.cfg** file in the current directory and save it to the root directory of a file system in a specific slot as **testbackup.cfg**.

```
<Sysname> copy test.cfg slot2#flash:/
Copy flash:/test.cfg to slot2#flash:/test.cfg? [Y/N]:y
Copying file flash:/test.cfg to slot2#flash:/test.cfg...Done.
```

Copy **test.cfg** from the working directory on FTP server 1.1.1.1. Save the copy to the local current directory as **testbackup.cfg.** The FTP username is **user**. The password is **private**.

```
<Sysname> copy ftp://user:private@1.1.1.1/test.cfg testbackup.cfg
```

```
Copy ftp://user:private@1.1.1.1/test.cfg to flash:/testbackup.cfg? [Y/N]:y
Copying file ftp://user:private@1.1.1.1/test.cfg to flash:/testbackup.cfg... Done.
```

Copy **test.cfg** from the current directory. Save the copy to the working directory on FTP server 1.1.1.1 as **testbackup.cfg**. The FTP username is **user**. The password is **private**.

```
<Sysname> copy test.cfg ftp://user:private@1.1.1.1/testbackup.cfg
Copy flash:/test.cfg to ftp://user:private@1.1.1.1/testbackup.cfg? [Y/N]:y
Copying file flash:/test.cfg to ftp://user:private@1.1.1.1/testbackup.cfg... Done.
```

Copy **test.cfg** from the working directory on TFTP server 1.1.1.1. Save the copy to the local current directory as **testbackup.cfg**.

```
<Sysname> copy tftp://1.1.1.1/test.cfg testbackup.cfg
Copy tftp://1.1.1.1/test.cfg to flash:/testbackup.cfg? [Y/N]:y
Copying file tftp://1.1.1.1/test.cfg to flash:/testbackup.cfg... Done.
```

Copy **test.cfg** from the current directory. Save the copy to the working directory on TFTP server 1.1.1.1 as **testbackup.cfg**.

```
<Sysname> copy test.cfg tftp://1.1.1.1/testbackup.cfg
Copy flash:/test.cfg to tftp://1.1.1.1/testbackup.cfg? [Y/N]:y
Copying file flash:/test.cfg to tftp://1.1.1.1/testbackup.cfg... Done.
```

Copy **test.cfg** from the working directory on FTP server 1.1.1.1. Save the copy to the local current directory as **testbackup.cfg**. The FTP username is **user**. The password is **private**. The FTP server belongs to VPN instance **vpn1**.

```
<Sysname> copy ftp://user:private@1.1.1.1/test.cfg testbackup.cfg vpn-instance vpn1
Copy ftp://user:private@1.1.1.1/test.cfg to flash:/testbackup.cfg? [Y/N]:y
Copying file ftp://user:private@1.1.1.1/test.cfg to flash:/testbackup.cfg... Done.
```

Copy **test.cfg** from the working directory on TFTP server 1.1.1.1. Save the copy to the local current directory as **testbackup.cfg**. The TFTP server belongs to VPN instance **vpn1**.

```
<Sysname> copy tftp://1.1.1.1/test.cfg testbackup.cfg vpn-instance vpn1
Copy tftp://1.1.1.1/test.cfg to flash:/testbackup.cfg? [Y/N]:y
Copying file tftp://1.1.1.1/test.cfg to flash:/testbackup.cfg... Done.
```

Copy **test.cfg** from the working directory on FTP server 2001::1. Save the copy to the local current directory as **testbackup.cfg**. The FTP username is **user**. The password is **private**.

```
<Sysname> copy ftp://user:private@[2001::1]/test.cfg testbackup.cfg
Copy ftp://user:private@[2001::1]/test.cfg to flash:/testbackup.cfg? [Y/N]:y
Copying file ftp://user:private@[2001::1]/test.cfg to flash:/testbackup.cfg... Done.
```

Copy **test.cfg** from the working directory on TFTP server 2001::1. Save the copy to the local current directory as **testbackup.cfg**.

```
<Sysname> copy tftp://[2001::1]/test.cfg testbackup.cfg
Copy tftp://[2001::1]/test.cfg to flash:/testbackup.cfg? [Y/N]:y
Copying file tftp://[2001::1]/test.cfg to flash:/testbackup.cfg... Done.
```

Copy **test.cfg** from the authorized directory on HTTP server 1.1.1.1. Save the copy to the local current directory as **testbackup.cfg**. The HTTP login username is **user**. The password is **private**.

```
<Sysname> copy http://user:private@1.1.1.1/test.cfg testbackup.cfg
Copy http://user:private@1.1.1.1/test.cfg to flash:/testbackup.cfg? [Y/N]:y
Copying file http://user:private@1.1.1.1/test.cfg to flash:/testbackup.cfg... Done.
```

Copy **test.cfg** from the current directory. Save the copy to the authorized directory on HTTP server 1.1.1.1 as **testbackup.cfg**. The HTTP login username is **user**. The password is **private**.

```
<Sysname> copy test.cfg http://user:private@1.1.1.1/testbackup.cfg
Copy flash:/test.cfg to http://user:private@1.1.1.1/testbackup.cfg? [Y/N]:y
Copying file flash:/test.cfg to http://user:private@1.1.1.1/testbackup.cfg... Done.
```

Copy **test.cfg** from the authorized directory on HTTP server 2001::1. Save the copy to the local current directory as **testbackup.cfg**. The HTTP login username is **user**. The password is **private**.

```
<Sysname> copy http://user:private@[2001::1]/test.cfg testbackup.cfg
Copy http://user:private@[2001::1]/test.cfg to flash:/testbackup.cfg? [Y/N]:y
Copying file http://user:private@[2001::1]/test.cfg to flash:/testbackup.cfg... Done.
```

Copy **test.cfg** from the working directory on FTP server 1.1.1.1 in append mode. Save the copy to the local current directory as **testbackup.cfg**. The FTP username is **user**. The password is **private**.

```
<Sysname> copy ftp://user:private@1.1.1.1/test.cfg testbackup.cfg append
Copy ftp://user:private@1.1.1.1/test.cfg to flash:/testbackup.cfg? [Y/N]:y
Copying file ftp://user:private@1.1.1.1/test.cfg to flash:/testbackup.cfg... Done
```

Copy **test.cfg** from the authorized directory on HTTP server 1.1.1.1 in append mode. Save the copy to the local current directory as **testbackup.cfg**. The HTTP login username is **user**. The password is **private**.

```
<Sysname> copy http://user:private@1.1.1.1/test.cfg testbackup.cfg append
Copy http://user:private@1.1.1.1/test.cfg to flash:/testbackup.cfg? [Y/N]:y
Copying file http://user:private@1.1.1.1/test.cfg to flash:/testbackup.cfg... Done.
```

delete

Use **delete** to delete a file.

Syntax

delete [**/unreserved**] *file*

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

/unreserved: Permanently deletes the specified file. If you do not specify this keyword, the command moves the file to the recycle bin.

file: Specifies the name of the file to be deleted. Asterisks (*) are acceptable as wildcards. For example, to remove files with the **.txt** extension in the current directory, enter **delete *.txt**.

Usage guidelines

CAUTION:

- The **delete /unreserved** *file* command deletes a file permanently. The file cannot be restored.

A file moved to the recycle bin can be restored by using the **undelete** command.

Do not use the **delete** command to delete files from the recycle bin. To delete files from the recycle bin, use the **reset recycle-bin** command.

If you delete two files that have the same name from different directories, both files are retained in the recycle bin. If you successively delete two files that have the same name from the same directory, only the most recently deleted file is retained in the recycle bin.

Examples

Remove the **1.cfg** file from the current directory.

```
<Sysname> delete 1.cfg
Delete flash:/1.cfg? [Y/N]:y
Deleting file flash:/1.cfg...Done.
```

Permanently delete the **1.cfg** file from the current directory.

```
<Sysname> delete /unreserved 1.cfg
The file cannot be restored. Delete flash:/1.cfg? [Y/N]:y
Deleting the file permanently will take a long time. Please wait...
Deleting file flash:/1.cfg...Done.
```

Related commands

reset recycle-bin

undelete

dir

Use **dir** to display files or directories.

Syntax

dir [**/all**] [*file* | *directory* | **/all-filesystems**]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

/all: Displays all files and directories in the current directory, visible or hidden. If you do not specify this option, only visible files and directories are displayed.

file: Displays a specific file. This argument can use the asterisk (*) as a wildcard. For example, to display files with the **.txt** extension in the current directory, enter **dir *.txt**.

directory: Displays a specific directory.

/all-filesystems: Displays files and directories in the root directories of all file systems on the device.

Usage guidelines

If no option is specified, the command displays all visible files and directories in the current directory.

The directory name of the recycle bin is **.trash**. To display files in the recycle bin, use either of the following methods:

- Execute the **dir /all .trash** command.
- Execute the **cd .trash** command and then the **dir** command.

In an ext4 file system, 1% space is reserved. This command does not take account of the reserved space in the amount of free space.

If multiple users perform file operations (for example, creating or deleting files or directories) at the same time, the output for this command might be incorrect.

Examples

Display information about all files and directories in the current directory.

```
<Sysname> dir /all
Directory of flash: (YAFFS2)
...
```

Display files and directories in the root directories of all file systems on the device.

```
<Sysname> dir /all-filesystems
Directory of flash: (YAFFS2)
...
```

Table 1 Command output

Field	Description
Directory of *xx* (*yy*)	Current directory. The *xx* indicates the directory name. The *yy* indicates the type of the current file system.
0 -rwh 3144 Apr 26 2014 13:45:28 xx.xx	File or directory information: • **0**—File or directory number, which is automatically allocated by the system. • **-rwh**—Attributes of the file or directory. The first character is the directory indicator (**d** for directory and **–** for file). The second character indicates whether the file or directory is readable (**r** for readable). The third character indicates whether the file or directory is writable (**w** for writable). The fourth character indicates whether the file or directory is hidden (**h** for hidden, **-** for visible). Modifying, renaming, or deleting hidden files might affect functions. • **3144**—File size in bytes. For a directory, a hyphen (-) is displayed. • **Apr 26 2014 13:45:28**—Last date and time when the file or directory was modified. • **xx.xx**—File or directory name.

fdisk

Use **fdisk** to partition a storage medium.

Syntax

fdisk *medium* [*partition-number*]

Views

User view

Predefined user roles

network-admin

Parameters

medium: Specifies the name of the storage medium to be partitioned.

partition-number: Specifies the number of partitions, in the range of 1 to 4. If you specify this argument, the storage medium is divided evenly into the specified number of partitions. To customize the sizes of partitions, do not provide this argument.

Usage guidelines

This command is supported only on the default context.

The flash memory cannot be partitioned. A partition cannot be partitioned.

Before partitioning a storage medium, perform the following tasks:

- Back up the files in the storage medium. The partition operation clears all data on the medium.
- Make sure no other users are accessing the medium.
- Make sure the storage medium to be partitioned is not write protected. If the storage medium is write protected, the operation will fail, and you must remount or reinstall the storage medium to restore access to the storage medium.

After partitioning a storage medium, you must format the partitions to create the file systems before you can access the file systems.

The actual partition size and the specified partition size might have a difference of less than 5% of the storage medium's total size.

To change the sizes of partitions on a storage medium, partition the storage medium again and specify the required sizes for the partitions.

Before removing a partitioned storage medium, you must unmount all file systems on the storage medium.

Examples

Divide the USB disk on the device evenly into three partitions.

```
<Sysname> fdisk usba: 3
Capacity of usba: : 256M bytes
cfa: will be divided into the following partitions:
DeviceName      Capacity
usba0:            85MB
usba1:            85MB
usba2:            86MB
All data on usba: will be lost, continue? [Y/N]:y
Partitioning usba:...Done.
```

file prompt

Use **file prompt** to set the operation mode for files and directories.

Use **undo file prompt** to restore the default.

Syntax

file prompt { **alert** | **quiet** }

undo file prompt

Default

The operation mode is **alert**. The system prompts for confirmation when you perform a destructive file or directory operation.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

alert: Prompts for confirmation when a destructive file or directory operation is being performed.

quiet: Gives no confirmation prompt for file or directory operations except the recycle bin emptying operation.

Usage guidelines

In quiet mode, the system does not prompt for confirmation when a user performs a file or directory operation except the recycle bin emptying operation. The **alert** mode provides an opportunity to cancel a disruptive operation.

Examples

Set the file and directory operation mode to **alert**.

```
<Sysname> system-view
[Sysname] file prompt alert
```

fixdisk

Use **fixdisk** to check a file system for damage and repair any damage.

Syntax

fixdisk *filesystem*

Views

User view

Predefined user roles

network-admin

Parameters

filesystem: Specifies the name of a file system.

Usage guidelines

This command is supported only on the default context.

Use this command to fix a file system when space in the file system cannot be used or released.

You can repair a file system only when no other users are accessing the file system.

Examples

Repair file system **flash:**.

```
<Sysname> fixdisk flash:
Restoring flash: may take some time...
Restoring flash:...Done.
```

format

Use **format** to format a file system.

Syntax

format *filesystem* [**ext4** | **vfat**]

Views

User view

Predefined user roles

network-admin

Parameters

filesystem: Specifies the name of a file system.

ext4: Formats the file system as an EXT4 file system.

vfat: Formats the file system as a VFAT file system.

Usage guidelines

CAUTION:

Formatting a file system permanently deletes all files and directories in the file system. You cannot restore the deleted files or directories. If a startup configuration file exists in the file system, back up the file if necessary.

This command is supported only on the default context.

The flash memory does not support the **ext4** or **vfat** keyword. The file system on the flash memory can be formatted only as a file system of the default type.

File systems on storage media except the flash memory can and must be formatted as EXT4 or VFAT file systems.

You can use the **dir** command to display the types of the file systems.

You can format a file system only when no other users are accessing the file system.

A file system to be formatted cannot contain security log files. Only a user with the security-audit user role can delete security log files. For more information about the security-audit user role, see RBAC in *Fundamentals Configuration Guide*.

Examples

Format file system **flash:**.

```
<Sysname> format flash:
All data on flash: will be lost, continue? [Y/N]:y
Formatting flash:... Done.
```

Format the file system on the third partition of the USB disk.

```
<Sysname> format usba2:
All data on usba2: will be lost, continue? [Y/N]:y
Formatting usba2:... Done.
```

fuser

Use **fuser** to display processes that are using a file system, directory, or file.

Syntax

fuser { *directory* | *file* | *filesystem* }

Views

User view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

directory: Specifies a directory by its name.

file: Specifies a file by its name.

filesystem: Specifies a file system by its name.

Usage guidelines

Execute this command if you fail to execute a command such as **fdisk**, **fixdisk, format**, **umount, rmdir**, **rename**, **delete**, or **copy** command for a file system, directory, or file. View the command output to identify whether a process is using the file system, directory, or file.

When a user logs in to the CLI of the device, a process named **comsh** starts to monitor the user's behavior. Such a process uses file system resources but does not affect management of file systems, directories, or files.

Examples

Display processes that are using file system **flash:**.

```
<Sysname> fuser flash:
Job ID      PID         Process name
198         198         comsh
223         223         ttymgrd
332         332         ntopd
```

Table 2 Command output

Field	Description
Job ID	Task ID, which uniquely identifies a process. This ID does not change when the process reboots.
PID	Process ID, which identifies a process. This ID changes when the process reboots.

gunzip

Use **gunzip** to decompress a file.

Syntax

gunzip *file*

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

file: Specifies the name of the file to be decompressed. This argument must use the **.gz** extension.

Usage guidelines

This command deletes the specified file after decompressing it.

Examples

Decompress file **system.bin.gz**:

1. Before decompressing the file, you can display files whose names start with the **system.** string.

```
<Sysname> dir system.*
Directory of flash:
   1 -rw-          20 Jun 14 2012 10:18:53   system.bin.gz
```

```
252164 KB total (251820 KB free)
```

2. Decompress the file **system.bin.gz**.

```
<Sysname> gunzip system.bin.gz
Decompressing file flash:/system.bin.gz..... Done.
```

3. Verify the decompress operation.

```
<Sysname> dir system.*
Directory of flash:
   1 -rw-           0 May 30 2012 11:42:25   system.bin

252164 KB total (251820 KB free)
```

gzip

Use **gzip** to compress a file.

Syntax

gzip *file*

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

file: Specifies the name of the file to be compressed.

Usage guidelines

This command saves the compressed file to the *file***.gz** file and deletes the source file.

Examples

Compress file **system.bin**:

1. Before compressing the file, you can display files whose names start with the **system.** string.

```
<Sysname> dir system.*
Directory of flash:
   1 -rw-           0 May 30 2012 11:42:24   system.bin

252164 KB total (251820 KB free)
```

2. Compress the file **system.bin**.

```
<Sysname> gzip system.bin
Compressing file flash:/system.bin..... Done.
```

3. Verify the compress operation.

```
<Sysname> dir system.*
Directory of flash:
   1 -rw-          20 Jun 14 2012 10:18:53   system.bin.gz
```

```
252164 KB total (251820 KB free)
```

md5sum

Use **md5sum** to use the MD5 algorithm to calculate the digest of a file.

Syntax

md5sum *file*

Views

User view

Predefined user roles

network-admin

network-operator

Parameters

file: Specifies the name of a file.

Usage guidelines

You can use file digests to verify file integrity.

Examples

Use the MD5 algorithm to calculate the digest of file **system.bin**.

```
<Sysname> md5sum system.bin
MD5 digest:
4f22b6190d151a167105df61c35f0917
```

mkdir

Use **mkdir** to create a directory.

Syntax

mkdir *directory*

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

directory: Specifies a directory.

Usage guidelines

The name of the directory to be created must be unique in the parent directory.

You can create a directory only in an existing directory. For example, to create the **flash:/test/mytest** directory, make sure the **test** directory already exists.

Examples

Create the **test** directory in the current directory.

```
<Sysname> mkdir test
Creating directory flash:/test... Done.
```

Create the **test/subtest** directory in the current directory.

```
<Sysname> mkdir test/subtest
Creating directory flash:/test/subtest... Done.
```

more

Use **more** to display the contents of a text file.

Syntax

more *file*

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

file: Specifies the name of a file.

Examples

Display the contents of the **test.txt** file.

```
<Sysname> more test.txt
Have a nice day.
```

Display the contents of the **testcfg.cfg** file.

```
<Sysname> more testcfg.cfg

#
 version 7.1.070, Release 1201
#
 sysname Sysname
#
vlan 2
#
return
<Sysname>
```

mount

Use **mount** to mount a file system.

Syntax

mount *filesystem*

Views

User view

Predefined user roles

network-admin

Parameters

filesystem: Specifies the name of a file system.

Usage guidelines

This command is supported only on the default context.

Generally, file systems on a hot-swappable storage medium are automatically mounted when the storage medium is connected to the device. If the system cannot recognize a file system, however, you must mount the file system before you can access it.

To avoid file system corruption, do not perform the following tasks while the system is mounting a file system:

- Reboot, power cycle, or power off the device.
- Install or remove storage media.
- Perform a switchover.

To remove a hot-swappable storage medium from the device, you must first unmount all file systems on the storage medium. Removing a mounted hot-swappable storage medium might damage files on the storage medium or even the storage medium.

Examples

Mount a file system on a USB disk.

```
<Sysname> mount usba0:
```

Related commands

umount

move

Use **move** to move a file.

Syntax

move *source-file* { *dest-file* | *dest-directory* }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

source-file: Specifies the name of the source file.

dest-file: Specifies the name of the destination file.

dest-directory: Specifies the name of the destination directory.

Usage guidelines

If you specify a destination directory, the system moves the source file to the specified directory without changing the file name.

Examples

Move the **flash:/test/sample.txt** file to **flash:/**, and save it as **1.txt**.

```
<Sysname> move test/sample.txt 1.txt
Move flash:/test/sample.txt to flash:/1.txt? [Y/N]:y
Moving file flash:/test/sample.txt to flash:/1.txt ...Done.
```

Move the **b.cfg** file to the **test2** directory.

```
<Sysname> move b.cfg test2
Move flash:/b.cfg to flash:/test2/b.cfg? [Y/N]:y
Moving file flash:/b.cfg to flash:/test2/b.cfg... Done.
```

pwd

Use **pwd** to display the working directory.

Syntax

pwd

Views

User view

Predefined user roles

network-admin

context-admin

Examples

Display the working directory.

```
<Sysname> pwd
flash:
```

rename

Use **rename** to rename a file or directory.

Syntax

rename { *source-file* | *source-directory* } { *dest-file* | *dest-directory* }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

source-file: Specifies the name of the source file.

source-directory: Specifies the name of the source directory.

dest-file: Specifies the name of the destination file.

dest-directory: Specifies the name of the destination directory.

Usage guidelines

This command is not executed if the destination file or directory name is already used by an existing file or directory in the working directory.

Examples

Rename the **copy.cfg** file as **test.cfg**.

```
<Sysname> rename copy.cfg test.cfg
Rename flash:/copy.cfg as flash:/test.cfg? [Y/N]:y
Renaming flash:/copy.cfg as flash:/test.cfg... Done.
```

reset recycle-bin

Use **reset recycle-bin** to delete files from the recycle bin.

Syntax

reset recycle-bin [**/force**]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

/force: Deletes all files in the recycle bin without prompting for confirmation. If you do not specify this option, the command prompts you to confirm the deletion operation for each file.

Usage guidelines

CAUTION:

The files in a recycle bin can be restored by using the **undelete** command. If you delete a file from the recycle bin, that file cannot be restored. Before you delete files from a recycle bin, make sure the files are no longer in use.

The **delete** *file* command only moves a file to the recycle bin. To permanently delete the file, use the **reset recycle-bin** command to delete the file from the recycle bin.

Examples

Empty the recycle bin. (In this example there are two files in the recycle bin.)

```
<Sysname> reset recycle-bin
Clear flash:/a.cfg? [Y/N]:y
Clearing file flash:/a.cfg... Done.
Clear flash:/b.cfg? [Y/N]:y
Clearing file flash:/b.cfg... Done.
```

Delete the **b.cfg** file from the recycle bin. (In this example there are two files in the recycle bin.)

```
<Sysname> reset recycle-bin
Clear flash:/a.cfg? [Y/N]:n
Clear flash:/b.cfg? [Y/N]:y
Clearing file flash:/b.cfg... Done.
```

Related commands

delete

rmdir

Use **rmdir** to delete a directory.

Syntax

rmdir *directory*

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

directory: Specifies a directory.

Usage guidelines

CAUTION:

To delete a directory, you must first delete all files and subdirectories in the directory permanently or move them to the recycle bin. If you move them to the recycle bin, executing the **rmdir** command to delete the directory will delete them permanently. Before you use the **rmdir** command to delete a directory, you must make sure the directory and its files and subdirectories are no longer in use.

Examples

Delete the **subtest** directory.

```
<Sysname> rmdir subtest/
Remove directory flash:/test/subtest and the files in the recycle-bin under this directory
will be deleted permanently. Continue? [Y/N]:y
Removing directory flash:/test/subtest... Done.
```

sha256sum

Use **sha256sum** to use the SHA-256 algorithm to calculate the digest of a file.

Syntax

sha256sum *file*

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

file: Specifies the name of a file.

Usage guidelines

You can use file digests to verify file integrity.

Examples

Use the SHA-256 algorithm to calculate the digest of file **system.bin**.

```
<Sysname> sha256sum system.bin
SHA256 digest:
0851e0139f2770e87d01ee8c2995ca9e59a8f5f4062e99af14b141b1a36ca152
```

tar create

Use **tar create** to archive files and directories.

Syntax

tar create [**gz**] **archive-file** *dest-file* [**verbose**] **source** { *source-file* | *source-directory* }&<1-5>

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

gz: Uses gzip to compress the files and directories before archiving them. If you do not specify this keyword, the command archives the files and directories without compressing them.

archive-file *dest-file*: Specifies the archive file name. If you specified the **gz** keyword, the extension of the archive file name must be **.tar.gz**. If you did not specify the **gz** keyword, the extension of the archive file name must be **.tar**.

verbose: Displays the names of the successfully archived files and directories. If you do not specify this keyword, the command does not display the names of the successfully archived files and directories.

source { *source-file* | *source-directory* }&<1-5>: Specifies the files and directories to be archived. The argument can be a space-separated list of up to five items. Each item can be a file or directory name. The files and directories must be in the current working directory.

Examples

Archive the **1.cfg** and **2.cfg** files and the **test** directory to **a.tar**.

```
<Sysname> tar create archive-file a.tar source 1.cfg 2.cfg test
Creating archive flash:/a.tar Done.
```

Compress and archive the **1.cfg** and **2.cfg** files and the **test** directory to **b.tar.gz**.

```
<Sysname> tar create gz archive-file b.tar.gz source 1.cfg 2.cfg test
Creating archive flash:/b.tar.gz Done.
```

Compress and archive files and directories, and display the successfully archived files and directories.

```
<Sysname> tar create gz archive-file c.tar.gz verbose source 1.cfg 2.cfg test
1.cfg
2.cfg
test/
test/a.log
```

```
test/subtest/
test/subtest/aa.log
```

Related commands

tar extract

tar list

tar extract

Use **tar extract** to extract files and directories.

Syntax

tar extract archive-file *file* [**verbose**] [**screen** | **to** *directory*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

archive-file *file*: Specifies the archive file name. The extension can be **.tar** or **.tar.gz**.

verbose: Displays the names of the successfully extracted files and directories.

screen: Displays the content of the extracted files and directories on the screen. The extracted files are not saved.

to *directory*: Saves the extracted files and directories to a different directory. The *directory* argument specifies the directory.

Usage guidelines

IMPORTANT:

Before specifying the **screen** keyword for this command, use the **tar list** command to identify the types of the archived files. As a best practice, specify the keyword only if all archived files are text files. Displaying the content of an archived non-text file that contains terminal control characters might result in garbled characters and even cause the terminal unable to operate correctly. To use the terminal again, you must close the current connection and log in to the device again.

If you do not specify the **screen** keyword or the **to** *directory* option, the command saves the extracted files and directories to the working directory.

The command saves the extracted files and directories by using their original names. If a file or directory that has the same name as an extracted file or directory already exists in the destination directory, the file or directory is overwritten.

Examples

Extract files and directories from archive file **a.tar**.

```
<Sysname> tar extract archive-file a.tar
Extracting archive flash:/a.tar Done.
```

Extract files and directories from archive file **b.tar.gz**, and display the names of the successfully extracted files and directories.

```
<Sysname> tar extract archive-file b.tar.gz verbose
1.cfg
```

```
2.cfg
test/
test/a.log
test/subtest/
test/subtest/aa.log
```

Extract files and directories from archive file **c.tar.gz**, and display the content of the files on the screen.

```
<Sysname> tar extract archive-file c.tar.gz screen
#
 version 7.1.070, Release 1201
#
 sysname Sysname
#
...
```

Related commands

tar create

tar list

tar list

Use **tar list** to display the names of archived files and directories.

Syntax

tar list archive-file *file*

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

archive-file *file*: Specifies the archive file name. The extension can be **.tar** or **.tar.gz**.

Examples

Display the names of archived files and directories.

```
<Sysname> tar list archive-file a.tar
1.cfg
2.cfg
test/
test/a.log
test/subtest/
test/subtest/aa.log
```

Related commands

tar create

tar extract

umount

Use **umount** to unmount a file system.

Syntax

umount *filesystem*

Views

User view

Predefined user roles

network-admin

Parameters

filesystem: Specifies the name of a file system.

Usage guidelines

This command is supported only on the default context.

File systems on a storage medium are automatically mounted when the storage medium is connected to the device. To remove a hot-swappable storage medium from the device, you must first unmount all file systems on the storage medium. Removing a mounted hot-swappable storage medium might damage files on the storage medium or even the storage medium.

You can unmount a file system only when no other users are accessing the file system.

To avoid file system corruption, do not perform the following tasks while the system is unmounting a file system:

- Reboot, power cycle, or power off the device.
- Install, remove, or access storage media.
- Perform a switchover.

Examples

Unmount a file system on a USB disk.

```
<Sysname> umount usba0:
```

Related commands

mount

undelete

Use **undelete** to restore a file from the recycle bin.

Syntax

undelete *file*

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

file: Specifies the name of the file to be restored.

Usage guidelines

If a file with the same name already exists in the directory, the system prompts whether or not you want to overwrite the existing file. If you enter **Y**, the existing file is overwritten. If you enter **N**, the command is not executed.

Examples

Restore the **copy.cfg** file, which was moved from the root directory of the **flash:** file system to the recycle bin.

```
<Sysname> undelete copy.cfg
Undelete flash:/copy.cfg? [Y/N]:y
Undeleting file flash:/copy.cfg... Done.
```

Restore the **startup.cfg** file, which was moved from the **flash:/seclog** directory to the recycle bin.

- Method 1:

  ```
  <Sysname> undelete seclog/startup.cfg
  Undelete flash:/seclog/startup.cfg? [Y/N]:y
  Undeleting file flash:/seclog/startup.cfg... Done.
  <Sysname>
  ```

- Method 2:

  ```
  <Sysname> cd seclog
  <Sysname> undelete startup.cfg
  Undelete flash:/seclog/startup.cfg? [Y/N]:y
  Undeleting file flash:/seclog/startup.cfg... Done.
  ```

Contents

Configuration file management commands

archive configuration

Use **archive configuration** to manually archive the running configuration to the configuration archive directory.

Syntax

archive configuration

Views

User view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command saves the running configuration to the specified configuration archive directory with file names generated from the specified name prefix.

Before executing this command, you must use one of the following methods to specify a directory and a name prefix for the configuration archives:

- For local archiving, use the **archive configuration location** command to specify a local configuration archive directory and a name prefix.
- For remote archiving, use the **archive configuration server** command to configure server parameters.

If you specify a local configuration archive directory, manual configuration archiving saves the running configuration only on the master device.

Examples

Archive the running configuration.

```
<Sysname> archive configuration
Save the running configuration to an archive file. Continue? [Y/N]: Y
The archive configuration file myarchive_1.cfg is saved.
```

Related commands

archive configuration interval

archive configuration location

archive configuration max

archive configuration server user

display archive configuration

archive configuration interval

Use **archive configuration interval** to enable automatic running-configuration archiving and set the archiving interval for local archiving.

Use **undo archive configuration interval** to disable automatic running-configuration archiving for local archiving.

Syntax

archive configuration interval *interval*

undo archive configuration interval

Default

The automatic running-configuration archiving feature is disabled for local archiving.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the interval for automatically saving the running configuration. The value range is 10 to 525600, in minutes.

Usage guidelines

Automatic configuration archiving enables the system to periodically save the running configuration to the archive directory. After the system finishes an automatic archive, it resets the archiving interval timer.

Before enabling automatic configuration archiving, you must use the **archive configuration location** command to specify a directory and a name prefix for the configuration archives.

Automatic configuration archiving saves the running configuration only on the master device.

Examples

Set the system to archive the running configuration every 60 minutes.

```
<Sysname> system-view
[Sysname] archive configuration interval 60
Archive file will be saved every 60 minutes.
```

Related commands

archive configuration

archive configuration location

archive configuration max

display archive configuration

archive configuration location

Use **archive configuration location** to specify a local directory and file name prefix for archiving the running configuration.

Use **undo archive configuration location** to restore the default.

Syntax

archive configuration location *directory* **filename-prefix** *filename-prefix*

undo archive configuration location

Default

No local directory or file name prefix is specified on the device for archiving the running configuration.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

directory: Specifies the archive directory, a string of 1 to 63 characters. The value for this argument must take the format of *storage-medium-name:/folder-name*. The directory must already exist on the master.

filename-prefix: Specifies a file name prefix for configuration archives, a case-insensitive string of 1 to 30 characters. Valid characters are letters, digits, underscores (_), and hyphens (-).

Usage guidelines

Before archiving the running configuration, either manually or automatically, you must specify a directory and file name prefix for configuration archives.

The configuration archives are named in the format of *prefix_serial number***.cfg**, for example, **archive_1.cfg** and **archive_2.cfg**. The serial number is automatically assigned from 1 to 1000, increasing by 1. After the serial number reaches 1000, it restarts from 1.

If you change the file directory or file name prefix, the following events occur:

- The old configuration archives change to common configuration files.
- The configuration archive counter is reset. The serial number for new configuration archives starts at 1.
- The **display archive configuration** command no longer displays the old configuration archives.

The configuration archive counter does not restart when you delete configuration archives from the archive directory. However, if the device reboots after all configuration archives have been deleted, the configuration archive counter restarts. The serial number for new configuration archives starts at 1.

The **undo archive configuration location** command removes the local configuration archive directory and file name prefix settings. The command also performs the following operations:

- Disables the configuration archive feature (both manual and automatic methods).
- Restores the default settings of the **archive configuration interval** and **archive configuration max** commands.
- Clears the configuration archive information displayed by using the **display archive configuration** command.

Examples

Set the configuration archive directory as **flash:/archive** and the archive file name prefix as **my_archive**.

```
<Sysname> mkdir flash:/archive
Creating directory flash:/archive... Done.
```

```
<Sysname> system-view
[Sysname] archive configuration location flash:/archive filename-prefix my_archive
```

archive configuration max

Use **archive configuration max** to set the maximum number of configuration archives that can be saved on the device.

Use **undo archive configuration max** to restore the default.

Syntax

archive configuration max *file-number*

undo archive configuration max

Default

The maximum number is 5.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

file-number: Specifies the maximum number of configuration archives that can be saved on the device. The value range is 1 to 10. Adjust the setting depending on the amount of storage space available.

Usage guidelines

Before you execute this command, use the **archive configuration location** command to specify a configuration archive directory and archive file name prefix on the device.

After the maximum number of configuration archives is reached, the system deletes the oldest archive for the new archive.

Changing the limit setting to a lower value does not cause immediate deletion of excess archives. Instead, the configuration archive feature deletes the oldest *n* files when a new archive is manually or automatically saved, where *n* = current archive count – new archive limit + 1. For example, seven configuration archives have been saved before the archive limit is set to four. When saving a new configuration archive, the system first deletes the oldest four (7 – 4 + 1) archives.

If you execute the **undo archive configuration location** command, the default archive limit is restored.

Examples

Set the maximum number of configuration archives to 10.

```
<Sysname> system-view
[Sysname] archive configuration max 10
```

Related commands

archive configuration

archive configuration location

archive configuration interval

archive configuration server

Use **archive configuration server** to configure the parameters for archiving the running configuration to a remote server.

Use **undo archive configuration server** to restore the default.

Syntax

archive configuration server { **ftp** | **tftp** | **scp** } { *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**vpn-instance** *vpn-instance-name*] [**directory** *directory*] **filename-prefix** *filename-prefix* [**interval** *interval*]

undo archive configuration server

Default

No parameters are configured for archiving the running configuration to a remote server.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ftp: Specifies a remote FTP server.

tftp: Specifies a remote TFTP server.

scp: Specifies a remote SCP server.

ipv4-address: Specifies the IPv4 address of the remote server.

ipv6 *ipv6-address*: Specifies the IPv6 address of the remote server.

port *port-number*: Specifies the TCP port number of the remote server, in the range of 1 to 65535. By default, the FTP port number is 21 and the TFTP port number is 69.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If the remote server is on the public network, do not specify this option.

directory *directory*: Specifies the remote archive directory, a case-insensitive string. If you do not specify this option, the archive directory is the root directory of the remote server.

filename-prefix *filename-prefix*: Specifies a file name prefix for configuration archives, a case-insensitive string of 1 to 30 characters. Valid characters are letters, digits, underscores (_), and hyphens (-).

interval *interval*: Enables automatic running-configuration remote archiving and sets the archiving interval. The value range for the *interval* argument is 10 to 525600 minutes.

Usage guidelines

Local archiving (the **archive configuration location** command) and remote archiving (the **archive configuration server** command) are mutually exclusive. You cannot use the two features at the same time.

If you use a remote FTP or SCP server, make sure the device is consistent with that server in FTP or SCP settings. If a login username and password is configured on the server, you must use the **archive configuration server user** and **archive configuration server password** commands to specify that login username and password on the device.

If you use the **archive configuration server** command multiple times to configure parameters for remote archiving, the most recent configuration takes effect.

After you configure the remote archiving parameters, you can use the **archive configuration** command to manually archive the running configuration.

By default, automatic running-configuration remote archiving is disabled. To enable automatic running-configuration remote archiving, specify the **interval** *interval* option when you use the **archive configuration server** command. To disable automatic running-configuration remote archiving, use the **undo archive configuration server** command.

On the specified remote server, configuration archives are named in the format of *filename-prefix*_*YYYYMMDD*_*HHMMSS***.cfg** (for example, **archive_20170526_203430.cfg**).

Examples

Set the configuration archive directory as **archive/** on the server at 192.168.1.1 and configure the archive file name prefix as **my_archive**.

```
<Sysname> system-view
[Sysname] archive configuration server ftp 192.168.1.1 port 22 directory /archive/
filename-prefix my_archive
```

Syntax

backup startup-configuration to { *ipv4-server* | **ipv6** *ipv6-server* } [*dest-filename*] [**vpn-instance** *vpn-instance-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-server: Specifies a TFTP server by its IPv4 address or host name. The host name is a case-insensitive string of 1 to 253 characters. Valid characters include letters, digits, hyphens (-), underscores (_), and dots (.).

ipv6 *ipv6-server*: Specifies a TFTP server by its IPv6 address or host name. The host name is a case-insensitive string of 1 to 253 characters. Valid characters include letters, digits, hyphens (-), underscores (_), and dots (.).

dest-filename: Specifies the name of the target file used for saving the file on the server. The file must be a .cfg file. The file name is a case-insensitive string of up to 255 characters. If you do not specify a target file name, the source file name is used.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If the TFTP server is on the public network, do not specify this option.

Examples

Back up the main next-startup configuration file to the IPv4 TFTP server at 2.2.2.2 in the public network, and set the target file name to **192-168-1-26.cfg**.

```
<Sysname> backup startup-configuration to 2.2.2.2 192-168-1-26.cfg
Backing up the main startup configuration file to 2.2.2.2...
Done.
```

Back up the main next-startup configuration file to the IPv4 TFTP server at 2.2.2.2 in MPLS L3VPN instance **VPN1**, and set the target file name to **192-168-1-26.cfg**.

```
<Sysname> backup startup-configuration to 2.2.2.2 192-168-1-26.cfg vpn-instance VPN1
Backing up the main startup configuration file to 2.2.2.2 in VPN VPN1...
```

```
Done.
```

Back up the main next-startup configuration file to the IPv6 TFTP server at 2001::2 in the public network, and set the target file name to **192-168-1-26.cfg**.

```
<Sysname> backup startup-configuration to ipv6 2001::2 192-168-1-26.cfg
Backing up the main startup configuration file to 2001::2...
Done.
```

Related commands

`restore startup-configuration`

configuration encrypt

Use **`configuration encrypt`** to enable configuration encryption.

Use **`undo configuration encrypt`** to disable configuration encryption.

Syntax

`configuration encrypt` { **`private-key`** | **`public-key`** }

`undo configuration encrypt`

Default

Configuration encryption is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

`private-key`: Encrypts configuration with a private key. All devices running NF software use the same private key.

`public-key`: Encrypts configuration with a public key. All devices running NSFOCUS software use the same public key.

Usage guidelines

Configuration encryption enables the device to automatically encrypt a configuration file when saving the running configuration to the file.

Any devices running NSFOCUS software can decrypt the encrypted configuration file. To prevent an encrypted file from being decoded by unauthorized users, make sure the file is accessible only to authorized users.

Examples

Enable the public-key method for configuration encryption.

```
<Sysname> system-view
[Sysname] configuration encrypt public-key
```

configuration replace file

Use **`configuration replace file`** to roll the running configuration back by using a local replacement configuration file.

Syntax

configuration replace file *filename*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

filename: Specifies the path of the replacement configuration file, a string of up to 255 characters. The file must be a .cfg file. The file and file path must be valid and on the local system.

Usage guidelines

CAUTION:

The configuration rollback feature replaces the running configuration with the configuration in a configuration file without rebooting the device. This operation will cause settings not in the replacement configuration file to be lost, which might cause service interruption. When you perform configuration rollback, make sure you fully understand its impact on your network.

This command helps you revert to a previous configuration state or adapt the running configuration to different network environments.

To ensure a successful rollback, follow these guidelines:

- Make sure the replacement configuration file is created by using the configuration archive feature or the **save** command on the device.
- If the configuration file is not created on the device, make sure the command lines in the configuration file are fully compatible with the device.
- Make sure the replacement configuration file is not encrypted.

Examples

Replace the running configuration with the configuration in the **my_archive_1.cfg** configuration file.

```
<Sysname> system-view
[Sysname] configuration replace file my_archive_1.cfg
Current configuration will be lost, save current configuration? [Y/N]:n
Now replacing the current configuration. Please wait...
Succeeded in replacing current configuration with the file my_archive_1.cfg.
```

configuration replace server

Use **configuration replace server** to roll the running configuration back by using a configuration file on a remote server.

Use **undo configuration replace server** to restore the default.

Syntax

configuration replace server { **ftp** | **tftp** } { *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**vpn-instance** *vpn-instance-name*] [**directory** *directory*] **file** *filename*

undo configuration replace server

Default

No parameters are configured for remote configuration rollback.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ftp: Specifies a remote FTP server.

tftp: Specifies a remote TFTP server.

ipv4-address: Specifies the IPv4 address of the remote server.

ipv6 *ipv6-address*: Specifies the IPv6 address of the remote server.

port *port-number*: Specifies the TCP port number of the remote server, in the range of 1 to 65535. By default, the FTP port number is 21 and the TFTP port number is 69.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If the remote server is on the public network, do not specify this option.

directory *directory*: Specifies the remote rollback directory. The *directory* argument is a case-insensitive string. If you do not specify this option, the rollback directory is the root directory of the remote server.

file *filename*: Specifies the default replacement configuration file for running-configuration remote rollback. The *filename* argument is a case-insensitive string. The file must be a .cfg file.

Usage guidelines

If you use a remote FTP server, make sure the device is consistent with that FTP server in FTP settings. If a login username and password is configured on the FTP server, you must use the **configuration replace server user** and **configuration replace server password** commands to specify that login username and password on the device.

Examples

Replace the running configuration with the configuration in the **archive/** directory of the FTP server at 192.168.1.1.

```
<Sysname> system-view
[Sysname] configuration replace server ftp 192.168.1.1 port 22 directory /archive/
```

Related commands

configuration replace server file

Use **undo configuration replace server file** to disable remote configuration rollback.

Syntax

configuration replace server file [*filename*] [**at** *time* [*date*]]

undo configuration replace server file

Default

Remote configuration rollback is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

filename: Specifies a replacement configuration file by its name, a string of up to 255 characters. The file must be a .cfg file. If you do not specify a replacement configuration file, this command uses the default replacement configuration file specified by using the **configuration replace server** command for a rollback.

at *time*: Specifies the time at which the system downloads the replacement configuration file and performs configuration rollback. The *time* argument is in the format of HH:MM. HH represents the hours, in the range of 0 to 23. MM represents the minutes, in the range of 0 to 59.

date: Specifies the date on which the system downloads the replacement configuration file and performs configuration rollback. This argument is in the format of MM/DD/YYYY or YYYY/MM/DD. YYYY represents the year, in the range of 2000 to 2035. MM represents the month, in the range of 1 to 12. DD represents the day, in the range of 1 to N. The value for N depends on the month.

Usage guidelines

CAUTION:

The remote configuration rollback feature replaces the running configuration with the configuration in a remote configuration file without rebooting the device. This operation will cause settings not in the replacement configuration file to be lost, which might cause service interruption. When you perform configuration rollback, make sure you fully understand its impact on your network.

This command enables the device to perform the following operations:

1. Downloads the replacement configuration file from the remote rollback server.
2. Saves the downloaded file as a temporary file.
3. Replaces the running configuration with the configuration in the temporary file.
4. Deletes the temporary file after the configuration rollback finishes.

To perform an immediate configuration rollback, do not specify a rollback time or date. An immediate configuration rollback cannot be canceled.

To schedule a configuration rollback, specify a rollback time and optionally a date. A configuration rollback schedule can be canceled before the specified rollback time. When you schedule a rollback, follow these restrictions and guidelines:

- If you specify a rollback date with the rollback time, the specified date must be the same or later than the current system date. If the specified date is the same as the current system date, the specified time must be later than the current system time. After you create the rollback schedule, be careful with changing the system clock backward. The rollback schedule will be canceled automatically if it expires before it could be executed because the system date or time is changed backward.

- If you do not specify a rollback date with the rollback time, the device compares the specified rollback time with the current system time.
  - If the specified rollback time is later than the current system time, the device performs a rollback at the specified time on the current day.
  - If the specified rollback time is earlier than the current system time, the device performs a rollback at the specified time on the next day.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Roll back the running configuration immediately with the specified replacement configuration file on the remote server for configuration rollback.

```
<Sysname> system-view
[Sysname] configuration replace server file my_archive_2017-05-09.cfg
The running configuration will be lost. Do you want to save the running configuration?
[Y/N]: N
Now replacing the running configuration...
Successfully replaced running configuration with file my_archive_2017-05-09.cfg.
```

Related commands

configuration replace server

configuration replace server password

configuration replace server user

configuration replace server password

Use **configuration replace server password** to configure the password for accessing the remote FTP server for configuration rollback.

Use **undo configuration replace server password** to restore the default.

Syntax

configuration replace server password { **cipher** | **simple** } *string*

undo configuration replace server password

Default

No password is configured for accessing the remote FTP server for remote configuration rollback.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 63 characters. Its encrypted form is a case-sensitive string of 33 to 117 characters.

Examples

Set the password to **admin** in plaintext form for accessing the remote FTP server for configuration rollback.

```
<Sysname> system-view
[Sysname] configuration replace server password simple admin
```

context-operator

Usage guidelines

If you use remote archiving, this command displays configuration archive information on the remote server. If you use local archiving, this command displays configuration archive information on the local device.

Examples

Display information about the configuration archives. The sample output was created based on local archiving.

```
<Sysname> display archive configuration
Location: flash:/archive
Filename prefix: my_archive
Archive interval in minutes: 120
Maximum number of archive files: 10
Archive history:
  No. TimeStamp               FileName
   1  Sat Oct 20 22:50:26 2018 my_archive_1.cfg
   2  Sat Oct 20 22:50:31 2018 my_archive_2.cfg
 # 3  Sat Oct 20 22:50:35 2018 my_archive_3.cfg
The pound sign (#) indicates the most recent archive file.
Next archive file to be saved: my_archive_4.cfg
```

Display information about the configuration archives. The sample output was created based on remote archiving.

```
<Sysname> display archive configuration
Username: test
Location: ftp://192.168.21.21:21/archive
VPN instance: VPN1
Filename prefix: my_archive
Archive interval in minutes: 120
Archive history:
  No. TimeStamp               FileName
 ! 1  Thu Oct 18 14:23:51 2018 my_archive_20181018_142351.cfg
 ! 2  Sat Oct 20 22:46:44 2018 my_archive_20181020_224644.cfg
#! 3  Sat Oct 20 22:46:49 2018 my_archive_20181020_224649.cfg
The exclamation mark (!) indicates that the remote archiving attempt failed.
```

```
The pound sign (#) indicates the most recent archive file.
```

Table 1 Command output

Field	Description
Username	Username for accessing the remote FTP or SCP server that stores the configuration archives. If the remote server is a TFTP server, this field is not available.
Location	Absolute path of the directory for saving running-configuration archives.
VPN instance	VPN instance to which the remote server belongs.
Filename prefix	File name prefix for configuration archives.
Archive interval in minutes	Interval (in minutes) for the system to automatically archive the running configuration. If automatic configuration archiving is disabled, this field is not available.
Maximum number of archive files	Maximum number of configuration archives that can be saved on the device.
Archive history	History configuration archive information.
No.	Number of a configuration archive.
TimeStamp	Time when the configuration archive was created.

`configuration replace server file`

`configuration replace server password`

`configuration replace server user`

display current-configuration

Use **`display current-configuration`** to display the running configuration.

Syntax

display current-configuration [**configuration** [*module-name*] | **interface** [*interface-type* [*interface-number*]] | **vpn-instance** [*vpn-instance-name*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

configuration [*module-name*]: Displays the feature configuration. The *module-name* argument specifies a feature module. If you do not specify a feature module, the command displays all feature settings you have made.

interface [*interface-type* [*interface-number*]]: Displays interface configuration, where the *interface-type* argument represents the interface type and the *interface-number* argument represents the interface number. If you do not specify the *interface-type interface-number* arguments, the command displays the running configuration for all interfaces. If you specify only the *interface-type* argument, the command displays the running configuration for all interfaces of this type.

vpn-instance [*vpn-instance-name*]: Specifies one or all MPLS L3VPN instances. Use the *vpn-instance-name* argument to specify one MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you specify the **vpn-instance** keyword without specifying the *vpn-instance-name* argument, this command displays the running configuration for all VPN instances. If you do not specify VPN instances, this command displays the running configuration for all VPN instances and the public network.

Usage guidelines

Use this command to verify the configuration you have made.

If the system has automatically changed the setting you have made for a parameter, this command displays the effective setting instead of the configured one. An automatic change typically occurs because of system restrictions.

This command does not display parameters that are using the default settings.

Executing this command with the **vpn-instance** [*vpn-instance-name*] option displays only part of the running configuration for the specified VPN instances. The displayed information includes settings made on the VPN instances, interfaces associated with the VPN instances, and routing protocol settings. To obtain the complete running configuration, execute the **display current-configuration** command without specifying any parameters. To obtain the desired running configuration related to VPN instances, use the **| include** *regular-expression* option. With the **include** *regular-expression* option, you can specify a regular expression to identify the configuration you want to display.

Examples

Display local user configuration.

```
<Sysname> display current-configuration configuration local-user
#
local-user ftp class manage
```

```
 password hash
$h$6$D5A6pqcGpnZXxFUO$OJqnqffG7m1wTNSFOCUS6v+FBCjZZBzqgJjTZlbATl1dnKNlYwFMJcWDMbDn8HD

 service-type ssh telnet terminal
 authorization-attribute user-role network-admin
#
return
```

Display Ethernet interface configuration.

```
<Sysname> display current-configuration interface gigabitethernet
#
interface GigabitEthernet1/0/1
 port link-mode route
#
return
```

display current-configuration diff

Use **display current-configuration diff** to display the differences that the running configuration has as compared with the next-startup configuration.

Syntax

display current-configuration diff

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Usage guidelines

This command searches for the next-startup configuration in the following order:

1. The .cfg main next-startup configuration file.
2. The .cfg backup next-startup configuration file if the .cfg main next-startup configuration file is unavailable.

If both configuration files are unavailable, the system displays a message indicating that no next-startup configuration files exist.

Examples

Display the differences that the running configuration has as compared with the next-startup configuration.

```
<Sysname> display current-configuration diff
--- Startup configuration
+++ Current configuration
@@ -5,7 +5,7 @@
 #
  sysname Sysname
 #
-alias dhc display history-command
+alias dh display hotkey
<Sysname>
```

Table 3 Command output

Field	Description
- - - *A* +++ *B*	• *A* represents the source configuration for comparison, which can be **Startup configuration**, **Current configuration**, or the name of the source configuration file with its directory information. • *B* represents the target configuration for comparison, which can be **Current configuration**, **Startup configuration**, or the name of the target configuration file with its directory information. In this example, the startup configuration and the current configuration are the source and target, respectively.
@@ -*linenumber1*,*number1* +*linenumber2*,*number2* @@	Location information for identifying the command line differences: • -*linenumber1*,*number1*—Source configuration section that contains differences. The *linenumber1* argument represents the start line of the section. The *number1* argument represents the number of lines between the start line and the end line of the section. • +*linenumber2*,*number2*—Target configuration section that contains differences. The *linenumber2* argument represents the start line of the section. The *number2* argument represents the number of lines between the start line and the end line of the section.
cmd1 - *cmd2* + *cmd3* *cmd4*	Displays command differences. • *cmd1* and *cmd4*—Command lines are contained in both source and target configurations if they are not prefixed with a minus (-) or plus (+) sign. They provide a context for locating command line differences. • - *cmd2*—Command lines are prefixed with a minus sign if they are contained in the source configuration but not in the target configuration. • + *cmd3*—Command lines are prefixed with a plus sign if they are contained in the target configuration but not in the source configuration. In this example, the sample output shows that the **`alias dhc display history-command`** command is contained only in the source configuration, and the **`alias dh display hotkey`** command is contained only in the target configuration.

context-operator

Parameters

configfile *file-name-s*: Specifies the source configuration file for comparison.

configfile *file-name-d*: Specifies the target configuration file for comparison.

current-configuration: Specifies the running configuration. In the **display diff current-configuration** command, this keyword specifies the source configuration for comparison. In the **display diff configfile** *file-name-s* and **display diff startup-configuration** commands, this keyword specifies the target configuration.

startup-configuration: Specifies the next-startup configuration. In the **display diff startup-configuration** command, this keyword specifies the source configuration for comparison. In the **display diff configfile** *file-name-s* and **display diff current-configuration** commands, this keyword specifies the target configuration.

Usage guidelines

If you specify the **startup-configuration** keyword, the system searches for the next-startup configuration in the following order:

1. The .cfg main next-startup configuration file.
2. The .cfg backup next-startup configuration file if the .cfg main next-startup configuration file is unavailable.

If both configuration files are unavailable, the system displays a message indicating that no next-startup configuration files exist.

Examples

Display the differences between **startup.cfg** and **test.cfg**.

```
<Sysname> display diff configfile startup.cfg configfile test.cfg

network-admin

network-operator

context-admin

context-operator

Usage guidelines

Use this command to verify that important settings have been saved to the configuration file for the next system startup.

This command selects the configuration file to display in the following order:

1. If the main startup configuration file is available, this command displays the contents of the main startup configuration file.
2. If only the backup startup configuration file is available, this command displays the contents of the backup file.
3. If both the main and backup startup configuration files are not available, this command does not display anything.

Examples

Display the contents of the configuration file for the next system startup.

```
<Sysname> display saved-configuration
#
 version 7.1.070, Release 1201
#
 sysname Sysname
#
 ftp server enable
#
 telnet server enable
#

Syntax

display startup

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Usage guidelines

All IRF members use the same current startup configuration file as the master.

After a master/subordinate switchover, it is normal that the current startup configuration files on all IRF members are displayed as NULL. This is because the new master continues to run with the running configuration rather than rebooting with a startup configuration file.

Examples

Display names of the startup configuration files.

```
<Sysname> display startup
 Current startup saved-configuration file: flash:/startup.cfg(*)
 Next main startup saved-configuration file: flash:/startup.cfg
 Next backup startup saved-configuration file: NULL
```

Table 4 Command output

Field	Description
Current startup saved-configuration file	Configuration file that the device has started up with. If the field is suffixed with an asterisk (*), the startup configuration file is a binary configuration file.
Next main startup saved-configuration file	Primary configuration file to be used at the next startup.
Next backup startup saved-configuration file	Backup configuration file to be used at the next startup.

Related commands

startup saved-configuration

display this

Use **display this** to display the running configuration in the current view.

Syntax

display this

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Usage guidelines

Use this command to verify the configuration you have made in a certain view.

This command does not display parameters that are using the default settings.

Some parameters can be successfully set even if their dependent features are not enabled. For these parameters, this command displays their settings after the dependent features are enabled.

This command can be executed in any user line view to display the running configuration of all user lines.

Examples

Display the running configuration on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] display this
#
interface GigabitEthernet1/0/1
#
return
```

reset saved-configuration

Use **reset saved-configuration** to delete a next-startup configuration file.

Syntax

reset saved-configuration [**backup** | **main**]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

backup: Specifies the backup next-startup configuration file.

main: Specifies the main next-startup configuration file.

Usage guidelines

CAUTION:

This command permanently deletes the specified next-startup configuration file from all IRF member devices. As a best practice, make sure you have a configuration backup before you use this command.

You can delete the main file, the backup file, or both.

To delete a file that is set as both main and backup next-startup configuration files, you must execute both the **reset saved-configuration backup** command and the **reset saved-configuration main** command. Using only one of the commands sets the target file attribute to NULL instead of deleting the file.

If you do not specify a configuration file attribute, the **reset saved-configuration** command deletes the main next-startup configuration file.

Examples

Delete the main next-startup configuration file.

```
<Sysname> reset saved-configuration
The saved configuration file will be erased. Are you sure? [Y/N]:y
Configuration file in flash: is being cleared.
Please wait ..........
Configuration file is cleared.
```

Related commands

display saved-configuration

restore startup-configuration

Use **restore startup-configuration** to download a configuration file from a TFTP server and specify it as the main next-startup configuration file.

Syntax

restore startup-configuration from { *ipv4-server* | **ipv6** *ipv6-server* } *src-filename* [**vpn-instance** *vpn-instance-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-server: Specifies a TFTP server by its IPv4 address or host name. The host name is a case-insensitive string of 1 to 253 characters. Valid characters include letters, digits, hyphens (-), underscores (_), and dots (.).

ipv6 *ipv6-server*: Specifies a TFTP server by its IPv6 address or host name. The host name is a case-insensitive string of 1 to 253 characters. Valid characters include letters, digits, hyphens (-), underscores (_), and dots (.).

src-filename: Specifies the name of the configuration file to be downloaded. The file must be a .cfg file. The file name is a case-insensitive string of up to 255 characters.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If the TFTP server is on the public network, do not specify this option.

Usage guidelines

Before restoring the configuration file for the next startup, make sure the following requirements are met:

- The server is reachable.
- The server is enabled with TFTP service.
- You have read and write permissions to the server.

This command downloads the configuration file to the root directory of the default storage medium on each member device and specifies the file as the main next-startup configuration file. If the default storage medium has been partitioned, the configuration file is saved on the first partition. Make sure all IRF members use the same type of default storage media. If a subordinate device uses a different type of default storage medium than the master, the command cannot propagate the configuration file to the subordinate device. For example, the subordinate device uses a USB disk, but the master uses a flash memory. In this situation, you must manually restore the main next-startup configuration file on the subordinate device.

Examples

Download **test.cfg** from the IPv4 TFTP server at 2.2.2.2 in the public network, and specify the file as the main next-startup configuration file.

```
<Sysname> restore startup-configuration from 2.2.2.2 test.cfg
Restoring the next startup-configuration file from 2.2.2.2...
Done.
```

Download **test.cfg** from the IPv4 TFTP server at 2.2.2.2 in MPLS L3VPN instance **VPN1**, and specify the file as the main next-startup configuration file.

```
<Sysname> restore startup-configuration from 2.2.2.2 test.cfg vpn-instance VPN1
Restoring the next startup-configuration file from 2.2.2.2...
Done.
```

Download **test.cfg** from the IPv6 TFTP server at 2001::2 in the public network, and specify the file as the main next-startup configuration file.

```
<Sysname> restore startup-configuration from ipv6 2001::2 test.cfg
Restoring the next startup-configuration file from 2001::2...
Done.
```

Related commands

backup startup-configuration

save

Use **save** *file-url* [**all** | **slot** *slot-number*] to save the running configuration to a configuration file, without specifying the file as a next-startup configuration file.

Use **save** [**safely**] [**backup** | **main**] [**force**] [**context-all** | **changed**] to save the running configuration to a file in the root directory of the storage medium. This command automatically saves the file on each IRF member device and specifies the file as a next-startup configuration file.

Syntax

save *file-url* [**all** | **slot** *slot-number*]

save [**safely**] [**backup** | **main**] [**force**] [**context-all** | **changed**]

Views

Any view

Predefined user roles

network-admin

context-admin

Parameters

file-url: Specifies a file path, a string of up to 255 characters. The file must be a .cfg file. If you specify the **all** keyword or the **slot** *slot-number* option, the file path cannot include a member ID. If the file path includes a folder name, the folder must already exist on all IRF member devices.

all: Saves the running configuration to all member devices. If you do not specify this keyword or the **slot** *slot-number* option, the command saves the running configuration only to the master.

slot *slot-number*: Specifies a subordinate device by its member ID. If you do not specify a subordinate device or the **all** keyword, this command saves the running configuration only to the master.

safely: Saves the configuration file in safe mode. If you do not specify this keyword, the device saves the configuration file in fast mode.

backup: Saves the running configuration to a configuration file, and specifies the file as the backup next-startup configuration file. If you do not specify this keyword or the **main** keyword, the command specifies the saved file as the main next-startup configuration file.

main: Saves the running configuration to a configuration file, and specifies the file as the main next-startup configuration file. If you do not specify this keyword or the **backup** keyword, the command specifies the saved file as the main next-startup configuration file.

force: Saves the running configuration to the existing next-startup configuration file without prompting for confirmation. If you do not specify this keyword, the system prompts you to confirm the operation. If you do not confirm the operation within 30 seconds, the system automatically aborts the operation. If you enter **Y** within the time limit, you can continue the save process and change the target file name during the process.

context-all: Saves the running configuration for each context. The running configuration for each context is saved to the storage medium of the firewall module. If you do not specify this keyword, the **save** command saves the running configuration only for the context where you are logged in.

changed: Overwrites the target configuration file with the running configuration if an inconsistency is detected between the settings in the configuration file and the running configuration. The **save** command does not take effect if no inconsistency is detected. If you do not specify this keyword, the **save** command always overwrites the target configuration file with the running configuration.

Usage guidelines

CAUTION:

Use the **save** command with caution. This command will overwrite the settings in the target configuration file. When you execute this command, carefully read the messages displayed by the system and make sure you fully understand the impact of this command on services.

If the file specified for this command does not exist, the system creates the file before saving the configuration. If the file already exists, the system prompts you to confirm whether to overwrite the file. If you choose to not overwrite the file, the system cancels the save operation.

This command saves the running configuration to an .mdb binary file as well as a .cfg text file. The two files use the same file name. An .mdb file takes less time to load than a .cfg file.

When you use the **save** [**safely**] [**backup** | **main**] [**force**] [**context-all** | **changed**] command, follow these guidelines:

- In safe mode, the system saves configuration in a temporary file and starts overwriting the target next-startup configuration file after the save operation is complete. If a reboot, power failure, or out of memory or storage space event occurs during the save operation, the next-startup configuration file is retained.

- In fast mode, the device directly overwrites the target next-startup configuration file. If a reboot, power failure, or out of memory or storage space event occurs during this process, all settings in the next-startup configuration file are lost.

Safe mode is slower than fast mode, but more secure. As a best practice, specify the **safely** keyword for reliable configuration saving.

Examples

Save the running configuration to **backup.cfg**, without specifying the file as a next-startup configuration file.

```
<Sysname> save backup.cfg
The current configuration will be saved to flash:/backup.cfg. Continue? [Y/N]:y
Now saving current configuration to the device.
Saving configuration flash:/backup.cfg. Please wait...
Configuration is saved to device successfully.
```

Save the running configuration to the main next-startup configuration file without any confirmation required.

```
<Sysname> save force
Validating file. Please wait....
Saved the current configuration to mainboard device successfully.
```

Save the running configuration to a file in the root directory of the default storage medium, and specify the file as the main next-startup configuration file.

```
<Sysname> save
The current configuration will be written to the device. Are you sure? [Y/N]:y
Please input the file name(*.cfg)[flash:/backup.cfg]
(To leave the existing filename unchanged, press the enter key):test.cfg
Validating file. Please wait.....
Saved the current configuration to mainboard device successfully.
```

Save the running configuration to a file in the root directory of the storage medium for each context, and specify the file as the main next-startup configuration file.

```
<Sysname> save context-all
Save current configuration in all context? [Y/N]:y
Please input the file name(*.cfg)[flash:/startup.cfg]
(To leave the existing filename unchanged, press the enter key):
flash:/startup.cfg exists, overwrite? [Y/N]:y
Validating file. Please wait...
Saved the current configuration of context Admin to mainboard device successfully.
```

Related commands

display current-configuration

display saved-configuration

startup saved-configuration

Use **startup saved-configuration** to specify a file as a next-startup configuration file.

Use **undo startup saved-configuration** to configure the system to start up with the factory defaults at the next startup.

Syntax

startup saved-configuration *cfgfile* [**backup** | **main**]

undo startup saved-configuration

Default

No next-startup configuration files are specified.

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

cfgfile: Specifies the path of a configuration file, a string of up to 255 characters. The file must be a .cfg file. The file path can include only the file name, or the storage medium information and file name. If the file is not on the default storage medium, you must specify the file name with storage medium information.

backup: Specifies the configuration file as the backup next-startup configuration file.

main: Specifies the configuration file as the main next-startup configuration file. This is the primary configuration file that the device attempts to load at startup. If the loading attempt fails, the device tries the backup next-startup configuration file.

Usage guidelines

CAUTION:

In an IRF fabric, the **undo startup saved-configuration** command can cause an IRF split after the IRF fabric or an IRF member reboots.

The **startup saved-configuration** command applies to all IRF members. To successfully execute this command, make sure the specified file has been saved in the root directory of the storage medium on each member.

If you do not specify the **backup** or **main** keyword, the **startup saved-configuration** command specifies the main next-startup configuration file.

As a best practice, specify different files as the main and backup next-startup configuration files.

The **undo startup saved-configuration** command changes the file attribute of the main and backup next-startup configuration files to NULL. However, the command does not delete the two configuration files.

You can also specify a configuration file as a next startup file when you use the **save** command to save the running configuration.

Examples

Specify the main next-startup configuration file.

```
<Sysname> startup saved-configuration testcfg.cfg
Please wait ....... Done.
```

Related commands

display startup

Contents

Software upgrade commands

As a best practice, store the startup images in the factory default file system. If you store the startup images in a hot swappable storage medium, do not remove the hot swappable storage medium during the startup process.

boot-loader file

Use **boot-loader file** to specify startup image files.

Syntax

boot-loader file boot *filename* **system** *filename* [**feature** *filename*&<1-30>] { **all** | **slot** *slot-number* } { **backup** | **main** }

boot-loader file *ipe-filename* { **all** | **slot** *slot-number* } { **backup** | **main** }

Views

User view

Predefined user roles

network-admin

Parameters

boot: Specifies a boot image file.

system: Specifies a system image file.

feature: Specifies a space-separated list of up to 30 feature image files.

filename: Specifies a .bin file in the *filesystemnameIfilename***.bin** format. The file must be stored in the root directory of a file system on the device. Excluding the file system location section (if any), the value string can have a maximum of 63 characters. For more information about specifying a file, see file system management in *Fundamentals Configuration Guide*.

ipe-filename: Specifies an .ipe image package file in the *filesystemnameIfilename***.ipe** format. The file must be stored in the root directory of a file system on the device. Excluding the file system location section (if any), the value string can have a maximum of 63 characters. For more information about specifying a file, see file system management in *Fundamentals Configuration Guide*.

all: Specifies all hardware components to which the specified images apply.

slot *slot-number*: Specifies the IRF member ID of a member device.

backup: Specifies the files as backup startup image files. Backup images are used only when main images are not available.

main: Specifies the files as main startup image files. The device always first attempts to start up with main startup files.

Usage guidelines

The **boot-loader file** command overwrites the entire startup image list. To add new startup feature images, specify all feature image files in the old startup image list, including feature image files. The new startup image list will contain only the feature image files that are specified in the command.

Before you specify startup image files, register and activate a license for each upgrade image that requires a license. If a license-based software image lacks a license, the command execution result is as follows:

- If .bin files are specified, the command cannot be executed.
- If an .ipe file is specified, the command sets all images as startup images except for the image that does not have a license.

For more information about licensing, see *Fundamentals Configuration Guide*.

To load the specified startup software images, you must reboot the system.

If the upgrade images are not found in the file system on the slot specified to upgrade, the system automatically copies the images to that file system. The destination directory is the root directory of the file system. If the destination root directory already contains a startup image with the same name as an upgrade image, you must choose whether to overwrite the image.

Incremental patches cannot be installed by using the **boot-loader file** command.

NOTE:

The system will verify the digital signature of the specified images before it updates the startup image list with the specified images. If the digital signature verification fails, the system will not update the startup image list and you will receive a digital signature verification failure message.

Examples

Specify **flash:/all.ipe** as the main startup image file for slot 1.

```
<Sysname> boot-loader file flash:/all.ipe slot 1 main
Verifying the file flash:/all.ipe on slot 1.............Done.
NSFOCUS NFNX3-HDB680 images in IPE:
  boot.bin
  system.bin
This command will set the main startup software images. Please do not reboot any
 MPU during the upgrad. Continue? [Y/N]:Y
Add images to slot 1.
File flash:/boot.bin already exists on slot 1.
File flash:/system.bin already exists on slot 1.
Overwrite the existing files? [Y/N]:Y
Decompressing file boot.bin to flash:/boot.bin.....................Done.
Decompressing file system.bin to flash:/system.bin.............................Done.
Verifying the file flash:/boot.bin on slot 1...Done.
Verifying the file flash:/system.bin on slot 1.............Done.
The images that have passed all examinations will be used as the main startup software
images at the next reboot on slot 1.
```

Specify **flash:/all.ipe** as the main startup image file for all IRF member devices.

```
<Sysname> boot-loader file slot1#flash:/all.ipe all main
Verifying the file flash:/all.ipe on slot 1.................................Done.
NSFOCUS NFNX3-HDB680 images in IPE:
  Boot.bin
  System.bin
This command will set the main startup software images. Please do not reboot any
 MPU during the upgrad. Continue? [Y/N]:y
Add images to slot 1.
File flash:/Boot.bin already exists on slot 1.
File flash:/System.bin already exists on slot 1.
Overwrite the existing files? [Y/N]:y
Decompressing file Boot.bin to flash:/Boot.bin.....................Done.
```

```
Decompressing file System.bin to flash:/System.bin.....................Done.
The images that have passed all examinations will be used as the main startup software
images at the next reboot on slot 1.
File flash:/Boot.bin already exists on slot 2.
Do you want to overwrite the file?
 Y: Overwrite the file.
 N: Not overwrite the file.
 A: From now on, overwrite or not overwrite without prompt.
Please make a choice. [Y/N/A]:a
What type of overwrite operation do you want to perform?
 Y: Overwrite without prompt.
 N: Not overwrite or display prompt.
 Q: Return to the previous step.
Please make a choice. [Y/N/Q]:y
An existing file will be overwritten without prompt if it has the same name as any upgrade
file.
Loading.....................Done.
Loading.....................Done.
Loading.....................Done.
Loading.....................Done.
Loading.....................Done.
Loading.....................Done.
The images that have passed all examinations will be used as the main startup software
images at the next reboot on slot 2.
Decompression completed.
Do you want to delete flash:/all.ipe now? [Y/N]:n
```

Related commands

display boot-loader

boot-loader update

Use **boot-loader update** to synchronize startup images.

Syntax

boot-loader update { **all** | **slot** *slot-number* }

Views

User view

Predefined user roles

network-admin

Parameters

all: Synchronizes startup images from the master to all subordinate devices.

slot *slot-number*: Specifies the IRF member ID of a subordinate device.

Usage guidelines

You can use this command to synchronize startup images after adding new member devices.

If any of the startup software images require a license, register and activate a license for the image on the new subordinate device before executing this command. Use the **display license feature** command to verify the licensing state of software images.

The startup images synchronized to the subordinate device are set as main startup images, regardless of whether the source startup images are main or backup.

- If the master device has started up with main startup images, its main startup images are synchronized to the subordinate device, regardless of whether any main startup image has been respecified on the master device.
- If the master device has started up with backup startup images, its backup startup images are synchronized to the subordinate device, regardless of whether any backup startup image has been respecified on the master device.

If a patch installation or ISSU has been performed on the master, use the **install commit** command to update the set of main startup images on the master before software synchronization. This command ensures startup image consistency between the master and the subordinate device.

Do not reboot any member device during the execution of the **boot-loader update** command. Member devices might not be able to come up.

Startup image synchronization fails if any software image being synchronized is not available or is corrupted.

Examples

Synchronize startup images from the active MPU to the standby MPU in slot 1.

```
<Sysname> boot-loader update slot 1
This command will update the specified standby MPU. Please do not reboot any MPU during
the upgrade. Continue? [Y/N]:y
Updating. Please wait...
Verifying the file flash:/BOOT.bin on slot 1.............Done.
Verifying the file flash:/SYSTEM.bin on slot 1.....................Done.
Successfully updated the startup software images of slot 1.
```

Related commands

display boot-loader

install commit

bootrom backup

Use **bootrom backup** to back up the BootWare image in the Normal area to the Backup area on a BootWare.

Syntax

bootrom backup slot *slot-number-list* [**all** | **part**]

Views

User view

Predefined user roles

network-admin

Parameters

slot *slot-number-list*: Specifies a space-separated list of up to seven slot number items. An item specifies an IRF member device by its member ID or a range of IRF member devices in the form of *start-slot-number* **to** *end-slot-number*. The end slot number must be equal to or greater than the start slot number.

all: Backs up the entire BootWare image, including the basic segment and the extended segment. If you do not specify the **all** or **part** keyword, this command backs up the entire BootWare image.

part: Backs up the extended BootWare image section.

Usage guidelines

A BootWare is divided into a Normal area and a Backup area. The BootWare image is stored in the Normal area and backed up to the Backup area. At startup, the system reads the BootWare image automatically from the Normal area. If the image is inaccessible, the system reads the BootWare image from the Backup area.

If the BootWare image in the Normal area is corrupted or requires a version rollback, use the **bootrom restore** command to copy the BootWare image in the Backup area to the Normal area.

Examples

Back up the entire BootWare image from the Normal area to the Backup area.

```
<Sysname> bootrom backup slot 1
Now backing up the Boot ROM, please wait...
......Done.
```

Related commands

bootrom restore

bootrom read

Use **bootrom read** to back up the BootWare image in the Normal area of a BootWare to the default file system.

Syntax

bootrom read slot *slot-number-list* [**all** | **part**]

Views

User view

Predefined user roles

network-admin

Parameters

slot *slot-number-list*: Specifies a space-separated list of up to seven slot number items. An item specifies an IRF member device by its member ID or a range of IRF member devices in the form of *start-slot-number* **to** *end-slot-number*. The end slot number must be equal to or greater than the start slot number.

all: Backs up the entire BootWare image, including the basic segment and the extended segment. If you do not specify the **all** or **part** keyword, this command backs up the entire BootWare image.

part: Backs up the extended BootWare image section.

Usage guidelines

For each BootWare image you are backing up, this command creates two files in the default file system: **basicbtm.bin** for the basic segment and **extendbtm.bin** for the extended segment.

Examples

Back up the BootWare image from the Normal area of BootWare to the flash memory.

```
<Sysname> bootrom read slot 1
  Now reading the Boot ROM, please wait...
.........Done.
```

Related commands

bootrom update

bootrom restore

Use **bootrom restore** to replace the BootWare image in the Normal area with the BootWare image in the Backup area for image restoration or version rollback.

Syntax

bootrom restore slot *slot-number-list* [**all** | **part**]

Views

User view

Predefined user roles

network-admin

Parameters

slot *slot-number-list*: Specifies a space-separated list of up to seven slot number items. An item specifies an IRF member device by its member ID or a range of IRF member devices in the form of *start-slot-number* **to** *end-slot-number*. The end slot number must be equal to or greater than the start slot number.

all: Restores the entire BootWare image, including the basic segment and the extended segment. If you do not specify the **all** or **part** keyword, this command restores the entire BootWare image.

part: Restores the extended BootWare image section.

Examples

Restore the entire BootWare image.

```
<Sysname> bootrom restore slot 1
  This command will restore the Boot ROM file on the specified board(s), Continue? [Y/N]:y
  Now restoring the Boot ROM, please wait...
......Done.
```

Related commands

bootrom backup

bootrom update

Use **bootrom update** to load the BootWare image from a file system to the Normal BootWare area.

Syntax

bootrom update file *file* **slot** *slot-number-list* [**all** | **part**]

Views

User view

Predefined user roles

network-admin

Parameters

file *file*: Specifies the file that contains the BootWare image. The *file* argument represents the file name, a string of 1 to 63 characters.

slot *slot-number-list*: Specifies a space-separated list of up to seven slot number items. An item specifies an IRF member device by its member ID or a range of IRF member devices in the form of *start-slot-number* **to** *end-slot-number*. The end slot number must be equal to or greater than the start slot number.

all: Loads the entire BootWare image, including the basic segment and the extended segment. If you do not specify the **all** or **part** keyword, this command restores the entire BootWare image.

part: Loads the extended BootWare image section.

Usage guidelines

BootWare images are contained in the .bin NF boot image file. You can specify a NF boot image file in this command to upgrade the BootWares in the system before you upgrade the NF images. If you do not upgrade BootWares before upgrading NF images, the system automatically upgrades BootWares as necessary when loading NF images.

The new BootWare images take effect after you reboot the device.

NOTE:

The system verifies a BootWare image before it loads that image to the Normal area of BootWare. If the digital signature verification fails, the system will not load the image and you will receive a digital signature verification failure message.

Examples

Use the file **a.bin** in the root directory of the flash memory to upgrade the BootWare image.

```
<Sysname> bootrom update file flash:/a.bin slot 1
   This command will update the Boot ROM file on the specified board(s), Continue? [Y/N]:y
   Now updating the Boot ROM, please wait..............Done.
```

Related commands

Any view

Predefined user roles

network-admin

network-operator

Parameters

slot *slot-number*: Specifies the member ID of an IRF member device. If you do not specify a member device, this command displays the software images on each IRF member device.

Examples

Display the current software images and startup software images.

```
<Sysname> display boot-loader
Software images on slot 1:
Current software images:
  flash:/boot.bin
  flash:/system.bin
Main startup software images:
  flash:/boot.bin
  flash:/system.bin
Backup startup software images:
  flash:/boot.bin
  flash:/system.bin
```

Display the current software images and startup software images.

```
<Sysname> display boot-loader
Software images on slot 1:
Current software images:
  Image              Version
  flash:/boot.bin      Release 0053
  flash:/system.bin    Release 0053
Main startup software images:
  Image              Version
  flash:/boot.bin      Release 0054
  flash:/system.bin    Release 0054
Backup startup software images:
  Image              Version
  flash:/boot.bin      --
```

```
flash:/system.bin    --
```

Table 1 Command output

Field	Description
Current software images	NF images that have been loaded.
Main startup software images	Primary NF images for the next startup.
Image	Image name.
Version	Image version. If an image is corrupted or deleted, this field displays two hyphens (**--**).
Backup startup software images	Backup NF images for the next startup. If the backup startup software images are not specified, this field displays **None**.

Related commands

`install active`

display install backup

Use **`display install backup`** to display backup startup software images.

Syntax

`display install backup` [**`slot`** *`slot-number`*] [**`verbose`**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information for all IRF members.

verbose: Displays detailed information. If you do not specify this keyword, the command displays only image names.

Usage guidelines

Backup startup images are used only when the main boot or system image is missing or corrupt. For more information, see *Fundamentals Configuration Guide*.

To modify the backup startup image list, use the **boot-loader file** command.

Examples

Display the backup startup software images.

```
<Sysname> display install backup
Backup startup software images on slot 1:
  flash:/boot.bin
  flash:/system.bin
```

Display detailed information about backup startup software images.

```
<Sysname> display install backup verbose
Backup startup software images on slot 1:
 flash:/boot.bin
 [Package]
 Vendor: NFNX3-HDB680
 Product: xxxx
 Service name: boot
 Platform version: 7.1.070
 Product version: Test 0001015
 Supported board: mpu
 [Component]
 Component: boot
 Description: boot package

 flash:/system.bin
 [Package]
 Vendor: NFNX3-HDB680
 Product: xxxx
 Service name: system
 Platform version: 7.1.070
 Product version: Test 0001015
 Supported board: mpu
 [Component]
 Component: system
 Description: system package
```

For information about the command output, see Table 1.

Related commands

boot-loader file

display install committed

display install committed

Use **display install committed** to display main startup software images.

Syntax

display install committed [**slot** *slot-number*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information for all member devices.

verbose: Displays detailed information. If you do not specify this keyword, the command displays only image names.

Usage guidelines

Some **install** commands modify the current software image list but do not modify the main startup image list. For the software image changes to take effect after a reboot, you must execute the **install commit** command to update the main startup image list with the image changes. You can use the **display install committed** command to verify the operation results.

Both the **install commit** and **boot-loader file** commands modify the main startup software image list.

Examples

Display the main startup software images.

```
<Sysname> display install committed
Committed packages on slot 1:
 flash:/boot.bin
 flash:/system.bin
 flash:/feature1.bin
```

Display detailed information about main startup software images.

```
<Sysname> display install committed verbose
Committed packages on slot 1:
 flash:/boot.bin
 [Package]
 Vendor: NFNX3-HDB680
 Product: xxxx
 Service name: boot
 Platform version: 7.1.070
 Product version: Test 0001015
 Supported board: mpu
 [Component]
 Component: boot
 Description: boot package
```

```
 flash:/system.bin
 [Package]
 Vendor: NFNX3-HDB680
 Product: xxxx
 Service name: system
 Platform version: 7.1.070
 Product version: Test 0001015
 Supported board: mpu
 [Component]
 Component: system
 Description: system package

flash:/feature1.bin
 [Package]
 Vendor: NFNX3-HDB680
 Product: xxxx
 Service name: feature1
 Platform version: 7.1.070
 Product version: Test 0001015
 Supported board: mpu
 [Component]
 Component: feature1
 Description: feature1 package
```

For information about the command output, see Table 1.

boot-loader file

display install backup

install commit

display install inactive

Use **display install inactive** to display inactive software images in the root directories of file systems.

Syntax

display install inactive [**slot** *slot-number*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information for all member devices.

verbose: Displays detailed information. If you do not specify this keyword, the command displays only image names.

Examples

Display brief information about inactive software images in the root directories of the file systems.

```
<Sysname> display install inactive
Inactive packages on slot 1:
 flash:/feature1.bin
```

Display detailed information about inactive software images in the root directories of the file systems.

```
<Sysname> display install inactive verbose
Inactive packages on slot 1:
flash:/feature1.bin
 [Package]
 Vendor: NFNX3-HDB680
 Product: xxxx
 Service name: feature1
 Platform version: 7.1.070
 Product version: Test 0001015
 Supported board: mpu
 [Component]
 Component: feature1
 Description: feature1 package
```

For information about the command output, see Table 1.

Related commands

install deactivate

display install ipe-info

Use **display install ipe-info** to display the software images included in an .ipe file.

Syntax

display install ipe-info *ipe-filename*

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

ipe-filename: Specifies an .ipe file in the *filesystemname*/*filename*.**ipe** format. The file must be stored in the root directory of a file system on the device. The value string excluding the file system location section (if any) can have a maximum of 63 characters. For more information about specifying a file, see file system management in *Fundamentals Configuration Guide.*

Examples

Display information about .ipe file **flash:/test.ipe**.

```
<Sysname> display install ipe-info flash:/test.ipe
Verifying the file flash:/test.ipe on slot 1.............Done.
```

```
XX images in IPE:
  boot.bin
  system.bin
```

display install package

display install job

Use **display install job** to display ongoing ISSU activate, deactivate, and rollback operations.

Syntax

display install job

Views

Any view

Predefined user roles

network-admin

network-operator

Examples

Display ongoing ISSU activate, deactivate, and rollback operations.

```
<Sysname> display install job
 JobID:5
  Action:install activate flash:/feature1.bin on slot 1
```

The output shows that the device is executing the **install activate flash:/feature1.bin slot 1** command.

display install log

Use **display install log** to display ISSU log information.

Syntax

display install log [*log-id*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

log-id: Specifies a log entry by its ID. If you do not specify this argument, the command displays all ISSU log entries.

verbose: Displays detailed ISSU log information. If you do not specify this keyword, the command displays brief ISSU log information.

Usage guidelines

The device creates one log entry for each ISSU operation to track the ISSU process and operation result.

The ISSU log can contain a maximum of 50 entries. The latest entry overwrites the oldest entry if the log is full.

Examples

Display all ISSU log entries.

```
<Sysname> display install log
Install job 1 started by user root at 04/28/2001 08:39:29.
Job 1 completed successfully at 04/28/2001 08:39:30.
Install job 1 started by user root at 04/28/2001 08:39:29.
    Install activate flash:/feature1.bin on slot 1
Job 1 completed successfully at 04/28/2001 08:39:30.
Install job 1 started by user root at 04/28/2001 08:39:29.
Job 1 completed successfully at 04/28/2001 08:39:30.
------------------------------------------------------------
Install job 2 started by user root at 04/28/2001 08:40:29.
Job 2 completed successfully at 04/28/2001 08:40:30.
Install job 2 started by user root at 04/28/2001 08:40:29.
    Install activate flash:/route.bin on slot 1
Job 2 completed successfully at 04/28/2001 08:40:30.
Install job 2 started by user root at 04/28/2001 08:40:29.
Job 2 completed successfully at 04/28/2001 08:40:30.
```

Displays detailed information about ISSU log entry 1.

```
<Sysname> display install log 1 verbose
Install job 1 started by user root at 04/28/2001 08:39:29.
Job 1 completed successfully at 04/28/2001 08:39:30.
Install job 1 started by user root at 04/28/2001 08:39:29.
    Install activate flash:/feature1.bin on slot 1
Job 1 completed successfully at 04/28/2001 08:39:30.
Install job 1 started by user root at 04/28/2001 08:39:29.
Job 1 completed successfully at 04/28/2001 08:39:30.
Detail of activating packages on slot 1.
    Get upgrade policy successfully.
Detail of activating packages on slot 1.
    Uncompress package to system successfully.
    Remove files from system successfully.
```

Table 2 Command output

Field	Description
Detail of xxx	Detailed information about an ISSU operation.
Get upgrade policy successfully.	Obtained the upgrade policy.
Uncompress package to system successfully.	Decompressed the package successfully.
Remove files from system successfully.	Deleted files from the system successfully.

reset install log-history oldest

display install package

Use **display install package** to display software image file information.

Syntax

display install package { *filename* | **all** } [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

filename: Specifies a .bin file in the *filesystemnameIfilename***.bin** format. The file must be stored in the root directory of a file system on the device. The value string excluding the file system location section (if any) can have a maximum of 63 characters. For more information about specifying a file, see file system management in *Fundamentals Configuration Guide.*

all: Specifies all software image files in the root directories of the master's file systems.

verbose: Displays detailed information. If you do not specify this keyword, the command displays only basic software image information.

Examples

Display information about **system.bin**.

```
<Sysname> display install package flash:/system.bin
  flash:/system.bin
  [Package]
  Vendor: NFNX3-HDB680
  Product: xxxx
  Service name: system
  Platform version: 7.1.070
  Product version: Test 0001015
  Supported board: mpu
```

Display detailed information about **system.bin**.

```
<Sysname> display install package flash:/system.bin verbose
  flash:/system.bin
  [Package]
  Vendor: NFNX3-HDB680
  Product: xxxx
  Service name: system
  Platform version: 7.1.070
  Product version: Test 0001015
  Supported board: mpu
  [Component]
  Component: system
  Description: system package
```

For information about the command output, see Table 1.

display install rollback

Use **display install rollback** to display rollback point information.

Syntax

display install rollback [*point-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

point-id: Specifies a rollback point ID. If you do not specify a rollback point ID, the command displays all rollback points.

Usage guidelines

Use this command to identify available rollback points during an ISSU that uses **install** commands. The system does not record rollback points during an ISSU that uses **issu** commands.

Examples

Display all rollback points.

```
<Sysname> display install rollback
Install rollback information 1 on slot 1:
  Updating from flash:/route-1.bin
         to flash:/route-2.bin.

Install rollback information 2 on slot 1:
   Deactivating flash:/route-2.bin
```

The output shows that the device has two rollback points.

- At rollback point 1, **flash:/route-1.bin** was upgraded to **flash:/route-2.bin**.
- At rollback point 2, **flash:/route-2.bin** was deactivated.

Related commands

install rollback

reset install rollback oldest

display install which

Use **display install which** to display all software image files that include a specific component or file.

Syntax

display install which { **component** *name* | **file** *filename* } [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

component *name*: Specifies a component name.

file *filename*: Specifies a file in the *filename.extension* format, a case-insensitive string of up to 63 characters. It cannot contain path information.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information for all IRF members.

Usage guidelines

A component is a collection of features. The features of a component are installed or uninstalled at the same time.

When the system displays a component or file error, use this command to identify the image files that include the component or file. Then, you can use the **install verify** command to identify image file problems.

This command searches only the root directories of the file systems at the specified location.

Examples

Display the software image file that includes **pkg_ctr**.

```
<Sysname> display install which file pkg_ctr
Verifying the file flash:/system-t0001015.bin on slot 1.......................Done.
Found pkg_ctr in flash:/system-t0001015.bin on slot 1.
  flash:/system-t0001015.bin
  [Package]
  Vendor: NFNX3-HDB680
  Product: xxxx
  Service name: system
  Platform version: 7.1.070
  Product version: Test 0001015
  Supported board: mpu

Verifying the file flash:/boot-d2601007.bin on slot 1....Done.
```

Table 3 Command output

Field	Description
Verifying the file	The system was verifying the validity of the file.
[Package]	Detailed information about the software image.
Service name	Image type: • **boot**—Boot image. • **system**—System image. • **patch**—Patch image. • Any other value indicates a feature image.
Supported board	Hardware types supported by the software image: **mpu**—Member device.

display issu rollback-timer

Use **display issu rollback-timer** to display automatic rollback timer information.

Syntax

display issu rollback-timer

Views

Any view

Predefined user roles

network-admin

network-operator

Usage guidelines

Change to the automatic rollback interval does not take effect on the ongoing ISSU process. The current remaining rollback time might be greater than the specified automatic rollback interval.

Examples

Display automatic rollback timer information after the **issu run switchover** command is executed.

```
<Sysname> display issu rollback-timer
Rollback timer: Working
Rollback interval: 45 minutes
Rollback time remaining : 40 minutes
```

Display automatic rollback timer information after the **issu accept** command is executed.

```
<Sysname> display issu rollback-timer
Rollback timer: Not working
Rollback interval: 30 minutes
```

Display automatic rollback timer information when no ISSU process is taking place.

```
<Sysname> display issu rollback-timer
Rollback timer: Not working
Rollback interval: 45 minutes
```

Related commands

issu rollback-timer

display issu state

Use **display issu state** to display ISSU status information.

Syntax

display issu state

Views

Any view

Predefined user roles

network-admin

network-operator

Usage guidelines

During an ISSU that uses **issu** commands, you can use this command to verify the ISSU status and determine what to do next.

This command does not apply to an ISSU that uses **install** commands, because the ISSU state machine is not involved.

Examples

Display ISSU status information when no upgrade is taking place.

```
<Sysname> display issu state
ISSU state: Init
Compatibility: Unknown
Work state: Normal
Upgrade method: Card by card
Upgraded slot: None
Current upgrading slot: None
Current version list:
  boot: 7.1.070, Test 0001015
  system: 7.1.070, Test 0001015
  feature1: 7.1.070, Test 0001015
Current software images:
  flash:/boot-t0001015.bin
  flash:/system-t0001015.bin
  flash:/feature1-t0001015.bin
```

Display ISSU status information while the **issu load** command is being executed.

```
<Sysname> display issu state
ISSU state: Loading
Compatibility: Incompatible
Work state: Normal
Upgrade method: Card by card
Upgraded slot: None
Current upgrading slot:
  slot 1
Previous version list:
  boot: 7.1.070, Test 0001015
  system: 7.1.070, Test 0001015
  feature1: 7.1.070, Test 0001015
Previous software images:
  flash:/boot-t0001015.bin
  flash:/system-t0001015.bin
  flash:/feature1-t0001015.bin
Upgrade version list:
  boot: 7.1.070, Test 0001016
  system: 7.1.070, Test 0001016
  feature1: 7.1.070, Test 0001016
Upgrade software images:
  flash:/boot-t0001016.bin
  flash:/system-t0001016.bin
  flash:/feature1-t0001016.bin
```

Table 4 Command output

Field	Description
ISSU state	ISSU status: • **Init**—The ISSU process has not started or has finished. • **Loading**—The system is executing the **issu load** command. • **Loaded**—The **issu load** command is completed. • **Switching**—The system is executing the **issu run switchover** command. • **Switchover**—The **issu run switchover** command is completed. • **Accepted**—The **issu accept** command is completed. • **Committing**—The system is executing the **issu commit** command. • **Rollbacking**—A rollback is in progress. • **Unknown**—An upgrade is in progress. This value is displayed if you execute the command on an original subordinate member.
Compatibility	Version compatibility: • **Compatible**—Upgrade to a compatible version. • **Incompatible**—Upgrade to an incompatible version. • **Unknown**—No upgrade is in progress.
Work state	Operating status of the device: • **Normal**—The device is operating correctly. • **Independent active**—When you perform an ISSU to an incompatible version, a subordinate member that is upgraded first enters this state. In this state, member devices are not running the same software versions.
Upgrade method	Upgrade mode. The value of this field is fixed at **Card by card**. In this mode, member devices are upgraded one by one.
Upgraded slot	Upgraded members. During a rollback, this field displays **Unknown**.
Current upgrading slot	Members that are being upgraded. During a rollback, this field displays **Unknown**.
Current version list	Versions of currently running images. This field is displayed if no upgrade is taking place.
Current software images	File names of currently running images. This field is displayed if no upgrade is taking place.
Previous version list	Versions of the images that were running on the device before the ISSU. If you execute the command on an original subordinate member while the member is being upgraded to an incompatible version, this field displays **Unknown**.
Previous software images	File names of the images that were running on the device before the ISSU. If you execute the command on an original subordinate member while the member is being upgraded to an incompatible version, this field displays **Unknown**.
Upgrade version list	Versions of the upgrade images. If you execute the command on an original subordinate member while the member is being upgraded to an incompatible version, this field displays **Unknown**.
Upgrade software images	File names of the upgrade images. If you execute the command on an original subordinate member while the member is being upgraded to an incompatible version, this field displays **Unknown**.

display version comp-matrix

Use **display version comp-matrix** to display the recommended ISSU methods.

Syntax

display version comp-matrix file { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> | **patch** *filename*&<1-30> } *

display version comp-matrix file ipe *ipe-filename* [**patch** *filename*&<1-30>]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

boot: Specifies a boot image file.

system: Specifies a system image file.

feature: Specifies a space-separated list of up to 30 feature image files.

patch: Specifies a space-separated list of up to 30 patch image files.

filename: Specifies a .bin file in the *filesystemnameIfilename***.bin** format. The file must be stored in the root directory of a file system on the device. The value string excluding the file system location section (if any) can have a maximum of 63 characters. For more information about specifying a file, see file system management in *Fundamentals Configuration Guide.*

ipe-filename: Specifies an .ipe file in the *filesystemnameIfilename***.ipe** format. The file must be stored in the root directory of a file system on the device. The value string excluding the file system location section (if any) can have a maximum of 63 characters. For more information about specifying a file, see file system management in *Fundamentals Configuration Guide.*

Usage guidelines

If one or more images are incompatible, the incompatible upgrade method applies. The entire system needs to be rebooted during an incompatible upgrade.

Examples

Display the recommended ISSU methods. In this example, the specified images are compatible with the running images.

```
<Sysname> display version comp-matrix file boot flash:/boot-t0001015.bin system
flash:/system-t0001015.bin feature flash:/feature1-t0001015.bin
Verifying the file flash:/boot-t0001015.bin on slot 1.....Done.
Verifying the file flash:/system-t0001015.bin on slot 1.....Done.
```

```
Verifying the file flash:/feature1-t0001015.bin on slot 1.....Done.

  Slot     Upgrade Way
  1        File Upgrade
```

Table 5 Command output

Field	Description
Verifying the file	The system was verifying the validity of the file.
Influenced service according to following table	Services that will be affected by the upgrade. This field is displayed only for compatible versions.
Incompatible upgrade	You are upgrading the software to an incompatible version.
Upgrade Way	ISSU method: • **Service Upgrade**. • **File Upgrade**. • **Reboot**. This field is displayed only for compatible versions. For more information about ISSU methods, see *Fundamentals Configuration Guide*.

Related commands

`issu load`

install abort

Use **`install abort`** to abort an ongoing activate or deactivate operation.

Syntax

`install abort` [*`job-id`*]

Views

User view

Predefined user roles

network-admin

Parameters

`job-id`: Specifies the job ID of an ISSU operation. If you do not specify this argument, the command aborts all ongoing software image activate and deactivate operations.

Usage guidelines

The system creates a software image management job each time you use the **`install activate`**, **`install add`**, **`install commit`**, **`install deactivate`**, **`install remove`**, or **`install rollback to`** command. Each job represents one command and is assigned a unique job ID. To obtain the ID of a job, use the **`display install job`** command.

When you abort an ongoing activate or deactivate operation, the system rolls back to the status it was in before the operation was started.

Examples

Abort all ongoing software image activate and deactivate operations.

```
<Sysname> install abort
```

Related commands

display install job

install activate

Use **install activate** to activate software images, or identify the ISSU method and the possible impact on the device.

Syntax

install activate { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> } * **slot** *slot-number* [**test**]

install activate patch *filename* { **all** | **slot** *slot-number* }

Views

User view

Predefined user roles

network-admin

Parameters

boot: Specifies a boot image file.

system: Specifies a system image file.

feature: Specifies a space-separated list of up to 30 feature image files

patch: Specifies a patch image file. You can specify only one patch image file for the command at a time. However, you can execute the command multiple times to activate multiple patch image files. You can specify both incremental and non-incremental patch image files. The device can use a maximum of 30 incremental patch image files. Because the boot, system, and feature images each can have one non-incremental patch image file, the device can use a maximum of 16 non-incremental patch image files. For more information about incremental and non-incremental patch image files, see software upgrade in *Fundamentals Configuration Guide*.

filename: Specifies a .bin file in the *filesystemnameIfilename***.bin** format. The file must be stored in the root directory of a file system on the device. The value string excluding the file system location section (if any) can have a maximum of 63 characters. For more information about specifying a file, see file system management in *Fundamentals Configuration Guide.*

all: Specifies all member devices.

slot *slot-number*: Specifies an IRF member device by its member ID.

test: Only identifies the ISSU method to be used for the upgrade. If you do not specify this keyword, the command activates the specified software images.

Usage guidelines

Before you use this command to activate a software image, read the release notes to identify the licensing requirements for the image. If the image requires a license, make sure the device has a valid license installed for the image.

Images run in memory immediately after they are activated. However, only images activated by using the **install activate patch** *filename* **all** command still run in memory after a reboot. For other images to take effect after a reboot, you must commit the software change by using the **install commit** command.

If the specified files are not stored on the member device to be upgraded, the command copies the images to the member device automatically.

At reboot, a subordinate device automatically synchronizes the master device's configuration and status data. You must wait for the synchronization to complete before using the **install activate** command on the subordinate device. To identify whether the synchronization is complete, use the **display system stable state** command. The synchronization is complete if the **System State** field displays **Stable**.

Examples

Identify the ISSU method for feature upgrade with **feature1.bin** on subordinate member 2 and the upgrade impact.

```
<Sysname> install activate feature flash:/feature1.bin slot 2 test
Copying file flash:/feature1.bin to slot2#flash:/feature1.bin......Done.
Verifying the file flash:/feature1.bin on slot 2.....Done.
Upgrade summary according to following table:

flash:/feature1.bin
  Running Version             New Version
  Test 0001015                Test 0001016

  Slot                        Upgrade Way
  2                           Reboot

Influenced service according to following table:
flash:/feature1.bin
     Feature1
```

The output shows that a reboot upgrade is recommended.

Activate the system image in **system.bin** and the feature images in **feature1.bin** on member device 2.

```
<Sysname> install activate system flash:/system.bin feature flash:/feature1.bin slot 2
Copying file flash:/system.bin to slot2#flash:/system.bin......Done.
Verifying the file flash:/system.bin on slot 2.....Done.
Copying file flash:/feature1.bin to slot2#flash:/feature1.bin......Done.
Verifying the file flash:/feature1.bin on slot 2.....Done.
Upgrade summary according to following table:

flash:/system.bin
  Running Version             New Version
  Test 0001015                Test 0001016

flash:/feature1.bin
  Running Version             New Version
  None                        Test 0001016

  Slot                        Upgrade Way
  2                           Service Upgrade
Upgrading software images to compatible versions. Continue? [Y/N]:y
This operation might take several minutes, please wait...Done.
```

Table 6 Command output

Field	Description
Verifying the file	The system was verifying the validity of the file.
Upgrade summary according to following table	Upgrade summary.
Running Version	Version number of the running software.
New Version	Version number of the new software.
Upgrade Way	ISSU methods: • **Service Upgrade**. • **File Upgrade**. • **Reboot**. This field is displayed only for an upgrade to a compatible version. For more information about ISSU methods, see *Fundamentals Configuration Guide*.
Influenced service according to following table	Services influenced by the upgrade.

Related commands

`display install active`

`install commit`

`install deactivate`

install add

Use **`install add`** to decompress an .ipe file.

Syntax

`install add` *`ipe-filename filesystem`*

Views

User view

Predefined user roles

network-admin

Parameters

`ipe-filename`: Specifies an .ipe file in the *filesystemnameIfilename***.ipe** format. The file must be stored in the root directory of a file system on the device. The value string excluding the file system location section (if any) can have a maximum of 63 characters. For more information about specifying a file, see file system management in *Fundamentals Configuration Guide.*

`filesystem`: Specifies the destination file system for the software images, in the *filesystemname* format.

Usage guidelines

To use the **`install activate`** command to activate software images, you must use .bin image files. If the upgrade file is an .ipe file, use this command to decompress the .ipe file before you start the upgrade.

To identify software images that are included in an .ipe file, use the **display install ipe-info** command.

Examples

Decompress **all.ipe** to the flash memory.

```
<Sysname> install add flash:/all.ipe flash:
Verifying the file flash:/all.ipe on slot 1...Done.
Decompressing file boot.bin to flash:/boot.bin.....................Done.
Decompressing file system.bin to
flash:/system.bin.............................Done.
```

install commit

Use **install commit** to commit software changes.

Syntax

install commit

Views

User view

Predefined user roles

network-admin

Usage guidelines

Before you use this command, read the release notes to identify software image licensing requirements. Make sure the device has valid licenses for all license-based images.

This command adds the patch image file to the startup software image list that the device used at startup.

- If the device used the main startup software image list at startup, this command adds the patch image file to the main startup software image list.
- If the device used the backup startup software image list at startup, this command adds the patch image file to the backup startup software image list.

You must execute this command after using the following commands:

- The **install activate** command in an incremental upgrade.
- The **install deactivate** command.
- The **install rollback** command.

In a reboot or ISSU reboot upgrade, the **install activate** command modifies both the current and startup software image lists. You do not need to commit software changes.

Both the **install commit** and **boot-loader file** commands modify the main startup software image list. To modify the backup startup image list or add inactive images as main startup images, however, you must use the **boot-loader file** command.

For more information about main and backup startup software images, see *Fundamentals Configuration Guide*.

Examples

Commit software changes.

```
<Sysname> install commit
This operation will take several minutes, please wait.........................Done.
```

Related commands

install activate

install deactivate

install rollback

install deactivate

Use **install deactivate** to deactivate feature images and patch images.

Syntax

install deactivate feature *filename*&<1-30> **slot** *slot-number*

install deactivate patch *filename* { **all** | **slot** *slot-number* }

Views

User view

Predefined user roles

network-admin

Parameters

feature: Specifies a space-separated list of up to 30 feature image files.

patch: Specifies a patch image file. You can specify only one patch image file for the command at a time. However, you can execute the command multiple times to deactivate multiple patch image files.

filename: Specifies a .bin file in the *filesystemname*/*filename*.**bin** format. The value string can have a maximum of 63 characters. The file system name cannot contain file system location information. For more information about specifying a file, see file system management in *Fundamentals Configuration Guide.*

all: Specifies all member devices on which the specified patch image file has been activated.

slot *slot-number*: Specifies an IRF member device by its member ID.

Usage guidelines

At reboot, a subordinate device automatically synchronizes the master device's configuration and status data. You must wait for the synchronization to complete before using the **install deactivate** command on the subordinate device. To identify whether the synchronization is complete, use the **display system stable state** command. The synchronization is complete if the **System State** field displays **Stable**.

You can deactivate only active feature and patch images.

Images deactivated by using the **install deactivate patch** *filename* **all** command do not run after a reboot. To prevent other deactivated images from running after a reboot, you must commit the software change by using the **install commit** command.

Examples

Deactivate the patch images in the **route-patch.bin** file for a slot.

```
<Sysname> install deactivate patch flash:/route-patch.bin slot 1
This operation might take several minutes, please wait...Done.
```

Related commands

display install active

display install inactive

install remove

Use **install remove** to delete an inactive software image file.

Syntax

install remove [**slot** *slot-number*] { *filename* | **inactive** }

Views

User view

Predefined user roles

network-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command deletes inactive software images from all IRF members.

filename: Specifies a .bin file in the *filesystemnameIfilename***.bin** format. The value string can have a maximum of 63 characters. The file must be stored in the root directory of a file system on the device. The file system name cannot contain file system location information. For more information about specifying a file, see file system management in *Fundamentals Configuration Guide.*

inactive: Deletes all inactive software image files in the root directories of the specified file systems.

Usage guidelines

This command permanently deletes the image files from the device. You cannot use the **install rollback to** command to revert the operation, or use the **install abort** command to abort the operation.

Examples

Delete inactive software image file **flash:/feature1.bin**.

```
<Sysname> install remove flash:/feature1.bin
```

install rollback to

Use **install rollback to** to roll back the software to an earlier rollback point.

Syntax

install rollback to { *point-id* | **original** }

Views

User view

Predefined user roles

network-admin

Parameters

point-id: Specifies a rollback point ID. This option is supported only when there are two or more rollback points. To identify available rollback points, use the **display install rollback** command.

original: Rolls back to the status before any activate or deactivate operations were performed.

Usage guidelines

During an incremental upgrade, the system creates a rollback point for each activate or deactivate operation of a boot, system, or feature image. The device supports a maximum of 50 rollback points. The earliest rollback point is deleted if this limit has been reached when a rollback point is created.

During a reboot or ISSU reboot upgrade, the system does not create rollback points. After the upgrade, you can roll back the software only to the status before any activate or deactivate operations were performed.

For a rollback to take effect after a reboot, you must perform a commit operation to update the main startup software image list.

After a commit operation is performed, you cannot perform a rollback.

Patch images do not support rollback.

Examples

Roll back the software to rollback point 1.

```
<Sysname>install rollback to 1
This operation might take several minutes, please wait...Done.
```

Roll back the software to the original software versions and observe the change made by the rollback.

```
<Sysname> display install active
Active packages on slot 1:
  flash:/boot-t0001015.bin
  flash:/system-t0001015.bin
  flash:/feature1-t0001015.bin
<Sysname> display install rollback
Install rollback information 1 on slot 1:
  Updating from no package
         to flash:/feature1-t0001015.bin.
```

The output shows that currently three image files are active but only two of them are confirmed. Image file flash:/feature1-t0001015.bin is not confirmed yet.

```
<Sysname> install rollback to original
This operation might take several minutes, please wait...Done.
<Sysname> display install active
Active packages on slot 1:
  flash:/boot-t0001015.bin
  flash:/system-t0001015.bin
<Sysname> display install committed
Committed packages on slot 1:
  flash:/boot-t0001015.bin
  flash:/system-t0001015.bin
```

The output shows the software has been rolled back to the original version. Image file flash:/feature1-t0001015.bin has been removed.

Related commands

`display install rollback`

install verify

Use **`install verify`** to verify the software change commit status, image integrity, and image consistency.

Syntax

`install verify`

Views

User view

Predefined user roles

network-admin

Usage guidelines

To ensure a successful ISSU and make sure that the system can start up and operate correctly after an ISSU, execute this command to verify the following items:

- **Integrity**—Verify that the boot, system, and feature images are integral.
- **Consistency**—Verify that the same active images are running across the entire system.
- **Software commit status**—Verify that the active images are committed as needed.

If a software image fails the verification, perform the following tasks to resolve the problem:

- To ensure software integrity, download and install the software images again.
- To guarantee software image consistency or change software commit status, use the **`install activate`**, **`install deactivate`**, and **`install commit`** commands as appropriate.

Examples

Verify the software change confirmation status and software image integrity and consistency.

```
<Sysname> install verify
Active packages on slot 1 are the reference packages.
Packages will be compared with the reference packages.
This operation will take several minutes, please wait...
  Verifying packages on slot 1:
  Start to check active package completeness.
Verifying the file flash:/boot-t0001015.bin on slot 1.....................Done.
    flash:/boot-t0001015.bin verification successful.
Verifying the file flash:/system-t0001015.bin on slot 1.....................Done.
    flash:/system-t0001015.bin verification successful.
  Start to check active package consistency.
    Active packages are consistent with committed packages on their own board.
    Active packages are consistent with the reference packages.
  Verifying packages on slot 2:
  Start to check active package completeness.
Verifying the file flash:/boot-t0001015.bin on slot 2.....................Done.
    flash:/boot-t0001015.bin verification successful.
Verifying the file flash:/system-t0001015.bin on slot 2.....................Done.
    flash:/system-t0001015.bin verification successful.
  Start to check active package consistency.
    Active packages are consistent with committed packages on their own board.
    Active packages are consistent with the reference packages.
Verification is done.
```

issu accept

Use **issu accept** to accept the upgrade to a compatible version and delete the automatic rollback timer.

Syntax

issu accept

Views

User view

Predefined user roles

network-admin

Usage guidelines

The system cannot perform automatic rollback for the ISSU process after you execute this command. However, you can use the **issu rollback** command to perform a manual rollback.

The **issu accept** command does not apply to an ISSU to an incompatible version.

Examples

Accept the upgrade to a compatible version.

```
<Sysname> issu accept
```

Related commands

issu load

issu run switchover

issu commit

Use **issu commit** to upgrade the original master and the subordinate members that have not been upgraded and complete the ISSU upgrade.

Syntax

issu commit slot *slot-number*

Views

User view

Predefined user roles

network-admin

Parameters

slot *slot-number*: Specifies the member ID of the original master or a subordinate member that has not been upgraded.

Usage guidelines

CAUTION:

Use this command to upgrade the original master and the subordinate members that have not been upgraded, one by one. You must wait for one upgraded member to start up again and join the IRF fabric before upgrading another member. The ISSU process cannot be rolled back automatically or manually after you execute this command. After all members are upgraded, the ISSU status changes to Init.

At reboot, a subordinate device automatically synchronizes the master device's configuration and status data. You must wait for the synchronization to complete before using the **issu commit** command on the subordinate device. To identify whether the synchronization is complete, use the **display system stable state** command. The synchronization is complete if the **System State** field displays **Stable**.

Examples

After member 2 is upgraded and becomes the new master, upgrade the original master (member 3) and the other subordinate members that have not been upgraded (member 4 and member 1).

```
<Sysname> issu commit slot 3
Upgrade summary according to following table:

flash:/feature1.bin
  Running Version             New Version

```

For information about the command output, see Table 5.

Related commands

issu accept

issu load

issu run switchover

issu load

Use **issu load** to upgrade the software images of subordinate members and configure the new images as main startup software images for those members.

Syntax

issu load file { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> | **patch** *filename*&<1-30> } * **slot** *slot-number*&<1-9> [**reboot**]

issu load file ipe *ipe-filename* **slot** *slot-number*&<1-9> [**patch** *filename*&<1-30>] [**reboot**]

Views

User view

Predefined user roles

network-admin

Parameters

boot: Specifies a boot image file.

system: Specifies a system image file.

feature: Specifies a space-separated list of up to 30 feature image files.

patch: Specifies a space-separated list of up to 30 patch image files. You can specify both incremental and non-incremental patch image files. The device can use a maximum of 30 incremental patch image files. Because the boot, system, and feature images each can have one non-incremental patch image file, the device can use a maximum of 16 non-incremental patch image files. For more information about incremental and non-incremental patch image files, see software upgrade in *Fundamentals Configuration Guide*.

filename: Specifies a .bin file in the *filesystemnameIfilename***.bin** format. The file must be stored in the root directory of a file system on the master device. The value string excluding the file system location section (if any) can have a maximum of 63 characters. For more information about specifying a file, see file system management in *Fundamentals Configuration Guide.*

ipe-filename: Specifies an .ipe file in the *filesystemnameIfilename***.ipe** format. The file must be stored in the root directory of a file system on the master device. The value string excluding the file system location section (if any) can have a maximum of 63 characters. For more information about specifying a file, see file system management in *Fundamentals Configuration Guide.*

slot *slot-number*: Specifies the member ID of a subordinate member. You can specify a space-separated list of up to nine member IDs. On a single-chassis IRF fabric, enter the member ID of the member device to upgrade the entire fabric. On a multichassis IRF fabric, you can specify only one member ID for a compatible upgrade and can specify multiple member IDs for an incompatible upgrade. As a best practice, specify half of the subordinate members if the member devices form a ring. Make sure the specified subordinate members are directly connected by physical links.

reboot: Uses the reboot method for the upgrade. For an incremental upgrade or ISSU reboot upgrade, specify this keyword if you want to use the reboot upgrade method. If you do not specify this keyword, the recommended upgrade method is used.

Usage guidelines

NOTE:

The software images for the device are digitally signed. The system verifies the digital signatures of

the specified software images for authenticity and integrity before it sets or loads them as main startup images. If the digital signature verification fails, the system will not set or load the specified images as main startup images and you will receive a digital signature verification failure message.

You may upgrade all or some of the software images. If you are upgrading only some of the images, make sure the new images are compatible with the images that are not to be upgraded. The upgrade will fail if a conflict exists.

This command performs the following operations:

- Checks the version compatibility.
- Identifies the upgrade method.
- Loads the new images to upgrade the member devices.
- Sets the new images as the main startup software images so the upgrade can survive a reboot.

At reboot, a subordinate device automatically synchronizes the master device's configuration and status data. You must wait for the synchronization to complete before using the **issu load** command on the subordinate device. To identify whether the synchronization is complete, use the **display system stable state** command. The synchronization is complete if the **System State** field displays **Stable**.

Examples

Upgrade member device 2 (a subordinate member) with feature image file **flash:/feature1.bin**. (In this example, the image is compatible with the running images.)

```
<Sysname> issu load file feature flash:/feature1.bin slot 2
This operation will delete the rollback point information for the previous upgrade and maybe get unsaved configuration lost. Continue? [Y/N]:Y
Verifying the file flash:/feature1.bin on slot 1...Done.

Field	Description
Verifying the file	The system was verifying the validity of the file.
Copying file	The system was copying the upgrade file to a subordinate member. This field is displayed if you specified a subordinate member for the command.
Upgrade Way	ISSU method: • **Service Upgrade**. • **File Upgrade**. • **Reboot**. This field is displayed only for an upgrade to a compatible version. For more information about ISSU methods, see *Fundamentals Configuration Guide*.

issu quit

Use **issu quit** to terminate the ongoing ISSU process forcibly.

Syntax

issu quit

Views

System view

Predefined user roles

network-admin

Usage guidelines

Use this command to terminate the ISSU process if one of the following exceptions occurs and you cannot perform an upgrade or rollback:

- The ISSU status is not **Init** but the upgrade has stopped.
- The ISSU status is **Init** but the upgrade has not completed.

After using this command to terminate the ISSU process, identify whether the requirements for an ISSU are met. If yes, use **boot-loader** or **install** commands as needed to restore the device to the state prior to the terminated ISSU and then try an ISSU again. If the ISSU fails again, contact the technical support.

Examples

Terminate the ongoing ISSU process forcibly.

```
<Sysname> system-view
[Sysname] issu quit
This command stops the ongoing ISSU process. Execute this command only under the guidance
of the technical support. Continue? [Y/N]:y

Succeeded.
```

Related commands

install activate

issu load

issu rollback

Use **issu rollback** to cancel the ISSU and roll back to the original software versions.

Syntax

issu rollback

Views

User view

Predefined user roles

network-admin

Usage guidelines

The device supports automatic rollback and manual rollback. This command performs a manual rollback.

You can perform a manual rollback while an ISSU is in one of the following states:

- Loaded.
- Switching (during an upgrade to a compatible version).
- Switchover (during an upgrade to a compatible version).

- Accepted.

As a best practice, do not perform a manual rollback while an ISSU is in Switching state and specify a value that is great enough for the automatic rollback timer. If a rollback occurs for a reboot ISSU in Switching state or an automatic rollback occurs for an incompatible ISSU in Switching state, you might have the following issues:

- The upgraded subordinate members reboot. If a master/subordinate switchover is in progress, a service outage occurs.
- The rollback cannot ensure that the member devices have the same master/subordinate roles as they have before the ISSU.

Examples

Roll back to the original software versions.

```
<Sysname> issu rollback
This command will quit the ISSU process and roll back to the previous version. Continue? [Y/N]:y
```

Related commands

issu accept

issu commit

issu load

issu run switchover

issu rollback-timer

Use **issu rollback-timer** to set the automatic rollback timer.

Use **undo issu rollback-timer** to restore the default.

Syntax

issu rollback-timer *minutes*

undo issu rollback-timer

Default

The automatic rollback timer is set to 45 minutes.

Views

System view

Predefined user roles

network-admin

Parameters

minutes: Specifies the automatic rollback interval, in the range of 0 to 120 minutes. Setting it to 0 disables automatic rollback.

Usage guidelines

The automatic software version rollback feature is available only during an ISSU to a compatible version when the IRF fabric has multiple members.

The system starts the automatic rollback timer when you execute the **issu run switchover** command in a scenario where automatic rollback is supported. If you do not execute the **issu accept** or **issu commit** command before the timer expires, the system automatically rolls back to the software version used before the ISSU.

Change to the automatic rollback interval does not take effect on the ongoing ISSU process.

Examples

Set the automatic rollback timer to 50 minutes.

```
<Sysname> system-view
[Sysname] issu rollback-timer 50
```

Related commands

issu rollback

issu run switchover

Use **issu run switchover** to perform an ISSU switchover.

Syntax

issu run switchover

Views

User view

Predefined user roles

network-admin

Usage guidelines

Use this command on a multichassis IRF fabric.

- For a compatible upgrade, this command performs operations depending on the ISSU method.
  - **Incremental upgrade**—Performs a process-level master/subordinate switchover for the processes to be upgraded.
  - **Reboot upgrade** or **ISSU upgrade**—Reboots the current master with the old software version, causing the upgraded subordinate member to be elected as the new master.
- For an incompatible upgrade, the **issu load** command splits the IRF fabric into two fabrics, with the upgraded members forming a new fabric. The **issu run switchover** command reboots the members in the old IRF fabric with the upgrade images to upgrade the members. After startup, the members join the new IRF fabric as subordinate members.

At reboot, a subordinate device automatically synchronizes the master device's configuration and status data. You must wait for the synchronization to complete before using the **issu run switchover** command on the subordinate device. To identify whether the synchronization is complete, use the **display system stable state** command. The synchronization is complete if the **System State** field displays **Stable**.

When you execute the **issu run switchover** command during an ISSU to a compatible version, the system starts the automatic rollback timer. If you do not execute the **issu accept** or **issu commit** command before the timer expires, the system automatically rolls back to the original software versions.

Examples

On a multichassis IRF fabric, perform a master/subordinate switchover during an ISSU to a compatible version.

```
<Sysname> issu run switchover
Upgrade summary according to following table:

flash:/feature1.bin
  Running Version             New Version
```

```
  Test 0001015                Test 0001016

  Slot                        Switchover Way
  1                           Active standby process switchover
Upgrading software images to compatible versions. Continue? [Y/N]:y
This operation might take several minutes, please wait...Done.
```

On a multichassis IRF fabric, perform a master/subordinate switchover, and upgrade members that have not been upgraded (member 1 and member 2) during an ISSU to an incompatible version.

```
<Sysname> issu run switchover
Upgrade summary according to following table:

flash:/feature1.bin
  Running Version             New Version
  Test 0001015                Test 0001016

  Slot                        Upgrade Way
  1                           Reboot
  2                           Reboot
Upgrading software images to incompatible versions. Continue? [Y/N]:y
This operation might take several minutes, please wait...Done.
```

Table 8 Command output

Field	Description
Switchover Way	Switchover method: • **Active standby process switchover**—Switch from the active process to the standby process. • **Master subordinate switchover**—Switch from the master to a subordinate member.

For more information about the command output, see Table 5.

Tcl commands

cli

Use **cli** to enable a NF command to be executed in Tcl configuration view when it conflicts with a Tcl command.

Syntax

cli *command*

Views

Tcl configuration view

Predefined user roles

network-admin

context-admin

Parameters

command: Specifies the commands to be executed. They must be complete command lines.

Usage guidelines

In Tcl configuration view, if a NF command conflicts with a Tcl command, the Tcl command will be executed. To execute the NF command when a conflict occurs, execute the **cli** command.

Examples

Perform the following steps to execute a NF command that conflicts with a Tcl command in Tcl configuration view.

1. Execute a NF command in Tcl configuration view. The output shows that the NF command cannot be executed because it conflicts with a Tcl command.

```
<Sysname> tclsh
<Sysname-tcl> system-view
[Sysname-tcl] route-policy 1 permit node 10
[Sysname-tcl-route-policy-1-10] apply cost 10
can't interpret "cost" as a lambda expression
```

2. Configure the **cli** command to execute the NF command again.

```
[Sysname-tcl-route-policy-1-10] cli apply cost 10
```

Execute multiple NF commands in one operation to enter OSPF area view.

Method 1:

```
[Sysname-tcl] cli "ospf 100 ; area 0"
[Sysname-tcl-ospf-100-area-0.0.0.0]
```

Method 2:

```
[Sysname-tcl] cli ospf 100 ; cli area 0
[Sysname-tcl-ospf-100-area-0.0.0.0]
```

tclquit

Use **tclquit** to return from Tcl configuration view to user view.

Syntax

tclquit

Views

Tcl configuration view

Predefined user roles

network-admin

context-admin

Usage guidelines

To return from Tcl configuration view to user view, you can also use the **quit** command.

To return to the upper-level view after you execute NF commands to enter system view or a NF feature view, use the **quit** command.

Examples

Return from Tcl configuration view to user view.

```
<Sysname-tcl> tclquit
<Sysname>
```

Related commands

tclsh

tclsh

Use **tclsh** to enter Tcl configuration view from user view.

Syntax

tclsh

Views

User view

Predefined user roles

network-admin

context-admin

Usage guidelines

In Tcl configuration view, you can execute the following commands:

- All Tcl 8.5 commands.
- NF commands. The Tcl configuration view is equivalent to the user view. You can use NF commands in Tcl configuration view in the same way they are used in user view.

Examples

Enter Tcl configuration view from user view.

```
<Sysname> tclsh
<Sysname-tcl>
```

Related commands

tclquit

Contents

Python commands

exit()

Use **exit()** to exit the Python shell.

Syntax

exit()

Views

Python shell

Predefined user roles

network-admin

context-admin

Usage guidelines

To return to user view from the Python shell, you cannot use the **quit** command. You must use the **exit()** command.

Examples

Exit the Python shell.

```
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>>
>>> exit()
<Sysname>
```

python

Use **python** to enter the Python shell.

Syntax

python

Views

User view

Predefined user roles

network-admin

context-admin

Usage guidelines

In the Python shell, you can use the following items:

- Python 2.7 commands.
- Python 2.7 standard API.
- NF extended API.

Examples

Enter the Python shell.

```
<Sysname> python
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>>
```

python *filename*

Use **python** *filename* to execute a Python script.

Syntax

python *filename* [*param*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

filename: Specifies the name of a Python script on a storage medium of the device. The script name is case sensitive and must use the extension .py. The extension .py is case insensitive.

param: Specifies the parameters to be passed to the script. To enter multiple parameters, use spaces as the delimiter.

Usage guidelines

You cannot perform any operations while you are executing a Python script.

Make sure the statements in the script meet the syntax requirements. The system stops executing a Python script if it finds a statement with syntax errors.

When executing a script, the system uses the defaults for interactive statements. The system does not stop for human input.

Examples

Execute Python script **test.py**.

```
<Sysname> python test.py 1 2
['/flash:/test.py', '1', '2']
```

NSFOCUS Firewall Series

NF Virtual Technologies

Command Reference

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

This command reference describes the commands for configuring virtual technologies features, including IRF, context and Reth interface and redundancy group.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

IRF commands

The following compatibility matrixes show the support of hardware platforms for IRF:

Models	IRF compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

All IRF commands are available only on the default context, except for the commands in Table 1.

Table 1 IRF commands available on both default and non-default contexts

Command category	Commands
Display commands	**display irf link** **display mad**
MAD commands	**mad arp enable** **mad enable** **mad nd enable** **mad exclude interface**

For more information about contexts, see *Virtual Technologies Configuration Guide*.

display irf

Use **display irf** to display IRF fabric information.

Syntax

display irf

Views

Any view

Predefined user roles

network-admin

network-operator

Examples

Display IRF fabric information.

```
<Sysname> display irf
MemberID   Role     Priority    CPU-Mac           Description
   1       Loading  1           00e0-fcbe-3102    F1Num001
 *+2       Master   1           00e0-fcb1-ade2    F1Num002
-------------------------------------------------------

 * indicates the device is the master.
 + indicates the device through which the user logs in.
```

```
The Bridge MAC of the IRF is: 00e0-fc00-1000
Auto upgrade                  : yes
Mac persistent                : always
Domain ID                     : 30
```

Table 2 Command output

Field	Description
MemberID	IRF member ID: • ID of the master is prefixed with an asterisk (*) sign. • ID of the device where you are logged in is prefixed with a plus (+) sign.
Role	Role of the member device in the IRF fabric: • **Standby**—Subordinate device. • **Master**—Master device. • **Loading**—The device is loading software images.
Priority	IRF member priority.
CPU-MAC	MAC address of the CPU in the device.
Description	Description you have configured for the member device. • If no description is configured, this field displays a dashed line (-----). • If the description exceeds the maximum number of characters that can be displayed, an ellipsis (…) is displayed in place of the exceeding text. To display the complete description, use the **`display current-configuration`** command.
Auto upgrade	Status of the software auto-update feature: • **yes**—Enabled. • **no**—Disabled.
MAC persistent	IRF bridge MAC persistence setting: • ***n*** **min**—Bridge MAC address of the IRF fabric remains unchanged for *n* minutes after the address owner leaves. • **always**—Bridge MAC address of the IRF fabric does not change after the address owner leaves. • **no**—Bridge MAC address of the current master replaces the original bridge MAC address as soon as the owner of the original address leaves.
Domain ID	Domain ID of the IRF fabric. The domain ID you assign to an IRF fabric must uniquely identify the fabric in a multi-IRF fabric network.

Related commands

`display irf configuration`

`display irf topology`

display irf configuration

Use **`display irf configuration`** to display basic IRF settings for each member device.

Syntax

`display irf configuration`

Views

Any view

Predefined user roles

network-admin

network-operator

Examples

Display basic IRF settings for all members.

```
<Sysname> display irf configuration
 MemberID  NewID    IRF-Port1                  IRF-Port2
 1         1        Ten-GigabitEthernet1/0/1   Ten-GigabitEthernet1/0/2
 2         2        Ten-GigabitEthernet2/0/1   Ten-GigabitEthernet2/0/2
```

Table 3 Command output

Field	Description
MemberID	Current member ID of the device.
NewID	Member ID assigned to the device. This member ID takes effect at reboot.
IRF-Port1	Physical interfaces bound to IRF-port 1. This field displays **disable** if no physical interfaces are bound to the IRF port.
IRF-Port2	Physical interfaces bound to IRF-port 2. This field displays **disable** if no physical interfaces are bound to the IRF port.

Related commands

display irf

display irf topology

display irf link

Use **display irf link** to display IRF link information.

Syntax

display irf link

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display IRF link information.

```
<Sysname> display irf link
Member 1
 IRF Port    Interface                     Status
 1           disable                       --
 2           Ten-GigabitEthernet1/0/1      UP
             Ten-GigabitEthernet1/0/2      ADM
```

```
             Ten-GigabitEthernet1/0/3           DOWN
Member 2
 IRF Port    Interface                          Status
 1           Ten-GigabitEthernet2/0/1           UP
             Ten-GigabitEthernet2/0/2           DOWN
             Ten-GigabitEthernet2/0/3           ADM
 2           disable                            --
```

Table 4 Command output

Field	Description
Member *ID*	IRF member ID.
IRF Port	IRF port number: • **1**—IRF-port 1. • **2**—IRF-port 2.
Interface	Physical interfaces bound to the IRF port. This field displays **disable** if no physical interfaces have been bound to the IRF port.
Status	Link state of the IRF physical interface: • **UP**—The link is up. • **DOWN**—The link is down. • **ADM**—The interface has been manually shut down by using the **shutdown** command. • **ABSENT**—Interface module or expansion interface card that hosts the interface is not present.

display irf topology

Use **display irf topology** to display IRF fabric topology information.

Syntax

display irf topology

Views

Any view

Predefined user roles

network-admin

network-operator

Examples

Display the IRF fabric topology.

```
<Sysname> display irf topology
                          Topology Info
 -------------------------------------------------------------------------
              IRF-Port1                 IRF-Port2
 MemberID   Link        neighbor      Link        neighbor     Belong To
 1          DOWN        ---           UP          2            000f-cbb8-1a82
 2          UP          1             DIS         ---          000f-cbb8-1a82
```

Table 5 Command output

Field	Description
IRF-Port1	Information about IRF-port 1, including its link state and neighbor.
IRF-Port2	Information about IRF-port 2, including its link state and neighbor.
MemberID	IRF member ID.

Link	Link state of the IRF port:
	• **UP**—The IRF link is up.
	• **DOWN**—The IRF link is down because the port has no physical link or has not been activated by the **irf-port-configuration active** command.
	• **DIS**—No physical interfaces have been bound to the IRF port.
	• **TIMEOUT**—IRF hello interval has timed out.
	• **ISOLATE**—The device is isolated from the IRF fabric. This issue might be caused by the following reasons:
	  ○ The IRF fabric does not support the device model.
	  ○ The maximum number of member devices has exceeded the upper limit.

neighbor	IRF member ID of the device connected to the IRF port. This field displays three hyphens (---) if no device is connected to the port.
Belong To	IRF fabric that has the device, represented by the CPU MAC address of the master in the IRF fabric.

Related commands

display irf

display irf configuration

display irf-port load-sharing mode

Use **display irf-port load-sharing mode** to display IRF link load sharing mode.

Syntax

display irf-port load-sharing mode [**irf-port** [*member-id/irf-port-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

irf-port: Displays IRF port-specific load sharing modes. If you do not specify this keyword, the command displays the global load sharing mode for IRF links.

member-id/irf-port-number: Specifies an IRF port number. The *member-id* argument represents an IRF member ID. The *irf-port-number* argument represents the index number (1 or 2) of the IRF port on the member device. If you do not specify the *member-id* and *irf-port-number* arguments, this command displays the load sharing mode used on each IRF port in the IRF fabric. If no IRF ports are in up state, this command displays **No IRF link exists**.

Usage guidelines

To display the global load sharing mode for IRF links, execute this command without any keywords or arguments.

To display the load sharing mode used on each IRF port in the IRF fabric, specify the **irf-port** keyword without specifying an IRF port.

To display the load sharing mode used on a specific IRF port, specify both the **irf-port** keyword and the port number of that IRF port.

Examples

Display the global load sharing mode for IRF links. In this example, because no user-defined global load sharing mode has been configured, the default global load sharing mode applies.

```
<Sysname> display irf-port load-sharing mode
irf-port Load-Sharing Mode:
Layer 2 traffic: packet type-based sharing
Layer 3 traffic: packet type-based sharing
```

Display the global load sharing mode for IRF links. In this example, because a global load sharing mode has been configured, the configured mode applies.

```
<Sysname> display irf-port load-sharing mode
irf-port Load-Sharing Mode:
destination-mac address, source-mac address
```

Display the load sharing mode of IRF-port 1/1. In this example, because neither port-specific load sharing mode nor user-defined global load sharing mode has been configured, the default global load sharing mode applies.

```
<Sysname> display irf-port load-sharing mode irf-port 1/1
irf-port1/1 Load-Sharing Mode:
Layer 2 traffic: packet type-based sharing
Layer 3 traffic: packet type-based sharing
```

Display the load sharing mode of IRF-port 1/1 after a load sharing mode is configured on the port.

```
<Sysname> display irf-port load-sharing mode irf-port 1/1
irf-port 1/1 Load-Sharing Mode:
destination-mac address, source-mac address
```

Display the load sharing mode used on each IRF port.

```
<Sysname> display irf-port load-sharing mode irf-port
irf-port 1/2 Load-Sharing Mode:
  destination-ip address,  source-ip address

irf-port 2/1 Load-Sharing Mode:
Layer 2 traffic: destination-mac address, source-mac address
Layer 3 traffic: destination-ip address,  source-ip address
```

Table 6 Command output

Field	Description
irf-port Load-Sharing Mode	Global load sharing mode for IRF links: • If no global IRF link load sharing mode has been configured, the default global load sharing mode applies. • If a user-defined global load sharing mode has been configured, the configured mode applies.

Field	Description
irf-port1/1 Load-Sharing Mode	Link load sharing mode of IRF-port 1/1: • If you have not configured a port-specific load sharing mode, the global IRF link load sharing mode applies. • If you have configured a port-specific load sharing mode, the configured mode applies.
Layer 2 traffic: packet type-based sharing	Default load sharing mode for traffic that has no IP header. By default, packets are distributed based on the load sharing mode automatically selected depending on the packet type.
Layer 3 traffic: packet type-based sharing	Default load sharing mode for non-TCP/-UDP IP packets. By default, packets are distributed based on the load sharing mode automatically selected depending on the packet type.

display mad

Use **display mad** to display MAD status and settings.

Syntax

display mad [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

verbose: Displays detailed MAD information. If you do not specify this keyword, the command only displays whether a MAD mechanism is enabled or disabled.

Examples

Display brief MAD information.

```
<Sysname> display mad
MAD ARP disabled.
MAD ND disabled.
MAD LACP enabled.
MAD BFD enabled.
```

Display detailed MAD information.

```
<Sysname> display mad verbose
Multi-active recovery state: No
Excluded ports (user-configured):
  GigabitEthernet1/0/1
  GigabitEthernet2/0/1
Excluded ports (system-configured):
  GigabitEthernet1/0/2
  GigabitEthernet2/0/2
MAD ARP disabled.
```

```
MAD ND disabled.
MAD LACP enabled interface: Route-Aggregation2
  MAD status                 : Normal
  Member ID       Port                              MAD status
  1               GigabitEthernet1/0/3              Normal
  2               GigabitEthernet2/0/3              Normal
MAD BFD enabled interface: Route-Aggregation2
  MAD status                 : Normal
  Member ID   MAD IP address       Neighbor    MAD status
  1           192.168.1.1/24       2           Normal
  2           192.168.1.2/24       1           Normal
```

Table 7 Command output

Field	Description
MAD ARP disabled.	Status of ARP MAD. This field displays **MAD ARP enabled** if ARP MAD is enabled.
MAD ND disabled.	Status of ND MAD. This field displays **MAD ND enabled** if ND MAD is enabled.
MAD LACP enabled.	Status of LACP MAD. This field displays **MAD LACP disabled** if LACP MAD is disabled.
MAD BFD enabled.	Status of BFD MAD. This field displays **MAD BFD disabled** if BFD MAD is disabled.
Multi-active recovery state	Whether the IRF fabric is in Recovery state: • **Yes**—The IRF fabric is in Recovery state. When MAD detects that an IRF fabric has split into multiple IRF fabrics, it allows one fabric to forward traffic. All the other IRF fabrics are set to the Recovery state. In Recovery state, MAD shuts down all network interfaces in the fabric except for the system- and user-excluded network interfaces. • **No**—The IRF fabric is not in Recovery state. It is active and can forward traffic.
Excluded ports (user-configured)	Network interfaces manually configured to not shut down when the IRF fabric transits to the Recovery state.
Excluded ports (system-configured)	Network interfaces set to not shut down by the system when the IRF fabric transits to the Recovery state. These network interfaces are not manually configured. • IRF physical interfaces. • Member interfaces of a Layer 2 aggregate interface if the aggregate interface is excluded from the MAD shutdown action. • Member interfaces of a Layer 3 aggregate interface if the aggregate interface is excluded from the MAD shutdown action.
MAD ARP enabled interface:	Interfaces on which ARP MAD is enabled. This field displays **MAD ARP disabled** if ARP MAD is disabled.
MAD ND enabled interface:	Interfaces on which ND MAD is enabled. This field displays **MAD ND disabled** if ND MAD is disabled.
MAD LACP enabled interface	Interface on which LACP MAD is enabled. This field is displayed for each interface enabled with LACP MAD. This field displays **MAD LACP disabled** if LACP MAD is disabled.

Field	Description

MAD status	LACP MAD operating status:
	• **Normal**—LACP MAD is operating correctly.
	• **Faulty**—LACP MAD is not operating correctly. Verify the following items:
	  ◦ Verify that the ports on LACP MAD links are up.
	  ◦ Verify that the intermediate device supports extended LACPDUs.
	  ◦ Verify that all member devices have member ports used for LACP MAD.

Member ID Port MAD status	LACP MAD details: • **Member ID**—IRF member ID of a device. • **Port**—Member ports of the aggregate interface used for LACP MAD. • **MAD status**—LACP MAD operating state on a member port. Values include **Normal** and **Faulty**.
MAD BFD enabled interface:	Layer 3 interface on which BFD MAD is enabled. This field displays **MAD BFD disabled** if BFD MAD is disabled.
MAD status	BFD MAD operating status: • **Normal**—BFD MAD is operating correctly. • **Faulty**—BFD MAD is not operating correctly. Check the BFD MAD link for connectivity issues. • **N/A**—BFD MAD link status cannot be detected.

Member ID
MAD IP address
Neighbor
MAD status
	BFD MAD details:
	• **Member ID**—IRF member ID of the local device.
	• **MAD IP address**—MAD IP address of a member device.
	• **Neighbor**—IRF member ID of the neighboring member device.
	• **MAD status**—BFD MAD link state. Available states:
	  ◦ **Normal**—BFD MAD is operating correctly.
	  ◦ **Faulty**—BFD MAD is not operating correctly. Check the BFD MAD link for connectivity issues.

easy-irf

Use **easy-irf** to bulk-configure basic IRF settings for an IRF member device.

Syntax

easy-irf [**member** *member-id* [**renumber** *new-member-id*] **domain** *domain-id* [**priority** *priority*] [**irf-port1** *interface-list1*] [**irf-port2** *interface-list2*]]

Views

System view

Predefined user roles

network-admin

Parameters

member *member-id*: Specifies the member ID of a member device. The member ID can be 1 or 2.

renumber *new-member-id*: Specifies a new member ID for the device. The member ID can be 1 or 2. The member device automatically reboots for the new member ID to take effect. If you do not specify this option, the command does not change the member ID.

domain *domain-id*: Specifies an IRF domain ID in the range of 0 to 4294967295. Assign the same domain ID to all devices you are adding to the same IRF fabric.

priority *priority*: Specifies an IRF priority in the range of 1 to 32. The greater the priority value, the higher the priority. A member with higher priority is more likely to be the master.

irf-port1 *interface-list1*: Specifies interfaces bound to IRF-port 1. The *interface-list1* argument represents a space-separated list of up to *n* interface items. Each interface item specifies one interface in the *interface-type interface-number* form.

irf-port2 *interface-list2*: Specifies interfaces bound to IRF-port 2. A physical interface can be bound to only one IRF port. The *interface-list2* argument represents a space-separated list of up to *n* interface items. Each interface item specifies one interface in the *interface-type interface-number* form.

The following compatibility matrixes show the values for the *n* argument in the **irf-port1** *interface-list1* and **irf-port2** *interface-list2* options:

Models	Value for the n argument (maximum number of physical interfaces for each IRF port)
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	8
NFNX3-HDB680, NFNX3-HDB1080	Not supported

Usage guidelines

This command bulk-configures basic IRF settings for a member device, including the member ID, domain ID, priority, and IRF port bindings.

The easy IRF feature provides the following configuration methods:

- **Interactive method**—Enter the **easy-irf** command without parameters. The system will guide you to set the parameters step by step.
- **Non-interactive method**—Enter the **easy-irf** command with parameters.

As a best practice, use the interactive method if you are new to IRF.

If you execute this command multiple times, the following settings take effect:

- The most recent settings for the member ID, domain ID, and priority.
- IRF port bindings added through repeated executions of the command.

When you specify physical interfaces for an IRF port, you must follow the IRF port binding requirements in *Virtual Technologies Configuration Guide*.

If you specify physical interfaces by using the interactive method, you must also follow these restrictions and guidelines:

- Do not enter spaces between the interface type and interface number.
- Use a comma (,) to separate two physical interfaces. No spaces are allowed between interfaces.

To remove an IRF physical interface from an IRF port, you must use the **undo port group interface** command in IRF port view.

Examples

Bulk-configure basic IRF settings by using the non-interactive method. Change the member ID from 2 to 1, set the domain ID to 10, configure the member priority as 10, and bind Ten-GigabitEthernet 2/0/1 and Ten-GigabitEthernet 2/0/2 to IRF-port 1.

```
<Sysname> system-view
```

```
[Sysname] easy-irf member 2 renumber 1 domain 10 priority 10 irf-port1 ten-gigabitethernet
2/0/1 ten-gigabitethernet 2/0/2

irf auto-update enable

Use **irf auto-update enable** to enable the software auto-update feature.

Use **undo irf auto-update enable** to disable the software auto-update feature.

Syntax

irf auto-update enable

undo irf auto-update enable

Default

Software auto-update is enabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

This command automatically propagates the current software images of the master device in the IRF fabric to any devices you are adding to the IRF fabric.

To ensure a successful software update, verify that the new device you are adding to the IRF fabric has sufficient storage space for the new software images. If sufficient storage space is not available, the device automatically deletes the current software images. If the reclaimed space is still insufficient, the device cannot complete the auto-update. You must reboot the device, and then access the BootWare menu to delete files.

Examples

Enable the software auto-update feature.

```
<Sysname> system-view
[Sysname] irf auto-update enable
```

irf domain

Use **irf domain** to assign a domain ID to the IRF fabric.

Use **undo irf domain** to restore the default.

Syntax

irf domain *domain-id*

undo irf domain

Default

The IRF domain ID is 0.

Views

System view

Predefined user roles

network-admin

Parameters

domain-id: Specifies a domain ID for the IRF fabric. The value range is 0 to 4294967295.

Usage guidelines

CAUTION:

Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the remaining member devices in the IRF fabric.

One IRF fabric forms one IRF domain. IRF uses IRF domain IDs to uniquely identify IRF fabrics and prevent IRF fabrics from interfering with one another.

If one IRF fabric uses another IRF fabric as the intermediate device for LACP MAD, ARP MAD, or ND MAD, you must assign the two IRF fabrics different domain IDs for correct split detection. False detection causes IRF split.

An IRF fabric has only one IRF domain ID. You can change the IRF domain ID by using the following commands: **irf domain**, **mad enable**, **mad arp enable**, or **mad nd enable**. The IRF domain IDs configured by using these commands overwrite each other.

The **irf domain** command is available only on the default context. The **mad enable**, **mad arp enable**, and **mad nd enable** commands are available on all contexts. If you change the IRF domain ID in one context, the IRF domain IDs in all other contexts change automatically.

Examples

Set the IRF domain ID to 10.

```
<Sysname> system-view
[Sysname] irf domain 10
```

irf mac-address persistent

Use **irf mac-address persistent** to configure IRF bridge MAC persistence.

Use **undo irf mac-address persistent** to disable IRF bridge MAC persistence.

Syntax

irf mac-address persistent { **always** | **timer** }

undo irf mac-address persistent

Default

The IRF bridge MAC address remains unchanged for 6 minutes after the address owner leaves.

Views

System view

Predefined user roles

network-admin

Parameters

always: Enables the IRF bridge MAC address to be permanent. The IRF bridge MAC address does not change after the address owner leaves the fabric.

timer: Enables the IRF bridge MAC address to remain unchanged for 6 minutes after the address owner leaves. If the owner rejoins the IRF fabric within the time limit, the IRF bridge MAC address does not change. If the owner does not rejoin the IRF fabric within the time limit, the IRF fabric uses the bridge MAC address of the current master as the bridge MAC address.

Usage guidelines

CAUTION:

IRF bridge MAC address change will cause transient traffic disruption.

If the **undo** form of this command is used, bridge MAC address of the current master replaces the original IRF bridge MAC as soon as the original address owner leaves.

If the IRF fabric uses a daisy-chain topology and has aggregate links with upstream or downstream devices, do not execute the **undo irf mac-address persistent** command. Use of this command might result in transmission delay or packet loss after the address owner leaves or reboots.

If the IRF fabric has multichassis aggregate links, do not use the **undo irf mac-address persistent** command. Use of this command might cause traffic disruption.

By default, an IRF fabric uses the bridge MAC address of the master device as its bridge MAC address.

On a switched LAN, the IRF bridge MAC address must be unique for correct traffic transmission.

When IRF fabrics merge, IRF ignores the IRF bridge MAC address and checks the bridge MAC address of each member device in the IRF fabrics. IRF merge fails if any two member devices have the same bridge MAC address.

Examples

Enable the IRF bridge MAC address to persist forever.

```
<Sysname> system-view
[Sysname] irf mac-address persistent always
```

irf member description

Use **irf member description** to configure a description for an IRF member device.

Use **undo irf member description** to restore the default.

Syntax

irf member *member-id* **description** *text*

undo irf member *member-id* **description**

Default

No description is configured for an IRF member device.

Views

System view

Predefined user roles

network-admin

Parameters

member-id: Specifies the ID of an IRF member.

text: Specifies a description, a string of 1 to 127 characters.

Examples

Configure the description as **F1Num001** for IRF member 1.

```
<Sysname> system-view
[Sysname] irf member 1 description F1Num001
```

irf member priority

Use **irf member priority** to change the priority of an IRF member device.

Use **undo irf member priority** to restore the default.

Syntax

irf member *member-id* **priority** *priority*

undo irf member *member-id* **priority**

Default

The IRF member priority is 1.

Views

System view

Predefined user roles

network-admin

Parameters

member-id: Specifies an IRF member ID. The member ID can be 1 or 2.

priority: Sets priority in the range of 1 to 32. The greater the priority value, the higher the priority. A member with higher priority is more likely to be the master.

Usage guidelines

The new priority setting takes effect at the next master election, but it does not trigger a master election.

Examples

Set the priority of IRF member 2 to 32.

```
<Sysname> system-view
[Sysname] irf member 2 priority 32
```

irf member renumber

Use **irf member renumber** to change the member ID of an IRF member device.

Use **undo irf member renumber** to restore the previous IRF member ID of the device.

Syntax

irf member *member-id* **renumber** *new-member-id*

undo irf member *member-id* **renumber**

Default

The IRF member ID is 1.

Views

System view

Predefined user roles

network-admin

Parameters

member-id: Specifies the ID of an IRF member. The IRF member ID can be 1 or 2.

new-member-id: Assigns a new ID to the IRF member. The IRF member ID can be 1 or 2.

Usage guidelines

CAUTION:

IRF member ID change can invalidate member ID-related settings, including interface and file path settings, and cause data loss. Make sure you fully understand its impact on your live network.

To have the new ID take effect, you must reboot the IRF member. To cancel the member ID change before you reboot the member device, use the **undo irf member renumber** command. In the command, set the new member ID to be the same as the old member ID.

When adding a device into an IRF fabric, you must assign a unique IRF member ID to the device. If its IRF member ID has been used in the IRF fabric, the device cannot join the IRF fabric.

Interchanging member IDs between IRF member devices might cause undesirable configuration changes and data loss. For example, the IRF member IDs of Device A and Device B are 2 and 1, respectively. After you interchange their member IDs, their port settings also interchange.

Examples

Change the ID of an IRF member device from 1 to 2.

```
<Sysname> display irf
[Sysname] irf member 1 renumber 2
Renumbering the member ID may result in configuration change or loss. Continue?[Y/N]Y
```

Before rebooting the device, cancel the change in the preceding example.

```
[Sysname] undo irf member 1 renumber
Renumbering the member ID may result in configuration change or loss. Continue?[Y/N]y
```

If you reboot the device after executing the **irf member 1 renumber 2** command, the device member ID changes to 2 at system reboot. Using **undo irf member 1 renumber** cannot restore the member ID to 1. You must use the **irf member 2 renumber 1** command to reconfigure the member ID.

irf-port

Use **irf-port** to enter IRF port view.

Use **undo irf-port** to remove all port bindings on an IRF port.

Syntax

irf-port *member-id/irf-port-number*

undo irf-port *member-id/irf-port-number*

Views

System view

Predefined user roles

network-admin

Parameters

member-id: Specifies an IRF member device by its member ID.

irf-port-number: Specifies an IRF port on the member device. The *irf-port-number* argument represents the IRF port index and must be 1 or 2.

Usage guidelines

To bind physical interfaces to an IRF port, you must enter IRF port view.

Examples

Enter IRF-port 2/1 view.

```
<Sysname> system-view
[Sysname] irf-port 2/1
[Sysname-irf-port2/1]
```

Related commands

port group interface

irf-port global load-sharing mode

Use **irf-port global load-sharing mode** to set the global load sharing mode for IRF links.

Use **undo irf-port global load-sharing mode** to restore the default.

Syntax

irf-port global load-sharing mode { **destination-ip** | **destination-mac** | **source-ip** | **source-mac** } *

undo irf-port global load-sharing mode

Default

Packets are distributed based on the load sharing mode automatically selected depending on the packet type.

Views

System view

Predefined user roles

network-admin

Parameters

destination-ip: Distributes traffic across IRF member links based on destination IP address.

destination-mac: Distributes packets across IRF member links based on destination MAC address.

source-ip: Distributes packets across IRF member links based on source IP address.

source-mac: Distributes packets across IRF member links based on source MAC address.

Usage guidelines

The global IRF link load sharing mode applies to all IRF ports in the IRF fabric. You can also configure a port-specific load sharing mode for an IRF port in IRF port view by using the **irf-port load-sharing mode** command.

An IRF port preferentially uses the port-specific load sharing mode. If no port-specific load sharing mode is available, the port uses the global load sharing mode.

You can configure the sharing mode to include a combination of multiple criteria for making traffic distribution decisions. If your device does not support a criterion combination, the system displays an error message.

If you configure the global load sharing mode multiple times, the most recent configuration takes effect.

Examples

Configure the global IRF link load sharing mode to distribute traffic based on destination MAC address.

```
<Sysname> system-view
[Sysname] irf-port global load-sharing mode destination-mac
```

Related commands

irf-port load-sharing mode

irf-port load-sharing mode

Use **irf-port load-sharing mode** to configure a port-specific load sharing mode for an IRF port to distribute traffic across its physical links.

Use **undo irf-port load-sharing mode** to restore the default.

Syntax

irf-port load-sharing mode { **destination-ip** | **destination-mac** | **source-ip** | **source-mac** } *

undo irf-port load-sharing mode

Default

Packets are distributed based on the load sharing mode automatically selected depending on the packet type.

Views

IRF port view

Predefined user roles

network-admin

Parameters

destination-ip: Distributes traffic across IRF member links based on destination IP address.

destination-mac: Distributes packets across IRF member links based on destination MAC address.

source-ip: Distributes packets across IRF member links based on source IP address.

source-mac: Distributes packets across IRF member links based on source MAC address.

Usage guidelines

To successfully configure a port-specific load sharing mode for an IRF port, make sure you have bound a minimum of one physical interface to the IRF port.

You can configure an IRF port-specific load sharing mode to include a combination of multiple criteria for making traffic distribution decisions. If your device does not support a criterion combination, the system displays an error message.

If you configure the port-specific load sharing mode multiple times on an IRF port, the most recent configuration takes effect.

An IRF port preferentially uses the port-specific load sharing mode. If no port-specific load sharing mode is available, the port uses the global load sharing mode.

Examples

Configure a port-specific load sharing mode for IRF-port 1/1 to distribute traffic based on destination MAC address.

```
<Sysname> system-view
[Sysname] irf-port 1/1
[Sysname-irf-port1/1] irf-port load-sharing mode destination-mac
```

Related commands

`irf-port global load-sharing mode`

irf-port-configuration active

Use **`irf-port-configuration active`** to activate IRF ports.

Syntax

`irf-port-configuration active`

Views

System view

Predefined user roles

network-admin

Usage guidelines

After connecting the physical interfaces between two devices and binding them to the correct IRF ports, you must use this command to activate the settings on the IRF ports. This command merges the two devices into one IRF fabric.

The system activates the IRF port settings automatically in the following situations:

- The configuration file that the device starts with contains IRF port bindings.
- You are binding physical interfaces to an IRF port after an IRF fabric is formed.

Examples

To configure and activate IRF-port 1/2 when the port is in DIS state:

Bind a physical interface to IRF-port 1/2.

```
<Sysname> system-view
[Sysname] interface ten-gigabitethernet 1/0/1
[Sysname-Ten-GigabitEthernet1/0/1] shutdown
[Sysname-Ten-GigabitEthernet1/0/1] quit
[Sysname] irf-port 1/2
[Sysname-irf-port1/2] port group interface ten-gigabitethernet 1/0/1
You must perform the following tasks for a successful IRF setup:
Save the configuration after completing IRF configuration.
Execute the "irf-port-configuration active" command to activate the IRF ports.
[Sysname-irf-port1/2] quit
[Sysname] interface ten-gigabitethernet 1/0/1
[Sysname-Ten-GigabitEthernet1/0/1] undo shutdown
[Sysname-Ten-GigabitEthernet1/0/1] quit
```

Save the configuration so the IRF port settings can take effect after the device reboots.

```
[Sysname] save
The current configuration will be written to the device. Are you sure? [Y/N]:y
Please input the file name(*.cfg)[flash:/startup.cfg]
(To leave the existing filename unchanged, press the enter key):
flash:/startup.cfg exists, overwrite? [Y/N]:y
Validating file. Please wait.........................
Saved the current configuration to mainboard device successfully.
```

Activate the IRF port.

```
[Sysname] irf-port-configuration active
```

mad arp enable

Use **mad arp enable** to enable ARP MAD.

Use **undo mad arp enable** to disable ARP MAD.

Syntax

mad arp enable

undo mad arp enable

Default

ARP MAD is disabled.

Views

VLAN interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

Do not configure ARP MAD together with LACP MAD or BFD MAD, because they handle collisions differently.

When you configure ARP MAD, follow these restrictions and guidelines:

Category	Restrictions and guidelines

ARP MAD VLAN	• Do not enable ARP MAD on VLAN-interface 1.
	• If you are using an intermediate device, perform the following tasks:
	  ○ On the IRF fabric and the intermediate device, create a VLAN for ARP MAD.
	  ○ On the IRF fabric and the intermediate device, assign the ports of ARP MAD links to the ARP MAD VLAN.
	  ○ On the IRF fabric, create a VLAN interface for the ARP MAD VLAN.
	• As a best practice, do not use the ARP MAD VLAN for any other purposes.

ARP MAD and feature configuration	If an intermediate device is used, make sure the following requirements are met: • Run the spanning tree feature between the IRF fabric and the intermediate device to ensure that there is only one ARP MAD link in forwarding state. For more information about the spanning tree feature and its configuration, see *Layer 2—LAN Switching Configuration Guide*. • Enable the IRF fabric to change its bridge MAC address as soon as the address owner leaves. • If the intermediate device is also an IRF fabric, assign the two IRF fabrics different domain IDs for correct split detection.

When you use the **mad arp enable** command, the system prompts you to enter a domain ID. If you do not want to change the current domain ID, press **enter** at the prompt.

An IRF fabric has only one IRF domain ID. You can change the IRF domain ID by using the following commands: **irf domain**, **mad enable**, **mad arp enable**, or **mad nd enable**. The IRF domain IDs configured by using these commands overwrite each other.

You can execute the **mad arp enable** command on any contexts. If you change the IRF domain ID in one context, the new IRF domain ID takes effect immediately on all contexts.

Examples

Enable ARP MAD on VLAN-interface 3.

```
<Sysname> system-view
[Sysname] interface vlan-interface 3
[Sysname-Vlan-interface3] mad arp enable
You need to assign a domain ID (range: 0-4294967295)
[Current domain is: 0]: 1
The assigned domain ID is: 1
```

Related commands

irf domain

mad bfd enable

Use **mad bfd enable** to enable BFD MAD.

Use **undo mad bfd enable** to disable BFD MAD.

Syntax

mad bfd enable

undo mad bfd enable

Default

BFD MAD is disabled.

Views

Layer 3 aggregate interface view

Predefined user roles

network-admin

Usage guidelines

Do not configure BFD MAD together with ARP MAD or ND MAD, because they handle collisions differently.

When you configure BFD MAD on a Layer 3 aggregate interface, follow these restrictions and guidelines:

Category	Restrictions and guidelines
BFD MAD-enabled Layer 3 aggregate interface	• Make sure the Layer 3 aggregate interface operates in static aggregation mode. • Make sure the member ports in the aggregation group do not exceed the maximum number of Selected ports allowed for an aggregation group. If the number of member ports exceeds the maximum number of Selected ports, some member ports cannot become Selected. BFD MAD will be unable to work correctly and its state will change to Faulty.

Category	Restrictions and guidelines
BFD MAD VLAN	• On the intermediate device (if any), assign the ports on the BFD MAD links to the same VLAN. Do not assign the ports to an aggregate interface. If the ports are hybrid ports, make sure these ports are untagged members of their PVIDs. • If the intermediate device acts as a BFD MAD intermediate device for multiple IRF fabrics, assign different BFD MAD VLANs to the IRF fabrics. • Do not use the BFD MAD VLAN on the intermediate device for any purposes other than BFD MAD. • Make sure the BFD MAD VLAN on the intermediate device contains only ports on the BFD MAD links. Exclude a port from the BFD MAD VLAN if that port is not on a BFD MAD link. If you have assigned that port to all VLANs by using the **port trunk permit vlan all** command, use the **undo port trunk permit** command to exclude that port from the BFD MAD VLAN.
BFD MAD-enabled Layer 3 aggregate interface and feature compatibility	Use only the **mad bfd enable** and **mad ip address** commands on the BFD MAD-enabled interface. If you configure other features, both BFD MAD and other features on the interface might run incorrectly.
MAD IP address	• To avoid network issues, only use the **mad ip address** command to configure IP addresses on the BFD MAD-enabled interface. Do not configure an IP address by using the **ip address** command on the BFD MAD-enabled interface. • Make sure all the MAD IP addresses are on the same subnet.

Examples

Enable BFD MAD on Route-Aggregation 3.

```
<Sysname> system-view
[Sysname] interface route-aggregation 3
[Sysname-Route-Aggregation3] mad bfd enable
```

mad enable

Use **mad enable** to enable LACP MAD.

Use **undo mad enable** to disable LACP MAD.

Syntax

mad enable

undo mad enable

Default

LACP MAD is disabled.

Views

Aggregate interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

LACP MAD handles collisions differently than ARP MAD and ND MAD. To avoid conflicts, do not enable LACP MAD together with ARP MAD and ND MAD on an IRF fabric.

LACP MAD requires a device that supports extended LACPDUs for MAD to act as the intermediate device. You must set up a dynamic link aggregation group that spans all IRF member devices between the IRF fabric and the intermediate device. To enable dynamic link aggregation, configure the **link-aggregation mode dynamic** command on the aggregate interface.

If one IRF fabric uses another IRF fabric as the intermediate device for LACP MAD, you must assign the two IRF fabrics different domain IDs for correct split detection. False detection causes IRF split.

When you use the **mad enable** command, the system prompts you to enter a domain ID. If you do not want to change the current domain ID, press **enter** at the prompt.

An IRF fabric has only one IRF domain ID. You can change the IRF domain ID by using the following commands: **irf domain**, **mad enable**, **mad arp enable**, or **mad nd enable**. The IRF domain IDs configured by using these commands overwrite each other.

Examples

Enable LACP MAD on Bridge-Aggregation 1, a Layer 2 dynamic aggregate interface.

```
<Sysname> system-view
[Sysname] interface bridge-aggregation 1
[Sysname-Bridge-Aggregation1] link-aggregation mode dynamic
[Sysname-Bridge-Aggregation1] mad enable
You need to assign a domain ID (range: 0-4294967295)
[Current domain is: 0]: 1
The assigned domain ID is: 1
MAD LACP only enable on dynamic aggregation interface.
```

Enable LACP MAD on Route-Aggregation 1, a Layer 3 dynamic aggregate interface.

```
<Sysname> system-view
[Sysname] interface route-aggregation 1
[Sysname-Route-Aggregation1] link-aggregation mode dynamic
[Sysname-Route-Aggregation1] mad enable
You need to assign a domain ID (range: 0-4294967295)
[Current domain is: 0]: 1
The assigned domain ID is: 1
MAD LACP only enable on dynamic aggregation interface.
```

Related commands

irf domain

mad exclude interface

Use **mad exclude interface** to exclude an interface from being shut down when the IRF fabric transits to the Recovery state upon detection of a multi-active collision.

Use **undo mad exclude interface** to configure the IRF fabric to shut down an interface when it transits to the Recovery state upon detection of a multi-active collision.

Syntax

mad exclude interface *interface-type interface-number*

undo mad exclude interface *interface-type interface-number*

Default

All network interfaces on a Recovery-state IRF fabric are shut down, except for the network interfaces automatically excluded by the system.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface-type interface-number: Specifies an interface by its type and number.

Usage guidelines

If an interface must be kept in up state for special purposes such as Telnet connection, exclude the interface from the shutdown action. As a best practice to avoid incorrect traffic forwarding, do not exclude any interfaces except the interfaces used for Telnet.

The interfaces that have been shut down by MAD come up when the member devices reboot to join the recovered IRF fabric. If the active IRF fabric fails before the IRF link is recovered, use the **mad restore** command on the inactive IRF fabric to recover the inactive IRF fabric. This command also brings up all interfaces that were shut down by MAD.

Examples

Exclude GigabitEthernet 1/0/1 from being shut down when the MAD status transits to Recovery.

```
<Sysname> system-view
[Sysname] mad exclude interface gigabitethernet 1/0/1
```

Related commands

mad restore

mad ip address

Use **mad ip address** to assign a MAD IP address to an IRF member device for BFD MAD.

Use **undo mad ip address** to delete the MAD IP address for an IRF member device.

Syntax

mad ip address *ip-address* { *mask* | *mask-length* } **member** *member-id*

undo mad ip address *ip-address* { *mask* | *mask-length* } **member** *member-id*

Default

No MAD IP address is configured for an IRF member device.

Views

VLAN interface view

Layer 3 aggregate interface view

Predefined user roles

network-admin

Parameters

ip-address: Specifies an IP address in dotted decimal notation.

mask: Specifies a subnet mask in decimal dotted notation.

mask-length: Specifies a subnet mask in length, in the range of 0 to 32.

member *member-id*: Specifies the ID of an IRF member.

Usage guidelines

To use BFD MAD, configure a MAD IP address for each IRF member. Make sure all the MAD IP addresses are on the same subnet.

Do not configure a MAD IP address by using the **ip address** command on the BFD MAD-enabled port or interface.

The master attempts to establish BFD sessions with other member devices by using its MAD IP address as the source IP address.

- If the IRF fabric is integrated, only the MAD IP address of the master takes effect. The master cannot establish a BFD session with any other member. If you execute the **display bfd session** command, the state of the BFD sessions is **Down**.
- When the IRF fabric splits, the IP addresses of the masters in the partitioned IRF fabrics take effect. The masters can establish a BFD session. If you execute the **display bfd session** command, the state of the BFD session between the two devices is **Up**.

Examples

Assign a MAD IP address to IRF member 1 on Route-Aggregation 3.

```
<Sysname> system-view
[Sysname] interface route-aggregation 3
[Sysname-Route-Aggregation3] mad ip address 192.168.0.1 255.255.255.0 member 1
```

Assign a MAD IP address to IRF member 2 on Route-Aggregation 3.

```
[Sysname-Route-Aggregation 3] mad ip address 192.168.0.2 255.255.255.0 member 2
```

Related commands

mad bfd enable

mad nd enable

Use **mad nd enable** to enable ND MAD.

Use **undo mad nd enable** to disable ND MAD.

Syntax

mad nd enable

undo mad nd enable

Default

ND MAD is disabled.

context-admin

Usage guidelines

Do not configure ND MAD together with LACP MAD or BFD MAD, because they handle collisions differently.

Do not configure ND MAD on VLAN-interface 1.

If one IRF fabric uses another IRF fabric as the intermediate device for ND MAD, you must assign the two IRF fabrics different domain IDs for correct split detection. False detection causes IRF split.

When you use the **mad nd enable** command, the system prompts you to enter a domain ID. If you do not want to change the current domain ID, press **enter** at the prompt.

An IRF fabric has only one IRF domain ID. You can change the IRF domain ID by using the following commands: **irf domain**, **mad enable**, **mad arp enable**, or **mad nd enable**. The IRF domain IDs configured by using these commands overwrite each other.

You can execute the **mad nd enable** command on any contexts. If you change the IRF domain ID in one context, the new IRF domain ID takes effect immediately on all contexts.

Examples

Enable ND MAD on VLAN-interface 3.

```
<Sysname> system-view
[Sysname] interface vlan-interface 3
[Sysname-Vlan-interface3] mad nd enable
You need to assign a domain ID (range: 0-4294967295)
[Current domain is: 0]: 1
The assigned domain ID is: 1
```

Related commands

irf domain

mad restore

Use **mad restore** to restore the normal MAD state of the IRF fabric in Recovery state.

Syntax

mad restore

Views

System view

Predefined user roles

network-admin

Usage guidelines

If the active IRF fabric has failed to work before the IRF split problem is fixed, use this command to restore an IRF fabric in Recovery state. The recovered IRF fabric will take over the active IRF fabric role.

Examples

Restore the normal MAD state of the IRF fabric in Recovery state.

```
<Sysname> system-view
[Sysname] mad restore
This command will restore the device from multi-active conflict state. Continue? [Y/N]:Y
Restoring from multi-active conflict state, please wait...
```

port group interface

Use **port group interface** to bind a physical interface to an IRF port.

Use **undo port group interface** to remove the binding of a physical interface to an IRF port.

Syntax

port group interface *interface-type interface-number*

undo port group interface *interface-name*

Default

No physical interfaces are bound to an IRF port.

Views

IRF port view

Predefined user roles

network-admin

Parameters

interface-type interface-number: Specifies a physical interface by its type and number.

interface-name: Specifies a physical interface in the *interface-typeinterface-number* format. No space is allowed between the *interface-type* and *interface-number* arguments.

Usage guidelines

CAUTION:

Use the **undo port group interface** command with caution. If the physical interface is the only up member interface of the IRF port, the IRF fabric will split after you remove the binding.

Execute this command multiple times to bind multiple physical interfaces to an IRF port. The following compatibility matrix shows the maximum number of physical interfaces for each IRF port on different hardware platforms:

Models	Maximum number of physical interfaces for each IRF port
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	8
NFNX3-HDB680, NFNX3-HDB1080	Not supported

Use the **shutdown** command to shut down a physical interface before you bind it to or remove it from an IRF port. To bring up the physical interface after a binding or binding removal operation, use the **undo shutdown** command.

The system does not dynamically remove IRF port bindings when IRF links are lost, for example, because an interface card is removed. To remove IRF port bindings, you must use the **undo port group interface** command.

For more information about IRF port binding requirements, see *Virtual Technologies Configuration Guide*.

Examples

Bind Ten-GigabitEthernet 1/0/1 to IRF-port 1/1 on IRF member 1.

```
<Sysname> system-view
[Sysname] interface ten-gigabitethernet 1/0/1
[Sysname-Ten-GigabitEthernet1/0/1] shutdown
[Sysname-Ten-GigabitEthernet1/0/1] quit
[Sysname] irf-port 1/1
[Sysname-irf-port1/1] port group interface ten-gigabitethernet 1/0/1
[Sysname-irf-port1/1] quit
```

```
[Sysname] interface ten-gigabitethernet 1/0/1
[Sysname-Ten-GigabitEthernet1/0/1] undo shutdown
```

Related commands

irf-port

Context commands

The following compatibility matrixes show the support of hardware platforms for context configuration:

Models	Context compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080	Yes
NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	No

Context commands for the default context

This section describes the context commands that you can use after logging in to the default context (the physical device).

allocate interface

Use **`allocate interface`** to assign interfaces to a context.

Use **`undo allocate interface`** to reclaim interfaces assigned to a context.

Syntax

`allocate interface` { *`interface-type interface-number`* }&<1-24> [**`share`**]

`undo allocate interface` { *`interface-type interface-number`* }&<1-24>

`allocate interface` *`interface-type interface-number1`* **`to`** *`interface-type interface-number2`* [**`share`**]

`undo allocate interface` *`interface-type interface-number1`* **`to`** *`interface-type interface-number2`*

Default

All interfaces on the firewall belong to the default context. A non-default context cannot use any interfaces.

Views

Context view

Predefined user roles

network-admin

Parameters

{ *`interface-type interface-number`* }&<1-24>: Assigns 1 to 24 individual interfaces to the context.

`interface-type interface-number1` **`to`** *`interface-type interface-number2`*: Assigns a range of interfaces to the context. The specified interfaces must be the same interface type and must belong to the same interface card.

`share`: Assigns the interfaces in shared mode. If you do not specify this keyword, the command assigns the interfaces exclusively to the context.

Usage guidelines

IMPORTANT:

- Do not assign IRF physical interfaces to a non-default context.
- If a subinterface of a Layer 3 interface is a member interface of a Reth interface, do not assign the Layer 3 interface to a non-default context.
- Logical interfaces support only shared mode, and physical interfaces support both exclusive mode and shared mode.

You can assign interfaces in exclusive or shared mode.

- **Exclusive mode**—You assign an interface exclusively to a context, and only the context can use the interface. The administrator of the context can see the interface and use all commands supported on the interface.
- **Shared mode**—You assign an interface to multiple contexts in shared mode, and the system creates a virtual interface for each context. The virtual interfaces use the same name as the physical interface but have different MAC addresses and IP addresses. They forward and receive packets through the physical interface. The shared mode improves interface usage.

  You can see the physical interface and perform all commands supported on the interface from the default context. The administrator of a context can only see the context's virtual interface and use the **shutdown**, **description**, and network- and security-related commands.

Examples

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to context **sub1** in shared mode.

```
<Sysname> system-view
[Sysname] context sub1
[Sysname-context-2-sub1] allocate interface gigabitethernet 1/0/1 gigabitethernet 1/0/3
share
```

allocate vlan

Use **allocate vlan** to assign VLANs to a context.

Use **undo allocate vlan** to reclaim VLANs assigned to a context.

Syntax

allocate vlan *vlan-id*&<1-24>

undo allocate vlan *vlan-id*&<1-24>

allocate vlan *vlan-id1* **to** *vlan-id2*

undo allocate vlan *vlan-id1* **to** *vlan-id2*

Default

No VLAN is assigned to a context.

Views

Context view

Predefined user roles

network-admin

Parameters

vlan-id&<1-24>: Assigns 1 to 24 individual VLANs to the context.

vlan-id1 **to** *vlan-id2*: Assigns a range of VLANs to the context.

Usage guidelines

You assign static VLANs except for VLAN 1 to contexts without the VLAN-unshared attribute. Before doing so, you must create the VLANs on the default context. A VLAN can be assigned only to one context. After the assignment to a context, you can use only the **display** commands on the context, but you can use all VLAN commands on the default context.

A context with the VLAN-unshared attribute has its own VLAN resources (VLAN 2 through VLAN 4094). It does not share VLAN resources with any other context. To create VLANs for the context, log in to the context and use the **vlan** command. VLAN 1 is system defined. You cannot create or delete VLAN 1.

Examples

Assign VLAN 100 to context **sub1**.

```
<Sysname> system-view
[Sysname] context sub1
[Sysname-context-2-sub1] allocate vlan 100
```

Related commands

display context vlan

capability security-policy-rule maximum

Use **capability security-policy-rule maximum** to set the maximum number of security policy rules for a context.

Use **undo capability security-policy-rule maximum** to restore the default.

Syntax

capability security-policy-rule maximum *max-number*

undo capability security-policy-rule maximum

Default

The number of security policy rules is not limited for a context.

Views

Context view

Predefined user roles

network-admin

Parameters

max-number: Specifies the maximum number of security policy rules for the context, in the range of 1 to 4294967295.

Usage guidelines

A large number of rules occupy too much memory, affecting other features on the context. This command sets the maximum number of security policy rules for a context. When the maximum number is reached, you cannot add new rules.

If the maximum number you set is smaller than the number of existing security policy rules, this setting takes effect. The context does not delete extra existing security policy rules and allows new security policy rules to be created only when the number of security policy rules drops below the maximum number.

Examples

Set the maximum number of security policy rules to 1000 for context **cnt2**.

```
<Sysname> system-view
[Sysname] context cnt2
[Sysname-context-2-cnt2] capability security-policy-rule maximum 1000
```

Related commands

display security-policy ip (*Security Command Reference*)

capability session maximum

Use **capability session maximum** to set the maximum number of concurrent unicast sessions for a context.

Use **undo capability session maximum** to restore the default.

Syntax

capability session maximum *max-number*

undo capability session maximum

Default

The number of concurrent unicast sessions is not limited for a context.

Views

Context view

Predefined user roles

network-admin

Parameters

max-number: Specifies the maximum number of concurrent unicast sessions for the context. The value range is 1 to 4294967295.

Usage guidelines

A large number of concurrent unicast sessions occupy too much memory, affecting other features on the context. This command sets the maximum number of concurrent unicast sessions for a context. When the maximum number is reached, you cannot establish additional unicast sessions.

If the maximum number you set is smaller than the number of existing concurrent unicast sessions, this setting takes effect. The context does not delete extra existing concurrent unicast sessions and allows new unicast sessions to be created only when the number of concurrent unicast sessions drops below the maximum number.

This command does not affect local traffic, such as FTP traffic, Telnet traffic, SSH traffic, HTTP traffic, and HTTP-based load balancing traffic.

Examples

Set the maximum number of concurrent unicast sessions to 1000000 for context **cnt2**.

```
<Sysname> system-view
[Sysname] context cnt2
[Sysname-context-2-cnt2] capability session maximum 1000000
```

Related commands

context

display session statistics (*Security Command Reference*)

capability session rate

Use **capability session rate** to set the upper limit of the session establishment rate for a context.

Use **undo capability session rate** to restore the default.

Syntax

capability session rate *max-value*

undo capability session rate

Default

The session establishment rate is not limited for a context.

Views

Context view

Predefined user roles

network-admin

Parameters

max-value: Specifies the maximum number of sessions that can be established per second.

Usage guidelines

Establishing sessions too frequently consumes too much CPU resources. If a context establishes sessions too frequently, other contexts in the same security engine will not be able to establish sessions. This command sets the number of sessions that can be established per second for a context. When the limit is reached, no additional sessions can be established.

This command does not affect local traffic, such as FTP traffic, Telnet traffic, SSH traffic, HTTP traffic, and HTTP-based load balancing traffic.

Examples

Configure context **cnt2** to establish a maximum of 20000 sessions per second.

```
<Sysname> system-view
[Sysname] context cnt2
[Sysname-context-2-cnt2] capability session rate 20000
```

Related commands

context

display session statistics (*Security Command Reference*)

capability sslvpn-user maximum

Use **capability sslvpn-user maximum** to set the maximum number of SSL VPN users for a context.

Use **undo capability sslvpn-user maximum** to restore the default.

Syntax

capability sslvpn-user maximum *max-number*

undo capability sslvpn-user maximum

Default

The number of SSL VPN users is not limited for a context. The number is determined by the usage of the SSL VPN licenses installed on the device.

Views

Context view

Predefined user roles

network-admin

Parameters

max-number: Specifies the maximum number of SSL VPN users for the context. The value range is 1 to 1048575.

Usage guidelines

This command limits the number of SSL VPN users that can log in to a context. When the maximum number is reached, the context will reject the login requests of new SSL VPN users.

If the maximum number you set is smaller than the number of SSL VPN users that already have logged in to a context, this setting takes effect. The context does not log out the currently logged-in users and allows new users to log in only when the number of the logged-in users drops below the maximum number.

Examples

Set the maximum number of SSL VPN users to 1000000 for context **cnt2**.

```
<Sysname> system-view
[Sysname] context cnt2
[Sysname-context-2-cnt2] capability sslvpn-user maximum 1000000
```

Related commands

context

capability throughput

Use **capability throughput** to set the outbound throughput threshold for a context.

Use **undo capability throughput** to restore the default.

Syntax

capability throughput { **kbps** | **pps** } *threshold*

undo capability throughput

Default

The outbound throughput of a context is not limited on a context.

Views

Context view

Predefined user roles

network-admin

Parameters

kbps: Specifies the throughput in kilobits per second.

pps: Specifies the throughput in number of packets per second.

threshold: Specifies the throughput threshold in the range of 1000 to 100000000.

Examples

Set the outbound throughput threshold to 100000 kbps for context **cnt2**.

```
<Sysname> system-view
[Sysname] context cnt2
[Sysname-context-2-cnt2] capability throughput kbps 100000
```

Set the outbound throughput threshold to 10000 pps for context **cnt3**.

```
<Sysname> system-view
[Sysname] context cnt3
[Sysname-context-3-cnt3] capability throughput pps 10000
```

context

Use **context** to create a context and enter its view, or enter the view of an existing context.

Use **undo context** to delete a context.

Syntax

context *context-name* [**id** *context-id*] [**vlan-unshared**]

undo context *context-name*

Default

A default context exists. The context name is **Admin** and the context ID is 1.

Views

System view

Predefined user roles

network-admin

Parameters

context-name: Specifies the context name, a case-sensitive string of 1 to 15 characters.

id *context-id*: Specifies the context ID. If you do not specify this option, the system assigns the lowest ID among the available IDs to the context.

vlan-unshared: Configures the context to not share VLAN resources with any contexts. If you do not specify this keyword, the context shares the same VLAN resources with other contexts.

Usage guidelines

A context with the VLAN-unshared attribute has its own VLAN resources (VLAN 1 through VLAN 4094). It does not share VLAN resources with any other contexts. You log in to the context and use the **vlan** command to create VLANs for the context.

All contexts without the VLAN-unshared attribute share the same VLAN resources (VLAN 1 through VLAN 4094). You create VLANs on the default context and use the **allocate vlan** command to assign VLANs to the contexts. A VLAN can be assigned only to one context.

Examples

Create a context named **test**.

```
<Sysname> system-view
[Sysname] context test
[Sysname-context-2-test]
```

Create a context named **test**. Set its ID to 2.

```
<Sysname> system-view
```

```
[Sysname] context test id 2
[Sysname-context-2-test]
```

context start

Use **context start** to start a context.

Use **undo context start** to stop a context.

Syntax

context start [**force**]

undo context start [**force**]

Default

A context is not started.

Views

Context view

Predefined user roles

network-admin

Parameters

force: Forcibly starts or stops a context. If you do not specify this keyword, the command starts or stops a context through normal procedures.

Usage guidelines

CAUTION:

Stop a context with caution. Stopping a context stops all services on the context and logs out all users on the context. To avoid configuration data loss, save the running configuration of a context before you stop the context.

You must use this command to initiate a newly created context. You can configure a context only after it is started.

Examples

Start context **cnt2**.

```
<Sysname> system-view
[Sysname] context cnt2
[Sysname-context-2-cnt2] context start
```

context-capability inbound broadcast single

Use **context-capability inbound broadcast single** to set the inbound broadcast rate limit for a context.

Use **undo context-capability inbound broadcast single** to restore the default.

Syntax

context-capability inbound broadcast single pps *threshold*

undo context-capability inbound broadcast single

Default

The inbound broadcast rate limit for a context is the total inbound broadcast rate limit divided by the number of active contexts that share interfaces with other contexts.

Views

System view

Context view

Predefined user roles

network-admin

Parameters

pps *threshold*: Specifies the inbound broadcast rate limit in pps, in the range of 1000 to 100000.

Usage guidelines

The rate limit takes effect only on active contexts that share interfaces with other contexts on the device.

If you execute this command in system view, you set the limit for the default context. If you execute this command in context view, you set the limit for the non-default context.

When both a per-context inbound broadcast rate limit and the total inbound broadcast rate limit are reached, the device drops subsequent broadcast packets that arrive at the context. To set the total inbound broadcast rate limit, use the **context-capability inbound broadcast total** command.

Examples

Set the inbound broadcast rate limit for the default context to 10000 pps.

```
<Sysname> system-view
[Sysname] context-capability inbound broadcast single pps 10000
```

Set the inbound broadcast rate limit to 10000 pps on context **ctx1**.

```
<Sysname> system-view
[Sysname] context ctx1
[Sysname-context-1-ctx1] context-capability inbound broadcast single pps 10000
```

Related commands

context-capability inbound broadcast total

context-capability inbound broadcast total

Use **context-capability inbound broadcast total** to set the total inbound broadcast rate limit for all contexts.

Use **undo context-capability inbound broadcast total** to restore the default.

Syntax

context-capability inbound broadcast total pps *threshold*

undo context-capability inbound broadcast total

Default

The total inbound broadcast rate limit for all contexts is 20000 pps.

Views

System view

Predefined user roles

network-admin

Parameters

pps *threshold*: Specifies the total inbound broadcast rate limit in pps. The limit can be 0 or a value in the range of 1000 to 100000. Setting the limit to 0 disables inbound broadcast rate limiting.

Usage guidelines

The rate limit takes effect only on active contexts that share interfaces with other contexts.

The total inbound broadcast rate is the sum of the inbound broadcast rates on all active contexts that share interfaces with other contexts.

When both a per-context inbound broadcast rate limit and the total inbound broadcast rate limit are reached, the device drops subsequent broadcast packets that arrive at the context. To set the inbound broadcast rate limit for a context, use the **context-capability inbound broadcast single** command.

Examples

Set the total inbound broadcast rate limit to 10000 pps.

```
<Sysname> system-view
[Sysname] context-capability inbound broadcast total pps 10000
```

Related commands

context-capability inbound broadcast single

context-capability inbound drop-logging enable

Use **context-capability inbound drop-logging enable** to enable logging for incoming packets dropped because of rate limiting on contexts.

Use **undo context-capability inbound drop-logging enable** to disable logging for incoming packets dropped because of rate limiting on contexts.

Syntax

context-capability inbound drop-logging enable

undo context-capability inbound drop-logging enable

Default

Logging is disabled for incoming packets that are dropped because of rate limiting on contexts.

Views

System view

Predefined user roles

network-admin

Usage guidelines

This logging feature generates and sends a log message to the information center when an incoming packet is dropped because of broadcast or multicast rate limiting on contexts. For more information about how the information center manages log messages, see information center configuration in *Network Management and Monitoring Configuration Guide*.

Examples

Enable logging for incoming packets dropped because of rate limiting on contexts.

```
<Sysname> system-view
```

```
[Sysname] context-capability inbound drop-logging enable
```

context-capability inbound multicast single

Use **context-capability inbound multicast single** to set the inbound multicast rate limit for a context.

Use **undo context-capability inbound multicast single** to restore the default.

Syntax

context-capability inbound multicast single pps *threshold*

undo context-capability inbound multicast single

Default

The inbound multicast rate limit for a context is the total inbound multicast rate limit divided by the number of active contexts that share interfaces with other contexts.

Views

System view

Context view

Predefined user roles

network-admin

Parameters

pps *threshold*: Specifies the inbound multicast rate limit in pps, in the range of 1000 to 100000.

Usage guidelines

The rate limit takes effect only on active contexts that share interfaces with other contexts on the device.

If you execute this command in system view, you set the limit for the default context. If you execute this command in context view, you set the limit for the non-default context.

When both a per-context inbound multicast rate limit and the total inbound multicast rate limit are reached, the device drops subsequent multicast packets that arrive at the context. To set the total inbound multicast rate limit, use the **context-capability inbound multicast total** command.

Examples

Set the inbound multicast rate limit to 10000 pps for the default context.

```
<Sysname> system-view
[Sysname] context-capability inbound multicast single pps 10000
```

Set the inbound multicast rate limit to 10000 pps for context **ctx1**.

```
<Sysname> system-view
[Sysname] context ctx1
[Sysname-context-1-ctx1] context-capability inbound multicast single pps 10000
```

Related commands

context-capability inbound multicast total

context-capability inbound multicast total

Use **context-capability inbound multicast total** to set the total inbound multicast rate limit for all contexts.

Use **undo context-capability inbound multicast total** to restore the default.

Syntax

context-capability inbound multicast total pps *threshold*

undo context-capability inbound multicast total

Default

The total inbound multicast rate limit for all contexts is 0 pps.

Views

System view

Predefined user roles

network-admin

Parameters

pps *threshold*: Specifies the total inbound multicast rate limit in pps. The limit can be 0 or a value in the range of 1000 to 100000. Setting the limit to 0 disables inbound multicast rate limiting.

Usage guidelines

The rate limit takes effect only on active contexts that share interfaces with other contexts.

The total inbound multicast rate is the sum of the inbound multicast rates on all active contexts that share interfaces with other contexts.

When both a per-context inbound multicast rate limit and the total inbound multicast rate limit are reached, the device drops subsequent multicast packets that arrive at the context. To set the inbound multicast rate limit for a context, use the **context-capability inbound multicast single** command.

Examples

Set the total inbound multicast rate limit to 10000 pps.

```
<Sysname> system-view
[Sysname] context-capability inbound multicast total pps 10000
```

Related commands

context-capability inbound multicast single

context-capability inbound unicast total

Use **context-capability inbound unicast total** to set the CPU usage threshold per CPU core for all inbound packets from all contexts.

Use **undo context-capability inbound unicast total** to restore the default.

Syntax

context-capability inbound unicast total cpu-usage *threshold*

undo context-capability inbound unicast total

The following compatibility matrixes show the support of hardware platforms for this command:

Models	Command compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280	Yes

Models	Command compatibility
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	No

Default

The CPU usage threshold per CPU core for all inbound packets is 95%.

Views

System view

Predefined user roles

network-admin

Parameters

cpu-usage *threshold*: Specifies the CPU usage threshold per CPU core for inbound packets, in percentage. The value range for the *threshold* argument is 1 to 100.

Usage guidelines

The threshold set by using this command applies to all inbound packets, including broadcast, unicast, and multicast packets.

If the shared queue in the driver is full when the total usage of a CPU core reaches the specified threshold, the system determines that an attack risk is present. Then, it takes the attack prevention action configured by using the **attack-defense cpu-core action** command until the attack risk is eliminated. For more information about the **attack-defense cpu-core action** command, see attack detection and prevention commands in *Security Command Reference*.

Examples

Set the CPU usage threshold per CPU core for all inbound packets to 70%.

```
<Sysname> system-view
[Sysname] context-capability inbound unicast total cpu-usage 70
```

Related commands

attack-defense cpu-core action (*Security Command Reference*)

description

Use **description** to configure the description of the default context, or configure a description for a non-default context.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

The default context uses the description **DefaultContext**. A non-default context does not have a description.

Views

Context view

Predefined user roles

network-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 255 characters.

Usage guidelines

You can configure a description for each context, which is useful when there are a number of contexts.

Examples

Configure a description for context **cnt2**.

```
<Sysname> system-view
[Sysname] context cnt2
[Sysname-context-2-cnt2] description test
```

display context

Use **display context** to display contexts.

Syntax

display context [**name** *context-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *context-name*: Specifies a context by its name, a case-sensitive string of 1 to 15 characters.

Usage guidelines

On the default context, this command displays the context specified by the **name** *context-name* option. Without the option, this command displays all contexts on the device.

Examples

Display all contexts.

```
<Sysname> display context
ID     Name          Status          Description
1      cnt1          active          context1
2      cnt2          inactive        context2
3      cnt3          inactive        context3
```

Table 1 Command output

Field	Description
Status	Status of the context: • **active**—The context is operating correctly. • **inactive**—The context is not started. • **starting**—The context is starting up.

Field	Description
	• **stopping**—The context is being stopped.

display context capability

Use **display context capability** to display usage of allocable service resources on contexts.

Syntax

display context [**name** *context-name*] **capability** [**security-policy** | **session** [**slot** *slot-number*] | **sslvpn-user**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *context-name*: Specifies a context by its name, a case-sensitive string of 1 to 15 characters. If you do not specify a context, this command displays usage of allocable service resources on all contexts.

security-policy: Displays usage of allocable security policy rule resources.

session: Displays usage of allocable session resources.

sslvpn-user: Displays usage of allocable SSL VPN user resources.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays the usage on all member devices.

Usage guidelines

This command is supported only on the default context.

Examples

Display usage of allocable service resources on all contexts.

```
<Sysname> display context capability
Session usage and establishment rate:
 Slot 1 CPU 0:
  ID    Name     Maximum    Used    Free    Total(/s)  Rate(/s)   Usage(%)
  1    Admin     NA         500     NA      NA         1000       NA
  2    context1  10000      300     9700    1000       100        10
  3    context2  2000       1000    1000    2000       1000       50
Security policy rule usage:
  ID    Name            Maximum        Used                Free
  1     Admin           NA             500                 NA

  3     context2        2000           1000                1000
Online SSL VPN users:
  ID    Name            Maximum        Used          Free
  1     Admin           NA             0             NA
```

```
2     conetxt1        10000          3000           7000
3     context2        2000           0              2000
```

Table 2 Command output

Field	Description
ID	Context ID.
Name	Context name.
Maximum	Maximum number of allocable resources.
Used	Number of used resources.
Free	Number of available resources.
Total	Maximum session establishment rate, which is the maximum number of sessions that can be established in a second.
Rate	Current session establishment rate.
Usage	Ratio of the current session establishment rate to the maximum session establishment rate, in percentage.

Related commands

- **capability security-policy-rule maximum**
- **capability session maximum**
- **capability session rate**
- **capability sslvpn-user maximum**

display context capability inbound broadcast

Use **display context capability inbound broadcast** to display the inbound broadcast rate limit statistics for a context.

Syntax

display context name *context-name* **capability inbound broadcast slot** *slot-number*

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *context-name*: Specifies a context by its name, a case-sensitive string of 1 to 15 characters.

slot *slot-number*: Specifies an IRF member device by its member ID.

Examples

Display the inbound broadcast rate limit statistics for context **abc** on a slot.

```
<Sysname> display context name abc capability inbound broadcast slot 1
Context name: abc
Context ID: 2
```

```
 Drop Rate: 1000 pps
 Inbound throughput limit: 8000 pps
 Total inbound throughput limit: 10000 pps
```

Table 3 Command output

Field	Description
Drop Rate	Broadcast packet drop rate of the context.
Inbound throughput limit	Inbound broadcast rate limit for the context.
Total inbound throughput limit	Total inbound broadcast rate limit.

display context capability inbound multicast

Use **display context capability inbound multicast** to display the inbound multicast rate limit statistics for a context.

Syntax

display context name *context-name* **capability inbound multicast slot** *slot-number*

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *context-name*: Specifies a context by its name, a case-sensitive string of 1 to 15 characters.

slot *slot-number*: Specifies an IRF member device by its member ID.

Examples

Display the inbound multicast rate limit statistics for context **abc** on a slot.

```
<Sysname> display context name abc capability inbound multicast slot 1
Context name: abc
Context ID: 2
 Drop Rate: 1000 pps
 Inbound throughput limit: 8000 pps
 Total inbound throughput limit: 10000 pps
```

Table 4 Command output

Field	Description
Drop Rate	Multicast packet drop rate of the context.
Inbound throughput limit	Inbound multicast rate limit for the context.
Total inbound throughput limit	Total inbound multicast rate limit.

display capability inbound unicast

Use **display capability inbound unicast** to display attack prevention statistics for CPU cores.

Syntax

display capability inbound unicast slot *slot-number*

The following compatibility matrixes show the support of hardware platforms for this command:

Models	Command compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280	Yes
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	No

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID.

Examples

Display attack prevention statistics for CPU cores on a slot.

```
<Sysname> display capability inbound unicast slot 1
CPU usage threshold: 95%
Current attack-defense cpu-core action: Per-packet-balance
CPU ID          Up rate         Packet rate    CPU usage      Effective percentage
CPU0            0/s             0/s            1%             95%
CPU1            0/s             0/s            2%             95%
CPU2            0/s             0/s            1%             95%
CPU3            0/s             0/s            3%             95%
CPU4            0/s             0/s            1%             95%
CPU5            0/s             0/s            2%             95%
CPU6            0/s             0/s            1%             95%
CPU7            50000/s         40000/s        90%            70%
CPU8            0/s             0/s            1%             95%
CPU9            0/s             0/s            5%             95%
CPU10           0/s             0/s            2%             95%
CPU11           0/s             0/s            1%             95%
CPU12           0/s             0/s            6%             95%
CPU13           0/s             0/s            1%             95%
CPU14           0/s             0/s            3%             95%
CPU15           0/s             0/s            1%             95%
```

Table 5 Command output

Field	Description
CPU usage threshold	Total CPU usage threshold per CPU core for all inbound broadcast, multicast, and unicast packets from all contexts, in percentage. When this threshold is reached, attack prevention action will be taken on excessive packets to protect the CPU core.
Current attack-defense cpu-core action	Attack prevention action on excessive packets for CPU core protection. Options: • **Drop**—Drops the packets in the driver. • **Per-packet-balance**—Distributes the packets across CPU cores on a per-packet basis in the driver. • **Isolate**—Puts the packets in the isolation queue in hardware for future processing.
CPU ID	CPU core ID.
Pass rate	Number of packets permitted per second when the attack prevention action is drop or isolate.
Drop rate	Number of packets dropped per second when the attack prevention action is drop or isolate.
Up rate	Number of packets that are delivered to the CPU core per second when the attack prevention action is **Per-packet-balance**.
Balance rate	Number of packets sent to the CPU core per second when the attack prevention action is per-packet-balance.
CPU usage	Current usage of the CPU core, in percentage. When this value reaches the CPU usage threshold per CPU core, the attack prevention action is triggered.
Effective percentage	Maximum percentage of CPU time available for packet processing. The CPU core will use all its available processing capability to process packets after the attack prevention action is triggered, in order to minimize the impact of the action and decrease the CPU usage as quickly as possible. The attack prevention action will take on a packet only if it is beyond the maximum available capability of the CPU core.

display context configuration

Use **display context configuration** to display or save context configuration information.

Syntax

display context [**name** *context-name*] **configuration** [**file** *filename*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *context-name*: Specifies a context by its name, a case-sensitive string of 1 to 15 characters. If you do not specify this option, the command displays the configurations of all contexts.

file *filename*: Saves the information to a file. The *filename* argument specifies the file name, a case-insensitive string of 1 to 255 characters. The file name must use the .tar.gz extension, and

cannot be **..tar.gz** or **…tar.gz**. It cannot start with a hyphen (-) or contain any of the following characters: quote marks ("), forward slashes (/), colons (:), backward slashes (\), question marks (?), less than signs (<), greater than signs (>), vertical bars (|), and asterisks (*). If you do not specify this option, the system prompts you to choose whether to display or save the information.

Usage guidelines

This command is supported only on the default context.

This command does not take effect on contexts that have not started up.

Executing this command is equivalent to executing the **display current-configuration** command on the specified context or each context.

Examples

Display the configurations of all contexts.

```
<Sysname> display context configuration
Save or display context configuration(Y=save, N=display)? [Y/N]:n
===========inner configuration of context Admin===========

============================================================
display current-configuration
#
 version 7.1.064, Feature 9321
#
sysname Sysname
#
context Admin id 1
#
context cnt1 id 2
#
return
<Sysname>

===========inner configuration of context cnt1===========

============================================================
display current-configuration
#
 version 7.1.064, Feature 9321
#
sysname Sysname
#
context Admin id 1
#
context cnt1 id 2
---- More ----
```

Save the configurations of all contexts to a file in interactive mode.

```
<Sysname> display context configuration
Save or display context configuration (Y=save, N=display)? [Y/N]:y
Please input the file name(*.tar.gz)[flash:/diag.tar.gz]: test.tar.gz
Saving context configuration to flash:/test.tar.gz. Please wait....
```

Save the configurations of all contexts to a file by specifying a file name for the command.

```
<Sysname> display context configuration file test.tar.gz
Saving context configuration to flash:/test.tar.gz. Please wait...
```

display context interface

Use **display context interface** to display interfaces assigned to contexts.

Syntax

display context [**name** *context-name*] **interface**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *context-name*: Specifies a context by its name, a case-sensitive string of 1 to 15 characters.

Usage guidelines

This command cannot display interfaces created on non-default contexts.

On the default context, this command displays the interfaces allocated to the non-default context specified by using the **name** *context-name* option. If you do not specify the option, this command displays the interfaces allocated to all non-default contexts on the device.

Examples

Display the interfaces allocated to all non-default contexts.

```
<Sysname> display context interface
Context stub1's interfaces:
  GigabitEthernet1/0/2
Context stub2's interfaces:
  GigabitEthernet1/0/3
```

Related commands

allocate interface

display context online-users sslvpn

Use **display context online-users sslvpn** to display the number of online SSL VPN users on all contexts.

Syntax

display context online-users sslvpn

Views

Any view

Predefined user roles

network-admin

network-operator

Usage guidelines

The number of online SSL VPN users collected by this command equals to the number of SSL VPN sessions.

Examples

Display the number of online SSL VPN users on all contexts.

```
<Sysname> display context online-users sslvpn
Total number of SSL VPN online users: 50
```

display context reboot

Use **display context name reboot** to display non-default context reboot information.

Syntax

display context name *context-name* **reboot** *show-number* [*offset*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *context-name*: Specifies a non-default context by its name, a case-sensitive string of 1 to 15 characters.

show-number: Specifies the number of non-default context reboot records to be displayed, in the range of 1 to 20.

offset: Specifies the offset of the first non-default context reboot record to be displayed, starting from the most recent record. The value range is 0 to 19. The default value is 0, which means starting from the most recent record.

Usage guidelines

To view the reboot information about the default context, execute the **display version** command and view the **Last reboot reason** field. For more information about this command, see *Fundamentals Command Reference*.

Examples

Display the most recent reboot record of context **test**.

```
<Sysname> display context name test reboot 1
----------------- Reboot record 1 -----------------
Recorded at          : 2019-05-01  11:16:00
Reason               : 0x0
Process              : comsh (PID: 120) from Context 3 on slot 1 cpu 0
```

Table 6 Command output

Field	Description
Reason	Reboot reason.
Process	Process that triggered the reboot, in the format of *process-name* **(PID:** *process-ID***) from Context** *context-ID* **on slot** *slot-number* **CPU** *CPU-number*.

Related commands

display version (*Fundamentals Command Reference*)

reset context name reboot

display context resource

Use **display context resource** to display CPU, disk space, and memory usage for contexts.

Syntax

display context [**name** *context-name*] **resource** [**cpu** | **disk** | **memory**] [**slot** *slot-number* **cpu** *cpu-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *context-name*: Specifies a context by its name, a case-sensitive string of 1 to 15 characters. If you do not specify this option, the command displays the usage for all contexts.

cpu: Displays the CPU usage.

disk: Displays the disk space usage.

memory: Displays the memory usage.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays the usage on all member devices.

cpu *cpu-number*: Specifies a CPU by its number.

Usage guidelines

If you do not specify the **cpu**, **disk**, or **memory** keyword, the command displays the CPU, disk space, and memory space usage.

Examples

Display the CPU usage for all contexts on all member devices.

```
<Sysname> display context resource cpu
CPU usage:
Slot 1 CPU 0:
  ID   Name        Weight       Usage(%)
  1    cnt1        10           24
  2    cnt2        10           0

Slot 2 CPU 0:
  ID   Name        Weight       Usage(%)
  1    cnt3        10           0
  2    cnt4        10           0
```

Related commands

limit-resource cpu

limit-resource disk

limit-resource memory

display context statistics

Use **display context statistics** to display or save resource statistics for contexts.

Syntax

display context [**name** *context-name*] **statistics** [**file** *filename*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *context-name*: Specifies a context by its name, a case-sensitive string of 1 to 15 characters. If you do not specify this option, the command displays or saves resource statistics for all contexts.

file *filename*: Saves the information to a file. The *filename* argument specifies the file name, a case-insensitive string of 1 to 255 characters. The file name must use the .tar.gz extension, and cannot be **..tar.gz** or **…tar.gz**. It cannot start with a hyphen (-) or contain any of the following characters: quote marks ("), forward slashes (/), colons (:), backward slashes (\), question marks (?), less than signs (<), greater than signs (>), vertical bars (|), and asterisks (*). If you do not specify this argument, the system prompts you to choose whether to display or save the information.

Usage guidelines

This command is supported only on the default context.

Executing this command is equivalent to executing the following commands:

- **display context capability**
- **display counters inbound interface**
- **display counters outbound interface**
- **display counters rate inbound interface**
- **display counters rate outbound interface**
- **display interface**
- **display ip statistics**
- **display ipv6 statistics**
- **display nat statistics**
- **display session statistics**

Examples

Display resource statistics for all contexts.

```
<Sysname> display context statistics
Save or display context statistics (Y=save, N=display)? [Y/N]:n
=======================================================
    =============== display session statistics =================
Slot 1:
Current sessions: 0
```

```
          TCP sessions:                   0
          UDP sessions:                   0
         ICMP sessions:                   0
       ICMPv6 sessions:                   0
     UDP-Lite sessions:                   0
         SCTP sessions:                   0
         DCCP sessions:                   0
        RAWIP sessions:                   0
...
```

Save resource statistics for all contexts to a file in interactive mode.

```
<Sysname> display context statistics
Save or display context statistics(Y=save, N=display)? [Y/N]:y
Please input the file name(*.tar.gz)[flash:/diag.tar.gz]: test.tar.gz
Saving context statistics to flash:/test.tar.gz. Please wait....
```

Save resource statistics for all contexts to a file by specifying a file name for the command.

```
<Sysname> display context statistics file test.tar.gz
Saving context statistics to flash:/test.tar.gz. Please wait...
```

Related commands

display context vlan

Use **display context vlan** to display VLAN lists for contexts.

Syntax

display context [**name** *context-name*] **vlan**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *context-name*: Specifies a context by its name, a case-sensitive string of 1 to 15 characters.

Usage guidelines

On the default context, if you specify the **name** *context-name* option, this command displays the VLAN list for the specified context. If you do not specify the **name** *context-name* option, this command displays VLAN lists for all contexts.

Examples

Display VLAN lists for all contexts.

```
<Sysname> display context vlan
Context stub1's VLAN(s):

Context stub2's VLAN(s):
  2,4094
Context stub3's VLAN(s):
5,6,800-3000,3400
```

Display the VLAN list for context **sub1**.

```
<Sysname> display context name sub1 vlan
Context stub1's VLAN(s):
  5,6,11-23,3400
```

Related commands

allocate vlan

limit-resource cpu

Use **limit-resource cpu** to set a CPU weight for a context.

Use **undo limit-resource cpu** to restore the default.

Syntax

limit-resource cpu weight *weight-value*

undo limit-resource cpu

Default

Each context has a CPU weight of 10.

Views

Context view

Predefined user roles

network-admin

Parameters

weight *weight-value*: Specifies a CPU weight value in the range of 1 to 10.

Examples

Set the CPU weight to 2 for context **cnt2**.

```
<Sysname> system-view
[Sysname] context cnt2
[Sysname-context-2-cnt2] limit-resource cpu weight 2
```

limit-resource memory

Use **limit-resource memory** to set a memory space percentage for a context. A memory space percentage defines the maximum memory space that the context can use.

Use **undo limit-resource memory** to restore the default.

Syntax

limit-resource memory slot *slot-number* **cpu** *cpu-number* **ratio** *limit-ratio*

undo limit-resource memory slot *slot-number* **cpu** *cpu-number*

Default

All contexts share the memory space in the system. A context can use all free memory space.

Views

Context view

Predefined user roles

network-admin

Parameters

slot *slot-number* **cpu** *cpu-number*: Specifies a security engine on an IRF member device. The *slot-number* argument represents the member ID of the IRF member device. The *cpu-number* argument represents the CPU number.

ratio *limit-ratio*: Specifies the ratio of the memory space that the context can use on the specified security engine to the total memory space of the engine. The value range is 1 to 100.

Usage guidelines

When you assign a context to a security engine group, the system automatically assigns memory space resources on the security engines to the context. All contexts residing on the same security engine share and compete for the engine's free memory resources. To prevent one context from occupying too many memory space resources, assign memory space resources to the contexts. When the limit for a context is reached, the context cannot apply for more memory space.

When you assign memory space to a context, follow these guidelines:

- Use the **display context resource** command to view the amount of memory space that has been used by the context before assigning memory space to the context.
- Assign an amount of memory space that is larger than the memory space used by the context to avoid the following problems:
  - The context cannot apply for more memory space.
  - The context cannot create, copy, or save additional folders or files.

Examples

Configure context **cnt2** to use up to 30% of the memory space on CPU 0 of member device 1.

```
<Sysname> system-view
[Sysname] context cnt2
[Sysname-context-2-cnt2] limit-resource memory slot 1 cpu 0 ratio 30
```

reset context capability inbound broadcast

Use **reset context capability inbound broadcast** to clear the inbound broadcast rate limit statistics for a context.

Syntax

reset context name *context-name* **capability inbound broadcast slot** *slot-number*

Views

User view

Predefined user roles

network-admin

Parameters

name *context-name*: Specifies a context by its name, a case-sensitive string of 1 to 15 characters.

slot *slot-number*: Specifies an IRF member device by its member ID.

Examples

Clear the inbound broadcast rate limit statistics for context **abc** on a slot.

```
<Sysname> reset context name abc capability inbound broadcast slot 1
```

reset context capability inbound multicast

Use **reset context capability inbound multicast** to clear the inbound multicast rate limit statistics for a context.

Syntax

reset context name *context-name* **capability inbound multicast slot** *slot-number*

Views

User view

Predefined user roles

network-admin

Parameters

name *context-name*: Specifies a context by its name, a case-sensitive string of 1 to 15 characters.

slot *slot-number*: Specifies an IRF member device by its member ID.

Examples

Clear the inbound multicast rate limit statistics for context **abc** on a slot.

```
<Sysname> reset context name abc capability inbound multicast slot 1
```

reset context reboot

Use **reset context name reboot** to clear non-default context reboot information.

Syntax

reset context [**name** *context-name*] **reboot**

Views

User view

Predefined user roles

network-admin

Parameters

name *context-name*: Specifies a non-default context by its name, a case-sensitive string of 1 to 15 characters. If you do not specify a non-default context, this command clears reboot information for all non-default contexts.

Examples

Clear reboot information about non-default context **test**.

```
<Sysname> reset context name test reboot
```

Related commands

display context name reboot

switchto context

Use **switchto context** to log in to a context.

Syntax

switchto context *context-name*

Views

System view

Predefined user roles

network-admin

network-operator

Parameters

context-name: Specifies a context that has been started.

Usage guidelines

Use this command to log in to a non-default context from the system view of the default context. The connection uses the internal interfaces between the physical device and the context.

Examples

Log in to context **test2**.

```
<Sysname> system-view
[Sysname] switchto context test2
******************************************************************************

```

tar context log

Use **tar context log** to archive log messages for contexts.

Syntax

tar context [**name** *context-name*] **log file** *filename*

Views

User view

Predefined user roles

network-admin

Parameters

name *context-name*: Specifies a context by its name, a case-sensitive string of 1 to 15 characters. If you do not specify this option, the command archives log messages for all contexts.

file *filename*: Specifies a file name, a case-insensitive string of 1 to 255 characters. The file name must use the .tar.gz extension, and cannot be **..tar.gz** or **…tar.gz**. It cannot start with a hyphen (-) or contain any of the following characters: quote marks ("), forward slashes (/), colons (:), backward slashes (\), question marks (?), less than signs (<), greater than signs (>), vertical bars (|), and asterisks (*).

Usage guidelines

This command is supported only on the default context.

This command does not take effect on contexts that have never started up.

This command archives all files in the **logfile** directory and **diagfile** directory.

Examples

Archive log messages for all contexts to file **test.tar.gz**.

```
<Sysname> tar context log file test.tar.gz
```

Context commands for non-default contexts

This section describes the context commands that you can use after logging in to a non-default context.

display context interface

Use **display context interface** to display interfaces assigned to the current context.

Syntax

display context interface

Views

Any view

Predefined user roles

network-admin

network-operator

Examples

Display the interfaces assigned to the current context.

```
<Sysname> display context interface
Context stub1's interfaces:
  GigabitEthernet1/0/2
```

Related commands

allocate interface

display context reboot

Use **display context reboot** to display reboot information about the current context.

Syntax

display context reboot *show-number* [*offset*]

Views

Any view

Predefined user roles

context-admin

context-operator

Parameters

show-number: Specifies the number of context reboot records to be displayed, in the range of 1 to 20.

offset: Specifies the offset of the first context reboot record to be displayed, starting from the most recent record. The value range is 0 to 19. The default value is 0, which means starting from the most recent record.

Examples

Display the most recent reboot record of the current CONTEXT.

```
<Sysname> display context reboot 1
----------------- Reboot record 1 -----------------
Recorded at          : 2019-05-01  11:16:00
Reason               : 0x0
Process              : comsh (PID: 120) from Context 3 on slot 1 cpu 0
```

For information about the command output fields, see Table 6.

Related commands

reset context reboot

reset context reboot

Use **reset context reboot** to clear reboot information about the current context.

Syntax

reset context reboot

Views

User view

Predefined user roles

context-admin

Examples

Clear reboot information about the current context.

```
<Sysname> reset context reboot
```

Related commands

display context reboot

Contents

Reth interface commands

The following matrixes show the compatibility of hardware and the Reth interface feature:

Models	Reth interface compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

bandwidth

Use **bandwidth** to set the expected bandwidth for a Reth interface or subinterface.

Use **undo bandwidth** to restore the default.

Syntax

bandwidth *bandwidth-value*

undo bandwidth

Default

The expected bandwidth is 10000 kbps for a Reth interface or subinterface.

Views

Reth interface view

Reth subinterface view

Predefined user roles

network-admin

context-admin

Parameters

bandwidth-value: Specifies the expected bandwidth in the range of 1 to 400000000 kbps.

Usage guidelines

The expected bandwidth is an informational parameter used only by higher-layer protocols for calculation. You cannot adjust the actual bandwidth of an interface by using this command.

Examples

Set the expected bandwidth to 50 kbps for Reth 1.

```
<Sysname> system-view
[Sysname] interface reth 1
[Sysname-Reth1] bandwidth 50
```

default

Use **default** to restore the default settings for a Reth interface or subinterface.

Syntax

default

Views

Reth interface view

Reth subinterface view

Predefined user roles

network-admin

context-admin

Usage guidelines

CAUTION:

The **default** command might interrupt ongoing network services. Make sure you are fully aware of the impacts of this command when you execute it on a live network.

This command might fail to restore the default settings for some commands for reasons such as command dependencies and system restrictions.

To resolve this problem:

1. Use the **display this** command in interface view to identify these commands.
2. Use their **undo** forms or follow the command reference to restore their default settings.
3. If the restoration attempt still fails, follow the error message instructions to resolve the problem.

Examples

Restore the default settings for Reth 1.

```
<Sysname> system-view
[Sysname] interface reth 1
[Sysname-Reth1] default
```

description

Use **description** to configure the description of an interface or subinterface.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

The description of a Reth interface or subinterface is *interface-name* plus **Interface** (for example, **Reth1 Interface**).

Views

Reth interface view

Reth subinterface view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 255 characters.

Examples

Configure the description of Reth 1 as **master-interface**.

```
<Sysname> system-view
[Sysname] interface reth 1
[Sysname-Reth1] description master-interface
```

display counters interface reth

Use **display counters interface reth** to display Reth interface traffic statistics.

Syntax

display counters { **inbound** | **outbound** } **interface** [**reth** [*interface-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

inbound: Displays inbound traffic statistics.

outbound: Displays outbound traffic statistics.

reth: Specifies Reth interfaces. If you do not specify this keyword, the command displays traffic statistics for all interfaces that have traffic counters.

interface-number: Specifies a Reth interface by its number. If you do not specify this argument, the command displays traffic statistics for all Reth interfaces.

Usage guidelines

This command displays traffic statistics within a statistics polling interval. You can use the **flow-interval** command to set the statistics polling interval.

To clear Reth interface traffic statistics, use the **reset counters interface reth** command.

Examples

Display inbound traffic statistics for Reth 1.

```
<Sysname> display counters inbound interface reth 1
Interface            Total (pkts)    Broadcast (pkts)    Multicast (pkts)  Err (pkts)
Reth1                         100                 100                   0           0

 Overflow: More than 14 digits (7 digits for column "Err").
       --: Not supported.
```

Table 1 Command output

Field	Description
Interface	Abbreviated interface name.
Total (pkts)	Total number of packets received or sent through the interface.
Broadcast (pkts)	Total number of broadcast packets received or sent through the interface.
Multicast (pkts)	Total number of multicast packets received or sent through the interface.
Err (pkts)	Total number of error packets received or sent through the interface.
Overflow: More than 14 digits (7 digits for column "Err").	This **Overflow** field is displayed when any of the following conditions exist: • The data length of the **Err** field exceeds 7 decimal digits. • The data length of a non-**Err** field exceeds 14 decimal digits.
--: Not supported.	If a statistical item is not supported, two hyphens (**--**) are displayed for the item.

Related commands

`flow-interval` (*Interface Command Reference*)

`reset counters interface reth`

display counters rate interface reth

Use **`display counters rate interface reth`** to display traffic rate statistics for Reth interfaces in up state during the most recent statistics polling interval.

Syntax

`display counters rate` { **`inbound`** | **`outbound`** } **`interface`** [**`reth`** [*`interface-number`*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`inbound`: Displays inbound traffic rate statistics.

`outbound`: Displays outbound traffic rate statistics.

`reth`: Specifies Reth interfaces. If you do not specify this keyword, the command displays traffic rate statistics for all up interfaces that have traffic counters during the most recent statistics polling interval.

`interface-number`: Specifies a Reth interface by its number. If you do not specify this argument, the command displays traffic rate statistics for all up Reth interfaces during the most recent statistics polling interval.

Usage guidelines

This command displays traffic rate statistics within a statistics polling interval. You can use the **`flow-interval`** command to set the statistics polling interval.

To clear Reth interface traffic rate statistics, use the **reset counters interface reth** command.

Examples

Display inbound traffic rate statistics for Reth1.

```
<Sysname> display counters rate inbound interface reth 1
Usage: Bandwidth utilization in percentage
Interface            Usage (%)   Total (pps)   Broadcast (pps)   Multicast (pps)
Reth1                        3           200               100               100

 Overflow: More than 14 digits.
       --: Not supported.
```

Table 2 Command output

Field	Description
Interface	Abbreviated interface name.
Usage (%)	Bandwidth usage (in percentage) of the interface during the most recent statistics polling interval.
Total (pps)	Average receiving or sending rate (in pps) for all packets during the most recent statistics polling interval.
Broadcast (pps)	Average receiving or sending rate (in pps) for broadcast packets during the most recent statistics polling interval.
Multicast (pps)	Average receiving or sending rate (in pps) for multicast packets during the most recent statistics polling interval.
Overflow: More than 14 digits.	The **Overflow** field is displayed if the data length of a statistical item exceeds 14 decimal digits.
--: Not supported.	If a statistical item is not supported, two hyphens (**--**) are displayed for the item.

Related commands

flow-interval (*Interface Command Reference*)

reset counters interface reth

display interface reth

Use **display interface reth** to display Reth interface or subinterface information.

Syntax

display interface [**reth** [*interface-number* | *interface-number.subnumber*]] [**brief** [**description** | **down**]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

reth: Specifies Reth interfaces or subinterfaces.

interface-number: Specifies an existing Reth interface by its number.

interface-number.subnumber: Specifies a subinterface of a Reth interface. The *interface-number* argument specifies the main interface number. The *subnumber* argument specifies the subinterface number and is separated from the main interface number by a dot (.).

brief: Displays brief interface information. If you do not specify this keyword, the command displays detailed interface information.

down: Displays information about interfaces in down state and the causes for the down state. If you do not specify this keyword, the command displays information about interfaces in all states.

description: Displays complete interface descriptions. If you do not specify this keyword, the command displays only the first 27 characters of each interface description.

Usage guidelines

If you do not specify the **reth** keyword, the command displays information about all interfaces except for VA interfaces. For more information about VA interfaces, see PPPoE configuration in *Layer 2—WAN Access Configuration Guide*.

If you specify the **reth** keyword but do not specify an interface or subinterface, the command displays information about all Reth interfaces and subinterfaces.

If you specify the **reth** *interface-number* option or the **reth** *interface-number.subnumber* option, the command displays information about the specified Reth interface or subinterface.

Examples

Display detailed information about Reth 1.

```
<Sysname> display interface reth 1
Reth1
Current state: UP
Line protocol state: UP
Description: Reth1 Interface
Bandwidth: 10000kbps
Maximum transmission unit: 1500
Internet protocol processing: Disabled
IP packet frame type: Ethernet II, hardware address: 0cda-41b5-cf30
IPv6 packet frame type: Ethernet II, hardware address: 0cda-41b5-cf30
Physical: Reth, baudrate: 10000000 bps
Last clearing of counters: Never
Last 300 seconds input rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Last 300 seconds output rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Input: 0 packets, 0 bytes, 0 drops
Output: 0 packets, 0 bytes, 0 drops
```

Table 3 Command output

Field	Description
Current state	Physical link state of the interface: • **Administratively DOWN**—The interface has been shut down by using the **shutdown** command. • **DOWN**—The interface is administratively up, but its physical state is

Field	Description
	down (possibly because no physical link exists or the link has failed). • **UP**—The interface is both administratively and physically up. A Reth interface is both administratively and physically up when a minimum of one member interface is administratively and physically up.
Line protocol state	Data link layer state of the interface. The state is determined through automatic parameter negotiation at the data link layer. • **UP**—The data link layer protocol is up. • **DOWN**—The data link layer protocol is down.
Description	Description of the interface.
Bandwidth	Expected bandwidth of the interface.
Maximum transmission unit	MTU of the interface.
Internet protocol processing: Disabled	The interface is not assigned an IP address and cannot process IP packets.
Internet address: *ip-address*/*mask-length* (*Type*)	IP address of the interface and type of the address in parentheses. Possible IP address types include: • **Primary**—Manually configured primary IP address. • **Sub**—Manually configured secondary IP address. If the interface has both primary and secondary IP addresses, the primary IP address is displayed. If the interface has only secondary IP addresses, the lowest secondary IP address is displayed. • **DHCP-allocated**—DHCP allocated IP address. For more information, see DHCP client configuration in *Layer 3—IP Services Configuration Guide*. • **BOOTP-allocated**—BOOTP allocated IP address. For more information, see BOOTP client configuration in *Layer 3—IP Services Configuration Guide*. • **PPP-negotiated**—IP address assigned by a PPP server during PPP negotiation. For more information, see PPP configuration in *Layer 2—WAN Access Configuration Guide*. • **Unnumbered**—IP address borrowed from another interface. • **Cellular-allocated**—IP address allocated through the modem-manufacturer's proprietary protocol. For more information, see mobile communication modem management in *Layer 2—WAN Access Configuration Guide*. • **MAD**—IP address assigned to an IRF member device for MAD on the interface. For more information, see IRF configuration in *Virtual Technologies Configuration Guide*.
IP packet frame type	IPv4 packet framing format.
hardware address	MAC address of the interface.
IPv6 packet frame type	IPv6 packet framing format.
Physical	Interface type.
Last clearing of counters	Last time when the **`reset counters interface`** command was used to clear the interface statistics. If the **`reset counters interface`** command has never been used on the interface since the device startup, this field displays **Never**.
Last 300 seconds input rate	Average input rate (in Bps and pps) over the last 300 seconds. This field is displayed for a Reth subinterface only after you execute the **`sub-interface rate-statistic`** command.
Last 300 seconds output	Average output rate (in Bps and pps) over the last 300 seconds. This field is displayed for a Reth subinterface only after you execute the

Field	Description
rate	**sub-interface rate-statistic** command. Support for the **sub-interface rate-statistic** command depends on the device model.
Input	Incoming traffic statistics on the interface: • Number of packets. • Number of bytes. • Number of dropped packets. (A Reth interface directly drops packets received by an inactive member interface. An interface also drops packets due to insufficient receive buffer.)
Output	Outgoing traffic statistics on the interface: • Number of packets. • Number of bytes. • Number of dropped packets due to insufficient send buffer.
Brief information on interfaces in route mode	Brief information about Layer 3 interfaces.
Interface	Abbreviated interface name.
Link	Physical link state of the interface: • **UP**—The interface is physically up. • **DOWN**—The interface is physically down. • **ADM**—The interface has been shut down by using the **shutdown** command. To restore the physical state of the interface, use the **undo shutdown** command. • **Stby**—The interface is a backup interface in standby state. To see the primary interface, use the **display interface-backup state** command.
Protocol	Data link layer protocol state of the interface: • **UP**—The data link layer protocol of the interface is up. • **DOWN**—The data link layer protocol of the interface is down. • **UP(s)**—The data link layer protocol of the interface is up, but the link is an on-demand link or does not exist. The **(s)** attribute represents the spoofing flag.
Primary IP	Primary IP address of the interface. This field displays two hyphens (**--**) if the interface does not have an IP address.
Description	Partial or complete interface description configured by using the **description** command: • If you specify the **description** keyword in the **display interface brief** command, this field displays only the first 27 characters of the interface description. • If you do not specify the **description** keyword in the **display interface brief** command, this field displays the complete interface description.

Display brief information about Reth 1.

```
<Sysname> display interface reth 1 brief
Brief information on interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Protocol: (s) - spoofing
Interface            Link Protocol Primary IP         Description
Reth1                DOWN DOWN     --
```

Display the causes for the down state of Reth 1.

```
<Sysname> display interface reth 1 brief down
Brief information on interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Interface            Link Cause
Reth1                DOWN Not connected
```

Table 4 Command output

Field	Description
Brief information on interfaces in route mode:	Brief information about Layer 3 interfaces.
Interface	Interface name.
Link	Physical link state of the interface: • **UP**—The interface is physically up. • **DOWN**—The interface is physically down. • **ADM**—The interface has been shut down by using the **shutdown** command. To restore the physical state of the interface, use the **undo shutdown** command. • **Stby**—The interface is a backup interface in standby state. To see the primary interface, use the **display interface-backup state** command.
Protocol	Data link layer protocol state of the interface: • **UP**—The data link layer protocol of the interface is up. • **DOWN**—The data link layer protocol of the interface is down. • **UP(s)**—The data link layer protocol of the interface is up, but the link is an on-demand link or does not exist. The **(s)** attribute represents the spoofing flag. This value is typical of null interfaces and loopback interfaces.
Primary IP	Primary IP address of the interface. This field displays two hyphens (**--**) if the interface does not have an IP address.
Description	Description of the interface.
Cause	Cause for the physical link state of an interface to be **DOWN**: • **Administratively**—The interface has been manually shut down by using the **shutdown** command. To restore the physical state of the interface, use the **undo shutdown** command. • **Not connected**—No physical connection exists (possibly because the network cable is disconnected or faulty).

display reth interface

Use **display reth interface** to display information about the member interfaces of a Reth interface.

Syntax

display reth interface reth *interface-number*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

reth *interface-number*: Specifies a Reth interface by its number. The Reth interface must exist.

Examples

Display information about the member interfaces of Reth 1.

```
<Sysname> display reth interface reth 1
Reth1 :
  Redundancy group  : aaa
  Member          Physical status       Forwarding status      Presence status
  GE1/0/1         UP                    Active                 Normal
  GE1/0/2         UP                    Inactive               Normal
```

Table 5 Command output

Field	Description
Redundancy group	The redundancy group to which the Reth interface belongs. If the Reth interface is not in any redundancy group, this field displays **N/A**.
Member	Name of the member interface.
Physical status	Physical status of the member interface: • **Down (redundancy down)**—The interface has been shut down by the Reth module. • **Down**—The interface is administratively up but physically down possibly because no physical link is present or the link has failed. • **UP**—The interface is both administratively and physically up.
Forwarding status	Forwarding status of the member interface: • **Active**—The member interface can forward packets. • **Inactive**—The member interface cannot forward packets.
Presence status	Status of the member interface: • **Normal**—The member interface exists. • **Absent**—The member interface does not exist.

fast-switch enable

Use **fast-switch enable** to enable fast switchover on a Reth interface.

Use **undo interface reth** to disable fast switchover on a Reth interface.

Syntax

fast-switch enable

undo fast-switch enable

The following matrixes show the hardware and command compatibility:

Models	Command compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080	Yes
NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	No

Default

Fast traffic switchover is disabled.

Views

Reth interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

IMPORTANT:

This feature introduces low possibility of forwarding traffic on the inactive member interface while the system is operating correctly. Make sure you understand this impact on your services when you use this feature.

This feature enables faster traffic switchover between Reth member interfaces than the standard switchover mechanism of Reth when the master device is powered off or reboots unexpectedly.

This feature implements fast switchover by allowing the inactive member interface to forward packets. In rare cases, the neighbor device might learn MAC address entries on the link connected to the inactive interface and sends traffic to the inactive interface.

For this feature to take effect and operate effectively, follow these restrictions and guidelines:

- Make sure the Reth member interfaces are physical interfaces.
- Enable fast switchover on both the Reth interface for uplink traffic and the Reth interface for downlink traffic.
- Assign the downlink and uplink Reth interfaces to a redundancy group.
- Make sure the high-priority Reth member interfaces are on the master device (high-priority redundancy group node).
- To minimize the chance of receiving traffic on the inactive interface, use the **`arp timer aging`** command on the neighbor device to shorten the ARP entry aging timer.

Examples

Enable fast traffic switchover on Reth 1.

```
<Sysname> system-view
[Sysname] interface reth 1
[Sysname-Reth1] fast-switch enable
```

Related commands

`arp timer aging` (*Layer 3—IP Services Command Reference*)

interface reth

Use **interface reth** to create a Reth interface or subinterface and enter its view, or enter the view of an existing Reth interface or subinterface.

Use **undo interface reth** to delete a Reth interface or subinterface.

Syntax

interface reth { *interface-number* | *interface-number.subnumber* }

undo interface reth { *interface-number* | *interface-number.subnumber* }

Default

No Reth interfaces or subinterfaces exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface-number: Specifies a Reth interface by its number. The value range for this argument is 1 to 255.

interface-number.subnumber: Specifies a subinterface of a Reth interface. The *interface-number* argument specifies the main interface number. The *subnumber* argument specifies the subinterface number and is separated from the main interface number by a dot (.). The value range for the *subnumber* argument is 1 to 4094.

Usage guidelines

A Reth interface is a virtual Layer 3 interface that uses two member interfaces to ensure link availability.

To create a Reth subinterface, create the Reth interface first.

You cannot create subinterfaces for a Reth interface in any of the following situations:

- The members of the Reth interface are Layer 3 Ethernet subinterfaces or Layer 3 aggregate subinterfaces.
- A minimum of one subinterface is created on the member interfaces of the Reth interface.

You cannot delete a Reth interface if it has member interfaces.

Examples

Create Reth 1 and enter its view.

```
<Sysname> system-view
[Sysname] interface reth 1
[Sysname-Reth1]
```

Create Reth 1.1 and enter its view.

```
<Sysname> system-view
[Sysname] interface reth 1.1
[Sysname-Reth1.1]
```

member interface

Use **member interface** to assign a member interface to a Reth interface.

Use **undo member interface** to remove a member interface from a Reth interface.

Syntax

member interface *interface-type interface-number* **priority** *priority*

undo member interface *interface-type interface-number*

Default

A Reth interface does not have member interfaces.

Views

Reth interface view

Predefined user roles

network-admin

context-admin

Parameters

interface-type interface-number: Specifies an interface by its type and number.

The interface can be any of the following interfaces and their subinterfaces:

- Layer 3 Ethernet interfaces.
- Layer 3 aggregate interfaces.

priority: Specifies an interface priority in the range of 1 to 255. The higher the value, the higher the interface priority.

Usage guidelines

You can assign a maximum of two member interfaces to a Reth interface. An interface can belong to only one Reth interface.

As a best practice, assign interfaces of the same type and same speed to a Reth interface.

If a Layer 3 Ethernet interface is marked as a bypass interface on the panel or has the bypass feature enabled, do not use that interface as a member interface of a Reth interface. If you do so, communication errors will occur. For more information about the bypass feature, see bridge forwarding in *Layer 2—LAN Switching Configuration Guide*.

If both member interfaces of a Reth interface are subinterfaces, make sure they are on different main interfaces and terminate the same VLAN ID. For more information about VLAN termination, see *Layer 2—LAN Switching Configuration Guide*.

When the two member interfaces of a Reth interface are up, the system chooses the interface with the higher priority as the active interface to forward packet. The interface with the lower priority is inactive and cannot forward packets.

You cannot assign subinterfaces or interfaces that have subinterfaces to a Reth interface if the Reth interface has Reth subinterfaces.

Do not specify a Reth interface as the outgoing interface in IPv6 static neighbor entries if its member interfaces contain subinterfaces. For more information about IPv6 static neighbor entries, see *Layer 3—IP Services Configuration Guide*.

Examples

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to Reth 1, and set their priority to 100 and 50, respectively.

```
<Sysname> system-view
[Sysname] interface reth 1
[Sysname-Reth1] member interface gigabitethernet 1/0/1 priority 100
[Sysname-Reth1] member interface gigabitethernet 1/0/2 priority 50
```

mtu

Use **mtu** to set the MTU of a Reth interface or subinterface.

Use **undo mtu** to restore the default.

Syntax

mtu *size*

undo mtu

Default

The MTU is 1500 bytes for a Reth interface or subinterface.

Views

Reth interface view

Reth subinterface view

Predefined user roles

network-admin

context-admin

Parameters

size: Specifies the MTU in bytes. The value range for this argument is 46 to 8192.

Usage guidelines

The MTU size of a Reth interface or subinterface affects the fragmentation and reassembly of IP packets on the interface or subinterface.

For the configured MTU size to take effect, execute the **shutdown** command, and then the **undo shutdown** command on the interface.

Examples

Set the MTU to 200 bytes for Reth 1.

```
<Sysname> system-view
[Sysname] interface reth 1
[Sysname-Reth1] mtu 200
```

reset counters interface reth

Use **reset counters interface reth** to clear statistics for Reth interfaces or subinterfaces.

Syntax

reset counters interface [**reth** [*interface-number* | *interface-number.subnumber*]]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface-number: Specifies a Reth interface by its number.

interface-number.subnumber: Specifies a subinterface of a Reth interface. The *interface-number* argument specifies the main interface number. The *subnumber* argument specifies the subinterface number and is separated from the main interface number by a dot (.).

Usage guidelines

Use this command to clear history statistics before you collect traffic statistics for a time period.

If you do not specify the **reth** keyword, the command clears statistics for all interfaces except for VA interfaces.

If you specify the **reth** keyword but do not specify an interface or subinterface, the command clears statistics for all Reth interfaces and subinterfaces.

If you specify the **reth** *interface-number* option or the **reth** *interface-number.subnumber* option, the command clears statistics for the specified Reth interface or subinterface.

Examples

Clear statistics for Reth 1.

```
<Sysname> reset counters interface reth 1
```

Related commands

display counters interface reth

display counters rate interface reth

display interface reth

reth advertise retransmit

Use **reth advertise retransmit** to set the parameters for retransmitting advertisement messages to neighbors after a Reth member interface switchover.

Use **undo reth advertise retransmit** to restore the default.

Syntax

reth advertise retransmit *times* **interval** *seconds*

undo reth advertise retransmit

Default

After a Reth member interface switchover, a Reth interface retransmits advertisement messages to neighbors five times at an interval of 1 second.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

times: Specifies the number of retransmissions, in the range of 5 to 30.

seconds: Specifies the interval for retransmitting the advertisement messages, in the range of 1 to 10 seconds.

Usage guidelines

After you configure this command, a Reth interface performs the following operations when a Reth member interface switchover occurs on it:

1. Sends advertisement messages (including gratuitous ARP messages and NA messages) to neighbors immediately.
2. Retransmits the advertisement messages according to the number of retransmissions and the retransmission interval you have configured.

If a Reth interface has subinterfaces, the subinterfaces also send advertisement messages upon a Reth member interface switchover. To save CPU resources, this command takes effect only on Reth interfaces. Reth subinterfaces are not controlled by this command.

Examples

Configure Reth interfaces to retransmit advertisement messages to neighbors ten times at an interval of 5 seconds after a Reth member interface switchover.

```
<Sysname> system-view
[Sysname] reth advertise retransmit 10 interval 5
```

shutdown

Use **shutdown** to shut down a Reth interface or subinterface.

Use **undo shutdown** to bring up a Reth interface or subinterface.

Syntax

shutdown

undo shutdown

Default

A Reth interface or subinterface is not manually shut down.

Views

Reth interface view

Reth subinterface view

Predefined user roles

network-admin

context-admin

Usage guidelines

CAUTION:

This command disconnects all links set up on a Reth interface. Make sure you are fully aware of its impacts when you use it on a live network.

Examples

Shut down Reth 1.

```
<Sysname> system-view
```

```
[Sysname] interface reth 1
[Sysname-Reth1] shutdown
```

sub-interface rate-statistic

Use **sub-interface rate-statistic** to enable subinterface rate statistics collection on a Reth interface.

Use **undo sub-interface rate-statistic** to disable subinterface rate statistics collection on a Reth interface.

Syntax

sub-interface rate-statistic

undo sub-interface rate-statistic

Default

Subinterface rate statistics collection is disabled on a Reth interface.

Views

Reth interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

CAUTION:

This command is resource intensive. When you use this command, make sure you fully understand its impact on system performance.

After you execute this command, the device periodically refreshes subinterface rate statistics for the Reth interface. The statistics is displayed in the **Last 300 seconds input rate** and **Last 300 seconds output rate** fields of the command output from the **display interface reth** command.

Examples

Enable subinterface rate statistics collection on Reth 1.

```
<Sysname> system-view
[Sysname] interface reth 1
[Sysname-Reth1] sub-interface rate-statistic
```

Related commands

display interface reth

Redundancy group commands

The following matrixes show the compatibility of hardware and the redundancy group feature:

Models	Redundancy group compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

bind slot

Use **bind slot** to bind a redundancy group node to an IRF member device.

Use **undo bind slot** to remove the binding between a redundancy group node and an IRF member device.

Syntax

bind slot *slot-number*

undo bind slot

Default

A redundancy group node is not bound to an IRF member device.

Views

Redundancy group node view

Predefined user roles

network-admin

context-admin

Parameters

slot-number: Specifies an IRF member device by its member ID.

Usage guidelines

You can create only one-to-one bindings between redundancy group nodes and IRF member devices.

The node in a binding can use interfaces of the bound IRF member device as members. Member interfaces on one node of a redundancy group back up the member interfaces on the other node.

You cannot change the binding for a node if the node has member interfaces.

Examples

Bind node 1 in redundancy group **aaa** to IRF member device 1.

```
<Sysname> system-view
[Sysname] redundancy group aaa
[Sysname-redundancy-group-aaa] node 1
[Sysname-redundancy-group-aaa-node1] bind slot 1
```

display redundancy group

Use **display redundancy group** to display redundancy group information.

Syntax

display redundancy group [*group-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

group-name: Specifies a redundancy group by its name, a case-sensitive string of 1 to 15 characters. If you do not specify a redundancy group, this command displays information about all redundancy groups.

Examples

Display information about redundancy group **aaa**.

```
<Sysname> display redundancy group aaa
Redundancy group aaa (ID 1):
  Node ID      Slot        Priority   Status           Track weight
  1            Slot1       100        Secondary        -255
  2            Slot2       99         Primary          255

Preempt delay time remained   : 0    min
Preempt delay timer setting   : 1    min
Remaining hold-down time      : 0    sec
Hold-down timer setting       : 300  sec
Manual switchover request     : No

Member interfaces:
    Reth1          Reth2

Node 1:
  Node member     Physical status
    GE1/0/2       DOWN
    GE1/0/4       DOWN(redundancy down)
  Track info:
    Track    Status               Reduced weight     Interface
    1        Negative(Faulty)     255                GE1/0/2
    2        Negative             255                GE1/0/4
Node 2:
  Node member    Physical status
    GE2/0/2      UP
    GE2/0/4      UP
```

```
Track info:
  Track    Status       Reduced weight     Interface
  3        Positive     55                 GE2/0/2
  4        Positive     55                 GE2/0/4
```

Table 6 Command output

Field	Description
Priority	Priority of the node.
Status	Node status: • **Primary**—The primary node. It can forward packets. • **Secondary**—The secondary node. When the high-priority node acts as the secondary node, all its member interfaces are shut down by the Reth module and cannot forward packets. When the low-priority node acts as the secondary node, all its member interfaces can forward packets.
Track weight	Weight of the node.
Preempt delay time remained	Remaining preemption delay time in minutes.
Preempt delay timer setting	Configured preemption delay timer in minutes.
Remaining hold-down time	Remaining hold-down time in seconds.
Hold-down timer setting	Configured hold-down timer in seconds.
Manual switchover request	Manual switchover request: • **Yes**—A request is issued. • **No**—No request is issued.
Member interfaces	Reth interfaces in the redundancy group.
Node 1	Detailed information about the redundancy group node.
Node member	Member interfaces on the redundancy group node.
Physical status	Physical status of the member interfaces on the node: • **Down (redundancy down)**—The interface is shut down by the Reth module. • **Down**—The interface is administratively up but physically down possibly because no physical link is present or the link has failed. • **UP**—The interface is both administratively and physically up.
Track info	Information about the track entries associated with the node.
Track	Track entry number.
Status	Track entry status. For the high-priority node, the first track entry that changed to **NotReady** or **Negative** state is identified as **Faulty**.
Reduced weight	Weight decrement rate of the node.
Interface	The interface excluded from the shutdown action by the Reth module. **Absent** indicates that the interface does not exist.

hold-down-interval

Use **`hold-down-interval`** to set the hold-down timer for a redundancy group.

Use **undo hold-down-interval** to restore the default.

Syntax

hold-down-interval *second*

undo hold-down-interval

Default

The hold-down timer is 1 second for a redundancy group.

Views

Redundancy group view

Predefined user roles

network-admin

context-admin

Parameters

second: Specifies the hold-down timer in the range of 0 to 1800 seconds.

Usage guidelines

Set the hold-down timer to prevent frequent switchovers. The hold-down timer specifies the minimum interval between two switchovers. This timer starts when a switchover is finished. The redundancy group can perform another switchover only after the hold-down timer expires.

Examples

Set the hold-down timer to 300 seconds for redundancy group **aaa**.

```
<Sysname> system-view
[Sysname] redundancy group aaa
[Sysname-redundancy-group-aaa] hold-down-interval 300
```

member interface

Use **member interface** to assign a Reth interface to a redundancy group.

Use **undo member interface** to remove a Reth interface from a redundancy group.

Syntax

member interface reth *interface-number* [**quick-fallback**]

undo member interface reth *interface-number*

Default

A redundancy group does not contain Reth interfaces.

Views

Redundancy group view

Predefined user roles

network-admin

context-admin

Parameters

reth *interface-number*: Specifies a Reth interface by its number. The Reth interface must exist.

quick-fallback: Enables quick fallback for the Reth interface. If quick fallback is enabled on a Reth interface, the physical state and protocol state of the higher-priority member interface are not set to down when it becomes inactive. When this feature is disabled on a Reth interface, both the physical state and protocol state of the inactive member interface are set to down. As a best practice, enable this feature if the preemption delay timer is set in seconds.

Usage guidelines

You can assign a Reth interface to only one redundancy group.

A redundancy group can contain a maximum of 32 Reth interfaces.

Examples

Assign Reth 1 to redundancy group **aaa**.

```
<Sysname> system-view
[Sysname] redundancy group aaa
[Sysname-redundancy-group-aaa] member interface reth 1
```

node

Use **node** to create a redundancy group node and enter its view, or enter the view of an existing redundancy group node.

Use **undo node** to remove a redundancy group node.

Syntax

node *node-id*

undo node *node-id*

Default

No redundancy group nodes exist.

Views

Redundancy group view

Predefined user roles

network-admin

context-admin

Parameters

node-id: Specifies a redundancy group node ID in the range of 1 to 2.

Usage guidelines

You can create a maximum of two nodes for a redundancy group. One is the primary node, and the other is the secondary node.

Before you delete a redundancy group node, you must remove the binding between the node and its IRF member device.

Examples

Create node 1 for redundancy group **aaa**.

```
<Sysname> system-view
[Sysname] redundancy group aaa
[Sysname-redundancy-group-aaa] node 1
```

Related commands

bind slot

node-member interface

Use **node-member interface** to assign a physical Ethernet interface to a redundancy group node.

Use **undo node-member interface** to remove a physical Ethernet interface from a redundancy group node.

Syntax

node-member interface *interface-type interface-number*

undo node-member interface *interface-type interface-number*

Default

A redundancy group node does not have member interfaces.

Views

Redundancy group node view

Predefined user roles

network-admin

context-admin

Parameters

interface-type interface-number: Specifies a physical interface by its type and number. The interface must belong to the IRF member device that is bound to the node.

Usage guidelines

Before you assign physical Ethernet interfaces to a redundancy group node, you must use the **bind slot** command to bind the node to an IRF member device.

The physical Ethernet interfaces cannot be members of Reth interfaces.

An interface can be assigned to only one redundancy group node.

Examples

Assign GigabitEthernet 1/0/1 to node 1 of redundancy group **aaa**.

```
<Sysname> system-view
[Sysname] redundancy group aaa
[Sysname-redundancy-group-aaa] node 1
[Sysname-redundancy-group-aaa-node1]node-member interface gigabitethernet 1/0/1
```

Related commands

bind slot

preempt-delay

Use **preempt-delay** to set the preemption delay timer for a redundancy group.

Use **undo preempt-delay** to restore the default.

Syntax

preempt-delay seconds *sec*

undo preempt-delay

Default

The preemption delay timer is 1 minute (60 seconds) for a redundancy group.

Views

Redundancy group view

Predefined user roles

network-admin

context-admin

Parameters

seconds *sec*: Specifies the preemption delay timer in the range of 0 to 720 seconds.

Usage guidelines

The preemption delay timer specifies the delay before a switchover to the high-priority node occurs after the switchover is triggered. The delay allows the system to process events (such as interface state changes) required for the switchover.

If you set the preemption delay timer to 0, automatic switchover to the high-priority node is disabled. You can perform only manual switchover.

Examples

Set the preemption delay timer to 120 seconds for redundancy group **aaa**.

```
<Sysname> system-view
[Sysname] redundancy group aaa
[Sysname-redundancy-group-aaa] preempt-delay seconds 120
```

priority

Use **priority** to set the priority of a redundancy group node.

Use **undo priority** to restore the default.

Syntax

priority *priority*

undo priority

Default

The priority of a redundancy group node is 1.

Views

Redundancy group node view

Predefined user roles

network-admin

context-admin

Parameters

priority: Specifies the priority in the range of 1 to 255. The higher the value, the higher the priority.

Usage guidelines

By default, the high-priority node is the primary node, and the low-priority node is the secondary node. If both nodes have the same priority, the lower-numbered node is the primary node.

Examples

Set the priority to 3 for node 1 of redundancy group **aaa**.

```
<Sysname> system-view
[Sysname] redundancy group aaa
[Sysname-redundancy-group-aaa] node 1
[Sysname-redundancy-group-aaa-node1] priority 3
```

redundancy group

Use **redundancy group** to create a redundancy group and enter its view, or enter the view of an existing redundancy group.

Use **undo redundancy group** to remove a redundancy group.

Syntax

redundancy group *group-name*

undo redundancy group *group-name*

Default

No redundancy groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a redundancy group name, a case-sensitive string of 1 to 15 characters.

Usage guidelines

Before you delete a redundancy group, make sure all its Reth interfaces and nodes are removed.

Examples

Create redundancy group **aaa** and enter its view.

```
<Sysname> system-view
[Sysname] redundancy group aaa
```

snmp-agent trap enable rddc

Use **snmp-agent trap enable rddc** to enable SNMP notifications for redundancy groups.

Use **undo snmp-agent trap enable rddc** to disable SNMP notifications for redundancy groups.

Syntax

snmp-agent trap enable rddc

undo snmp-agent trap enable rddc

Default

SNMP notifications are enabled for redundancy groups.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command enables SNMP notifications for the following events:

- A manual switchover is performed.
- An interface goes down.
- A faulty interface is recovered.

For redundancy group event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Examples

Enable SNMP notifications for redundancy groups.

```
<Sysname> system-view
[Sysname] snmp-agent trap enable rddc
```

switchover request

Use **switchover request** to request a switchover to the low-priority node.

Syntax

switchover request

Views

Redundancy group view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this command to request a switchover to the low-priority node when both of the redundancy group nodes are operating correctly. This command can be used in scenarios where component replacement is required for the high-priority node.

Examples

Request a switchover to the low-priority node for redundancy group **aaa**.

```
<Sysname> system-view
[Sysname] redundancy group aaa
[Sysname-redundancy-group-aaa] switchover request
```

Related commands

switchover reset

switchover reset

Use **switchover reset** to request a switchover to the high-priority node.

Syntax

switchover reset

Views

Redundancy group view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this command to request a switchover to the high-priority node when both of the redundancy group nodes are operating correctly.

Examples

Request a switchover to the high-priority node for redundancy group **aaa**.

```
<Sysname> system-view
[Sysname] redundancy group aaa
[Sysname-redundancy-group-aaa] switchover reset
```

Related commands

preempt-delay

switchover request

track

Use **track** to associate a track entry with a redundancy group node.

Use **undo track** to remove the association between a track entry and a redundancy group node.

Syntax

track *track-entry-number* [**reduced** *weight-reduced*] [**interface** *interface-type interface-number*]

undo track *track-entry-number*

Default

A redundancy group node is not associated with track entries.

Views

Redundancy group node view

Predefined user roles

network-admin

context-admin

Parameters

track-entry-number: Specifies a track entry by its number in the range of 1 to 1024.

reduced *weight-reduced*: Specifies the weight decrement rate in the range of 1 to 255. The default is 255.

interface *interface-type interface-number*: Specifies an interface by its type and number. The interface will be excluded from the shutdown action by the Reth module. If you do not specify this option, no interface is excluded from the shutdown action by the Reth module. You must specify the tracked interface for this option if the interface has one of the following roles:

- Member of the redundancy group.
- Member of a Reth interface in the redundancy group.

Usage guidelines

You can associate a maximum of 64 track entries with a redundancy group node.

As a best practice, associate a redundancy group node with an existing track entry. If the track entry does not exist, a switchover might occur.

Do not exclude a subinterface from the shutdown action if both the subinterface and its main interface have one of the following roles on the high-priority node:

- Member of the redundancy group.
- Member of a Reth interface in the redundancy group.

When the Reth module shuts down the main interface, the subinterface is also shut down. The shutdown subinterface cannot recover automatically to trigger an automatic switchover.

Examples

Associate track entries 1 and 2 with redundancy group node 1. Exclude GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 from the shutdown action by the Reth module.

```
<Sysname> system-view
[Sysname] track 1 interface gigabitethernet 1/0/1
[Sysname] track 2 interface gigabitethernet 1/0/2
[Sysname] redundancy group aaa
[Sysname-redundancy-group-aaa] node 1
[Sysname-redundancy-group-aaa-node1] track 1 reduced 50 interface gigabitethernet 1/0/1
[Sysname-redundancy-group-aaa-node1] track 2 reduced 50 interface gigabitethernet 1/0/2
```

NSFOCUS Firewall Series

NF Security Command Reference

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

This command reference describes the commands for configuring security features, including:

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Security zone commands

display security-zone

Use **display security-zone** to display security zone information.

Syntax

display security-zone [**name** *zone-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

name *zone-name*: Specifies the security zone name, a case-insensitive string of 1 to 31 characters. If you do not specify this option, the command displays all security zones, including system-defined and user-defined security zones.

Usage guidelines

When displaying all security zones, the command uses the following order:

1. System-defined security zones.
2. User-defined security zones in alphabetical order of security zone names.

Examples

Display information about security zone **myZone**.

```
<Sysname> display security-zone name myZone
Name: myZone
Members:
  GigabitEthernet1/0/1
  GigabitEthernet1/0/2 in VLAN 3
  VLAN 150-200
  192.168.1.0 255.255.255.0
  192.168.0.0 255.255.0.0 vpn-instance abc
  1001:1002::0 32
```

Table 1 Command output

Field	Description
Name	Security zone name.

Field	Description
Members	Members in the security zone: • Type and number of a Layer 3 interface. • Type and number of a Layer 2 Ethernet interface, and IDs of the VLANs to which the interface belongs. • VLAN IDs. • Address and mask (or mask length) of an IPv4 subnet on the public network. • Address and prefix length of an IPv6 subnet on the public network. • Address, mask (or mask length), and VPN instance name of an IPv4 subnet on a VPN. • Address, prefix length, and VPN instance name of an IPv6 subnet on a VPN. If a security zone does not have members, this field displays **None**.

display zone-pair security

Use **display zone-pair security** to display all zone pairs.

Syntax

display zone-pair security

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display all zone pairs.

```
<Sysname> display zone-pair security
Source zone   Destination zone
DMZ           Local
Trust         Local
```

import interface

Use **import interface** to add a Layer 3 interfaces to a security zone.

Use **undo import interface** to remove Layer 3 interfaces from a security zone.

Syntax

import interface *layer3-interface-type layer3-interface-number*

undo import interface *layer3-interface-type layer3-interface-number*

Default

A security zone does not have Layer 3 interface members.

Views

Security zone view

Predefined user roles

network-admin

context-admin

Parameters

interface *layer3-interface-type layer3-interface-number*: Specifies a Layer 3 interface by its type and number. Layer 3 interfaces include Layer 3 Ethernet interfaces, Layer 3 Ethernet subinterfaces, and other types of Layer 3 logical interfaces.

Usage guidelines

You cannot add a member to the system-defined security zone **Local**. You can add members to the other system-defined security zones.

To add multiple Layer 3 interfaces to a security zone, execute this command multiple times.

A Layer 3 interface can belong to only one security zone. To move a Layer 3 interface from one security zone to another security zone, perform the following tasks:

1. Use the **undo import interface** command to remove the interface from the current security zone.
2. Use the **import interface** command to add the interface to the new security zone.

Examples

Add Layer 3 Ethernet interface GigabitEthernet 1/0/1 to security zone **Trust**.

```
<Sysname> system-view
[Sysname] security-zone name trust
[Sysname-security-zone-Trust] import interface gigabitethernet 1/0/1
```

import interface vlan

Use **import interface vlan** to add Layer 2 interface-VLAN combinations to a security zone.

Use **undo import interface vlan** to remove Layer 2 interface-VLAN combinations from a security zone .

Syntax

import interface *layer2-interface-type layer2-interface-number* **vlan** *vlan-list*

undo import interface *layer2-interface-type layer2-interface-number* **vlan** *vlan-list*

Default

A security zone does not have Layer 2 interface-VLAN combination members.

Views

Security zone view

Predefined user roles

network-admin

context-admin

Parameters

interface *layer2-interface-type layer2-interface-number*: Specifies a Layer 2 interface by its type and number.

vlan *vlan-list*: Specifies a list of VLANs. The *vlan-list* argument must be a space-separated list of up to 10 VLAN items that meet the following requirements:

- Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-VLAN-ID* **to** *end-VLAN-ID*. The *end-VLAN-ID* is greater than the *start-VLAN-ID*.
- The VLAN IDs are in the range of 1 to 4094.
- The VLANs already exist.

Usage guidelines

You cannot add a member to the system-defined security zone **Local**. You can add members to the other system-defined security zones.

To add multiple Layer 2 Ethernet interface-VLAN combinations to a security zone, execute this command multiple times.

A Layer 2 interface-VLAN combination can belong to only one security zone. To move a Layer 2 interface-VLAN combination from one security zone to another security zone, perform the following tasks:

1. Use the **undo import interface vlan** command to remove the combination from the current security zone.
2. Use the **import interface vlan** command to add the combination to the new security zone.

Examples

Add the combination of Layer 2 Ethernet interface GigabitEthernet 1/0/1 and VLAN 10 to security zone **Untrust**.

```
<Sysname> system-view
[Sysname] security-zone name untrust
[Sysname-security-zone-Untrust] import interface gigabitethernet 1/0/1 vlan 10
```

import ip

Use **import ip** to add an IPv4 subnet to a security zone.

Use **undo import ip** to remove an IPv4 subnet from a security zone.

Syntax

import ip *ip-address* { *mask-length* | *mask* } [**vpn-instance** *vpn-instance-name*]

undo import ip *ip-address* { *mask-length* | *mask* } [**vpn-instance** *vpn-instance-name*]

Default

A security zone does not have IPv4 subnet members.

Views

Security zone view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies an IPv4 subnet by its subnet address or a host address on the subnet.

mask-length: Specifies the mask length in the range of 0 to 32.

mask: Specifies the subnet mask in dotted decimal notation.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN to which the subnet belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the subnet resides on the public network, do not specify this option. As a best practice, specify an existing VPN instance. If you specify a non-existent VPN instance, this command will be successfully executed but will not take effect. Additionally, this command will get lost after the device restarts.

Usage guidelines

You cannot add a member to the system-defined security zone **Local**. You can add members to the other system-defined security zones.

To add multiple IPv4 subnets to a security zone, execute this command multiple times.

A subnet can be added to only one security zone.

If one subnet includes another subnet, the system identifies them as different subnets. You can add them to the same security zone or different security zones. If you add them to different security zones, packets that match both subnets are identified as packets of the security zone to which the smaller subnet belongs. For example, you can assign 1.1.1.1/24 and 1.1.2.2/16 to different security zones. A packet with the IP address 1.1.1.3 is identified as a packet of the security zone to which 1.1.1.1/24 belongs.

For a dynamic routing protocol to operate correctly, add the multicast and broadcast addresses used by the protocol to security zones as needed.

Examples

Add the 192.168.1.0/24 subnet to security zone **a**.

```
<Sysname> system-view
[Sysname] security-zone name a
[Sysname-security-zone-a] import ip 192.168.1.0 24
```

Add the subnet that is identified by the address 192.168.2.1 and mask 255.255.255.0 to security zone **a**.

```
<Sysname> system-view
[Sysname] security-zone name a
[Sysname-security-zone-a] import ip 192.168.2.1 255.255.255.0
```

Add the subnet that is identified by the address 192.168.2.1 and mask 255.255.255.0 on VPN **abc** to the security zone **a**.

```
<Sysname> system-view
[Sysname] security-zone name a
[Sysname-security-zone-a] import ip 192.168.2.1 255.255.255.0 vpn-instance abc
```

import ipv6

Use **import ipv6** to add an IPv6 subnet to a security zone.

Use **undo import ipv6** to remove an IPv6 subnet from a security zone.

Syntax

import ipv6 *ipv6-address prefix-length* [**vpn-instance** *vpn-instance-name*]

undo import ipv6 *ipv6-address prefix-length* [**vpn-instance** *vpn-instance-name*]

Default

A security zone does not have IPv6 subnet members.

Views

Security zone view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies an IPv6 subnet by its subnet address or a host address on the subnet.

prefix-length: Specifies the prefix length in the range of 1 to 128.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN to which the subnet belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the subnet resides on the public network, do not specify this option. As a best practice, specify an existing VPN instance. If you specify a non-existent VPN instance, this command will be successfully executed but will not take effect. Additionally, this command will get lost after the device restarts.

Usage guidelines

You cannot add a member to the system-defined security zone **Local**. You can add members to the other system-defined security zones.

To add multiple IPv6 subnets to a security zone, execute this command multiple times.

A subnet can be added to only one security zone.

If one subnet includes another subnet, the system identifies them as different subnets. You can add them to the same security zone or different security zones. If you add them to different security zones, packets that match both subnets are identified as packets of the security zone to which the smaller subnet belongs. For example, you can assign 1:1:1::0/48 and 1:1:1::0/32 to different security zones. A packet with the address 1:1:1::2 is identified as a packet of the security zone to which 1:1:1::0/48 belongs.

Examples

Add IPv6 subnet 1001:1002::0/32 (on the public network) to security zone **a**.

```
<Sysname> system-view
[Sysname] security-zone name a
[Sysname-security-zone-a] import ipv6 1001:1002::1 32
```

Add IPv6 subnet 1001:1002::0/32 (on VPN **abc**) to security zone **a**.

```
<Sysname> system-view
[Sysname] security-zone name a
[Sysname-security-zone-a] import ipv6 1001:1002::1 32 vpn-instance abc
```

import vlan

Use **import vlan** to add VLANs to a security zone.

Use **undo import vlan** to remove VLANs from a security zone.

Syntax

import vlan *vlan-list*

undo import vlan *vlan-list*

Default

A security zone does not have VLAN members.

Views

Security zone view

Predefined user roles

network-admin

context-admin

Parameters

vlan *vlan-list*: Specifies a list of VLANs. The *vlan-list* argument must be a space-separated list of up to 10 VLAN items that meet the following requirements:

- Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-VLAN-ID* **to** *end-VLAN-ID*. The *end-VLAN-ID* is greater than the *start-VLAN-ID*.
- The VLAN IDs are in the range of 1 to 4094.
- The VLANs already exist.

Usage guidelines

You cannot add a member to system-defined security zone **Local**. You can add members to the other system-defined security zones.

To add multiple VLANs to a security zone, specify multiple VLANs for this command or execute this command multiple times.

A VLAN can belong to only one security zone. To move a VLAN from one security zone to another security zone, perform the following tasks:

1. Use the **undo import vlan** command to remove the VLAN from the current security zone.
2. Use the **import vlan** command to add the VLAN to the new security zone.

This command requires the cooperation of inter-VLAN bridge forwarding. After adding VLANs to a security zone, you must create an inter-VLAN bridge instance and add the VLANs to the bridge instance. For more information, see Layer 2 forwarding configuration in *Layer 2—LAN Switching Configuration Guide*.

Examples

Add VLAN 3, and VLAN 5 through VLAN 7 to security zone **trust**.

```
<Sysname> system-view
[Sysname] security-zone name trust
[Sysname-security-zone-Trust] import vlan 3 5 to 7
```

manage

Use **manage** to specify a permitted protocol on an interface.

Use **undo manage** to remove a permitted protocol.

Syntax

manage { { **http** | **https** | **ping** | **ssh** | **telnet** } { **inbound** | **outbound** } | { **netconf-http** | **netconf-https** | **netconf-ssh** | **snmp** } **inbound** }

undo manage { { **http** | **https** | **ping** | **ssh** | **telnet** } { **inbound** | **outbound** } | { **netconf-http** | **netconf-https** | **netconf-ssh** | **snmp** } **inbound** }

Default

The device permits packets only from other devices that are connected through interfaces in security zone **Management**.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

`http`: Specifies the HTTP protocol.

`https`: Specifies the HTTPS protocol.

`netconf-http`: Specifies the NETCONF over SOAP over HTTP protocol.

`netconf-https`: Specifies the NETCONF over SOAP over HTTPS protocol.

`netconf-ssh`: Specifies the NETCONF over SSH protocol.

`ping`: Specifies the Ping protocol.

`snmp`: Specifies the SNMP protocol.

`ssh`: Specifies the SSH protocol.

`telnet`: Specifies the Telnet protocol.

`inbound`: Permits incoming packets of the specified protocol.

`outbound`: Permits outgoing packets of the specified protocol.

Usage guidelines

After you specify a permitted protocol on an interface, the device will permit packets of the specified protocol from the device that is connected to the interface. The packets will not be limited based on security policies or traffic policies.

You can configure this command multiple times to specify multiple permitted protocols.

Examples

Specify HTTP and HTTPS as permitted protocols on GigabitEthernet1/0/1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] manage http inbound
[Sysname-GigabitEthernet1/0/1] manage https inbound
```

security-zone

Use **`security-zone`** to create a security zone and enter its view, or enter the view of an existing security zone.

Use **`undo security-zone`** to delete a security zone.

Syntax

`security-zone name` *`zone-name`*

`undo security-zone name` *`zone-name`*

Default

By default, the device has the following security zones: Local, Trust, DMZ, Management, and Untrust.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

name *zone-name*: Specifies the security zone name, a case-insensitive string of 1 to 31 characters. It cannot be **any**. To include a backward slash (\) or quotation mark (") in the security zone name, you must use the escape character (\).

Usage guidelines

The device provides the following system-defined security zones: **Local**, **Trust**, **DMZ**, **Management**, and **Untrust**. The system creates these security zones automatically when one of following events occurs:

- The first command for creating a security zone is executed.
- The first command related to creating an interzone policy is executed.

System-defined security zones cannot be deleted.

You can use this command multiple times to create multiple security zones.

Deleting a security zone also deletes the following items:

- All zone pairs that use the security zone as the source or destination security zone.
- All interzone policy applications on the zone pairs.

Examples

Create a security zone named **zonetest** and enter security zone view.

```
<Sysname> system-view
[Sysname] security-zone name zonetest
[Sysname-security-zone-zonetest]
```

Related commands

display security-zone

security-zone intra-zone default permit

Use **security-zone intra-zone default permit** to set the default action to **permit** for packets exchanged between interfaces in the same security zone.

Use **undo security-zone intra-zone default permit** to set the default action to **deny** for packets exchanged between interfaces in the same security zone.

Syntax

security-zone intra-zone default permit

undo security-zone intra-zone default permit

The following compatibility matrixes show the support of hardware platforms for this command:

Models	Command compatibility
NFNX5-HD6480, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No

Default

The default action is **deny** for packets exchanged between interfaces in the same security zone.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The system uses the default action for packets that are exchanged between interfaces in the same security zone in the following situations:

- A zone pair from the security zone to the security zone itself is not configured.
- A zone pair from the security zone to the security zone itself is configured, but no interzone policy is applied to the zone pair.

Examples

Set the default action to **permit** for packets exchanged between interfaces in the same security zone.

```
<Sysname> system-view
[Sysname] security-zone intra-zone default permit
```

zone-pair security

Use **zone-pair security** to create a zone pair and enter its view, or enter the view of an existing zone pair.

Use **undo zone-pair security** to delete a zone pair.

Syntax

zone-pair security source { *source-zone-name* | **any** } **destination** { *destination-zone-name* | **any** }

undo zone-pair security source { *source-zone-name* | **any** } **destination** { *destination-zone-name* | **any** }

Default

No zone pair exists.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

source *source-zone-name*: Specifies the name of the source security zone, a case-insensitive string of 1 to 31 characters. This security zone must already exist.

destination *destination-zone-name*: Specifies the name of the destination security zone, a case-insensitive string of 1 to 31 characters. This security zone must already exist.

any: Specifies any security zone.

Usage guidelines

A zone pair has a source security zone and a destination security zone. The device examines received first data packets and uses zone pairs to identify data flows. You can apply interzone policies to zone pairs so the device processes data flows based on interzone policies.

You can use the **zone-pair security source any destination any** command to define the any-to-any zone pair. This zone pair matches all packets from one security zone to another security zone.

A zone pair between specific security zones has a higher priority than the any-to-any zone pair.

A packet between the **Management** and **Local** zones matches only zone pairs of the two zones. It does not match the any-to-any zone pair.

Deleting a zone pair deletes all interzone policy applications on the zone pair.

Examples

Create a zone pair with the source security zone **Trust** and destination zone **Untrust**.

```
<Sysname> system-view
[Sysname] zone-pair security source trust destination untrust
[Sysname-zone-pair-security-Trust-Untrust]
```

Related commands

display zone-pair security

zone-pair vsip-filter enable

Use **zone-pair vsip-filter enable** to enable filtering based on virtual service IP address for zone pairs.

Use **undo zone-pair vsip-filter enable** to restore the default.

Syntax

zone-pair vsip-filter enable

undo zone-pair vsip-filter enable

Default

Filtering based on virtual service IP address is disabled for zone pairs.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

In scenarios where server load balancing is deployed, configure this command to enable the device to filter packets from external networks to internal servers by virtual service IP address. By default, filtering based on virtual service IP address is disabled. Before matching each of the packets against ACLs, the device translates the destination IP address (the virtual service IP address) to the real server IP address. For more information about packet filtering, see ACL configuration in *ACL and QoS Configuration Guide*.

Examples

Configure an IPv4 advanced ACL to permit packets destined for virtual server IP address 10.10.10.10. Configure a zone pair from **Untrust** to **DMZ**, apply the ACL to the zone pair, and enable filtering based on virtual service IP address.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule permit ip source any destination 10.10.10.10 0
[Sysname-acl-ipv4-adv-3000] quit
[Sysname] zone-pair security source untrust destination dmz
[Sysname-zone-pair-security-Untrust-DMZ] packet-filter 3000
[Sysname-zone-pair-security-Untrust-DMZ] quit
[Sysname] zone-pair vsip-filter enable
```

Contents

Security policy commands

accelerate enhanced enable

Use **accelerate enhanced enable** to manually activate rule matching acceleration.

Syntax

accelerate enhanced enable

Views

IPv4 security policy view

IPv6 security policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

Rule matching acceleration enhances connection establishment and packet forwarding performance, especially for a device using multiple rules to match packets from multiple users.

Rule matching acceleration does not take effect on newly added, modified, and moved rules unless the feature is activated for the rules. By default, the system automatically activates rule matching acceleration for such rules at specific intervals. The interval is 2 seconds if 100 or fewer rules exist and 20 seconds if over 100 rules exist.

To activate rule matching acceleration immediately after a rule change, you can execute this command.

If no rule change is detected, the system does not perform an activation operation.

Insufficient memory can cause rule matching acceleration failures. Unaccelerated rules do not take effect, and rules that have been accelerated are not affected.

Examples

Activate rule matching acceleration.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] accelerate enhanced enable
```

action

Use **action** to set the action for a security policy rule.

Use **undo action** to restore the default.

Syntax

action { **drop** | **pass** }

undo action pass

Default

The action for a security policy rule is **drop**.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

drop: Discards matched packets.

pass: Allows matched packets to pass.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Set the action for security policy rule **rule1** to **drop**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] action drop
```

Related commands

display security-policy

app-group

Use **app-group** to specify an application group as a filtering criterion of a security policy rule.

Use **undo app-group** to remove the specified application group filtering criterion from a security policy rule.

Syntax

app-group *app-group-name*

undo app-group [*app-group-name*]

Default

No application group is specified as a filtering criterion for a security policy rule.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

app-group-name: Specifies the name of an application policy, a case-insensitive string of 1 to 63 characters. The name cannot be **invalid** or **other**. If you do not specify this argument when executing the **undo app-group** command, the command removes all application groups from the rule. For more information about application groups, see APR in *Security Configuration Guide*.

Usage guidelines

You can execute the command multiple times to specify multiple application groups as the filtering criteria.

Examples

Specify application groups **app1** and **app2** as the filtering criteria of security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] app-group app1
[Sysname-security-policy-ip-0-rule1] app-group app2
```

Related commands

app-group

display security-policy

application

Use **application** to specify an application as a filtering criterion of a security policy rule.

Use **undo application** to remove the specified application filtering criterion from a security policy rule.

Syntax

application *application-name*

undo application [*application-name*]

Default

No application is specified as a filtering criterion for a security policy rule.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

application-name: Specifies the name of an application, a case-insensitive string of 1 to 63 characters. The name cannot be **invalid** or **other**. If you do not specify this argument when executing the **undo application** command, the command removes all applications from the rule. For more information about applications, see APR in *Security Configuration Guide*.

Usage guidelines

You can execute the command multiple times to specify multiple applications as the filtering criteria.

For the application filtering criteria to be identified, you must permit the packets of the protocols on which the applications depend to pass through. If port-based packet filtering is configured and a dependent protocol uses a non-default port, you must permit the packets from the port to pass.

Examples

Specify applications **139Mail** and **51job** as the filtering criteria of security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
```

```
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] application 139Mail
[Sysname-security-policy-ip-0-rule1] application 51job
```

counting enable

Use **counting enable** to enable statistics collection for matched packets.

Use **undo counting enable** to disable statistics collection for matched packets.

Syntax

counting enable [**period** *value*]

undo counting enable

Default

Statistics collection for matched packets is disabled.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

period *value*: Specifies the period during which the statistics collection feature is enabled, in the range of 1 to 4294967295 minutes. If you do not specify this option, the command enables statistics collection permanently.

Usage guidelines

This feature enables the device to collect statistics about matched packets. The collected statistics can be viewed by executing the **display security-policy statistics** command.

If an enabling period is specified, the system disables the statistics collection feature and removes the configuration at period expiration. If no enabling period is specified, you must execute the **undo** command to disable the statistics collection feature.

Examples

Enable matched packet statistics collection for security policy rule **rule1** and set the enabling period to 20 minutes.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] counting enable period 20
```

display object-policy ipv6

description (security policy view)

Use **description** to configure a description for the IPv4 or IPv6 security policy.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

No description is configured for the IPv4 or IPv6 security policy.

Views

IPv4 security policy view

IPv6 security policy view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 127 characters.

Examples

Configure the description as **zone-pair security office to library** for the IPv4 security policy.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] description zone-pair security office to library
```

Related commands

display security-policy

destination-ip

Use **destination-ip** to specify a destination IP address object group as a filtering criterion of a security policy rule.

Use **undo destination-ip** to remove the specified destination IP address object group from a security policy rule.

Syntax

destination-ip *object-group-name*

undo destination-ip [*object-group-name*]

Default

No destination IP address object group is specified as a filtering criterion for a security policy rule.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

object-group-name: Specifies the name of a destination IP address object group, a case-insensitive string of 1 to 63 characters. The name cannot be **any**. If you do not specify this argument when executing the **undo destination-ip** command, the command removes all destination IP address object groups from the rule. For more information about object groups, see *Security Configuration Guide*.

Usage guidelines

You can execute the command multiple times to specify multiple destination IP address object groups as the filtering criteria.

If you specify a nonexistent object group, the device automatically creates the specified object group with empty configuration. A rule that contains an object group with empty configuration does not match any packets.

For a security policy rule, the number of configured destination IP addresses cannot exceed 1024. If the limit has been reached, any command execution to add such a filtering criterion fails and the system prompts an error.

Examples

Specify destination IP address object groups **client1** and **client2** as the filtering criteria of security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] destination-ip client1
[Sysname-security-policy-ip-0-rule1] destination-ip client2
```

Use **destination-ip-host** to specify a destination IPv4 host address as a filtering criterion of a security policy rule.

Use **undo destination-ip-host** to remove the specified destination IPv4 host address from a security policy rule.

Syntax

destination-ip-host *ip-address*

undo destination-ip-host [*ip-address*]

Default

No destination IPv4 host address is specified as a filtering criterion for a security policy rule.

Views

IPv4 security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IPv4 address of a host. If you do not specify this argument when executing the **undo** command, the command removes all destination IPv4 host addresses from the rule.

Usage guidelines

You can execute the command multiple times to specify multiple destination IPv4 host addresses as the filtering criteria.

If you specify an IP address that has been configured as a destination host filtering criterion, the command execution fails and the system prompts an error.

For a security policy rule, the sum of configured destination host addresses, destination subnets, and destination address ranges cannot exceed 1024. If the limit has been reached, any command execution to add such a filtering criterion fails and the system prompts an error.

Examples

Specify destination IPv4 host address **192.167.0.1** as the filtering criteria of IPv4 security policy rule **rule1**.

```
<Sysname> system-view
```

```
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] destination-ip-host 192.167.0.1
```

Related commands

destination-ip-host (IPv6 security policy view)

Use **destination-ip-host** to specify a destination IPv6 host address as a filtering criterion of a security policy rule.

Use **undo destination-ip-host** to remove the specified destination IPv6 host address from a security policy rule.

Syntax

destination-ip-host *ipv6-address*

undo destination-ip-host [*ipv6-address*]

Default

No destination IPv6 host address is specified as a filtering criterion for a security policy rule.

Views

IPv6 security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies the IPv6 address of a host. If you do not specify this argument when executing the **undo** command, the command removes all destination IPv6 host addresses from the rule.

Usage guidelines

You can execute the command multiple times to specify multiple destination IPv6 host addresses as the filtering criteria.

If you specify an IP address that has been configured as a destination host filtering criterion, the command execution fails and the system prompts an error.

For a security policy rule, the sum of configured destination host addresses, destination subnets, and destination address ranges cannot exceed 1024. If the limit has been reached, any command execution to add such a filtering criterion fails and the system prompts an error.

Examples

Specify destination IPv6 host address **192::167:1** as the filtering criteria of IPv6 security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ipv6
[Sysname-security-policy-ipv6] rule 0 name rule1
[Sysname-security-policy-ipv6-0-rule1] destination-ip-host 192::167:1
```

destination-ip-range (IPv4 security policy view)

Use **destination-ip-range** to specify a destination IPv4 address range as a filtering criterion of a security policy rule.

Use **undo destination-ip-range** to remove the specified destination IPv4 address range from a security policy rule.

Syntax

destination-ip-range *ip-address1 ip-address2*

undo destination-ip-range [*ip-address1 ip-address2*]

Default

No destination IPv4 address range is specified as a filtering criterion for a security policy rule.

Views

IPv4 security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

ip-address1 ip-address2: Specifies an IPv4 address range. The *ip-address1* argument represents the start IP address and the *ip-address2* argument represents the end IP address. If you do not specify the arguments when executing the **undo** command, the command removes all destination IPv4 address ranges from the rule.

Usage guidelines

You can execute the command multiple times to specify multiple destination IPv4 address ranges as the filtering criteria.

If you specify an IP address range that has been configured as a destination IP range filtering criterion, the command execution fails and the system prompts an error.

For a security policy rule, the sum of configured destination host addresses, destination subnets, and destination address ranges cannot exceed 1024. If the limit has been reached, any command execution to add such a filtering criterion fails and the system prompts an error.

When you specify an IP address range, follow these restrictions and guidelines:

- If the start IP address is the same as the end IP address, the command creates a host address filtering criteria.
- If the start IP address and the end IP address define a subnet, the command creates a subnet filtering criteria.
- If *ip-address1* is greater than *ip-address2*, the system automatically adjusts the range to [*ip-address2*, *ip-address1*].

Examples

Specify destination IPv4 address range 192.165.0.100 to 192.165.0.200 as the filtering criteria of IPv4 security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] destination-ip-range 192.165.0.100 192.165.0.200
```

Related commands

display security-policy

destination-ip-range (IPv6 security policy view)

Use **destination-ip-range** to specify a destination IPv6 address range as a filtering criterion of a security policy rule.

Use **undo destination-ip-range** to remove the specified destination IPv6 address range from a security policy rule.

Syntax

destination-ip-range *ipv6-address1 ipv6-address2*

undo destination-ip-range [*ipv6-address1 ipv6-address2*]

Default

No destination IPv6 address range is specified as a filtering criterion for a security policy rule.

Views

IPv6 security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address1 ipv6-address2: Specifies an IPv6 address range. The *ipv6-address1* argument represents the start IP address and the *ipv6-address2* argument represents the end IP address. If you do not specify the arguments when executing the **undo** command, the command removes all destination IPv6 address ranges from the rule.

Usage guidelines

You can execute the command multiple times to specify multiple destination IPv6 address ranges as the filtering criteria.

If you specify an IP address range that has been configured as a destination IP range filtering criterion, the command execution fails and the system prompts an error.

For a security policy rule, the sum of configured destination host addresses, destination subnets, and destination address ranges cannot exceed 1024. If the limit has been reached, any command execution to add such a filtering criterion fails and the system prompts an error.

When you specify an IP address range, follow these restrictions and guidelines:

- If the start IP address is the same as the end IP address, the command creates a host address filtering criteria.
- If the start IP address and the end IP address define a subnet, the command creates a subnet filtering criteria.
- If *ipv6-address1* is greater than *ipv6-address2*, the system automatically adjusts the range to [*ipv6-address2*, *ipv6-address1*].

Examples

Specify destination IPv6 address range 192:165::100 to 192:165::200 as the filtering criteria of IPv6 security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ipv6
```

```
[Sysname-security-policy-ipv6] rule 0 name rule1
[Sysname-security-policy-ipv6-0-rule1] destination-ip-range 192:165::100 192:165::200
```

Related commands

display security-policy

destination-ip-subnet (IPv4 security policy view)

Use **destination-ip-subnet** to specify a destination IPv4 subnet as a filtering criterion of a security policy rule.

Use **undo destination-ip-subnet** to remove the specified destination IPv4 subnet from a security policy rule.

Syntax

destination-ip-subnet *ip-address* { *mask-length* | *mask* }

undo destination-ip-subnet [*ip-address* { *mask-length* | *mask* }]

Default

No destination IPv4 subnet is specified as a filtering criterion for a security policy rule.

Views

IPv4 security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

ip-address { *mask-length* | *mask* }: Specifies an IPv4 subnet. You can specify the mask length or the mask in dotted decimal notation. The mask length is in the range of 0 to 32. If you set the mask length to 32 or the mask to 255.255.255.255, the command creates a host address filtering criterion. If you do not specify the arguments when executing the **undo** command, the command removes all destination IPv4 subnets from the rule.

Usage guidelines

You can execute the command multiple times to specify multiple destination IPv4 subnets as the filtering criteria.

If you specify a subnet that has been configured as a destination subnet filtering criterion, the command execution fails and the system prompts an error.

For a security policy rule, the sum of configured destination host addresses, destination subnets, and destination address ranges cannot exceed 1024. If the limit has been reached, any command execution to add such a filtering criterion fails and the system prompts an error.

Examples

Specify the destination subnet with IP address 192.167.0.0 and mask length 24 as a filtering criteria of IPv4 security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] destination-ip-subnet 192.167.0.0 24
```

Specify the destination subnet with IP address 192.166.0.0 and mask 255.255.0.0 as a filtering criteria of IPv4 security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] destination-ip-subnet 192.166.0.0 255.255.0.0
```

Use **undo destination-ip-subnet** to remove the specified destination IPv6 subnet from a security policy rule.

Syntax

destination-ip-subnet *ipv6-address prefix-length*

undo destination-ip-subnet [*ipv6-address prefix-length*]

Default

No destination IPv6 subnet is specified as a filtering criterion for a security policy rule.

Views

IPv6 security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address prefix-length: Specifies an IPv6 subnet. The prefix length is in the range of 1 to 128. If you set the prefix length to 128, the command creates a host address filtering criterion. If you do not specify the arguments when executing the **undo** command, the command removes all destination IPv4 subnets from the rule.

Usage guidelines

You can execute the command multiple times to specify multiple destination IPv6 subnets as the filtering criteria.

If you specify a subnet that has been configured as a destination subnet filtering criterion, the command execution fails and the system prompts an error.

For a security policy rule, the sum of configured destination host addresses, destination subnets, and destination address ranges cannot exceed 1024. If the limit has been reached, any command execution to add such a filtering criterion fails and the system prompts an error.

Examples

Specify the destination subnet with IP address 192::167:0 and prefix length 64 as a filtering criteria of IPv6 security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ipv6
[Sysname-security-policy-ipv6] rule 0 name rule1
[Sysname-security-policy-ipv6-0-rule1] destination-ip-subnet 192::167:0 64
```

Related commands

display security-policy

destination-zone

Use **destination-zone** to specify a destination security zone as a filtering criterion of a security policy rule.

Use **undo destination-zone** to remove the specified destination security zone from a security policy rule.

Syntax

destination-zone *destination-zone-name*

undo destination-zone [*destination-zone-name*]

Default

No destination security zone is specified as a filtering criterion for a security policy rule.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

object-group-name: Specifies the name of a destination security zone, a case-insensitive string of 1 to 31 characters. If you do not specify this argument when executing the **undo destination-zone** command, the command removes all destination security zones from the rule. For more information about security zones, see *Security Configuration Guide*.

Usage guidelines

You can execute the command multiple times to specify multiple destination security zones as the filtering criteria.

Examples

Specify destination security zones **trust** and **server** as the filtering criteria of security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] destination-zone trust

Table 1 Command output

Field	Description
rule *id* name *rule-name*	Rule ID and rule name.
action pass	Rule action: • **pass**—Allows matched packets to pass. • **drop**—Drops matched packets.
profile *app-profile-name*	DPI application profile applied to the rule.
vrf *vrf-name*	MPLS L3VPN instance whose packets can be filtered by the rule.
logging enable	Indicates that logging for matched packets is enabled.
counting enable period *value*	Indicates that statistics collection for matched packets is enabled. The *value* argument represents the enabling period in minutes.
counting enable TTL *time-value*	Indicates that statistics collection for matched packets is

Field	Description
	enabled. The *time-value* argument represents the remaining enabling period in seconds.
time-range *time-range-name*	Time range during which the rule is in effect.
track negative 1 (Active)	Track entry and track entry state associated with the security policy rule.
session aging-time *time-value*	Session aging time.
session persistent aging-time *time-value*	Persistent session aging time.
source-zone *zone-name*	Source security zone that acts as a filtering criterion.
destination-zone *zone-name*	Destination security zone that acts as a filtering criterion.
source-ip *object-group-name*	Source IP address object group that acts as a filtering criterion.
source-ip-host *ip-address*	Source IP host address that acts as a filtering criterion.
source-ip-subnet *ip-address*	Source IP subnet that acts as a filtering criterion.
source-ip-range *ip-address1 ip-address2*	Source IP address range that acts as a filtering criterion.
destination-ip *object-group-name*	Destination IP address object group that acts as a filtering criterion.
destination-ip-host ip-address	Destination IP host address that acts as a filtering criterion.
destination-ip-subnet ip-address	Destination IP subnet that acts as a filtering criterion.
destination-ip-range *ip-address1 ip-address2*	Destination IP address range that acts as a filtering criterion.
service *object-group-name*	Service object group that acts as a filtering criterion.
service-port *protocol*	Service port that acts as a filtering criterion.
app-group *app-group-name*	Application group that acts as a filtering criterion.
application *application-name*	Application that acts as a filtering criterion.
user *user-name*	User that acts as a filtering criterion.
user-group *user-group-name*	User group that acts as a filtering criterion.

Related commands

security-policy ip

security-policy ipv6

display security-policy statistics

Use **display security-policy statistics** to display security policy statistics.

Syntax

display security-policy statistics { **ip** | **ipv6** } [**rule** *rule-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ip: Specifies the IPv4 security policy.

ipv6: Specifies the IPv6 security policy.

rule *rule-name*: Specifies a security policy rule by its name, a case-insensitive string of 1 to 127 characters. If you do not specify this option, the command displays statistics about all security policy rules of the specified IP version.

Examples

Display statistics about IPv4 security policy rule **abc**.

```
<Sysname> display security-policy statistics ip rule abc
rule 0 name abc
 action: pass (5 packets, 1000 bytes)
```

Table 2 Command output

Field	Description
rule *id* name *rule-name*	Rule ID and rule name.
action	Rule action: • **pass**—Allows matched packets to pass. • **drop**—Drops matched packets.
x packets, y bytes	The rule has matched x packets, a total of y bytes. This field is displayed only if the **counting enable** or the **logging enable** command has been executed for the rule.

Related commands

reset security-policy statistics

group move

Use **group move** to move a security policy rule group to change the match order of security policy rules.

Syntax

group move *group-name1* { **after** | **before** } { **group** *group-name2* | **rule** *rule-name* }

Views

Security policy view

Predefined user roles

network-admin

context-admin

Parameters

group-name1: Specifies the name of the security policy rule group to be moved, a case-insensitive string of 1 to 63 characters.

after: Moves the security policy rule group to the place after the target security policy rule group or the target security policy rule.

before: Moves the security policy rule group to the place before the target security policy rule group or the target security policy rule.

group *group-name2*: Specifies the name of the target security policy rule group, a case-insensitive string of 1 to 63 characters.

rule *rule-name*: Specifies the name of the target security policy rule, a case-insensitive string of 1 to 127 characters.

Usage guidelines

If you specify a target security policy rule that belongs to a security policy rule group, follow these restrictions and guidelines:

- If the target rule is neither the start nor end rule of the group, you cannot move a security policy rule group to the place before or after the rule.
- If the target rule is the start rule of the group, you can only move a security policy rule group to the place before the rule.
- If the target rule is the end rule of the group, you can only move a security policy rule group to the place after the rule.

Examples

Move security policy rule group **group1** to the place before security policy rule group **group2**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] group move group1 before group group2
```

group name

Use **group name** to create a security policy rule group and add security policy rules to the group, or add security policy rules to an existing security policy rule group.

Use **undo group name** to delete a security policy rule group.

Syntax

group name *group-name* [**from** *rule-name1* **to** *rule-name2*] [**description** *description-text*] [**disable** | **enable**]

undo group name *group-name* [**description** | **include-member**]

Default

No security policy rule group exists.

Views

Security policy view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a security policy rule group name, a case-insensitive string of 1 to 63 characters.

from *rule-name1*: Specifies the start rule of a rule list. The *rule-name1* argument represents the security policy rule name, a case-insensitive string of 1 to 127 characters.

to *rule-name2*: Specifies the end rule of the rule list. The *rule-name2* argument represents the security policy rule name, a case-insensitive string of 1 to 127 characters.

description *description-text*: Specifies the security policy description, a case-sensitive string of 1 to 127 characters. By default, no description is specified for a security policy rule group.

disable: Disables the security policy rule group.

enable: Enables the security policy rule group. By default, a security policy rule group is enabled.

include-member: Specifies security policy rules in the security policy rule group.

Usage guidelines

Security policy rule grouping allows users to enable, disable, delete, and move security policy rules in batches.

A security policy rule in a security policy rule group takes effect only when both the rule and the group are enabled.

To add a list of security policy rules, make sure the end rule is listed behind the start rule and the specified rules do not belong to any other security policy rule group.

When you execute the **undo** command, follow these restrictions and guidelines:

- The **undo group name** *group-name* command deletes only the specified security policy rule group.
- The **undo group name** *group-name* **description** command deletes only the description for the specified security policy rule group.
- The **undo group name** *group-name* **include-member** command deletes both the specified security policy rule group and all the security policy rules in the group.

Examples

Create security policy rule group **group1**, add security policy rules **rule-name1** through **rule-name10** to the group, and specify the group description as **marketing**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] group name group1 from rule-name1 to rule-name10 enable
description marketing
```

group rename

Use **group rename** to rename a security policy rule group.

Syntax

group rename *old-name new-name*

Views

Security policy view

Predefined user roles

network-admin

context-admin

Parameters

old-name: Specifies the name of a security policy rule group, a case-insensitive string of 1 to 63 characters.

new-name: Specifies a new name for the security policy rule group, a case-insensitive string of 1 to 63 characters.

Examples

Rename security policy rule group **group1** to **group2**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] group rename group1 group2
```

logging enable

Use **logging enable** to enable logging for matched packets.

Use **undo logging enable** to disable logging for matched packets.

Syntax

logging enable

undo logging enable

Default

Logging for matched packets is disabled.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the security policy module to send log messages to the information center or to fast output log messages when packets match a security policy.

With the information center or fast log output, you can set log message filtering and output rules, including output destinations.

The information center can output packet matching logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view packet matching logs stored on the device, use the **display logbuffer** command or open the security policy log page from the Web interface of the device. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Enable matched packet logging for security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] logging enable
```

Related commands

display security-policy

move rule

Use **move rule** to move a security policy rule by rule ID.

Syntax

move rule *rule-id1* { { **after** | **before** } *rule-id2* | **bottom** | **down** | **top** | **up** }

Views

IPv4 security policy view

IPv6 security policy view

Predefined user roles

network-admin

context-admin

Parameters

rule-id1: Specifies the ID of a rule to be moved, in the range of 0 to 4294967290.

after: Moves the rule to the position after the target rule.

before: Moves the rule to the position before the target rule.

rule-id2: Specifies the ID of the target rule. The target rule ID is in the range of 0 to 4294967295. If you specify 4294967295 as the target rule ID, the rule is moved to the end of the list.

bottom: Moves the rule to the end of the list.

down: Moves the rule one position down.

top: Moves the rule to the beginning of the list.

up: Moves the rule one position up.

Usage guidelines

The system does not execute the command in the following situations:

- You specify the same value for the *rule-id1* and *rule-id2* arguments.
- You specify a nonexistent rule.

Examples

Insert rule 5 before rule 2 for the IPv4 security policy.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] move rule 5 before 2
```

Views

Security policy view

Predefined user roles

network-admin

context-admin

Parameters

rule-name1: Specifies the name of the rule to move, a case-insensitive string of 1 to 127 characters.

after: Move the rule to the place after the destination rule.

before: Move the rule to the place before the destination rule.

name *rule-name2*: Specify the name of the destination rule, a case-insensitive string of 1 to 127 characters.

bottom: Move the rule to the end of the security policy.

down: Move the rule down one place.

top: Move the rule to the beginning of the security policy.

up: Move the rule up one place.

Usage guidelines

You can move a rule to change its packet matching priority.

Examples

Move rule **rule1** to the place before rule **rule2**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] move rule name rule1 before name rule2
```

parent-group *group-name*

undo parent-group

Default

A security policy rule does not belong to any security policy rule group.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies the name of a security policy rule group, a case-insensitive string of 1 to 63 characters.

Examples

Assign security policy rule **rule1** to security policy rule group **group1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 1 name rule1
[Sysname-security-policy-ip-1-rule1] parent-group group1
```

profile

Use **profile** to apply a DPI application profile to a security policy rule.

Use **undo profile** to remove the DPI application profile applied to a security policy rule.

Syntax

profile *app-profile-name*

undo profile

Default

No DPI application profile is applied to a security policy rule.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

app-profile-name: Specifies the name of a DPI application profile, a case-insensitive string of 1 to 63 characters. For more information about DPI application profiles, see DPI engine in *DPI Configuration Guide*.

Usage guidelines

This feature enables the device to perform DPI on packets matching the specified rule. For more information about DPI, see *DPI Configuration Guide*.

This feature takes effect only when the rule action is **pass**.

Examples

Apply DPI application profile **p1** to IPv4 security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
```

```
[Sysname-security-policy-ip-0-rule1] action pass
[Sysname-security-policy-ip-0-rule1] profile p1
```

Related commands

display security-policy ip

reset security-policy statistics

Use **reset security-policy statistics** to clear security policy statistics.

Syntax

reset security-policy statistics [**ip** | **ipv6**] [**rule** *rule-name*]

Views

Any view

Predefined user roles

network-admin

context-admin

Parameters

ip: Specifies the IPv4 security policy.

ipv6: Specifies the IPv6 security policy.

rule *rule-name*: Specifies a security policy rule by its name, a case-insensitive string of 1 to 127 characters.

Usage guidelines

If you do not specify any keyword or option, the command clears all security policy statistics.

Examples

Clear the security policy statistics about IPv4 security policy rule **abc**.

```
<Sysname> reset security-policy statistics ip rule abc
```

Related commands

display security-policy statistics

rule

Use **rule** to create a security policy rule and enter its view, or enter the view of an existing security policy rule.

Use **undo rule** to delete the specified security policy rule.

Syntax

rule { *rule-id* | [*rule-id*] **name** *rule-name* }

undo rule { *rule-id* | **name** *rule-name* } *

Default

No security policy rules exist.

Views

IPv4 security policy view

IPv6 security policy view

Predefined user roles

network-admin

context-admin

Parameters

rule-id: Specifies a rule ID in the range of 0 to 4294967290. If you do not specify an ID for the rule, the system automatically assigns the rule the integer next to the greatest ID being used. If the greatest ID is 4294967290, the system assigns the rule the smallest unused number in the range.

rule-name: Specifies a globally unique rule name, a case-insensitive string of 1 to 127 characters. The name cannot be **default**. You must specify a rule name when creating a rule.

Examples

Create an IPv4 security policy rule with rule ID **0** and rule name **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1]
```

security-policy ipv6

security-policy

Use **security-policy** to enter security policy view.

Use **undo security-policy** to delete all configurations in security policy view.

Syntax

security-policy { **ip** | **ipv6** }

undo security-policy { **ip** | **ipv6** }

Default

No configurations exist in security policy view.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ip: Specifies the IPv4 security policy.

ipv6: Specifies the IPv6 security policy.

Usage guidelines

CAUTION:

- The **undo security-policy** { **ip** | **ipv6** } command directly deletes all security policy configurations and might cause network interruptions.
- If the security policy feature is enabled, object policy settings lose effect the first time you enter the security policy view. Make sure policy settings have been switched to security policy settings before you enter the security policy view.

Examples

Enter IPv4 security policy view.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip]
```

Delete all IPv4 security policy configurations.

```
<Sysname> system-view
[Sysname] undo security-policy ip
This command willdelete all rules from the current policy. Continue anyway? [Y/N]:
```

display security-policy

security-policy config-logging send-time

Use **security-policy config-logging send-time** to set the time at which the device fast outputs security policy settings as logs every day.

Use **undo security-policy config-logging send-time** to restore the default.

Syntax

security-policy config-logging send-time *time*

undo security-policy config-logging send-time

Default

The device fast outputs security policy settings as logs every day at 0 o'clock.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

time: Specify the time at which the device fast outputs security policy settings as logs, in the format of *hh*:*mm*. The value range for the *hh* argument is 00 to 23 and the value range for the *mm* argument is 00 to 59.

Usage guidelines

After the **customlog format security-policy sgcc** command is executed, the device fast outputs settings of enabled security policies as logs in SGCC format every day at the specified time. For more information about fast log output, see *Network Management and Monitoring Configuration Guide*.

Examples

Configure the device to fast output security policy settings as logs every day at 13:15.

```
<Sysname>system-view
[Sysname] security-policy config-loggging send-time 13:15
```

Related commands

customlog format security-policy sgcc (*Network Management and Monitoring Command Reference*)

customlog host export security-policy (*Network Management and Monitoring Command Reference*)

security-policy disable

Use **security-policy disable** to disable the security policy feature.

Use **undo security-policy disable** to enable the security policy feature.

Syntax

security-policy disable

undo security-policy disable

Default

The security policy feature is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

CAUTION:

The **security-policy disable** command disables the security policy feature and might cause traffic interruption.

Security policy settings take effect only when the security policy feature is enabled.

Examples

Disable the security policy feature.

```
<Sysname> system-view
[Sysname] security-policy disable
```

service

Use **service** to specify a service object group as a filtering criterion of a security policy rule.

Use **undo service** to remove the specified service object group from a security policy rule.

Syntax

service { *object-group-name* | **any** }

undo service [*object-group-name* | **any**]

Default

No service object group is specified as a filtering criterion for a security policy rule.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

object-group-name: Specifies the name of a service object group, a case-insensitive string of 1 to 63 characters.

any: Specifies all service object groups.

Usage guidelines

You can execute the command multiple times to specify multiple service object groups as the filtering criteria.

If you specify a nonexistent object group, the device automatically creates the specified object group with empty configuration. A rule that contains an object group with empty configuration does not match any packets.

If you specify neither an object group nor the **any** keyword when executing the **undo service** command, the command removes all service object groups from the security policy rule.

For a security policy rule, the number of configured service object groups cannot exceed 1024. If the limit has been reached, any command execution to add such a filtering criterion fails and the system prompts an error.

Examples

Specify service object groups **http** and **ftp** as the filtering criteria of security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] service http
[Sysname-security-policy-ip-0-rule1] service ftp
```

Related commands

display security-policy

object-group

service-port

Use **service-port** to specify a service port as a filtering criterion of a security policy rule.

Use **undo service-port** to remove the specified service port range from a security policy rule.

Syntax

service-port *protocol* [{ **destination** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } | **source** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } } * | *icmp-type icmp-code* | *icmpv6-type icmpv6-code*]

undo service-port [*protocol* [{ **destination** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } | **source** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } } * | *icmp-type icmp-code* | *icmpv6-type icmpv6-code*]]

Default

No service port is specified as a filtering criterion for a security policy rule.

Views

IPv4 security policy rule view

IPv6 security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

protocol: Specify the number or name of a protocol. The protocol number value ranges and available protocol names vary by command execution view.

- In IPv4 security policy view, the value range for protocol numbers is 0 to 57 and 59 to 255. Available protocol names include **tcp**, **udp**, and **icmp**, whose protocol numbers are 6, 17, and 1, respectively.
- In IPv6 security policy view, the value range for protocol numbers is 0 and 2 to 255. Available protocol names include **tcp**, **udp**, and **icmp**, whose protocol numbers are 6, 17, and 58, respectively.

destination: Specifies the destination port. This configuration takes effect only when the protocol is TCP or UDP.

source: Specifies the source port. This configuration takes effect only when the protocol is TCP or UDP.

eq: Specifies the specified port.

lt: Specifies all ports whose port numbers are smaller than the specified port. If you specify this keyword, the specified port number cannot be 0.

gt: Specifies all ports whose port numbers are larger than the specified port. If you specify this keyword, the specified port number cannot be 65535.

port: Specifies a port number in the range of 0 to 65535.

range *port1 port2*: Specifies a range of port numbers. The *port1* argument represents the start port and the *port2* argument represents the end port. Each port number is in the range of 0 to 65535.

icmp-type: Specifies an ICMP message type in the range of 0 to 255. This configuration takes effect only when the protocol is ICMP.

icmp-code: Specifies the ICMP message code in the range of 0 to 255.

icmpv6-type: Specifies an ICMPv6 message type in the range of 0 to 255. This configuration takes effect only when the protocol is ICMPv6.

icmpv6-code: Specifies the ICMPv6 message code in the range of 0 to 255.

Usage guidelines

You can execute this command multiple times to specify multiple service ports as the filtering criteria.

If you specify a service port that has been configured as a service port filtering criterion, the command execution fails.

For a security policy rule, the number of configured service ports cannot exceed 1024. If the limit has been reached, any command execution to add such a filtering criterion fails and the system prompts an error.

When you specify the **range** keyword, following these restrictions and guidelines:

- If *port1* is the same as *port2*, the command takes effect as if you specified the **eq** keyword.
- If *port1* is 0, the command takes effect as if you specified the **lt** keyword with *port2* as the specified port.
- If *port2* is 65535, the command takes effect as if you specified the **gt** keyword with *port1* as the specified port.
- If *port1* is larger than *port2*, the system automatically changes the port range to [*port2*, *port1*].

If you do not specify any keyword or argument when executing the **undo** command, the command removes all service ports from the security policy rule.

Examples

Specify TCP destination and source ports as the filtering criteria of security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] service-port tcp destination range 100 200 source eq 100
```

Specify ICMP destination and source ports as the filtering criteria of security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] service-port icmp 100 150
```

Related commands

display security-policy

session aging-time

Use **session aging-time** to set the session aging time for a security policy rule.

Use **undo session aging-time** to restore the default.

Syntax

session aging-time *time-value*

undo session aging-time

Default

The session aging time is not configured for a security policy rule.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

time-value: Specifies the aging time in the range of 1 to 2000000 seconds.

Usage guidelines

CAUTION:

Setting too long an aging time might cause persistent sessions to increase rapidly and therefore cause the CPU usage to be high.

This command sets the aging time for stable sessions created for packets matching the specified security policy rule, and takes effect only on newly created sessions.

If the aging time is not configured for a rule, the stable sessions use the aging time set by using the **session aging-time application** or the **session aging-time state** command. For more information about session management, see *Security Configuration Guide*.

Unstable sessions age based on the default session aging time configured.

Examples

Set the session aging time to 5000 seconds for security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] action pass
[Sysname-security-policy-ip-0-rule1] session aging-time 5000
```

Related commands

session aging-time application

session aging-time state

session persistent acl

session persistent aging-time

Use **session persistent aging-time** to set the aging time for persistent sessions.

Use **undo session persistent aging-time** to restore the default.

Syntax

session persistent aging-time *time-value*

undo session persistent aging-time

Default

The persistent session aging time is not configured for a security policy rule.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

time-value: Specifies the aging time in the range of 0 to 24000 hours. If you set the aging time to 0, persistent sessions do not age out.

Usage guidelines

This command is effective only on TCP sessions in ESTABLISHED state.

It sets the aging time for persistent sessions created for packets matching the specified security policy rule, and takes effect only on newly created sessions.

The aging time configured by using this command takes precedence over the aging times configured by using the **session aging-time** and **session persistent acl** commands.

Examples

Set the persistent session aging time to one hour for security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] action pass
[Sysname-security-policy-ip-0-rule1] session persistent aging-time 1
```

source-ip

Use **source-ip** to specify a source IP address object group as a filtering criterion of a security policy rule.

Use **undo source-ip** to remove the specified source IP address object group from a security policy rule.

Syntax

source-ip *object-group-name*

undo source-ip [*object-group-name*]

Default

No source IP address object group is specified as a filtering criterion for a security policy rule.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

object-group-name: Specifies the name of a source IP address object group, a case-insensitive string of 1 to 63 characters. The name cannot be **any**. If you do not specify this argument when executing the **undo source-ip** command, the command removes all source IP address object groups from the rule. For more information about object groups, see *Security Configuration Guide*.

Usage guidelines

You can execute the command multiple times to specify multiple source IP address object groups as the filtering criteria.

If you specify a nonexistent object group, the device automatically creates the specified object group with empty configuration. A rule that contains an object group with empty configuration does not match any packets.

For a security policy, the number of configured source IP addresses cannot exceed 1024. If the limit has been reached, any command execution to add such a filtering criterion fails and the system prompts an error.

Examples

Specify source IP address object groups **server1** and **server2** as the filtering criteria of security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] source-ip server1
[Sysname-security-policy-ip-0-rule1] source-ip server2
```

Use **source-ip-range** to specify a source IPv4 address range as a filtering criterion of a security policy rule.

Use **undo source-ip-range** to remove the specified source IPv4 address range from a security policy rule.

Syntax

source-ip-range *ip-address1 ip-address2*

undo source-ip-range [*ip-address1 ip-address2*]

Default

No source IPv4 address range is specified as a filtering criterion for a security policy rule.

Views

IPv4 security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

ip-address1 ip-address2: Specifies an IPv4 address range. The *ip-address1* argument represents the start IP address and the *ip-address2* argument represents the end IP address. If you do not specify the arguments when executing the **undo** command, the command removes all source IPv4 address ranges from the security policy rule.

Usage guidelines

You can execute the command multiple times to specify multiple source IPv4 address ranges as the filtering criteria.

If you specify an IP address range that has been configured as a source IP range filtering criterion, the command execution fails and the system prompts an error.

For a security policy rule, the sum of configured source host addresses, source subnets, and source address ranges cannot exceed 1024. If the limit has been reached, any command execution to add such a filtering criterion fails and the system prompts an error.

When you specify an IP address range, follow these restrictions and guidelines:

- If the start IP address is the same as the end IP address, the command creates a host address filtering criteria.
- If the start IP address and the end IP address define a subnet, the command creates a subnet filtering criteria.
- If *ip-address1* is greater than *ip-address2*, the system automatically adjusts the range to [*ip-address2*, *ip-address1*].

Examples

Specify source IPv4 address range 192.165.0.100 to 192.165.0.200 as the filtering criteria of IPv4 security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] source-ip-range 192.165.0.100 192.165.0.200
```

source-ip-subnet (IPv4 security policy view)

Use **source-ip-subnet** to specify a source IPv4 subnet as a filtering criterion of a security policy rule.

Use **undo source-ip-subnet** to remove the specified source IPv4 subnet from a security policy rule.

Syntax

source-ip-subnet *ip-address* { *mask-length* | *mask* }

undo source-ip-subnet [*ip-address* { *mask-length* | *mask* }]

Default

No source IPv4 subnet is specified as a filtering criterion for a security policy rule.

Views

IPv4 security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

ip-address { *mask-length* | *mask* }: Specifies an IPv4 subnet. You can specify the mask length or the mask in dotted decimal notation. The mask length is in the range of 0 to 32. If you set the mask length to 32 or the mask to 255.255.255.255, the command creates a host address filtering criterion. If you do not specify the arguments when executing the **undo** command, the command removes all source IPv4 subnets from the security policy rule.

Usage guidelines

You can execute the command multiple times to specify multiple source IPv4 subnets as the filtering criteria.

If you specify a subnet that has been configured as a source subnet filtering criterion, the command execution fails and the system prompts an error.

For a security policy rule, the sum of configured source host addresses, source subnets, and source address ranges cannot exceed 1024. If the limit has been reached, any command execution to add such a filtering criterion fails and the system prompts an error.

Examples

Specify the source subnet with IP address 192.167.0.0 and mask length 24 as a filtering criteria of IPv4 security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] source-ip-subnet 192.167.0.0 24
```

Specify the source subnet with IP address 192.166.0.0 and mask 255.255.0.0 as a filtering criteria of IPv4 security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1

time-range

Use **time-range** to specify the time range during which a security policy rule is in effect.

Use **undo time-range** to restore the default.

Syntax

time-range *time-range-name*

undo time-range [*time-range-name*]

Default

A security policy rule is in effect at any time.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

time-range-name: Specifies the name of a time range, a case-insensitive string of 1 to 32 characters. If you do not specify this parameter for an undo operation, the command deletes the time range during which the rule takes effect. For more information about time ranges, see *ACL and QoS Configuration Guide*.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Enable security policy rule **rule1** to be in effect during time range **work**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] time-range work
```

track

Use **track** to associate a security policy rule with a track entry.

Use **undo track** to disassociate a security policy rule from the track entry.

Syntax

track { **negative** | **positive** } *track-entry-number*

undo track

Default

No track entry is associated with a security policy rule.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

negative: Specifies the Negative state of a track entry.

positive: Specifies the Positive state of a track entry.

track-entry-number: Specifies the number of a track entry, in the range of 1 to 1024. For more information about Track, see *Network Management and Monitoring Configuration Guide*.

Usage guidelines

Use this command to enable the collaboration between the track module and a security policy rule. The collaboration operates as follows:

- If a rule is associated with the Negative state of a track entry, the device:
  - Sets the rule state to Active if the track entry is in Negative state.
  - Sets the rule state to Inactive if the track entry is in Positive state.
- If a rule is associated with the Positive state of a track entry, the device:
  - Sets the rule state to Active if the track entry is in Positive state.
  - Sets the rule state to Inactive if the track entry is in Negative state.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Associate security policy rule **rule1** with the Positive state of track entry 10.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] track positive 10
```

user

Use **user** to specify a user as a filtering criterion of a security policy rule.

Use **undo user** to remove the specified user filtering criterion from a security policy rule.

Syntax

user *username* [**domain** *domain-name*]

undo user [*username* [**domain** *domain-name*]]

Default

No user is specified as a filtering criterion for a security policy rule.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

username: Specifies a username, a case-sensitive string of 1 to 55 characters. The name cannot be **a**, **al**, or **all** and cannot contain at signs (@). If you do not specify this argument when executing the **undo user** command, the command removes all users from the rule. For more information about users and identity domains, see user identification in *Security Configuration Guide*.

domain *domain-name*: Matches the user in an identity domain. The *domain-name* argument represents the identity domain name, a case-insensitive string of 1 to 255 characters. The string cannot contain forward slashes (/), backslashes (\), vertical bars (|), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), or at signs (@). If you do not specify this option, the command matches the user among users that do not belong to any identity domain.

Usage guidelines

You can execute the command multiple times to specify multiple users as the filtering criteria.

Examples

Specify users **usera** and **userb** in identity domain **test** as the filtering criteria of security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] user usera domain test
[Sysname-security-policy-ip-0-rule1] user userb domain test
```

user-identity static-user

user-group

Use **user-group** to specify a user group as a filtering criterion of a security policy rule.

Use **undo user-group** to remove the specified user group filtering criterion from a security policy rule.

Syntax

user-group *user-group-name* [**domain** *domain-name*]

undo user-group [*user-group-name* [**domain** *domain-name*]]

Default

No user group is specified as a filtering criterion for a security policy rule.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

user-group-name: Specifies the name of a user group, a case-insensitive string of 1 to 200 characters. If you do not specify this argument when executing the **undo user-group** command, the command removes all user groups from the rule. For more information about user groups and identity domains, see user identification in *Security Configuration Guide*.

domain *domain-name*: Matches the user group in an identity domain. The *domain-name* argument represents the identity domain name, a case-insensitive string of 1 to 255 characters. The string cannot contain forward slashes (/), backslashes (\), vertical bars (|), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), or at signs (@). If you do not specify this option, the command matches the user group among user groups that do not belong to any identity domain.

Usage guidelines

You can execute the command multiple times to specify multiple user groups as the filtering criteria.

Examples

Specify user groups **groupa** and **groupb** in identity domain **test** as the filtering criteria of security policy rule **rule1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
```

```
[Sysname-security-policy-ip-0-rule1] user-group groupa domain test
[Sysname-security-policy-ip-0-rule1] user-group groupb domain test
```

Related commands

vrf

Use **vrf** to configure a security policy rule to take effect on received packets of the specified MPLS L3VPN instance.

Use **undo vrf** to restore the default.

Syntax

vrf *vrf-name*

undo vrf

Default

A security policy rule takes effect on received packets of the public network.

Views

Security policy rule view

Predefined user roles

network-admin

context-admin

Parameters

vrf-name: Specifies the name of an MPLS L3VPN instance, a case-sensitive string of 1 to 31 characters.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure security policy rule **rule1** to take effect on received packets of MPLS L3VPN instance **vpn1**.

```
<Sysname> system-view
[Sysname] security-policy ip
[Sysname-security-policy-ip] rule 0 name rule1
[Sysname-security-policy-ip-0-rule1] user-group groupa
[Sysname-security-policy-ip-0-rule1] user-group groupb
```

display security-policy

Contents

ASPF commands

aspf apply policy

Use **aspf apply policy** to apply an ASPF policy to a zone pair.

Use **undo aspf apply policy** to remove an ASPF policy application from a zone pair.

Syntax

aspf apply policy *aspf-policy-number*

undo aspf apply policy *aspf-policy-number*

Default

The system applies the predefined ASPF policy to a zone pair when the zone pair is created.

Views

Zone pair view

Predefined user roles

network-admin

context-admin

Parameters

aspf-policy-number: Specifies an ASPF policy number. The value range for this argument is 1 to 256.

Usage guidelines

With the predefined policy, ASPF inspects FTP packets and packets of all transport layer protocols, but it does not perform ICMP error message check or the TCP SYN packet check.

The predefined ASPF policy cannot be modified. To change the ASPF policy application, define an ASPF policy and apply it to the zone pair.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Apply an ASPF policy to a zone pair.

```
<Sysname> system-view
[Sysname] security-zone name trust
[Sysname-security-zone-Trust] import interface gigabitethernet 1/0/1
[Sysname-security-zone-Trust] quit
[Sysname] security-zone name untrust
[Sysname-security-zone-Untrust] import interface gigabitethernet 1/0/2
[Sysname-security-zone-Untrust] quit
[Sysname] zone-pair security source trust destination untrust
[Sysname-zone-pair-security-Trust-Untrust] aspf apply policy 1
```

zone-pair security

aspf icmp-error reply

Use **aspf icmp-error reply** to enable the device to send ICMP error messages upon packet dropping by interzone policies applied to zone pairs.

Use **undo aspf icmp-error reply** to restore the default.

Syntax

aspf icmp-error reply

undo aspf icmp-error reply

Default

The device does not send ICMP error messages when the device drops packets that do not match interzone policies applied to zone pairs.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Typically, to reduce useless packets transmitted over the network and save bandwidth, do not use this command.

However, you must use this command when you use traceroute because ICMP error messages in this situation are required.

Examples

Enable ICMP error message sending upon packet dropping by interzone policies applied to zone pairs.

```
<Sysname> system-view
[Sysname] aspf icmp-error reply
```

aspf policy

Use **aspf policy** to create an ASPF policy and enter its view, or enter the view of an existing ASPF policy.

Use **undo aspf policy** to remove an ASPF policy.

Syntax

aspf policy *aspf-policy-number*

undo aspf policy *aspf-policy-number*

Default

No ASPF policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

aspf-policy-number: Assigns a number to the ASPF policy. The value range for this argument is 1 to 256.

Examples

Create ASPF policy 1 and enter its view.

```
<Sysname> system-view
[Sysname] aspf policy 1
[Sysname-aspf-policy-1]
```

Related commands

display aspf all

display aspf policy

detect

Use **detect** to configure ASPF inspection for an application layer protocol.

Use **undo detect** to restore the default.

Syntax

detect { **dns** [**action** { **drop** | **logging** } *] | { **ftp** | **h323** | **http** | **sccp** | **sip** | **smtp** } [**action drop**] | **gtp** | **ils** | **mgcp** | **nbt** | **pptp** | **rsh** | **rtsp** | **sqlnet** | **tftp** | **xdmcp** }

undo detect { **dns** | **ftp** | **gtp** | **h323** | **http** | **ils** | **mgcp** | **nbt** | **pptp** | **rsh** | **rtsp** | **sccp** | **sip** | **smtp** | **sqlnet** | **tftp** | **xdmcp** }

Default

ASPF inspects only transport layer protocols and application protocol FTP.

Views

ASPF policy view

Predefined user roles

network-admin

context-admin

Parameters

dns: Specifies DNS, an application layer protocol.

ftp: Specifies FTP, an application layer protocol.

gtp: Specifies GPRS Tunneling Protocol (GTP), an application layer protocol.

h323: Specifies H.323 protocol stack, application layer protocols.

http: Specifies HTTP, an application layer protocol.

ils: Specifies Internet Locator Service (ILS), an application layer protocol.

mgcp: Specifies Media Gateway Control Protocol (MGCP), an application layer protocol.

nbt: Specifies NetBIOS over TCP/IP (NBT), an application layer protocol.

pptp: Specifies Point-to-Point Tunneling Protocol (PPTP), an application layer protocol.

rsh: Specifies Remote Shell (RSH), an application layer protocol.

rtsp: Specifies Real Time Streaming Protocol (RTSP), an application layer protocol.

sccp: Specifies Skinny Client Control Protocol (SCCP), an application layer protocol.

sip: Specifies Session Initiation Protocol (SIP), an application layer protocol.

smtp: Specifies SMTP, an application layer protocol.

sqlnet: Specifies SQLNET, an application layer protocol.

tftp: Specifies TFTP, an application layer protocol.

xdmcp: Specifies X Display Manager Control Protocol (XDMCP), an application layer protocol.

action: Specifies an action on the packets that do not pass the protocol status validity check. If you do not specify an action, ASPF does not perform the protocol status validity check, and it only maintains connection status information.

drop: Drops the packets that do not pass the protocol status validity check.

logging: Generates log messages for packets that do not pass the protocol status validity check.

Usage guidelines

This command is required to ensure successful data connections for multichannel protocols when either of the following conditions exists:

- The ALG feature is disabled in other service modules (such as NAT).
- Other service modules with the ALG feature (such as DPI) are not configured.

This command is optional for multichannel protocols if ALG is enabled in other service modules (such as NAT) or if other service modules with the ALG feature are configured.

Application protocols supported by this command (except HTTP, SMTP, and TFTP) are multichannel protocols.

Repeat the **detect** command to configure ASPF inspection for multiple application protocols.

ASPF inspection for transport layer protocols is always enabled and is not configurable. The supported transport layer protocols include TCP, UDP, UDP-Lite, SCTP, Raw IP, ICMP, ICMPv6, and DCCP.

This command configures ASPF inspection for application protocols. ASPF inspection supports protocol status validity check for application protocols of DNS, FTP, H323, HTTP, SCCP, SIP, and SMTP. The device deals with packets with invalid protocol status according to the actions you have specified. To configure protocol status validity check for an application protocol, you must specify the **action** keyword.

Examples

Configure ASPF inspection for FTP packets.

```
<Sysname> system-view
[Sysname] aspf policy 1
[Sysname-aspf-policy-1] detect ftp
```

Configure ASPF inspection for DNS packets, drop packets that fail protocol status validity check and generate log messages for these packets.

```
<Sysname> system-view
[Sysname] aspf policy 1
[Sysname-aspf-policy-1] detect dns action drop logging
```

Examples

Display the configuration of all ASPF policies and their applications.

```
<Sysname> display aspf all
ASPF policy configuration:
  Policy default:
    ICMP error message check: Disabled
    Inspected protocol    Action
      FTP                  None
  Policy number: 1
    ICMP error message check: Disabled
    TCP SYN packet check: Disabled
    Inspected protocol    Action
      FTP                  None

Zone-pair security application:
  Source Trust destination Untrust
    Apply ASPF policy: default
```

Table 1 Command output

Field	Description
Policy default	Predefined ASPF policy.
ICMP error message check	Whether ICMP error message check is enabled.
TCP SYN packet check	Whether TCP SYN check is enabled.
Inspected protocol	Protocols to be inspected by ASPF.
Action	Actions on the detected illegal packets: • **Drop**—Drops illegal packets. • **Log**—Generates log messages for illegal packets. • **None**—Allows illegal packets to pass. If the protocol does not support the action configuration, this field displays a hyphen (-).
Zone-pair security application	Information about zone-pair security application.

Field	Description
Source *XXX* destination *XXX*	Source zone and destination zone.
Apply ASPF policy	Number of ASPF policy applied to the zone pair.

Parameters

aspf-policy-number: Specifies the number of an ASPF policy. The value range for this argument is 1 to 256.

default: Specifies the predefined ASPF policy.

Examples

Display the configuration of ASPF policy 1.

```
<Sysname> display aspf policy 1
ASPF policy configuration:
  Policy number: 1
    ICMP error message check: Disabled
    TCP SYN packet check: Enabled
    Inspected protocol   Action
     FTP                  Drop
     HTTP                 None
     RSH                  -
```

Table 2 Command output

Field	Description
ICMP error message check	Whether ICMP error message check is enabled.
TCP SYN packet check	Whether TCP SYN check is enabled.
Inspected protocol	Protocols to be inspected by ASPF.

Field	Description
Action	Actions on the detected illegal packets: • **Drop**—Drops illegal packets. • **Log**—Generates log messages for illegal packets. • **None**—Allows illegal packets to pass. If the protocol does not support the action configuration, this field displays a hyphen (-).

Related commands

aspf policy

display aspf session

Use **display aspf session** to display ASPF sessions.

Syntax

display aspf session [**ipv4** | **ipv6**] [**slot** *slot-number*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ipv4: Displays IPv4 ASPF sessions.

ipv6: Displays IPv6 ASPF sessions.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays ASPF sessions for all member devices.

verbose: Displays detailed information about ASPF sessions. If you do not specify this keyword, the command displays the brief information about ASPF sessions.

Usage guidelines

If you do not specify the **ipv4** keyword or the **ipv6** keyword, this command displays all ASPF sessions on the device.

Examples

Display brief information about IPv4 ASPF sessions.

```
<Sysname> display aspf session ipv4
Slot 1:
Initiator:
  Source      IP/port: 192.168.1.18/1877
  Destination IP/port: 192.168.1.55/22
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
```

```
  Inbound interface: GigabitEthernet1/0/1
  Source security zone: SrcZone
Initiator:

Responder->Initiator:         0 packets          0 bytes

Total sessions found: 2
```

Table 3 Command output

Field	Description
Initiator	Session information from initiator to responder.
Responder	Session information from responder to initiator.
Source IP/port	Source IP address and port number.
Destination IP/port	Destination IP address and port number.
DS-Lite tunnel peer	IP address of the DS-Lite tunnel peer. If the session is not tunneled by DS-Lite, this field displays a hyphen (-).
VPN-instance/VLAN ID/Inline ID	• **VPN-instance**—MPLS L3VPN instance where the session is initiated. • **VLAN ID**—VLAN to which the session belongs during Layer 2 forwarding. • **Inline ID**—Inline to which the session belongs during Layer 2 forwarding. If no MPLS L3VPN instance, VLAN ID, or Inline ID is specified, a hyphen (-) is displayed for each field.
Protocol	Transport layer protocols, including DCCP, ICMP, ICMPv6, Raw IP, SCTP, TCP, UDP, and UDP-Lite. Number in parentheses represents the protocol number.
Source security zone	Security zone to which the inbound interface belongs. If the inbound interface does not belong to any security zone, this field displays a hyphen (-).
State	Protocol status of the session.
Application	Application layer protocol, including FTP and DNS. If it is an unknown protocol identified by an unknown port, this field displays **OTHER**.
Start time	Establishment time of the session.
TTL	Remaining lifetime of the session, in seconds.
Initiator->Responder	Number of packets and bytes from initiator to responder.
Responder->Initiator	Number of packets and bytes from responder to initiator.

Related commands

reset aspf session

icmp-error drop

Use **icmp-error drop** to enable ICMP error message dropping.

Use **undo icmp-error drop** to disable ICMP error message dropping.

Syntax

icmp-error drop

undo icmp-error drop

Default

ICMP error message dropping is disabled.

Views

ASPF policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

An ICMP error message carries information about the corresponding connection. ICMP error message dropping verifies the information. If the information does not match the connection, ASPF drops the message.

Examples

Enable ICMP error message dropping for ASPF policy 1.

```
<Sysname> system-view
[Sysname] aspf policy 1
[Sysname-aspf-policy-1] icmp-error drop
```

Related commands

aspf policy

display aspf policy

reset aspf session

Use **reset aspf session** to clear ASPF session statistics.

Syntax

reset aspf session [**ipv4** | **ipv6**] [**slot** *slot-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

ipv4: Clears IPv4 ASPF session statistics.

ipv6: Clears IPv6 ASPF session statistics.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command clears ASPF session statistics for all member devices.

Usage guidelines

If you do not specify the **ipv4** keyword or the **ipv6** keyword, this command clears all ASPF session statistics.

Examples

Clear all ASPF session statistics.

```
<Sysname> reset aspf session
```

Related commands

display aspf session

tcp syn-check

Use **tcp syn-check** to enable TCP SYN check.

Use **undo tcp syn-check** to disable TCP SYN check.

Syntax

tcp syn-check

undo tcp syn-check

Default

TCP SYN check is disabled.

Views

ASPF policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

TCP SYN check checks the first packet to establish a TCP connection whether it is a SYN packet. If the first packet is not a SYN packet, ASPF drops the packet.

When a router attached to the network is started up, it can receive a non-SYN packet of an existing TCP connection for the first time. If you do not want to interrupt the existing TCP connection, you can disable the TCP SYN check. Then, the router allows the non-SYN packet that is the first packet to establish a TCP connection to pass. After the network topology becomes steady, you can enable TCP SYN check again.

Examples

Enable TCP SYN check for ASPF policy 1.

```
<Sysname> system-view
[Sysname] aspf policy 1
[Sysname-aspf-policy-1] tcp syn-check
```

display session dual-active transparent statistics

Use **display session dual-active transparent statistics** to display statistics about transparently transmitted packets in session dual-active mode.

Syntax

display session dual-active transparent statistics [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays packet statistics for all member devices.

Examples

Display statistics about transparently transmitted packets in session dual-active mode.

```
<Sysname> display session dual-active transparent statistics
Slot 1:
          UDP relay packets :                   0
         Hash relay packets :                   0
      Sent relay packets :                      0
    Received relay packets :                    0
```

Table 3 Command output

Field	Description
UDP relay packets	Number of transparently transmitted UDP packets.
Hash relay packets	Number of packets for which sessions are created according to the result of source IP-based hashing.
Sent relay packets	Number of sent packets that are transparently transmitted.
Received relay packets	Number of received packets that are transparently transmitted.

```

Table 4 Command output

Field	Description
Current	Total number of unicast deny sessions.
Session type	Deny session type: • TCP. • UDP. • ICMP. • ICMPv6. • UDP-Lite. • SCTP.

Field	Description
	• DCCP. • RAWIP. • DNS. • FTP. • GTP. • H323. • HTTP. • ILS. • MGCP. • NBT. • PPTP. • RSH. • RTSP. • SCCP. • SIP. • SMTP. • SQLNET. • SSH. • TELNET. • TFTP. • XDMCP.
Est count	Number of deny sessions created for each protocol.
Deny session establishment rate	Rate of deny session establishment.
Session type	Deny session type: • TCP. • UDP. • ICMP. • ICMPv6. • UDP-Lite. • SCTP. • DCCP. • RAWIP.
Est count	Number of deny sessions created per second for each protocol.

Display summary information about unicast deny session statistics.

```
<Sysname> display session fast-drop statistics summary
Slot 1:
type      Sessions  TCP sessions  UDP sessions  Rate      TCP rate  UDP rate
Est       1         0             0             1/s       0/s       0/s
Try       47        0             0             1/s       0/s       0/s
```

Table 5 Command output

Field	Description
type	Deny session type: • **Est**—Successfully created deny session. • **Try**—Deny session that the system attempted to create.

Field	Description
Sessions	Total number of unicast deny sessions.
TCP sessions	Number of TCP unicast deny sessions.
UDP sessions	Number of UDP unicast deny sessions.
Rate	Rate of unicast deny session creation.
TCP rate	Rate of TCP unicast deny session creation.
UDP rate	Rate of UDP unicast deny session creation.

display session fast-drop table ipv4

Use **display session fast-drop table ipv4** to display IPv4 unicast deny session entries.

Syntax

display session fast-drop table ipv4 [**slot** *slot-number*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information on all member devices.

verbose: Displays detailed information about IPv4 unicast deny session entries. If you do not specify this keyword, the command displays brief information about IPv4 unicast deny session entries.

Examples

Display brief information about all IPv4 unicast deny session entries.

```
<Sysname> display session fast-drop table ipv4
Slot 1:
Initiator:
  Source      IP/port: 192.168.1.18/1877
  Destination IP/port: 192.168.1.55/22
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/1
  Source security zone: Trust
Total deny session found: 1
```

Display detailed information about all IPv4 unicast deny session entries.

```
<Sysname> display session fast-drop table ipv4 verbose
Slot 1:
```

```
Initiator:
  Source      IP/port: 192.168.1.18/1877
  Destination IP/port: 192.168.1.55/22
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/1
  Source security zone: Trust
Responder:
  Source      IP/port: 192.168.1.55/22
  Destination IP/port: 192.168.1.18/1877
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/2
  Source security zone: Local
State: TCP_SYN_SENT
Application: SSH
Rule ID: 1
Rule name: test
Start time: 2011-07-29 19:12:36  TTL: 28s
Initiator->Responder:         1 packets         48 bytes
Responder->Initiator:         0 packets          0 bytes
Total deny session found: 1
```

Table 6 Command output

Field	Description
Initiator	Information about the unicast deny session from the initiator to the responder.
Responder	Information about the unicast deny session from the responder to the initiator.
DS-Lite tunnel peer	Address of the DS-Lite tunnel peer. When the unicast deny session is not tunneled by DS-Lite, this field displays a hyphen (**-**).
VPN instance/VLAN ID/Inline ID	MPLS L3VPN instance to which the unicast deny session belongs. VLAN and inline to which the deny session belongs during Layer 2 forwarding. If a parameter is not specified, a hyphens (-) is displayed for the proper field.
Protocol	Transport layer protocol: • DCCP. • ICMP. • ICMPv6. • Raw IP. • SCTP. • TCP. • UDP. • UDP-Lite. The number in the brackets indicates the protocol number.
Inbound interface	Interface on which packets are received.

Field	Description
Source security zone	Security zone to which the inbound interface belongs. If the inbound interface does not belong to any security zone, this field displays a hyphen (**-**).
State	Unicast deny session state.
Application	Application layer protocol, FTP or DNS. If it is an unknown protocol identified by an unknown port, this field displays **OTHER**.
Rule ID	ID of the security policy rule.
Rule name	Name of the security policy rule.
Start time	Unicast deny session establishment time.
TTL	Remaining lifetime of the unicast deny session, in seconds.
Initiator->Responder	Number of packets and bytes from the initiator to the responder.
Responder->Initiator	Number of packets and bytes from the responder to the initiator.
Total deny session found	Total number of found unicast deny session entries.

display session fast-drop table ipv6

Use **display session fast-drop table ipv6** to display IPv6 unicast deny session entries.

Syntax

display session fast-drop table ipv6 [**slot** *slot-number*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information on all member devices.

verbose: Displays detailed information about IPv6 unicast deny session entries. If you do not specify this keyword, the command displays brief information about IPv6 unicast deny session entries.

Examples

Display brief information about all IPv6 unicast deny session entries.

```
<Sysname> display session fast-drop table ipv6
Slot 1:
Initiator:
  Source      IP/port: 2011::2/58473
  Destination IP/port: 2011::8/32768
  DS-Lite tunnel peer: -
```

```
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/1
  Source security zone: Trust
Total deny session found: 1
```

Display detailed information about all IPv6 unicast deny session entries.

```
<Sysname> display session fast-drop table ipv6 verbose
Slot 1:
Initiator:
  Source      IP/port: 2011::2/58473
  Destination IP/port: 2011::8/32768
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/1
  Source security zone: Trust
Responder:
  Source      IP/port: 192.168.1.55/22

  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/2
  Source security zone: Local
State: TCP_SYN_SENT
Application: SSH
Rule ID: 1
Rule name: test
Start time: 2011-07-29 19:12:36  TTL: 28s
Initiator->Responder:         1 packets         48 bytes
Responder->Initiator:         0 packets          0 bytes
Total deny session found: 1
```

Table 7 Command output

Field	Description
Initiator	Information about the unicast deny session from the initiator to the responder.
Responder	Information about the unicast deny session from the responder to the initiator.
DS-Lite tunnel peer	Address of the DS-Lite tunnel peer. When the unicast deny session is not tunneled by DS-Lite, this field displays a hyphen (**-**).
VPN instance/VLAN ID/Inline ID	MPLS L3VPN instance to which the unicast deny session belongs. VLAN and inline to which the unicast deny session belongs during Layer 2 forwarding. If a parameter is not specified, a hyphens (**-**) is displayed for the proper field.
Protocol	Transport layer protocol: • DCCP.

Field	Description
	• ICMP. • ICMPv6. • Raw IP. • SCTP. • TCP. • UDP. • UDP-Lite. The number in the brackets indicates the protocol number.
Inbound interface	Interface on which packets are received.
Source security zone	Security zone to which the inbound interface belongs. If the inbound interface does not belong to any security zone, this field displays a hyphen (-).
State	Unicast deny session state.
Application	Application layer protocol, FTP or DNS. If it is an unknown protocol identified by an unknown port, this field displays **OTHER**.
Rule ID	ID of the security policy rule.
Rule name	Name of the security policy rule.
Start time	Unicast deny session establishment time.
TTL	Remaining lifetime of the unicast deny session, in seconds.
Initiator->Responder	Number of packets and bytes from the initiator to the responder.
Responder->Initiator	Number of packets and bytes from the responder to the initiator.
Total deny session found	Total number of found unicast deny session entries.

display session fast-drop top-statistics

Use **display session fast-drop top-statistics** to display top deny session statistics.

Syntax

display session fast-drop top-statistics { last-1-hour | last-24-hours | last-30-days }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

last-1-hour: Displays top deny session statistics in last hour.

last-24-hours: Displays top deny session statistics in last 24 hours.

last-30-days: Displays top deny session statistics in last 30 days.

Usage guidelines

This command displays nothing if the top deny session statistics feature is disabled. A maximum of 10 session items can be displayed.

Examples

Display top deny session statistics in last hour.

```
<Sysname> display session fast-drop top-statistics last-1-hour
Counting by source addresses:
No.      Source address          Sessions
1        8.1.1.1                 6085
2        111.15.111.16           10
3        6::2                    2

Counting by destination addresses:
No.      Destination address     Sessions
1        8.1.1.2                 6085
2        6::3                    2
3        30.1.1.8                1
4        30.1.1.4                1
5        30.1.1.11               1
6        30.1.1.9                1
7        30.1.1.6                1
8        30.1.1.5                1
9        30.1.1.7                1
10       30.1.1.3                1
```

Table 8 Command output

Field	Description
Counting by source addresses	Top deny session statistics based on source addresses.
Counting by destination addresses	Top deny session statistics based on destination addresses.
No.	Ranking number.
Source address	Source IP address of the deny sessions.
Destination address	Destination IP address of the deny sessions.
Sessions	Total number of deny sessions.

display session relation-table

Use **display session relation-table** to display relation entries.

Syntax

display session relation-table { **ipv4** | **ipv6** } [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ipv4: Specifies IPv4 relation entries.

ipv6: Specifies IPv6 relation entries.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays relation entries for all member devices.

Examples

Display all IPv4 relation entries.

```
<Sysname> display session relation-table ipv4
Slot 1:
Source IP/port:      192.168.1.100/-
Destination IP/port: 192.168.2.100/99
DS-Lite tunnel peer: -
VPN instance/VLAN ID/Inline ID: 1/-/-
Protocol: TCP(6)    TTL: 1234s    App: FTP-DATA

Source IP/port:      -/-
Destination IP/port: 192.168.2.200/1212
DS-Lite tunnel peer: -
VPN instance/VLAN ID/Inline ID: 1/-/-
Protocol: TCP(6)    TTL: 3100s    App: H225

Total entries found:  2
```

Display all IPv6 relation entries.

```
<Sysname> display session relation-table ipv6
Slot 1:
Source IP:             2011::0002
Destination IP/port: 2011::0008/1212
DS-Lite tunnel peer: -
VPN instance/VLAN ID/Inline ID: -/-/-
Protocol: TCP(6)    TTL: 567s    App: FTP-DATA

Total entries found:  1
```

Table 9 Command output

Field	Description
Source IP/port	Source IP address and port number of the session. If the IP or port number is not specified, this field displays a hyphen (-). For an IPv6 relation entry, the source port number is not displayed.
Destination IP/port	Destination IP address and port number of the session.

Field	Description
DS-Lite tunnel peer	Peer tunnel interface address of the DS-Lite tunnel to which the session belongs. If no peer tunnel interface address is specified, a hyphen (-) is displayed.
VPN instance/VLAN ID/ Inline ID	MPLS L3VPN instance to which the relation entry belongs. VLAN and inline to which the relation entry belongs during Layer 2 forwarding. If a parameter is not specified, a hyphen (-) is displayed for the proper field.
Protocol	Transport layer protocol.
TTL	Remaining lifetime of the relation entry, in seconds.
App	Application layer protocol.
Total entries found	Total number of found relation entries.

display session statistics

Use **display session statistics** to display unicast session statistics.

Syntax

display session statistics [**history-max** | **summary**] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

history-max: Displays history statistics of the maximum unicast sessions and the maximum unicast session establishment rates. If you do not specify this keyword, the command displays all unicast session statistics.

summary: Displays summary information about unicast session statistics. If you do not specify this keyword, the command displays detailed information about unicast session statistics.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays unicast session statistics for all member devices.

Usage guidelines

If you do not specify any parameters, this command displays detailed information about the current unicast session statistics.

Examples

Display detailed information about unicast session statistics.

```
<Sysname> display session statistics
Slot 1:
Current sessions: 3
```

```
          TCP sessions:                   0
          UDP sessions:                   0
         ICMP sessions:                   3
       ICMPv6 sessions:                   0
     UDP-Lite sessions:                   0
         SCTP sessions:                   0
         DCCP sessions:                   0
        RAWIP sessions:                   0
          DNS sessions:                   0
          FTP sessions:                   0
          GTP sessions:                   0
         H323 sessions:                   0
         HTTP sessions:                   0
          ILS sessions:                   0
         MGCP sessions:                   0
          NBT sessions:                   0
         PPTP sessions:                   0
          RSH sessions:                   0
         RTSP sessions:                   0
         SCCP sessions:                   0
          SIP sessions:                   0
         SMTP sessions:                   0
       SQLNET sessions:                   0
          SSH sessions:                   0
       TELNET sessions:                   0
         TFTP sessions:                   0
        XDMCP sessions:                   0
History average sessions per second:
      Past hour: 1
      Past 24 hours: 0
      Past 30 days: 0
History average session establishment rate:
      Past hour: 0/s
      Past 24 hours: 0/s
      Past 30 days: 0/s
Current relation-table entries: 0
Relation table establishment rate: 0/s
Session establishment rate: 0/s
          TCP:                  0/s
          UDP:                  0/s
         ICMP:                  0/s
       ICMPv6:                  0/s
     UDP-Lite:                  0/s
         SCTP:                  0/s
         DCCP:                  0/s
        RAWIP:                  0/s
Received TCP      :                  0 packets                  0 bytes
Received UDP      :                118 packets              13568 bytes
```

```
Received ICMP     :                105 packets                 8652 bytes
Received ICMPv6   :                  0 packets                    0 bytes
Received UDP-Lite :                  0 packets                    0 bytes
Received SCTP     :                  0 packets                    0 bytes
Received DCCP     :                  0 packets                    0 bytes
Received RAWIP    :                  0 packets                    0 bytes
```

Table 10 Command output

Field	Description
Current sessions	Total number of unicast sessions.
TCP sessions	Number of TCP sessions.
UDP sessions	Number of UDP sessions.
ICMP sessions	Number of ICMP sessions.
ICMPv6 sessions	Number of ICMPv6 sessions.
UDP-Lite sessions	Number of UDP-Lite sessions.
SCTP sessions	Number of SCTP sessions.
DCCP sessions	Number of DCCP sessions.
RAWIP sessions	Number of Raw IP sessions.
DNS sessions	Number of DNS unicast sessions.
FTP sessions	Number of FTP unicast sessions.
GTP sessions	Number of GTP unicast sessions.
H323 sessions	Number of H.323 unicast sessions.
HTTP sessions	Number of HTTP unicast sessions.
ILS sessions	Number of ILS unicast sessions.
MGCP sessions	Number of MGCP unicast sessions.
NBT sessions	Number of NBT unicast sessions.
PPTP sessions	Number of PPTP unicast sessions.
RSH sessions	Number of RSH unicast sessions.
RTSP sessions	Number of RTSP unicast sessions.
SCCP sessions	Number of SCCP unicast sessions.
SIP sessions	Number of SIP unicast sessions.
SMTP sessions	Number of SMTP unicast sessions.
SQLNET sessions	Number of SQLNET unicast sessions.
SSH sessions	Number of SSH unicast sessions.
TELNET sessions	Number of Telnet unicast sessions.

Field	Description
TFTP sessions	Number of TFTP unicast sessions.
XDMCP sessions	Number of XDMCP unicast sessions.
History average sessions per second	History statistics of average sessions per second.
Past hour	The average number of sessions per second in the most recent hour.
Past 24 hours	The average number of sessions per second in the most recent 24 hours.
Past 30 days	The average number of sessions per second in the most recent 30 days.
History average session establishment rate	History statistics of average session establishment rates.
Past hour	The average session establishment rate in the most recent hour.
Past 24 hours	The average session establishment rate in the most recent 24 hours.
Past 30 days	The average session establishment rate in the most recent 30 days.
Current relation-table entries	Total number of relation entries.
Relation table establishment rate	Rate of relation table establishment.
Session establishment rate	Unicast session establishment rate, and rates for establishing unicast sessions of different protocols.
Received TCP	Number of received TCP packets and bytes.
Received UDP	Number of received UDP packets and bytes.
Received ICMP	Number of received ICMP packets and bytes.
Received ICMPv6	Number of received ICMPv6 packets and bytes.
Received UDP-Lite	Number of received UDP-Lite packets and bytes.
Received SCTP	Number of received SCTP packets and bytes.
Received DCCP	Number of received DCCP packets and bytes.
Received RAWIP	Number of received Raw IP packets and bytes.

Display summary information about unicast session statistics.

```
<Sysname> display session statistics summary
Slot Sessions  TCP       UDP       Rate      TCP rate  UDP rate
1    3         0         0         0/s       0/s       0/s
```

Table 11 Command output

Field	Description
Sessions	Total number of unicast sessions.
TCP	Number of TCP unicast sessions.

Field	Description
UDP	Number of UDP unicast sessions.
Rate	Rate of unicast session creation.
TCP rate	Rate of TCP unicast session creation.
UDP rate	Rate of UDP unicast session creation.

Display history statistics of the maximum unicast sessions and maximum unicast session establishment rates.

```
<Sysname> display session statistics history-max
Slot 1
Max sessions: 20084                           Time: 2017-03-04 12:03:53
Max session establishment rate: 9080/s        Time: 2017-03-04 12:03:53
Max TCP sessions: 20084                       Time: 2017-03-04 12:03:53
Max TCP session establishment rate: 9080/s    Time: 2017-03-04 12:03:53
Max UDP sessions: 0                           Time: 2017-03-04 12:03:53
Max UDP session establishment rate: 0         Time: 2017-03-04 12:03:53
```

Table 12 Command output

Field	Description
Max sessions	History statistics of the maximum unicast sessions.
Max session establishment rate	History statistics of the maximum rate at which unicast sessions were created.
Max TCP sessions	History statistics of the maximum TCP unicast sessions.
Max TCP session establishment rate	History statistics of the maximum rate at which TCP unicast sessions were created.
Max UDP sessions	History statistics of the maximum UDP unicast sessions.
Max UDP session establishment rate	History statistics of the maximum rate at which UDP unicast sessions were created.

display session statistics ipv4

Use **display session statistics ipv4** to display IPv4 unicast session statistics.

Syntax

display session statistics ipv4 [[**responder**] { **application** *application-name* | **destination-ip** *destination-ip* | **destination-port** *destination-port* | **destination-zone** *destination-zone-name* | **interface** *interface-type interface-number* | **protocol** { **dccp** | **dns** | **ftp** | **gtp** | **h323** | **http** | **icmp** | **ils** | **mgcp** | **nbt** | **pptp** | **raw-ip** | **rsh** | **rtsp** | **sccp** | **sctp** | **sip** | **smtp** | **sqlnet** | **ssh** | **tcp** | **telnet** | **tftp** | **udp** | **udp-lite** | **xdmcp** } | **security-policy-rule** *rule-name* | **source-ip** *source-ip* | **source-port** *source-port* | **source-zone** *source-zone-name* | **state** { **dccp-closereq** | **dccp-closing** | **dccp-open** | **dccp-partopen** | **dccp-request** | **dccp-respond** | **dccp-timewait** | **icmp-reply** | **icmp-request** | **rawip-open** | **rawip-ready** | **sctp-closed** | **sctp-cookie-echoed** | **sctp-cookie-wait** | **sctp-established** | **sctp-shutdown-ack-sent** | **sctp-shutdown-recd** | **sctp-shutdown-sent** |

tcp-close | **tcp-close-wait** | **tcp-est** | **tcp-fin-wait** | **tcp-last-ack** | **tcp-syn-recv** | **tcp-syn-sent** | **tcp-syn-sent2** | **tcp-time-wait** | **udp-open** | **udp-ready** | **udplite-open** | **udplite-ready** } | **vpn-instance** *vpn-instance-name* } *] [**slot** *slot-number*]

Parameters

responder: Displays statistics about IPv4 unicast sessions from the responder to the initiator. If you do not specify this keyword, the command displays statistics about IPv4 unicast sessions from the initiator to the responder.

application *application-name*: Specifies an application protocol by its name. The *application-name* argument is a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed.

destination-ip *destination-ip*: Specifies a destination IPv4 address for a unicast session.

destination-port *destination-port*: Specifies a destination port by its number. The *destination-port* argument specifies the destination port of an IPv6 unicast session. The value range for the *destination-port* argument is 0 to 65535.

destination-zone *destination-zone-name*: Specifies a destination security zone by its name, a case-insensitive string of 1 to 31 characters.

interface *interface-type interface-num*: Specifies an interface by its type and number.

protocol { **dccp** | **dns** | **ftp** | **gtp** | **h323** | **http** | **icmp** | **ils** | **mgcp** | **nbt** | **pptp** | **raw-ip** | **rsh** | **rtsp** | **sccp** | **sctp** | **sip** | **smtp** | **sqlnet** | **ssh** | **tcp** | **telnet** | **tftp** | **udp** | **udp-lite** | **xdmcp** }: Specifies an IPv4 protocol.

security-policy-rule *rule-name*: Specifies a security policy rule by its name for session filtering. The *rule-name* argument represents the name of the security policy rule, a case-sensitive string of 1 to 127 characters.

source-ip *source-ip*: Specifies a source IPv4 address for a unicast session.

source-port *source-port*: Specifies a source port by its number. The *source-port* argument specifies the source port of an IPv4 unicast session. The value range for the *source-port* argument is 0 to 65535.

source-zone *source-zone-name*: Specifies a source security zone by its name, a case-insensitive string of 1 to 31 characters.

state { **dccp-closereq** | **dccp-closing** | **dccp-open** | **dccp-partopen** | **dccp-request** | **dccp-respond** | **dccp-timewait** | **icmp-reply** | **icmp-request** | **rawip-open** | **rawip-ready** | **sctp-closed** | **sctp-cookie-echoed** | **sctp-cookie-wait** | **sctp-established** | **sctp-shutdown-ack-sent** | **sctp-shutdown-recd** | **sctp-shutdown-sent** | **tcp-close** | **tcp-close-wait** | **tcp-est** | **tcp-fin-wait** | **tcp-last-ack** | **tcp-syn-recv** | **tcp-syn-sent** | **tcp-syn-sent2** | **tcp-time-wait** | **udp-open** | **udp-ready** | **udplite-open** | **udplite-ready** }: Specifies a protocol state.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays IPv4 unicast session statistics in the public network.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv4 unicast session statistics for all member devices.

Usage guidelines

If you do not specify any parameters, this command displays all IPv4 unicast session statistics.

Examples

Display statistics for unicast sessions from IP address 111.15.111.66.

```
<Sysname> display session statistics ipv4 source-ip 111.15.111.66
Slot 1:
Current sessions: 3
          TCP sessions:                   0
          UDP sessions:                   0
         ICMP sessions:                   3
     UDP-Lite sessions:                   0
         SCTP sessions:                   0
         DCCP sessions:                   0
        RAWIP sessions:                   0

          DNS sessions:                   0
          FTP sessions:                   0
          GTP sessions:                   0
         H323 sessions:                   0
         HTTP sessions:                   0
          ILS sessions:                   0
         MGCP sessions:                   0
          NBT sessions:                   0
         PPTP sessions:                   0
          RSH sessions:                   0
         RTSP sessions:                   0
         SCCP sessions:                   0
          SIP sessions:                   0
         SMTP sessions:                   0
       SQLNET sessions:                   0
          SSH sessions:                   0
       TELNET sessions:                   0
         TFTP sessions:                   0
        XDMCP sessions:                   0
```

Display statistics for IPv4 unicast TCP sessions.

```
<Sysname> display session statistics ipv4 protocol tcp
Slot 1:
Current sessions: 3
          TCP sessions:                   3
```

Table 13 Command output

Field	Description
Current sessions	Total number of unicast sessions.
TCP sessions	Number of TCP unicast sessions.
UDP sessions	Number of UDP unicast sessions.

Parameters

responder: Displays statistics about IPv6 unicast sessions from the responder to the initiator. If you do not specify this keyword, the command displays statistics about IPv6 unicast sessions from the initiator to the responder.

application *application-name*: Specifies an application protocol by its name. The *application-name* argument is a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed.

destination-ip *destination-ip*: Specifies a destination IPv6 address for a unicast session.

destination-port *destination-port*: Specifies a destination port by its number. The *destination-port* argument specifies the destination port of an IPv6 unicast session. The value range for the *destination-port* argument is 0 to 65535.

destination-zone *destination-zone-name*: Specifies a destination security zone by its name, a case-insensitive string of 1 to 31 characters.

interface *interface-type interface-num*: Specifies an interface by its type and number.

protocol { **dccp** | **dns** | **ftp** | **gtp** | **h323** | **http** | **icmpv6** | **ils** | **mgcp** | **nbt** | **pptp** | **raw-ip** | **rsh** | **rtsp** | **sccp** | **sctp** | **sip** | **smtp** | **sqlnet** | **ssh** | **tcp** | **telnet** | **tftp** | **udp** | **udp-lite** | **xdmcp** }: Specifies an IPv6 protocol.

security-policy-rule *rule-name*: Specifies a security policy rule by its name for session filtering. The *rule-name* argument represents the name of the security policy rule, a case-sensitive string of 1 to 127 characters.

source-ip *source-ip*: Specifies a source IPv6 address for a unicast session.

source-port *source-port*: Specifies a source port by its number. The *source-port* argument specifies the source port of an IPv6 unicast session. The value range for the *source-port* argument is 0 to 65535.

source-zone *source-zone-name*: Specifies a source security zone by its name, a case-insensitive string of 1 to 31 characters.

state { **dccp-closereq** | **dccp-closing** | **dccp-open** | **dccp-partopen** | **dccp-request** | **dccp-respond** | **dccp-timewait** | **icmpv6-reply** | **icmpv6-request** | **rawip-open** | **rawip-ready** | **sctp-closed** | **sctp-cookie-echoed** | **sctp-cookie-wait** | **sctp-established** | **sctp-shutdown-ack-sent** | **sctp-shutdown-recd** | **sctp-shutdown-sent** | **tcp-close** | **tcp-close-wait** | **tcp-est** | **tcp-fin-wait** | **tcp-last-ack** | **tcp-syn-recv** | **tcp-syn-sent** | **tcp-syn-sent2** | **tcp-time-wait** | **udp-open** | **udp-ready** | **udplite-open** | **udplite-ready** }: Specifies a protocol state.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays IPv6 unicast session statistics in the public network.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv6 unicast session statistics for all member devices.

Examples

Display statistics for unicast sessions from IPv6 address 100::2.

```
<Sysname> display session statistics ipv6 source-ip 100::2
Slot 1:
Current sessions: 3
          TCP sessions:                  0
          UDP sessions:                  0
       ICMPv6 sessions:                  3
     UDP-Lite sessions:                  0
         SCTP sessions:                  0
         DCCP sessions:                  0
        RAWIP sessions:                  0

          DNS sessions:                  0
          FTP sessions:                  0
          GTP sessions:                  0
         H323 sessions:                  0
         HTTP sessions:                  0
          ILS sessions:                  0
         MGCP sessions:                  0
          NBT sessions:                  0
         PPTP sessions:                  0
          RSH sessions:                  0
         RTSP sessions:                  0

       TELNET sessions:                  0
         TFTP sessions:                  0
```

```
        XDMCP sessions:                    0
```

Display statistics for IPv6 unicast TCP sessions.

```
<Sysname> display session statistics ipv6 protocol tcp
Slot 1:
Current sessions: 3
          TCP sessions:                    3
```

Table 14 Command output

Field	Description
Current sessions	Total number of unicast sessions.
TCP sessions	Number of TCP unicast sessions.
UDP sessions	Number of UDP unicast sessions.
ICMPv6 sessions	Number of ICMPv6 unicast sessions.
UDP-Lite sessions	Number of UDP-Lite unicast sessions.
SCTP sessions	Number of SCTP unicast sessions.
DCCP sessions	Number of DCCP unicast sessions.
RAWIP sessions	Number of Raw IP unicast sessions.
DNS sessions	Number of DNS unicast sessions.
FTP sessions	Number of FTP unicast sessions.
GTP sessions	Number of GTP unicast sessions.
H323 sessions	Number of H.323 unicast sessions.
HTTP sessions	Number of HTTP unicast sessions.
ILS sessions	Number of ILS unicast sessions.
MGCP sessions	Number of MGCP unicast sessions.
NBT sessions	Number of NBT unicast sessions.
PPTP sessions	Number of PPTP unicast sessions.
RSH sessions	Number of RSH unicast sessions.
RTSP sessions	Number of RTSP unicast sessions.
SCCP sessions	Number of SCCP unicast sessions.
SIP sessions	Number of SIP unicast sessions.
SMTP sessions	Number of SMTP unicast sessions.
SQLNET sessions	Number of SQLNET unicast sessions.
SSH sessions	Number of SSH unicast sessions.
TELNET sessions	Number of Telnet unicast sessions.
TFTP sessions	Number of TFTP unicast sessions.

Field	Description
XDMCP sessions	Number of XDMCP unicast sessions.

display session statistics multicast

Use **display session statistic multicast** to display multicast session statistics.

Syntax

display session statistics multicast [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays multicast session statistics for all member devices.

Examples

Display information about multicast session statistics.

```
<Sysname> display session statistics multicast
Slot 1:
Current sessions: 0
Session establishment rate: 0/s
History max sessions: 0                                Time: 2017-04-25 11:28:00
History max session establishment rate: 0/s            Time: 2017-04-25 11:28:00
Received:                   0 packets                    0 bytes
Sent    :                   0 packets                    0 bytes
```

Table 15 Command output

Field	Description
Current sessions	Total number of multicast sessions.
Session establishment rate	Rate of multicast session creation.
History max sessions	History statistics of the maximum multicast sessions.
History max session establishment rate	History statistics of the maximum rate at which multicast sessions were created.
Received	Number of received multicast packets and bytes.
Sent	Number of sent multicast packets and bytes.

display session table ipv4

Use **display session table ipv4** to display information about IPv4 unicast session entries that match specific criteria.

Syntax

display session table ipv4 [**slot** *slot-number*] [[**responder**] { **application** *application-name* | **destination-ip** *start-destination-ip* [*end-destination-ip*] | **destination-port** *destination-port* | **destination-zone** *destination-zone-name* | **interface** *interface-type interface-number* | **protocol** { **dccp** | **icmp** | **raw-ip** | **sctp** | **tcp** | **udp** | **udp-lite** } | **security-policy-rule** *rule-name* | **source-ip** *start-source-ip* [*end-source-ip*] | **source-port** *source-port* | **source-zone** *source-zone-name* | **state** { **dccp-closereq** | **dccp-closing** | **dccp-open** | **dccp-partopen** | **dccp-request** | **dccp-respond** | **dccp-timewait** | **icmp-reply** | **icmp-request** | **rawip-open** | **rawip-ready** | **sctp-closed** | **sctp-cookie-echoed** | **sctp-cookie-wait** | **sctp-established** | **sctp-shutdown-ack-sent** | **sctp-shutdown-recd** | **sctp-shutdown-sent** | **tcp-close** | **tcp-close-wait** | **tcp-est** | **tcp-fin-wait** | **tcp-last-ack** | **tcp-syn-recv** | **tcp-syn-sent** | **tcp-syn-sent2** | **tcp-time-wait** | **udp-open** | **udp-ready** | **udplite-open** | **udplite-ready** } | **vpn-instance** *vpn-instance-name* } *] [**verbose**]

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information for all member devices.

responder: Displays entries of IPv4 unicast sessions from the responder to the initiator. If you do not specify this keyword, the command displays entries of IPv4 unicast sessions from the initiator to the responder.

application *application-name*: Specifies an application protocol by its name. The *application-name* argument is a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed.

destination-ip *start-destination-ip* [*end-destination-ip*]: Specifies a destination IPv4 address or IPv4 address range for a unicast session. The *start destination-ip* argument specifies the start destination IPv4 address. The *end destination-ip* argument specifies the end destination IPv4 address.

destination-port *destination-port*: Specifies a destination port by its number. The *destination-port* argument specifies the destination port of a unicast session. The value range for the *destination-port* argument is 0 to 65535.

destination-zone *destination-zone-name*: Specifies a destination security zone by its name, a case-insensitive string of 1 to 31 characters.

interface *interface-type interface-num*: Specifies an interface by its type and number.

protocol { **dccp** | **icmp** | **raw-ip** | **sctp** | **tcp** | **udp** | **udp-lite** }: Specifies an IPv4 transport layer protocol, including DCCP, ICMP, Raw IP, SCTP, TCP, UDP, and UDP-Lite.

security-policy-rule *rule-name*: Specifies a security policy rule by its name for session filtering. The *rule-name* argument represents the name of the security policy rule, a case-sensitive string of 1 to 127 characters.

source-ip *start-source-ip* [*end-source-ip*]: Specifies a source IPv4 address or IPv4 address range for a unicast session. The *start source-ip* argument specifies the start source IPv4 address. The *end source-ip* argument specifies the end source IPv4 address.

source-port *source-port*: Specifies a source port by its number. The *source-port* argument specifies the source port of a unicast session. The value range for the *source-port* argument is 0 to 65535.

source-zone *source-zone-name*: Specifies a source security zone by its name, a case-insensitive string of 1 to 31 characters.

state { **dccp-closereq** | **dccp-closing** | **dccp-open** | **dccp-partopen** | **dccp-request** | **dccp-respond** | **dccp-timewait** | **icmp-reply** | **icmp-request** | **rawip-open** | **rawip-ready** | **sctp-closed** | **sctp-cookie-echoed** | **sctp-cookie-wait** | **sctp-established** | **sctp-shutdown-ack-sent** | **sctp-shutdown-recd** | **sctp-shutdown-sent** | **tcp-close** | **tcp-close-wait** | **tcp-est** | **tcp-fin-wait** | **tcp-last-ack** | **tcp-syn-recv** | **tcp-syn-sent** | **tcp-syn-sent2** | **tcp-time-wait** | **udp-open** | **udp-ready** | **udplite-open** | **udplite-ready** }: Specifies a protocol state.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays IPv4 unicast session entries in the public network.

verbose: Displays detailed information about IPv4 unicast session entries. If you do not specify this keyword, the command displays brief information about IPv4 unicast session entries.

Usage guidelines

If you do not specify any parameters, this command displays all IPv4 unicast session entries.

Examples

Display brief information about all IPv4 unicast session entries.

```
<Sysname> display session table ipv4
Slot 1:
Initiator:
  Source      IP/port: 192.168.1.18/1877
  Destination IP/port: 192.168.1.55/22
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/1
  Source security zone: Trust

Total sessions found: 1
```

Display detailed information about all IPv4 unicast session entries.

```
<Sysname> display session table ipv4 verbose
Slot 1:
Initiator:
  Source      IP/port: 192.168.1.18/1877
  Destination IP/port: 192.168.1.55/22
```

```
  DS-Lite tunnel peer:-
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/1
  Source security zone: Trust
Responder:
  Source      IP/port: 192.168.1.55/22
  Destination IP/port: 192.168.1.18/1877
  DS-Lite tunnel peer:-
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/2
  Source security zone: Local
State: TCP_SYN_SENT
Application: SSH
Rule ID: 1
Rule name: test
Start time: 2011-07-29 19:12:36  TTL: 28s
Initiator->Responder:         1 packets         48 bytes
Responder->Initiator:         0 packets          0 bytes

Total sessions found: 1
```

Table 16 Command output

Field	Description
Initiator	Information about the unicast session from the initiator to the responder.
Responder	Information about the unicast session from the responder to the initiator.
DS-Lite tunnel peer	Address of the DS-Lite tunnel peer. When the unicast session does not belong to any DS-Lite tunnel, this field displays a hyphen (-).
VPN instance/VLAN ID/Inline ID	MPLS L3VPN instance to which the unicast session belongs. VLAN and inline to which the session belongs during Layer 2 forwarding. If a parameter is not specified, a hyphens (-) is displayed for the proper field.
Protocol	Transport layer protocol: • DCCP. • ICMP. • ICMPv6. • Raw IP. • SCTP. • TCP. • UDP. • UDP-Lite. The number in the brackets indicates the protocol number.
Inbound interface	Interface on which packets are received.
Source security zone	Security zone to which the inbound interface belongs. If the inbound interface does not belong to any security zone, this field displays a hyphen

Field	Description
	(-).
State	Unicast session state.
Application	Application layer protocol, FTP or DNS. If it is an unknown protocol identified by an unknown port, this field displays **OTHER**.
Rule ID	ID of the security policy rule.
Rule name	Name of the security policy rule.
Start time	Unicast session establishment time.
TTL	Remaining lifetime of the unicast session, in seconds.
Initiator->Responder	Number of packets and bytes from the initiator to the responder.
Responder->Initiator	Number of packets and bytes from the responder to the initiator.
Total sessions found	Total number of found unicast session entries.

display session table ipv6

Use **display session table ipv6** to display information about IPv6 unicast session entries that match specific criteria.

Syntax

display session table ipv6 [**slot** *slot-number*] [[**responder**] { **application** *application-name* | **destination-ip** *start-destination-ip* [*end-destination-ip*] | **destination-port** *destination-port* | **destination-zone** *destination-zone-name* | **interface** *interface-type interface-number* | **protocol** { **dccp** | **icmpv6** | **raw-ip** | **sctp** | **tcp** | **udp** | **udp-lite** } | **security-policy-rule** *rule-name* | **source-ip** *start-source-ip* [*end-source-ip*] | **source-port** *source-port* | **source-zone** *source-zone-name* | **state** { **dccp-closereq** | **dccp-closing** | **dccp-open** | **dccp-partopen** | **dccp-request** | **dccp-respond** | **dccp-timewait** | **icmpv6-reply** | **icmpv6-request** | **rawip-open** | **rawip-ready** | **sctp-closed** | **sctp-cookie-echoed** | **sctp-cookie-wait** | **sctp-established** | **sctp-shutdown-ack-sent** | **sctp-shutdown-recd** | **sctp-shutdown-sent** | **tcp-close** | **tcp-close-wait** | **tcp-est** | **tcp-fin-wait** | **tcp-last-ack** | **tcp-syn-recv** | **tcp-syn-sent** | **tcp-syn-sent2** | **tcp-time-wait** | **udp-open** | **udp-ready** | **udplite-open** | **udplite-ready** } | **vpn-instance** *vpn-instance-name* } *] [**verbose**]

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information for all member devices.

responder: Displays entries of IPv6 unicast sessions from the responder to the initiator. If you do not specify this keyword, the command displays entries of IPv6 unicast sessions from the initiator to the responder.

application *application-name*: Specifies an application protocol by its name. The *application-name* argument is a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed.

destination-ip *start-destination-ip* [*end-destination-ip*]: Specifies a destination IPv6 address or IPv6 address range for a unicast session. The *start destination-ip* argument specifies the start destination IPv6 address. The *end destination-ip* argument specifies the end destination IPv6 address.

destination-port *destination-port*: Specifies a destination port by its number. The *destination-port* argument specifies the destination port of a unicast session. The value range for the *destination-port* argument is 0 to 65535.

destination-zone *destination-zone-name*: Specifies a destination security zone by its name, a case-insensitive string of 1 to 31 characters.

interface *interface-type interface-num*: Specifies an interface by its type and number.

protocol { **dccp** | **icmpv6** | **raw-ip** | **sctp** | **tcp** | **udp** | **udp-lite** }: Specifies an IPv6 transport layer protocol, including DCCP, ICMPv6, Raw IP, SCTP, TCP, UDP, and UDP-Lite.

security-policy-rule *rule-name*: Specifies a security policy rule by its name for session filtering. The *rule-name* argument represents the name of the security policy rule, a case-sensitive string of 1 to 127 characters.

source-ip *start-source-ip* [*end-source-ip*]: Specifies a source IPv6 address or IPv6 address range for a unicast session. The *start source-ip* argument specifies the start source IPv6 address. The *end source-ip* argument specifies the end source IPv6 address.

source-port *source-port*: Specifies a source port by its number. The *source-port* argument specifies the source port of a unicast session. The value range for the *source-port* argument is 0 to 65535.

source-zone *source-zone-name*: Specifies a source security zone by its name, a case-insensitive string of 1 to 31 characters.

state { **dccp-closereq** | **dccp-closing** | **dccp-open** | **dccp-partopen** | **dccp-request** | **dccp-respond** | **dccp-timewait** | **icmpv6-reply** | **icmpv6-request** | **rawip-open** | **rawip-ready** | **sctp-closed** | **sctp-cookie-echoed** | **sctp-cookie-wait** | **sctp-established** | **sctp-shutdown-ack-sent** | **sctp-shutdown-recd** | **sctp-shutdown-sent** | **tcp-close** | **tcp-close-wait** | **tcp-est** | **tcp-fin-wait** | **tcp-last-ack** | **tcp-syn-recv** | **tcp-syn-sent** | **tcp-syn-sent2** | **tcp-time-wait** | **udp-open** | **udp-ready** | **udplite-open** | **udplite-ready** }: Specifies a protocol state.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays IPv6 unicast session entries in the public network.

verbose: Displays detailed information about IPv6 unicast session entries. If you do not specify this keyword, the command displays brief information about IPv6 unicast session entries.

Usage guidelines

If you do not specify any parameters, this command displays all IPv6 unicast session entries.

Examples

Display brief information about all IPv6 unicast session entries.

```
<Sysname> display session table ipv6

  Protocol: IPV6-ICMP(58)
  Inbound interface: GigabitEthernet1/0/2
  Source security zone: Local
State: ICMPV6_REQUEST
Application: OTHER
Rule ID: 1
Rule name: test
Start time: 2011-07-29 19:23:41  TTL: 55s
Initiator->Responder:         1 packets         104 bytes
Responder->Initiator:         0 packets          0 bytes

Total sessions found: 1
```

Table 17 Command output

Field	Description
Initiator	Information about the unicast session from the initiator to the responder.
Responder	Information about the unicast session from the responder to the initiator.

Field	Description
DS-Lite tunnel peer	Address of the DS-Lite tunnel peer. When the unicast session is not tunneled by DS-Lite, this field displays a hyphen (-).
VPN instance/VLAN ID/Inline ID	MPLS L3VPN instance to which the unicast session belongs. VLAN and inline to which the unicast session belongs during Layer 2 forwarding. If a parameter is not specified, a hyphens (-) is displayed for the proper field.
Protocol	Transport layer protocol: • DCCP. • ICMP. • ICMPv6. • Raw IP. • SCTP. • TCP. • UDP. • UDP-Lite. The number in the brackets indicates the protocol number.
Inbound interface	Interface on which packets are received.
Source security zone	Security zone to which the inbound interface belongs. If the inbound interface does not belong to any security zone, this field displays a hyphen (-).
State	Unicast session state.
Application	Application layer protocol, FTP or DNS. If it is an unknown protocol identified by an unknown port, this field displays **OTHER**.
Rule ID	ID of the security policy rule.
Rule name	Name of the security policy rule.
Start time	Unicast session establishment time.
TTL	Remaining lifetime of the unicast session, in seconds.
Initiator->Responder	Number of packets and bytes from the initiator to the responder.
Responder->Initiator	Number of packets and bytes from the responder to the initiator.
Total sessions found	Total number of found unicast session entries.

display session table multicast ipv4

Use **display session table multicast ipv4** to display information about IPv4 multicast session entries that match specific criteria.

Syntax

display session table multicast ipv4 [**slot** *slot-number*] [[**responder**] { **destination-ip** *start-destination-ip* [*end-destination-ip*] | **destination-port** *destination-port* | **protocol** { **dccp** | **icmp** | **raw-ip** | **sctp** |

Inbound initiator	Information about the multicast session from the initiator to the responder on the inbound interface.
Inbound responder	Information about the multicast session from the responder to the initiator on the inbound interface.
Outbound initiator	Information about the multicast session from the initiator to the responder on the outbound interface.
Outbound responder	Information about the multicast session from the responder to the initiator on the outbound interface.
DS-Lite tunnel peer	Address of the DS-Lite tunnel peer. If the multicast session is not tunneled by DS-Lite, this field displays a hyphen (-).
VPN instance/VLAN ID/Inline ID	MPLS L3VPN instance to which the multicast session belongs. VLAN and inline to which the multicast session belongs during Layer 2 forwarding. If a parameter is not specified, a hyphens (-) is displayed for the proper field.
Protocol	Transport layer protocol: • DCCP. • ICMP. • Raw IP. • SCTP. • TCP. • UDP. • UDP-Lite. The number in the brackets indicates the protocol number.

Field	Description
State	Multicast session state.
Application	Application layer protocol, FTP or DNS. If it is an unknown protocol identified by an unknown port, this field displays **OTHER**.
Start time	Time when the multicast session was created.
TTL	Remaining lifetime of the multicast session, in seconds.
Inbound interface	Inbound interface of the first packet from the initiator to responder.
Outbound interface	Outbound interface of the first packet from the initiator to responder.
Outbound interface list	Outbound interfaces of the first packet from the initiator to responder.
Source security zone	Security zone to which the inbound interface belongs. If the inbound interface does not belong to any security zone, this field displays a hyphen (-).
Destination security zone	Security zone to which the outbound interface belongs. If the outbound interface does not belong to any security zone, this field displays a hyphen (-).
Initiator->Responder	Number of packets and bytes from the initiator to the responder.
Total sessions found	Total number of found multicast session entries.

display session table multicast ipv6

Use **display session table multicast ipv6** to display information about IPv6 multicast session entries that match specific criteria.

Syntax

display session table multicast ipv6 [**slot** *slot-number*] [[**responder**] { **destination-ip** *start-destination-ip* [*end-destination-ip*] | **destination-port** *destination-port* | **protocol** { **dccp** | **icmpv6** | **raw-ip** | **sctp** | **tcp** | **udp** | **udp-lite** } | **source-ip** *start-source-ip* [*end-source-ip*] | **source-port** *source-port* } *] [**verbose**]

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information for all member devices.

responder: Displays entries of IPv6 multicast sessions from the responder to the initiator. If you do not specify this keyword, the command displays entries of IPv4 multicast sessions from the initiator to the responder.

destination-ip *start-destination-ip* [*end-destination-ip*]: Specifies a destination IPv6 address or IPv6 address range for a multicast session. The *start destination-ip* argument specifies the start destination IPv6 address. The *end destination-ip* argument specifies the end destination IPv6 address.

destination-port *destination-port*: Specifies a destination port by its number. The *destination-port* argument specifies the destination port of a multicast session. The value range for the *destination-port* argument is 0 to 65535.

protocol { **dccp** | **icmpv6** | **raw-ip** | **sctp** | **tcp** | **udp** | **udp-lite** }: Specifies an IPv6 transport layer protocol.

source-ip *start-source-ip* [*end-source-ip*]: Specifies a source IPv6 address or IPv6 address range for a multicast session. The *start source-ip* argument specifies the start source IPv6 address. The *end source-ip* argument specifies the end source IPv6 address.

source-port *source-port*: Specifies a source port by its number. The *source-port* argument specifies the source port of a multicast session. The value range for the *source-port* argument is 0 to 65535.

verbose: Displays detailed information about IPv6 multicast session entries. If you do not specify this keyword, the command displays brief information about IPv6 multicast session entries.

Usage guidelines

If you do not specify any parameters, this command displays all IPv6 multicast session entries.

Examples

Display brief information about all IPv6 multicast session entries.

```
<Sysname> display session table multicast ipv6
Slot 1:
Inbound initiator:
  Source      IP/port: 3::4/1617
  Destination IP/port: FF0E::1/1025
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: UDP(17)
Inbound interface: GigabitEthernet1/0/1
Outbound interface list:
    GigabitEthernet1/0/2
    GigabitEthernet1/0/3

Total sessions found: 3
```

Display detailed information about all IPv6 multicast session entries.

```
<Sysname> display session table multicast ipv6 verbose
Slot 1:
Inbound initiator:
  Source      IP/port: 3::4/1617
  Destination IP/port: FF0E::1/1025
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: UDP(17)
Inbound responder:
  Source      IP/port: FF0E::1/1025
  Destination IP/port: 3::4/1617
```

```
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: UDP(17)
Inbound interface: GigabitEthernet1/0/1
Source security zone: Trust
State: UDP_OPEN
Application: OTHER
Start time: 2014-03-03 16:10:58  TTL: 23s
Initiator->Responder:            5 packets        520 bytes

Outbound initiator:
  Source      IP/port: 3::4/1617
  Destination IP/port: FF0E::1/1025
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: UDP(17)

```

```
Total sessions found: 3
```

Table 19 Command output

Field	Description
Inbound initiator	Information about the multicast session from the initiator to the responder on the inbound interface.
Inbound responder	Information about the multicast session from the responder to the initiator on the inbound interface.
Outbound initiator	Information about the multicast session from the initiator to the responder on the outbound interface.
Outbound responder	Information about the multicast session from the responder to the initiator on the outbound interface.
DS-Lite tunnel peer	Address of the DS-Lite tunnel peer. If the multicast session is not tunneled by DS-Lite, this field displays a hyphen (-).
VPN instance/VLAN ID/Inline ID	MPLS L3VPN instance to which the multicast session belongs. VLAN and inline to which the multicast session belongs during Layer 2 forwarding. If a parameter is not specified, a hyphens (-) is displayed for the proper field.
Protocol	Transport layer protocol: • DCCP. • ICMPv6. • Raw IP. • SCTP. • TCP. • UDP. • UDP-Lite. The number in the brackets indicates the protocol number.
State	Multicast session state.
Application	Application layer protocol, FTP or DNS. If it is an unknown protocol identified by an unknown port, this field displays **OTHER**.
Start time	Time when the multicast session was created.
TTL	Remaining lifetime of the multicast session, in seconds.
Inbound interface	Inbound interface of the first packet from the initiator to responder.
Outbound interface	Outbound interface of the first packet from the initiator to responder.
Outbound interface list	Outbound interfaces of the first packet from the initiator to responder.
Source security zone	Security zone to which the inbound interface belongs. If the inbound interface does not belong to any security zone, this field displays a hyphen (-).
Destination security zone	Security zone to which the outbound interface belongs. If the outbound interface does not belong to any security zone, this field displays a hyphen (-).
Initiator->Responder	Number of packets and bytes from the initiator to the responder.

Field	Description
Total sessions found	Total number of found multicast session entries.

display session top-statistics

Use **display session top-statistics** to display top session statistics.

Syntax

display session top-statistics { last-1-hour | last-24-hours | last-30-days }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

last-1-hour: Displays top session statistics in last hour.

last-24-hours: Displays top session statistics in last 24 hours.

last-30-days: Displays top session statistics in last 30 days.

Usage guidelines

This command displays nothing if the top session statistics feature is not enabled. A maximum of ten session items can be displayed.

Examples

Display top session statistics in last hour.

```
<Sysname> display session top-statistics last-1-hour

Counting by source addresses:
No.      Source address               Sessions
1        10.1.2.3                     50004302

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command clears information for all member devices.

source-ip *source-ip*: Specifies a source IPv4 address. The *source-ip* argument specifies the source IPv4 address of a unicast session from the initiator to the responder.

destination-ip *destination-ip*: Specifies a destination IPv4 address. The *destination-ip* argument specifies the destination IPv4 address of a unicast session from the initiator to the responder.

protocol { **dccp** | **icmp** | **raw-ip** | **sctp** | **tcp** | **udp** | **udp-lite** }: Specifies an IPv4 transport layer protocol, including DCCP, ICMP, Raw IP, SCTP, TCP, UDP, and UDP-Lite.

source-port *source-port*: Specifies a source port by its number. The *source-port* argument specifies the source port of a unicast session from the initiator to the responder. The value range for the *source-port* argument is 0 to 65535.

destination-port *destination-port*: Specifies a destination port by its number. The *destination-port* argument specifies the destination port of a unicast session from the initiator to the responder. The value range for the *destination-port* argument is 0 to 65535.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you want to clear IPv4 unicast session entries on the public network, do not specify this option.

Usage guidelines

If you do not specify any parameters, this command clears all IPv4 unicast session entries on the public network.

Examples

Clear all IPv4 unicast session entries.

```
<Sysname> reset session table ipv4
```

Clear the IPv4 unicast session entries with the source IP address of 10.10.10.10.

```
<Sysname> reset session table ipv4 source-ip 10.10.10.10
```

session aging-time application

Use **session aging-time application** to set the aging time for sessions of an application layer protocol or an application.

Use **undo session aging-time application** to restore the default. If you do not specify an application layer protocol or an application, this command restores the default aging time for all sessions of the supported application layer protocols and applications.

Syntax

session aging-time application *application-name time-value*

undo session aging-time application [*application-name*]

Default

The aging time is 1200 seconds for sessions of application layer protocols or applications except for the following sessions:

- BOOTPC sessions: 120 seconds.
- BOOTPS sessions: 120 seconds.
- DNS sessions: 30 seconds.
- FTP sessions: 3600 seconds.
- FTP-DATA sessions: 240 seconds.
- GPRS-DATA sessions: 60 seconds.
- GPRS-SIG sessions: 60 seconds.
- GTP-CONTROL sessions: 60 seconds.
- GTP-USER sessions: 60 seconds.
- H.225 sessions: 3600 seconds.
- H.245 sessions: 3600 seconds.
- HTTPS sessions: 600 seconds.
- ILS sessions: 3600 seconds.
- L2TP sessions: 120 seconds.
- MGCP-CALLAGENT sessions: 60 seconds.
- MGCP-GATEWAY sessions: 60 seconds.
- NETBIOS-DGM sessions: 3600 seconds.
- NETBIOS-NS sessions: 3600 seconds.
- NETBIOS-SSN sessions: 3600 seconds.
- NTP sessions: 120 seconds.
- PPTP sessions: 3600 seconds.
- QQ sessions: 120 seconds.
- RAS sessions: 300 seconds.
- RIP sessions: 120 seconds.
- RSH sessions: 60 seconds.
- RTSP session: 3600 seconds.
- SCCP sessions: 3600 seconds.
- SIP sessions: 300 seconds.
- SNMP sessions: 120 seconds.

- SNMPTRAP sessions: 120 seconds.
- SQLNET sessions: 600 seconds.
- STUN sessions: 600 seconds.
- SYSLOG sessions: 120 seconds.
- TACACS-DS sessions: 120 seconds.
- TFTP sessions: 60 seconds.
- WHO sessions: 120 seconds.
- XDMCP sessions: 3600 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

application-name: Specifies an application layer protocol or an application by its name, a case-insensitive string of 1 to 63 characters. Valid characters can be digits, letters, hyphens (-), and underscores (_). The names **invalid** and **other** are not allowed. The application layer protocol or application must exist on the device.

time-value: Specifies the aging time in seconds. The value range 1 to 100000.

Usage guidelines

This command sets the aging time for stable sessions of the specified application layer protocols or applications. For TCP sessions, the stable state is ESTABLISHED. For UDP sessions, the stable state is READY.

For sessions of application layer protocols or applications that are not supported by this command, the aging time is set by the **session aging-time state** command. For persistent sessions, the aging time is set by the **session persistent acl** command.

Supported application layer protocols or applications specified in this command depend on the APR module. For information about APR, see *Security Configuration Guide*.

Examples

Set the aging time for FTP sessions to 1800 seconds.

```
<Sysname> system-view
[Sysname] session aging-time application ftp 1800
```

Set the aging time for 126WebEmail sessions to 1800 seconds.

```
<Sysname> system-view
[Sysname] session aging-time application 126WebEmail 1800
```

session aging-time state

Use **session aging-time state** to set the aging time for the sessions in a protocol state.

Use **undo session aging-time state** to restore the default for the sessions in a protocol state. If you do not specify a protocol state, this command restores all aging time for sessions in different protocol states to the default.

Syntax

session aging-time state { **fin** | **icmp-reply** | **icmp-request** | **icmpv6-reply** | **icmpv6-request** | **rawip-open** | **rawip-ready** | **syn** | **tcp-close** | **tcp-est** | **tcp-time-wait** | **udp-open** | **udp-ready** } *time-value*

undo session aging-time state [**fin** | **icmp-reply** | **icmp-request** | **icmpv6-reply** | **icmpv6-request** | **rawip-open** | **rawip-ready** | **syn** | **tcp-close** | **tcp-est** | **tcp-time-wait** | **udp-open** | **udp-ready**]

Default

The aging time for sessions in different protocol states is as follows:

- FIN_WAIT: 30 seconds.
- ICMP-REPLY: 30 seconds.
- ICMP-REQUEST: 60 seconds.
- ICMPv6-REPLY: 30 seconds.
- ICMPv6-REQUEST: 60 seconds.
- RAWIP-OPEN: 30 seconds.
- RAWIP-READY: 60 seconds.
- TCP SYN-SENT and SYN-RCV: 30 seconds.
- TCP-CLOSE: 2 seconds.
- TCP ESTABLISHED: 3600 seconds.
- TCP TIME-WAIT: 2 seconds.
- UDP-OPEN: 30 seconds.
- UDP-READY: 60 seconds.

System view

Predefined user roles

network-admin

context-admin

Parameters

fin: Specifies the TCP FIN_WAIT state.

icmp-reply: Specifies the ICMP REPLY state.

icmp-request: Specifies the IGMP REQUEST state.

icmpv6-reply: Specifies the ICMPv6 REPLY state.

icmpv6-request: Specifies the IGMPv6 REQUEST state.

rawip-open: Specifies the RAWIP-OPEN state.

rawip-ready: Specifies the RAWIP-READY state.

syn: Specifies the TCP SYN-SENT and SYN-RCV states.

tcp-close: Specifies the TCP CLOSE state.

tcp-est: Specifies the TCP ESTABLISHED state.

tcp-time-wait: Specifies the TCP TIME-WAIT state.

udp-open: Specifies the UDP OPEN state.

udp-ready: Specifies the UDP READY state.

time-value: Specifies the aging time in seconds. For the TCP CLOSE and TCP TIME-WAIT states, the value range is 0 to 100000. For other states, the value range is 1 to 100000.

Usage guidelines

This command sets the aging time for stable sessions of the application layer protocols that are not supported by the **session aging-time application** command. For persistent sessions, the aging time is set by the **session persistent acl** command.

Examples

Set the aging time for TCP sessions in SYN-SENT and SYN-RCV states to 60 seconds.

```
<Sysname> system-view
[Sysname] session aging-time state syn 60
```

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Sets the session creation rate change threshold in percentage. The value range for this argument is 1 to 100.

base-threshold *base-value*: Sets the base session creation rate threshold in percentage. The value range for this argument is 1 to 100. If you do not specify this option, the default setting applies.

Usage guidelines

With alarms enabled for abrupt session creation rate changes, the system collects the session creation rate at an interval of 10 seconds and checks whether the following indicators reach the corresponding alarm thresholds:

- **Session creation rate change in percentage**—Obtained by dividing the difference between the session creation rates at the beginning and end of a collection interval by the session creation rate at the beginning of the collection interval.
- **Base session creation rate in percentage**—Obtained by dividing the session creation rate at the beginning of a collection interval by 100000.

If both of the following conditions are met in a detection interval, the system generates an alarm for the abrupt change of the session creation rate:

- The session creation rate change threshold is reached.
- The base session creation rate threshold is crossed.

Examples

Set the session creation rate change threshold to 30%.

session dual-active create-mode

Use **session dual-active create-mode** to set the session creation mode when the device is operating in session dual-active mode.

Use **undo session dual-active create-mode** to restore the default.

Syntax

session dual-active create-mode { **hash** | **local** }

undo session dual-active create-mode

Default

Local-based session creation is used in session dual-active mode.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

hash: Specifies hash-based session creation.

local: Specifies local-based session creation.

Usage guidelines

This feature takes effect only in session dual-active mode.

In a hot backup system operating in session dual-active mode, both devices process services. To balance the service load on the devices, you can use one of the following session creation modes:

- **Hash-based session creation**—A session is created on the device to which its first packet is relayed according to the hash result. The device where a session is created might not be the device that receives the traffic. This mode applies if traffic is unevenly distributed among the devices.
- **Local-based session creation**—A session is created on the device where the first packet of the session arrives. This mode applies if traffic is evenly distributed among the devices.

Examples

Enable hash-based session creation when the device is operating in session dual-active mode.

```
<Sysname> system-view
[Sysname] session dual-active create-mode hash
```

Syntax

session dual-active transparent udp enable

undo session dual-active transparent udp enable

Default

Transparent transmission for UDP packets is disabled in session dual-active mode.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature takes effect only in session dual-active mode.

In a hot backup system operating in session dual-active mode, a device cannot identify the direction of packets in a UDP traffic flow due to UDP mechanisms. By default, if the return packets of a

session do not match any sessions, the device creates a new session. This results in the following issues:

- If the security control policy permits a UDP traffic flow in one direction, the return packets of the flow are dropped.
- If the security control policy permits a UDP traffic flow in both directions, two sessions are created for the flow. This affects traffic processing of security services.

To resolve these issues, you can enable transparent transmission for UDP packets. This feature allows a device to relay UDP packets that do not match any sessions to the other device in the hot back system. If the UDP packets also do not match any sessions on the other device, a new session is created locally.

As a best practice, enable this feature only when asymmetric UDP traffic exists in the hot backup system and sessions cannot be synchronized timely. This feature degrades forwarding performance. Make sure you are fully aware of the impact of this feature when you use it on a live network.

Transparent transmission for UDP packets takes effect only when local-based session creation is used. If hash-based session creation is used, the devices do not relay UDP packets.

Examples

Enable transparent transmission for UDP packets in session dual-active mode.

```
<Sysname> system-view
[Sysname] session dual-active transparent udp enable
```

Related commands

session dual-active enable

session fast-drop aging-time

Use **session fast-drop aging-time** to set the aging time for deny sessions.

Use **undo session fast-drop aging-time** to restore the default.

Syntax

session fast-drop aging-time *time-value*

undo session fast-drop aging-time

Default

The aging time for deny sessions is 3 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

time-value: Specifies the aging time in seconds. The value range 1 to 3.

Usage guidelines

The system deletes deny sessions based on the deny session aging time. The deny session aging time is not refreshed when packets match deny sessions.

Examples

Set the aging time for deny sessions to 1 second.

```
<Sysname> system-view
[Sysname] session fast-drop aging-time 1
```

Related commands

Use **undo session fast-drop enable** to disable the deny session feature for modules.

Syntax

session fast-drop { **aspf** | **connection-limit** } * **enable**

undo session fast-drop { **aspf** | **connection-limit** } * **enable**

Default

The deny session feature is disabled.

Views

System view

Parameters

aspf: Specifies the ASPF module.

connection-limit: Specifies the connection limit module.

Predefined user roles

network-admin

context-admin

Usage guidelines

The deny session feature allows the device to create sessions for dropped packets. These sessions are called deny sessions. To improve forwarding performance, the device drops all packets that match deny sessions.

The device generates deny sessions only for the packets dropped by the ASPF or connection limit module.

Examples

Enable the deny session feature for ASPF.

```
<Sysname> system-view
[Sysname] session fast-drop aspf enable
```

Related commands

session log { bytes-active | packets-active }

Use **session log** { **bytes-active** | **packets-active** } to set a threshold for traffic-based logging.

Use **undo session log** { **bytes-active** | **packets-active** } to restore the default.

Syntax

session log { **bytes-active** *bytes-value* | **packets-active** *packets-value* }

undo session log { **bytes-active** | **packets-active** }

Default

No threshold is set for traffic-based logging.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

bytes-value: Specifies the byte-based threshold in the range of 1 to 100000 MB.

packets-value: Specifies the packet-based threshold in the range of 1 to 100000 mega-packets.

Usage guidelines

For this command to take effect, make sure the session statistics collection for software fast forwarding feature is enabled.

If you set both the traffic-based and time-based logging, the device outputs a session log when whichever is reached. After outputting a session log, the device resets the traffic counter and restarts the interval for the session.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure the device to output session logs on a per-10-mega-packet basis.

```
<Sysname> system-view
[Sysname] session statistics enable
```

```
[Sysname] session log packets-active 10
```

session log enable { **ipv4** | **ipv6** } [**acl** *acl-number*] { **inbound** | **outbound** }

undo session log enable { **ipv4** | **ipv6** } [**acl** *acl-number*] { **inbound** | **outbound** }

Default

Session logging is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv4: Logs IPv4 sessions.

ipv6: Logs IPv6 sessions.

acl *acl-number*: Specifies an ACL by its number in the range of 2000 to 3999. If you do not specify an ACL, this command enables session logging for all IPv4 or IPv6 sessions on the interface.

inbound: Specifies the inbound direction.

outbound: Specifies the outbound direction.

Usage guidelines

If you do not specify the **inbound** or the **outbound** keyword, this command enables session logging on both directions.

A maximum of one IPv4 ACL and one IPv6 ACL can be applied to each direction.

After session logging is enabled, the device outputs session logs as follows:

- Outputs a session log when the specified traffic threshold or interval is reached.
- Outputs a session log when a session entry is created or removed only if the logging for session creation or deletion is enabled.

The session logging feature must work with the flow log or fast log output feature to generate session logs. Session logs can be output in flow log or fast log output format. By default, they are output in flow log format. For information about flow log and fast log output, see *Network Management and Monitoring*.

Examples

Enable IPv4 session logging in the inbound direction of GigabitEthernet 1/0/1.

```
<Sysname> system-view
```

```
[Sysname] session log flow-begin
[Sysname] session log flow-end
[Sysname] interface gigabitethernet 1/0/1

Default

The device does not output session logs.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

time-value: Specifies the interval in minutes. The value range for the *time-value* argument is 10 to 120 and the value must be integer times of 10.

Usage guidelines

If you set both time-based and traffic-based logging, the device outputs a session log when whichever is reached. After outputting a session log, the device resets the traffic counter and restarts the interval for the session.

Examples

Configure the device to output session logs every 50 minutes.

```
<Sysname> system
[Sysname] session log time-active 50
```

Related commands

session log enable

session log { **bytes-active** | **packets-active** }

session persistent acl

Use **session persistent acl** to specify persistent sessions.

Use **undo session persistent acl** to restore the default.

Syntax

session persistent acl [**ipv6**] *acl-number* [**aging-time** *time-value*]

undo session persistent acl [**ipv6**] *acl-number*

Default

No persistent sessions exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies an IPv6 ACL. To specify an IPv4 ACL, do not specify this keyword.

acl-number: Specifies an ACL by its number in the range of 2000 to 3999.

aging-time *time-value*: Specifies the aging time for persistent sessions in hours. The value range for the *time-value* argument is 0 to 360, and the default value is 24. To disable the aging for persistent sessions, set the value to 0.

Usage guidelines

This command is effective only on TCP sessions in ESTABLISHED state.

For a TCP session in ESTABLISHED state, the priority of the aging time is as follows:

- Aging time for persistent sessions.
- Aging time for sessions of application layer protocols.
- Aging time for sessions in different protocol states.

A persistent session is not removed until one of the following events occurs:

- The session entry ages out.
- The device receives a connection close request from the initiator or responder.
- You manually clear the session entries.

The configuration of persistent sessions applies only to new sessions. It has no effect on existing sessions.

Repeat this command to use multiple ACLs to specify persistent sessions.

Examples

Specify IPv4 ACL 2000 for identifying persistent sessions and set the aging time to 72 hours.

```
<Sysname> system-view
[Sysname] session persistent acl 2000 aging-time 72
```

Specify IPv6 ACL 3000 for identifying persistent sessions and set the aging time to 100 hours.

```
<Sysname> system-view
[Sysname] session persistent acl ipv6 3000 aging-time 100
```

Related commands

session state-machine mode

Use **session state-machine mode** to set the mode of session state machine.

Use **undo session state-machine mode** to restore the default.

Syntax

session state-machine mode { **compact** | **loose** }

undo session state-machine mode

Default

The session state machine is in strict mode.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

compact: Specifies compact mode.

loose: Specifies loose mode.

Usage guidelines

When asymmetric-path traffic exists in a hot backup system operating in session active/standby mode, set the mode of session state machine to loose to avoid abnormal traffic loss.

When asymmetric-path traffic exists in a hot backup system operating in session dual-active mode, set the mode of session state machine to compact for disconnected sessions to age out timely.

As a best practice, change the mode of session state machine only when asymmetric-path traffic exists. This feature degrades performance of session-based security check. Make sure you are fully aware of the impact of this command when you use it on a live network.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Set the mode of session state machine to loose.

```
<Sysname> system-view
[Sysname] session state-machine mode loose
```

Usage guidelines

This command enables the device to collect the session-based outbound and inbound packets and bytes for software fast forwarding.

To display statistics per session, use the **display session table** command. To display statistics per packet type, use the **display session statistics** command.

This command is CPU and memory intensive. Before using this command, make sure you fully understand its impact on system performance.

Examples

Enable session statistics collection for software fast forwarding.

```
<Sysname> system-view
[Sysname] session statistics enable
```

Related commands

display session table

session synchronization { dns | http } *

Use **session synchronization** { **dns** | **http** } * to enable session synchronization for DNS, HTTP, or both.

Use **undo session synchronization** { **dns** | **http** } * to disable session synchronization for DNS, HTTP, or both.

Syntax

session synchronization { **dns** | **http** } *

undo session synchronization { **dns** | **http** } *

Default

Session synchronization is disabled for DNS and HTTP.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dns: Specifies the DNS protocol.

http: Specifies the HTTP protocol.

Usage guidelines

DNS or HTTP connections usually do not last long. When a DNS or HTTP connection is terminated because of an active/standby switchover, the client will immediately reinitiate a connection request. The connection exception is barely noticed.

DNS and HTTP sessions do not require session synchronization except for the following conditions:

- Users are aware that the current HTTP or DNS sessions will last for a long time.
- HTTP or DNS session backup is required.

For this command to take effect, you must also configure the **session synchronization enable** command.

This command takes effect only on sessions of the application protocols HTTP and DNS. Sessions of other application protocols will be backed up if the **session synchronization enable** command is configured.

Examples

Enable session synchronization for stateful failover, and enable session synchronization for HTTP.

```
<Sysname> system-view
[Sysname] session synchronization enable
[Sysname] session synchronization http
```

Related commands

session synchronization enable

session synchronization enable

Use **session synchronization enable** to enable session synchronization for stateful failover.

Use **undo session synchronization enable** to disable session synchronization for stateful failover.

Syntax

session synchronization enable [**asymmetric**]

undo session synchronization enable

Default

Session synchronization for stateful failover is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

asymmetric: Specifies asymmetric traffic. If you do not specify this keyword, this command supports only symmetric traffic.

Usage guidelines

This features enables the master and backup devices to synchronize sessions and dynamic entries of session-based services.

In a network that has asymmetric traffic, heavy service traffic might cause service delay or service unavailable because sessions cannot be backed up timely. For example, one device forwards the TCP SYN packets, and another device forwards its ACK packets. If the session tables of the two devices are not synchronized, the TCP packets will be dropped because of state error. To resolve this issue, use the **session synchronization enable asymmetric** command.

This command cannot be used together with the **hot-backup enable** command. For information about the **hot-backup enable** command, see RBM-based hot backup in *High Availability Command Reference*.

Examples

Enable session synchronization for stateful failover.

```
<Sysname> system-view
<Sysname> session synchronization enable
```

Enable session synchronization for both symmetric and asymmetric traffic.

```
<Sysname> system-view
```

```
<Sysname> session synchronization enable asymmetric
```

Related commands

hot-backup enable (*High Availability Command Reference*)

session top-statistics enable

Use **session top-statistics enable** to enable the top session statistics feature.

Use **undo session top-statistics enable** to disable the top session statistics feature.

Syntax

session top-statistics enable

undo session top-statistics enable

Default

The top session statistics feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command collects the number of sessions for session-based services and ranks the sessions by source address and by destination address.

To display the top session statistics, use the **display session top-statistics** command.

Examples

Enable the top session statistics feature.

```
<Sysname> system-view
[Sysname] session top-statistics enable
```

Related commands

display session top-statistics

Contents

Object group commands

description

Use **description** to configure a description for an object group.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

No description is configured for an object group.

Views

Object group view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 127 characters.

Examples

Configure the description as **This is an IPv4 object-group** for an IPv4 address object group.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
[Sysname-obj-grp-ip-ipgroup] description This is an IPv4 object-group
```

display object-group

Use **display object-group** to display information about object groups.

Syntax

display object-group [{ { **ip** | **ipv6** } **address** | **mac-address** | **service** } [**default**] [**name** *object-group-name*] | **name** *object-group-name*]

Views

context-operator

Parameters

ip address: Specifies the IPv4 address object groups.

ipv6 address: Specifies the IPv6 address object groups.

mac-address: Specifies the MAC address object groups.

service: Specifies the service object groups.

default: Specifies the default object groups.

name *object-group-name*: Specifies an object group by its name, a case-insensitive string of 1 to 63 characters.

Examples

Display information about all object groups.

```
<Sysname> display object-group
IP address object group obj1: 0 object(in use)

IP address object group obj2: 6 objects(out of use)
0 network host address 1.1.1.1
object 0 description this is a description for object 0
10 network host name host
object 10 description this is a description for object 10
20 network subnet 1.1.1.1 255.255.255.0
30 network range 1.1.1.1 1.1.1.2
40 network group-object obj1
50 network user-group group1

IPv6 address object-group obj3: 0 object(in use)

IPv6 address object-group obj4: 5 objects(out of use)
0 network host address 1::1:1
10 network host name host
20 network subnet 1::1:0 112
30 network range 1::1:1 1::1:2
40 network group-object obj3

Service object-group obj5: 0 object(in use)

Service object-group obj6: 6 objects(out of use)
0 service 200
10 service tcp source lt 50 destination range 30 40
20 service udp source range 30 40 destination gt 30
30 service icmp 20 20
40 service icmpv6 20 20
50 service group-object obj5

MAC object-group obj7: 0 object(in use)

MAC object-group obj8: 2 objects(out of use)
0 MAC address 0010-dc28-11ac
10 MAC group-object obj7
```

Display information about object group **obj2**.

```
<Sysname> display object-group name obj2
IP address object-group obj2: 5 objects(out of use)
0 network host address 1.1.1.1
10 network host name host
20 network subnet 1.1.1.1 255.255.255.0
30 network range 1.1.1.1 1.1.1.2
40 network group-object obj1
```

Display information about all IPv4 address object groups.

```
<Sysname> display object-group ip address
IP address object-group obj1: 0 object(in use)

IP address object-group obj2: 5 objects(out of use)
0 network host address 1.1.1.1
10 network host name host
20 network subnet 1.1.1.1 255.255.255.0
30 network range 1.1.1.1 1.1.1.2
40 network group-object obj1
```

Display information about IPv6 address object group **obj4**.

```
<Sysname> display object-group ipv6 address name obj4
IPv6 address object-group obj4: 5 objects(out of use)
0 network host address 1::1:1
10 network host name host
20 network subnet 1::1:0 112
30 network range 1::1:1 1::1:2
40 network group-object obj3
```

Table 1 Command output

Field	Description
in use	The object group is used by an ACL or object group.
out of use	The object group is not used.

display object-group host

Use **display object-group host** to display IPv4 or IPv6 addresses for host names.

Syntax

display object-group { **ip** | **ipv6** } **host** { **object-group-name** *object-group-name* | **name** *host-name* [**vpn-instance** *vpn-instance-name*] } * [**slot** *slot-number*]

Views

Any view

network-admin

network-operator

context-admin

context-operator

Parameters

object-group-name *object-group-name*: Specifies an object group by its name, a case-insensitive string of 1 to 63 characters. If you do not specify this option, the command displays information about the specified host name.

name *host-name*: Specifies a host by its name, a case-insensitive string of 1 to 60 characters. If you do not specify this option, the command displays information about all the included and excluded host names in the specified object group.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN to which the host belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the host resides on the public network, do not specify this option.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify this option, this command displays information about host names of all member devices.

Examples

Display IPv4 addresses for host name **www.a.com** in object group **group1**.

```
[Sysname] display object-group ip host object-group-name group1 name www.a.com
Object group      : group1
  Object ID       : 0
    Host name     : www.a.com
    VPN instance  : -
      Updated at  : 2019-05-20 11:04:24
      IP addresses :
        169.0.0.10
        169.0.0.11
```

Display IPv6 addresses for all host names in object group **group1**.

```
<Sysname> display object-group ipv6 host object-group-name group1
Object group : group1
  Object ID       : 0
    Host name     : www.a.com
    VPN instance  : -
      Updated at  : 2019-05-20 11:04:24
      IP addresses :
        169:0::0:10
        169:0::0:11
  Object ID       : 10
    Host name     : www.b.com
    VPN instance  : -
      Updated at  : 2019-05-20 11:04:24
      IP addresses :
        169:0::0:11
        169:0::0:12
```

Related commands

object-group

mac

Use **mac** to configure a MAC address object.

Use **undo mac** to delete a MAC address object.

Syntax

[*object-id*] **mac** { *mac-address* | **group-object** *object-group-name* }

undo mac { *mac-address* | **group-object** *object-group-name* }

undo *object-id*

Default

No MAC address objects exist.

Views

MAC address object group view

Predefined user roles

network-admin

context-admin

Parameters

object-id: Specifies an object ID in the range of 0 to 4294967294. If you do not specify an object ID, the system automatically assigns the object a multiple of 10 next to the greatest ID being used. For example, if the greatest ID is 22, the system automatically assigns 30.

mac-address: Specifies a MAC address in format H-H-H.

group-object *object-group-name*: Specifies a MAC address object group by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

You can execute this command multiple times to create multiple MAC address objects for a MAC address object group.

This command creates a MAC address object if the specified object ID does not exist. Otherwise, the command overwrites the configuration of the specified object.

When you use the **group-object** *object-group-name* option, follow these guidelines:

- The object group to be used must be a MAC address object group.
- If the specified object group does not exist, the system creates a MAC address object group with the name you specified and uses the object group for the object.
- Two object groups cannot use each other at the same time.
- The system supports a maximum of five object group hierarchy layers. For example, if groups 1, 2, 3, and 4 use groups 2, 3, 4, and 5, respectively, group 5 cannot use another group and group 1 cannot be used by another group.

Examples

Configure a MAC address object with MAC address 0010-dc28-a4e9.

```
<Sysname> system-view
[Sysname] object-group mac-address groupmac
[Sysname-obj-grp-mac-groupmac] mac 0010-dc28-a4e9
```

Examples

display object-group

object-group

network (IPv4 address object group view)

Use **network** to configure an IPv4 address object.

Use **undo network** to delete an IPv4 address object.

Syntax

[*object-id*] **network** { **host** { **address** *ip-address* | **name** *host-name* [**vpn-instance** *vpn-instance-name*] } | **subnet** *ip-address* { *mask-length* | *mask* | **wildcard** *wildcard* } | **range** *ip-address1 ip-address2* | **group-object** *object-group-name* | **user** *user-name* [**domain** *domain-name*] | **user-group** *user-group-name* [**domain** *domain-name*] }

undo network { **host** { **address** *ip-address* | **name** *host-name* [**vpn-instance** *vpn-instance-name*] } | **subnet** *ip-address* { *mask-length* | *mask* | **wildcard** *wildcard* } | **range** *ip-address1 ip-address2* | **group-object** *object-group-name* | **user** *user-name* [**domain** *domain-name*] | **user-group** *user-group-name* [**domain** *domain-name*] }

undo *object-id*

Default

No IPv4 address objects exist.

Views

IPv4 address object group view

Predefined user roles

network-admin

context-admin

Parameters

object-id: Specifies an object ID in the range of 0 to 4294967294. If you do not specify an object ID, the system automatically assigns the object a multiple of 10 next to the greatest ID being used. For example, if the greatest ID is 22, the system automatically assigns 30.

host: Configures an IPv4 address object with the host address or name.

address *ip-address*: Specifies an IPv4 host address.

name *host-name*: Specifies a host name, a case-insensitive string of 1 to 60 characters. This parameter supports fuzzy matching. You can add an asterisk (*) to the front, end, or both of a string to indicate all host names that include the string. If no asterisks are attached, the system performs exact matching with the specified host name.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN to which the host belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the host resides on the public network, do not specify this option.

subnet *ip-address* { *mask-length* | *mask* | **wildcard** *wildcard* }: Configures an IPv4 address object with the subnet address followed by a mask length in the range of 0 to 32 or a mask in dotted decimal notation. The **wildcard** *wildcard* option specifies a wildcard mask in dotted decimal notation. A wildcard mask of zeros represents a host address.

range *ip-address1 ip-address2*: Configures an IPv4 address object with the address range.

group-object *object-group-name*: Specifies an IPv4 address object group by its name, a case-insensitive string of 1 to 63 characters.

user *user-name*: Specifies a user by its name, a case-sensitive string of 1 to 55 characters.

user-group *user-group-name*: Specifies a user group by its name, a case-insensitive string of 1 to 32 characters.

domain *domain-name*: Specifies the name of a domain to which the user or the user group belongs, a case-insensitive string of 1 to 255 characters. The string cannot contain question marks (?). If you do not specify this option, the command considers that the user or the user group does not belong to any domains.

Usage guidelines

This command fails if you use it to configure or change an IPv4 address object to be identical with an existing object.

This command creates an IPv4 address object if the specified object ID does not exist. Otherwise, the command overwrites the configuration of the specified object.

If you configure a subnet with the mask length of 32 or the mask of 255.255.255.255, the system configures the object with a host address.

When you use the **range** *ip-address1 ip-address2* option, follow these guidelines:

- If *ip-address1* is equal to *ip-address2,* the system configures the object with a host address.
- If *ip-address1* is not equal to *ip-address2*, the system compares the two IPv4 addresses, configures a range starting with the lower IPv4 address, and performs the following operations:
  - Configures the object with an address range if the two addresses are in different subnets.
  - Configures the object with a subnet address if the two addresses are in the same subnet.

When you use the **group-object** *object-group-name* option, follow these guidelines:

- The object group to be used must be an IPv4 address object group.
- If the specified object group does not exist, the system creates an IPv4 address object group with the name you specified and uses the object group for the object.
- Two object groups cannot use each other at the same time.
- The system supports a maximum of five object group hierarchy layers. For example, if groups 1, 2, 3, and 4 use groups 2, 3, 4, and 5, respectively, group 5 cannot use another group and group 1 cannot be used by another group.

Examples

Configure an IPv4 address object with the host address of **192.168.0.1**.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
[Sysname-obj-grp-ip-ipgroup] network host address 192.168.0.1
```

Configure an IPv4 address object with exact-matching host name **pc3**.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
[Sysname-obj-grp-ip-ipgroup] network host name pc3
```

Configure an IPv4 address object with fuzzy-matching host name **abc**.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup1
[Sysname-obj-grp-ip-ipgroup1] network host name *abc*
```

Configure an IPv4 address object with the IPv4 address of **192.167.0.0** and mask length of **24**.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
[Sysname-obj-grp-ip-ipgroup] network subnet 192.167.0.0 24
```

Configure an IPv4 address object with the IPv4 address of **192.166.0.0** and mask of **255.255.0.0**.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
[Sysname-obj-grp-ip-ipgroup] network subnet 192.166.0.0 255.255.0.0
```

Configure an IPv4 address object with the address range of **192.165.0.100** to **192.165.0.200**.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
[Sysname-obj-grp-ip-ipgroup] network range 192.165.0.100 192.165.0.200
```

Configure an IPv4 address object using object group **ipgroup2**.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
[Sysname-obj-grp-ip-ipgroup] network group-object ipgroup2
```

Configure an IPv4 address object with the IPv4 address of **192.168.0.1** and wildcard mask of **0.0.255.0**.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
[Sysname-obj-grp-ip-ipgroup] network subnet 192.168.0.1 wildcard 0.0.255.0
```

Configure an IPv4 address object using user **user1** in domain **domain1**.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
[Sysname-obj-grp-ip-ipgroup] network user user1 domain domain1
```

Configure an IPv4 address object using user group **usergroup1** in domain **domain1**.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
[Sysname-obj-grp-ip-ipgroup] network user-group usergroup1 domain domain1
```

network (IPv6 address object group view)

Use **network** to configure an IPv6 address object.

Use **undo network** to delete an IPv6 address object.

Syntax

[*object-id*] **network** { **host** { **address** *ipv6-address* | **name** *host-name* [**vpn-instance** *vpn-instance-name*] } | **subnet** *ipv6-address prefix-length* | **range** *ipv6-address ipv6-address2* | **group-object** *object-group-name* | **user** *user-name* [**domain** *domain-name*] | **user-group** *user-group-name* [**domain** *domain-name*] }

undo network { **host** { **address** *ipv6-address* | **name** *host-name* [**vpn-instance** *vpn-instance-name*] } | **subnet** *ipv6-address prefix-length* | **range** *ipv6-address1 ipv6-address2* | **group-object** *object-group-name* | **user** *user-name* [**domain** *domain-name*] | **user-group** *user-group-name* [**domain** *domain-name*] }

undo *object-id*

Default

No IPv6 address objects exist.

Views

IPv6 address object group view

Predefined user roles

network-admin

context-admin

Parameters

object-id: Specifies an object ID in the range of 0 to 4294967294. If you do not configure an object ID, the system automatically assigns the object a multiple of 10 next to the greatest ID being used. For example, if the greatest ID is 22, the system automatically assigns 30.

host: Configures an IPv6 address object with the host address or name.

address *ipv6-address*: Specifies an IPv6 host address.

name *host-name*: Specifies a host name, a case-insensitive string of 1 to 60 characters. This parameter supports fuzzy matching. You can add an asterisk (*) to the front, end, or both of a string to indicate all host names that include the string. If no asterisks are attached, the system performs exact matching with the specified host name.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN to which the host belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the host resides on the public network, do not specify this option.

subnet *ipv6-address prefix-length*: Configures an IPv6 address object with the subnet address followed by the prefix length in the range of 1 to 128.

range *ipv6-address1 ipv6-address2*: Configures an IPv6 address object.

group-object *object-group-name*: Specifies an IPv6 address object group by its name, a case-insensitive string of 1 to 63 characters.

user *user-name*: Specifies a user by its name, a case-sensitive string of 1 to 55 characters.

user-group *user-group-name*: Specifies a user group by its name, a case-insensitive string of 1 to 32 characters.

domain *domain-name*: Specifies the name of a domain to which the user or the user group belongs, a case-insensitive string of 1 to 255 characters. The string cannot contain question marks (?). If you do not specify this option, the command considers that the user or the user group does not belong to any domains.

Usage guidelines

This command fails if you use it to configure or change an IPv6 address object to be identical with an existing object.

This command creates an IPv6 address object if the specified object ID does not exist. Otherwise, the command overwrites the configuration of the specified object.

If you configure a subnet address with the prefix length of 128, the system configures the object with a host address.

When you use the **range** *ipv6-address1 ipv6-address2* option, follow these guidelines:

- If *ipv6-address1* is equal to *ipv6-address2,* the system configures the object with a host address.
- If *ipv6-address1* is not equal to *ipv6-address2*, the system compares the two IPv6 addresses, configures a range starting with the lower IPv6 address, and performs the following operations:

- Configures the object with an address range if the two addresses are in different subnets.
- Configures the object with a subnet address if the two addresses are in the same subnet.

When you use the **group-object** *object-group-name* option, follow these guidelines:

- The object group to be used must be an IPv6 address object group.
- If the specified object group does not exist, the system creates an IPv6 address object group with the name you specified and uses the object group for the object.
- Two object groups cannot use each other at the same time.
- The system supports a maximum of five object group hierarchy layers. For example, if groups 1, 2, 3, and 4 use groups 2, 3, 4, and 5, respectively, group 5 cannot use another group and group 1 cannot be used by another group.

Examples

Configure an IPv6 address object with the host address of **1::1**.

```
<Sysname> system-view
[Sysname] object-group ipv6 address ipv6group
[Sysname-obj-grp-ipv6-ipv6group] network host address 1::1
```

Configure an IPv6 address object with exact-matching host name **pc3**.

```
<Sysname> system-view
[Sysname] object-group ipv6 address ipv6group
[Sysname-obj-grp-ipv6-ipv6group] network host name pc3
```

Configure an IPv6 address object with fuzzy-matching host name **abc**.

```
<Sysname> system-view
[Sysname] object-group ipv6 address ipv6group1
[Sysname-obj-grp-ipv6-ipv6group1] network host name *abc*
```

Configure an IPv6 address object with the IPv6 address of **1:1:1::1** and prefix length of **24**.

```
<Sysname> system-view
[Sysname] object-group ipv6 address ipv6group
[Sysname-obj-grp-ipv6-ipv6group] network subnet 1:1:1::1 24
```

Configure an IPv6 address object with the address range of **1:1:1::1** to **1:1:1::100**

```
<Sysname> system-view
[Sysname] object-group ipv6 address ipv6group
[Sysname-obj-grp-ipv6-ipv6group] network range 1:1:1::1 1:1:1::100
```

Configure an IPv6 address object using object group **ipv6group2**.

```
<Sysname> system-view
[Sysname] object-group ipv6 address ipv6group
[Sysname-obj-grp-ipv6-ipv6group] network group-object ipv6group2
```

Configure an IPv6 address object using user **user1** in domain **domain1**.

```
<Sysname> system-view
[Sysname] object-group ipv6 address ipv6group
[Sysname-obj-grp-ipv6-ipv6group] network user user1 domain domain1
```

Configure an IPv6 address object using user group **usergroup1** in domain **domain1**.

```
<Sysname> system-view
[Sysname] object-group ipv6 address ipv6group
[Sysname-obj-grp-ipv6-ipv6group] network user-group usergroup1 domain domain1
```

network exclude (IPv4 address object group view)

Use **network exclude** to exclude an IPv4 address or a subnet from an address object.

Use **undo network exclude** to restore the default.

Syntax

object-id **network exclude** { *ip-address* | **subnet** *ip-address* { *mask-length* | *mask* } }

undo *object-id* **network exclude** { *ip-address* | **subnet** *ip-address* { *mask-length* | *mask* } }

Default

No IPv4 address or subnet in an address object is excluded.

Views

IPv4 address object group view

Predefined user roles

network-admin

context-admin

Parameters

object-id: Specifies an address object by its ID in the range of 1 to 4294967294. The specified address object must have been created.

ip-address: Specifies the IPv4 address to be excluded.

subnet *ip-address* { *mask-length* | *mask* }: Specifies the IPv4 address and mask of a subnet to be excluded. You can specify the mask length or specify the mask in dotted decimal notation. The mask length is in the range of 0 to 32.

Usage guidelines

You can execute this command multiple times to exclude multiple IPv4 addresses or subnets from an address object.

The configuration fails if either of the following conditions exists:

- The specified address is the same as an existing excluded address or is contained in an existing excluded subnet.
- The specified subnet contains an existing excluded address or overlaps with an existing excluded subnet.

Examples

Configure an IPv4 address object with the IPv4 address of **192.166.0.0** and mask of **255.255.0.0**. Exclude IPv4 address **192.166.0.10** and subnet **192.166.1.0/24** from the address object.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
[Sysname-obj-grp-ip-ipgroup] 10 network subnet 192.166.0.0 255.255.0.0
[Sysname-obj-grp-ip-ipgroup] 10 network exclude 192.166.0.10
[Sysname-obj-grp-ip-ipgroup] 10 network exclude subnet 192.166.1.0 255.255.255.0
```

network exclude (IPv6 address object group view)

Use **network exclude** to exclude an IPv6 address or a subnet from an address object.

Use **undo network exclude** to restore the default.

Syntax

object-id **network exclude** { *ipv6-address* | **subnet** *ipv6-address prefix-length* }

undo *object-id* **network exclude** { *ipv6-address* | **subnet** *ipv6-address prefix-length* }

Default

No IPv6 address or subnet in an address object is excluded.

Views

IPv6 address object group view

Predefined user roles

network-admin

context-admin

Parameters

object-id: Specifies an address object by its ID in the range of 1 to 4294967294. The specified address object must have been created.

ip-address: Specifies the IPv6 address to be excluded.

subnet *ipv6-address prefix-length*: Specifies the IPv6 subnet to be excluded. The prefix length is in the range of 1 to 128.

Usage guidelines

You can execute this command multiple times to exclude multiple IPv6 addresses or subnets from an address object.

The configuration fails if either of the following conditions exists:

- The specified address is the same as an existing excluded address or is contained in an existing excluded subnet.
- The specified subnet contains an existing excluded address or overlaps with an existing excluded subnet.

Examples

Configure an IPv6 address object with the IPv6 address of **1:1:1::1** and prefix length of **24**. Exclude IPv6 address **1:1:1::10** and subnet **1:1:1::2:0** with a prefix length of **112** from the address object.

```
<Sysname> system-view
[Sysname] object-group ipv6 address ipv6group
[Sysname-obj-grp-ipv6-ipv6group] 10 network subnet 1:1:1::1 24
[Sysname-obj-grp-ipv6-ipv6group] 10 network exclude 1:1:1::10
[Sysname-obj-grp-ipv6-ipv6group] 10 network exclude subnet 1:1:1::2:0 112
```

object description

Use **object description** to configure a description for an object.

Use **undo object description** to restore the default.

Syntax

object *object-id* **description** *text*

undo object *object-id* **description**

Default

No description is configured for an object.

Views

Object group view

Predefined user roles

network-admin

context-admin

Parameters

object-id: Specifies an object ID in the range of 0 to 4294967294. The object must already exist.

text: Specifies a description, a case-sensitive string of 1 to 127 characters.

Examples

Configure the description as **This is a description for object 0** for the object 0.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
[Sysname-obj-grp-ip-ipgroup] 0 network host address 1.2.3.4
[Sysname-obj-grp-ip-ipgroup] object 0 description This is a description for object 0
```

Related commands

- **object-group**

object-group

Use **object-group** to create an object group and enter its view, or enter the view of an existing object group.

Use **undo object-group** to delete an object group.

Syntax

object-group { { **ip** | **ipv6** } **address** | **mac-address** | **service** } *object-group-name*

undo object-group { { **ip** | **ipv6** } **address** | **mac-address** | **service** } *object-group-name*

Default

Default object groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ip address: Creates an IPv4 address object group.

ipv6 address: Creates an IPv6 address object group.

mac-address: Creates a MAC object group.

service: Creates a service object group.

object-group-name: Specifies an object group name, a case-insensitive string of 1 to 63 characters. The object group name must be globally unique.

Usage guidelines

The **object-group** command execution results vary with the specified object group.

- If the specified group does not exist, the system creates a new object group and enters the object group view.
- If the specified group exists but the group type is different from that in the command, the command fails.

The **undo object-group** command execution results vary with the specified object group.

- If the specified group does not exist, the system executes the command without any system prompt.
- If the specified group exists and the group type is the same as that in the command, the system deletes the group.
- If the specified group exists but the group type is different from that in the command, the command fails.
- If the specified object group is being used by an ACL or another object group, the command fails.

Default object groups cannot be deleted.

Examples

Create an IPv4 address object group named **ipgroup**.

```
<Sysname> system-view
[Sysname] object-group ip address ipgroup
```

Create an IPv6 address object group named **ipv6group**.

```
<Sysname> system-view
[Sysname] object-group ipv6 address ipv6group
```

Create a MAC object group named **groupmac**.

```
<Sysname> system-view
[Sysname] object-group mac-address groupmac
```

Create a service object group named **servicegroup**.

```
<Sysname> system-view
[Sysname] object-group service servicegroup
```

object-group dns-aging

Use **object-group dns-aging** to enable aging of DNS-resolved IP addresses from host names.

Use **undo object-group dns-aging** to disable aging of DNS-resolved IP addresses from host names.

Syntax

object-group dns-aging [**time** *aging-time*]

undo object-group dns-aging

The following compatibility matrixes show the support of hardware platforms for this command:

Models	Command compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No

Default

Aging of DNS-resolved IP addresses from host names is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

time *aging-time*: Specifies the aging time in the range of 1 to 70000000 minutes. The default value is 120.

Usage guidelines

In load balancing scenarios where one host name maps to several IP addresses, DNS-resolved IP address for a host name changes between these mapping addresses. Upon every change, the object group module notifies relevant policies (such as security policy) of the change, which causes policies to submit changes frequently and consumes memory. To resolve this issue, you can enable aging of DNS-resolved IP addresses from host names.

With this feature enabled, the system maintains an IP address group for each host name. If a resolved IP address is not in the group, the system adds the address to the group and notifies relevant policies of the change. If a resolved IP address is in the group, the system does not notify relevant policies.

As a best practice, set the aging time to be longer than the TTL of resolution records on the DNS server.

Examples

Enable aging of DNS-resolved IP addresses from host names and set the aging time to 5 minutes.

```
<Sysname> system-view
[Sysname] object-group dns-aging
[Sysname] object-group dns-aging time 5
```

object-group rename

Use **object-group rename** to rename an object group.

Syntax

object-group rename *old-object-group-name new-object-group-name*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

old-object-group-name: Specifies the name of the object group to be renamed, a case-insensitive string of 1 to 63 characters.

new-object-group-name: Specifies a new name for the object group, a case-insensitive string of 1 to 63 characters. The object group name must be globally unique.

Usage guidelines

You can only rename non-default object groups.

Examples

Rename object group **ipgroup1** to **ipgroup2**.

```
<Sysname> system-view
[Sysname] object-group rename ipgroup1 ipgroup2
```

Related commands

object-group

security-zone

Use **security-zone** to specify a security zone for an IP address object group.

Use **undo security-zone** to restore the default.

Syntax

security-zone *security-zone-name*

undo security-zone

Default

No security zone is specified for an IP address object group.

Views

IPv4 address object group view

IPv6 address object group view

Predefined user roles

network-admin

context-admin

Parameters

security-zone-name: Specifies the security zone name, a case-insensitive string of 1 to 31 characters. The string cannot contain hyphens (-) and cannot be **any**.

Usage guidelines

This feature enables fast selection of IP address object groups when you specify IP address filtering criteria for a security policy from the Web interface. If a security policy uses an IP address object group specified with a security zone, you can specify only IP address object groups from the same or no security zone for the policy.

You can specify only one security zone for an IP address object group. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the security zone for IPv4 address object group 1 as **Local**.

```
<Sysname> system-view
[Sysname] object-group ip address 1
[Sysname-obj-grp-ip-1] security-zone Local
```

Related commands

object-group

service (service object group view)

Use **service** to configure a service object.

Use **undo service** to delete a service object.

Syntax

[*object-id*] **service** { *protocol* [{ **source** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } | **destination** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } } * | *icmp-type icmp-code* | *icmpv6-type icmpv6-code*] | **group-object** *object-group-name* }

undo service { *protocol* [{ **source** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } | **destination** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } } * | *icmp-type icmp-code* | *icmpv6-type icmpv6-code*] | **group-object** *object-group-name* }

undo *object-id*

Default

No service objects exist.

Views

Service object group view

Predefined user roles

network-admin

context-admin

Parameters

object-id: Configures an object ID in the range of 0 to 4294967294. If you do not configure an ID for the object, the system automatically assigns the object a multiple of 10 next to the greatest ID being used. For example, if the greatest ID is 22, the automatically assigned ID is 30.

protocol: Configures the protocol number in the range of 0 to 255, or the protocol name such as TCP, UDP, ICMP, and ICMPv6.

source: Configures a service object with a source port when the protocol is TCP or UDP.

destination: Configures a service object with a destination port when the protocol is TCP or UDP.

eq: Configures a port equal to the specified port.

lt: Configures a port smaller than the specified port.

gt: Configures a port greater than the specified port.

port: Specifies a port number in the range of 0 to 65535.

range *port1 port2*: Configures a service object with a port range. The value range for the *port1* and *port2* arguments is 0 to 65535.

icmp-type: Configures the ICMP message type in the range of 0 to 255.

icmp-code: Configures the ICMP message code in the range of 0 to 255.

icmpv6-type: Configures the ICMPv6 message type in the range of 0 to 255.

icmpv6-code: Configures the ICMPv6 message code in the range of 0 to 255.

group-object *object-group-name*: Specifies a service object group by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

This command fails if you use it to configure or change a service object to be identical with an existing object.

This command creates a service object if the specified object ID does not exist. Otherwise, the command overwrites the configuration of the specified object.

When you use the **lt** *port* option, follow these guidelines:

- The value of *port* cannot be 0.
- If the value of *port* is 1, the system configures the object with a port number of 0.
- If the value of *port* is in the range of 2 to 65535, the system configures the object with a port number range of [0, *port*–1].

When you use the **gt** *port* option, follow these guidelines:

- The value of *port* cannot be 65535.
- If the value of *port* is 65534, the system configures the object with a port number of 65535.
- If the value of *port* is in the range of 0 to 65533, the system configures the object with a port number range of [*port*+1, 65535].

When you use the **range** *port1 port2* option, follow these guidelines:

- If *port1* is equal to *port2*, the system configures the object with the port number *port1*.
- If *port1* is smaller than *port2*, the system configures the object with the port number range.
- If *port1* is greater than *port2*, the system changes the range to [*port2*, *port1*] and configures the object with the changed port number range.
- If *port1* is 0, the range is displayed as **lt** *port2*+1.
- If *port2* is 65535, the range is displayed as **gt** *port1*–1.

When use the **group-object** *object-group-name* option, follow these guidelines:

- The object group to be used must be a service object group.
- If the specified object group does not exist, the system creates a service object group with the name you specified and uses the object group for the object.
- Two object groups cannot use each other at the same time.
- The system supports a maximum of five object group hierarchy layers. For example, if groups 1, 2, 3, and 4 use groups 2, 3, 4, and 5, respectively, group 5 cannot use another group and group 1 cannot be used by another group.

Examples

Configure a service object with a protocol number of **100**.

```
<Sysname> system-view
[Sysname] object-group service servicegroup
[Sysname-obj-grp-service-servicegroup] service 100
```

Configure a service object with the source and destination port numbers for the TCP service.

```
<Sysname> system-view
[Sysname] object-group service servicegroup
```

```
[Sysname-obj-grp-service-servicegroup] service tcp source eq 100 destination range 10 100
```

Configure a service object with the message type and code for the ICMP service.

```
<Sysname> system-view
[Sysname] object-group service servicegroup
[Sysname-obj-grp-service-servicegroup] service icmp 100 150
```

Configure a service object using object group **servicegroup2**.

```
<Sysname> system-view
[Sysname] object-group service servicegroup
[Sysname-obj-grp-service-servicegroup] service group-object servicegroup2
```

Contents

IP source guard commands

display ip source binding

Use **display ip source binding** to display IPv4SG bindings.

Syntax

display ip source binding [**static** | [**vpn-instance** *vpn-instance-name*] [**dhcp-relay** | **dhcp-server** | **ip-mac-vlan** | **ip-mac-vpn**]] [**ip-address** *ip-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

static: Displays static IPv4SG bindings.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. To display dynamic IPv4SG bindings for the public network, do not specify a VPN instance.

dhcp-relay: Specifies the DHCP relay agent module.

dhcp-server: Specifies the DHCP server module.

ip-mac-vlan: Specifies IPv4SG IP-MAC-VLAN bindings that are generated based on the IP-MAC binding module.

ip-mac-vpn: Specifies IPv4SG IP-MAC-VPN bindings that are generated based on the IP-MAC binding module.

ip-address *ip-address*: Specifies an IPv4 address.

mac-address *mac-address*: Specifies a MAC address in H-H-H format.

vlan *vlan-id*: Specifies a VLAN ID in the range of 1 to 4094.

interface *interface-type interface-number*: Specifies an interface by its type and number.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv4SG bindings for the master device.

Examples

Display all IPSG bindings on the public network.

```
<Sysname> display ip source binding
Total entries found: 7
IP Address      MAC Address    Interface               VLAN Type
Total entries found: 7
```

```
IP Address      MAC Address    Interface                VLAN Type
10.1.0.5        040a-0000-4000 GE1/0/1                  1    Static
10.1.0.6        040a-0000-3000 GE1/0/1                  1    Static
10.1.0.7        040a-0000-2000 GE1/0/1                  1    Static
10.1.0.8        040a-0000-1000 GE1/0/2                  N/A  DHCP relay
10.1.0.9        040a-0000-2000 GE1/0/2                  N/A  Static
10.1.0.10       040a-0000-3000 N/A                      1    IP-MAC VLAN
10.1.0.11       040a-0000-4000 N/A                      N/A  IP-MAC VPN
```

Table 1 Command output

Field	Description
Total entries found	Total number of IPv4SG bindings.
IP Address	IPv4 address in the IPv4SG binding. If no IP address is bound in the binding, this field displays **N/A**.
MAC Address	MAC address in the IPv4SG binding. If no MAC address is bound in the binding, this field displays **N/A**.
Interface	Interface of the binding. This field displays **N/A** for a global IPv4SG binding.
VLAN	VLAN information in the IPv4SG binding. If the binding contains no VLAN information, this field displays **N/A**.
Type	IPSG binding type: • **Static**—Manually configured by using the **ip source binding** command. Static bindings are for packet filtering in IPSG or used by other modules to provide security services. • **DHCP relay**—Dynamically generated based on DHCP relay agent. The binding is for packet filtering in IPSG. • **DHCP server**—Dynamically generated based on DHCP server. The binding is used by other modules to provide security services. • **IP-MAC VLAN**—Dynamically generated based on IP-MAC binding module. This type of IPSG bindings binds IPv4 address, MAC address, and VLAN ID. • **IP-MAC VPN**—Dynamically generated based on IP-MAC binding module. This type of IPSG bindings binds IPv4 address, MAC address, and VPN instance.

Parameters

`static`: Displays static IPv6SG bindings.

`vpn-instance` *`vpn-instance-name`*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. To display dynamic IPv6SG bindings for the public network, do not specify a VPN instance.

`ipv6-mac-vlan`: Specifies IPv6SG IPv6-MAC-VLAN bindings that are generated based on the IP-MAC binding module.

`ipv6-mac-vpn`: Specifies IPv6SG IPv6-MAC-VPN bindings that are generated based on the IP-MAC binding module.

`ip-address` *`ipv6-address`*: Specifies an IPv6 address.

`mac-address` *`mac-address`*: Specifies a MAC address in H-H-H format.

`vlan` *`vlan-id`*: Specifies a VLAN ID in the range of 1 to 4094.

`interface` *`interface-type interface-number`*: Specifies an interface by its type and number.

`slot` *`slot-number`*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv6SG bindings for the master device.

Examples

Display all IPv6SG bindings on the public network.

```
<Sysname> display ipv6 source binding
Total entries found: 4
IPv6 Address         MAC Address    Interface              VLAN Type
Total entries found: 4
IPv6 Address         MAC Address    Interface              VLAN Type
2012:1222:2012:1222: 000f-2202-0435 GE1/0/1                1    Static
2012:1222:2012:1222
2012:1222:2012:1222: 000f-2202-0436 GE1/0/1                N/A  Static
2012:1222:2012:1223
2012:1222:2012:1222: 040a-0000-3000 N/A                    1    IPv6-MAC VLAN
2012:1222:2012:1224
2012:1222:2012:1222: 040a-0000-4000 N/A                    N/A  IPv6-MAC VPN
2012:1222:2012:1225
```

Table 2 Command output

Field	Description
Total entries found	Total number of IPv6SG bindings.
IPv6 Address	IPv6 address in the IPv6SG binding. If no IPv6 address is bound in the binding, this field displays **N/A**.
MAC Address	MAC address in the IPv6SG binding. If no MAC address is bound in the binding, this field displays **N/A**.

Field	Description
Interface	Interface of the IPv6SG binding. This field displays **N/A** for a global IPv6SG binding.
VLAN	VLAN information in the IPv6SG binding. If the binding contains no VLAN information, this field displays **N/A**.
Type	Type of the IPv6SG binding: • **Static**—Manually configured by using the **ipv6 source binding** command. Static bindings are for packet filtering in IPv6SG or used by other modules to provide security services. • **IPv6-MAC VLAN**—Dynamically generated based on IP-MAC binding module. This type of IPSG bindings binds IPv6 address, MAC address, and VLAN ID. • **IPv6-MAC VPN**—Dynamically generated based on IP-MAC binding module. This type of IPSG bindings binds IPv6 address, MAC address, and VPN instance.

Related commands

ipv6 source binding

ipv6 verify source

ip source binding (interface view)

Use **ip source binding** to configure a static IPv4SG binding on an interface.

Use **undo ip source binding** to delete the static IPv4SG bindings configured on an interface.

Syntax

ip source binding { **ip-address** *ip-address* | **ip-address** *ip-address* **mac-address** *mac-address* | **mac-address** *mac-address* } [**vlan** *vlan-id*]

undo ip source binding { **all** | **ip-address** *ip-address* | **ip-address** *ip-address* **mac-address** *mac-address* | **mac-address** *mac-address* } [**vlan** *vlan-id*]

Default

No static IPv4SG bindings are configured on an interface.

Views

Layer 2 Ethernet interface view

Layer 3 Ethernet interface view

Layer 3 Ethernet subinterface view

VLAN interface view

Reth interface view

Reth subinterface view

Predefined user roles

network-admin

context-admin

Parameters

all: Removes all static IPv4SG bindings on the interface.

ip-address *ip-address*: Specifies an IPv4 address for the static binding. The IPv4 address must be a class A, B, or C address, and cannot be 127.x.x.x or 0.0.0.0.

mac-address *mac-address*: Specifies a MAC address for the static binding. The MAC address must be in H-H-H format, and cannot be all 0s, all Fs (a broadcast MAC address), or a multicast MAC address.

vlan *vlan-id*: Specifies a VLAN ID for the static binding. The value range is 1 to 4094. This option is supported only in Layer 2 Ethernet interface view.

Usage guidelines

Static IPv4SG bindings on an interface implement the following functions:

- Filter incoming IPv4 packets on the interface.
- Check user validity by cooperating with the ARP attack detection feature.

Examples

Configure a static IPv4SG binding on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip source binding ip-address 192.168.0.1 mac-address
0001-0001-0001
```

Related commands

Use **undo ip source binding** to delete one or all global static IPv4SG bindings.

Syntax

ip source binding ip-address *ip-address* **mac-address** *mac-address*

undo ip source binding { **all** | **ip-address** *ip-address* **mac-address** *mac-address* }

Default

No global static IPv4SG bindings exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ip-address *ip-address*: Specifies the IPv4 address for the static binding. The IPv4 address must be a class A, B, or C address, and cannot be 127.x.x.x or 0.0.0.0.

mac-address *mac-address*: Specifies the MAC address for the static binding. The MAC address is in the format H-H-H but cannot be all 0s, all Fs (a broadcast MAC address), or a multicast MAC address.

all: Removes all global static IPv4SG bindings.

Usage guidelines

A global static IPv4SG binding takes effect on all interfaces.

Examples

Configure a global static IPv4SG binding.

```
<Sysname> system-view
[Sysname] ip source binding ip-address 192.168.0.1 mac-address 0001-0001-0001
```

Reth subinterface view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Filters incoming packets by source IPv4 addresses.

ip-address mac-address: Filters incoming packets by source IPv4 addresses and source MAC addresses.

mac-address: Filters incoming packets by source MAC addresses.

Usage guidelines

After you enable IPv4SG on an interface, this feature uses static and dynamic IPv4SG bindings to match incoming packets on the interface. Packets that match an IPv4SG binding are forwarded and packets that do not match any IPv4SG binding are discarded.

The matching criterion specified by this command applies only to dynamic IPSG. Static IPv4SG uses static bindings configured by using the **ip source binding** command.

Examples

Enable IPv4SG on Layer 2 Ethernet interface GigabitEthernet 1/0/1 and verify the source IPv4 address and MAC address for dynamic IPSG.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip verify source ip-address mac-address
```

Enable IPv4SG on VLAN-interface 100 and verify the source IPv4 address and MAC address for dynamic IPSG.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname-Vlan-interface100] ip verify source ip-address mac-address
```

Enable IPv4SG on Layer 3 Ethernet interface GigabitEthernet 1/0/2 and verify the source IPv4 address and MAC address for dynamic IPSG.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] ip verify source ip-address mac-address
```

Enable IPv4SG on Layer 3 Ethernet interface GigabitEthernet 1/0/2 and verify the source MAC address for dynamic IPSG.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] ip verify source mac-address
```

Related commands

display ip source binding

ipv6 source binding (interface view)

Use **ipv6 source binding** to configure a static IPv6SG binding.

Use **undo ipv6 source binding** to delete the static IPv6SG bindings configured on an interface.

Syntax

ipv6 source binding { **ip-address** *ipv6-address* | **ip-address** *ipv6-address* **mac-address** *mac-address* | **mac-address** *mac-address* } [**vlan** *vlan-id*]

undo ipv6 source binding { **all** | **ip-address** *ipv6-address* | **ip-address** *ipv6-address* **mac-address** *mac-address* | **mac-address** *mac-address* } [**vlan** *vlan-id*]

Default

No static IPv6SG bindings exist on an interface.

Views

VLAN interface view

Reth interface view

Reth subinterface view

Predefined user roles

network-admin

context-admin

Parameters

all: Removes all the static IPv6SG bindings on the interface.

ip-address *ipv6-address*: Specifies an IPv6 address for the static binding. The IPv6 address cannot be an all-zero address, a multicast address, or a loopback address.

mac-address *mac-address*: Specifies a MAC address for the static binding. The MAC address must be in H-H-H format, and cannot be all 0s, all Fs (a broadcast MAC address), or a multicast MAC address.

vlan *vlan-id*: Specifies a VLAN ID for the static binding. The value range is 1 to 4094. This option is supported only in Layer 2 Ethernet interface view.

Usage guidelines

Static IPv6SG bindings on an interface filter incoming IPv6 packets.

Examples

Configure a static IPv6SG binding on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 source binding ip-address 2001::1 mac-address
0002-0002-0002
```

General AAA commands

aaa nas-id profile

Use **aaa nas-id profile** to create a NAS-ID profile and enter its view, or enter the view of an existing NAS-ID profile.

Use **undo aaa nas-id profile** to delete a NAS-ID profile.

Syntax

aaa nas-id profile *profile-name*

undo aaa nas-id profile *profile-name*

Default

No NAS-ID profiles exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

profile-name: Specifies the NAS-ID profile name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

Configure a NAS-ID profile to maintain NAS-ID and VLAN bindings on the device.

During RADIUS authentication, the device uses a NAS-ID to set the NAS-Identifier attribute of RADIUS packets so that the RADIUS server can identify the access location of users.

The device selects the NAS-ID for the NAS-Identifier attribute in the following order:

1. NAS-ID bound with VLANs in a NAS-ID profile.
2. NAS-ID in an ISP domain.

By default, the device uses the device name as the NAS-ID.

Examples

Create a NAS-ID profile named **aaa** and enter its view.

```
<Sysname> system-view
[Sysname] aaa nas-id profile aaa
[Sysname-nas-id-prof-aaa]
```

Related commands

aaa session-id mode

Use **aaa session-id mode** to specify the format for attribute Acct-Session-Id.

Use **undo aaa session-id mode** to restore the default.

Syntax

aaa session-id mode { **common** | **simplified** }

undo session-id mode

Default

The device uses the common mode for attribute Acct-Session-Id.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

common: Specifies the common format for attribute Acct-Session-Id. In this format, the Acct-Session-Id attribute is a string with a minimum length of 38 characters. This string contains the prefix (indicating the access type), date and time, sequence number, LIP address of the access node, device ID, and job ID of the access process.

simplified: Specifies the simple format for attribute Acct-Session-Id. In this format, the Acct-Session-Id attribute is a string of 16 characters. This string contains the prefix (indicating the access type), month, sequence number, device ID, and LIP address of the access node.

Usage guidelines

Configure the format for attribute Acct-Session-Id to meet the requirements of the RADIUS servers.

Examples

Specify the simple format for attribute Acct-Session-Id.

```
<Sysname> system-view
[Sysname] aaa session-id mode simplified
```

aaa session-limit

Use **aaa session-limit** to set the maximum number of concurrent users that can log on to the device through the specified method.

Use **undo aaa session-limit** to restore the default maximum number of concurrent users for the specified login method.

Syntax

aaa session-limit { **ftp** | **http** | **https** | **ssh** | **telnet** } *max-sessions*

undo aaa session-limit { **ftp** | **http** | **https** | **ssh** | **telnet** }

Default

The maximum number of concurrent users is 32 for each user type.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ftp: FTP users.

http: HTTP users.

https: HTTPS users.

ssh: SSH users.

telnet: Telnet users.

max-sessions: Specifies the maximum number of concurrent login users. The value range is 1 to 64 for HTTP and HTTPS services, is 1 to 32 for SSH and Telnet services, and is 1 to 64 for FTP service.

Usage guidelines

After the maximum number of concurrent login users for a user type exceeds the upper limit, the system denies the subsequent users of this type.

For HTTP and HTTPS services, the number of concurrent users of an application is separately limited. For example, if the maximum number of concurrent HTTP users is 20, a maximum of 20 concurrent users are allowed for each HTTP-based application, such as RESTful, Web, and NETCONF.

Examples

Set the maximum number of concurrent FTP users to 4.

```
<Sysname> system-view
[Sysname] aaa session-limit ftp 4
```

accounting advpn

Use **accounting advpn** to specify accounting methods for ADVPN users.

Use **undo accounting advpn** to restore the default.

Syntax

accounting advpn { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

undo accounting advpn

Default

The default accounting methods of the ISP domain are used for ADVPN users.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

local: Performs local accounting.

none: Does not perform accounting.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

You can specify one primary accounting method and multiple backup accounting methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **accounting advpn radius-scheme** *radius-scheme-name* **local none** command specifies a primary RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

The remote accounting method is invalid in the following situations:

- The specified accounting scheme does not exist.
- Accounting packet sending fails.
- The device does not receive any accounting response packets from an accounting server.

The local accounting method is invalid if the device fails to find the matching local user configuration.

When the primary accounting method is local, the following rules apply to the accounting of a user:

- The device uses the backup accounting methods in sequence only if local accounting is invalid for one of the following reasons:
  - An exception occurs in the local accounting process.
  - The user account is not configured on the device or the user is not allowed to use the ADVPN service.
- The device does not turn to the backup accounting methods if local accounting is invalid because of any other reason. Accounting fails for the user.

Examples

In ISP domain **test**, perform local accounting for ADVPN users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting advpn local
```

In ISP domain **test**, perform RADIUS accounting for ADVPN users based on scheme **rd** and use local accounting as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting advpn radius-scheme rd local
```

Use **undo accounting command** to restore the default.

Syntax

accounting command hwtacacs-scheme *hwtacacs-scheme-name*

undo accounting command

Default

The default accounting methods of the ISP domain are used for command line accounting.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The command line accounting feature works with the accounting server to record valid commands that have been successfully executed on the device.

- When the command line authorization feature is disabled, the accounting server records all valid commands that have been successfully executed.
- When the command line authorization feature is enabled, the accounting server records only authorized commands that have been successfully executed.

Command line accounting can use only a remote HWTACACS server.

Examples

In ISP domain **test**, perform command line accounting based on HWTACACS scheme **hwtac**.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting command hwtacacs-scheme hwtac
```

Related commands

accounting default

command accounting (*Fundamentals Command Reference*)

hwtacacs scheme

accounting default

Use **undo accounting default** to restore the default.

Syntax

accounting default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

undo accounting default

Default

The default accounting method of an ISP domain is local.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local accounting.

none: Does not perform accounting.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The default accounting method is used for all users that support this method and do not have an accounting method configured.

Local accounting is only used for monitoring and controlling the number of local user connections. It does not provide the statistics function that the accounting feature generally provides.

You can specify one primary default accounting method and multiple backup default accounting methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **accounting default radius-scheme** *radius-scheme-name* **local none** command specifies the primary default RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

The remote accounting method is invalid in the following situations:

- The specified accounting scheme does not exist.
- Accounting packet sending fails.
- The device does not receive any accounting response packets from an accounting server.

The local accounting method is invalid if the device fails to find the matching local user configuration.

When the primary accounting method is local, the following rules apply to the accounting of a user:

- The device uses the backup accounting methods in sequence only if local accounting is invalid for one of the following reasons:
  - An exception occurs in the local accounting process.
  - The user account is not configured on the device or the user is not allowed to use the access service.
- The device does not turn to the backup accounting methods if local accounting is invalid because of any other reason. Accounting fails for the user.

Examples

In ISP domain **test**, use RADIUS scheme **rd** as the primary default accounting method and use local accounting as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting default radius-scheme rd local
```

Parameters

broadcast: Broadcasts accounting requests to servers in RADIUS schemes.

radius-scheme *radius-scheme-name1*: Specifies the primary broadcast RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

radius-scheme *radius-scheme-name2*: Specifies the backup broadcast RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local accounting.

none: Does not perform accounting.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

You can specify one primary accounting method and multiple backup accounting methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **accounting ipoe radius-scheme** *radius-scheme-name* **local none** command specifies a primary RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

The remote accounting method is invalid in the following situations:

- The specified accounting scheme does not exist.
- Accounting packet sending fails.

- The device does not receive any accounting response packets from an accounting server.

The local accounting method is invalid if the device fails to find the matching local user configuration.

The following guidelines apply to broadcast accounting:

- The device sends accounting requests to the primary accounting servers in the specified broadcast RADIUS schemes at the real-time accounting interval set in the primary broadcast RADIUS scheme. If the primary server is unavailable in a scheme, the device sends accounting requests to the secondary servers of the scheme in the order the servers are configured.
- The accounting result is determined by the primary broadcast RADIUS scheme. The accounting result from the backup scheme is used as reference only. If the primary scheme does not return any result, the device considers the accounting as a failure.

When the primary accounting method is local, the following rules apply to the accounting of a user:

- The device uses the backup accounting methods in sequence only if local accounting is invalid for one of the following reasons:
  - An exception occurs in the local accounting process.
  - The user account is not configured on the device or the user is not allowed to use the IPoE service.
- The device does not turn to the backup accounting methods if local accounting is invalid because of any other reason. Accounting fails for the user.

local: Performs local accounting.

none: Does not perform accounting.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

Accounting is not supported for FTP, SFTP, and SCP users.

You can specify one primary accounting method and multiple backup accounting methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **accounting login radius-scheme** *radius-scheme-name* **local none** command specifies a primary default RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

The remote accounting method is invalid in the following situations:

- The specified accounting scheme does not exist.
- Accounting packet sending fails.
- The device does not receive any accounting response packets from an accounting server.

The local accounting method is invalid if the device fails to find the matching local user configuration.

When the primary accounting method is local, the following rules apply to the accounting of a user:

- The device uses the backup accounting methods in sequence only if local accounting is invalid for one of the following reasons:
  - An exception occurs in the local accounting process.
  - The user account is not configured on the device.
- The device does not turn to the backup accounting methods if local accounting is invalid because of any other reason. Accounting fails for the user.

none: Does not perform accounting.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

You can specify one primary accounting method and multiple backup accounting methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **accounting portal radius-scheme** *radius-scheme-name* **local none** command specifies a primary default RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

The remote accounting method is invalid in the following situations:

- The specified accounting scheme does not exist.
- Accounting packet sending fails.
- The device does not receive any accounting response packets from an accounting server.

The local accounting method is invalid if the device fails to find the matching local user configuration.

The following guidelines apply to broadcast accounting:

- The device sends accounting requests to the primary accounting servers in the specified broadcast RADIUS schemes at the real-time accounting interval set in the primary broadcast RADIUS scheme. If the primary server is unavailable in a scheme, the device sends accounting requests to the secondary servers of the scheme in the order the servers are configured.
- The accounting result is determined by the primary broadcast RADIUS scheme. The accounting result from the backup scheme is used as reference only. If the primary scheme does not return any result, the device considers the accounting as a failure.

When the primary accounting method is local, the following rules apply to the accounting of a user:

- The device uses the backup accounting methods in sequence only if local accounting is invalid for one of the following reasons:
  - An exception occurs in the local accounting process.
  - The user account is not configured on the device or the user is not allowed to use the portal service.
- The device does not turn to the backup accounting methods if local accounting is invalid because of any other reason. Accounting fails for the user.

Examples

In ISP domain **test**, perform local accounting for portal users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting portal local
```

In ISP domain **test**, perform RADIUS accounting for portal users based on scheme **rd** and use local accounting as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting portal radius-scheme rd local
```

In ISP domain **test**, broadcast accounting requests of portal users to RADIUS servers in schemes **rd1** and **rd2**, and use local accounting as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting portal broadcast radius-scheme rd1 radius-scheme rd2 local
```

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

broadcast: Broadcasts accounting requests to servers in RADIUS schemes.

radius-scheme *radius-scheme-name1*: Specifies the primary broadcast RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

radius-scheme *radius-scheme-name2*: Specifies the backup broadcast RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local accounting.

none: Does not perform accounting.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

You can specify one primary accounting method and multiple backup accounting methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **accounting ppp radius-scheme** *radius-scheme-name* **local none** command specifies a primary RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

The remote accounting method is invalid in the following situations:

- The specified accounting scheme does not exist.
- Accounting packet sending fails.
- The device does not receive any accounting response packets from an accounting server.

The local accounting method is invalid if the device fails to find the matching local user configuration.

The following guidelines apply to broadcast accounting:

- The device sends accounting requests to the primary accounting servers in the specified broadcast RADIUS schemes at the real-time accounting interval set in the primary broadcast RADIUS scheme. If the primary server is unavailable for a scheme, the device sends accounting requests to the secondary servers of the scheme in the order the servers are configured.

- The accounting result is determined by the primary broadcast RADIUS scheme. The accounting result from the backup scheme is used as reference only. If the primary scheme does not return any result, the device considers the accounting as a failure.

When the primary accounting method is local, the following rules apply to the accounting of a user:

- The device uses the backup accounting methods in sequence only if local accounting is invalid for one of the following reasons:
  - An exception occurs in the local accounting process.
  - The user account is not configured on the device or the user is not allowed to use the PPP service.
- The device does not turn to the backup accounting methods if local accounting is invalid because of any other reason. Accounting fails for the user.

Examples

In ISP domain **test**, perform local accounting for PPP users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting ppp local
```

In ISP domain **test**, perform RADIUS accounting for PPP users based on scheme **rd** and use local accounting as the backup.

```
<Sysname> system-view
[Sysname] domain test

Parameters

local: Performs local authentication.

none: Does not perform authentication.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

You can specify one primary authentication method and multiple backup authentication methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **authentication advpn radius-scheme** *radius-scheme-name* **local none** command specifies a primary RADIUS authentication method and two backup methods (local authentication and no authentication). The device performs RADIUS authentication by default and performs local authentication when the RADIUS server is invalid. The device does not perform authentication when both of the previous methods are invalid.

The remote authentication method is invalid in the following situations:

- The specified authentication scheme does not exist.
- Authentication packet sending fails.
- The device does not receive any authentication response packets from an authentication server.

The local authentication method is invalid if the device fails to find the matching local user configuration.

When the primary authentication method is local, the following rules apply to the authentication of a user:

- The device uses the backup authentication methods in sequence only if local authentication is invalid for one of the following reasons:
  - An exception occurs in the local authentication process.
  - The user account is not configured on the device or the user is not allowed to use the ADVPN service.

- The device does not turn to the backup authentication methods if local authentication is invalid because of any other reason. Authentication fails for the user.

Examples

In ISP domain **test**, perform local authentication for ADVPN users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authentication advpn local
```

In ISP domain **test**, perform RADIUS authentication for ADVPN users based on scheme **rd** and use local authentication as the backup.

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

ldap-scheme *ldap-scheme-name*: Specifies an LDAP scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local authentication.

none: Does not perform authentication.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The default authentication method is used for all users that support this method and do not have an authentication method configured.

You can specify one primary default authentication method and multiple backup default authentication methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **authentication default radius-scheme** *radius-scheme-name* **local none** command specifies a primary default RADIUS authentication method and two backup methods (local authentication and no authentication). The device performs RADIUS authentication by default and performs local authentication when the RADIUS server is invalid. The device does not perform authentication when both of the previous methods are invalid.

The remote authentication method is invalid in the following situations:

- The specified authentication scheme does not exist.
- Authentication packet sending fails.
- The device does not receive any authentication response packets from an authentication server.

The local authentication method is invalid if the device fails to find the matching local user configuration.

When the primary authentication method is local, the following rules apply to the authentication of a user:

- The device uses the backup authentication methods in sequence only if local authentication is invalid for one of the following reasons:
  - An exception occurs in the local authentication process.
  - The user account is not configured on the device or the user is not allowed to use the access service.
- The device does not turn to the backup authentication methods if local authentication is invalid because of any other reason. Authentication fails for the user.

Examples

In ISP domain **test**, use RADIUS scheme **rd** as the primary default authentication method and use local authentication as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authentication default radius-scheme rd local
```

authentication ppp

Use **authentication ppp** to specify authentication methods for PPP users.

Use **undo authentication ppp** to restore the default.

Syntax

authentication ppp { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **local** [**ldap-scheme** *ldap-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

undo authentication ppp

Default

The default authentication methods of the ISP domain are used for PPP users.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

ldap-scheme *ldap-scheme-name*: Specifies an LDAP scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local authentication.

none: Does not perform authentication.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

You can specify one primary authentication method and multiple backup authentication methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **authentication ppp radius-scheme** *radius-scheme-name* **local none** command specifies a primary RADIUS authentication method and two backup methods (local authentication and no authentication). The device performs RADIUS authentication by default and performs local authentication when the RADIUS server is invalid. The device does not perform authentication when both of the previous methods are invalid.

The remote authentication method is invalid in the following situations:

- The specified authentication scheme does not exist.
- Authentication packet sending fails.
- The device does not receive any authentication response packets from an authentication server.

The local authentication method is invalid if the device fails to find the matching local user configuration.

When the primary authentication method is local, the following rules apply to the authentication of a user:

- The device uses the backup authentication methods in sequence only if local authentication is invalid for one of the following reasons:
  - An exception occurs in the local authentication process.
  - The user account is not configured on the device or the user is not allowed to use the PPP service.
- The device does not turn to the backup authentication methods if local authentication is invalid because of any other reason. Authentication fails for the user.

Examples

In ISP domain **test**, perform local authentication for PPP users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authentication ppp local
```

In ISP domain **test**, perform RADIUS authentication for PPP users based on scheme **rd** and use local authentication as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authentication ppp radius-scheme rd local
```

Related commands

authentication default

authentication sslvpn

Use **authentication sslvpn** to specify authentication methods for SSL VPN users.

Use **undo authentication sslvpn** to restore the default.

Syntax

authentication sslvpn { **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**ldap-scheme** *ldap-scheme-name* | **radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

undo authentication sslvpn

Default

The default authentication methods of the ISP domain are used for SSL VPN users.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

ldap-scheme *ldap-scheme-name*: Specifies an LDAP scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local authentication.

none: Does not perform authentication.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

You can specify one primary authentication method and multiple backup authentication methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **authentication sslvpn radius-scheme** *radius-scheme-name* **local none** command specifies a primary RADIUS authentication method and two backup methods (local authentication and no authentication). The device performs RADIUS authentication by default and performs local authentication when the RADIUS server is invalid. The device does not perform authentication when both of the previous methods are invalid.

The remote authentication method is invalid in the following situations:

- The specified authentication scheme does not exist.
- Authentication packet sending fails.
- The device does not receive any authentication response packets from an authentication server.

The local authentication method is invalid if the device fails to find the matching local user configuration.

When the primary authentication method is local, the following rules apply to the authentication of a user:

- The device uses the backup authentication methods in sequence only if local authentication is invalid for one of the following reasons:
  - An exception occurs in the local authentication process.
  - The user account is not configured on the device or the user is not allowed to use the SSL VPN service.
- The device does not turn to the backup authentication methods if local authentication is invalid because of any other reason. Authentication fails for the user.

If you specify multiple authentication methods for SSL VPN users in an ISP domain, the device does not support the online user password change feature for the SSL VPN users.

If you specify an LDAP scheme for SSL VPN users in an ISP domain, the device does not support the online user password change feature for the SSL VPN users.

Examples

In ISP domain **test**, perform local authentication for SSL VPN users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authentication sslvpn local
```

In ISP domain **test**, perform LDAP authentication for SSL VPN users based on scheme **ldp** and use local authentication as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authentication sslvpn ldap-scheme ldp local
```

authentication super

Use **authentication super** to specify a method for user role authentication.

Use **undo authentication super** to restore the default.

Syntax

authentication super { **hwtacacs-scheme** *hwtacacs-scheme-name* | **radius-scheme** *radius-scheme-name* } *

undo authentication super

Default

The default authentication methods of the ISP domain are used for user role authentication.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

To enable a user to obtain another user role without reconnecting to the device, you must configure user role authentication. The device supports local and remote methods for user role authentication. For more information about user role authentication, see RBAC configuration in *Fundamentals Configuration Guide*.

You can specify one authentication method and one backup authentication method to use in case that the previous authentication method is invalid.

Examples

In ISP domain **test**, perform user role authentication based on HWTACACS scheme **tac**.

```
<Sysname> system-view
[Sysname] super authentication-mode scheme
[Sysname] domain test
```

```
[Sysname-isp-test] authentication super hwtacacs-scheme tac
```

context-admin

Parameters

local: Performs local authorization.

none: Does not perform authorization.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The RADIUS authorization configuration takes effect only when authentication and authorization methods of the ISP domain use the same RADIUS scheme.

You can specify one primary authorization method and multiple backup authorization methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **authorization advpn radius-scheme** *radius-scheme-name* **local none** command specifies a primary RADIUS authorization method and two backup methods (local authorization and no authorization). The device performs RADIUS authorization by default and performs local authorization when the RADIUS server is invalid. The device does not perform authorization when both of the previous methods are invalid.

The remote authorization method is invalid in the following situations:

- The specified authorization scheme does not exist.
- Authorization packet sending fails.
- The device does not receive any authorization response packets from an authorization server.

The local authorization method is invalid if the device fails to find the matching local user configuration.

When the primary authorization method is local, the following rules apply to the authorization of a user:

- The device uses the backup authorization methods in sequence only if local authorization is invalid for one of the following reasons:
  - An exception occurs in the local authorization process.
  - The user account is not configured on the device or the user is not allowed to use the ADVPN service.
- The device does not turn to the backup authorization methods if local authorization is invalid because of any other reason. Authorization fails for the user.

Examples

In ISP domain **test**, perform local authorization for ADVPN users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization advpn local
```

In ISP domain **test**, perform RADIUS authorization for ADVPN users based on scheme **rd** and use local authorization as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization advpn radius-scheme rd local
```

Use **undo authorization command** to restore the default.

Syntax

authorization command { **hwtacacs-scheme** *hwtacacs-scheme-name* [**local**] [**none**] | **local** [**none**] | **none** }

undo authorization command

Default

The default authorization methods of the ISP domain are used for command authorization.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local authorization.

none: Does not perform authorization. The authorization server does not verify whether the entered commands are permitted by the user role. The commands are executed successfully if the user role has permission to the commands.

Usage guidelines

Command authorization restricts login users to execute only authorized commands by employing an authorization server to verify whether each entered command is permitted.

When local command authorization is configured, the device compares each entered command with the user's configuration on the device. The command is executed only when it is permitted by the user's authorized user roles.

The commands that can be executed are controlled by both the access permission of user roles and command authorization of the authorization server. Access permission only controls whether the authorized user roles have access to the entered commands, but it does not control whether the user roles have obtained authorization to these commands. If a command is permitted by the access permission but denied by command authorization, this command cannot be executed.

You can specify one primary command authorization method and multiple backup command authorization methods.

When the default authorization method is invalid, the device attempts to use the backup authorization methods in sequence. For example, the **authorization command hwtacacs-scheme** *hwtacacs-scheme-name* **local none** command specifies the default HWTACACS authorization method and two backup methods (local authorization and no authorization). The device performs HWTACACS authorization by default and performs local authorization when the HWTACACS server is invalid. The device does not perform command authorization when both of the previous methods are invalid.

The remote authorization method is invalid in the following situations:

- The specified authorization scheme does not exist.
- Authorization packet sending fails.
- The device does not receive any authorization response packets from an authorization server.

The local authorization method is invalid if the device fails to find the matching local user configuration.

Examples

In ISP domain **test**, configure the device to perform local command authorization.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization command local
```

In ISP domain **test**, perform command authorization based on HWTACACS scheme **hwtac** and use local authorization as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization command hwtacacs-scheme hwtac local
```

Related commands

authorization default

Use **authorization default** to specify default authorization methods for an ISP domain.

Use **undo authorization default** to restore the default.

Syntax

authorization default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

undo authorization default

Default

The default authorization method of an ISP domain is local.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local authorization.

none: Does not perform authorization. The following default authorization information applies after users pass authentication:

- Login users obtain the level-0 user role. Login users include the Telnet, FTP, SFTP, SCP, and terminal users. Terminal users can access the device through the console port. For more information about the level-0 user role, see RBAC configuration in *Fundamentals Configuration Guide*.
- The working directory for FTP, SFTP, and SCP login users is the root directory of the NAS. However, the users do not have permission to access the root directory.
- Non-login users can access the network.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The default authorization method is used for all users that support this method and do not have an authorization method configured.

The RADIUS authorization configuration takes effect only when the authentication method and authorization method of the ISP domain use the same RADIUS scheme.

You can specify one primary authorization method and multiple backup authorization methods.

When the default authorization method is invalid, the device attempts to use the backup authorization methods in sequence. For example, the **authorization default radius-scheme** *radius-scheme-name* **local none** command specifies the default RADIUS authorization method and two backup methods (local authorization and no authorization). The device performs RADIUS authorization by default and performs local authorization when the RADIUS server is invalid. The device does not perform authorization when both of the previous methods are invalid.

The remote authorization method is invalid in the following situations:

- The specified authorization scheme does not exist.

- Authorization packet sending fails.
- The device does not receive any authorization response packets from an authorization server.

The local authorization method is invalid if the device fails to find the matching local user configuration.

When the primary authorization method is local, the following rules apply to the authorization of a user:

- The device uses the backup authorization methods in sequence only if local authorization is invalid for one of the following reasons:
  - An exception occurs in the local authorization process.
  - The user account is not configured on the device or the user is not allowed to use the access service.
- The device does not turn to the backup authorization methods if local authorization is invalid because of any other reason. Authorization fails for the user.

Examples

In ISP domain **test**, use RADIUS scheme **rd** as the primary default authorization method and use local authorization as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization default radius-scheme rd local
```

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The RADIUS authorization configuration takes effect only when the authentication method and authorization method of the ISP domain use the same RADIUS scheme.

You can specify one primary authorization method and multiple backup authorization methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **authorization ppp radius-scheme** *radius-scheme-name* **local none** command specifies a primary RADIUS authorization method and two backup methods (local authorization and no authorization). The device performs RADIUS authorization by default and performs local authorization when the RADIUS server is invalid. The device does not perform authorization when both of the previous methods are invalid.

The remote authorization method is invalid in the following situations:

- The specified authorization scheme does not exist.
- Authorization packet sending fails.
- The device does not receive any authorization response packets from an authorization server.

The local authorization method is invalid if the device fails to find the matching local user configuration.

When the primary authorization method is local, the following rules apply to the authorization of a user:

- The device uses the backup authorization methods in sequence only if local authorization is invalid for one of the following reasons:
  - An exception occurs in the local authorization process.
  - The user account is not configured on the device or the user is not allowed to use the PPP service.
- The device does not turn to the backup authorization methods if local authorization is invalid because of any other reason. Authorization fails for the user.

Examples

In ISP domain **test**, perform local authorization for PPP users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization ppp local
```

In ISP domain **test**, perform RADIUS authorization for PPP users based on scheme **rd** and use local authorization as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization ppp radius-scheme rd local
```

Related commands

authorization default

hwtacacs scheme

ldap scheme

local-user

radius scheme

authorization sslvpn

Use **authorization sslvpn** to specify authorization methods for SSL VPN users.

Use **undo authorization sslvpn** to restore the default.

Syntax

authorization sslvpn { **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**ldap-scheme** *ldap-scheme-name* | **radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

undo authorization sslvpn

Default

The default authorization methods of the ISP domain are used for SSL VPN users.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

ldap-scheme *ldap-scheme-name*: Specifies an LDAP scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local authorization.

none: Does not perform authorization. Authenticated SSL VPN users can access the network directly.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The RADIUS authorization configuration takes effect only when the authentication method and authorization method of the ISP domain use the same RADIUS scheme.

You can specify one primary authorization method and multiple backup authorization methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **authorization sslvpn radius-scheme** *radius-scheme-name* **local none** command specifies a primary RADIUS authorization method and two backup methods (local authorization and no authorization). The device performs RADIUS authorization by default and performs local authorization when the RADIUS server is invalid. The device does not perform authorization when both of the previous methods are invalid.

The remote authorization method is invalid in the following situations:

- The specified authorization scheme does not exist.
- Authorization packet sending fails.
- The device does not receive any authorization response packets from an authorization server.

The local authorization method is invalid if the device fails to find the matching local user configuration.

When the primary authorization method is local, the following rules apply to the authorization of a user:

- The device uses the backup authorization methods in sequence only if local authorization is invalid for one of the following reasons:
  - An exception occurs in the local authorization process.
  - The user account is not configured on the device or the user is not allowed to use the SSL VPN service.
- The device does not turn to the backup authorization methods if local authorization is invalid because of any other reason. Authorization fails for the user.

Examples

In ISP domain **test**, perform local authorization for SSL VPN users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization sslvpn local
```

In ISP domain **test**, perform LDAP authorization for SSL VPN users based on scheme **ldp** and use local authorization as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization sslvpn ldap-scheme ldp local
```

authorization-attribute (ISP domain view)

Use **authorization-attribute** to configure authorization attributes for users in an ISP domain.

Use **undo authorization-attribute** to restore the default of an authorization attribute.

Syntax

authorization-attribute { **acl** *acl-number* | **car inbound cir** *committed-information-rate* [**pir** *peak-information-rate*] **outbound cir** *committed-information-rate* [**pir** *peak-information-rate*] | **idle-cut** *minutes* [*flow*] | **igmp max-access-number** *max-access-number* | **ip-pool** *ipv4-pool-name* | **ipv6-pool** *ipv6-pool-name* | **ipv6-prefix** *ipv6-prefix prefix-length* | { **primary-dns** | **secondary-dns** } { **ip** *ipv4-address* | **ipv6** *ipv6-address* } | **session-timeout** *minutes* | **url** *url-string* | **user-group** *user-group-name* | **vpn-instance** *vpn-instance-name* }

undo authorization-attribute { **acl** | **car** | **idle-cut** | **igmp** | **ip-pool** | **ipv6-pool** | **ipv6-prefix** | **primary-dns** | **secondary-dns** | **session-timeout** | **url** | **user-group** | **vpn-instance** }

Default

The idle cut feature is disabled.

An IPv4 user can concurrently join a maximum of four IGMP multicast groups.

An IPv6 user can concurrently join a maximum of four MLD multicast groups.

No other authorization attributes exist.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

acl *acl-number*: Specifies an ACL to filter traffic for users. The value range for the *acl-number* argument is 2000 to 5999. This option is applicable only to portal and LAN users. The device processes the traffic that matches the rules in the authorization ACL based on the permit or deny statement in the rules.

car: Specifies a CAR action for users. Typically, the attribute applies to authenticated users. If you configure the attribute in a portal preauthentication domain, the CAR action applies before portal authentication. This keyword is applicable only to IPoE, portal, and PPP users.

inbound: Specifies the upload rate of users.

outbound: Specifies the download rate of users.

cir *committed-information-rate*: Specifies the committed information rate in kbps, in the range of 1 to 4194303.

pir *peak-information-rate*: Specifies the peak information rate in kbps, in the range of 1 to 4194303. The peak information rate cannot be smaller than the committed information rate. If you do not specify this option, the CAR action does not restrict users by peak information rate.

idle-cut *minutes*: Specifies an idle timeout period in minutes. The value range for the *minutes* argument is 1 to 600. This option is applicable only to IPoE, portal, and PPP users.

flow: Specifies the minimum traffic that must be generated in the idle timeout period in bytes. The value range is 1 to 10240000, and the default value is 10240.

igmp max-access-number *max-access-number*: Specifies the maximum number of IGMP groups that an IPv4 user can join concurrently. The value range for the *max-access-number* argument is 1 to 64. This option is applicable only to IPoE, portal, and PPP users.

ip-pool *ipv4-pool-name*: Specifies an IPv4 address pool for users. The *ipv4-pool-name* argument is a case-insensitive string of 1 to 63 characters. This option is applicable only to PPP, IKE, IPoE, and portal users.

ipv6-pool *ipv6-pool-name*: Specifies an IPv6 address pool for users. The *ipv6-pool-name* argument is a case-insensitive string of 1 to 63 characters. This option is applicable only to IPoE, portal, and PPP users.

ipv6-prefix *ipv6-prefix prefix-length*: Specifies an IPv6 prefix for users. The value range for the *prefix-length* argument is 1 to 128. The IPv6 prefix cannot be ::/128, ::1/128, or an IPv6 multicast prefix. This option is applicable only to IPoE and PPP users.

primary-dns ip *ipv4-address*: Specifies the IPv4 address of the primary DNS server for users. This option is applicable only to IPoE and PPP users.

primary-dns ipv6 *ipv6-address*: Specifies the IPv6 address of the primary DNS server for users. This option is applicable only to IPoE and PPP users.

secondary-dns ip *ipv4-address*: Specifies the IPv4 address of the secondary DNS server for users. This option is applicable only to IPoE and PPP users.

secondary-dns ipv6 *ipv6-address*: Specifies the IPv6 address of the secondary DNS server for users. This option is applicable only to IPoE and PPP users.

session-timeout *minutes*: Specifies the session timeout timer for users, in minutes. The value range for the *minutes* argument is 1 to 4294967295. The device logs off a user when the user's session timeout timer expires. This option is applicable only to PPP, portal, IPoE, and LAN users.

url *url-string*: Specifies a redirect URL for users. The *url-string* argument is a case-sensitive string of 1 to 255 characters. The URL must start with **http://** or **https://**. You can configure the redirect URL attribute to push advertisements or notifications to users after the users pass authentication or push bill overdue notifications to users. This option is applicable only to PPPoE users. For IPoE users, you must specify a URL with port number 80 or 443.

user-group *user-group-name*: Specifies a user group for users. The *user-group-name* argument is a case-insensitive string of 1 to 32 characters. Authenticated users obtain all attributes of the user group.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the users belong. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. When a user passes authentication, it has permission to access the network resources in the specified VPN. This option is applicable only to PPP and IPoE users.

Usage guidelines

When the idle cut feature is configured, the device periodically detects the traffic of each online user. The device logs out users that do not meet the minimum traffic requirement in the idle timeout period. When the idle cut feature is disabled on the device, the idle cut feature of the server takes effect. The server considers a user idle if the user's traffic is less than 10240 bytes in a configurable idle timeout period.

If the server or NAS does not authorize a type of attribute to an authenticated user, the device authorizes the attribute in the ISP domain to the user.

You can configure multiple authorization attributes for users in an ISP domain. If you execute the command multiple times with the same attribute specified, the most recent configuration takes effect.

When you specify an authorized ACL, follow these restrictions and guidelines:

- If the specified ACL does not exist or the ACL does not contain any rules, the system considers that no ACL is specified. If the strict check method is enabled for portal authorized ACLs, the system logs off portal users.
- For portal users to come online after passing authentication, make sure ACLs assigned to portal users do not have rules specified with a source IP or MAC address.

Examples

Specify user group **abc** as the authorization user group for users in ISP domain **test**.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization-attribute user-group abc
```

Related commands

display domain

basic-service-ip-type

Use **basic-service-ip-type** to specify the types of IP addresses that L2TP users must rely on to use the basic services.

Use **undo basic-service-ip-type** to restore the default.

Syntax

basic-service-ip-type { **ipv4** | **ipv6** | **ipv6-pd** } *

undo basic-service-ip-type

Default

L2TP users do not rely on any types of IP addresses to use the basic services.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

ipv4: Specifies the IPv4 address type.

ipv6: Specifies the IPv6 address type.

ipv6-pd: Specifies the IPv6-PD address type. This type of IPv6 addresses are generated based on the DHCPv6 server-assigned prefix.

Usage guidelines

This command takes effect only when the device acts as an L2TP LNS and only on L2TP users.

A user might request multiple services of different IP address types. By default, the device logs off the user if the user does not obtain an IP address. This command enables the device to allow the user to come online if the user has obtained IP addresses of all the specified types for the basic services.

The device does not allow a user to come online if the user does not obtain IP addresses of all the specified types for the basic services. For example, if you execute the **basic-service-ip-type ipv6** command, the device does not allow a user to come online if the user does not obtain an IPv6 address.

If you specify both the **ipv6** and **ipv6-pd** keywords, the device does not allow a user that fails IPv6 address negotiation or PD negotiation to come online.

Examples

In ISP domain **test**, specify L2TP users to rely on IPv4 addresses to use the basic services.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] basic-service-ip-type ipv4
```

dhcpv6-follow-ipv6cp

Use **dhcpv6-follow-ipv6cp** to set the IPv6 address wait timer for L2TP users.

Use **undo dhcpv6-follow-ipv6cp** to restore the default.

Syntax

dhcpv6-follow-ipv6cp timeout *delay-time*

undo dhcpv6-follow-ipv6cp

Default

The IPv6 address wait timer for L2TP users is 60 seconds.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

timeout *delay-time*: Sets the IPv6 address wait timer, in the range of 30 to 120 seconds.

Usage guidelines

This command takes effect only when the device acts as an L2TP LNS and only on L2TP users.

The IPv6 address wait timer defines the maximum amount of time that a user can wait before the device determines that the user fails to obtain an IPv6 address or PD prefix.

The device starts an IPv6 address wait timer for a user after it finishes IPv6CP negotiation with the user. If the user's basic service relies on an IPv6 address or PD prefix but it fails to obtain any IPv6 address or PD prefix when the timer expires, the user cannot come online.

As a best practice, increase the IPv6 address wait timer in the following situations:

- The network communication is unstable.
- The device uses DHCPv6 to assign IPv6 addresses to users.
- The ISP domain serves a large number of users.

Examples

In ISP domain **test**, set the IPv6 address wait timer to 90 seconds for L2TP users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] dhcpv6-follow-ipv6cp timeout 90
```

Table 1 Command output

Field	Description
Domain	ISP domain name.
State	Status of the ISP domain.
Default authentication scheme	Default authentication methods.
Default authorization scheme	Default authorization methods.
Default accounting scheme	Default accounting methods.
ADVPN authentication scheme	Authentication methods for ADVPN users.
ADVPN authorization scheme	Authorization methods for ADVPN users.
ADVPN accounting scheme	Accounting methods for ADVPN users.
Login authentication scheme	Authentication methods for login users.
Login authorization scheme	Authorization methods for login users.
Login accounting scheme	Accounting methods for login users.
Super authentication scheme	Authentication methods for obtaining another user role without reconnecting to the device.
PPP authentication scheme	Authentication methods for PPP users.
PPP authorization scheme	Authorization methods for PPP users.
PPP accounting scheme	Accounting methods for PPP users.
Command authorization scheme	Command line authorization methods.
Command accounting scheme	Command line accounting method.
LAN access authentication scheme	Authentication methods for LAN users.
LAN access authorization scheme	Authorization methods for LAN users.
LAN access accounting scheme	Accounting methods for LAN users.
Portal authentication scheme	Authentication methods for portal users.
Portal authorization scheme	Authorization methods for portal users.
Portal accounting scheme	Accounting methods for portal users.
IKE authentication scheme	IKE extended authentication methods.
IKE authorization scheme	Authorization methods for IKE extended authentication.
IPoE authentication scheme	Authentication methods for IPoE users.
IPoE authorization scheme	Authorization methods for IPoE users.
IPoE accounting scheme	Accounting methods for IPoE users.

Field	Description
SSL VPN authentication scheme	Authentication methods for SSL VPN users.
SSL VPN authorization scheme	Authorization methods for SSL VPN users.
SSL VPN accounting scheme	Accounting methods for SSL VPN users.
RADIUS	RADIUS scheme.
HWTACACS	HWTACACS scheme.
LDAP	LDAP scheme.
Local	Local scheme.
None	No authentication, no authorization, or no accounting.
Accounting start failure action	Access control for users that encounter accounting-start failures: • **Online**—Allows the users to stay online. • **Offline**—Logs off the users.
Accounting update failure max-times	Maximum number of consecutive accounting-update failures allowed by the device for each user in the domain.
Accounting update failure action	Access control for users that have failed all their accounting-update attempts: • **Online**—Allows the users to stay online. • **Offline**—Logs off the users.
Accounting quota out action	Access control for users that have used up their accounting quotas: • **Online**—Allows the users to stay online. • **Offline**—Logs off the users.
Service type	Service type of the ISP domain, including HSI, STB, and VoIP.
Session time	Online duration sent to the server for users that went offline due to connection failure or malfunction: • **Include idle time**—The online duration includes the idle timeout period. • **Exclude idle time**—The online duration does not include the idle timeout period.
User address type	Type of IP addresses for users in the ISP domain. This field is not available if no user address type is specified in the ISP domain.
NAS-ID	NAS-ID of the device. This field displays **N/A** if no NAS-ID is set in the ISP domain.
User basic service IP type	Types of IP addresses that PPPoE and L2TP users rely on to use the basic services: • **IPv4**. • **IPv6**. • **IPv6-PD**.
DHCPv6-follow-IPv6CP timeout	IPv6 address wait timer (in seconds) that starts after IPv6CP negotiation for PPPoE and L2TP users.
Authorization attributes	Authorization attributes for users in the ISP domain.
Idle cut	Idle cut feature status: • **Enabled**—The feature is enabled. The device logs off users that do not meet the minimum traffic requirements in an idle timeout period.

Field	Description
	• **Disabled**—The feature is disabled. It is the default idle cut state.
Idle timeout	Idle timeout period, in minutes.
Flow	Minimum traffic that a login user must generate in an idle timeout period, in bytes.
Session timeout	Session timeout time for users in the ISP domain, in minutes.
IP pool	Name of the authorization IPv4 address pool.
Inbound CAR	Authorization inbound CAR: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps.
Outbound CAR	Authorization outbound CAR: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps.
ACL number	Authorization ACL for users.
User group	Authorization user group for users.
IPv6 prefix	Authorization IPv6 prefix for users.
IPv6 pool	Name of the authorization IPv6 address pool for users.
Primary DNS server	IPv4 address of the authorization primary DNS server for users.
Secondary DNS server	IPv4 address of the authorization secondary DNS server for users.
Primary DNSV6 server	IPv6 address of the authorization primary DNS server for users.
Secondary DNSV6 server	IPv6 address of the authorization secondary DNS server for users.
URL	Authorization redirect URL for users.
VPN instance	Name of the authorization VPN instance for users.
IGMP access limit	Maximum number of IGMP groups that an IPv4 user is authorized to join concurrently.
MLD access limit	This field is not supported in the current software version. Maximum number of MLD groups that an IPv6 user is authorized to join concurrently.

domain

Use **domain** to create an ISP domain and enter its view, or enter the view of an existing ISP domain.

Use **undo domain** to delete an ISP domain.

Syntax

domain *isp-name*

undo domain *isp-name*

Default

A system-defined ISP domain exists. The domain name is **system**.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

isp-name: Specifies the ISP domain name, a case-insensitive string of 1 to 255 characters. The name must meet the following requirements:

- The name cannot contain a forward slash (/), backslash (\), vertical bar (|), quotation marks ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).
- The name cannot be **d**, **de**, **def**, **defa**, **defau**, **defaul**, **default**, **i**, **if**, **if-**, **if-u**, **if-un**, **if-unk**, **if-unkn**, **if-unkno**, **if-unknow**, or **if-unknown**.

Usage guidelines

All ISP domains are in active state when they are created.

You can modify settings for the system-defined ISP domain **system**, but you cannot delete this domain.

An ISP domain cannot be deleted when it is the default ISP domain. Before you use the **undo domain** command, change the domain to a non-default ISP domain by using the **undo domain default enable** command.

Use short domain names to ensure that user names containing a domain name do not exceed the maximum name length required by different types of users.

Examples

Create an ISP domain named **test** and enter ISP domain view.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test]
```

Related commands

display domain

domain default enable

domain if-unknown

state (ISP domain view)

domain default enable

Use **domain default enable** to specify the default ISP domain. Users without any domain name included in the usernames are considered in the default domain.

Use **undo domain default enable** to restore the default.

Syntax

domain default enable *isp-name*

undo domain default enable

Default

The default ISP domain is the system-defined ISP domain **system**.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

isp-name: Specifies the ISP domain name, a case-insensitive string of 1 to 255 characters. The ISP domain must already exist.

Usage guidelines

The system has only one default ISP domain.

An ISP domain cannot be deleted when it is the default ISP domain. Before you use the **undo domain** command, change the domain to a non-default ISP domain by using the **undo domain default enable** command.

Examples

Create an ISP domain named **test**, and configure the domain as the default ISP domain.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] quit
[Sysname] domain default enable test
```

Related commands

display domain

domain

domain if-unknown

Use **domain if-unknown** to specify an ISP domain to accommodate users that are assigned to nonexistent domains.

Use **undo domain if-unknown** to restore the default.

Syntax

domain if-unknown *isp-name*

undo domain if-unknown

Default

No ISP domain is specified to accommodate users that are assigned to nonexistent domains.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

isp-name: Specifies the ISP domain name, a case-insensitive string of 1 to 255 characters. The name must meet the following requirements:

- The name cannot contain a forward slash (/), backslash (\), vertical bar (|), quotation marks ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).
- The name cannot be **d**, **de**, **def**, **defa**, **defau**, **defaul**, **default**, **i**, **if**, **if-**, **if-u**, **if-un**, **if-unk**, **if-unkn**, **if-unkno**, **if-unknow**, or **if-unknown**.

Usage guidelines

The device chooses an authentication domain for each user in the following order:

1. The authentication domain specified for the access module.
2. The ISP domain in the username.
3. The default ISP domain of the device.

If the chosen domain does not exist on the device, the device searches for the ISP domain that accommodates users assigned to nonexistent domains. If no such ISP domain is configured, user authentication fails.

NOTE:

Support for the authentication domain configuration depends on the access module.

Examples

Specify ISP domain **test** to accommodate users that are assigned to nonexistent domains.

```
<Sysname> system-view
[Sysname] domain if-unknown test
```

Related commands

display domain

domain-delimiter

Use **domain-delimiter** to configure global domain name delimiters.

Use **undo domain-delimiter** to restore the default.

Syntax

domain-delimiter [**advpn** | **ike** | **ipoe** | **lanaccess** | **login** | **portal** | **ppp** | **sslvpn** | **super**] *string*

undo domain-delimiter [**advpn** | **ike** | **ipoe** | **lanaccess** | **login** | **portal** | **ppp** | **sslvpn** | **super**]

Default

Global domain name delimiters include at sign (@), slash (/), and backslash (\).

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

advpn: Specifies ADVPN tunnel users.

ike: Specifies IKE users that access the network through IKE extended authentication.

ipoe: Specifies IPoE users.

lanaccess: Specifies LAN access users.

login: Specifies users that log in to the device.

portal: Specifies portal users.

ppp: Specifies PPP users.

ssh: Specifies SSH users.

sslvpn: Specifies SSL VPN users.

super: Specifies users that obtain temporary user role authorization.

string: Specifies a string of 1 to 16 global domain name delimiters. Valid delimiters include at sign (@), dot (.), slash (/), and backslash (\). To specify a backslash (\), you must precede the backslash with an escape character (\).

Usage guidelines

A domain name delimiter separates the username part from the domain name part in a username. For the device to correctly extract the username and domain name parts in usernames, you can configure domain name delimiters. Table 2 shows the way that the device interprets a username based on different domain name delimiters.

Table 2 Domain name delimiters and username formats

Domain name delimiter	Username format
At sign (@)	*username@domain-name*
Backslash (\)	*domain-name\username*
Slash (/)	*username/domain-name*
Dot (.)	*username.domain-name*

If a username includes multiple domain name delimiters, the device selects the first delimiter in the search direction specified by using the **domain-delimiter search-from** command.

If you do not specify a user type, the configured domain name delimiters take effect on all types of users.

The access module-specific domain name delimiters have higher priority than global domain name delimiters.

Modification of global domain name delimiters takes effect only on users that come online after the modification.

Examples

Configure global domain name delimiters as at sign (@) and slash (/).

```
<Sysname> system-view
[Sysname] domain-delimiter login @/
```

Related commands

domain-delimiter search-from

domain-delimiter search-direction

Use **domain-delimiter search-direction** to specify the search direction for the domain name delimiter.

Use **undo domain-delimiter search-direction** to restore the default.

Syntax

domain-delimiter search-direction { **backward** | **forward** }

undo domain-delimiter search-direction

Default

The device searches for a domain name delimiter in usernames from right to left.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

backward: Specifies the right-to-left search direction.

forward: Specifies the left-to-right search direction.

Usage guidelines

In authentication, it is very import for the device to correctly extract the username and domain name parts in a username. If a username includes multiple domain name delimiters, the search direction for the domain name delimiter determines how the device interprets a username. For example, if a username is 1234@456@789 and the domain name delimiter is at sign (@), the device can interpret the username in the following ways:

- If the search direction is left-to-right, the device uses the first at sign (@) as the delimiter. The username part is 1234 and the domain name part is 456@789.
- If the search direction is right-to-left, the device uses the second at sign (@) as the delimiter. The username part is 1234@789 and the domain name part is 789.

Use this command to specify the direction in which the device search for a domain name delimiter in usernames.

If you execute this command multiple times, the most recent configuration takes effect.

Modification of the search direction takes effect only on users that come online after the modification.

Examples

Specify the left-to-right direction for the device to search for a domain name delimiter in usernames.

```
<Sysname> system-view
[Sysname] domain-delimiter search-direction forward
```

Related commands

domain-delimiter

local-server log change-password-prompt

Use **local-server log change-password-prompt** to enable password change prompt logging.

Use **undo local-server log change-password-prompt** to disable password change prompt logging.

Syntax

local-server log change-password-prompt

undo local-server log change-password-prompt

Default

Password change prompt logging is enabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

Non-default vSystems do not support this command.

Use this feature to enhance the protection of passwords for Telnet, SSH, HTTP, HTTPS, NETCONF over SSH, and NETCONF over SOAP users and improve the system security.

This feature enables the device to generate logs to prompt users to change their weak passwords at an interval of 24 hours and at the users' login.

A password is a weak password if it does not meet the following requirements:

- Password composition restriction configured by using the **password-control composition** command.
- Minimum password length restriction set by using the **password-control length** command.
- Password complexity checking policy configured by using the **password-control complexity** command.

For a NETCONF over SSH or NETCONF over SOAP user, the device also generates a password change prompt log if any of the following conditions exists:

- The current password of the user is the default password or has expired.
- The user logs in to the device for the first time or uses a new password to log in after global password control is enabled.

The device will no longer generate password change prompt logs for a user when one of the following conditions exists:

- The password change prompt logging feature is disabled.
- The user has changed the password and the new password meets the password control requirements.
- The enabling status of a related password control feature has changed so the current password of the user meets the password control requirements.
- The password composition policy or the minimum password length has changed.

You can use the **display password-control** command to display password control configuration. For more information about password control commands, see "Password control commands."

Examples

Enable password change prompt logging.

```
<Sysname> system-view
[Sysname] local-server log change-password-prompt
```

Related commands

display password-control

password-control composition

password-control length

local-server log change-password-prompt

Use **local-server log change-password-prompt** to enable password change prompt logging.

Use **undo local-server log change-password-prompt** to disable password change prompt logging.

Syntax

local-server log change-password-prompt

undo local-server log change-password-prompt

Default

Password change prompt logging is enabled.

Usage guidelines

Use this feature to enhance the protection of passwords for Telnet, SSH, HTTP, HTTPS, NETCONF over SSH, and NETCONF over SOAP users and improve the system security.

This feature enables the device to generate logs to prompt users to change their weak passwords at an interval of 24 hours and at the users' login.

A password is a weak password if it does not meet the following requirements:

- Password composition restriction configured by using the **password-control composition** command.
- Minimum password length restriction set by using the **password-control length** command.
- Password complexity checking policy configured by using the **password-control complexity** command.

For a NETCONF over SSH or NETCONF over SOAP user, the device also generates a password change prompt log if any of the following conditions exists:

- The current password of the user is the default password or has expired.
- The user logs in to the device for the first time or uses a new password to log in after global password control is enabled.

The device will no longer generate password change prompt logs for a user when one of the following conditions exists:

- The password change prompt logging feature is disabled.
- The user has changed the password and the new password meets the password control requirements.
- The enabling status of a related password control feature has changed so the current password of the user meets the password control requirements.
- The password composition policy or the minimum password length has changed.

You can use the **display password-control** command to display password control configuration. For more information about password control commands, see "Password control commands."

Examples

Enable password change prompt logging.

```
<Sysname> system-view
[Sysname] local-server log change-password-prompt
```

nas-id

Use **nas-id** to set the NAS-ID in an ISP domain.

Use **undo nas-id** to restore the default.

Syntax

nas-id *nas-identifier*

undo nas-id

Default

No NAS-ID is set in an ISP domain.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

nas-identifier: Specifies a NAS-ID, a case-sensitive string of 1 to 31 characters.

Usage guidelines

During RADIUS authentication, the device uses a NAS-ID to set the NAS-Identifier attribute of RADIUS packets so that the RADIUS server can identify the access location of users.

You can configure a NAS-ID in VSRP instance view, in NAS-ID profile view, or in ISP domain view. The device selects the NAS-ID for the NAS-Identifier attribute in the following order:

1. NAS-ID bound with VLANs in a NAS-ID profile.
2. NAS-ID in an ISP domain.

If no NAS-ID is selected, the device uses the device name as the NAS-ID.

Examples

Set the NAS-ID to **test** for ISP domain **test**.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] nas-id test
```

Related commands

aaa nas-id profile

nas-id bind vlan

Use **nas-id bind vlan** to bind a NAS-ID with a VLAN.

Use **undo nas-id bind vlan** to remove a NAS-ID and VLAN binding.

Syntax

nas-id *nas-identifier* **bind vlan** *vlan-id*

undo nas-id *nas-identifier* **bind vlan** *vlan-id*

Default

No NAS-ID and VLAN bindings exist.

Views

NAS-ID profile view

Predefined user roles

network-admin

context-admin

Parameters

nas-identifier: Specifies a NAS-ID, a case-sensitive string of 1 to 31 characters.

vlan-id: Specifies a VLAN ID in the range of 1 to 4094.

Usage guidelines

You can configure multiple NAS-ID and VLAN bindings in a NAS-ID profile.

A NAS-ID can be bound with more than one VLAN, but a VLAN can be bound with only one NAS-ID. If you configure multiple bindings for the same VLAN, the most recent configuration takes effect.

Examples

Bind NAS-ID 222 with VLAN 2 in NAS-ID profile **aaa**.

```
<Sysname> system-view
[Sysname] aaa nas-id profile aaa
[Sysname-nas-id-prof-aaa] nas-id 222 bind vlan 2
```

Related commands

aaa nas-id profile

service-type (ISP domain view)

Use **service-type** to specify the service type for users in an ISP domain.

Use **undo service-type** to restore the default.

Syntax

service-type { **hsi** | **stb** | **voip** }

undo service-type

Default

The service type is **hsi** for users in an ISP domain.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

hsi: Specifies the High Speed Internet (HSI) service. This service is applicable to users that access the network through PPP or leased IPoE.

stb: Specifies the Set Top Box (STB) service. This service is applicable to users that access the network through STB.

voip: Specifies the Voice over IP (VoIP) service. This service is applicable to users that access the network through IP phones.

Usage guidelines

When the HSI service is specified, the multicast feature of the access module is disabled to save system resources.

When the STB service is specified, the multicast feature of the access module is enabled to improve the performance of the multicast module.

When the VoIP service is specified, the QoS module increases the priority of voice traffic to reduce the transmission delay for IP phone users.

For PPP (excluding PPPoE) users, the system uses the HSI service forcibly even if the STB or VoIP service is specified.

You can configure only one service type for an ISP domain.

Examples

Specify the STB service for users in ISP domain **test**.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] service-type stb
```

session-time include-idle-time

Use **session-time include-idle-time** to configure the device to include the idle timeout period in the user online duration sent to the server.

Use **undo session-time include-idle-time** to restore the default.

Syntax

session-time include-idle-time

undo session-time include-idle-time

Default

The device does not include the idle timeout period in the user online duration sent to the server.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Usage guidelines

Whether to configure the device to include the idle timeout period in the user online duration sent to the server, depending on the accounting policy in your network. The idle timeout period is assigned to users by the authorization server after the users pass authentication. For portal users, the device includes the idle timeout period set for the online portal user detection feature in the user online duration. For more information about online detection for portal users, see portal authentication configuration in *Security Configuration Guide*.

If the user goes offline due to connection failure or malfunction, the user online duration sent to the server is not the same as the actual online duration.

- If the **session-time include-idle-time** command is used, the user's online duration sent to the server includes the idle timeout period. The online duration that is generated on the server is longer than the actual online duration of the user.
- If the **undo session-time include-idle-time** command is used, the user's online duration sent to the server excludes the idle timeout period. The online duration that is generated on the server is shorter than the actual online duration of the user.

Examples

Configure the device to include the idle timeout period in the online duration sent to the server for users in ISP domain **test**.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] session-time include-idle-time
```

Related commands

display domain

state (ISP domain view)

Use **state** to set the status of an ISP domain.

Use **undo state** to restore the default.

Syntax

state { **active** | **block** }

undo state

Default

An ISP domain is in active state.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

active: Places the ISP domain in active state to allow the users in the ISP domain to request network services.

block: Places the ISP domain in blocked state to prevent users in the ISP domain from requesting network services.

Usage guidelines

By blocking an ISP domain, you disable offline users of the domain from requesting network services. However, the online users are not affected.

Examples

Place ISP domain **test** in blocked state.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] state block
```

Related commands

display domain

user-address-type

Use **user-address-type** to specify the user address type in the ISP domain.

Use **undo user-address-type** to restore the default.

Syntax

user-address-type { **ds-lite** | **ipv6** | **nat64** | **private-ds** | **private-ipv4** | **public-ds** | **public-ipv4** }

undo user-address-type

Default

No user address type is specified for the ISP domain.

Views

ISP domain view

Predefined user roles

network-admin

context-admin

Parameters

ds-lite: Specifies the DS-Lite address type.

ipv6: Specifies the IPv6 address type.

nat64: Specifies the NAT64 address type.

private-ds: Specifies the private-DS address type.

private-ipv4: Specifies the private IPv4 address type.

public-ds: Specifies the public-DS address type.

public-ipv4: Specifies the public IPv4 address type.

Usage guidelines

Any change to the user address type does not affect online users.

Examples

Specify the private IPv4 address type for users in ISP domain **test**.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] user-address-type private-ipv4
```

Related commands

display domain

Local user commands

access-limit

Use **access-limit** to set the maximum number of concurrent logins using the local user name.

Use **undo access-limit** to restore the default.

Syntax

access-limit *max-user-number*

undo access-limit

Default

The number of concurrent logins using the local user name is not limited.

Views

Local user view

Predefined user roles

network-admin

context-admin

Parameters

max-user-number: Specifies the maximum number of concurrent logins, in the range of 1 to 1024.

Usage guidelines

This command takes effect only when local accounting is configured for the local user.

The command does not apply to FTP, SFTP, or SCP users. These users do not support accounting.

For this command to take effect on network access users, you also need to execute the **accounting start-fail offline** command in the ISP domain view.

Examples

Set the maximum number of concurrent logins to 5 for users using the local user name **abc**.

```
<Sysname> system-view
[Sysname] local-user abc
[Sysname-luser-manage-abc] access-limit 5
```

Related commands

display local-user

access-user email authentication

Use **access-user email authentication** to specify the username and password used to log in to the SMTP server that sends email notifications to network access users.

Use **undo access-user email authentication** to restore the default.

Syntax

access-user email authentication username *user-name* **password** { **cipher** | **simple** } *string*

undo access-user email authentication

Default

No SMTP server username or password is specified.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

username *user-name*: Specifies the username, a case-sensitive string of 1 to 63 characters.

password: Specifies the password.

cipher: Specifies the password in encrypted form.

simple: Specifies the password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password string. Its plaintext form is a case-sensitive string of 1 to 63 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

If the SMTP server requires a username and password for login, you must use this command to specify the username and password on the device.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Set the username to **abc** and the password to **123** for logging in to the SMTP server that sends email notifications to network access users.

```
<Sysname> system-view
[Sysname] access-user email authentication username abc password simple 123
```

Related commands

access-user email format

access-user email sender

access-user email smtp-server

access-user email format

Use **access-user email format** to configure the subject and body for the email notifications to send to network access users.

Use **undo access-user email format** to restore the default.

Syntax

access-user email format { **body** *body-string* | **subject** *sub-string* }

undo access-user email format { **body** | **subject** }

Default

The email subject is **Password reset notification**.

The email body is as follows:

```
A random password has been generated for your account.
Username: xxx
Password: yyy
Validity: YYYY/MM/DD hh:mm:ss to YYYY/MM/DD hh:mm:ss
```

The xxx string represents the username, the yyy string represents the password, and the YYYY/MM/DD hh:mm:ss to YYYY/MM/DD hh:mm:ss string represents the validity period.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

body *body-string*: Configures the body content. The *body-string* argument is a case-sensitive string of 1 to 255 characters.

subject *sub-string*: Configures the email subject. The *sub-string* argument is a case-sensitive string of 1 to 127 characters.

Usage guidelines

You can configure the device to generate a random password for a network access user on the Web interface. The random password is sent to the user by email. Use this command to configure the email subject and body content.

The email body includes the string configured by using the *body-string* argument and the following information:

```
Username: xxx
Password: yyy
Validity: YYYY/MM/DD hh:mm:ss to YYYY/MM/DD hh:mm:ss
```

The xxx string represents the username, the yyy string represents the password, and the YYYY/MM/DD hh:mm:ss to YYYY/MM/DD hh:mm:ss string represents the validity period.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure the subject and body for the email notifications to send to network access users.

```
<Sysname> system-view
[Sysname] access-user email format subject new password setting
[Sysname] access-user email format body The username, password, and validity period of
the account are given below.
```

Use **access-user email sender** to configure the email sender address in email notifications sent by the device to network access users.

Use **undo access-user email sender** to restore the default.

Syntax

access-user email sender *email-address*

undo access-user email sender

Default

No email sender address is configured for the email notifications sent by the device to network access users.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

email-address: Specifies the email sender address, a case-sensitive string of 1 to 255 characters. The string must contain an at sign (@), and it can contain only one at sign (@). In addition, the string cannot contain only the at sign (@).

Usage guidelines

If you do not specify the email sender address, the device cannot send email notifications to any network access users.

The device supports only one email sender address for network access users. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the email sender address as **abc@yyy.com** for email notifications of network access users.

```
<Sysname> system-view
[Sysname] access-user email sender abc@yyy.com
```

Related commands

access-user email smtp-server

access-user email smtp-server

Use **access-user email smtp-server** to specify an SMTP server to send email notifications of network access users.

Use **undo access-user email smtp-server** to restore the default.

Syntax

access-user email smtp-server *url-string*

undo access-user email smtp-server

Default

No SMTP server is specified to send email notifications of network access users.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the path of the SMTP server, a case-sensitive string of 1 to 255 characters. The path must comply with the standard SMTP protocol and start with **smtp://**.

Usage guidelines

You can specify only one SMTP server to send email notifications of network access users.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the SMTP server at **smtp://www.test.com/smtp** to send email notifications of network access users.

```
<Sysname> system-view
[Sysname] access-user email smtp-server smtp://www.test.com/smtp
```

authorization-attribute (local user view/user group view)

Use **authorization-attribute** to configure authorization attributes for a local user or user group. After the local user or a local user in the user group passes authentication, the device assigns these attributes to the user.

Use **undo authorization-attribute** to restore the default of an authorization attribute.

Syntax

authorization-attribute { **acl** *acl-number* | **callback-number** *callback-number* | **idle-cut** *minutes* | **ip** *ipv4-address* | **ip-pool** *ipv4-pool-name* | **ipv6** *ipv6-address* | **ipv6-pool** *ipv6-pool-name* | **ipv6-prefix** *ipv6-prefix prefix-length* | { **primary-dns** | **secondary-dns** } { **ip** *ipv4-address* | **ipv6** *ipv6-address* } | **session-timeout** *minutes* | **sslvpn-policy-group** *group-name* | **url** *url-string* | **user-role** *role-name* | **vlan** *vlan-id* | **vpn-instance** *vpn-instance-name* | **work-directory** *directory-name* } *

undo authorization-attribute { **acl** | **callback-number** | **idle-cut** | **ip** | **ip-pool** | **ipv6** | **ipv6-pool** | **ipv6-prefix** | **primary-dns** | **secondary-dns**| **session-timeout** | **sslvpn-policy-group** | **url** | **user-role** *role-name* | **vlan** | **vpn-instance** | **work-directory** } *

Default

The working directory for FTP, SFTP, and SCP users is the root directory of the NAS. However, the users do not have permission to access the root directory.

The local users created by a network-admin or level-15 user on the default context are assigned the network-operator user role. The local users created by a context-admin or level-15 user on a non-default context are assigned the context-operator user role.

Views

Local user view

User group view

Predefined user roles

network-admin

context-admin

Parameters

acl *acl-number*: Specifies an authorization ACL. The value range for the *acl-number* argument is 2000 to 5999. The device processes the traffic that matches the rules in the authorization ACL based on the permit or deny statement in the rules.

callback-number *callback-number*: Specifies an authorized PPP callback number. The *callback-number* argument is a case-sensitive string of 1 to 64 characters. After a local user passes authentication, the device uses this number to call the user.

idle-cut *minutes*: Specifies an idle timeout period in minutes. The value range for the *minutes* argument is 1 to 120. An online user is logged out if its idle period exceeds the specified idle timeout period.

ip *ipv4-address*: Assigns a static IPv4 address to the user after it passes authentication. You can specify this option only in local user view. This option is not supported in user group view.

ip-pool *ipv4-pool-name*: Specifies an IPv4 address pool for the user. The *ipv4-pool-name* argument is a case-insensitive string of 1 to 63 characters.

ipv6 *ipv6-address*: Assigns a static IPv6 address to the user after it passes authentication. You can specify this option only in local user view. This option is not supported in user group view.

ipv6-pool *ipv6-pool-name*: Specifies an IPv6 address pool for the user. The *ipv6-pool-name* argument is a case-insensitive string of 1 to 63 characters.

ipv6-prefix *ipv6-prefix prefix-length*: Specifies an IPv6 prefix for the user. The value range for the *prefix-length* argument is 1 to 128. The IPv6 prefix cannot be ::/128, ::1/128, or an IPv6 multicast prefix. After passing authentication, a local user can use the IPv6 prefix.

primary-dns ip *ipv4-address*: Specifies the IPv4 address of the primary DNS server for the user.

primary-dns ipv6 *ipv6-address*: Specifies the IPv6 address of the primary DNS server for the user.

secondary-dns ip *ipv4-address*: Specifies the IPv4 address of the secondary DNS server for the user.

secondary-dns ipv6 *ipv6-address*: Specifies the IPv6 address of the secondary DNS server for the user.

session-timeout *minutes*: Specifies the session timeout timer for the user, in minutes. The value range for the *minutes* argument is 1 to 1440. The device logs off the user after the timer expires.

sslvpn-policy-group *group-name*: Specifies an SSL VPN policy group for the user. The *group-name* argument is a case-insensitive string of 1 to 31 characters. For information about SSL VPN policy groups, see *Security Configuration Guide*.

url *url-string*: Specifies a redirect URL. The *url-string* argument is a case-sensitive string of 1 to 255 characters. The URL must start with **http://** or **https://**. You can configure the redirect URL attribute to push advertisements or notifications to users after the users pass authentication or push bill overdue notifications to users. This option is applicable only to IPoE and LAN users. For IPoE users, you must specify a URL with port number 80 or 443.

user-role *role-name*: Specifies an authorized user role. The *role-name* argument is a case-sensitive string of 1 to 63 characters. A maximum of 64 user roles can be specified for a user. For user role-related commands, see *Fundamentals Command Reference* for RBAC commands. This option is available only in local user view, and is not available in user group view.

vlan *vlan-id*: Specifies an authorized VLAN. The value range for the *vlan-id* argument is 1 to 4094. After passing authentication and being authorized a VLAN, a local user can access only the resources in this VLAN.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the user belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. After passing authentication, the user has permission to access the network resources in the specified VPN.

work-directory *directory-name*: Specifies the working directory for FTP, SFTP, or SCP users. The *directory-name* argument is a case-insensitive string of 1 to 255 characters. The directory must already exist.

Usage guidelines

Configure authorization attributes according to the application environments and purposes. Support for authorization attributes depends on the service types of users.

For PPP users, only the following authorization attributes take effect: **callback-number**, **idle-cut**, **ip**, **ip-pool**, **ipv6-pool**, **ipv6-prefix**, **primary-dns**, **secondary-dns**, **vpn-instance**, and **session-timeout**.

For IPoE users, only the following authorization attributes take effect: **idle-cut**, **ip-pool**, **ipv6-pool**, **ipv6-prefix**, **url**, **user-profile**, **vpn-instance**, **primary-dns**, **secondary-dns**, and **session-timeout**.

For portal users, only the following authorization attributes take effect: **idle-cut**, **acl**, **ip-pool**, **ipv6-pool**, **vpn-instance**, and **session-timeout**.

For SSH, Telnet, and terminal users, only the **user-role** authorization attribute takes effect.

For HTTP and HTTPS users, only the authorization attribute **user-role** takes effect.

For FTP users, only the authorization attributes **user-role** and **work-directory** take effect.

For SSL VPN users, only the authorization attribute **sslvpn-policy-group** takes effect.

For IKE users, only the authorization attribute **ip-pool** takes effect.

For other types of local users, no authorization attribute takes effect.

Authorization attributes configured for a user group are intended for all local users in the group. You can group local users to improve configuration and management efficiency. An authorization attribute configured in local user view takes precedence over the same attribute configured in user group view.

When you specify an authorized ACL, follow these restrictions and guidelines:

- If the specified ACL does not exist or the ACL does not contain any rules, the system considers that no ACL is specified. If the strict check method is enabled for portal authorized ACLs, the system logs off portal users.

- For portal users to come online after passing authentication, make sure ACLs assigned to them do not have rules specified with a source IP or MAC address.

To make sure FTP, SFTP, and SCP users can access the directory after an IRF master/subordinate switchover, do not specify slot information for the working directory.

To make sure the user have only the user roles authorized by using this command, use the **undo authorization-attribute user-role** command to remove the default user role.

The security-audit user role has access to the commands for managing security log files and security log file system. To display all the accessible commands of the security-audit user role, use the **display role name security-audit** command. For more information about security log management, see information center configuration in *Network Management and Monitoring Configuration Guide*. For more information about file system management, see *Fundamentals Configuration Guide*.

You cannot delete a local user if the local user is the only user that has the security-audit user role.

The security-audit user role is mutually exclusive with other user roles.

The users assigned with the system-admin, security-admin, or audit-admin user role have access to specific Web pages and the **ping** and **tracert** commands. For more information about the access permissions of these user roles, see RBAC in *Fundamentals Configuration Guide*.

The system-admin, security-admin, and audit-admin user roles are mutually exclusive in a user account. In addition, these user roles are mutually exclusive with other user roles in a user account.

When you assign user roles to a user, the system prompts you to confirm the deletion of the user roles that are mutually exclusive with the new user roles.

Examples

Configure the authorized VLAN of network access user **abc** as VLAN 2.

```
<Sysname> system-view
[Sysname] local-user abc class network
[Sysname-luser-network-abc] authorization-attribute vlan 2
```

Configure the authorized VLAN of user group **abc** as VLAN 3.

```
<Sysname> system-view
[Sysname] user-group abc
[Sysname-ugroup-abc] authorization-attribute vlan 3
```

Assign the **security-audit** user role to device management user **xyz** as the authorized user role.

```
<Sysname> system-view
[Sysname] local-user xyz class manage
[Sysname-luser-manage-xyz] authorization-attribute user-role security-audit
This operation will delete all other roles of the user. Are you sure? [Y/N]:y
```

Related commands

display user-group

bind-attribute

Use **bind-attribute** to configure binding attributes for a local user.

Use **undo bind-attribute** to remove binding attributes of a local user.

Syntax

bind-attribute { **call-number** *call-number* [**:** *subcall-number*] | **location interface** *interface-type interface-number* | **mac** *mac-address* | **vlan** *vlan-id* } *

undo bind-attribute { **call-number** | **location** | **mac** | **vlan** } *

Default

No binding attributes are configured for a local user.

Views

Local user view

Predefined user roles

network-admin

context-admin

Parameters

call-number *call-number*: Specifies a calling number for PPP user authentication. The *call-number* argument is a string of 1 to 64 characters. This option applies only to PPP users.

subcall-number: Specifies the subcalling number. The total length of the calling number and the subcalling number cannot be more than 62 characters.

location interface *interface-type interface-number*: Specifies the interface to which the user is bound. The *interface-type* argument represents the interface type, and the *interface-number* argument represents the interface number. To pass authentication, the user must access the network through the bound interface. This option applies only to LAN, PPP, IPoE, and portal users.

mac *mac-address*: Specifies the MAC address of the user in the format H-H-H. This option applies only to SSL VPN users that log in through iNode clients, LAN users, PPP users, IPoE users, and portal users.

vlan *vlan-id*: Specifies the VLAN to which the user belongs. The *vlan-id* argument is in the range of 1 to 4094. This option applies only to LAN, PPP, IPoE, and portal users.

Usage guidelines

To perform local authentication of a user, the device matches the actual user attributes with the configured binding attributes. If the user has a non-matching attribute or lacks a required attribute, the user will fail authentication.

Binding attribute check takes effect on all access services. Configure the binding attributes for a user based on the access services and make sure the device can obtain all attributes to be checked from the user's packet.

The binding interface type must meet the requirements of the local user. Configure the binding interface based on the service type of the user. If the user is a portal user, specify the portal-enabled interface. Specify the Layer 2 Ethernet interface if portal is enabled on a VLAN interface and the **portal roaming enable** command is not configured.

Examples

Bind MAC address 11-11-11 with network access user **abc**.

```
<Sysname> system-view
[Sysname] local-user abc class network
[Sysname-luser-network-abc] bind-attribute mac 11-11-11
```

Related commands

display local-user

company

Use **company** to specify the company of a local guest.

Use **undo company** to restore the default.

Syntax

company *company-name*

undo company

Default

No company is specified for a local guest.

Views

Local guest view

Predefined user roles

network-admin

context-admin

Parameters

company-name: Specifies the company name, a case-sensitive string of 1 to 255 characters.

Examples

Specify company **yyy** for local guest **abc**.

```
<Sysname> system-view
[Sysname] local-user abc class network guest
[Sysname-luser-network(guest)-abc] company yyy
```

Related commands

display local-user

description

Use **description** to configure a description for a network access user.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

No description is configured for a network access user.

Views

Network access user view

Predefined user roles

network-admin

context-admin

Parameters

text: Configures a description, case-sensitive string of 1 to 127 characters.

Usage guidelines

To mark a network access user for special displaying or management purposes in the Web interface, configure description **#user_from_server#** for the user. The purposes depend on the implementation of the Web interface.

Examples

Configure a description for network access user **123**.

```
<Sysname> system-view
[Sysname] local-user 123 class network
[Sysname-luser-network-123] description Manager of MSC company
```

Related commands

display local-user

display local-guest waiting-approval

Use **display local-guest waiting-approval** to display pending registration requests for local guests.

Syntax

display local-guest waiting-approval [**user-name** *user-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

user-name *user-name*: Specifies a local guest by its username, a string of 1 to 55 characters. If you do not specify a guest, this command displays pending registration requests for all local guests. The username can contain a domain name or not.

- If the username does not contain an at sign (@), all characters in the username string are case sensitive. The device parses the username as a pure username. The username cannot be **a**, **al**, or **all**, and it cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), or right angle bracket (>).
- If the username contains an at sign (@), it must be in the format of xxx@yyy. The at sign (@) is the delimiter between the pure username and the domain name.
  - The xxx part is case sensitive. It cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@), and cannot be **a**, **al**, or **all**.
  - The yyy part is case insensitive and cannot contain an at sign (@).

Usage guidelines

On the Web registration page, users submit local guest registration requests for approval. The guest manager can add supplementary information to the guest accounts and approves the requests. The device then creates local guest accounts based on the approved requests.

Examples

Display all pending registration requests for local guests.

```
<Sysname> display local-guest waiting-approval
Total 1 guest informations matched.

Guest user Smith:
  Full name  : Smith Li
  Company    : YYY
  Email      : Smith@yyy.com
  Phone      : 139189301033
  Description: The employee of YYY company
```

Table 3 Command output

Field	Description
Total 1 guest informations matched.	Number of local guests that have pending registration requests.
Full name	Full name of the local guest.
Company	Company name of the local guest.
Email	Email address of the local guest.
Phone	Phone number of the local guest.
Description	Description of the local guest.

Related commands

context-operator

Parameters

class: Specifies the local user type.

manage: Device management user.

network: Network access user.

guest: Guest user account.

idle-cut { **disable** | **enable** }: Specifies local users by the status of the idle cut feature.

service-type: Specifies the local users that use a specific type of service.

advpn: ADVPN tunnel users.

ftp: FTP users.

http: HTTP users.

https: HTTPS users.

ike: IKE users that access the network through IKE extended authentication.

ipoe: IPoE users that access the network through Layer 2 or Layer 3 leased lines or STBs.

lan-access: LAN users that typically access the LAN network.

portal: Portal users.

ppp: PPP users.

ssh: SSH users.

sslvpn: SSL VPN users.

telnet: Telnet users.

terminal: Terminal users that log in through console ports.

state { **active** | **block** }: Specifies local users in active or blocked state. A local user in active state can access network services, but a local user in blocked state cannot.

user-name *user-name*: Specifies all local users using the specified username. The username must be a string of 1 to 55 characters, which can be a pure username or a username containing a domain name.

- If the username does not contain an at sign (@), all characters in the username string are case sensitive. The device parses the username as a pure username. The username cannot be **a**, **al**, or **all**, and it cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), or right angle bracket (>).
- If the username contains an at sign (@), it must be in the format of xxx@yyy. The at sign (@) is the delimiter between the pure username and the domain name.
  - The xxx part is case sensitive. It cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@), and cannot be **a**, **al**, or **all**.
  - The yyy part is case insensitive and cannot contain an at sign (@).

vlan *vlan-id*: Specifies all local users in a VLAN. The *vlan-id* argument is in the range of 1 to 4094.

Usage guidelines

If you do not specify any parameters, this command displays information about all local users.

Examples

Display information about all local users.

```
<Sysname> display local-user
Device management user root:
  State:                     Active
  Service type:              SSH/Telnet/Terminal
  Access limit:              Enabled           Max access number: 3
  Current access number:     1
```

```

Total 3 local users matched.
```

Table 4 Command output

Field	Description
State	Status of the local user: active or blocked.
Service type	Service types that the local user can use.
Access limit	Whether the concurrent login limit is enabled.
Max access number	Maximum number of concurrent logins using the local user name.
Current access number	Current number of concurrent logins using the local user name.
User group	Group to which the local user belongs.
Bind attributes	Binding attributes of the local user.
Location bound	Binding port of the local user.
MAC address	MAC address of the local user.
VLAN ID	Binding VLAN of the local user.
Authorization attributes	Authorization attributes of the local user.
Idle timeout	Idle timeout period of the user, in minutes.
Session-timeout	Session timeout timer for the user, in minutes.
Callback number	Authorized PPP callback number of the local user.
Work directory	Directory that the FTP, SFTP, or SCP user can access.
ACL number	Authorization ACL of the local user.
VLAN ID	Authorized VLAN of the local user.
User role list	Authorized roles of the local user.
IP pool	IPv4 address pool authorized to the local user.
SSL VPN policy group	SSL VPN policy group authorized to the local user.
IP address	IPv4 address authorized to the local user.
IPv6 address	IPv6 address authorized to the local user.
IPv6 prefix	IPv6 address prefix authorized to the local user.
IPv6 pool	IPv6 address pool authorized to the local user.
Primary DNS server	IPv4 address of the primary DNS server for the local user.
Secondary DNS server	IPv4 address of the secondary DNS server for the local user.
Primary DNSV6 server	IPv6 address of the primary DNS server for the local user.
Secondary DNSV6 server	IPv6 address of the secondary DNS server for the local user.
URL	Authorization PADM URL for the local user.
VPN instance	Authorization VPN instance for the local user.
Password control configurations	Password control attributes that are configured for the local user. Non-default vSystems do not support this field.
Password aging	Password expiration time. Non-default vSystems do not support this field.
Password length	Minimum number of characters that a password must contain. Non-default vSystems do not support this field.

Field	Description
Password composition	Password composition policy: • Minimum number of character types that a password must contain. • Minimum number of characters from each type in a password. Non-default vSystems do not support this field.
Password complexity	Password complexity checking policy: • Reject a password that contains the username or the reverse of the username. • Reject a password that contains any character repeated consecutively three or more times. Non-default vSystems do not support this field.
Maximum login attempts	Maximum number of consecutive failed login attempts. Non-default vSystems do not support this field.
Action for exceeding login attempts	Action to take on the user that failed to log in after using up all login attempts. Non-default vSystems do not support this field.
Password history was last reset	The most recent time that the history password records were cleared. Non-default vSystems do not support this field.
Full name	Name of the local guest.
Company	Company name of the local guest.
Email	Email address of the local guest.
Phone	Phone number of the local guest.
Sponsor full name	Name of the guest sponsor.
Sponsor department	Department of the guest sponsor.
Sponsor email	Email address of the guest sponsor.
Description	Description of the network access user.
Period of validity	Validity period of the network access user.
Start date and time	Date and time from which the network access user begins to take effect.
Expiration date and time	Date and time at which the network access user expires.

display user-group

Use **display user-group** to display user group configuration.

Syntax

display user-group { **all** | **name** *group-name* } [**identity-member** { **all** | **group** | **user** }]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

all: Specifies all user groups.

name *group-name*: Specifies a user group by its name, a case-insensitive string of 1 to 32 characters.

identity-member { **all** | **group** | **user** }: Specifies identity members in the specified user group or all user groups. If you do not specify these keywords, the command does not display identity member information.

all: Specifies all identity members, including identity users and identity groups.

group: Specifies identity groups.

user: Specifies identity users.

Examples

Display the configuration of all user groups.

```
<Sysname> display user-group all
Total 2 user groups matched.

User group: system
  Authorization attributes:
    Work directory:          flash:
User group: jj
  Authorization attributes:
    Idle timeout:            2 minutes
    Callback number:         2:2
    Work directory:          flash:/
    ACL number:              2000
    VLAN ID:                 2
    SSL VPN policy group:    policygroup1
  Password control configurations:
    Password aging:          2 days
```

Display information about all identity members for all user groups.

```
<Sysname> display user-group all identity-member all
Total 2 user groups matched.

User group: system
  Identity groups: 0
User group: jj
  Identity groups: 2
  Group ID        Group name
  0xffffffff      group1
  0x567           group2
  Identity users: 2
  User ID         Username
  0x234           user1
```

```
0xffffffff      user2
```

Table 5 Command output

Field	Description
User group	User group name.
Authorization attributes	Authorization attributes of the user group.
Idle timeout	Idle timeout period, in minutes.
Session-timeout	Session timeout timer, in minutes.
Callback number	Authorized PPP callback number.
Work directory	Directory that FTP, SFTP, or SCP users in the group can access.
ACL number	Authorization ACL.
VLAN ID	Authorized VLAN.
IP pool	IPv4 address pool authorized to the user group.
SSL VPN policy group	SSL VPN policy group authorized to the user group.
IPv6 prefix	IPv6 address prefix authorized to the user group.
IPv6 pool	IPv6 address pool authorized to the user group.
Primary DNS server	IPv4 address of the primary DNS server authorized to the user group.
Secondary DNS server	IPv4 address of the secondary DNS server authorized to the user group.
Primary DNSV6 server	IPv6 address of the primary DNS server authorized to the user group.
Secondary DNSV6 server	IPv6 address of the secondary DNS server authorized to the user group.
URL	Authorization PADM URL for the user group.
VPN instance	Authorization VPN instance for the user group.
Password control configurations	Password control attributes that are configured for the user group.
Password aging	Password expiration time.
Password length	Minimum number of characters that a password must contain.
Password composition	Password composition policy: • Minimum number of character types that a password must contain. • Minimum number of characters from each type in a password.
Password complexity	Password complexity checking policy: • Reject a password that contains the username or the reverse of the username. • Reject a password that contains any character repeated consecutively three or more times.
Maximum login attempts	Maximum number of consecutive failed login attempts.
Action for exceeding login attempts	Action to take on the user that failed to log in after using up all login attempts.
Identity users	Number of identity users.
Identity groups	Number of identity groups.
User ID	Identity user ID.

Field	Description
Group ID	Identity group ID.
Username	Identity user name.
Group name	Identity group name.

email

Use **email** to configure an email address for a local guest.

Use **undo email** to restore the default.

Syntax

email *email-string*

undo email

Default

No email address is configured for a local guest.

Views

Local guest view

Predefined user roles

network-admin

context-admin

Parameters

email-string: Specifies the email address for the local guest, a case-sensitive string of 1 to 255 characters. The string must contain an at sign (@), and it can contain only one at sign (@). In addition, the string cannot contain only the at sign (@).

Usage guidelines

The local guest uses the email address to receive notifications from the device.

Examples

Configure the email address as **abc@yyy.com** for local guest **abc**.

```
<Sysname> system-view
[Sysname] local-user abc class network guest
[Sysname-luser-network(guest)-abc] email abc@yyy.com
```

Related commands

display local-user

full-name

Use **full-name** to configure the name of a local guest.

Use **undo full-name** to restore the default.

Syntax

full-name *name-string*

undo full-name

Default

No name is configured for a local guest.

Views

Local guest view

Predefined user roles

network-admin

context-admin

Parameters

name-string: Specifies the local guest name, a case-sensitive string of 1 to 255 characters.

Examples

Configure the name as **abc Snow** for local guest **abc**.

```
<Sysname> system-view
[Sysname] local-user abc class network guest
[Sysname-luser-network(guest)-abc] full-name abc Snow
```

Related commands

display local-user

group

Use **group** to assign a local user to a user group.

Use **undo group** to restore the default.

Syntax

group *group-name*

undo group

Default

A local user belongs to user group **system**.

Views

Local user view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies the user group name, a case-insensitive string of 1 to 32 characters.

Examples

Assign device management user **111** to user group **abc**.

```
<Sysname> system-view
[Sysname] local-user 111 class manage
[Sysname-luser-manage-111] group abc
```

Related commands

display local-user

identity-group

Use **identity-group** to add a network access user to an identity group.

Use **undo identity-group** to remove a network access user from identity groups.

Syntax

identity-group *group-name*

undo identity-group [*group-name*]

Default

A network access user does not belong to any identity groups.

Views

Network access user view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies an identity group by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

Add users to an identity group as identity members for centralized management.

A user can belong to multiple identity groups.

After you add a user to an identity group in network access user view, the system automatically synchronizes the configuration to the identity group. Then, the user is available in user group view of the identity group.

If you do not specify a group name, the **undo identity-group** command removes the user from all identity groups.

Examples

Add network access user **user1** to identity group **group1**.

```
<Sysname> system-view
[Sysname] local-user user1 class network
[Sysname-luser-network-user1] identity-group group1
```

Related commands

identity-member

user-group

identity-member

Use **identity-member** to add an identity member to a user group.

Use **undo identity-member** to remove identity members from a user group.

Syntax

identity-member { **group** *group-name* | **user** *user-name* }

undo identity-member { **group** [*group-name*] | **user** [*user-name*] }

Default

No identity members exist in a user group.

Views

User group view

Predefined user roles

network-admin

context-admin

Parameters

group *group-name*: Specifies an identity group by its name, a case-insensitive string of 1 to 32 characters.

user *user-name*: Specifies an identity user by its name, a string of 1 to 55 characters. The username can be a pure username or a username containing a domain name.

- If the username does not contain an at sign (@), all characters in the username string are case sensitive. The device parses the username as a pure username. The username cannot be **a**, **al**, or **all**, and it cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), or right angle bracket (>).
- If the username contains an at sign (@), it must be in the format of xxx@yyy. The at sign (@) is the delimiter between the pure username and the domain name.
  - The xxx part is case sensitive. It cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@), and cannot be **a**, **al**, or **all**.
  - The yyy part is case insensitive and cannot contain an at sign (@).

Usage guidelines

Assign users or users groups that have the same user identification requirements to the same group.

When you add identity members, follow these restrictions and guidelines:

- You can add network access users as identity members.
- After you add an identity user to an identity group in user group view, the system automatically synchronizes the configuration to the identity user if the user exists. Then, the identity group is available in network access user view of the identity user.
- You cannot add an identity group to a lower-level group that is an identity member of the group.

If you do not specify a user name or group name, the **undo identity-member** command removes all identity users or groups from the user group.

If an identity group has been specified for a security policy, do not remove member identity groups from the identity group. A violation will cause the truncation of the tree where the identity group resides and further affect user traffic matching of the security policy.

Examples

Add identity user **user1** and identity group **group2** to user group **group1**.

```
<Sysname> system-view
[Sysname] user-group group1
[Sysname-ugroup-group1] identity-member user user1
[Sysname-ugroup-group1] identity-member group group2
```

Related commands

display user-group

identity-group

local-guest auto-delete enable

Use **local-guest auto-delete enable** to enable the guest auto-delete feature.

Use **undo local-guest auto-delete enable** to restore the default.

Syntax

local-guest auto-delete enable

undo local-guest auto-delete enable

Default

The guest auto-delete feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the device to automatically delete the local guest accounts when they expire.

Examples

Enable the guest auto-delete feature.

```
<Sysname> system-view
[Sysname] local-guest auto-delete enable
```

Related commands

validity-datetime

local-guest email format

Use **local-guest email format** to configure the subject and body for the email notifications of local guest information.

Use **undo local-guest email format** to delete the configured subject or body for the email notifications of local guest information.

Syntax

local-guest email format to { **guest** | **manager** | **sponsor** } { **body** *body-string* | **subject** *sub-string* }

undo local-guest email format to { **guest** | **manager** | **sponsor** } { **body** | **subject** }

Default

No subject or body is configured for the email notifications of local guest information.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

to: Specifies the email recipient.

guest: Specifies the local guest.

manager: Specifies the guest manager.

sponsor: Specifies the guest sponsor.

body *body-string*: Configures the body content. The *body-string* argument is a case-sensitive string of 1 to 255 characters.

subject *sub-string*: Configures the email subject. The *sub-string* argument is a case-sensitive string of 1 to 127 characters.

Usage guidelines

Email notifications need to be sent to notify the local guests, guest sponsors, or guest managers of the guest account information or guest registration requests. Use this command to configure the subject and body for the email notifications to be sent by the device.

You can configure one subject and one body for each email recipient. If you configure the subject or body content multiple times for the same recipient, the most recent configuration takes effect.

You must configure both the subject and body for each recipient.

Examples

Configure the subject and body for the email notifications to send to the local guest.

```
<Sysname> system-view
[Sysname] local-guest email format to guest subject Guest account information
[Sysname] local-guest email format to guest body A guest account has been created for you.
The username, password, and validity period of the account are given below.
```

local-guest send-email

local-guest email sender

Use **local-guest email sender** to configure the email sender address in email notifications of local guests sent by the device.

Use **undo local-guest email sender** to restore the default.

Syntax

local-guest email sender *email-address*

undo local-guest email sender

Default

No email sender address is configured for the email notifications of local guests sent by the device.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

email-address: Specifies the email sender address, a case-sensitive string of 1 to 255 characters. The string must contain an at sign (@), and it can contain only one at sign (@). In addition, the string cannot contain only the at sign (@).

Usage guidelines

If you do not specify the email sender address, the device cannot send email notifications of local guests.

The device supports only one email sender address for local guests. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the email sender address as **abc@yyy.com** for email notifications of local guests.

```
<Sysname> system-view
[Sysname] local-guest email sender abc@yyy.com
```

local-guest send-email

local-guest email smtp-server

Use **local-guest email smtp-server** to specify an SMTP server to send email notifications of local guests.

Use **undo local-guest email smtp-server** to restore the default.

Syntax

local-guest email smtp-server *url-string*

undo local-guest email smtp-server

Default

No SMTP server is specified to send email notifications of local guests.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the path of the SMTP server, a case-sensitive string of 1 to 255 characters. The path must comply with the standard SMTP protocol and start with **smtp://**.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the SMTP server at **smtp://www.test.com/smtp** to send local guest email notifications.

```
<Sysname> system-view
[Sysname] local-guest email smtp-server smtp://www.test.com/smtp
```

local-guest generate

Use **local-guest generate** to create local guests in batch.

Syntax

local-guest generate username-prefix *name-prefix* [**password-prefix** *password-prefix*] **suffix** *suffix-number* [**group** *group-name*] **count** *user-count* **validity-datetime** *start-date start-time* **to** *expiration-date expiration-time*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

username-prefix *name-prefix*: Specifies the name prefix. The *name-prefix* argument is a case-sensitive string of 1 to 45 characters. The prefix cannot contain any of the following characters: forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), and at sign (@).

password-prefix *password-prefix*: Specifies a prefix for the plaintext password. The *password-prefix* argument is a case-sensitive string of 1 to 53 characters. If you do not specify a password prefix, the device randomly generates passwords for the local guests.

suffix *suffix-number*: Specifies the start suffix number of the username and password. The *suffix-number* argument is a numeric string of 1 to 10 digits.

group *group-name*: Specifies a user group by its name. The *group-name* argument is a case-sensitive string of 1 to 32 characters. If you do not specify a user group, the guests are assigned to the system-defined user group **system**.

count *user-count*: Specifies the number of local guests to be created. The value range for the *user-count* argument is 1 to 256.

validity-datetime: Specifies the validity period of the local guests. The expiration date and time must be later than the start date and time.

start-date: Specifies the start date of the validity period, in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for the MM argument is 1 to 12. The value range for the DD argument varies with the specified month. The value range for the YYYY argument is 2000 to 2035.

start-time: Specifies the start time of the validity period, in the format of hh:mm:ss. The value range for the hh argument is 0 to 23. The value range for the mm and ss arguments is 0 to 59. The mm and ss arguments are optional. For example, enter 1 to indicate 1:00:00. A value of 0 indicates 00:00:00.

to: Specifies the end date and time of the validity period.

expiration-date: Specifies the expiration date in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for the MM argument is 1 to 12. The value range for the DD argument varies with the specified month. The value range for the YYYY argument is 2000 to 2035.

expiration-time: Specifies the expiration time in the format of hh:mm:ss. The value range for the hh argument is 0 to 23. The value range for the mm and ss arguments is 0 to 59. The mm and ss arguments are optional. For example, enter 1 to indicate 1:00:00. A value of 0 indicates 00:00:00.

Usage guidelines

Account names of batch created local guests start with the same string specified by the name prefix, and end with a different number as the suffix. The system increases the start suffix number by 1 for each new local guest created in the batch.

The device generates plaintext passwords by using the password prefix and suffix number in the same way it batch creates the local guest names.

Consider the system resources when you specify the number of local guests to create. The device might fail to create all accounts for a large batch of local guests because of insufficient resources.

If a local guest to be created has the same name as an existing local guest on the device, the new guest overrides the existing guest.

Examples

Create 20 local guests in batch with user names **abc01** through **abc20** for user group **visit**. The user accounts are effective from 2018/10/01 00:00:00 to 2019/10/02 12:00:00.

```
<Sysname> system-view
[Sysname] local-guest generate username-prefix abc suffix 01 group visit count 20
validity-datetime 2018/10/01 00:00:00 to 2019/10/02 12:00:00
```

Related commands

Syntax

local-guest send-email user-name *user-name* **to** { **guest** | **sponsor** }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

user-name *user-name*: Specifies a local guest by its username, a string of 1 to 55 characters. The username can be a pure username or a username containing a domain name.

- If the username does not contain an at sign (@), all characters in the username string are case sensitive. The device parses the username as a pure username. The username cannot be **a**, **al**, or **all**, and it cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), or right angle bracket (>).
- If the username contains an at sign (@), it must be in the format of xxx@yyy. The at sign (@) is the delimiter between the pure username and the domain name.
  - The xxx part is case sensitive. It cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@), and cannot be **a**, **al**, or **all**.
  - The yyy part is case insensitive and cannot contain an at sign (@).

to: Specifies the email recipient.

guest: Specifies the local guest.

sponsor: Specifies the guest sponsor.

Usage guidelines

Guest managers can use this command to inform local guests or guest sponsors of the guest password and validity period information.

Examples

Send an email to notify local guest **abc** of the guest password and validity period information.

```
<Sysname> local-guest send-email user-name abc to guest
```

Related commands

email

sponsor-email

local-guest timer

Use **local-guest timer** to set the waiting-approval timeout timer for local guests.

Syntax

local-guest timer waiting-approval *time-value*

undo local-guest timer waiting-approval

Default

The setting is 24 hours.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

time-value: Specifies the waiting-approval timeout timer in the range of 1 to 720, in hours.

Usage guidelines

The waiting-approval timeout timer starts when the registration request of a local guest is sent for approval. If the request is not approved within the timer, the device deletes the registration request.

Examples

Set the waiting-approval timeout timer to 12 hours.

```
<Sysname> system-view
[Sysname] local-guest timer waiting-approval 12
```

local-user

Use **local-user** to add a local user and enter its view, or enter the view of an existing local user.

Use **undo local-user** to delete local users.

Syntax

local-user *user-name* [**class** { **manage** | **network** [**guest**] }]

undo local-user { *user-name* **class** { **manage** | **network** [**guest**] } | **all** [**service-type** { **advpn** | **ftp** | **http** | **https** | **ike** | **ipoe** | **portal** | **ppp** | **ssh** | **sslvpn** | **telnet** | **terminal** } | **class** { **manage** | **network** [**guest**] }] }

Default

No local users exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

user-name: Specifies the local user name, a string of 1 to 55 characters. The username can be a pure username or a username containing a domain name.

- If the username does not contain an at sign (@), all characters in the username string are case sensitive. The device parses the username as a pure username. The username cannot be **a**, **al**, or **all**, and it cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), or right angle bracket (>).
- If the username contains an at sign (@), it must be in the format of xxx@yyy. The at sign (@) is the delimiter between the pure username and the domain name.
  - The xxx part is case sensitive. It cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@), and cannot be **a**, **al**, or **all**.
  - The yyy part is case insensitive and cannot contain an at sign (@).

class: Specifies the local user type. If you do not specify this keyword, the command adds a device management user.

manage: Device management user that can configure and monitor the device after login. Device management users can use FTP, HTTP, HTTPS, Telnet, SSH, and terminal services.

network: Network access user that accesses network resources through the device. Network access users can use ADVPN, IKE, IPoE, LAN access, portal, PPP, and SSL VPN services.

guest: Guest that can access network resources through the device during a specific validity period. Guests can use portal service.

all: Specifies all users.

service-type: Specifies the local users that use a specific type of service.

advpn: ADVPN tunnel users.

ftp: FTP users.

http: HTTP users.

https: HTTPS users.

ike: IKE users that access the network through IKE extended authentication.

ipoe: IPoE users that access the network through Layer 2 or Layer 3 leased lines or STBs.

portal: Portal users.

ppp: PPP users.

ssh: SSH users.

sslvpn: SSL VPN users.

telnet: Telnet users.

terminal: Terminal users that log in through console ports.

Usage guidelines

In local authentication, a username and user type uniquely identifiy a local user. The username is used to match the pure username parsed from the username entered by the user. The user type restricts the service types that can be used by the user.

In the current software version, only the pure username of an SSL VPN user can contain an at sign (@).

The device supports multiple local users. The maximum number of device management users varies by device model. The maximum number of network access users varies by device model.

If the local username contains Chinese characters, make sure the endpoint software used at device login uses the same character set encoding format as the encoding format (GB18030) used by the device to save local user configuration. If they use different encoding formats, the username cannot be correctly decoded on the device, which might cause local authentication failure.

Examples

Add a device management user named **user1** and enter local user view.

```
<Sysname> system-view
[Sysname] local-user user1 class manage
[Sysname-luser-manage-user1]
```

Add a network access user named **user2** and enter local user view.

```
<Sysname> system-view
[Sysname] local-user user2 class network
[Sysname-luser-network-user2]
```

Add a local guest named **user3** and enter local guest view.

```
Sysname> system-view
[Sysname] local-user user3 class network guest
[Sysname-luser-network(guest)-user3]
```

local-user-export class network

Use **local-user-export class network** to export network access user account information from the device to a .csv file in the specified path.

Syntax

local-user-export class network url *url-string* [**from** { **group** *group-name* | **user** *user-name* }]

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

url *url-string*: Specifies the URL of the destination file, a case-insensitive string of 1 to 255 characters.

from: Specifies the range of users to be exported. If you do not specify this keyword, the command exports all network access users on the device.

group *group-name*: Specifies a user group by its name, a case-insensitive string of 1 to 32 characters.

user *user-name*: Specifies a user by its name, a string of 1 to 55 characters. The username can be a pure username or a username containing a domain name.

- If the username does not contain an at sign (@), all characters in the username string are case sensitive. The device parses the username as a pure username. The username cannot be **a**, **al**, or **all**, and it cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), or right angle bracket (>).
- If the username contains an at sign (@), it must be in the format of xxx@yyy. The at sign (@) is the delimiter between the pure username and the domain name.
  - The xxx part is case sensitive. It cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@), and cannot be **a**, **al**, or **all**.
  - The yyy part is case insensitive and cannot contain an at sign (@).

Usage guidelines

You can import the user account information back to the device or to other devices that support the **local-user-import class network** command. Before the import, you can edit the .csv file as needed. However, you must follow the restrictions in "local-user-import class network."

The device supports TFTP and FTP file transfer modes. Table 6 describes the valid URL formats of the .csv file.

Table 6 URL formats

Protocol	URL format	Description
TFTP	**tftp://***server*/*path*/*filename*	Specify a TFTP server by IP address or hostname. For example, tftp://1.1.1.1/user/user.csv.
FTP	• With FTP user name and password: **ftp://***username*:*password*@*server*/*path*/*filename* • Without FTP user name and password: **ftp://***server*/*path*/*filename*	Specify an FTP server by IP address or hostname. The device ignores the domain name in the FTP user name. For example, specify the file path as **ftp://1:1@1.1.1.1/user/user.csv** or **ftp://1.1.1.1/user/user.csv**.

Examples

Export network access user account information to the **identityuser.csv** file in the **ftp://1.1.1.1/user/** path.

```
<Sysname> system-view
[Sysname] local-user-export class network url ftp://1.1.1.1/user/identityuser.csv
```

Related commands

display local-user

local-user-import class network

Use **local-user-export class network guest** to export local guest account information to a .csv file in the specified path.

Syntax

local-user-export class network guest url *url-string*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

url *url-string*: Specifies the URL of the destination file, a case-insensitive string of 1 to 255 characters.

Usage guidelines

You can import the user account information back to the device or to other devices that support the **local-user-import class network guest** command. Before the import, you can edit the .csv file as needed. However, you must follow the restrictions in "local-user-import class network guest."

The device supports TFTP and FTP file transfer modes. Table 7 describes the valid URL formats of the .csv file.

Table 7 URL formats

Protocol	URL format	Description
TFTP	**tftp://***server/path/filename*	Specify a TFTP server by IP address or hostname. For example, specify the file path as **tftp://1.1.1.1/user/user.csv**.
FTP	• With FTP user name and password: **ftp://***username*:*password@server/path/filename* • Without FTP user name and password: **ftp://***server/path/filename*	Specify an FTP server by IP address or hostname. The device ignores the domain name in the FTP user name. For example, specify the file path as **ftp://1:1@1.1.1.1/user/user.csv** or **ftp://1.1.1.1/user/user.csv**.

Examples

Export local guest account information to the **guest.csv** file in the **ftp://1.1.1.1/user/** path.

```
<Sysname> system-view
[Sysname] local-user-export class network guest url ftp://1.1.1.1/user/guest.csv
```

Related commands

display local-user

local-user-import class network guest

local-user-import class network

Use **local-user-import class network** to import user information from a .csv file in the specified path and create network access users based on the imported information.

Syntax

local-user-import class network url *url-string* [**auto-create-group** | **override** | **start-line** *line-number*] *

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

url *url-string*: Specifies the URL of the source file, a case-insensitive string of 1 to 255 characters.

auto-create-group: Enables the device to automatically create user groups for the imported network access users if the groups do not exist on the device. If you do not specify this keyword, the device ignores the nonexistent user groups of the network access users and assigns them to the predefined user group **system**.

override: Specifies the device to override the existing account with the same name as a user account to be imported. If you do not specify this keyword, the device retains the existing account information.

start-line *line-number*: Specifies the number of the line at which the account import begins. If you do not specify this option, the command imports information about all user accounts in the file.

Usage guidelines

The .csv file contains multiple parameters for each account and the parameters must be strictly arranged in the following order:

- **Username**—Username of an account. This parameter is required for each user account. The username is a case-sensitive string of 1 to 55 characters. The name cannot be **a**, **al**, or **all**. It cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), or right angle bracket (>). If the username of an account contains an invalid character, the import process interrupts.
- **Password form**—Plaintext or encrypted form. By default, a password is in encrypted form.
- **Password**—Password of an account. A password in encrypted form is a case-sensitive string of 1 to 117 characters. A password in plaintext form is a case-sensitive string of 1 to 63 characters. If the device fails to parse the password or the password is empty, the device imports the account without a password.
- **Authorization user group**—User group to which a user belongs after the user passes local authentication. The group name is a case-insensitive string of 1 to 32 characters. If the parameter is empty, the device assigns the user to the system-defined user group **system**.
- **Identity groups**—Groups for identity-based access control. A user can belong to multiple identity groups. An identity group name is a case-insensitive string of 1 to 32 characters. Separate identity group names by the string of 0x0A. If the parameter is empty for a user, the user does not belong to any identity group.
- **Service types**—Services to assign to the user. Available services include portal, PPP, IPoE, LAN access, ADVPN, SSL VPN, and IKE. A service name is case insensitive. Separate service types by the string of 0x0A. If the parameter is empty for a user, the user cannot use any service.

- **Max concurrent logins**—The maximum number of online users with the same user name. The value range is 1 to 1024. If the parameter is empty, the device does not restrict the number of online users with the same user name.

Separate different accounts by a carriage return and separate each parameter value of the same account by a comma (,). To ensure a successful user information import, make sure no spaces are included in the contents. For example,

```
Jack,$c$3$uM6DH5empTfbsx341Qk/ORGozkbxNE0=,author-group1,parent-group1(0x0A)parent-group2,portal,1024
Mary,$c$3$YpVonswJTN1dVMEev+zu2pgrCIIJ,author-group2,parent-group1(0x0A)parent-group2,portal,800
```

When you edit the .csv file, follow these restrictions and guidelines:

- Start lines with pound signs (#) to contain explanation information for usage guidelines. The device does not import the lines as user account information.
- Separate parameter values by a comma (,). To avoid ambiguity, you must enclose the value of a parameter into single quotation marks (') if the value contains a comma (,). For example, if the authorization user group of a user is named as **author,group**, you must specify the authorization user group name as **'author,group'** in the .csv file.

The device supports TFTP and FTP file transfer modes. Table 8 describes the valid URL formats of the .csv file.

Table 8 URL formats

Protocol	URL format	Description
TFTP	**tftp://***server*/*path*/*filename*	Specify a TFTP server by IP address or hostname. For example, tftp://1.1.1.1/user/user.csv.
FTP	• With FTP user name and password: **ftp://***username*:*password*@*server*/*path*/*filename* • Without FTP user name and password: **ftp://***server*/*path*/*filename*	Specify an FTP server by IP address or hostname. The device ignores the domain name in the FTP user name. For example, specify the file path as **ftp://1:1@1.1.1.1/user/user.csv** or **ftp://1.1.1.1/user/user.csv**.

Examples

Import user account information from the **localuser.csv** file in the **ftp://1.1.1.1/user/** path, and create network access users based on the imported information. Specify the device to ignore the accounts that have the same name as the existing accounts on the device. Enable the device to automatically create the user group of an imported network access user if the user group does not exist on the device.

```
<Sysname> system-view
[Sysname] local-user-import class network url ftp://1.1.1.1/user/localuser.csv auto-create-group
```

Related commands

display local-user

local-user-export class network

local-user-import class network guest

Use **local-user-import class network guest** to import local guest account information from a .csv file in the specified path to the device to create local guests based on the imported information.

Syntax

local-user-import class network guest url *url-string* **validity-datetime** *start-date start-time* **to** *expiration-date expiration-time* [**auto-create-group** | **override** | **start-line** *line-number*] *

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

url *url-string*: Specifies the source file path. The *url-string* argument is a case-insensitive string of 1 to 255 characters.

validity-datetime: Specifies the guest validity period of the local guests. The expiration date and time must be later than the start date and time.

start-date: Specifies the start date of the validity period, in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for the MM argument is 1 to 12. The value range for the DD argument varies with the specified month. The value range for the YYYY argument is 2000 to 2035.

start-time: Specifies the start time of the validity period, in the format of hh:mm:ss. The value range for the hh argument is 0 to 23. The value range for the mm and ss arguments is 0 to 59. The mm and ss arguments are optional. For example, enter 1 to indicate 1:00:00. A value of 0 indicates 00:00:00.

to: Specifies the end date and time of the validity period.

expiration-date: Specifies the expiration date in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for the MM argument is 1 to 12. The value range for the DD argument varies with the specified month. The value range for the YYYY argument is 2000 to 2035.

expiration-time: Specifies the expiration time in the format of hh:mm:ss. The value range for the hh argument is 0 to 23. The value range for the mm and ss arguments is 0 to 59. The mm and ss arguments are optional. For example, enter 1 to indicate 1:00:00. A value of 0 indicates 00:00:00.

auto-create-group: Enables the device to automatically create user groups for the imported local guests if the groups in the imported information do not exist on the device. If you do not specify this keyword, the device adds all imported local guests to the system-defined user group named **system**.

override: Enables the device to override the existing account with the same name as an imported guest account. If you do not specify this keyword, the device retains the existing account and does not import the local guest with the same name.

start-line *line-number*: Specifies the number of the line at which the account import begins. If you do not specify a line number, this command imports all accounts in the .csv file.

Usage guidelines

The .csv file contains multiple parameters for each account and the parameters must be strictly arranged in the following order:

- **Username**—Username of the guest account. The username is required for each guest account. The username cannot contain any of the following characters: forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), or right angle bracket (>). The name cannot be **a**, **al**, or **all**. Any invalid character results in account import failure and interruption.
- **Password**—Password of the guest account in plaintext form. If the password is empty, the device generates a random password in encrypted form for the guest.
- **User group**—User group to which the guest belongs. If the user group is empty, the device assigns the guest to the system-defined user group named **system**.
- **Guest full name**—Name of the guest.
- **Guest company**—Company of the guest.
- **Guest email**—Email address of the guest.
- **Guest phone**—Phone number of the guest.
- **Guest description**—Description of the guest.
- **Sponsor full name**—Name of the guest sponsor.
- **Sponsor department**—Department of the guest sponsor.
- **Sponsor email**—Email address of the guest sponsor.

The value of each parameter in the file must meet the requirements of the local user attributes on the device. Any violation results in account import failure and interruption. The system displays the number of the line where the account import is interrupted.

Separate different account entries by a carriage return and separate each parameter value in an account entry by a comma (,). If the value of a parameter contains a comma (,), you must enclose the value within a pair of quotation marks ("") to avoid ambiguity. For example,

```
Jack,abc,visit,Jack Chen,ETP,jack@etp.com,1399899,"The manager of ETP, come from TP.",Sam Wang,Ministry of personnel,Sam@yy.com
```

The device supports TFTP and FTP file transfer modes. Table 9 describes the valid URL formats of the .csv file.

Table 9 URL formats

Protocol	URL format	Description
TFTP	**tftp://***server*/*path*/*filename*	Specify a TFTP server by IP address or hostname. For example, specify the file path as **tftp://1.1.1.1/user/user.csv**.
FTP	• With FTP user name and password: **ftp://***username*:*password*@*server*/*path*/*filename* • Without FTP user name and password: **ftp://***server*/*path*/*filename*	Specify an FTP server by IP address or hostname. The device ignores the domain name in the FTP user name. For example, specify the file path as **ftp://1:1@1.1.1.1/user/user.csv** or **ftp://1.1.1.1/user/user.csv**.

Examples

Import guest account information from the **ftp://1.1.1.1/user/guest.csv** file and specify a validity period for the imported guests.

```
<Sysname> system-view
[Sysname] local-user-import class network guest url ftp://1.1.1.1/user/guest.csv
validity-datetime 2018/10/01 00:00:00 to 2019/10/02 12:00:00
```

Parameters

hash: Specifies a password encrypted by the hash algorithm.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in hashed form.

string: Specifies the password string. This argument is case sensitive. The hashed form of the password is a string of 1 to 110 characters. The plaintext form of the password is a string of 1 to 63 characters.

Usage guidelines

If you do not specify any parameters, you enter the interactive mode to set a plaintext password.

A device management user for which no password is specified can pass authentication after entering the correct username and passing attribute checks. To enhance security, configure a password for each device management user.

When global password control is enabled, the device handles passwords of device management users as follows:

- All passwords in the history records are saved in hashed form.
- If a user changes its own password in plaintext form, the system requests the user to enter the current plaintext password. The new password must be different from all passwords in the history records and the current password. In addition, the new password must have a minimum of four characters different from the current password.
- If a user changes the password for another user in plaintext form, the new password must be different from the latter user's all passwords in the history records and current password.
- If a user deletes its own password, the system requests the user to enter the current plaintext password.
- Except the above listed situations, the system does not request a user to enter the current plaintext password or compare the new password with passwords in the history records and the current password.

Examples

Set the password to **123456TESTplat&!** in plaintext form for device management user **user1**.

```
<Sysname> system-view
[Sysname] local-user user1 class manage
[Sysname-luser-manage-user1] password simple 123456TESTplat&!
```

Configure the password in interactive mode for device management user **test**.

```
<Sysname> system-view
[Sysname] local-user test class manage
[Sysname-luser-manage-test] password
Password:
confirm :
```

Related commands

display local-user

password (network access user view)

Use **password** to configure a password for a network access user.

Use **undo password** to restore the default.

Syntax

password { **cipher** | **simple** } *string*

undo password

Default

A network access user does not have a password and cannot pass authentication.

Views

Network access user view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password string. Its plaintext form is a case-sensitive string of 1 to 63 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

As a best practice to enhance security, configure a password for each network access user.

Examples

Set the password to **123456TESTuser&!** in plaintext form for network access user **user1**.

```
<Sysname> system-view
[Sysname] local-user user1 class network
[Sysname-luser-network-user1] password simple 123456TESTuser&!
```

Related commands

display local-user

phone

Use **phone** to specify the phone number of a local guest.

Use **undo phone** to restore the default.

Syntax

phone *phone-number*

undo phone

Default

No phone number is specified for a local guest.

Views

Local guest view

Predefined user roles

network-admin

context-admin

Parameters

phone-number: Specifies the phone number, a string of 1 to 32 characters.

Examples

Specify the phone number as **13813723920** for local guest **abc**.

```
<Sysname> system-view
[Sysname] local-user abc class network guest
[Sysname-luser-network(guest)-abc] phone 13813723920
```

Related commands

display local-user

reset local-guest waiting-approval

Use **reset local-guest waiting-approval** to clear pending registration requests for local guests.

Syntax

reset local-guest waiting-approval [**user-name** *user-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

user-name *user-name*: Specifies a local guest by its username, a string of 1 to 55 characters. If you do not specify a guest, this command clears information about all registration requests for local guests. The username can be a pure username or a username containing a domain name.

- If the username does not contain an at sign (@), all characters in the username string are case sensitive. The device parses the username as a pure username. The username cannot be **a**, **al**, or **all**, and it cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), or right angle bracket (>).
- If the username contains an at sign (@), it must be in the format of xxx@yyy. The at sign (@) is the delimiter between the pure username and the domain name.
  - The xxx part is case sensitive. It cannot contain a forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@), and cannot be **a**, **al**, or **all**.
  - The yyy part is case insensitive and cannot contain an at sign (@).

Examples

Clear information about all registration requests for local guests.

```
<Sysname> reset local-guest waiting-approval
```

Related commands

display local-guest waiting-approval

service-type (local user view)

Use **service-type** to specify the service types that a local user can use.

Use **undo service-type** to remove service types configured for a local user.

Syntax

service-type { **advpn** | **ftp** | **ike** | **ipoe** | **lan-access** | { **http** | **https** | **ssh** | **telnet** | **terminal** } * | **portal** | **ppp** | **sslvpn** }

undo service-type { **advpn** | **ftp** | **ike** | **ipoe** | **lan-access** | { **http** | **https** | **ssh** | **telnet** | **terminal** } * | **portal** | **ppp** | **sslvpn** }

Default

A local user is not authorized to use any service.

Views

Local user view

Predefined user roles

network-admin

context-admin

Parameters

advpn: Authorizes the user to use the ADVPN service.

ftp: Authorizes the user to use the FTP service. The authorized directory can be modified by using the **authorization-attribute work-directory** command.

http: Authorizes the user to use the HTTP service.

https: Authorizes the user to use the HTTPS service.

ike: Authorizes the user to use the IKE extended authentication service.

ipoe: Authorizes the user to use the IPoE service.

ssh: Authorizes the user to use the SSH service.

telnet: Authorizes the user to use the Telnet service.

terminal: Authorizes the user to use the terminal service and log in from a console port.

portal: Authorizes the user to use the portal service.

ppp: Authorizes the user to use the PPP service.

sslvpn: Authorizes the user to use the SSL VPN service.

Usage guidelines

You can assign multiple service types to a user.

Examples

Authorize device management user **user1** to use the Telnet and FTP services.

```
<Sysname> system-view
[Sysname] local-user user1 class manage
[Sysname-luser-manage-user1] service-type telnet
[Sysname-luser-manage-user1] service-type ftp
```

display local-user

state (local user view)

Use **state** to set the status of a local user.

Use **undo state** to restore the default.

Syntax

state { **active** | **block** }

undo state

Default

A local user is in active state.

Views

Local user view

Predefined user roles

network-admin

context-admin

Parameters

active: Places the local user in active state to allow the local user to request network services.

block: Places the local user in blocked state to prevent the local user from requesting network services.

Examples

Place device management user **user1** in blocked state.

```
<Sysname> system-view
[Sysname] local-user user1 class manage
[Sysname-luser-manage-user1] state block
```

Related commands

display local-user

user-group

Use **user-group** to create a user group and enter its view, or enter the view of an existing user group.

Use **undo user-group** to delete a user group.

Syntax

user-group *group-name*

undo user-group *group-name*

Default

A system-defined user group exists. The group name is **system**.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies the user group name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

A user group consists of a group of local users and has a set of local user attributes. You can configure local user attributes for a user group to implement centralized management of user attributes for the local users in the group.

You cannot use the **undo user-group** command to delete a user group that has local users.

You can modify settings for the system-defined user group named **system**, but you cannot delete the user group.

Examples

Create a user group named **abc** and enter user group view.

```
<Sysname> system-view
[Sysname] user-group abc
[Sysname-ugroup-abc]
```

Related commands

display user-group

validity-datetime

Use **validity-datetime** to specify the validity period for a network access user.

Use **undo validity-datetime** to restore the default.

Syntax

Network access user view:

validity-datetime { **from** *start-date start-time* **to** *expiration-date expiration-time* | **from** *start-date start-time* | **to** *expiration-date expiration-time* }

undo validity-datetime

Local guest view:

validity-datetime from *start-date start-time* **to** *expiration-date expiration-time*

undo validity-datetime

Default

The validity period for a network access user does not expire.

Views

Network access user view

Local guest view

Predefined user roles

network-admin

context-admin

Parameters

from: Specifies the validity start date and time for the user. If you do not specify this option, the command defines only the expiration date and time of the user.

start-date: Specifies the date on which the user becomes effective. The date is in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for the MM argument is 1 to 12. The value range for the DD argument varies with the specified month. The value range for the YYYY argument is 2000 to 2035.

start-time: Specifies the time on the day when the user becomes effective. The time is in the format of hh:mm:ss. The value range for the hh argument is 0 to 23. The value range for the mm and ss arguments is 0 to 59. The mm and ss arguments are optional. For example, enter 1 to indicate 1:00:00. A value of 0 indicates 00:00:00.

to: Specifies the expiration date and time for the user. If you do not specify this option, the command defines only the validity start date and time of the user.

expiration-date: Specifies the expiration date in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for the MM argument is 1 to 12. The value range for the DD argument varies with the specified month. The value range for the YYYY argument is 2000 to 2035.

expiration-time: Specifies the expiration time in the format of hh:mm:ss. The value range for the hh argument is 0 to 23. The value range for the mm and ss arguments is 0 to 59. The mm and ss arguments are optional. For example, enter 1 to indicate 1:00:00. A value of 0 indicates 00:00:00.

Usage guidelines

Expired network access user accounts cannot be used for authentication.

When both **from** and **to** options are specified, the expiration date and time must be later than the validity start date and time.

When only the **from** option is specified, the network access user is valid since the specified date and time.

When only the **to** option is specified, the network access user is valid until the specified date and time.

Examples

Specify the validity period for network access user **123**.

```
<Sysname> system-view
[Sysname] local-user 123 class network
[Sysname-luser-network-123] validity-datetime from 2018/10/01 00:00:00 to 2019/10/02
12:00:00
```

Related commands

display local-user

RADIUS commands

aaa device-id

Use **aaa device-id** to configure the device ID.

Use **undo aaa device-id** to restore the default.

Syntax

aaa device-id *device-id*

undo aaa device-id

Default

The device ID is 0.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

device-id: Specifies a device ID in the range of 1 to 255.

Usage guidelines

RADIUS uses the value of the Acct-Session-ID attribute as the accounting ID for a user. The device generates an Acct-Session-ID value that includes the device ID for each online user.

If you modify the device ID, the new device ID does not take effect on users that have been online during the change.

Examples

Configure the device ID as 1.

```
<Sysname> system-view
[Sysname] aaa device-id 1
```

accounting-on enable

Use **accounting-on enable** to configure the accounting-on feature.

Use **undo accounting-on enable** to disable the accounting-on feature.

Syntax

accounting-on enable [**interval** *interval* | **send** *send-times*] *

undo accounting-on enable

Default

The accounting-on feature is disabled.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

interval *interval*: Specifies the time interval for retransmitting an accounting-on packet in seconds. The value range for the *interval* argument is 1 to 15, and the default setting is 3.

send *send-times*: Specifies the maximum number of accounting-on packet transmission attempts. The value range for the *send-times* argument is 1 to 255, and the default setting is 50.

Usage guidelines

This feature enables the device to automatically monitor the status of all accounting servers in the RADIUS scheme and then send accounting-on packets to the reachable servers after a reboot. The accounting-on packets are used to request the RADIUS servers to stop accounting on all online users on the device and to log out the users.

Execute the **save** command to ensure that the **accounting-on enable** command takes effect at the next device reboot. For information about the **save** command, see *Fundamentals Command Reference*.

Parameters set by using the **accounting-on enable** command take effect immediately.

Examples

Enable the accounting-on feature for RADIUS scheme **radius1**, and set the retransmission interval to 5 seconds and the transmission attempts to 15.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] accounting-on enable interval 5 send 15
```

display radius scheme

attribute 15 check-mode

Use **attribute 15 check-mode** to configure the Login-Service attribute check method for SSH, FTP, and terminal users.

Use **undo attribute 15 check-mode** to restore the default.

Syntax

attribute 15 check-mode { **loose** | **strict** }

undo attribute 15 check-mode

Default

The strict check method applies for SSH, FTP, and terminal users.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

loose: Matches the standard Login-Service attribute value 0 for SSH, FTP, and terminal services.

strict: Matches Login-Service attribute values 50, 51, and 52 for SSH, FTP, and terminal services, respectively.

Usage guidelines

Use the loose check method only when the server does not issue Login-Service attribute values 50, 51, and 52 for SSH, FTP, and terminal users.

Examples

Configure the Login-Service attribute check method as **loose** for SSH, FTP, and terminal users in RADIUS scheme **radius1**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute 15 check-mode loose
```

Related commands

display radius scheme

attribute 17 old-password

Use **attribute 17 old-password** to enable online user password change by using RADIUS attribute 17.

Use **undo attribute 17 old-password** to restore the default.

Syntax

attribute 17 old-password

undo attribute 17 old-password

Default

Online user password change is disabled.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Usage guidelines

When this feature is enabled, the process of online password change is as follows for a user when the user passes authentication:

1. If the RADIUS authentication server sends an Access-Challenge packet that includes the Reply-Message attribute when a user passes authentication, the device prompts the user to change its password.
2. After receiving the password change request from the user, the device sends a RADIUS authentication request to the RADIUS authentication server.

   In the authentication request, the device uses attribute 2 to carry the new user password.
3. When the device receives a response from the RADIUS authentication server, the online user's password is changed successfully.

When this feature is enabled, the process of online password change is as follows for an online user:

1. After receiving the password change request from the user, the device sends a RADIUS authentication request to a reachable RADIUS server. In the authentication request, the device uses attribute 2 and attribute 17 to carry the new user password and old user password, respectively.

   The RADIUS server selection process for online password change is the same as the process used to select a RADIUS authentication server. Online password change might fail because the device selects a RADIUS server different from the RADIUS server that authenticated the user.
2. When the device receives a response from the selected RADIUS server, the online user's password is changed successfully.

This feature is applicable only to SSL VPN users.

Do not enable this feature if the RADIUS server does not support online user password change.

In a RADIUS scheme with this feature enabled, do not configure parsing rules for the Reply-Message attribute by using the **attribute 18 match** command. A violation will cause this feature fail to take effect.

Examples

In RADIUS scheme **radius1**, enable online user password change by using RADIUS attribute 17.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute 17 old-password
```

Related commands

attribute 18 match

display radius scheme

attribute 18 match

Use **attribute 18 match** to configure a parsing rule for the RADIUS Reply-Message attribute.

Use **undo attribute 18 match** to remove a parsing rule for the RADIUS Reply-Message attribute.

Syntax

attribute 18 match *string* **action** { **new-password** | **next-token** }

undo attribute 18 match *string* **action**

Default

No parsing rules for the RADIUS Reply-Message attribute are configured. The device parses the Reply-Message attribute as to prompt users to enter the next authentication factor for double-factor authentication.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

string: Specifies a match criterion, a case-sensitive string of 1 to 255 characters. To include spaces in the string, enclose the entire string in double quotation marks ("").

action: Specifies the action that the device prompts users to take if the attribute value matches the match criterion.

new-password: Enters the new password.

next-token: Enters the next authentication factor for double-factor authentication.

Usage guidelines

The RADIUS Reply-Message attribute (attribute 18) is intended for the RADIUS server to return a message to users. In the Access-Challenge packets, this attribute indicates the action that the RADIUS server expects users to take. For the access device to correctly parse this attribute, you can configure parsing rules for this attribute. For example, the device needs to parse the Reply-Message attribute containing the **new pin** string as to prompt users to change the passwords online.

Each parsing rule contains a match criterion and an action. The device uses the fuzzy match method to match the Reply-Message attribute value against the match criterion. If the attribute value partially matches the match criterion, the device prompts the users to take the action specified in the parsing rule.

This feature is applicable only to SSL VPN users.

Before you configure parsing rules, make sure you fully understand the implications of the Reply-Message attribute defined by the RADIUS server.

For a RADIUS scheme, you can configure a maximum of 18 parsing rules for the Reply-Message attribute. Make sure the match criterion in each parsing rule is not contained by the match criterion of another parsing rule.

When parsing rules for the Reply-Message attribute are configured, the online user password change feature configured by using the **attribute 17 old-password** command does not take effect. As a best practice, do not configure both parsing rules and online user password change in the same RADIUS scheme.

Examples

In RADIUS scheme **radius1**, configure a parsing rule for the Reply-Message attribute. According to this rule, the device will prompt users to enter the new password if the Reply-Message attribute contain string **new pin**.

```
<Sysname> system-view
[sysname] radius scheme radius1
[sysname-radius-radius1] attribute 18 match “new pin” action new-password
```

Related commands

attribute 30 mac-format

Use **attribute 30 mac-format** to configure the format of the MAC address in the RADIUS Called-Station-Id attribute.

Use **undo attribute 30 mac-format** to restore the default.

Syntax

attribute 30 mac-format section { **one** | { **six** | **three** } **separator** *separator-character* } { **lowercase** | **uppercase** }

undo attribute 30 mac-format

Default

The MAC address in the RADIUS Called-Station-Id attribute is in the format of HH-HH-HH-HH-HH-HH. The MAC address is separated by hyphens (-) into six sections with letters in upper case.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

section: Specifies the number of sections that a MAC address contains.

one: Specifies the one-section format HHHHHHHHHHHH.

six: Specifies the six-section format HH-HH-HH-HH-HH-HH.

three: Specifies the three-section format HHHH-HHHH-HHHH.

separator *separator-character*: Specifies a case-sensitive character that separates the sections.

lowercase: Specifies the letters in a MAC address to be in lower case.

uppercase: Specifies the letters in a MAC address to be in upper case.

Usage guidelines

Configure the format of the MAC address in the RADIUS Called-Station-Id attribute to meet the requirements of the RADIUS servers.

Examples

In RADIUS scheme **radius1**, specify **hhhhhhhhhhhh** as the format of the MAC address in the RADIUS Called-Station-Id attribute.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute 30 mac-format section one lowercase
```

Related commands

Syntax

attribute 31 mac-format section { **one** | { **six** | **three** } **separator** *separator-character* } { **lowercase** | **uppercase** }

undo attribute 31 mac-format

Default

The MAC address in the RADIUS Calling-Station-Id attribute (attribute 31) is in the format of HH-HH-HH-HH-HH-HH. The MAC address is separated by hyphens (-) into six sections with letters in upper case.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

section: Specifies the number of sections that a MAC address contains.

one: Specifies the one-section format HHHHHHHHHHHH.

six: Specifies the six-section format HH-HH-HH-HH-HH-HH.

three: Specifies the three-section format HHHH-HHHH-HHHH.

separator *separator-character*: Specifies a case-sensitive character that separates the sections.

lowercase: Specifies the letters in a MAC address to be in lower case.

uppercase: Specifies the letters in a MAC address to be in upper case.

Usage guidelines

Configure the format of the MAC address in the RADIUS Calling-Station-Id attribute to meet the requirements of the RADIUS servers.

Examples

In RADIUS scheme **radius1**, specify **hh:hh:hh:hh:hh:hh** as the format of the MAC address in the RADIUS Calling-Station-Id attribute.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute 31 mac-format section six separator : lowercase
```

Related commands

display radius scheme

attribute 182 vendor-id 25506 vlan

Use **attribute 182 vendor-id 25506 vlan** to enable the device to interpret the Microsegment-Id attribute to an authorization VLAN.

Use **undo attribute 182 vendor-id 25506 vlan** to disable the device from interpreting the Microsegment-Id attribute to an authorization VLAN.

Syntax

attribute 182 vendor-id 25506 vlan

undo attribute 182 vendor-id 25506 vlan

Default

The device is disabled from interpreting the Microsegment-Id attribute to an authorization VLAN.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this command only when the RADIUS server uses authorization microsegment IDs for granular user access control and the access device uses authorization VLANs to implement microsegment-based access control.

This feature enables the device to interpret the RADIUS Microsegment-Id attribute (attribute 182 with vendor ID 25506) assigned by the RADIUS server to an authorization VLAN.

- If the attribute value is an integer, the device interprets this attribute to a VLAN ID.
- If the attribute value is not an integer, the device interprets this attribute to a VLAN name.

If the RADIUS server uses a RADIUS attribute other than the Microsegment-Id attribute to assign microsegment IDs, you must first convert the attribute to the Microsegment-Id attribute. To enable RADIUS attribute translation feature, use the **attribute translate** command.

Examples

In RADIUS scheme **radius1**, enable the device to interpret the Microsegment-Id attribute to an authorization VLAN.

```
<Sysname> system-view
[Sysname] radius scheme radius1
```

```
[Sysname-radius-radius1] attribute 182 vendor-id 25506 vlan
```

Related commands

attribute translate

display radius scheme

attribute convert (RADIUS DAS view)

Use **attribute convert** to configure a RADIUS attribute conversion rule.

Use **undo attribute convert** to delete RADIUS attribute conversion rules.

Syntax

attribute convert *src-attr-name* **to** *dest-attr-name* { { **coa-ack** | **coa-request** } * | { **received** | **sent** } * }

undo attribute convert [*src-attr-name*]

Default

No RADIUS attribute conversion rules exist. The system processes RADIUS attributes according to the principles of the standard RADIUS protocol.

Views

RADIUS DAS view

Predefined user roles

network-admin

context-admin

Parameters

src-attr-name: Specifies the source RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The attribute must be supported by the system.

dest-attr-name: Specifies the destination RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The attribute must be supported by the system.

coa-ack: Specifies the CoA acknowledgment packets.

coa-request: Specifies the CoA request packets.

received: Specifies the received DAE packets.

sent: Specifies the sent DAE packets.

Usage guidelines

The device replaces the attribute in packets that match a RADIUS attribute conversion rule with the destination RADIUS attribute in the rule.

The conversion rules take effect only when the RADIUS attribute translation feature is enabled.

When you configure RADIUS attribute conversion rules, follow these restrictions and guidelines:

- The source and destination RADIUS attributes in a rule must use the same data type.
- The source and destination RADIUS attributes in a rule cannot use the same name.
- A source RADIUS attribute can be converted only by one criterion, packet type or direction.
- One source RADIUS attribute cannot be converted to multiple destination attributes.

If you do not specify a source RADIUS attribute, the **undo attribute convert** command deletes all RADIUS attribute conversion rules.

Examples

In RADIUS DAS view, configure a RADIUS attribute conversion rule to replace the Hw-Server-String attribute in the received DAE packets with the Connect-Info attribute.

```
<Sysname> system-view
[Sysname] radius dynamic-author server
[Sysname-radius-da-server] attribute convert Hw-Server-String to Connect-Info received
```

Related commands

attribute translate

attribute convert (RADIUS scheme view)

Use **attribute convert** to configure a RADIUS attribute conversion rule.

Use **undo attribute convert** to delete RADIUS attribute conversion rules.

Syntax

attribute convert *src-attr-name* **to** *dest-attr-name* { { **access-accept** | **access-request** | **accounting** } * | { **received** | **sent** } * }

undo attribute convert [*src-attr-name*]

Default

No RADIUS attribute conversion rules exist. The system processes RADIUS attributes according to the principles of the standard RADIUS protocol.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

src-attr-name: Specifies the source RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The attribute must be supported by the system.

dest-attr-name: Specifies the destination RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The attribute must be supported by the system.

access-accept: Specifies the RADIUS Access-Accept packets.

access-request: Specifies the RADIUS Access-Request packets.

accounting: Specifies the RADIUS accounting packets.

received: Specifies the received RADIUS packets.

sent: Specifies the sent RADIUS packets.

Usage guidelines

The device replaces the attribute in packets that match a RADIUS attribute conversion rule with the destination RADIUS attribute in the rule.

The conversion rules take effect only when the RADIUS attribute translation feature is enabled.

When you configure RADIUS attribute conversion rules, follow these restrictions and guidelines:

- The source and destination RADIUS attributes in a rule must use the same data type.
- The source and destination RADIUS attributes in a rule cannot use the same name.

- A source RADIUS attribute can be converted only by one criterion, packet type or direction.
- One source RADIUS attribute cannot be converted to multiple destination attributes.

If you do not specify a source RADIUS attribute, the **undo attribute convert** command deletes all RADIUS attribute conversion rules.

Examples

In RADIUS scheme **radius1**, configure a RADIUS attribute conversion rule to replace the Hw-Server-String attribute of received RADIUS packets with the Connect-Info attribute.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute convert Hw-Server-String to Connect-Info received
```

Related commands

attribute translate

attribute reject (RADIUS DAS view)

Use **attribute reject** to configure a RADIUS attribute rejection rule.

Use **undo attribute reject** to delete RADIUS attribute rejection rules.

Syntax

attribute reject *attr-name* { { **coa-ack** | **coa-request** } * | { **received** | **sent** } * }

undo attribute reject [*attr-name*]

Default

No RADIUS attribute rejection rules exist.

Views

RADIUS DAS view

Predefined user roles

network-admin

context-admin

Parameters

attr-name: Specifies a RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The attribute must be supported by the system.

coa-ack: Specifies the CoA acknowledgment packets.

coa-request: Specifies the CoA request packets.

received: Specifies the received DAE packets.

sent: Specifies the sent DAE packets.

Usage guidelines

Configure RADIUS attribute rejection rules for the following purposes:

- Delete attributes from the RADIUS packets to be sent if the destination RADIUS server does not identify the attributes.
- Ignore unwanted attributes in the RADIUS packets received from a RADIUS server.

The RADIUS attribute rejection rules take effect only when the RADIUS attribute translation feature is enabled.

A RADIUS attribute can be rejected only by one criterion, packet type or direction.

If you do not specify a RADIUS attribute, the **undo attribute reject** command deletes all RADIUS attribute rejection rules.

Examples

In RADIUS DAS view, configure a RADIUS attribute rejection rule to delete the Connect-Info attribute from the DAE packets to be sent.

```
<Sysname> system-view
[Sysname] radius dynamic-author server
[Sysname-radius-da-server] attribute reject Connect-Info sent
```

Related commands

Parameters

attr-name: Specifies a RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The attribute must be supported by the system.

access-accept: Specifies the RADIUS Access-Accept packets.

access-request: Specifies the RADIUS Access-Request packets.

accounting: Specifies the RADIUS accounting packets.

received: Specifies the received RADIUS packets.

sent: Specifies the sent RADIUS packets.

Usage guidelines

Configure RADIUS attribute rejection rules for the following purposes:

- Delete attributes from the RADIUS packets to be sent if the destination RADIUS server does not identify the attributes.
- Ignore unwanted attributes in the RADIUS packets received from a RADIUS server.

The RADIUS attribute rejection rules take effect only when the RADIUS attribute translation feature is enabled.

A RADIUS attribute can be rejected only by one criterion, packet type or direction.

If you do not specify a RADIUS attribute, the **undo attribute reject** command deletes all RADIUS attribute rejection rules.

Examples

In RADIUS scheme **radius1**, configure a RADIUS attribute rejection rule to delete the Connect-Info attribute from the RADIUS packets to be sent.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute reject Connect-Info sent
```

Related commands

attribute translate

attribute remanent-volume

Use **attribute remanent-volume** to set the data measurement unit for the Remanent_Volume attribute.

Use **undo attribute remanent-volume** to restore the default.

Syntax

attribute remanent-volume unit { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** }

undo attribute remanent-volume unit

Default

The data measurement unit is kilobyte for the Remanent_Volume attribute.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

byte: Specifies the unit as byte.

giga-byte: Specifies the unit as gigabyte.

kilo-byte: Specifies the unit as kilobyte.

mega-byte: Specifies the unit as megabyte.

Usage guidelines

Make sure the measurement unit is the same as the user data measurement unit on the RADIUS server.

Examples

In RADIUS scheme **radius1**, set the data measurement unit to **kilobyte** for the Remanent_Volume attribute.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute remanent-volume unit kilo-byte
```

Related commands

display radius scheme

attribute translate

Use **attribute translate** to enable the RADIUS attribute translation feature.

Use **undo attribute translate** to disable the RADIUS attribute translation feature.

Syntax

attribute translate

undo attribute translate

Default

The RADIUS attribute translation feature is disabled.

Views

RADIUS DAS view

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Usage guidelines

To cooperate with RADIUS servers of different vendors, enable the RADIUS attribute translation feature. Configure RADIUS attribute conversion rules and rejection rules to ensure that RADIUS attributes in the packets exchanged between the device and the server are supported by both sides.

Examples

Enable the RADIUS attribute translation feature for RADIUS scheme **radius1**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute translate
```

Related commands

attribute reject (RADIUS DAS view)

attribute reject (RADIUS scheme view)

attribute vendor-id 2011 version

Use **attribute vendor-id 2011 version** to specify the version of the RADIUS servers with a vendor ID of 2011.

Use **undo attribute vendor-id 2011 version** to restore the default.

Syntax

attribute vendor-id 2011 version { **1.0** | **1.1** }

undo attribute vendor-id 2011 version

Default

The version is 1.0.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

`1.0`: Specifies version 1.0.

`1.1`: Specifies version 1.1.

Usage guidelines

For the device to correctly interpret RADIUS attributes from the servers with a vendor ID of 2011, specify a server version the same as the actual version of the RADIUS servers.

The following table shows the differences in the way that the device interprets the vendor-specific RADIUS attributes assigned by different versions of RADIUS servers with vendor ID 2011.

RADIUS attribute	RADIUS server with version 1.0	RADIUS server with version 1.1
HW_ARRT_26_1	Upstream peak rate	Upstream burst size
HW_ARRT_26_2	Upstream average rate	Upstream average rate
HW_ARRT_26_3	N/A	Upstream peak rate
HW_ARRT_26_4	Downstream peak rate	Downstream burst size
HW_ARRT_26_5	Downstream average rate	Downstream average rate
HW_ARRT_26_6	N/A	Downstream peak rate

Examples

In RADIUS scheme **radius1**, specify the version of the RADIUS servers with a vendor ID of 2011 as version 1.1.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute vendor-id 2011 version 1.1
```

Related commands

`display radius scheme`

client

Use **`client`** to specify a RADIUS DAC.

Use **`undo client`** to remove a RADIUS DAC.

Syntax

client { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**key** { **cipher** | **simple** } *string* | **vendor-id 2011 version** { **1.0** | **1.1** } | **vpn-instance** *vpn-instance-name*] *

undo client { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

Default

No RADIUS DACs are specified.

Views

RADIUS DAS view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies a DAC by its IPv4 address.

ipv6 *ipv6-address*: Specifies a DAC by its IPv6 address.

key: Specifies the shared key for secure communication between the RADIUS DAC and server. Make sure the shared key is the same as the key configured on the RADIUS DAC. If the RADIUS DAC does not have any shared key, do not specify this option.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. The encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters.

vendor-id 2011: Specifies the vendor-ID of the DAC as 2011.

version: Specifies the version of the DAC.

1.0: Specifies the DAC version as version 1.0.

1.1: Specifies the DAC version as version 1.1.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the RADIUS DAC belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the server is on the public network, do not specify this option.

Usage guidelines

With the RADIUS DAS feature, the device listens to the default or specified UDP port to receive DAE requests from the specified DACs. The device processes the requests and sends DAE responses to the DACs.

The device discards any DAE packets sent from DACs that are not specified for the DAS.

You can execute the **client** command multiple times to specify multiple DACs for the DAS.

To work with a DAC with vendor-ID 2011 and version 1.0, you do not need to specify the vendor-ID or version attribute. To work with a DAC with vendor-ID 2011 and version 1.1, you must specify the **vendor-id 2011 version 1.1** keywords.

Examples

Specify the DAC as 10.110.1.2. Set the shared key to **123456** in plaintext form for secure communication between the DAS and DAC.

```
<Sysname> system-view
[Sysname] radius dynamic-author server
[Sysname-radius-da-server] client ip 10.110.1.2 key simple 123456
```

Related commands

radius dynamic-author server

port

data-flow-format (RADIUS scheme view)

Use **data-flow-format** to set the data flow and packet measurement units for traffic statistics.

Use **undo data-flow-format** to restore the default.

Syntax

data-flow-format { **data** { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** } | **packet** { **giga-packet** | **kilo-packet** | **mega-packet** | **one-packet** } } *

undo data-flow-format { **data** | **packet** }

Default

Traffic is counted in bytes and packets.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

data: Specifies the unit for data flows.

byte: Specifies the unit as byte.

giga-byte: Specifies the unit as gigabyte.

kilo-byte: Specifies the unit as kilobyte.

mega-byte: Specifies the unit as megabyte.

packet: Specifies the unit for data packets.

giga-packet: Specifies the unit as giga-packet.

kilo-packet: Specifies the unit as kilo-packet.

mega-packet: Specifies the unit as mega-packet.

one-packet: Specifies the unit as one-packet.

Usage guidelines

The data flow and packet measurement units for traffic statistics must be the same as configured on the RADIUS accounting servers. Otherwise, accounting results might be incorrect.

Examples

In RADIUS scheme **radius1**, set the data flow and packet measurement units for traffic statistics to kilobyte and kilo-packet, respectively.

```
<Sysname> system-view
```

```
[Sysname] radius scheme radius1
[Sysname-radius-radius1] data-flow-format data kilo-byte packet kilo-packet
```

Related commands

display radius scheme

display radius scheme

Use **display radius scheme** to display RADIUS scheme configuration.

Syntax

display radius scheme [*radius-scheme-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

radius-scheme-name: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters. If you do not specify a RADIUS scheme, this command displays the configuration of all RADIUS schemes.

Usage guidelines

When displaying configuration only for one scheme, this command also displays the active state duration for each active server and the most recent five state changes for all servers in the scheme.

When displaying configuration for all schemes, this command also displays the active state duration for each active server and the most recent blocked period for all servers in all schemes.

Examples

Display the configuration of all RADIUS schemes.

```
<Sysname> display radius scheme

Table 10 Command output

Field	Description
Index	Index number of the RADIUS scheme.
Primary authentication server	Information about the primary authentication server.
Primary accounting server	Information about the primary accounting server.
Second authentication server	Information about the secondary authentication server.
Second accounting server	Information about the secondary accounting server.
IP	IP address of the server. This field displays **Not configured** if the server is not configured.
Port	Service port number of the server. If no port number is specified, this field displays the default port number.
State	Status of the server: • **Active**—The server is in active state. • **Blocked**—The server is changed to blocked state automatically. • **Blocked (mandatory)**—The server is set to blocked state manually.
duration	The duration of the current active state for the server. This field is displayed only when the server is in active state.
Most recent blocked period	Most recent blocking start time and end time when the server stayed in blocked state. If the server still remains in blocked state, **now** is displayed for the end time.
Most recent state changes	Most recent five state changes of the server.
VPN	MPLS L3VPN instance to which the server or the RADIUS scheme belongs. If no VPN instance is specified for the server, this field displays **Not configured**.
Test profile	Test profile used for RADIUS server status detection.
Probe username	Username used for RADIUS server status detection.

Field	Description
Probe interval	Server status detection interval, in minutes.
Accounting-On function	Whether the accounting-on feature is enabled.
extended function	Whether the extended accounting-on feature is enabled.
retransmission times	Number of accounting-on packet transmission attempts.
retransmission interval(seconds)	Interval at which the device retransmits accounting-on packets, in seconds.
Timeout Interval(seconds)	RADIUS server response timeout period, in seconds.
Retransmission times	Maximum number of attempts for transmitting a RADIUS packet to a single RADIUS server.
Retransmission Times for Accounting Update	Maximum number of accounting attempts.
Server Quiet Period(minutes)	Quiet period for the servers, in minutes.
Realtime Accounting Interval(seconds)	Interval for sending real-time accounting updates, in seconds.
NAS IP Address	Source IP addresses for outgoing RADIUS packets. This field displays **Not configured** if no source IP addresses are specified for outgoing RADIUS packets.
User Name Format	Format for the usernames sent to the RADIUS server: • **with-domain**—Includes the domain name. • **without-domain**—Excludes the domain name. • **keep-original**—Forwards the username as the username is entered.
Data flow unit	Measurement unit for data flow.
Packet unit	Measurement unit for packets.
Attribute 15 check-mode	RADIUS Login-Service attribute check method for SSH, FTP, and terminal users: • **Strict**—Matches Login-Service attribute values 50, 51, and 52 for SSH, FTP, and terminal services, respectively. • **Loose**—Matches the standard Login-Service attribute value 0 for SSH, FTP, and terminal services.
Attribute 25	RADIUS attribute 25 interpretation status: • **Standard**—The attribute is not interpreted as CAR parameters. • **CAR**—The attribute is interpreted as CAR parameters.
Attribute Remanent-Volume unit	Data measurement unit for the RADIUS Remanent_Volume attribute.
RADIUS server version (vendor ID 2011)	Version of the RADIUS servers with a vendor ID of 2011: • 1.0. • 1.1.
Attribute 30 MAC format	Format of the MAC address in the RADIUS Called-Station-Id attribute.
Attribute 31 MAC format	Format of the MAC address in the RADIUS Calling-Station-Id attribute.
Attribute 17 carry old password	Status of online user password change by using RADIUS attribute 17: • **Enabled**—Online user password change by using RADIUS attribute 17 is enabled. The device uses RADIUS attribute 17 to carry a user's old password. • **Disabled**—Online user password change by using RADIUS attribute

Field	Description
	17 is disabled.
Attribute 182 vendor-ID 25506 VLAN	Whether the device is enabled to interpret the Microsegment-Id attribute (attribute 182 with vendor ID 25506) to an authorization VLAN.
Parsing rules for attribute 18	Rules for the device to parse the RADIUS Reply-Message attribute.
If match	Match criterion, a string enclosed by double quotation marks ("").
Action	Action for users to take when the Reply-Message attribute value matches the criterion: • **New password**—Enters the new password. • **Next token**—Enters the netxt authentication factor for double-factor authentication.

display radius statistics

Use **display radius statistics** to display RADIUS packet statistics.

Syntax

display radius statistics

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display RADIUS packet statistics.

```
<Sysname> display radius statistics

                            Auth.         Acct.       SessCtrl.
          Request Packet:     0             0             0
            Retry Packet:     0             0             -
          Timeout Packet:     0             0             -
       Access Challenge:      0             -             -
          Account Start:      -             0             -
         Account Update:      -             0             -
           Account Stop:      -             0             -
      Terminate Request:      -             -             0
             Set Policy:      -             -             0
   Packet With Response:      0             0             0
Packet Without Response:      0             0             -
          Access Rejects:     0             -             -
          Dropped Packet:     0             0             0
          Check Failures:     0             0             0
```

Table 11 Command output

Field	Description
Auth.	Authentication packets.
Acct.	Accounting packets.
SessCtrl.	Session-control packets.
Request Packet	Number of request packets.
Retry Packet	Number of retransmitted request packets.
Timeout Packet	Number of request packets timed out.
Access Challenge	Number of access challenge packets.
Account Start	Number of start-accounting packets.
Account Update	Number of accounting update packets.
Account Stop	Number of stop-accounting packets.
Terminate Request	Number of packets for logging off users forcibly.
Set Policy	Number of packets for updating user authorization information.
Packet With Response	Number of packets for which responses were received.
Packet Without Response	Number of packets for which no responses were received.
Access Rejects	Number of Access-Reject packets.
Dropped Packet	Number of discarded packets.
Check Failures	Number of packets with checksum errors.

Related commands

`reset radius statistics`

exclude

Use **`exclude`** to exclude an attribute from RADIUS requests.

Use **`undo exclude`** to cancel the configuration of excluding an attribute from RADIUS requests.

Syntax

`exclude` { **`accounting`** | **`authentication`** } **`name`** *`attribute-name`*

`undo exclude` { **`accounting`** | **`authentication`** } **`name`** *`attribute-name`*

Default

No attributes are configured to be excluded from RADIUS requests.

Views

RADIUS attribute test group view

Predefined user roles

network-admin

context-admin

Parameters

`accounting`: Specifies RADIUS accounting requests.

authentication: Specifies RADIUS authentication requests.

name *attribute-name*: Specifies a RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The specified attribute must be an attribute that RADIUS requests carry by default. Available attributes that you can specify for RADIUS authentication requests include Service-Type, Framed-Protocol, NAS-Identifier, Acct-Session-Id, and NAS-Port-Type. Available attributes that you can specify for RADIUS accounting requests include NAS-Identifier, Acct-Delay-Time, Acct-Session-Id, and Acct-Terminate-Cause.

Usage guidelines

Use this command to exclude an attribute from RADIUS requests sent during an AAA test to help troubleshoot authentication or accounting failures.

Before you exclude an attribute that is already configured to be included in RADIUS requests, you must cancel the inclusion configuration by using the **undo include** command.

Examples

In RADIUS attribute test group **t1**, exclude Service-Type attribute from RADIUS authentication requests.

```
<Sysname> system-view
[Sysname] radius attribute-test-group t1
[Sysname-radius-attr-test-grp-t1] exclude authentication name Service-Type
```

Related commands

include

test-aaa

include

Use **include** to include an attribute in RADIUS requests.

Use **undo include** to cancel the configuration of including an attribute in RADIUS requests.

Syntax

include { **accounting** | **authentication** } { **name** *attribute-name* | [**vendor** *vendor-id*] **code** *attribute-code* } **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** } **value** *attribute-value*

undo include { **accounting** | **authentication**} { **name** *attribute-name* | [**vendor** *vendor-id*] **code** *attribute-code* }

Default

No attributes are configured to be included in RADIUS authentication or accounting requests.

Views

RADIUS attribute test group view

Predefined user roles

network-admin

context-admin

Parameters

accounting: Specifies RADIUS accounting requests.

authentication: Specifies RADIUS authentication requests.

name *attribute-name*: Specifies a standard RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters.

vendor *vendor-id*: Specifies a vendor by its ID in the range of 1 to 65535. If you do not specify a vendor, this command includes a standard attribute in RADIUS requests. Table 12 shows the vendor IDs of supported vendors.

Table 12 Supported vendors and vendor IDs

Vendor	Vendor ID	Vendor	Vendor ID	Vendor	Vendor ID
HUAWEI	2011	NSFOCUS	25506	Microsoft	311
3COM	43	DSL Forum	3561	China Telecom	20942
Wi-Fi Alliance	40808	Juniper	2636	CMCC	28357
Cisco	9				

code *attribute-code*: Specifies a RADIUS attribute by its code in the range of 1 to 255.

type: Specifies a data type for the attribute content.

binary: Binary type.

date: Date type.

integer: Integer type.

interface-id: Interface ID type.

ip: IPv4 address type.

ipv6: IPv6 address type.

ipv6-prefix: IPv6 address prefix type.

octets: Octet type.

string: String type.

value *attribute-value*: Specifies the value for the attribute of the data type. The value range of the *attribute-value* argument varies by data type.

- For the binary type, the value is a string of 1 to 256 hexadecimal characters, which represents a binary number with a maximum of 128 bytes.
- For the date type, the value range is 0 to 4294967295.
- For the integer type, the value range is 0 to 4294967295.
- For the interface ID type, the value range is 1 to ffffffffffffffff.
- For the IPv6 address prefix type, the value is in the format of *prefix*/*prefix-length*.
- For the octet type, the value is a string of 1 to 256 hexadecimal characters, which represents an octet number with a maximum of 128 bytes.
- For the string type, the value of this argument is a string of 1 to 253 characters.

Usage guidelines

RADIUS requests carry some attributes by default. For these attributes, you can use the **include** command to change its value or use the **undo include** command to restore its value to the default. Table 13 shows the attributes that RADIUS requests carry by default.

Table 13 Attributes that RADIUS requests carry by default

Packet type	Attributes that the type of packets carry by default
RADIUS authentication request	User-Name CHAP-Password (or User-Password) CHAP-Challenge NAS-IP-Address (or NAS-IPv6-Address) Service-Type Framed-Protocol NAS-Identifier NAS-Port-Type Acct-Session-Id
RADIUS accounting request	User-Name Acct-Status-Type NAS-IP-Address (or NAS-IPv6-Address) NAS-Identifier Acct-Session-Id Acct-Delay-Time Acct-Terminate-Cause

For the accuracy of AAA tests, the value of an attribute must be of the data type specified for that attribute.

The attribute names of standard attributes saved in the configuration file will be converted to attribute codes.

Before you include an attribute that is already configured to be excluded from RADIUS requests, you must cancel the exclusion configuration by using the **undo exclude** command.

You can include multiple attributes in RADIUS requests. The device adds the included attributes to RADIUS packets in the order they are configured. If the length of a RADIUS request reaches 4096 bytes, the device will not add the remaining attributes to the request. As a best practice, include a reasonable number of attributes in RADIUS requests.

Examples

In RADIUS attribute test group **t1**, include Calling-Station-Id attribute with value 08-00-27-00-34-D8 in RADIUS authentication requests.

```
<Sysname> system-view
[Sysname] radius attribute-test-group t1
[Sysname-radius-attr-test-grp-t1] include authentication name Calling-Station-Id type
string value 08-00-27-00-34-d8
```

Related commands

exclude

test-aaa

key (RADIUS scheme view)

Use **key** to set the shared key for secure RADIUS authentication or accounting communication.

Use **undo key** to delete the shared key for secure RADIUS authentication or accounting communication.

Syntax

key { **accounting** | **authentication** } { **cipher** | **simple** } *string*

undo key { **accounting** | **authentication** }

Default

No shared key is configured for secure RADIUS authentication or accounting communication.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

accounting: Specifies the shared key for secure RADIUS accounting communication.

authentication: Specifies the shared key for secure RADIUS authentication communication.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. The encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters.

Usage guidelines

The shared keys configured by using this command apply to all servers in the scheme. Make sure the settings match the shared keys configured on the RADIUS servers.

The shared keys specified for specific RADIUS servers take precedence over the shared key specified with this command.

Examples

In RADIUS scheme **radius1**, set the shared key to **ok** in plaintext form for secure accounting communication.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] key accounting simple ok
```

Related commands

display radius scheme

nas-ip (RADIUS scheme view)

Use **nas-ip** to specify a source IP address for outgoing RADIUS packets.

Use **undo nas-ip** to delete the specified source IP address for outgoing RADIUS packets.

Syntax

nas-ip { *ipv4-address* | **ipv6** *ipv6-address* }

undo nas-ip [**ipv6**]

Default

The source IP address of an outgoing RADIUS packet is that specified by using the **radius nas-ip** command in system view.

If the **radius nas-ip** command is not used, the source IP address is the primary IP address of the outbound interface.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies an IPv4 address, which must be an address of the device. The IP address cannot be 0.0.0.0, 255.255.255.255, a class D address, a class E address, or a loopback address.

ipv6 *ipv6-address*: Specifies an IPv6 address, which must be a unicast address of the device and cannot be a loopback address or a link-local address.

Usage guidelines

The source IP address of RADIUS packets that a NAS sends must match the IP address of the NAS that is configured on the RADIUS server. A RADIUS server identifies a NAS by its IP address. Upon receiving a RADIUS packet, the RADIUS server checks the source IP address of the packet.

- If the source IP address of the packet is the IP address of a managed NAS, the server processes the packet.
- If the source IP address of the packet is not the IP address of a managed NAS, the server drops the packet.

As a best practice, specify a loopback interface address as the source IP address for outgoing RADIUS packets to avoid RADIUS packet loss caused by physical port errors.

If you use both the **nas-ip** command and **radius nas-ip** command, the following guidelines apply:

- The setting configured by using the **nas-ip** command in RADIUS scheme view applies only to the RADIUS scheme.
- The setting configured by using the **radius nas-ip** command in system view applies to all RADIUS schemes.
- The setting in RADIUS scheme view takes precedence over the setting in system view.

For a RADIUS scheme, you can specify only one source IPv4 address and one source IPv6 address for outgoing RADIUS packets.

If you do not specify any parameter for the **undo nas-ip** command, the command deletes the specified source IPv4 address for outgoing RADIUS packets.

Examples

In RADIUS scheme **radius1**, specify IP address 10.1.1.1 as the source IP address for outgoing RADIUS packets.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] nas-ip 10.1.1.1
```

Related commands

display radius scheme

radius nas-ip

port

Use **port** to specify the RADIUS DAS port.

Use **undo port** to restore the default.

Syntax

port *port-number*

undo port

Default

The RADIUS DAS port number is 3799.

Views

RADIUS DAS view

Predefined user roles

network-admin

context-admin

Parameters

port-number: Specifies a UDP port number in the range of 1 to 65535.

Usage guidelines

The destination port in DAE packets on the DAC must be the same as the RADIUS DAS port on the DAS.

Examples

Enable the RADIUS DAS to listen to UDP port 3790 for DAE requests.

```
<Sysname> system-view
[Sysname] radius dynamic-author server
[Sysname-radius-da-server] port 3790
```

Related commands

client

radius dynamic-author server

primary accounting (RADIUS scheme view)

Use **primary accounting** to specify the primary RADIUS accounting server.

Use **undo primary accounting** to restore the default.

Syntax

primary accounting { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **vpn-instance** *vpn-instance-name*] *

undo primary accounting

Default

The primary RADIUS accounting server is not specified.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies the IPv4 address of the primary RADIUS accounting server.

ipv6 *ipv6-address*: Specifies the IPv6 address of the primary RADIUS accounting server.

port-number: Specifies the service port number of the primary RADIUS accounting server. The value range for the UDP port number is 1 to 65535. The default setting is 1813.

key: Specifies the shared key for secure communication with the primary RADIUS accounting server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. The encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the primary RADIUS accounting server belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the server is on the public network, do not specify this option.

Usage guidelines

Make sure the port number and shared key settings of the primary RADIUS accounting server are the same as those configured on the server.

Two accounting servers specified for a scheme, primary or secondary, cannot have identical VPN instance, IP address, and port number settings.

The shared key configured by using this command takes precedence over the shared key configured with the **key accounting** command.

If the specified server resides on an MPLS L3VPN, specify the VPN instance by using the **vpn-instance** *vpn-instance-name* option. The VPN instance specified by this command takes precedence over the VPN instance specified for the RADIUS scheme.

If you use the **primary accounting** command to modify or delete the primary accounting server to which the device is sending a start-accounting request, communication with the primary server times out. The device tries to communicate with an active server that has the highest priority for accounting.

If you remove an actively used accounting server, the device no longer sends users' real-time accounting requests and stop-accounting requests. It does not buffer the stop-accounting requests. The device can generate incorrect accounting results.

Examples

In RADIUS scheme **radius1**, specify the primary accounting server with IP address 10.110.1.2, UDP port number 1813, and plaintext shared key **123456TESTacct&!**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] primary accounting 10.110.1.2 1813 key simple 123456TESTacct&!
```

Related commands

display radius scheme

key (RADIUS scheme view)

secondary accounting (RADIUS scheme view)

vpn-instance (RADIUS scheme view)

primary authentication (RADIUS scheme view)

Use **primary authentication** to specify the primary RADIUS authentication server.

Use **undo primary authentication** to restore the default.

Syntax

primary authentication { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **test-profile** *profile-name* | **vpn-instance** *vpn-instance-name*] *

undo primary authentication

Default

The primary RADIUS authentication server is not specified.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies the IPv4 address of the primary RADIUS authentication server.

ipv6 *ipv6-address*: Specifies the IPv6 address of the primary RADIUS authentication server.

port-number: Specifies the service port number of the primary RADIUS authentication server. The value range for the UDP port number is 1 to 65535. The default setting is 1812.

key: Specifies the shared key for secure communication with the primary RADIUS authentication server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. The encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters.

test-profile *profile-name*: Specifies a test profile for detecting the RADIUS server status. The *profile-name* argument is a case-sensitive string of 1 to 31 characters.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the primary RADIUS authentication server belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the server is on the public network, do not specify this option.

Usage guidelines

Make sure the service port and shared key settings of the primary RADIUS authentication server are the same as those configured on the server.

Two authentication servers specified for a scheme, primary or secondary, cannot have identical VPN instance, IP address, and port number settings.

The shared key configured by this command takes precedence over the shared key configured with the **key authentication** command.

The server status detection is triggered for the server if the specified test profile exists on the device.

If the specified server resides on an MPLS L3VPN, specify the VPN instance by using the **vpn-instance** *vpn-instance-name* option. The VPN instance specified by this command takes precedence over the VPN instance specified for the RADIUS scheme.

If you use the **primary authentication** command to modify or delete the primary authentication server during an authentication process, communication with the primary server times out. The device tries to communicate with an active server that has the highest priority for authentication.

Examples

In RADIUS scheme **radius1**, specify the primary authentication server with IP address 10.110.1.1, UDP port number 1812, and plaintext shared key **123456TESTauth&!**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] primary authentication 10.110.1.1 1812 key simple
123456TESTauth&!
```

radius attribute extended

Use **radius attribute extended** to define an extended RADIUS attribute.

Use **undo radius attribute extended** to delete user-defined extended RADIUS attributes.

Syntax

radius attribute extended *attribute-name* [**vendor** *vendor-id*] **code** *attribute-code* **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** }

undo radius attribute extended [*attribute-name*]

Default

No user-defined extended RADIUS attributes exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

attribute-name: Specifies the RADIUS attribute name, a case-insensitive string of 1 to 63 characters. The name must be unique among all RADIUS attributes, including the standard and extended RADIUS attributes.

vendor *vendor-id*: Specifies a vendor ID in the range of 1 to 65535. If you do not specify a vendor ID, the device processes the RADIUS attribute as a standard RADIUS attribute.

code *attribute-code*: Specifies the ID of the RADIUS attribute in the attribute set. The value range for the *attribute-code* argument is 1 to 255.

type: Specifies a data type for the attribute content.

binary: Binary type.

date: Date type.

integer: Integer type.

interface-id: Interface ID type.

ip: IPv4 address type.

ipv6: IPv6 address type.

ipv6-prefix: IPv6 prefix type.

octets: Octet type.

string: String type.

Usage guidelines

To support the proprietary RADIUS attributes of other vendors, perform the following tasks:

1. Use this command to define the attributes as extended RADIUS attributes.
2. Use the **attribute convert** command to map the extended RADIUS attributes to attributes supported by the system.
3. Use the **attribute translate** command to enable the RADIUS attribute translation feature for the mappings to take effect.

To cooperate with RADIUS servers of a third-party vendor, map attributes that cannot be identified by the server to server-supported attributes.

Two RADIUS attributes cannot have the same combination of attribute name, vendor ID, and attribute ID.

If you do not specify a RADIUS attribute name, the **undo radius attribute extended** command deletes all user-defined extended RADIUS attributes.

Examples

Define a string-type extended RADIUS attribute with attribute name **Owner-Password**, vendor ID 122, and attribute ID 80.

```
<Sysname> system-view
[Sysname] radius attribute extended Owner-Password vendor 122 code 80 type string
```

radius attribute-test-group

Use **radius attribute-test-group** to create a RADIUS attribute test group and enter its view, or enter the view of an existing RADIUS attribute test group.

Use **undo radius attribute-test-group** to remove a RADIUS attribute test group.

Syntax

radius attribute-test-group *attr-test-group-name*

undo radius attribute-test-group *attr-test-group-name*

Default

No RADIUS attribute test groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

attr-test-group-name: Specifies the name of a RADIUS attribute test group, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A RADIUS attribute test group is a collection of RADIUS attributes that will be included in or excluded from RADIUS requests.

The system can have multiple RADIUS attribute test groups.

Examples

Create a RADIUS attribute test group named **t1** and enter its view.

```
<Sysname> system-view
[Sysname] radius attribute-test-group t1
[Sysname-radius-attr-test-grp-t1]
```

radius dscp

Use **radius dscp** to change the DSCP priority of RADIUS packets.

Use **undo radius dscp** to restore the default.

Syntax

radius [**ipv6**] **dscp** *dscp-value*

undo radius [**ipv6**] **dscp**

Default

The DSCP priority of RADIUS packets is 0.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies the IPv6 RADIUS packets. If you do not specify this keyword, the command sets the DSCP priority for the IPv4 RADIUS packets.

dscp-value: Specifies the DSCP priority of RADIUS packets, in the range of 0 to 63. A larger value represents a higher priority.

Usage guidelines

Use this command to set the DSCP priority in the ToS field of RADIUS packets for changing their transmission priority.

Examples

Set the DSCP priority of IPv4 RADIUS packets to 10.

```
<Sysname> system-view
[Sysname] radius dscp 10
```

radius dynamic-author server

Use **radius dynamic-author server** to enable the RADIUS DAS feature and enter RADIUS DAS view.

Use **undo radius dynamic-author server** to disable the RADIUS DAS feature.

Syntax

radius dynamic-author server

undo radius dynamic-author server

Default

The RADIUS DAS feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

After you enable the RADIUS DAS feature, the device listens to the RADIUS DAS port to receive DAE packets from specified DACs. Based on the DAE packet type and contents, the device performs one of the following operations:

- Log off online users.
- Change online user authorization information.

Examples

Enable the RADIUS DAS feature and enter RADIUS DAS view.

```
<Sysname> system-view
```

```
[Sysname] radius dynamic-author server
[Sysname-radius-da-server]
```

radius nas-ip

Use **radius nas-ip** to specify a source IP address for outgoing RADIUS packets.

Use **undo radius nas-ip** to delete the specified source IP address for outgoing RADIUS packets.

Syntax

radius nas-ip { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

undo radius nas-ip { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

Default

The source IP address of an outgoing RADIUS packet is the primary IPv4 address or the IPv6 address of the outbound interface.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies an IPv4 address, which must be an address of the device. The IP address cannot be 0.0.0.0, 255.255.255.255, a class D address, a class E address, or a loopback address.

ipv6 *ipv6-address*: Specifies an IPv6 address, which must be a unicast address of the device and cannot be a loopback address or a link-local address.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the source IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. To configure a public-network source IP address, do not specify this option.

Usage guidelines

The source IP address of RADIUS packets that a NAS sends must match the IP address of the NAS that is configured on the RADIUS server. A RADIUS server identifies a NAS by its IP address. Upon receiving a RADIUS packet, the RADIUS server checks the source IP address of the packet.

- If the source IP address of the packet is the IP address of a managed NAS, the server processes the packet.
- If the source IP address of the packet is not the IP address of a managed NAS, the server drops the packet.

As a best practice, specify a loopback interface address as the source IP address for outgoing RADIUS packets to avoid RADIUS packet loss caused by physical port errors.

If you use both the **nas-ip** command and **radius nas-ip** command, the following guidelines apply:

- The setting configured by using the **nas-ip** command in RADIUS scheme view applies only to the RADIUS scheme.
- The setting configured by using the **radius nas-ip** command in system view applies to all RADIUS schemes.
- The setting in RADIUS scheme view takes precedence over the setting in system view.

You can specify a maximum of 16 source IP addresses in system view, including:

- Zero or one public-network source IPv4 address.
- Zero or one public-network source IPv6 address.
- Private-network source IP addresses.

Each VPN instance can have only one private-network source IPv4 address and one private-network source IPv6 address in system view.

Examples

Specify IP address 129.10.10.1 as the source IP address for outgoing RADIUS packets.

```
<Sysname> system-view
[Sysname] radius nas-ip 129.10.10.1
```

nas-ip (RADIUS scheme view)

radius scheme

Use **radius scheme** to create a RADIUS scheme and enter its view, or enter the view of an existing RADIUS scheme.

Use **undo radius scheme** to delete a RADIUS scheme.

Syntax

radius scheme *radius-scheme-name*

undo radius scheme *radius-scheme-name*

Default

No RADIUS schemes exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

radius-scheme-name: Specifies the RADIUS scheme name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

A RADIUS scheme can be used by more than one ISP domain at the same time.

The device supports a maximum of 16 RADIUS schemes.

Examples

Create a RADIUS scheme named **radius1** and enter RADIUS scheme view.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1]
```

Related commands

display radius scheme

radius session-control client

Use **radius session-control client** to specify a RADIUS session-control client.

Use **undo radius session-control client** to remove the specified RADIUS session-control clients.

Syntax

radius session-control client { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**key** { **cipher** | **simple** } *string* | **vpn-instance** *vpn-instance-name*] *

undo radius session-control client { **all** | { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] }

Default

No RADIUS session-control clients are specified.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies a session-control client by its IPv4 address.

ipv6 *ipv6-address*: Specifies a session-control client by its IPv6 address.

key: Specifies the shared key for secure communication with the session-control client.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. The encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the RADIUS session-control client belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the client is on the public network, do not specify this option.

all: Specifies all session-control clients.

Usage guidelines

To verify the session-control packets sent from a RADIUS server running on IMC, specify the RADIUS server as a session-control client to the device. The device matches a session-control packet to a session-control client based on the IP address and VPN instance, and then uses the shared key of the matched client to validate the packet.

The device searches the session-control client settings prior to searching all RADIUS scheme settings for a server with matching settings. This process narrows the search scope for finding the matched RADIUS server.

The session-control client settings take effect only when the RADIUS session-control feature is enabled.

The session-control client settings must be the same as the corresponding settings of the RADIUS server.

You can specify multiple session-control clients on the device.

Examples

Specify a session-control client with IP address 10.110.1.2 and shared key **12345** in plaintext form.

```
<Sysname> system-view
[Sysname] radius session-control client ip 10.110.1.2 key simple 12345
```

Related commands

radius session-control enable

radius session-control enable

Use **radius session-control enable** to enable the RADIUS session-control feature.

Use **undo radius session-control enable** to disable the RADIUS session-control feature.

Syntax

radius session-control enable

undo radius session-control enable

Default

The RADIUS session-control feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

An IMC RADIUS server uses session-control packets to deliver dynamic authorization change requests or disconnection requests to the device. The session-control feature enables the device to receive the RADIUS session-control packets on UDP port 1812.

This feature must work with IMC servers.

Examples

Enable the RADIUS session-control feature.

```
<Sysname> system-view
[Sysname] radius session-control enable
```

radius-server test-profile

Use **radius-server test-profile** to configure a test profile for detecting the RADIUS server status.

Use **undo radius-server test-profile** to delete a RADIUS test profile.

Syntax

radius-server test-profile *profile-name* **username** *name* [**interval** *interval*]

undo radius-server test-profile *profile-name*

Default

No RADIUS test profiles exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

profile-name: Specifies the name of the test profile, which is a case-sensitive string of 1 to 31 characters.

username *name*: Specifies the username in the detection packets. The *name* argument is a case-sensitive string of 1 to 253 characters.

interval *interval*: Specifies the interval for sending a detection packet, in minutes. The value range for the *interval* argument is 1 to 3600, and the default value is 60.

Usage guidelines

The device starts detecting the status of a RADIUS server only if the test profile specified for the server exists. If you specify a nonexistent test profile for a RADIUS server, the device does not detect the status of the server until you create the test profile on the device.

When you delete a test profile, the device stops detecting the status of RADIUS servers that use the test profile.

You can execute this command multiple times to configure multiple test profiles.

Examples

Configure a test profile named **abc** for RADIUS server status detection. A detection packet that uses username **admin** is sent every 10 minutes.

```
<Sysname> system-view
[Sysname] radius-server test-profile abc username admin interval 10
```

retry

Use **retry** to set the maximum number of attempts for transmitting a RADIUS packet to a single RADIUS server.

Use **undo retry** to restore the default.

Syntax

retry *retries*

undo retry

Default

The maximum number of RADIUS packet transmission attempts is 3.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

retries: Specifies the maximum number of RADIUS packet transmission attempts, in the range of 1 to 20.

Usage guidelines

Because RADIUS uses UDP packets to transmit data, the communication is not reliable.

If the device does not receive a response to its request from the RADIUS server within the response timeout period, the device retransmits the RADIUS request. To set the response timeout period, use the **timer response-timeout** command.

If the device does not receive a response from the RADIUS server after the maximum number of transmission attempts is reached, the device considers the request a failure.

If the client times out during the authentication process, the user is immediately logged off. To avoid user logoffs, the value multiplied by the following items cannot be larger than the client timeout period defined by the access module:

- The maximum number of RADIUS packet transmission attempts.
- The RADIUS server response timeout period.
- The number of RADIUS authentication servers in the RADIUS scheme.

When the device sends a RADIUS request to a new RADIUS server, it checks the total amount of time it has taken to transmit the RADIUS packet. If the amount of time has reached 300 seconds, the device stops sending the RADIUS request to the next RADIUS server. As a best practice, consider

the number of RADIUS servers when you configure the maximum number of packet transmission attempts and the RADIUS server response timeout period.

Examples

In RADIUS scheme **radius1**, set the maximum number of RADIUS packet transmission attempts to 5.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] retry 5
```

Related commands

timer response-timeout (RADIUS scheme view)

retry realtime-accounting

Use **retry realtime-accounting** to set the maximum number of accounting attempts.

Use **undo retry realtime-accounting** to restore the default.

Syntax

retry realtime-accounting *retries*

undo retry realtime-accounting

Default

The maximum number of accounting attempts is 5.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

retries: Specifies the maximum number of accounting attempts, in the range of 1 to 255.

Usage guidelines

Typically, a RADIUS accounting server checks whether a user is online by using a timeout timer. If the server does not receive a real-time accounting request for a user in the timeout period, it considers that a line or device failure has occurred. The server stops accounting for the user.

To work with the RADIUS server, the NAS needs to send real-time accounting requests to the server before the timer on the server expires and to keep pace with the server in disconnecting the user when a failure occurs. The NAS disconnects from a user according to the maximum number of accounting attempts and specific parameters.

For example, the following conditions exist:

- The RADIUS server response timeout period is 3 seconds (set by using the **timer response-timeout** command).
- The maximum number of RADIUS packet transmission attempts is 3 (set by using the **retry** command).
- The real-time accounting interval is 12 minutes (set by using the **timer realtime-accounting** command).

- The maximum number of accounting attempts is 5 (set by using the **retry realtime-accounting** command).

In the above case, the device generates an accounting request every 12 minutes, and retransmits the request if it sends the request but receives no response within 3 seconds. If the device receives no response after transmitting the request three times, it considers the accounting attempt a failure, and makes another accounting attempt. If five consecutive accounting attempts fail, the device cuts the user connection.

Examples

In RADIUS scheme **radius1**, set the maximum number of accounting attempts to 10.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] retry realtime-accounting 10
```

Related commands

timer realtime-accounting (RADIUS scheme view)

timer response-timeout (RADIUS scheme view)

secondary accounting (RADIUS scheme view)

Use **secondary accounting** to specify a secondary RADIUS accounting server.

Use **undo secondary accounting** to remove a secondary RADIUS accounting server.

Syntax

secondary accounting { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **vpn-instance** *vpn-instance-name*] *

undo secondary accounting [{ *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **vpn-instance** *vpn-instance-name*] *]

Default

No secondary RADIUS accounting servers are specified.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies the IPv4 address of a secondary RADIUS accounting server.

ipv6 *ipv6-address*: Specifies the IPv6 address of a secondary RADIUS accounting server.

port-number: Specifies the service port number of the secondary RADIUS accounting server. The value range for the UDP port number is 1 to 65535. The default setting is 1813.

key: Specifies the shared key for secure communication with the secondary RADIUS accounting server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. The encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the secondary RADIUS accounting server belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the server is on the public network, do not specify this option.

Usage guidelines

Make sure the port number and shared key settings of each secondary RADIUS accounting server are the same as those configured on the corresponding server.

A RADIUS scheme supports a maximum of 16 secondary RADIUS accounting servers. If the primary server fails, the device tries to communicate with a secondary server in active state. The device connects to the secondary servers in the order they are configured.

Two accounting servers specified for a scheme, primary or secondary, cannot have identical VPN instance, IP address, and port number settings.

The shared key configured by this command takes precedence over the shared key configured with the **key accounting** command.

If the specified server resides on an MPLS L3VPN, specify the VPN instance by using the **vpn-instance** *vpn-instance-name* option. The VPN instance specified by this command takes precedence over the VPN instance specified for the RADIUS scheme.

If you use the **secondary accounting** command to modify or delete a secondary accounting server to which the device is sending a start-accounting request, communication with the secondary server times out. The device tries to communicate with an active server that has the highest priority for accounting.

If you remove an actively used accounting server, the device no longer sends users' real-time accounting requests and stop-accounting requests. The device does not buffer the stop-accounting requests, either.

Examples

In RADIUS scheme **radius1**, specify a secondary accounting server with IP address 10.110.1.1 and UDP port 1813.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] secondary accounting 10.110.1.1 1813
```

In RADIUS scheme **radius2**, specify two secondary accounting servers with IP addresses 10.110.1.1 and 10.110.1.2 and UDP port 1813.

```
<Sysname> system-view
[Sysname] radius scheme radius2
[Sysname-radius-radius2] secondary accounting 10.110.1.1 1813
[Sysname-radius-radius2] secondary accounting 10.110.1.2 1813
```

secondary authentication (RADIUS scheme view)

Use **secondary authentication** to specify a secondary RADIUS authentication server.

Use **undo secondary authentication** to remove a secondary RADIUS authentication server.

Syntax

secondary authentication { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **test-profile** *profile-name* | **vpn-instance** *vpn-instance-name*] *

undo secondary authentication [{ *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **vpn-instance** *vpn-instance-name*] *]

Default

No secondary RADIUS authentication servers are specified.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies the IPv4 address of a secondary RADIUS authentication server.

ipv6 *ipv6-address*: Specifies the IPv6 address of a secondary RADIUS authentication server.

port-number: Specifies the service port number of the secondary RADIUS authentication server. The value range for the UDP port number is 1 to 65535. The default setting is 1812.

key: Specifies the shared key for secure communication with the secondary RADIUS authentication server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. The encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters.

test-profile *profile-name*: Specifies a test profile for detecting the RADIUS server status. The *profile-name* argument is a case-sensitive string of 1 to 31 characters.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the secondary RADIUS authentication server belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the server is on the public network, do not specify this option.

Usage guidelines

Make sure the port number and shared key settings of each secondary RADIUS authentication server are the same as those configured on the corresponding server.

A RADIUS scheme supports a maximum of 16 secondary RADIUS authentication servers. If the primary server fails, the device tries to communicate with a secondary server in active state. The device connects to the secondary servers in the order they are configured.

The server status detection is triggered for a server if the specified test profile exists on the device.

Two authentication servers specified for a scheme, primary or secondary, cannot have identical VPN instance, IP address, and port number settings.

The shared key configured by this command takes precedence over the shared key configured with the **key authentication** command.

If the specified server resides on an MPLS L3VPN, specify the VPN instance by using the **vpn-instance** *vpn-instance-name* option. The VPN instance specified by this command takes precedence over the VPN instance specified for the RADIUS scheme.

If you use the **secondary authentication** command to modify or delete a secondary authentication server during an authentication process, communication with the secondary server times out. The device tries to communicate with an active server that has the highest priority for authentication.

Examples

In RADIUS scheme **radius1**, specify a secondary authentication server with IP address 10.110.1.2 and UDP port 1812.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] secondary authentication 10.110.1.2 1812
```

In RADIUS scheme **radius2**, specify two secondary authentication servers with IP addresses 10.110.1.1 and 10.110.1.2 and UDP port 1812.

```
<Sysname> system-view
[Sysname] radius scheme radius2
[Sysname-radius-radius2] secondary authentication 10.110.1.1 1812
[Sysname-radius-radius2] secondary authentication 10.110.1.2 1812
```

snmp-agent trap enable radius

Use **snmp-agent trap enable radius** to enable SNMP notifications for RADIUS.

Use **undo snmp-agent trap enable radius** to disable SNMP notifications for RADIUS.

Syntax

snmp-agent trap enable radius [**accounting-server-down** | **accounting-server-up** | **authentication-error-threshold** | **authentication-server-down** | **authentication-server-up**] *

undo snmp-agent trap enable radius [**accounting-server-down** | **accounting-server-up** | **authentication-error-threshold** | **authentication-server-down** | **authentication-server-up**] *

Default

All RADIUS SNMP notifications are disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

accounting-server-down: Specifies notifications to be sent when the RADIUS accounting server becomes unreachable.

accounting-server-up: Specifies notifications to be sent when the RADIUS accounting server becomes reachable.

authentication-error-threshold: Specifies notifications to be sent when the number of authentication failures exceeds the specified threshold. The threshold is represented by the ratio of the authentication failures to the total number of authentication attempts. The value range is 1 to 100, and the default value is 30. This threshold can only be configured through the MIB.

authentication-server-down: Specifies notifications to be sent when the RADIUS authentication server becomes unreachable.

authentication-server-up: Specifies notifications to be sent when the RADIUS authentication server becomes reachable.

Usage guidelines

If you do not specify any keywords, this command enables or disables all types of notifications for RADIUS.

When SNMP notifications for RADIUS are enabled, the device supports the following notifications generated by RADIUS:

- **RADIUS server unreachable notification**—The RADIUS server cannot be reached. RADIUS generates this notification if it cannot receive any response to an accounting or authentication request within the specified RADIUS request transmission attempts.
- **RADIUS server reachable notification**—The RADIUS server can be reached. RADIUS generates this notification for a previously blocked RADIUS server after the quiet timer expires.
- **Excessive authentication failures notification**—RADIUS generates this notification when the number of authentication failures to the total number of authentication attempts exceeds the specified threshold.

Examples

Enable the device to send RADIUS accounting server unreachable notifications.

```
<Sysname> system-view
[Sysname] snmp-agent trap enable radius accounting-server-down
```

state primary

Use **state primary** to set the status of a primary RADIUS server.

Syntax

state primary { **accounting** | **authentication** } { **active** | **block** }

Default

A primary RADIUS server is in active state.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

accounting: Specifies the primary RADIUS accounting server.

authentication: Specifies the primary RADIUS authentication server.

active: Specifies the active state, the normal operation state.

block: Specifies the blocked state, the out-of-service state.

Usage guidelines

During an authentication or accounting process, the device first tries to communicate with the primary server if the primary server is in active state. If the primary server is unavailable, the device performs the following operations:

- Changes the status of the primary server to blocked.
- Starts a quiet timer for the server.
- Tries to communicate with a secondary server in active state.

When the quiet timer of the primary server times out, the status of the server automatically changes to active. If you set the server status to blocked before the quiet timer times out, the server status cannot change back to active unless you manually set the status to active.

When all servers are in blocked state, the device tries to communicate with a server as follows:

- If the primary server is placed in blocked state automatically, the device only tries to communicate with the primary server.
- If the primary server is placed in blocked state manually, the device tries to communicate with secondary servers automatically placed in blocked state in the sequence they are configured.

This command can affect the RADIUS server status detection feature when a valid test profile is specified for a primary RADIUS authentication server.

- If you set the status of the server to blocked, the device stops detecting the status of the server.
- If you set the status of the server to active, the device starts to detect the status of the server.

Examples

In RADIUS scheme **radius1**, set the status of the primary authentication server to blocked.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] state primary authentication block
```

Related commands

display radius scheme

radius-server test-profile

state secondary

state secondary

Use **state secondary** to set the status of a secondary RADIUS server.

Syntax

state secondary { **accounting** | **authentication** } [{ *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **vpn-instance** *vpn-instance-name*] *] { **active** | **block** }

Default

A secondary RADIUS server is in active state.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

accounting: Specifies a secondary RADIUS accounting server.

authentication: Specifies a secondary RADIUS authentication server.

ipv4-address: Specifies the IPv4 address of a secondary RADIUS server.

ipv6 *ipv6-address*: Specifies the IPv6 address of a secondary RADIUS server.

port-number: Specifies the service port number of a secondary RADIUS server. The value range for the UDP port number is 1 to 65535. The default port numbers for authentication and accounting are 1812 and 1813, respectively.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the secondary RADIUS server belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters.

active: Specifies the active state, the normal operation state.

block: Specifies the blocked state, the out-of-service state.

Usage guidelines

If you do not specify an IP address, this command changes the status of all configured secondary RADIUS servers.

If the device finds that a secondary server in active state is unreachable, the device performs the following operations:

- Changes the status of the secondary server to blocked.
- Starts a quiet timer for the server.
- Tries to communicate with another secondary server in active state.

When the quiet timer of a server times out, the status of the server automatically changes to active. If you set the server status to blocked before the quiet timer times out, the server status cannot change back to active unless you manually set the status to active. If all configured secondary servers are unreachable, the device considers the authentication or accounting attempt a failure.

This command can affect the RADIUS server status detection feature when a valid test profile is specified for a secondary RADIUS authentication server.

- If you set the status of the server to blocked, the device stops detecting the status of the server.
- If you set the status of the server to active, the device starts to detect the status of the server.

Examples

In RADIUS scheme **radius1**, set the status of all the secondary authentication servers to blocked.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] state secondary authentication block
```

test-aaa

Use **test-aaa** to perform an AAA test.

Syntax

test-aaa user *user-name* **password** *password* **radius-scheme** *radius-scheme-name* [**radius-server** { *ipv4-address* | **ipv6** *ipv6-address* } *port-number* [**vpn-instance** *vpn-instance-name*]] [**chap** | **pap**] [**attribute-test-group** attr-*test-group-name*] [**trace**]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

user *user-name*: Specifies the test username, a string of 1 to 80 characters. The username can be a pure username or contain a domain name. The format for a username containing a domain name is *pure-username@domain-name*. The pure username is case sensitive and the domain name is case insensitive.

password *password*: Specifies the password of the test user, a case-sensitive string of 1 to 63 characters.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

radius-server: Specifies a RADIUS server.

ipv4-address: Specifies the IPv4 address of the RADIUS server.

ipv6 *ipv6-address*: Specifies the IPv6 address of the RADIUS server.

port-number: Specifies the UDP port number of the RADIUS server, in the range of 1 to 65535.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the RADIUS server belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the server is on the public network, do not specify this option.

chap: Specifies the CHAP authentication method (the default).

pap: Specifies the PAP authentication method.

attribute-test-group *attr-test-group-name*: Specifies a RADIUS attribute test group by its name, a case-insensitive string of 1 to 31 characters. If you do not specify a RADIUS attribute test group or the specified RADIUS attribute test group does not exist, the device does not change the attributes carried in authentication or accounting requests.

trace: Displays detailed information about RADIUS packets exchanged during the AAA test. If you do not specify this keyword, the command displays brief information about the AAA test, including the sent and received packets and the test result.

Usage guidelines

Use this command to identify the reasons for the failure of interaction between the device and the AAA servers.

The device might communicate with the AAA servers incorrectly during an AAA test. Make sure no users come online or go offline during an AAA text.

If the configuration of the specified RADIUS scheme changes, the new configuration does not affect the current AAA test. The modification will take effect in the next test.

The system can have only one AAA test at a time. Another AAA test can be performed only after the current test finishes.

Examples

Perform an AAA test and display detailed information about the test. The test uses username **user1**, password **123456**, the CHAP authentication method, and RADIUS scheme **test**.

```
<Sysname> test-aaa user user1 password 123456 radius-scheme test chap trace

    [Acct-Terminate-Cause(49)]      [6]   [1] [User Request]

Received a RADIUS stop-accounting response.
  Server  IP   : 192.168.1.110
  Source  IP   : 192.168.1.166
  VPN instance : N/A
  Server port  : 1813
  Packet type  : Stop-accounting response
  Packet length: 20 bytes
  Packet ID    : 1

Test result: Failed
```

Perform an AAA test and display brief information about the test. The test uses username **user1**, password **123456** and the CHAP authentication method to test RADIUS server at 192.168.1.110 in RADIUS scheme **test**.

```
<Sysname> test-aaa user user1 password 123456 radius-scheme test radius-server
192.168.1.110 1812
Sent a RADIUS authentication request.
Received a RADIUS authentication response.

Test result: Successful
```

Table 14 Command output

Field	Description
Server IP	IP address of the server.
Source IP	Source IP address of the RADIUS packet.
VPN instance	MPLS L3VPN instance to which the server belongs. This field displays **N/A** if the server belongs to the public network.
Server port	UDP port number of the server.
Packet type	Type of the RADIUS packet: • Authentication request. • Access-Accept. • Access-Reject. • Start-accounting request. • Start-accounting response. • Stop-accounting request. • Stop-accounting response.
Packet length	Total length of the RADIUS packet, in bytes.
Packet ID	ID of the RADIUS packet. This field is used to identity a pair of request and response packets.
[*attribute-name* (*code*)] [*length*] [*value*] [*description*]	Information about a RADIUS attribute: • ***attribute-name***—Name of the attribute. • ***code***—Code of the attribute. • ***length***—Length of the attribute, in bytes. • ***value***—Value of the attribute. • ***description***—Description of the attribute.
Reply-Message:	The RADIUS server rejected the authentication request and replied a message.
Test result	Result of the AAA test: • **Successful**—The test has succeeded. • **Failed**—The test has failed. If any request is rejected, the test fails.

Related commands

`radius attribute-test-group`

`radius scheme`

timer quiet (RADIUS scheme view)

Use **`timer quiet`** to set the quiet timer for the servers specified in a RADIUS scheme.

Use **`undo timer quiet`** to restore the default.

Syntax

`timer quiet` *`minutes`*

`undo timer quiet`

Default

The server quiet timer period is 5 minutes in a RADIUS scheme.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

minutes: Specifies the server quiet period in minutes, in the range of 1 to 255.

Usage guidelines

Make sure the server quiet timer is set correctly.

A timer that is too short might result in frequent authentication or accounting failures. This is because the device will continue to attempt to communicate with an unreachable server that is in active state.

A timer that is too long might temporarily block a reachable server that has recovered from a failure. This is because the server will remain in blocked state until the timer expires.

Examples

In RADIUS scheme **radius1**, set the quiet timer to 10 minutes for the servers.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] timer quiet 10
```

Related commands

display radius scheme

timer realtime-accounting (RADIUS scheme view)

Use **timer realtime-accounting** to set the real-time accounting interval.

Use **undo timer realtime-accounting** to restore the default.

Syntax

timer realtime-accounting *interval* [**second**]

undo timer realtime-accounting

Default

The real-time accounting interval is 12 minutes.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the real-time accounting interval in the range of 0 to 71582.

second: Specifies the measurement unit as second. If you do not specify this keyword, the real-time accounting interval is measured in minutes.

Usage guidelines

When the real-time accounting interval on the device is not zero, the device sends online user accounting information to the RADIUS accounting server at the configured interval.

When the real-time accounting interval on the device is zero, the device sends online user accounting information to the RADIUS accounting server at the real-time accounting interval configured on the server. If the real-time accounting interval is not configured on the server, the device does not send online user accounting information.

If a user uses RADIUS accounting but not RADIUS authentication and authorization, the device performs real-time accounting for that user only based on the real-time accounting interval set in the user's RADIUS accounting scheme. The real-time accounting interval assigned by the RADIUS accounting server does not take effect.

A short interval helps improve accounting precision but requires many system resources.

Table 15 Recommended real-time accounting intervals

Number of users	Real-time accounting interval
1 to 99	3 minutes
100 to 499	6 minutes
500 to 999	12 minutes
1000 or more	15 minutes or longer

When you modify the real-time accounting interval, the following rules apply to users that have been online before the modification:

- If you modify the real-time accounting interval from a non-zero value to zero or from zero to a non-zero value, the modification does not take effect on these users. These users still use the old real-time accounting interval.
- If you modify the real-time accounting interval from a non-zero value to another non-zero value, the modification takes effect immediately on these users.

The device sends a start-accounting packet for a dual-stack user after the user obtains an IP address of one stack. No matter how long the real-time accounting interval is, the device sends an update-accounting packet for the user immediately after the user obtains an IP address of another stack.

Examples

In RADIUS scheme **radius1**, set the real-time accounting interval to 51 minutes.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] timer realtime-accounting 51
```

Related commands

retry realtime-accounting

timer response-timeout (RADIUS scheme view)

Use **timer response-timeout** to set the RADIUS server response timeout timer.

Use **undo timer response-timeout** to restore the default.

Syntax

timer response-timeout *seconds*

undo timer response-timeout

Default

The RADIUS server response timeout period is 3 seconds.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the RADIUS server response timeout period, in the range of 1 to 10 seconds.

Usage guidelines

If a NAS receives no response from the RADIUS server in a period of time after sending a RADIUS request, it resends the request so that the user has more opportunity to obtain the RADIUS service. The NAS uses the RADIUS server response timeout timer to control the transmission interval.

If the client times out during the authentication process, the user is immediately logged off. To avoid user logoffs, the value multiplied by the following items cannot be larger than the client timeout period defined by the access module:

- The maximum number of RADIUS packet transmission attempts.
- The RADIUS server response timeout period.
- The number of RADIUS servers in the RADIUS scheme.

When the device sends a RADIUS request to a new RADIUS server, it checks the total amount of time it has taken to transmit the RADIUS packet. If the amount of time has reached 300 seconds, the device stops sending the RADIUS request to the next RADIUS server. As a best practice, consider the number of RADIUS servers when you configure the maximum number of packet transmission attempts and the RADIUS server response timeout period.

Examples

In RADIUS scheme **radius1**, set the RADIUS server response timeout timer to 5 seconds.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] timer response-timeout 5
```

Related commands

display radius scheme

retry

user-name-format (RADIUS scheme view)

Use **user-name-format** to specify the format of the username to be sent to a RADIUS server.

Use **undo user-name-format** to restore the default.

Syntax

user-name-format { **keep-original** | **with-domain** | **without-domain** }

undo user-name-format

Default

The ISP domain name is included in the usernames sent to a RADIUS server.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

keep-original: Sends the username to the RADIUS server as the username is entered.

with-domain: Includes the ISP domain name in the username sent to the RADIUS server.

without-domain: Excludes the ISP domain name from the username sent to the RADIUS server.

Usage guidelines

A username is generally in the *userid@isp-name* format, of which the *isp-name* argument is used by the device to determine the ISP domain to which a user belongs. Some earlier RADIUS servers, however, cannot recognize a username containing an ISP domain name. Before sending a username including a domain name to such a RADIUS server, the device must remove the domain name. This command allows you to specify whether to include a domain name in a username sent to a RADIUS server.

If a RADIUS scheme defines that the username is sent without the ISP domain name, do not apply the scheme to more than one ISP domain. Otherwise, the RADIUS server will consider two users in different ISP domains but with the same *userid* as one user.

Examples

In RADIUS scheme **radius1**, configure the device to remove the domain name from the usernames sent to the RADIUS servers.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] user-name-format without-domain
```

Related commands

display radius scheme

vpn-instance (RADIUS scheme view)

Use **vpn-instance** to specify an MPLS L3VPN instance for a RADIUS scheme.

Use **undo vpn-instance** to restore the default.

Syntax

vpn-instance *vpn-instance-name*

undo vpn-instance

Default

The RADIUS scheme belongs to the public network.

Views

RADIUS scheme view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance-name: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

The VPN instance specified for a RADIUS scheme applies to all authentication and accounting servers in that scheme. If a VPN instance is also configured for an individual RADIUS server, the VPN instance specified for the RADIUS scheme does not take effect on that server.

Examples

Specify VPN instance **test** for RADIUS scheme **radius1**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] vpn-instance test
```

Related commands

display radius scheme

HWTACACS commands

data-flow-format (HWTACACS scheme view)

Use **data-flow-format** to set the data flow and packet measurement units for traffic statistics.

Use **undo data-flow-format** to restore the default.

Syntax

data-flow-format { **data** { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** } | **packet** { **giga-packet** | **kilo-packet** | **mega-packet** | **one-packet** } } *

undo data-flow-format { **data** | **packet** }

Default

Traffic is counted in bytes and packets.

Views

HWTACACS scheme view

Predefined user roles

network-admin

context-admin

Parameters

data: Specifies the unit for data flows.

byte: Specifies the unit as byte.

giga-byte: Specifies the unit as gigabyte.

kilo-byte: Specifies the unit as kilobyte.

mega-byte: Specifies the unit as megabyte.

packet: Specifies the unit for data packets.

giga-packet: Specifies the unit as giga-packet.

kilo-packet: Specifies the unit as kilo-packet.

mega-packet: Specifies the unit as mega-packet.

one-packet: Specifies the unit as one-packet.

Usage guidelines

The data flow and packet measurement units for traffic statistics must be the same as configured on the HWTACACS accounting servers. Otherwise, accounting results might be incorrect.

Examples

In HWTACACS scheme **hwt1**, set the data flow and packet measurement units for traffic statistics to kilobyte and kilo-packet, respectively.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] data-flow-format data kilo-byte packet kilo-packet
```

Related commands

display hwtacacs scheme

display hwtacacs scheme

Use **display hwtacacs scheme** to display the configuration or statistics of HWTACACS schemes.

Syntax

display hwtacacs scheme [*hwtacacs-scheme-name* [**statistics**]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

hwtacacs-scheme-name: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters. If you do not specify an HWTACACS scheme, this command displays the configuration of all HWTACACS schemes.

statistics: Displays the HWTACACS service statistics. If you do not specify this keyword, the command displays the configuration of the specified HWTACACS scheme.

Usage guidelines

When displaying configuration only for one scheme, this command also displays the active state duration for each active server and the most recent five state changes for all servers in the scheme.

When displaying configuration for all schemes, this command also displays the active state duration for each active server and the most recent blocked period for all servers in all schemes.

Examples

Displays the configuration of all HWTACACS schemes.

```
<Sysname> display hwtacacs scheme
Total 1 HWTACACS schemes
```

Table 16 Command output

Field	Description
Index	Index number of the HWTACACS scheme.
Primary Auth Server	Primary HWTACACS authentication server.
Primary Author Server	Primary HWTACACS authorization server.
Primary Acct Server	Primary HWTACACS accounting server.
Secondary Auth Server	Secondary HWTACACS authentication server.
Secondary Author Server	Secondary HWTACACS authorization server.
Secondary Acct Server	Secondary HWTACACS accounting server.
IP	IP address of the server. This field displays **Not configured** if the server is not configured.
Port	Service port of the HWTACACS server. If no port configuration is performed, this field displays the default port number.
VPN Instance	MPLS L3VPN instance to which the HWTACACS server or scheme belongs. If no VPN instance is specified for the server or scheme, this field displays **Not configured**.
State	Status of the server: • **Active**—The server is in active state.

Field	Description
	• **Blocked**—The server is in blocked state.
duration	The duration of the current active state for the server. This field is displayed only when the server is in active state.
Most recent blocked period	Most recent blocking start time and end time when the server stayed in blocked state. If the server still remains in blocked state, **now** is displayed for the end time.
Most recent state changes	Most recent five state changes of the server.
Single-connection	Single connection status: • **Enabled**—Establish only one TCP connection for all users to communicate with the server. • **Disabled**—Establish a TCP connection for each user to communicate with the server.
Track ID	ID of the track entry associated with the server. This field is not available if the server is not associated with a track entry.
NAS IP Address	Source IP addresses for outgoing HWTACACS packets. This field displays **Not configured** if no source IP addresses are specified for outgoing HWTACACS packets.
Server Quiet Period(minutes)	Quiet period for the primary servers, in minutes.
Realtime Accounting Interval(minutes)	Real-time accounting interval, in minutes.
Response Timeout Interval(seconds)	HWTACACS server response timeout period, in seconds.
Username Format	Format for the usernames sent to the HWTACACS server: • **with-domain**—Includes the domain name. • **without-domain**—Excludes the domain name. • **keep-original**—Forwards the username as the username is entered.
Data flow unit	Measurement unit for data flows.
Packet unit	Measurement unit for packets.
All-server-block action	Action to take for AAA requests when all servers in the scheme are blocked: • Attempt the top-priority server. • Skip all servers in the scheme.

Display the HWTACACS service statistics.

```

Table 17 Command output

Field	Description
Primary authentication server	Primary HWTACACS authentication server.
Primary authorization server	Primary HWTACACS authorization server.
Primary accounting server	Primary HWTACACS accounting server.
Secondary authentication server	Secondary HWTACACS authentication server.
Secondary authorization server	Secondary HWTACACS authorization server.
Secondary accounting server	Secondary HWTACACS accounting server.
Round trip time	Time between the device processes the latest pair of request and response, in seconds.
Request packets	Number of sent requests.
Response packets	Number of received responses.
Failure response packets	Number of responses for authentication or authorization failure.
Error response packets	Number of error authentication responses.
Follow response packets	Number of follow authentication responses.
Malformed response packets	Number of invalid responses.
Pending request packets	Number of requests for which the device waits for responses.
Timeout packets	Number of requests that timed out.
Unknown type response packets	Number of unknown responses.
Dropped response packets	Number of dropped responses.
Login request packets	Number of sent packets that request to log in to the device.
Change-password request packets	Number of sent packets that request to change user passwords.
Request packets including plaintext passwords	Number of sent requests that include user passwords in plaintext form.
Request packets including ciphertext passwords	Number of requests that include user passwords in encrypted form.
Pass response packets	Number of responses that indicate users pass authentication.
Get-data response packets	Number of responses that get data.
Get-username response packets	Number of responses that get usernames.
Get-password response packets	Number of responses that get user passwords.
Restart response packets	Number of responses that indicate reauthentication.
Continue packets	Number of sent continue packets.
Continue-abort packets	Number of sent continue-abort packets.
PassAdd response packets	Number of received PassAdd responses. This type of responses indicate that the server agrees to assign all requested authorization attributes and adds other authorization attributes.
PassReply response packets	Number of received PassReply responses. This type of responses indicate that the server uses the authorization attributes in the responses to replace the requested authorization attributes.
Accounting start request packets	Number of sent start-accounting requests.

Field	Description
Accounting stop request packets	Number of sent stop-accounting requests.
Accounting update request packets	Number of sent accounting-update requests.
Success response packets	Number of received responses that indicate accounting success.

reset hwtacacs statistics

hwtacacs nas-ip

Use **hwtacacs nas-ip** to specify a source IP address for outgoing HWTACACS packets.

Use **undo hwtacacs nas-ip** to delete the specified source IP address for outgoing HWTACACS packets.

Syntax

hwtacacs nas-ip { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

undo hwtacacs nas-ip { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

Default

The source IP address of an HWTACACS packet sent to the server is the primary IPv4 address or the IPv6 address of the outbound interface.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies an IPv4 address, which must be an address of the device. The IP address cannot be 0.0.0.0, 255.255.255.255, a class D address, a class E address, or a loopback address.

ipv6 *ipv6-address*: Specifies an IPv6 address, which must be a unicast address of the device and cannot be a loopback address or a link-local address.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the source IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. To configure a public-network source IP address, do not specify this option.

Usage guidelines

The source IP address of HWTACACS packets that a NAS sends must match the IP address of the NAS that is configured on the HWTACACS server. An HWTACACS server identifies a NAS by IP address. Upon receiving an HWTACACS packet, the HWTACACS server checks the source IP address of the packet.

- If the source IP address of the packet is the IP address of a managed NAS, the server processes the packet.
- If the source IP address of the packet is not the IP address of a managed NAS, the server drops the packet.

As a best practice, specify a loopback interface address as the source IP address for outgoing HWTACACS packets to avoid HWTACACS packet loss caused by physical port errors.

If you use both the **nas-ip** command and **hwtacacs nas-ip** command, the following guidelines apply:

- The setting configured by using the **nas-ip** command in HWTACACS scheme view applies only to the HWTACACS scheme.
- The setting configured by using the **hwtacacs nas-ip** command in system view applies to all HWTACACS schemes.
- The setting in HWTACACS scheme view takes precedence over the setting in system view.

You can specify a maximum of 16 source IP addresses in system view, including:

- Zero or one public-network source IPv4 address.
- Zero or one public-network source IPv6 address.
- Private-network source IP addresses.

Each VPN instance can have only one private-network source IPv4 address and one private-network source IPv6 address in system view.

Examples

Specify IP address 129.10.10.1 as the source IP address for HWTACACS packets.

```
<Sysname> system-view
[Sysname] hwtacacs nas-ip 129.10.10.1
```

Related commands

hwtacacs scheme

Use **hwtacacs scheme** to create an HWTACACS scheme and enter its view, or enter the view of an existing HWTACACS scheme.

Use **undo hwtacacs scheme** to delete an HWTACACS scheme.

Syntax

hwtacacs scheme *hwtacacs-scheme-name*

undo hwtacacs scheme *hwtacacs-scheme-name*

Default

No HWTACACS schemes exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

hwtacacs-scheme-name: Specifies the HWTACACS scheme name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

An HWTACACS scheme can be used by more than one ISP domain at the same time.

You can configure a maximum of 16 HWTACACS schemes.

Examples

Create an HWTACACS scheme named **hwt1** and enter HWTACACS scheme view.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1]
```

Related commands

hwtacacs server-probe track

Use **hwtacacs server-probe track** to associate an HWTACACS server with a track entry.

Use **undo hwtacacs server-probe track** to remove the association between an HWTACACS server and a track entry.

Syntax

hwtacacs server-probe { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-number*] **track** *track-entry-number*

undo hwtacacs server-probe { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-number*] **track**

Default

An HWTACACS server is not associated with any track entry.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies an HWTACACS server by its IPv4 address.

ipv6 *ipv6-address*: Specifies an HWTACACS server by its IPv6 address.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the HWTACACS server belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the server is on the public network, do not specify this option.

port *port-number*: Specifies the service port number of the HWTACACS server. The value range for the TCP port number is 1 to 65535. The default setting is 49.

track-entry-number: Specifies a track entry by its ID, in the range of 1 to 1024.

Usage guidelines

Use this command on a network that has high real-time requirements for HWTACACS authentication, authorization, and accounting.

By default, the device does not actively detect the status of an HWTACACS server. It changes the state of an HWTACACS server to active or blocked based on the server response timeout timer and the server quiet timer. This timer-based state transition mechanism needs time to determine the server state, and it cannot ensure that the device obtains the actual server state in time. To resolve this issue, associate the server with a track entry and associate the track entry with a TCP-type NQA

operation. This HWTACACS server-Track-NQA collaboration can actively detect the reachability of the server in real time.

By using HWTACACS server-Track-NQA collaboration, the device determines the status of an HWTACACS server only based on the detection result.

1. The NQA operation starts to detect the reachability of the server and obtains the result. NQA sends the detection result to the Track module for the Track module to set the state of the track entry.
   - If the server is reachable, the Track module sets the state of the track entry to Positive.
   - If the server is unreachable, the Track module sets the state of the track entry to Negative.
   - If the Track-NQA collaboration does not take effect, the Track module keeps the track entry in NotReady state or changes its state to NotReady.
2. AAA sets the status of the server based on the track entry state.
   - If the track entry is in Positive state, AAA sets the state of the server to active.
   - If the track entry is in Negative state, AAA sets the state of the server to blocked and disables the quiet timer for the server.
   - If the track entry stays in NotReady state or its state changes to NotReady, AAA sets the state of the server to active.

To start the NQA operation to detect the reachability of the server, use the **nqa schedule** command with appropriate settings for the scheduling parameters. For more information about associating Track with NQA, see Track configuration in *Network Management and Monitoring Configuration guide*. For more information about configuring a TCP-type NQA operation and scheduling the NQA operation, see NQA configuration in *Network Management and Monitoring Configuration Guide*.

Examples

Associate HWTACACS server that uses IP address 10.163.155.13 and TCP port number 49 with track entry 1.

```
<Sysname> system-view
[Sysname] hwtacacs server-probe ip 10.163.155.13 port 49 track 1
```

key (HWTACACS scheme view)

Use **key** to set the shared key for secure HWTACACS authentication, authorization, or accounting communication.

Use **undo key** to delete the shared key for secure HWTACACS authentication, authorization, or accounting communication.

Syntax

key { **accounting** | **authentication** | **authorization** } { **cipher** | **simple** } *string*

undo key { **accounting** | **authentication** | **authorization** }

Default

No shared key is configured for secure HWTACACS authentication, authorization, or accounting communication.

Views

HWTACACS scheme view

Predefined user roles

network-admin

context-admin

Parameters

accounting: Specifies the shared key for secure HWTACACS accounting communication.

authentication: Specifies the shared key for secure HWTACACS authentication communication.

authorization: Specifies the shared key for secure HWTACACS authorization communication.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. The encrypted form of the key is a string of 1 to 373 characters. The plaintext form of the key is a string of 1 to 255 characters.

Usage guidelines

The shared keys configured on the device must match those configured on the HWTACACS servers.

Examples

In HWTACACS scheme **hwt1**, set the shared key to **123456TESTauth&!** in plaintext form for secure HWTACACS authentication communication.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] key authentication simple 123456TESTauth&!
```

Set the shared key to **123456TESTautr&!** in plaintext form for secure HWTACACS authorization communication.

```
[Sysname-hwtacacs-hwt1] key authorization simple 123456TESTautr&!
```

Set the shared key to **123456TESTacct&!** in plaintext form for secure HWTACACS accounting communication.

```
[Sysname-hwtacacs-hwt1] key accounting simple 123456TESTacct&!
```

Related commands

display hwtacacs scheme

nas-ip (HWTACACS scheme view)

Use **nas-ip** to specify a source IP address for outgoing HWTACACS packets.

Use **undo nas-ip** to delete the specified source IP address for outgoing HWTACACS packets.

Syntax

nas-ip { *ipv4-address* | **ipv6** *ipv6-address* }

undo nas-ip [**ipv6**]

Default

The source IP address of an outgoing HWTACACS packet is that configured by using the **hwtacacs nas-ip** command in system view.

If the **hwtacacs nas-ip** command is not used, the source IP address is the primary IP address of the outbound interface.

Views

HWTACACS scheme view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies an IPv4 address, which must be an address of the device. The IP address cannot be 0.0.0.0, 255.255.255.255, a class D address, a class E address, or a loopback address.

ipv6 *ipv6-address*: Specifies an IPv6 address, which must be a unicast address of the device and cannot be a loopback address or a link-local address.

Usage guidelines

The source IP address of HWTACACS packets that a NAS sends must match the IP address of the NAS that is configured on the HWTACACS server. An HWTACACS server identifies a NAS by IP address. Upon receiving an HWTACACS packet, the HWTACACS server checks the source IP address of the packet.

- If the source IP address of the packet is the IP address of a managed NAS, the server processes the packet.
- If the source IP address of the packet is not the IP address of a managed NAS, the server drops the packet.

As a best practice, specify a loopback interface address as the source IP address for outgoing HWTACACS packets to avoid HWTACACS packet loss caused by physical port errors.

If you use both the **nas-ip** command and **hwtacacs nas-ip** command, the following guidelines apply:

- The setting configured by using the **nas-ip** command in HWTACACS scheme view applies only to the HWTACACS scheme.
- The setting configured by using the **hwtacacs nas-ip** command in system view applies to all HWTACACS schemes.
- The setting in HWTACACS scheme view takes precedence over the setting in system view.

For an HWTACACS scheme, you can specify only one source IPv4 address and one source IPv6 address for outgoing HWTACACS packets.

If you do not specify any parameter for the **undo nas-ip** command, the command deletes the configured source IPv4 address for outgoing HWTACACS packets.

Examples

In HWTACACS scheme **hwt1**, specify IP address 10.1.1.1 as the source address for outgoing HWTACACS packets.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] nas-ip 10.1.1.1
```

Related commands

primary accounting (HWTACACS scheme view)

Use **primary accounting** to specify the primary HWTACACS accounting server.

Use **undo primary accounting** to restore the default.

Syntax

primary accounting { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

undo primary accounting

Default

The primary HWTACACS accounting server is not specified.

Views

HWTACACS scheme view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies an IPv4 address of the primary HWTACACS accounting server.

ipv6 *ipv6-address*: Specifies an IPv6 address of the primary HWTACACS accounting server.

port-number: Specifies the service port number of the primary HWTACACS accounting server. The value range for the TCP port number is 1 to 65535. The default setting is 49.

key: Specifies the shared key for secure communication with the primary HWTACACS accounting server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. The encrypted form of the key is a string of 1 to 373 characters. The plaintext form of the key is a string of 1 to 255 characters.

single-connection: The device and the primary HWTACACS accounting server use the same TCP connection to exchange accounting packets for all users. If you do not specify this keyword, the device establishes a new TCP connection each time it exchanges accounting packets with the primary accounting server for a user.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the primary HWTACACS accounting server belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the server is on the public network, do not specify this option.

Usage guidelines

Make sure the port number and shared key settings of the primary HWTACACS accounting server are the same as those configured on the server.

Two accounting servers specified for a scheme, primary or secondary, cannot have identical VPN instance, IP address, and port number settings.

As a best practice, specify the **single-connection** keyword to reduce TCP connections for improving system performance if the HWTACACS server supports the single-connection method.

If the specified server resides on an MPLS L3VPN, specify the VPN instance by using the **vpn-instance** *vpn-instance-name* option. The VPN instance specified by this command takes precedence over the VPN instance specified for the HWTACACS scheme.

You can remove an accounting server only when it is not used for user accounting. Removing an accounting server affects only accounting processes that occur after the remove operation.

Examples

In HWTACACS scheme **hwt1**, specify the primary accounting server with IP address 10.163.155.12, TCP port number 49, and plaintext shared key **123456TESTacct&!**.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] primary accounting 10.163.155.12 49 key simple 123456TESTacct&!
```

Parameters

ipv4-address: Specifies the IPv4 address of a secondary HWTACACS authentication server.

ipv6 *ipv6-address*: Specifies the IPv6 address of a secondary HWTACACS authentication server.

port-number: Specifies the service port number of the secondary HWTACACS authentication server. The value range for the TCP port number is 1 to 65535. The default setting is 49.

key: Specifies the shared key for secure communication with the secondary HWTACACS authentication server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. The encrypted form of the key is a string of 1 to 373 characters. The plaintext form of the key is a string of 1 to 255 characters.

single-connection: The device and the secondary HWTACACS authentication server use the same TCP connection to exchange all authentication packets for all users. If you do not specify this keyword, the device establishes a new TCP connection each time it exchanges authentication packets with the secondary authentication server for a user.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the secondary HWTACACS authentication server belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the server is on the public network, do not specify this option.

Usage guidelines

Make sure the port number and shared key settings of each secondary HWTACACS authentication server are the same as those configured on the corresponding server.

An HWTACACS scheme supports a maximum of 16 secondary HWTACACS authentication servers. If the primary server fails, the device tries to communicate with a secondary server in active state. The device connects to the secondary servers in the order they are configured.

If you do not specify any parameters for the **undo secondary authentication** command, the command removes all secondary authentication servers.

Two authentication servers specified for a scheme, primary or secondary, cannot have identical VPN instance, IP address, and port number settings.

As a best practice, specify the **single-connection** keyword to reduce TCP connections for improving system performance if the HWTACACS server supports the single-connection method.

If the specified server resides on an MPLS L3VPN, specify the VPN instance by using the **vpn-instance** *vpn-instance-name* option. The VPN instance specified by this command takes precedence over the VPN instance specified for the HWTACACS scheme.

You can remove an authentication server only when it is not used for user authentication. Removing an authentication server affects only authentication processes that occur after the remove operation.

Examples

In HWTACACS scheme **hwt1**, specify a secondary authentication server with IP address 10.163.155.13, TCP port number 49, and plaintext shared key **123456TESTauth&!**.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] secondary authentication 10.163.155.13 49 key simple
123456TESTauth&!
```

Related commands

key (HWTACACS scheme view)

primary authentication (HWTACACS scheme view)

vpn-instance (HWTACACS scheme view)

secondary authorization

Use **secondary authorization** to specify a secondary HWTACACS authorization server.

Use **undo secondary authorization** to remove a secondary HWTACACS authorization server.

Syntax

secondary authorization { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

undo secondary authorization [{ *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **vpn-instance** *vpn-instance-name*] *]

Default

No secondary HWTACACS authorization servers are specified.

Views

HWTACACS scheme view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies the IPv4 address of a secondary HWTACACS authorization server.

ipv6 *ipv6-address*: Specifies the IPv6 address of a secondary HWTACACS authorization server.

port-number: Specifies the service port number of the secondary HWTACACS authorization server. The value range for the TCP port number is 1 to 65535. The default setting is 49.

key: Specifies the shared key for secure communication with the secondary HWTACACS authorization server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. The encrypted form of the key is a string of 1 to 373 characters. The plaintext form of the key is a string of 1 to 255 characters.

single-connection: The device and the secondary HWTACACS authorization server use the same TCP connection to exchange all authorization packets for all users. If you do not specify this keyword, the device establishes a new TCP connection each time it exchanges authorization packets with the secondary authorization server for a user.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the secondary HWTACACS authorization server belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the server is on the public network, do not specify this option.

Usage guidelines

Make sure the port number and shared key settings of the secondary HWTACACS authorization server are the same as those configured on the server.

An HWTACACS scheme supports a maximum of 16 secondary HWTACACS authorization servers. If the primary server fails, the device tries to communicate with a secondary server in active state. The device connects to the secondary servers in the order they are configured.

If you do not specify any parameters for the **undo secondary authorization** command, the command removes all secondary authorization servers.

Two authorization servers specified for a scheme, primary or secondary, cannot have identical VPN instance, IP address, and port number settings.

As a best practice, specify the **single-connection** keyword to reduce TCP connections for improving system performance if the HWTACACS server supports the single-connection method.

If the specified server resides on an MPLS L3VPN, specify the VPN instance by using the **vpn-instance** *vpn-instance-name* option. The VPN instance specified by this command takes precedence over the VPN instance specified for the HWTACACS scheme.

You can remove an authorization server only when it is not used for user authorization. Removing an authorization server affects only authorization processes that occur after the remove operation.

Examples

In HWTACACS scheme **hwt1**, specify a secondary authorization server with IP address 10.163.155.13, TCP port number 49, and plaintext shared key **123456TESTautr&!**.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] secondary authorization 10.163.155.13 49 key simple
123456TESTautr&!
```

server-block-action

Use **server-block-action** to specify the action to take for AAA requests if all servers in an HWTACACS scheme are blocked.

Use **undo server-block-action** to restore the default.

Syntax

server-block-action { **attempt** | **skip** }

undo server-block-action

Default

The device attempts to connect to the server with the highest priority in an HWTACACS scheme upon receiving AAA requests if all servers in the scheme are blocked.

Views

HWTACACS scheme view

Predefined user roles

network-admin

context-admin

Parameters

attempt: Attempts to connect to the server that has the highest priority in the scheme. (Typically, the highest-priority server is the primary server. If no primary server is specified, it is the firstly configured secondary server.) If the device fails to connect to the server, it turns to the backup method.

skip: Skips all servers in the scheme and turns to the backup method.

Usage guidelines

The **attempt** action gives the device a chance to use the scheme in case the server with the highest priority in the scheme might be available. However, the attempt to communicate with an unavailable server increases the response time for AAA requests. As a best practice, specify the **skip** action in scenarios that require quick responses to AAA requests.

When processing an AAA request, the device does not turn back to a skipped scheme even though the state of the servers in the scheme changes from blocked to active.

Examples

In HWTACACS scheme **hwt1**, configure the device to skip all servers in the scheme upon receiving AAA requests if all servers in the scheme are blocked.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] server-block-action skip
```

Related commands

display hwtacacs scheme

timer quiet (HWTACACS scheme view)

Use **timer quiet** to set the quiet timer for the servers specified in an HWTACACS scheme.

Use **undo timer quiet** to restore the default.

Syntax

timer quiet *minutes*

undo timer quiet

Default

The server quiet period is 5 minutes.

Views

HWTACACS scheme view

Predefined user roles

network-admin

context-admin

Parameters

minutes: Specifies the server quiet period in minutes, in the range of 1 to 255.

Examples

In HWTACACS scheme **hwt1**, set the server quiet timer to 10 minutes.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] timer quiet 10
```

Related commands

display hwtacacs scheme

timer realtime-accounting (HWTACACS scheme view)

Use **timer realtime-accounting** to set the real-time accounting interval.

Use **undo timer realtime-accounting** to restore the default.

Syntax

timer realtime-accounting *minutes*

undo timer realtime-accounting

Default

The real-time accounting interval is 12 minutes.

Views

HWTACACS scheme view

Predefined user roles

network-admin

context-admin

Parameters

minutes: Specifies the real-time accounting interval in minutes, in the range of 0 to 60. Setting this interval to 0 disables the device from sending online user accounting information to the HWTACACS accounting server.

Usage guidelines

For real-time accounting, a NAS must transmit the accounting information of online users to the HWTACACS accounting server periodically. This command is used to set the interval.

A short interval helps improve accounting precision but requires many system resources.

Table 18 Recommended real-time accounting intervals

Number of users	Real-time accounting interval
1 to 99	3 minutes
100 to 499	6 minutes
500 to 999	12 minutes
1000 or more	15 minutes or longer

The device sends a start-accounting packet for a dual-stack user after the user obtains an IP address of one stack. No matter how long the real-time accounting interval is, the device sends an update-accounting packet for the user immediately after the user obtains an IP address of another stack.

Examples

In HWTACACS scheme **hwt1**, set the real-time accounting interval to 51 minutes.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] timer realtime-accounting 51
```

Related commands

display hwtacacs scheme

timer response-timeout (HWTACACS scheme view)

Use **timer response-timeout** to set the HWTACACS server response timeout timer.

Use **undo timer response-timeout** to restore the default.

Syntax

timer response-timeout *seconds*

undo timer response-timeout

Default

The HWTACACS server response timeout time is 5 seconds.

Views

HWTACACS scheme view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the HWTACACS server response timeout time, in the range of 1 to 300 seconds.

Usage guidelines

HWTACACS is based on TCP. When the server response timeout timer or the TCP timeout timer times out, the device is disconnected from the HWTACACS server.

The client timeout period of the associated access module cannot be shorter than the total response timeout timer of all HWTACACS servers in the scheme. Any violation will result in user logoffs before the authentication, authorization, or accounting process is complete.

Examples

In HWTACACS scheme **hwt1**, set the HWTACACS server response timeout timer to 30 seconds.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] timer response-timeout 30
```

Related commands

display hwtacacs scheme

user-name-format (HWTACACS scheme view)

Use **user-name-format** to specify the format of the username to be sent to an HWTACACS server.

Use **undo user-name-format** to restore the default.

Syntax

user-name-format { **keep-original** | **with-domain** | **without-domain** }

undo user-name-format

Default

The ISP domain name is included in the usernames sent to an HWTACACS server.

Views

HWTACACS scheme view

Predefined user roles

network-admin

context-admin

Parameters

keep-original: Sends the username to the HWTACACS server as the username is entered.

with-domain: Includes the ISP domain name in the username sent to the HWTACACS server.

without-domain: Excludes the ISP domain name from the username sent to the HWTACACS server.

Usage guidelines

A username is generally in the *userid@isp-name* format, of which the *isp-name* argument is used by the device to determine the ISP domain to which a user belongs. However, some HWTACACS servers cannot recognize a username containing an ISP domain name. Before sending a username including a domain name to such an HWTACACS server, the device must remove the domain name. This command allows you to specify whether to include a domain name in a username to be sent to an HWTACACS server.

If an HWTACACS scheme defines that the username is sent without the ISP domain name, do not apply the scheme to more than one ISP domain. Otherwise, the HWTACACS server will consider two users in different ISP domains but with the same *userid* as one user.

Examples

In HWTACACS scheme **hwt1**, configure the device to remove the ISP domain name from the usernames sent to the HWTACACS servers.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] user-name-format without-domain
```

Related commands

display hwtacacs scheme

vpn-instance (HWTACACS scheme view)

Use **vpn-instance** to specify an MPLS L3VPN instance for an HWTACACS scheme.

Use **undo vpn-instance** to restore the default.

Syntax

vpn-instance *vpn-instance-name*

undo vpn-instance

Default

The HWTACACS scheme belongs to the public network.

Views

HWTACACS scheme view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance-name: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

The VPN instance specified for an HWTACACS scheme applies to all servers in that scheme. If a VPN instance is also configured for an individual HWTACACS server, the VPN instance specified for the HWTACACS scheme does not take effect on that server.

Examples

Specify VPN instance **test** for HWTACACS scheme **hwt1**.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] vpn-instance test
```

Related commands

display hwtacacs scheme

LDAP commands

attribute-map

Use **attribute-map** to specify the LDAP attribute map in an LDAP scheme.

Use **undo attribute-map** to restore the default.

Syntax

attribute-map *map-name*

undo attribute-map

Default

An LDAP scheme does not use an LDAP attribute map.

Views

LDAP scheme view

Predefined user roles

network-admin

context-admin

Parameters

map-name: Specifies an LDAP attribute map by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

When the LDAP scheme used for authorization contains an LDAP attribute map, the device converts server-assigned LDAP attributes to device-recognizable AAA attributes based on the mapping entries.

You can specify only one LDAP attribute map in an LDAP scheme. If you execute this command multiple times, the most recent configuration takes effect.

If you specify another attribute map or change the mapping entries, the new settings take effect only on the LDAP authorization that occurs after your operation.

Examples

Specify LDAP attribute map **map1** in LDAP scheme **ldap1**.

```
<Sysname> system-view
```

```
[Sysname] ldap scheme ldap1
[Sysname-ldap-ldap1] attribute-map map1
```

context-admin

Parameters

server-name: Specifies the name of an LDAP server, a case-sensitive string of 1 to 64 characters.

Usage guidelines

You can specify only one LDAP authorization server in an LDAP scheme. If you execute this command multiple times, the most recent configuration takes effect.

Examples

In LDAP scheme **ldap1**, specify the LDAP authorization server as **ccc**.

```
<Sysname> system-view
[Sysname] ldap scheme ldap1
[Sysname-ldap-ldap1] authorization-server ccc
```

Related commands

display ldap scheme

ldap server

character-encoding

Use **character-encoding** to specify the character encoding format for an LDAP server.

Use **undo character-encoding** to restore the default.

Syntax

character-encoding { **gb18030** | **utf-8** }

undo character-encoding

Default

No character encoding format is specified for an LDAP server. The device does not change the character encoding format for information exchanged with the LDAP server.

Views

LDAP server view

Predefined user roles

network-admin

context-admin

Parameters

gb18030: Specifies the GB18030 character encoding format.

utf-8: Specifies the UTF-8 character encoding format.

Usage guidelines

By default, the device encodes the configuration made through the Web interface in GB18030 and that made through terminal software in the character encoding format used by the software. If the device and the LDAP server use different character encoding formats, some characters in the exchanged information might fail to be interpreted, causing further issues. For example, if user DNs on the LDAP server are Chinese and the user DNs on the device are English, user DN search will fail and the users will fail to come online. To resolve this issue, use this command to ensure that the device and the LDAP server use the same character encoding format.

After you specify the character encoding format for an LDAP server, the device processes LDAP packets exchanged with the LDAP server as follows:

- For an LDAP packet sent to the LDAP server, the device first decodes the information in the packet by using GB18030. Then, the device uses the specified character encoding format to encode the information.
- For an LDAP packet received form the LDAP server, the device first uses the specified character encoding format to decode the information in the packet. Then, the device uses GB18030 to encode the information and saves the information.

As a best practice to avoid LDAP authentication failure caused by inconsistent character encoding format, change the character encoding format before using the LDAP server to perform authentication on users.

Examples

Specify UTF-8 as the character encoding format for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] character-encoding utf-8
```

```

Table 19 Command output

Field	Description
Authentication server	Name of the LDAP authentication server. If no server is configured, this field displays **Not configured**.
Authorization server	Name of the LDAP authorization server. If no server is configured, this field displays **Not configured**.
IP	IP address of the LDAP server. If no server is specified, this field

Field	Description
	displays **Not configured**.
Port	Port number of the server. If no port number is specified, this field displays the default port number.
VPN instance	MPLS L3VPN instance to which the LDAP server belongs. If no VPN instance is specified, this field displays **Not configured**.
Source IP	Source IP address of the LDAP packets sent to the LDAP server. If no source IP is specified, this field displays **Not configured**.
LDAP protocol version	LDAP version, LDAPv2 or LDAPv3.
Server timeout interval	LDAP server timeout period, in seconds.
Login account DN	DN of the administrator.
Base DN	Base DN for user search.
Search scope	User DN search scope, including: • **all-level**—All subdirectories. • **single-level**—Next lower level of subdirectories under the base DN.
User searching parameters	User search parameters.
User object class	User object class for user DN search. If no user object class is configured, this field displays **Not configured**.
Username attribute	User account attribute for login.
Username format	Format for the username sent to the server.
Group filter	User group filter.
Character encoding	Character encoding format for the LDAP server: • GB18030. • UTF-8. This field is not available if no character encoding format has been specified for the LDAP server.
Attribute map	LDAP attribute map used by the scheme. If no LDAP attribute map is used, this field displays **Not configured**.

group-filter

Use **group-filter** to configure the user group filter.

Use **undo group-filter** to restore the default.

Syntax

group-filter *group-filter*

undo group-filter

Default

The user group filter is **(objectclass=group)**.

Views

LDAP server view

Predefined user roles

network-admin

context-admin

Parameters

group-filter: Specifies the user group filter, a case-sensitive string of 1 to 127 characters. The syntax of the filter must meet the filter syntax requirements defined by LDAP servers.

Usage guidelines

When the device requests to import user group information from an LDAP server, the LDAP server sends only user groups that match the user group filter to the device.

Examples

Configure the user group filter as **(&(objectclass=group)(name=group1))** for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] group-filter (&(objectclass=group)(name=group1))
```

Related commands

display ldap scheme

ip

Use **ip** to configure the IP address of the LDAP server.

Use **undo ip** to restore the default.

Syntax

ip *ip-address* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]

undo ip

Default

An LDAP server does not have an IP address.

Views

LDAP server view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IP address of the LDAP server.

port *port-number*: Specifies the TCP port number of the LDAP server. The value range for the *port-number* argument is 1 to 65535, and the default value is 389.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the LDAP server belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the server is on the public network, do not specify this option.

Usage guidelines

The LDAP service port configured on the device must be consistent with the service port of the LDAP server.

If you change the IP address and port number of the LDAP server, the change takes effect only on the LDAP authentication that occurs after the change.

Examples

Specify the IP address and port number as 192.168.0.10 and 4300 for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] ip 192.168.0.10 port 4300
```

Use **undo login-password** to restore the default.

Syntax

login-password { **cipher** | **simple** } *string*

undo login-password

Default

No administrator password is configured.

Views

LDAP server view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 128 characters. Its encrypted form is a case-sensitive string of 1 to 201 characters.

Usage guidelines

This command takes effect only after the **login-dn** command is used.

Examples

Specify the administrator password as **abcdefg** in plaintext form for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] login-password simple abcdefg
```

Related commands

display ldap scheme

login-dn

map

Use **map** to configure a mapping entry in an LDAP attribute map.

Use **undo map** to delete the specified mapping entries from the LDAP attribute map.

Syntax

map ldap-attribute *ldap-attribute-name* [**prefix** *prefix-value* **delimiter** *delimiter-value*] **aaa-attribute user-group**

undo map [**ldap-attribute** *ldap-attribute-name*]

Default

An LDAP attribute map does not contain mapping entries.

Views

LDAP attribute map view

Predefined user roles

network-admin

context-admin

Parameters

ldap-attribute *ldap-attribute-name*: Specifies an LDAP attribute by its name. The *ldap-attribute-name* argument is a case-sensitive string of 1 to 63 characters.

prefix *prefix-value* **delimiter** *delimiter-value*: Specifies a partial value string of the LDAP attribute for attribute mapping. The *prefix-value* argument represents the position where the partial string starts. The prefix is a case-sensitive string of 1 to 7 characters, such as **cn=**. The *delimiter-value* argument represents the position where the partial string ends, such as a comma (,). If you do not specify the **prefix** *prefix-value* **delimiter** *delimiter-value* option, the mapping entry uses the entire value string of the LDAP attribute.

aaa-attribute: Specifies an AAA attribute.

user-group: Specifies the user group attribute.

Usage guidelines

Because the device ignores unrecognized LDAP attributes, configure the mapping entries to include important LDAP attributes that should not be ignored.

An LDAP attribute can be mapped only to one AAA attribute. Different LDAP attributes can be mapped to the same AAA attribute.

If you do not specify an LDAP attribute for the **undo map** command, the command deletes all mapping entries from the LDAP attribute map.

Examples

In LDAP attribute map **map1**, map a partial value string of the LDAP attribute named **memberof** to AAA attribute named **user-group**.

```
<Sysname> system-view
[Sysname] ldap attribute-map map1
[Sysname-ldap-map-map1] map ldap-attribute memberof prefix cn= delimiter , aaa-attribute user-group
```

Related commands

ldap attribute-map

user-group

protocol-version

Use **protocol-version** to specify the LDAP version.

Use **undo protocol-version** to restore the default.

Syntax

protocol-version { **v2** | **v3** }

undo protocol-version

Default

The LDAP version is LDAPv3.

Views

LDAP server view

Predefined user roles

network-admin

context-admin

Parameters

v2: Specifies the LDAP version LDAPv2.

v3: Specifies the LDAP version LDAPv3.

Usage guidelines

For successful LDAP authentication, the LDAP version used by the device must be consistent with the version used by the LDAP server.

If you change the LDAP version, the change takes effect only on the LDAP authentication that occurs after the change.

A Microsoft LDAP server supports only LDAPv3.

Examples

Specify the LDAP version as LDAPv2 for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] protocol-version v2
```

Related commands

display ldap scheme

search-base-dn

Use **search-base-dn to** specify the base DN for user search.

Use **undo search-base-dn** to restore the default.

Syntax

search-base-dn *base-dn*

undo search-base-dn

Default

No base DN is specified for user search.

Views

LDAP server view

Predefined user roles

network-admin

context-admin

Parameters

base-dn: Specifies the base DN for user search, a case-insensitive string of 1 to 255 characters.

Examples

Specify the base DN for user search as **dc=ldap,dc=com** for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] search-base-dn dc=ldap,dc=com
```

Related commands

display ldap scheme

ldap server

search-scope

Use **search-scope** to specify the user search scope.

Use **undo search-scope** to restore the default.

Syntax

search-scope { **all-level** | **single-level** }

undo search-scope

Default

The user search scope is **all-level**.

Views

LDAP server view

Predefined user roles

network-admin

context-admin

Parameters

all-level: Specifies that the search goes through all subdirectories of the base DN.

single-level: Specifies that the search goes through only the next lower level of subdirectories under the base DN.

Examples

Specify the search scope for the LDAP authentication as all subdirectories of the base DN for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] search-scope all-level
```

Related commands

display ldap scheme

ldap server

server-timeout

Use **server-timeout** to set the LDAP server timeout period, the maximum time that the device waits for an LDAP response.

Use **undo server-timeout** to restore the default.

Syntax

server-timeout *time-interval*

undo server-timeout

Default

The LDAP server timeout period is 10 seconds.

Views

LDAP server view

Predefined user roles

network-admin

context-admin

Parameters

time-interval: Specifies the LDAP server timeout period in the range of 5 to 20 seconds.

Usage guidelines

If you change the LDAP server timeout period, the change takes effect only on the LDAP authentication that occurs after the change.

Examples

Set the LDAP server timeout period to 15 seconds for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] server-timeout 15
```

Related commands

display ldap scheme

source-ip

Use **source-ip** to specify a source interface or source IP address for outgoing LDAP packets.

Use **undo source-ip** to remove the source interface or the source IP address of the specified type for outgoing LDAP packets.

Syntax

source-ip { *ipv4-address* | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

undo source-ip [**interface** | **ipv6**]

Default

No IP address is specified as the source IP address of LDAP packets sent to an LDAP server. The device uses the primary IPv4 address or the IPv6 address of the outbound interface that can reach the server as the source IP address of LDAP packets sent to the server.

Views

LDAP server view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies a source interface by its type and number. The device uses the primary IPv4 address or the IPv6 address of the interface as the source IP address of an outgoing LDAP packet.

ipv4-address: Specifies an IPv4 address, which must be an address of the device. The IP address cannot be 0.0.0.0, 255.255.255.255, a class D address, a class E address, or a loopback address.

ipv6 *ipv6-address*: Specifies an IPv6 address, which must be a unicast address of the device and cannot be a loopback address or a link-local address.

Usage guidelines

When you use this command for an LDAP server, follow these restrictions and guidelines:

- You can specify only one source IPv4 address and one source IPv6 address for LDAP packets sent to the server.
- You can specify only one source interface. Make sure the source interface can reach the server.
- To have the source interface configuration take effect, make sure the source interface is in the same VPN instance as the server.
- To have the source address configuration take effect, the IP version of the specified source address must be the same as that of the server IP address.
- The source interface configuration and the source address configuration overwrite each other.

Examples

Specify 3.3.3.3 as the source IP address of the LDAP packets sent to LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] source-ip 3.3.3.3
```

Specify GigabitEthernet 1/0/1 as the source interface of the LDAP packets sent to LDAP server **ddd**.

```
<Sysname> system-view
[Sysname] ldap server ddd
[Sysname-ldap-server-ddd] source-ip interface gigabitethernet 1/0/1
```

user-parameters

Use **user-parameters** to configure LDAP user attributes, including the username attribute, username format, and user-defined user object class.

Use **undo user-parameters** to restore the default of an LDAP user attribute.

Syntax

user-parameters { **user-name-attribute** { *name-attribute* | **cn** | **uid** } | **user-name-format** { **with-domain** | **without-domain** } | **user-object-class** *object-class-name* }

undo user-parameters { **user-name-attribute** | **user-name-format** | **user-object-class** }

Default

The LDAP username attribute is **cn** and the username format is **without-domain**. No user object class is specified and the default user object class of the LDAP server is used.

Views

LDAP server view

Predefined user roles

network-admin

context-admin

Parameters

user-name-attribute { *name-attribute* | **cn** | **uid** }: Specifies the username attribute. The *name-attribute* argument represents an attribute value, a case-insensitive string of 1 to 64 characters. The **cn** keyword represents the user account attribute of common name, and the **uid** keyword represents the user account attribute of user ID.

user-name-format { **with-domain** | **without-domain** }: Specifies the format of the username to be sent to the server. The **with-domain** keyword means that the username contains the domain name, and the **without-domain** keyword means that the username does not contain the domain name.

user-object-class *object-class-name*: Specifies the user object class for user search. The *object-class-name* argument represents a class value, a case-insensitive string of 1 to 64 characters.

Usage guidelines

If the username on the LDAP server does not contain the domain name, specify the **without-domain** keyword. If the username contains the domain name, specify the **with-domain** keyword.

Examples

Set the user object class to **person** for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] user-parameters user-object-class person
```

display dot1x

Use **`display dot1x`** to display information about 802.1X.

Syntax

`display dot1x` [**`sessions`** | **`statistics`**] [**`interface`** *`interface-type interface-number`*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`sessions`: Displays 802.1X session information.

`statistics`: Displays 802.1X statistics.

`interface` *`interface-type interface-number`*: Specifies a port by its type and number.

Usage guidelines

If you do not specify the **`sessions`** keyword or the **`statistics`** keyword, this command displays all information about 802.1X, including session information, statistics, and settings.

If you do not specify any parameters, this command displays all 802.1X information.

Examples

Display all information about 802.1X.

```
<Sysname> display dot1x

Table 1 Command output

Field	Description
Global 802.1X parameters	Global 802.1X configuration.
802.1X authentication	Whether 802.1X is enabled globally.
CHAP authentication	Performs EAP termination and uses CHAP to communicate with the RADIUS server.
EAP authentication	Relays EAP packets and supports any of the EAP authentication methods to communicate with the RADIUS server.
PAP authentication	Performs EAP termination and uses PAP to communicate with the RADIUS server.
Max-tx period	Username request timeout timer in seconds.
Handshake period	Handshake timer in seconds.
Quiet timer	Status of the quiet timer, enabled or disabled.
Quiet period	Quiet timer in seconds.
Supp timeout	Client timeout timer in seconds.
Server timeout	Server timeout timer in seconds.
Reauth period	Periodic reauthentication timer in seconds.
Max auth requests	Maximum number of attempts for sending an authentication request to a client.
SmartOn switch ID	Switch ID for SmartOn authentication.
SmartOn supp timeout	SmartOn client timeout timer in seconds.
SmartOn retry counts	Maximum number of attempts for retransmitting an EAP-Request/Notification packet to a client.
EAD assistant function	Whether EAD assistant is enabled.
URL	Redirect URL for unauthenticated users using a Web browser to access the network.
Free IP	Network segment accessible to unauthenticated users.
EAD timeout	EAD rule timer in minutes.
Domain delimiter	Domain delimiters supported by the device.
Online 802.1X wired users	Number of wired online 802.1X users, including users that have passed 802.1X authentication and users that are performing 802.1X authentication.
Online 802.1X wireless users	Number of wireless online 802.1X users, including users that have passed 802.1X authentication and users that are performing 802.1X authentication.
GigabitEthernet1/0/1 is link-up	Status of the port. In this example, GigabitEthernet 1/0/1 is up.
802.1X authentication	Whether 802.1X is enabled on the port.
Handshake	Whether the online user handshake feature is enabled on the port.
Handshake reply	Whether the online user handshake reply feature is enabled on the port.
Handshake security	Whether the online user handshake security feature is enabled on the port.

Field	Description
Unicast trigger	Whether the 802.1X unicast trigger is enabled on the port.
Periodic reauth	Whether 802.1X periodic reauthentication is enabled on the port.
Port role	Role of the port. The port functions only as an **Authenticator**.
Authorization mode	Authorization state of the port, which can be Force-Authorized, Auto, or Force-Unauthorized.
Port access control	Access control method of the port: • **MAC-based**—MAC-based access control. • **Port-based**—Port-based access control.
Multicast trigger	Whether the 802.1X multicast trigger feature is enabled.
Mandatory auth domain	Mandatory authentication domain on the port.
Guest VLAN	802.1X guest VLAN configured on the port. If no 802.1X guest VLAN is configured on the port, this field displays **Not configured**.
Auth-Fail VLAN	802.1X Auth-Fail VLAN configured on the port. If no 802.1X Auth-Fail VLAN is configured on the port, this field displays **Not configured**.
Critical VLAN	802.1X critical VLAN configured on the port. If no 802.1X critical VLAN is configured on the port, this field displays **Not configured**.
Re-auth server-unreachable	Whether to log off online 802.1X users or keep them online when no server is reachable for 802.1X reauthentication.
Max online users	Maximum number of concurrent 802.1X users on the port.
SmartOn	Whether SmartOn authentication is enabled on the port.
EAPOL packets	Number of sent (Tx) and received (Rx) EAPOL packets.
Sent EAP Request/Identity packets	Number of sent EAP-Request/Identity packets.
EAP Request/Challenge packets	Number of sent EAP-Request/MD5-Challenge packets.
EAP Success packets	Number of sent EAP-Success packets.
EAP Failure packets	Number of sent EAP-Failure packets.
Received EAPOL Start packets	Number of received EAPOL-Start packets.
EAPOL LogOff packets	Number of received EAPOL-LogOff packets.
EAP Response/Identity packets	Number of received EAP-Response/Identity packets.
EAP Response/Challenge packets	Number of received EAP-Response/MD5-Challenge packets.
Error packets	Number of received error packets.
Online 802.1X users	Number of online 802.1X users on the port, including users that have passed 802.1X authentication and users that are performing 802.1X authentication.
MAC address	MAC addresses of the online 802.1X users.
Auth state	Authentication status of the online 802.1X users.
SSID	SSID with which users are associated.
BSSID	ID of the BSS with which users are associated.

display dot1x connection

Use **display dot1x connection** to display information about online 802.1X users.

Syntax

display dot1x connection [**interface** *interface-type interface-number* | **slot** *slot-number* | **user-mac** *mac-address* | **user-name** *name-string*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number. If you do not specify a port, this command displays online 802.1X user information for all ports.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays online 802.1X user information for all member devices.

user-mac *mac-address*: Specifies an 802.1X user by MAC address. The *mac-address* argument represents the MAC address of the user, in the form of H-H-H. If you do not specify an 802.1X user, this command displays online user information for all 802.1X users.

user-name *name-string*: Specifies an 802.1X user by its name. The *name-string* argument represents the username, a case-sensitive string of 1 to 253 characters. If you do not specify an 802.1X user, this command displays online user information for all 802.1X users.

Usage guidelines

If you do not specify any parameters, this command displays information about online 802.1X users for all ports.

If you do not specify any parameters, this command displays information about online 802.1X users for all member devices.

Examples

Display all online 802.1X user information.

```
<Sysname> display dot1x connection
Total connections: 1

```

Table 2 Command output

Field	Description
Total connections	Number of online 802.1X users.
User MAC address	MAC address of the user.
Access interface	Interface through which the user access the device.
AP name	Name of the AP with which the user is associated.
Radio ID	ID of the radio with which the user is associated.
Authentication domain	ISP domain used for 802.1X authentication.
IPv4 address	IPv4 address of the user. If the device does not get the IPv4 address of the user, this field is not available.
IPv6 address	IPv6 address of the user. If the device does not get the IPv6 address of the user, this field is not available.

Field	Description
Authentication method	EAP message handling method: • **CHAP**—Performs EAP termination and uses CHAP to communicate with the RADIUS server. • **EAP**—Relays EAP packets and supports any of the EAP authentication methods to communicate with the RADIUS server. • **PAP**—Performs EAP termination and uses PAP to communicate with the RADIUS server.
Initial VLAN	VLAN to which the user belongs before 802.1X authentication.
Authorization untagged VLAN	Untagged VLAN authorized to the user.
Authorization tagged VLAN list	Tagged VLANs authorized to the user.
Authorization ACL number/name	Number or name of the ACL authorized to the user. If no ACL is authorized, this field displays **N/A**. If ACL authorization fails, this field displays **(Not effective)** after the ACL number or name.
Authorization user profile	User profile authorized to the user.
Authorization CAR	Authorization CAR attributes assigned by the server. • **Average input rate**—Average rate of inbound traffic in bps. • **Average output rate**—Average rate of outbound traffic in bps. If no authorization CAR attributes are assigned, this field displays **N/A**.
Termination action	Action attribute assigned by the server to terminate the user session: • **Default**—Logs off the online authenticated 802.1X user when the session timeout timer expires. This attribute does not take effect when 802.1X periodic reauthentication is enabled and the periodic reauthentication timer is shorter than the session timeout timer. • **Radius-request**—Reauthenticates the online user when the session timeout timer expires, regardless of whether the 802.1X periodic reauthentication feature is enabled or not. If the device performs local authentication, this field displays **N/A**.
Session timeout period	Session timeout timer assigned by the server. If the device performs local authentication, this field displays **N/A**.
Online from	Time from which the 802.1X user came online.
Online duration	Online duration of the 802.1X user.

dot1x

Use **dot1x** to enable 802.1X globally or on a port.

Use **undo dot1x** to disable 802.1X globally or on a port.

Syntax

dot1x

undo dot1x

Default

802.1X is neither enabled globally nor enabled for any port.

Views

System view

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

For the 802.1X feature to take effect on a port, you must enable the feature both globally and on the port.

Examples

Enable 802.1X globally.

```
<Sysname> system-view
[Sysname] dot1x
```

Enable 802.1X on GigabitEthernet 1/0/1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x
[Sysname-GigabitEthernet1/0/1] quit
```

Related commands

display dot1x

dot1x authentication-method

Use **dot1x authentication-method** to specify an EAP message handling method.

Use **undo dot1x authentication-method** to restore the default.

Syntax

dot1x authentication-method { **chap** | **eap** | **pap** }

undo dot1x authentication-method

Default

The access device performs EAP termination and uses CHAP to communicate with the RADIUS server.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

chap: Configures the access device to perform Extensible Authentication Protocol (EAP) termination and use the Challenge Handshake Authentication Protocol (CHAP) to communicate with the RADIUS server.

eap: Configures the access device to relay EAP packets, and supports any of the EAP authentication methods to communicate with the RADIUS server.

pap: Configures the access device to perform EAP termination and use the Password Authentication Protocol (PAP) to communicate with the RADIUS server.

Usage guidelines

The access device terminates or relays EAP packets.

- **In EAP termination mode**—The access device re-encapsulates and sends the authentication data from the client in standard RADIUS packets to the RADIUS server. The device performs either CHAP or PAP authentication with the RADIUS server. In this mode, the RADIUS server supports only MD5-Challenge EAP authentication and the username and password EAP authentication initiated by an iNode client.
  - PAP transports usernames and passwords in plain text. The authentication method applies to scenarios that do not require high security. To use PAP, the client can be an iNode 802.1X client.
  - CHAP transports usernames in plain text and passwords in encrypted form over the network. CHAP is more secure than PAP.
- **In EAP relay mode**—The access device relays EAP messages between the client and the RADIUS server. The EAP relay mode supports multiple EAP authentication methods, such as MD5-Challenge, EAP-TLS, and PEAP. To use this mode, make sure the RADIUS server meets the following requirements:
  - Supports the EAP-Message and Message-Authenticator attributes.
  - Uses the same EAP authentication method as the client.

  If this mode is used, the **user-name-format** command configured in RADIUS scheme view does not take effect. For more information about the **user-name-format** command, see "RADIUS commands."

If RADIUS authentication is used, you must configure the access device to use the same authentication method (PAP, CHAP, or EAP) as the RADIUS server.

Examples

Enable the access device to terminate EAP packets and perform PAP authentication with the RADIUS server.

```
<Sysname> system-view
[Sysname] dot1x authentication-method pap
```

display dot1x

dot1x auth-fail vlan

Use **dot1x auth-fail vlan** to configure an 802.1X Auth-Fail VLAN on a port.

Use **undo dot1x auth-fail vlan** to restore the default.

Syntax

dot1x auth-fail vlan *authfail-vlan-id*

undo dot1x auth-fail vlan

Default

No 802.1X Auth-Fail VLAN exists on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

authfail-vlan-id: Specifies the ID of the 802.1X Auth-Fail VLAN on the port. The value range for the VLAN ID is 1 to 4094. Make sure the VLAN has been created. If the port type is hybrid, verify that the VLAN to be specified as the Auth-Fail VLAN is not in the tagged VLAN list on the port.

Usage guidelines

An 802.1X Auth-Fail VLAN accommodates users that have failed 802.1X authentication for any reason other than unreachable servers. Users in the Auth-Fail VLAN can access a limited set of network resources.

To delete a VLAN that has been configured as an 802.1X Auth-Fail VLAN, you must first use the **undo dot1x auth-fail vlan** command.

Examples

Configure VLAN 100 as the Auth-Fail VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x auth-fail vlan 100
```

dot1x critical vlan

Use **dot1x critical vlan** to configure an 802.1X critical VLAN on a port.

Use **undo dot1x critical vlan** to restore the default.

Syntax

dot1x critical vlan *critical-vlan-id*

undo dot1x critical vlan

Default

No 802.1X critical VLAN exists on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

critical-vlan-id: Specifies the ID of the 802.1X critical VLAN on the port. The value range for the VLAN ID is 1 to 4094. Make sure the VLAN has been created. If the port type is hybrid, verify that the VLAN to be specified as the critical VLAN is not in the tagged VLAN list on the port.

Usage guidelines

An 802.1X critical VLAN accommodates users that fail 802.1X authentication because all the RADIUS servers in their ISP domains are unreachable. Users in the critical VLAN can access a limited set of network resources depending on the configuration.

To delete a VLAN that has been configured as an 802.1X critical VLAN, you must first use the **undo dot1x critical vlan** command.

Examples

Specify VLAN 100 as the 802.1X critical VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x critical vlan 100
```

Related commands

display dot1x

dot1x domain-delimiter

Use **dot1x domain-delimiter** to specify a set of domain name delimiters supported by the device.

Use **undo dot1x domain-delimiter** to restore the default.

Syntax

dot1x domain-delimiter *string*

undo dot1x domain-delimiter

Default

The device supports only the at sign (@) delimiter for 802.1X users.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

string: Specifies a set of 1 to 16 domain name delimiters for 802.1X users. No space is required between delimiters. Available delimiters include the at sign (@), backslash (\), dot (.), and forward slash (/). If you want to use backslash (\) as the domain name delimiter, you must enter the escape character (\) along with the backslash (\) sign.

Usage guidelines

Any character in the configured set can be used as the domain name delimiter for 802.1X authentication users. Usernames that include domain names can use the format of *username*@*domain-name*, *domain-name**username*, *username*.*domain-name*, or *username*/*domain-name*.

The delimiter set you configured overrides the default setting. If the at sign (@) is not included in the delimiter set, the device does not support the 802.1X users that use this sign as the domain name delimiter.

If a username string contains multiple configured delimiters, the device takes the rightmost delimiter in the username string as the domain name delimiter. For example, if you configure the forward slash (/), dot (.), and backslash (\) as delimiters, the domain name delimiter for the username string 121.123/22\@abc is the backslash (\). The username is **@abc** and the domain name is **121.123/22**.

Examples

Specify the at sign (@) and forward slash (/) as domain name delimiters.

```
<Sysname> system-view
[Sysname] dot1x domain-delimiter @/
```

Syntax

dot1x ead-assistant free-ip *ip-address* { *mask-address* | *mask-length* }

undo dot1x ead-assistant free-ip { *ip-address* { *mask-address* | *mask-length* } | **all** }

Default

No free IPs exist. Users cannot access any segments before they pass 802.1X authentication.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies a freely accessible IP address segment, also called a free IP.

mask: Specifies an IP address mask.

mask-length: Specifies IP address mask length in the range of 1 to 32.

all: Removes all free IP addresses.

Usage guidelines

With EAD assistant enabled on the device, unauthenticated 802.1X users can access the network resources in the free IP segments before they pass 802.1X authentication.

Execute this command multiple times to configure multiple free IPs.

Examples

Configure 192.168.1.1/16 as a free IP.

```
<Sysname> system-view
[Sysname] dot1x ead-assistant free-ip 192.168.1.1 255.255.0.0
```

dot1x ead-assistant url

Use **dot1x ead-assistant url** to configure a redirect URL for EAD assistant.

Use **undo dot1x ead-assistant url** to restore the default.

Syntax

dot1x ead-assistant url *url-string*

undo dot1x ead-assistant url

Default

No redirect URL exists for EAD assistant.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the redirect URL, a case-sensitive string of 1 to 64 characters.

Usage guidelines

When an unauthenticated user uses a Web browser to access any network other than the free IP, the device redirects the HTTP requests of the user to the redirect URL.

The redirect URL must be on the free IP subnet.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure the redirect URL as http://test.com.

```
<Sysname> system-view
[Sysname] dot1x ead-assistant url http://test.com
```

Use **undo dot1x guest-vlan** to restore the default.

Syntax

dot1x guest-vlan *guest-vlan-id*

undo dot1x guest-vlan

Default

No 802.1X guest VLAN exists on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

guest-vlan-id: Specifies the ID of the 802.1X guest VLAN. The value range for the VLAN ID is 1 to 4094. Make sure the VLAN has been created. If the port type is hybrid, verify that the VLAN to be specified as the guest VLAN is not in the tagged VLAN list on the port.

Usage guidelines

An 802.1X guest VLAN accommodates users that have not performed 802.1X authentication. In the guest VLAN, users can access a limited set of network resources, such as a software server, to download anti-virus software and system patches.

To delete a VLAN that has been configured as a guest VLAN, you must use the **undo dot1x guest-vlan** command first.

Examples

Specify VLAN 100 as the 802.1X guest VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
```

```

dot1x mandatory-domain

Use **dot1x mandatory-domain** to specify a mandatory 802.1X authentication domain on a port.

Use **undo dot1x mandatory-domain** to restore the default.

Syntax

dot1x mandatory-domain *domain-name*

undo dot1x mandatory-domain

Default

No mandatory 802.1X authentication domain is specified on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies the ISP domain name, a case-insensitive string of 1 to 255 characters.

Usage guidelines

When the system authenticates an 802.1X user trying to access a port, it selects an authentication domain in the following order:

1. Mandatory domain.
2. ISP domain specified in the username.
3. Default ISP domain.

Examples

Specify **my-domain** as the mandatory authentication domain for 802.1X users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x mandatory-domain my-domain
```

Use **dot1x max-user** to set the maximum number of concurrent 802.1X users on a port.

Use **undo dot1x max-user** to restore the default.

Syntax

dot1x max-user *max-number*

undo dot1x max-user

Default

The default is 4294967295.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Sets the maximum number of concurrent 802.1X users on a port. The value range is 1 to 4294967295.

Usage guidelines

Set the maximum number of concurrent 802.1X users on a port to prevent the system resources from being overused. When the maximum number is reached, the port denies subsequent 802.1X users.

Examples

Set the maximum number of concurrent 802.1X users to 32 on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x max-user 32
```

dot1x multicast-trigger

Use **dot1x multicast-trigger** to enable the 802.1X multicast trigger feature.

Use **undo dot1x multicast-trigger** to disable the 802.1X multicast trigger feature.

Syntax

dot1x multicast-trigger

undo dot1x multicast-trigger

Default

The 802.1X multicast trigger feature is enabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

The multicast trigger feature enables the device to act as the initiator. The device periodically multicasts EAP-Request/Identity packets out of a port to detect 802.1X clients and trigger authentication. You can use the **dot1x timer tx-period** command to set the interval for sending multicast EAP-Request/Identity packets.

Disable the multicast trigger in a wireless LAN. Wireless clients and the wireless module of the access device can both initiate 802.1X authentication.

Examples

Enable the multicast trigger feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x multicast-trigger
```

dot1x port-control

Use **dot1x port-control** to set the authorization state for the port.

Use **undo dot1x port-control** to restore the default.

Syntax

dot1x port-control { **authorized-force** | **auto** | **unauthorized-force** }

undo dot1x port-control

Default

The default port authorization state is **auto**.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

authorized-force: Places the port in authorized state, enabling users on the port to access the network without authentication.

auto: Places the port initially in unauthorized state to allow only EAPOL packets to pass, and places the port in authorized state after a user passes authentication. You can use this option in most scenarios.

unauthorized-force: Places the port in unauthorized state, denying any access requests from users on the port.

Usage guidelines

You can use this command to set the port authorization state to determine whether a client is granted access to the network.

Examples

Set the authorization state of GigabitEthernet 1/0/1 to **unauthorized-force**.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x port-control unauthorized-force
```

Related commands

display dot1x

dot1x port-method

Use **dot1x port-method** to specify an access control method for the port.

Use **undo dot1x port-method** to restore the default.

Syntax

dot1x port-method { **macbased** | **portbased** }

undo dot1x port-method

Default

MAC-based access control applies.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

macbased: Uses MAC-based access control on the port to separately authenticate each user attempting to access the network. Using this method, when an authenticated user logs off, no other online users are affected.

portbased: Uses port-based access control on the port. Using this method, once an 802.1X user passes authentication on the port, any subsequent user can access the network through the port without authentication. When the authenticated user logs off, all other users are logged off.

Usage guidelines

CAUTION:

If online 802.1X users are present on a port, changing its access control method will cause the online users to go offline.

MAC-based access control provides higher security than port-based access control.

Examples

Configure GigabitEthernet 1/0/1 to implement port-based access control.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x port-method portbased
```

dot1x retry

Use **dot1x retry** to set the maximum number of attempts for sending an authentication request to a client.

Use **undo dot1x retry** to restore the default.

Syntax

dot1x retry *retries*

undo dot1x retry

Default

A maximum of two attempts are made to send an authentication request to a client.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

retries: Specifies the maximum number of attempts for sending an authentication request to a client. The value range is 1 to 10.

Usage guidelines

The access device retransmits an authentication request to a client in any of the following situations:

- The device does not receive any responses from the client within the username request timeout interval. The timer is set by using the **dot1x timer tx-period** *tx-period-value* command for the EAP-Request/Identity packet.
- The device does not receive any responses from the client within the client timeout interval. The timer is set by using the **dot1x timer supp-timeout** *supp-timeout-value* command for the EAP-Request/MD5-Challenge packet.

The access device stops retransmitting the request, if it has made the maximum number of request transmission attempts but still received no response.

Examples

Set the maximum number of attempts to 9 for sending an authentication request to a client.

```
<Sysname> system-view
[Sysname] dot1x retry 9
```

Related commands

dot1x smarton

Use **dot1x smarton** to enable the SmartOn feature on a port.

Use **undo dot1x smarton** to disable the SmartOn feature on a port.

Syntax

dot1x smarton

undo dot1x smarton

Default

The SmartOn feature is disabled on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

When a SmartOn-enabled port receives an EAPOL-Start packet from an 802.1X client, it sends a unicast EAP-Request/Notification packet to the client. The client will respond with an EAP-Response/Notification packet, which contains the SmartOn switch ID and the MD5 digest of the SmartOn password. The device compares the digest in the packet with the digest on the device. If they are the same, the device continues to perform 802.1X authentication for the client. Otherwise, the device denies the client's 802.1X authentication request.

The SmartOn feature and the online user handshake feature are mutually exclusive.

Examples

Enable the SmartOn feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x smarton
```

display dot1x

dot1x smarton switched

dot1x smarton password

dot1x smarton password

Use **dot1x smarton password** to set a SmartOn password.

Use **undo dot1x smarton password** to restore the default.

Syntax

dot1x smarton password { **cipher** | **simple** } *string*

undo dot1x smarton password

Default

No SmartOn password is set.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies a password in encrypted form.

simple: Specifies password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 16 characters. Its encrypted form is a case-sensitive string of 1 to 53 characters

Usage guidelines

The device checks the MD5 digest of the SmartOn password in each received EAP-Response/Notification packet. If the digest is different from the SmartOn password digest on the device, the device stops the 802.1X authentication process for the client that sends this packet.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Set the SmartOn password to **abc** in plaintext form.

```
<Sysname> system-view
[Sysname] dot1x smarton password simple abc
```

dot1x smarton retry

Use **dot1x smarton retry** to set the maximum number of attempts for retransmitting an EAP-Request/Notification packet to a client.

Use **undo dot1x smarton retry** to restore the default.

Syntax

dot1x smarton retry *retries*

undo dot1x smarton retry

Default

A maximum of three attempts are made to retransmit an EAP-Request/Notification packet to a client.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

retries: Specifies the maximum attempts for retransmitting an EAP-Request/Notification packet to a client. The value range is 1 to 10.

Usage guidelines

When the device sends an EAP-Request/Notification packet to the client, the SmartOn client timeout timer (set by using the **dot1x smarton timer supp-timeout** command) starts. If the device does not receive any EAP-Response/Notification packets from the client before the timer expires, it retransmits the EAP-Request/Notification packet to the client. After the device has made the maximum retransmission attempts but received no response, it stops the 802.1X authentication process for the client.

Examples

Set the maximum attempts to 5 for retransmitting an EAP-Request/Notification packet.

```
<Sysname> system-view
[Sysname] dot1x smarton retry 5
```

dot1x smarton password

dot1x smarton timer supp-timeout

Use **dot1x smarton timer supp-timeout** to set the SmartOn client timeout timer.

Use **undo dot1x smarton timer supp-timeout** to restore the default.

Syntax

dot1x smarton timer supp-timeout *supp-timeout-value*

undo dot1x smarton timer supp-timeout

Default

The SmartOn client timeout timer is 30 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

supp-timeout-value: Sets the SmartOn client timeout timer in seconds. The value range is 10 to 120.

Usage guidelines

The SmartOn client timeout timer starts when the device sends an EAP-Request/Notification packet to the client. If the device does not receive any EAP-Response/Notification packets from the client within the timer interval, it retransmits the EAP-Request/Notification packet. After the device has made the maximum retransmission attempts but received no response, it stops the 802.1X authentication process for the client. To set the maximum retransmission attempts, use the **dot1x smarton retry** command.

Examples

Set the SmartOn client timeout timer to 20 seconds.

```
<Sysname> system-view
[Sysname] dot1x smarton timer supp-timeout 20
```

Related commands

display dot1x

dot1x smarton retry

dot1x timer

Use **dot1x timer** to set an 802.1X timer.

Use **undo dot1x timer** to restore the default of an 802.1X timer.

Syntax

dot1x timer { **ead-timeout** *ead-timeout-value* | **handshake-period** *handshake-period-value* | **quiet-period** *quiet-period-value* | **reauth-period** *reauth-period-value* | **server-timeout** *server-timeout-value* | **supp-timeout** *supp-timeout-value* | **tx-period** *tx-period-value* }

undo dot1x timer { **ead-timeout** | **handshake-period** | **quiet-period** | **reauth-period** | **server-timeout** | **supp-timeout** | **tx-period** }

Default

The following 802.1X timers apply:

- EAD rule timer: 30 minutes.
- Handshake timer: 15 seconds.
- Quiet timer: 60 seconds.
- Periodic reauthentication timer: 3600 seconds.
- Server timeout timer: 100 seconds.
- Client timeout timer: 30 seconds.
- Username request timeout timer: 30 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ead-timeout *ead-timeout-value*: Sets the EAD rule timer in minutes. The value range for the *ead-timeout-value* argument is 1 to 1440.

handshake-period *handshake-period-value*: Sets the handshake timer in seconds. The value range for the *handshake-period-value* argument is 5 to 1024.

quiet-period *quiet-period-value*: Sets the quiet timer in seconds. The value range for the *quiet-period-value* argument is 10 to 120.

reauth-period *reauth-period-value*: Sets the periodic reauthentication timer in seconds. The value range for the *reauth-period-value* argument is 60 to 7200.

server-timeout *server-timeout-value*: Sets the server timeout timer in seconds. The value range for the *server-timeout-value* argument is 100 to 300.

supp-timeout *supp-timeout-value*: Sets the client timeout timer in seconds. The value range for the *supp-timeout-value* argument is 1 to 120.

tx-period *tx-period-value*: Sets the username request timeout timer in seconds. The value range for the *tx-period-value* argument is 1 to 120.

Usage guidelines

In most cases, the default settings are sufficient. You can edit the timers, depending on the network conditions.

- In a low-speed network, increase the client timeout timer.
- In a vulnerable network, set the quiet timer to a high value.
- In a high-performance network with quick authentication response, set the quiet timer to a low value.
- In a network with authentication servers of different performance, adjust the server timeout timer.

The network device uses the following 802.1X timers:

- **EAD rule timer (ead-timeout)**—Sets the lifetime of each EAD rule. When the timer expires or the user passes authentication, the rule is removed. If users fail to download the EAD client

or fail to pass authentication within the timer interval, they must reconnect to the network to access the free IP.

- **Handshake timer (`handshake-period`)**—Sets the interval at which the access device sends client handshake requests to check the online status of a client that has passed authentication. If the device does not receive a response after sending the maximum number of handshake requests, it considers that the client has logged off.
- **Quiet timer (`quiet-period`)**—Starts when a client fails authentication. The access device must wait the time period before it can process the authentication attempts from the client.
- **Periodic reauthentication timer (`reauth-period`)**—Sets the interval at which the access device periodically reauthenticates online 802.1X users. To enable 802.1X periodic reauthentication on a port, use the **`dot1x re-authenticate`** command.
- **Server timeout timer (`server-timeout`)**—Starts when the access device sends a RADIUS Access-Request packet to the authentication server. If no response is received when this timer expires, 802.1X authentication fails.
- **Client timeout timer (`supp-timeout`)**—Starts when the access device sends an EAP-Request/MD5-Challenge packet to a client. If no response is received when this timer expires, the access device retransmits the request to the client.
- **Username request timeout timer (`tx-period`)**—Starts when the access device sends an EAP-Request/Identity packet to a client in response to an authentication request. If the device does not receive a response before this timer expires, it retransmits the request. The timer also sets the interval at which the access device sends multicast EAP-Request/Identity packets to detect clients that cannot actively request authentication.

The change to the periodic reauthentication timer applies to the users that have been online only after the old timer expires. Other timer changes take effect immediately on the device.

Examples

Set the server timeout timer to 150 seconds.

```
<Sysname> system-view
[Sysname] dot1x timer server-timeout 150
```

dot1x unicast-trigger

Use **`dot1x unicast-trigger`** to enable the 802.1X unicast trigger feature.

Use **`undo dot1x unicast-trigger`** to disable the 802.1X unicast trigger feature.

Syntax

`dot1x unicast-trigger`

`undo dot1x unicast-trigger`

Default

The 802.1X unicast trigger feature is disabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

The unicast trigger feature enables the access device to initiate 802.1X authentication when the device receives a data frame from an unknown source MAC address. The device sends a unicast EAP-Request/Identity packet to the unknown source MAC address. It will retransmit the packet if it does not receive any responses within a period of time (set by using the **dot1x timer tx-period** command). This process continues until the maximum number of request attempts (set by using the **dot1x retry** command) is reached.

As a best practice, do not use the unicast trigger on a port that performs port-based access control. If you do so, users on that port might fail to come online.

Examples

Enable the unicast trigger feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x unicast-trigger
```

reset dot1x guest-vlan

Use **reset dot1x guest-vlan** to remove users from the 802.1X guest VLAN on a port.

Syntax

reset dot1x guest-vlan interface *interface-type interface-number* [**mac-address** *mac-address*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number.

mac-address *mac-address*: Specifies the MAC address of an 802.1X user in the guest VLAN. If you do not specify this option, the command removes all 802.1X users from the 802.1X guest VLAN on the port.

Examples

Remove the 802.1X user with MAC address 1-1-1 from the 802.1X guest VLAN on GigabitEthernet 1/0/1.

```
<Sysname> reset dot1x guest-vlan interface gigabitethernet 1/0/1 mac-address 1-1-1
```

User identification commands

account-update-interval

Use **account-update-interval** to set the interval for automatic identity user account import.

Use **undo account-update-interval** to restore the default.

Syntax

account-update-interval *interval*

undo account-update-interval

Default

The interval is 24 hours for automatic identity user account import.

Views

Identity user import policy view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies an interval in the range of 1 to 65536 hours.

Usage guidelines

After you enable automatic import for an identity user import policy, the device automatically imports identity user accounts from the servers specified in the policy at the specified interval. Periodic auto-import ensures account consistency between the device and the servers.

Examples

Set the interval for automatic identity user account import to 12 hours for identity user import policy **policy1**.

```
<Sysname> system-view
[Sysname] user-identity user-import-policy policy1
[Sysname-identity-user-impt-policy-policy1] account-update-interval 12
```

Related commands

user-identity user-account auto-import policy

connection-detect

Use **connection-detect** to configure parameters for RESTful server reachability detection.

Use **undo connection-detect** to restore the default.

Syntax

connection-detect { **interval** *interval* | **maximum** *max-times* }

undo connection-detect { **interval** | **maximum** }

Default

The reachability detection interval is 5 minutes and the maximum number of probes per detection is 3.

Views

RESTful server view

Predefined user roles

network-admin

context-admin

Parameters

interval *interval*: Specifies the reachability detection interval, in minutes. The value range for the *interval* argument is 1 to 10.

maximum *max-times*: Specifies the maximum number of probes per detection, in the range of 1 to 5.

Usage guidelines

A smaller reachability detection interval and a larger number of probes provide more accurate detection results but increase the burden of the RESTful server. Considering the network connectivity requirement and the performance of the RESTful server, set reasonable values for the parameters.

Examples

Configure reachability detection parameters for RESTful server **rest1**. Set the reachability detection interval to 2 minutes and the maximum number of probes per detection to 3.

```
<Sysname> system-view
[Sysname] user-identity restful-server rest1
[Sysname-restfulserver-rest1] connection-detect interval 2
[Sysname-restfulserver-rest1] connection-detect maximum 3
```

Use **undo connection-detect enable** to disable RESTful server reachability detection.

Syntax

connection-detect enable

undo connection-detect enable

Default

RESTful server reachability detection is disabled.

Views

RESTful server view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this command to detect the reachability of a RESTful server. The detection results can be used as references to define user access control policies for other security modules.

Before you use this command, you must complete the following tasks:

- Specify the username and password used for logging in to the RESTful server by using the **login-name** command.
- Specify a URI for the RESTful server by using the **uri** command.

When RESTful server reachability detection is enabled, the device periodically starts a reachability detection and initiates probes within the detection interval.

- If the device receives a response from the RESTful server, it determines that the server is reachable and stops probe.
- If the device does not receive a response from the RESTful server after the maximum number of probes is reached, it determines that the server is unreachable.

The interval at which the device starts a detection and the maximum number of probes that the device can initiate per detection are set by using the **connection-detect** { **interval** *interval* | **maximum** *max-times* } command.

When RESTful server reachability detection is disabled, the device immediately stops detecting the reachability of the RESTful server.

Examples

Enable reachability detection for RESTful server **rest1**.

```
<Sysname> system-view
[Sysname] user-identity restful-server rest1
[Sysname-restfulserver-rest1] connection-detect enable
```

Parameters

domain *domain-name*: Specifies an identity domain by its domain name, a case-insensitive string of 1 to 255 characters.

null-domain: Specifies identity users or identity groups that do not belong to any identity domain.

user: Displays identity user information.

user-name: Specifies an identity user by its name, a case-sensitive string of 1 to 55 characters. If you do not specify an identity user, this command displays information about all identity users.

group: Displays information about the identity groups to which the identity user belongs. If you do not specify this keyword, the command does not display identity group information.

user-group: Display identity group information.

group-name: Specifies an identity group by its group name, a case-insensitive string of 1 to 200 characters. If you do not specify an identity group, this command displays information about all identity groups.

member: Displays information about members in the specified identity group. If you do not specify this keyword, the command does not display member information.

group: Specifies identity group members in the specified identity group.

user: Specifies identity user members in the specified identity group.

Usage guidelines

This command displays information about identity users or identity groups, including the information learned from the local user database and information imported from remote servers and .csv files.

Examples

Display information about all identity groups in identity domain **system**.

```
<Sysname> display user-identity domain system user-group

Field	Description
Policy name	Name of the identity user import policy.
Interval time	Interval for automatic identity user account import, in hours.
RESTful server name	Name of the RESTful server.
LDAP import type	Type of user information imported from LDAP servers: • **All**—User and user group information. • **User**—User information. • **Group**—User group information.
LDAP scheme name	Name of an LDAP scheme.
Total *n* records matched	Total number of matching identity user import policies.

user-identity user-import-policy

encryption

Use **encryption** to configure the encryption algorithm and shared key for securing communication with security management servers.

Use **undo encryption** to restore the default.

Syntax

encryption algorithm { **3des** | **aes128** } **key** { **simple** | **cipher** } *string*

undo encryption algorithm

Default

No encryption algorithm or shared key is configured for securing communication with security management servers.

Views

Security management server set view

Predefined user roles

network-admin

context-admin

Parameters

algorithm: Specifies the encryption algorithm.

3des: Specifies the 3DES algorithm.

aes128: Specifies the AES algorithm that uses a 128-bit key.

key: Specifies the shared key.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. The key string is case sensitive.

- If the encryption algorithm is 3DES, the plaintext form of the key is a string of 1 to 24 characters. The encrypted form of the key is a string of 1 to 65 characters.
- If the encryption algorithm is AES-128, the plaintext form of the key is a string of 1 to 16 characters. The encrypted form of the key is a string of 1 to 53 characters.

Usage guidelines

For the device to correctly exchange packets with security management servers, make sure the encryption algorithm and shared key are the same as those configured on the servers.

Examples

Configure 3DES as the encryption algorithm and plaintext string **123** as the shared key for securing communication with security management servers in security management sever set **sec1**.

```
<Sysname> system-view
[Sysname] user-identity security-manage-server sec1
[Sysname-identity-sec-manage-server-sec1] encryption algorithm 3des key simple 123
```

Related commands

import-type

Use **import-type** to specify the type of user information to be imported from LDAP servers.

Use **undo import-type** to restore the default.

Syntax

import-type { **all** | **group** | **user** }

undo import-type

Default

The type of user information to be imported from LDAP servers is not specified. The device imports both user information and user group information from LDAP servers.

Views

Identity user import policy view

Predefined user roles

network-admin

context-admin

Parameters

all: Specifies both the user and user group types.

group: Specifies the user group type.

user: Specifies the user type.

Usage guidelines

The device imports only user information of the specified type from LDAP servers.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure the device to import both user information and user group information from LDAP servers.

```
<Sysname> system-view
[Sysname] user-identity user-import-policy policy
[Sysname-identity-user-impt-policy-policy] import-type all
```

Related commands

display user-identity user-import-policy

ip

Use **ip** to specify IP addresses of security management servers.

Use **undo ip** to remove the specified IP addresses of security management servers.

Syntax

ip *ip-address*&<1-10>

undo ip { *ip-address*&<1-10> | **all** }

Default

No IP addresses of security management severs are specified.

Views

Security management server set view

Predefined user roles

network-admin

context-admin

Parameters

ip-address&<1-10>: Specifies a space-separated list of up to 10 IP addresses. The all-zero IP address is not allowed.

all: Specifies all the IP addresses of security management servers.

Usage guidelines

You can specify a maximum of 20 IP addresses of security management servers in a security management server set.

Examples

Specify security management servers at 192.168.0.1 and 10.113.0.1 for security management server set **sec1**.

```
<Sysname> system-view
[Sysname] user-identity security-manage-server sec1
[Sysname-identity-sec-manage-server-sec1] ip 192.168.0.1 10.113.0.1
```

Related commands

display user-identity security-manage-server

ldap-scheme

Use **ldap-scheme** to specify an LDAP scheme.

Use **undo ldap-scheme** to restore the default.

Syntax

ldap-scheme *ldap-scheme-name*

undo ldap-scheme *ldap-scheme-name*

Default

No LDAP schemes are specified.

Views

Identity user import policy view

Predefined user roles

network-admin

context-admin

Parameters

ldap-scheme-name: Specifies an LDAP scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

To import identity user account information from the LDAP server specified in the LDAP scheme, use the **user-identity user-account import policy** command. The device cannot import online identity user information from the LDAP server.

You can specify a maximum of 16 LDAP schemes in an identity user import policy for importing users from multiple LDAP servers in batch.

Examples

Specify LDAP scheme **ser2** for identity user import policy **policy1**.

```
<Sysname> system-view
[Sysname] user-identity user-import-policy policy1
[Sysname-identity-user-impt-policy-policy1] ldap-scheme ser2
```

Related commands

display user-identity user-import-policy

ldap scheme

listen-port

Use **listen-port** to set the port number for listening to security management servers.

Use **undo listen-port** to restore the default.

Syntax

listen-port *port-num*

undo listen-port

Default

The device listens to security management servers on port 8001.

Views

Security management server set view

Predefined user roles

network-admin

context-admin

Parameters

port-num: Specifies the UDP port number for listening to security management servers, in the range of 1 to 65535.

Usage guidelines

For the device to establish connections with security management servers, make sure the listening port is the same as the port that the servers use to send online user information.

Examples

Set the port to 8048 for listening to security management servers in security management server set **sec1**.

```
<Sysname> system-view
[Sysname] user-identity security-manage-server sec1
[Sysname-identity-sec-manage-server-sec1] listen-port 8084
```

Related commands

display user-identity security-manage-server

login-name

Use **login-name** to specify the username and password used for logging in to the RESTful server.

Use **undo login-name** to restore the default.

Syntax

login-name *user-name* **password** { **cipher** | **simple** } *string*

undo login-name

Default

No username or password is specified for logging in to the RESTful server.

Views

RESTful server view

Predefined user roles

network-admin

context-admin

Parameters

user-name: Specifies a username, a case-sensitive string of 1 to 55 characters.

password: Specifies a password.

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 63 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

The device uses the specified username and password to establish a connection with the RESTful server. If the device is authenticated as legitimate, the RESTful server permits the connection request of the device. Then, the device can request resources on the server.

The specified username and password must exist on the RESTful server.

Examples

Configure the device to use username **abc** and plaintext password **123** to log in to the RESTful server.

```
<Sysname> system-view
[Sysname] user-identity restful-server rest1
[Sysname-restfulserver-rest1] login-name abc password simple 123
```

Related commands

display user-identity restful-server

reset user-identity dynamic-online-user

Use **reset user-identity dynamic-online-user** to delete dynamic online identity users.

Syntax

reset user-identity dynamic-online-user { **all** | { **domain** *domain-name* | **null-domain** } [**name** *user-name*] | { { **ip** *ipv4-address* | **ipv6** *ipv6-address* } | **mac** *mac-address* } * }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

all: Specifies all dynamic online identity users.

domain *domain-name*: Specifies an identity domain by its domain name, a case-insensitive string of 1 to 255 characters.

null-domain: Specifies dynamic online identity users that do not belong to any identity domain.

name *user-name*: Specifies a dynamic online identity user by its username, a case-sensitive string of 1 to 55 characters. If you do not specify this option, the command deletes dynamic online identity users that belong to the specified domain or that do not belong to any domain.

ip *ipv4-address*: Specifies the IPv4 address of a dynamic online identity user.

ipv6 *ipv6-address*: Specifies the IPv6 address of a dynamic online identity user.

mac *mac-address*: Specifies the MAC address of a dynamic online identity user, in the format H-H-H. If you do not specify a MAC address, this command deletes dynamic online identity users that have the specified username regardless of their MAC addresses.

Usage guidelines

This command deletes dynamic online identity users created based on user information obtained from remote servers and it cannot delete static online identity users. To delete static online identity users, use the **undo user-identity static-user** command.

Examples

Delete all dynamic online identity users.

```
<Sysname> reset user-identity dynamic-online-user all
```

Delete dynamic online identity users in identity domain **abc**.

```
<Sysname> reset user-identity dynamic-online-user domain abc
```

Delete dynamic online identity user **user1** in identity domain **dom1**.

```
<Sysname> reset user-identity dynamic-online-user domain dom1 name user1
```

Delete dynamic online identity users that use username **user2** and do not belong to any identity domain.

```
<Sysname> reset user-identity dynamic-online-user null-domain name user2
```

Delete the dynamic online identity user whose IP address is 1.2.3.4.

```
<Sysname> reset user-identity dynamic-online-user ip 1.2.3.4
```

Delete the dynamic online identity user whose IP address is 1.2.3.4 and MAC address is 2222-3333-4444.

```
<Sysname> reset user-identity dynamic-online-user ip 1.2.3.4 mac 2222-3333-4444
```

Delete the dynamic online identity user whose MAC address is 2222-3333-4444.

```
<Sysname> reset user-identity dynamic-online-user mac 2222-3333-4444
```

Related commands

display user-identity online-user

reset user-identity user-account

Use **reset user-identity user-account** to delete identity user accounts.

Syntax

reset user-identity user-account { **all** | { **domain** *domain-name* | **null-domain** } [**name** *user-name*] }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

all: Specifies all identity user accounts.

domain *domain-name*: Specifies an identity domain by its domain name, a case-insensitive string of 1 to 255 characters.

null-domain: Specifies identity user accounts that do not belong to any identity domain.

name *user-name*: Specifies an identity user account by its name, a case-sensitive string of 1 to 55 characters. If you do not specify an identity user account, this command deletes identity user accounts that belong to the specified domain or that do not belong to any domain.

Usage guidelines

This command deletes identity user accounts created based on the information obtained from remote servers and .csv files. It cannot delete identity user accounts learned from the local user database.

Examples

Delete all identity user accounts.

```
<Sysname> reset user-identity user-account all
```

Delete identity user account **test** in identity domain **dom1**.

```
<Sysname> reset user-identity user-account domain dom1 name test
```

Related commands

display user-identity all user

reset user-identity user-group

Use **reset user-identity user-group** to delete identity groups.

Syntax

reset user-identity user-group { **all** | { **domain** *domain-name* | **null-domain** } [**name** *group-name*] }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

all: Specifies all identity groups.

domain *domain-name*: Specifies an identity domain by its domain name, a case-insensitive string of 1 to 255 characters.

null-domain: Specifies identity groups that do not belong to any identity domain.

name *group-name*: Specifies an identity group by its group name, a case-insensitive string of 1 to 200 characters. If you do not specify an identity group, this command deletes identity groups that belong to the specified domain or that do not belong to any domain.

Usage guidelines

Use this command to delete identity groups created based on user group information obtained from remote servers and .csv files and it cannot delete identity groups learned from the local user database.

Examples

Delete all identity groups.

```
<Sysname> reset user-identity user-group all
```

Delete identity group **g1** in identity domain **dom1**.

```
<Sysname> reset user-identity user-group domain dom1 name g1
```

Related commands

display user-identity all user-group

restful-server

Use **restful-server** to specify a RESTful server.

Use **undo restful-server** to restore the default.

Syntax

restful-server *server-name*

undo restful-server *server-name*

Default

No RESTful server is specified.

Views

Identity user import policy view

Predefined user roles

network-admin

context-admin

Parameters

server-name: Specifies a RESTful server by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

To import identity user accounts from the RESTful server, use the **user-identity user-account import policy** command. To import online identity user information from the RESTful server, use the **user-identity online-user import policy** command.

You can specify only one RESTful server. To specify a new RESTful server, first remove the currently specified RESTful server by using the **undo restful-server** command.

Examples

Specify RESTful server **ser1** for identity user import policy **policy1**.

```
<Sysname> system-view
[Sysname] user-identity user-import-policy policy1
[Sysname-identity-user-impt-policy-policy1] restful-server ser1
```

Related commands

display user-identity restful-server

display user-identity user-import-policy

user-identity restful-server

uri

Use **uri** to specify a URI for the RESTful server.

Use **undo uri** to delete a URI specified for the RESTful server.

Syntax

uri { **get-online-user** | **get-user-database** | **get-user-group-database** | **put-offline-user** | **put-online-user** } *uri-string*

undo uri { **get-online-user** | **get-user-database** | **get-user-group-database** | **put-offline-user** | **put-online-user** }

Default

No URIs are specified for the RESTful server.

Views

RESTful server view

Predefined user roles

network-admin

context-admin

Parameters

get-online-user: Specifies the URI used to request online network access user information.

get-user-database: Specifies the URI used to request network access user account information.

get-user-group-database: Specifies the URI used to request user group information.

put-offline-user: Specifies the URI used to upload offline user information.

put-online-user: Specifies the URI used to upload online user information.

uri-string: Specifies a URI, a case-insensitive string of 1 to 255 characters.

Usage guidelines

The specified URIs must be the same as those provided by the RESTful server. Otherwise, user information interaction will fail.

If the device adds or deletes an identity user that is not imported from the RESTful server, the device uploads the online or offline user information to the RESTful server.

You can repeat this command to specify multiple URIs for the RESTful server.

Examples

Specify **http://1.1.1.1:8080/imcrs/ssm/imcuser/onlineUser** as the URI used to request online network access user information from RESTful server **rest1**.

```
<Sysname> system-view
[Sysname] user-identity restful-server rest1
[Sysname-restfulserver-rest1] uri get-online-user
http://1.1.1.1:8080/imcrs/ssm/imcuser/onlineUser
```

Specify **http://1.1.1.1:8080/imcrs/ssm/imcuser/accessUser** as the URI used to request network access user account information from RESTful server **rest1**.

```
<Sysname> system-view
[Sysname] user-identity restful-server rest1
[Sysname-restfulserver-rest1] uri get-user-database
http://1.1.1.1:8080/imcrs/ssm/imcuser/accessUser
```

Specify **http://1.1.1.1:8080/imcrs/ssm/imcuser/accessUserGroup** as the URI used to request user group information from RESTful server **rest1**.

```
<Sysname> system-view
[Sysname] user-identity restful-server rest1
[Sysname-restfulserver-rest1] uri get-user-group-database
http://1.1.1.1:8080/imcrs/ssm/imcuser/accessUserGroup
```

Specify **http://1.1.1.1:8080/imcrs/ssm/imcuser/uploadOfflineUser** as the URI used to upload offline user information to RESTful server **rest1**.

```
<Sysname> system-view
[Sysname] user-identity restful-server rest1
[Sysname-restfulserver-rest1] uri put-offline-user
http://1.1.1.1:8080/imcrs/ssm/imcuser/uploadOfflineUser
```

Specify **http://1.1.1.1:8080/imcrs/ssm/imcuser/uploadOnlineUser** as the URI used to upload online user information to RESTful server **rest1**.

```
<Sysname> system-view
[Sysname] user-identity restful-server rest1
[Sysname-restfulserver-rest1] uri put-online-user
http://1.1.1.1:8080/imcrs/ssm/imcuser/uploadOnlineUser
```

Specify **http://1.1.1.1:8080/imcrs/uam/online** as the URI used to request online network access user information from the EIA component of RESTful server **rest2**.

```
<Sysname> system-view
[Sysname] user-identity restful-server rest2
[Sysname-restfulserver-rest1] uri get-online-user http://1.1.1.1:8080/imcrs/uam/online
```

Specify **http://1.1.1.1:8080/imcrs/uam/acmUser/acmUserList** as the URI used to request network access user account information from the EIA component of RESTful server **rest2**.

```
<Sysname> system-view
[Sysname] user-identity restful-server rest2
[Sysname-restfulserver-rest1] uri get-user-database http://
1.1.1.1:8080/imcrs/uam/acmUser/acmUserList
```

Specify **http://1.1.1.1:8080/imcrs/uam/acmUser/userGroup** as the URI used to request user group information from the EIA component of RESTful server **rest2**.

```
<Sysname> system-view
[Sysname] user-identity restful-server rest2
[Sysname-restfulserver-rest1] uri get-user-group-database http://
1.1.1.1:8080/imcrs/uam/acmUser/userGroup
```

Related commands

display user-identity restful-server

user-identity restful-server

user-identity enable

Use **user-identity enable** to enable the user identification feature.

Use **undo user-identity enable** to disable the user identification feature.

Syntax

user-identity enable

undo user-identity enable

Default

The user identification feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

With the user identification feature, the device learns online user information from the user access modules. The device uses the obtained information for user identification and works with other security features for identity-based network access control.

Examples

Enable the user identification feature.

```
<Sysname> system-view
[Sysname] user-identity enable
```

user-identity online-user import policy

Use **user-identity online-user import policy** to import online identity users from a server.

Syntax

user-identity online-user import policy *policy-name*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies an identity user import policy by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

After this command is executed, the device initiates a connection request to the server specified in the identity user import policy. Then, the device imports online network access user information from the server. The information includes the username, identity domain name, user group name, IP address, and MAC address of the users.

Before you execute this command, make sure the user identification feature is enabled.

Examples

Import online identity users from the server specified in identity user import policy **policy1**.

```
<Sysname> system-view
[Sysname] user-identity online-user import policy policy1
Loading...Done.
```

Related commands

user-identity user-account auto-import policy

user-identity user-import-policy

user-identity online-user-name-match

Use **user-identity online-user-name-match** to specify username match mode for user identification.

Use **undo user-identity online-user-name-match** to restore the default.

Syntax

user-identity online-user-name-match { **keep-original** | **with-domain** | **without-domain** }

undo user-identity online-user-name-match

Default

The username match mode for user identification is **keep-original**.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

keep-original: Uses the username entered by a user to perform username match. For example, if the authentication domain is **abc** and the entered username is **test@123**, the device searches username **test@123** in local user accounts.

with-domain: Uses the username that includes the authentication domain name of a user to perform username match. For example, if the authentication domain is **abc** and the entered username is **test@123**, the device searches username **test@abc** in local user accounts.

without-domain: Uses the username that excludes the domain name of a user to perform username match. For example, if the authentication domain is **abc** and the entered username is **test@123**, the device searches username **test** in local user accounts that do not join any identity domains.

Usage guidelines

This command specifies the username match mode for user identification. The device creates online identity users only for online users whose usernames can match the usernames in the local identity user accounts.

This command takes effect only on online identity users that access the current device.

Examples

Specify **with-domain** as the username match mode for user identification.

```
<Sysname> system-view
[Sysname] user-identity online-user-name-match with-domain
```

user-identity restful-server

Use **user-identity restful-server** to create a RESTful server and enter its view, or enter the view of an existing RESTful server.

Use **undo user-identity restful-server** to delete a RESTful server.

Syntax

user-identity restful-server *server-name*

undo user-identity restful-server *server-name*

Default

No RESTful server exists.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

server-name: Specifies the name of a RESTful server. The RESTful server name is a case-insensitive string of 1 to 31 characters.

Usage guidelines

You can configure parameters of the RESTful server in RESTful server view. The parameters include the URIs of the server and the login account.

You can create only one RESTful server.

Examples

Create a RESTful server named **rest1** and enter its view.

```
<Sysname> system-view
[Sysname] user-identity restful-server rest1
[Sysname-restfulserver-rest1]
```

Use **undo user-identity security-manage-server** to delete a security management server set.

Syntax

user-identity security-manage-server *server-set-name*

undo user-identity security-manage-server *server-set-name*

Default

No security management server set exists.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

server-set-name: Specifies the name of the security management server set, a case-insensitive string of 1 to 31 characters.

Usage guidelines

The security management server set view defines the related parameters of security management servers. The parameters include the IP addresses of the servers, the port number for listening to the servers, and the shared key to secure communication between the device and the servers.

You can create only one security management server set.

Examples

Create a security management server set named **sec1** and enter its view.

```
<Sysname> system-view
[Sysname] user-identity security-manage-server sec
[Sysname-identity-sec-manage-server-sec1]
```

encryption

ip

listen-port

user-identity static-user

Use **user-identity static-user** to configure a static identity user.

Use **undo user-identity static-user** to delete a static identity user.

Syntax

user-identity static-user *user-name* [**domain** *domain-name*] **bind** { **ipv4** *ipv4-address* | **ipv6** *ipv6-address* } | **mac** *mac-address* } *

undo user-identity static-user *user-name* [**domain** *domain-name*] [**bind** { { **ipv4** *ipv4-address* | **ipv6** *ipv6-address* } | **mac** *mac-address* } *]

Default

No static identity users exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

user-name: Specifies the name of the static identity user, a case-sensitive string of 1 to 55 characters.

domain *domain-name*: Specifies the identity domain to which the static identity user belongs. The *domain-name* argument represents an identity domain name, a case-insensitive string of 1 to 255 characters. If you do not specify an identity domain, the static identity user does not belong to any identity domain.

bind: Specifies address attributes bound to the static identity user.

ipv4 *ipv4-address*: Specifies an IPv4 address. The IPv4 address cannot be an all-zero address, all-one address, or multicast address.

ipv6 *ipv6-address*: Specifies an IPv6 address. The IPv6 address cannot be an all-zero address, multicast address, loopback address, or link local address.

mac *mac-address*: Specifies a MAC address in the format of H-H-H. If you do not specify a MAC address, the static identity user can use any MAC address.

Usage guidelines

To allow users to access the network without identity authentication and to use security features to control their access to the network, configure the users as static identity users.

If you do not specify the **bind** keyword in the **undo** form of this command, all static identity users that use the specified username are deleted.

Execute this command multiple times to add multiple static identity users.

You can bind one username with multiple IP addresses, multiple MAC addresses, or multiple IP-MAC address combinations. You cannot bind one IP address, one MAC address, or one IP-MAC address combination with multiple usernames.

Only when the user identification feature is enabled and static identity users match local identity user accounts, the device can generate corresponding static online identity user entries.

Examples

Configure a static identity user of which the username is **test**, the identity domain is **dom1**, and the IP address is 109.15.0.15.

```
<Sysname> system-view
[Sysname] user-identity static-user test domain dom1 bind ipv4 109.15.0.15
```

Configure a static identity user of which the username is **abc**, the identity domain is **dom1**, and the MAC address is 1-1-1.

```
<Sysname> system-view
[Sysname] user-identity static-user abc domain dom1 bind mac 1-1-1
```

Use **undo user-identity user-account auto-import policy** to disable automatic identity user account import.

Syntax

user-identity user-account auto-import policy *policy-name*

undo user-identity user-account auto-import policy *policy-name*

Default

Automatic identity user account import is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies an identity user import policy by its policy name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

After this feature is enabled, the device first imports all identity user accounts and online identity user information from the servers specified in the identity user import policy. Then, the device periodically imports identity user accounts from the servers at the interval set by the **account-update-interval** command.

For this feature to take effect, make sure the user identification feature is enabled. To enable the user identification feature, use the **user-identity enable** command.

Examples

Enable automatic identity user account import for identity user import policy **policy1**.

```
<Sysname> system-view
[Sysname] user-identity user-account auto-import policy policy1
```

user-identity user-account export url *url-string* [{ **domain** *domain-name* | **null-domain** } [**user** *user-name*] | **template**] [**vpn-instance** *vpn-instance-name*]

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies a URL, a case-insensitive string of 1 to 255 characters.

domain *domain-name*: Specifies an identity domain by its domain name, a case-insensitive string of 1 to 255 characters.

null-domain: Specifies identity user accounts that do not belong to any identity domain.

user *user-name*: Specifies an identity user account by its account name, a case-sensitive string of 1 to 55 characters. If you do not specify an identity user account, this command exports all identity user accounts.

template: Exports a standard .csv file template. You can use this file template as a reference when editing .csv files.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance where the .csv file will be saved. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the .csv file will be saved on the public network, do not specify this option.

Usage guidelines

You must save the exported identity user account information to a .csv file.

If you do not specify any parameters, the device exports all identity user account information to a .csv file.

The device supports TFTP and FTP file transfer modes. Table 9 describes the valid URL formats of the .csv file.

Table 9 URL formats

Protocol	URL format	Description
TFTP	**tftp://***server*/*path*/*filename*	Specify a TFTP server by IP address or hostname. For example, specify the file path as **tftp://1.1.1.1/user/user.csv**.
FTP	• With FTP username and password: **ftp://***username*:*password*@*server*/*path*/*filename* • Without FTP username and password: **ftp://***server*/*path*/*filename*	Specify an FTP server by IP address or hostname. The device ignores the domain name in the FTP username. For example, specify the file path as **ftp://1:1@1.1.1.1/user/user.csv** or **ftp://1.1.1.1/user/user.csv**.

For identity user account information to be correctly exported by using FTP, follow the input formats in Table 10 when you use special characters in the URL.

Table 10 Input formats for special characters

Special character	Input format
\	\\
"	\"
/	%2F
:	%3A
@	%40

If this command is successfully executed, a .csv file with the specified file name will be created on the specified server. If you execute this command with the same parameters multiple times, the new file will override the old file.

Examples

Export all identity user accounts in identity domain **dom1** to a .csv file and save the file to the path **tftp://1.1.1.1/user.csv**.

```
<Sysname> system-view
[Sysname] user-identity user-account export url tftp://1.1.1.1/user.csv domain dom1
```

Related commands

user-identity user-account import url

user-identity user-account import policy

Use **user-identity user-account import policy** to import identity user accounts from servers.

Syntax

user-identity user-account import policy *policy-name*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies an identity user import policy by its policy name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

After you execute this command, the device initiates an identity user account information request to the servers specified in the identity user import policy. Then, the device imports identity user account information from the servers.

Examples

Import identity user accounts from the servers specified in identity user import policy **policy1**.

```
<Sysname> system-view
[Sysname] user-identity user-account import policy policy1
```

Related commands

user-identity user-import-policy

user-identity user-account import url

Use **user-identity user-account import url** to import identity user accounts from a .csv file.

Syntax

user-identity user-account import url *url-string* [**vpn-instance** *vpn-instance-name*] [**auto-create-group** | **override** | **start-line** *line-number*] *

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the URL of the .csv file. The URL is a case-insensitive string of 1 to 255 characters.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance where the .csv file will be saved. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the .csv file will be saved on the public network, do not specify this option.

auto-create-group: Enables the device to automatically create an identity group for an account if the identity group to which the account belongs does not exist on the device. If you do not specify this keyword, the device does not create nonexistent identity groups.

override: Enables the device to override the existing identity user account with the same name as an identity user account to be imported. If you do not specify this keyword, the device retains the existing identity user account.

start-line *line-number*: Specifies the number of the line at which the account import begins. If you do not specify this option, the command imports identity user account information from the first line.

Usage guidelines

The file from which identity user accounts are imported must be a .csv file.

You can use the **user-identity user-account export url** command to export a standard .csv file template.

Examples

Import identity user accounts from the second line of the **user.csv** file in path **ftp://1.1.1.1/newpath**.

```
<Sysname> system-view
[Sysname] user-identity user-account import url ftp://1.1.1.1/newpath/user.csv
start-line 2
```

Related commands

user-identity user-account export url

user-identity user-import-policy

Use **user-identity user-import-policy** to create an identity user import policy and enter its view, or enter the view of an existing identity user import policy.

Use **undo user-identity user-import-policy** to delete an identity user import policy.

Syntax

user-identity user-import-policy *policy-name*

undo user-identity user-import-policy *policy-name*

Default

No identity user import policy exists.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies an identity user import policy by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

An identity user import policy determines the policy that the user identification feature uses to import identity user information from servers. The imported user information includes information about identity user accounts and online identity users. Supported servers include IMC servers and LDAP servers.

You can create only one identity user import policy. Before you create a new identity user import policy, first delete the existing identity user import policy by using the **undo** form of this command.

Examples

Create an identity user import policy named **policy1** and enter its view.

```
<Sysname> system-view
[Sysname] user-identity user-import-policy policy1
[Sysname-identity-user-impt-policy-policy1]
```

Related commands

display user-identity user-import-policy

vpn-instance

Use **vpn-instance** to specify an MPLS L3VPN instance for a RESTful server.

Use **undo vpn-instance** to restore the default.

Syntax

vpn-instance *vpn-instance-name*

undo vpn-instance

Default

The RESTful server belongs to the public network.

Views

RESTful server view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance-name: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

Use this command to specify the VPN instance of the interfaces that the device and the RESTful server use to communicate with each other.

Examples

Specify VPN instance **v1** for RESTful server **r1**.

```
<Sysname> system-view
[Sysname] user-identity restful-server r1
[Sysname-restfulserver-r1] vpn-instance v1
```

Password control commands

display password-control

Use **display password-control** to display password control configuration.

Syntax

display password-control [**super**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

super: Displays the password control information for the super passwords. If you do not specify this keyword, the command displays the global password control configuration.

Examples

Display the global password control configuration.

```
<Sysname> display password-control
 Global password control configurations:
 Password control:                     Enabled (device management users)
                                       Enabled (network access users)
 Password aging:                       Enabled (90 days)
 Password length:                      Enabled (10 characters)
 Password composition:                 Enabled (1 types, 1 characters per type)
 Password history:                     Enabled (max history records:4)
 Early notice on password expiration:  7 days
 Maximum login attempts:               3
 Action for exceeding login attempts:  Lock user for 1 minutes
 Password history was last reset:      0 days ago (device management users)
                                       0 days ago (network access users)
 Minimum interval between two updates: 24 hours
 User account idle time:               90 days
 Logins with aged password:            3 times in 30 days
 Password complexity:                  Disabled (username checking)
                                       Disabled (repeated characters checking)
 Password change:                      Enabled (first login)
                                       Enabled (mandatory weak password change)
User information in blacklist:        Username-only
```

Display the password control configuration for super passwords.

```
<Sysname> display password-control super
 Super password control configurations:
```

```
Password aging:                    Enabled (90 days)
Password length:                   Enabled (10 characters)
Password composition:              Enabled (1 types, 1 characters per type)
```

Table 1 Command output

Field	Description
Password control	Whether the password control feature is enabled for device management users or network access users.
Password aging	Whether password expiration is enabled and, if enabled, the aging time.
Password length	Whether the minimum password length restriction feature is enabled and, if enabled, the setting.
Password composition	Whether the password composition restriction feature is enabled and, if enabled, the settings.
Password history	Whether the password history management feature is enabled and, if enabled, the setting.
Early notice on password expiration	Number of days during which the user is notified of the pending password expiration.
Maximum login attempts	Allowed maximum number of consecutive failed login attempts for FTP and VTY users.
Action for exceeding login attempts	Action to be taken after a user fails to log in after the specified number of attempts.
Password history was last reset	Last time when the password history records of the device management or network access users were deleted.
Minimum interval between two updates	Minimum password update interval.
Logins with aged password	Number of times and maximum number of days a user can log in using an expired password.
Password complexity	Whether the following password complexity checking is enabled: • **username checking**—Checks whether a password contains the username or the reverse of the username. • **repeated characters checking**—Checks whether a password contains any character that appears consecutively three or more times.
Password change	Status of the password change at first login feature: • Enabled (first login). • Disabled (first login). • Enabled (mandatory weak password change). • Disabled (mandatory weak password change).
User information in blacklist	User information items added to the password control blacklist: • **Username-only**—Only usernames are added to the password control blacklist. • **Username and IP**—Both usernames and IP addresses are added to the password control blacklist.

display password-control blacklist

Use **`display password-control blacklist`** to display password control blacklist information.

Syntax

display password-control blacklist [**user-name** *user-name* | **ip** *ipv4-address* | **ipv6** *ipv6-address*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

user-name *user-name*: Specifies a user by its username, a string of 1 to 55 characters. You can specify a pure username or specify a pure username and its domain name in the format of *pure usernname@domain name*. The pure username is case sensitive. The domain name is case-insensitive.

ipv6 *ipv6-address*: Specifies the IPv6 address of a user.

Usage guidelines

If you do not specify any parameters, this command displays the maximum number of blacklist entries for a user account, the total number of blacklisted users, and detailed information about the blacklisted users.

When the console users fail login, only their user accounts can be added to the password control blacklist because the system is unable to obtain the IP addresses of these users. When FTP, Web, or virtual terminal line (VTY) users fail login, both their IP addresses and user accounts can be added to the password control blacklist. The user information items specified by the **password-control blacklist user-info** command will be added to the password control blacklist.

The device will create a blacklist entry for each IP address for a user account when the following conditions are both met:

- Both usernames and IP addresses are added to the password control blacklist.
- A user uses the same user account to log in to the device from different IP addresses and fails the logins.

When the maximum number of blacklist entries for the user account is reached, a blacklist entry for a new IP address of the user account will overwrite the earliest blacklist entry for the user account.

Examples

Display password control blacklist where only usernames are added.

```
<Sysname> display password-control blacklist
 Per-user blacklist limit: 32.
 Blacklist items matched: 1.
 Username                    Login failures     Lock flag
 con                         2                  unlock
 abcd                        4                  lock
 admin                       1                  unlock
```

Display password control blacklist where both usernames and IP addresses are added.

```
<Sysname> display password-control blacklist
 Per-user blacklist limit: 100.
 Blacklist items matched: 2.
```

```
Username                    IP address          Login failures   Lock flag
abcd                        169::168:34:1       4                lock
admin                       192.168.34.1        1                unlock
```

Table 2 Command output

Field	Description
Per-user blacklist limit	Maximum number of blacklist entries for a user account.
Blacklist items matched	Number of blacklisted users.
IP address	IP address of the user. This field displays hyphens (**-**) for users that log in to the device through console ports. This field is not available if the password control blacklist contains only usernames.
Login failures	Number of login failures.
Lock flag	Whether the user account is locked for the user: • **unlock**—Not locked. • **lock**—Locked temporarily or permanently, depending on the **password-control login-attempt** command.

password-control { aging | composition | history | length } enable

Use **password-control** { **aging** | **composition** | **history** | **length** } **enable** to enable a password restriction feature.

Use **undo password-control** { **aging** | **composition** | **history** | **length** } **enable** to disable a password restriction feature.

Syntax

password-control { **aging** | **composition** | **history** | **length** } **enable**

undo password-control { **aging** | **composition** | **history** | **length** } **enable**

Default

The password restriction features are all enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

aging: Enables the password expiration feature.

composition: Enables the password composition restriction feature.

history: Enables the password history management feature.

length: Enables the minimum password length restriction feature.

Usage guidelines

The password expiration feature or the password history management feature takes effect only after the global password control feature is also enabled.

The password composition restriction and the minimum password length restriction are enabled by default regardless of whether or not the global password control feature is enabled. By default, a password must contain a minimum of four different characters.

If a password of a device management user is in hashed form, a restriction setting does not take effect for the password even when the following requirements are met:

- The global password control is enabled.
- The specific password restriction feature is enabled.

For more information about configuring a password for a device management user, see "AAA commands."

If the password history management is disabled, the system will not compare the new password with history passwords, but the system will not stop recording history passwords. When the number of history password records of a user reaches the maximum number set by the **password-control history** command, the newest history record overwrites the earliest one.

Examples

Enable the password control feature globally.

```
<Sysname> system-view
[Sysname] password-control enable
```

Enable the password composition restriction feature.

```
[Sysname] password-control composition enable
```

Enable the password expiration feature.

```
[Sysname] password-control aging enable
```

Enable the minimum password length restriction feature.

```
[Sysname] password-control length enable
```

Enable the password history management feature.

```
[Sysname] password-control history enable
```

Related commands

display password-control

password-control enable

password-control aging

Use **password-control aging** to set the password aging time.

Use **undo password-control aging** to restore the default.

Syntax

password-control aging *aging-time*

undo password-control aging

Default

A password expires after 90 days. The password aging time for a user group equals the global setting. The password aging time for a local user equals that of the user group to which the local user belongs.

Views

System view

User group view

Local user view

Predefined user roles

network-admin

context-admin

Parameters

aging-time: Specifies the password aging time in days, in the range of 1 to 365.

Usage guidelines

The aging time depends on the view:

- The time in system view has global significance and applies to all user groups.
- The time in user group view applies to all local users in the user group.
- The time in local user view applies only to the local user.

A password aging time with a smaller application scope has higher priority. The system prefers to use the password aging time in local user view for a local user.

- If no password aging time is configured for the local user, the system uses the password aging time for the user group to which the local user belongs.
- If no password aging time is configured for the user group, the system uses the global password aging time.

Examples

Globally set the passwords to expire after 80 days.

```
<Sysname> system-view
[Sysname] password-control aging 80
```

Set the passwords for user group **test** to expire after 90 days.

```
[Sysname] user-group test
[Sysname-ugroup-test] password-control aging 90
[Sysname-ugroup-test] quit
```

Set the password for device management user **abc** to expire after 100 days.

```
[Sysname] local-user abc class manage
[Sysname-luser-manage-abc] password-control aging 100
```

password-control alert-before-expire

Use **password-control alert-before-expire** to set the number of days before a user's password expires during which the user is notified of the pending password expiration.

Use **undo password-control alert-before-expire** to restore the default.

Syntax

password-control alert-before-expire *alert-time*

undo password-control alert-before-expire

Default

The default is 7 days.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

alert-time: Specifies the number of days before a user password expires during which the user is notified of the pending password expiration. The value range is 1 to 30.

Usage guidelines

This command is effective only for non-FTP users. FTP users can only have their passwords changed by the administrator.

Examples

Configure the device to notify a user about pending password expiration 10 days before the user's password expires.

```
<Sysname> system-view
[Sysname] password-control alert-before-expire 10
```

Related commands

display password-control

password-control blacklist user-info username-only

Use **password-control blacklist user-info username-only** to add only usernames of users failing authentication to the password control blacklist.

Use **undo password-control blacklist user-info** to restore the default.

Syntax

password-control blacklist user-info username-only

undo password-control blacklist user-info

Default

Both usernames and IP addresses are added to the password control blacklist when users fail authentication.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

If the user information items to add to the password control blacklist change, the system will clear the password control blacklist and restart the recording.

Examples

Add only usernames to the password control blacklist when users fail authentication.

```
<Sysname> system-view
[Sysname] password-control blacklist user-info username-only
```

Use **undo password-control change-password weak-password enable** to disable mandatory weak password change.

Syntax

password-control change-password weak-password enable

undo password-control change-password weak-password enable

Default

The mandatory weak password change feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The system checks for weak login passwords for Telnet, SSH, HTTP, or HTTPS device management users. A password is weak if it does not meet the following requirements:

- Password composition restriction.
- Minimum password length restriction.
- Password complexity checking policy.

The mandatory weak password change feature is disabled by default. The system displays a message about a weak password but does not force the user to change it. To improve the device security, you can enable the mandatory weak password change feature, which forces the users to change the identified weak passwords. The users can log in to the device only after their passwords meet the password requirements.

To view the current password control settings, use the **display password-control** command. To change the password composition restriction, minimum password length, and password complexity checking policy, use the **password-control composition**, **password-control length**, and **password-control complexity** commands, respectively.

Examples

Enable the mandatory weak password change feature.

```
<Sysname> system-view
[Sysname] password-control change-password weak-password enable
```

Related commands

display password-control

password-control { **aging** | **composition** | **history** | **length** }

password-control complexity

password-control composition

password-control length

password-control enable

password-control complexity

Use **password-control complexity** to configure the password complexity checking policy.

Use **undo password-control complexity** to remove a password complexity checking item.

Syntax

password-control complexity { **same-character** | **user-name** } **check**

undo password-control complexity { **same-character** | **user-name** } **check**

Default

The global password complexity checking policy is that username checking is enabled and repeated character checking is disabled.

The password complexity checking policy for a user group equals the global setting.

The password complexity checking policy for a local user equals that of the user group to which the local user belongs.

Views

System view

User group view

Local user view

Predefined user roles

network-admin

context-admin

Parameters

same-character: Refuses a password that contains a minimum of three consecutive identical characters. For example, the password **aaabc** is not complex enough.

user-name: Refuses a password that contains the username or the reverse of the username. For example, if the username is **123**, a password such as **abc123** or **321df** is not complex enough.

Usage guidelines

The password complexity checking policy depends on the view:

- The policy in system view has global significance and applies to all user groups.
- The policy in user group view applies to all local users in the user group.
- The policy in local user view applies only to the local user.

A password complexity checking policy with a smaller application scope has higher priority. The system prefers to use the password complexity checking policy in local user view for a local user.

- If no policy is configured for the local user, the system uses the policy for the user group to which the local user belongs.
- If no policy is configured for the user group, the system uses the global policy.

Username checking is independent of whether or not the global password control feature is enabled.

You can enable both username checking and repeated character checking.

Examples

Configure the password complexity checking policy, refusing any password that contains the username or the reverse of the username.

```
<Sysname> system-view
[Sysname] password-control complexity user-name check
```

Related commands

display local-user

display password-control

display user-group

password-control composition

Use **password-control composition** to configure the password composition policy.

Use **undo password-control composition** to restore the default.

Syntax

password-control composition type-number *type-number* [**type-length** *type-length*]

undo password-control composition

Default

The global composition policy requires that a password must contain a minimum of two character types and a minimum of one character for each type.The password composition policy for a user group is the same as the global policy. The password composition policy for a local user is the same as that of the user group to which the local user belongs.

Views

System view

User group view

Local user view

Predefined user roles

network-admin

context-admin

Parameters

type-number *type-number*: Specifies the minimum number of character types that a password must contain. The value range for the *type-number* argument is 1 to 4.

type-length *type-length*: Specifies the minimum number of characters that are from each type in the password. The value range for the *type-length* argument is 1 to 63.

Usage guidelines

The password composition policy depends on the view:

- The policy in system view has global significance and applies to all user groups.
- The policy in user group view applies to all local users in the user group.
- The policy in local user view applies only to the local user.

A password composition policy with a smaller application scope has higher priority. The system prefers to use the password composition policy in local user view for a local user.

- If no policy is configured for the local user, the system uses the policy for the user group to which the local user belongs.
- If no policy is configured for the user group, the system uses the global policy.

The product of the minimum number of character types and minimum number of characters for each type cannot be greater than the maximum length of passwords.

Examples

Specify that all passwords must each contain a minimum of four character types and a minimum of five characters for each type.

```
<Sysname> system-view
[Sysname] password-control composition type-number 4 type-length 5
```

Specify that passwords in user group **test** must contain a minimum of four character types and a minimum of five characters for each type.

```
[Sysname] user-group test
[Sysname-ugroup-test] password-control composition type-number 4 type-length 5
[Sysname-ugroup-test] quit
```

Specify that the password of device management user **abc** must contain a minimum of four character types and a minimum of five characters for each type.

```
[Sysname] local-user abc class manage
[Sysname-luser-manage-abc] password-control composition type-number 4 type-length 5
```

Related commands

display local-user

display password-control

display user-group

password-control composition enable

password-control enable

Use **password-control enable** to enable the password control feature globally.

Use **undo password-control enable** to disable the password control feature globally.

Syntax

password-control enable [**network-class**]

undo password-control enable [**network-class**]

Default

The password control feature is disabled globally for device management and network access users.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

network-class: Enables global password control for network access users. If you do not specify this keyword, the command enables global password control for device management users.

Usage guidelines

When you enable global password control, the device automatically generates a .dat file and saves the file to the storage media. The file is used to record authentication and login information of local users. Do not manually delete or modify the file.

The password composition policy, minimum password length, and username checking are independent of the global password control feature. Other password control features take effect only after the global password control feature is also enabled.

After the global password control feature is enabled, the passwords configured for local users must contain a minimum of four different characters.

After the global password control feature is enabled for device management users, you cannot display the password and super password configuration for device management users by using the corresponding **display** commands.

After the global password control feature is enabled for network access users, you cannot display the password configuration for network access users by using the corresponding **display** commands.

You can configure all password control features for device management users.

You can configure only the following password control features for network access users:

- Password complexity checking policy.
- Password composition policy.
- Minimum password length.
- Minimum password update interval.
- Maximum number of history password records for each user.

Examples

Enable the password control feature globally for device management users.

```
<Sysname> system-view
[Sysname] password-control enable
```

Enable the password control feature globally for network access users.

```
<Sysname> system-view
[Sysname] password-control enable network-class
```

Related commands

display password-control

password-control complexity

password-control { **aging** | **composition** | **history** | **length** } **enable**

password-control update-interval

password-control expired-user-login

Use **password-control expired-user-login** to set the maximum number of days and maximum number of times that a user can log in after the password expires.

Use **undo password-control expired-user-login** to restore the defaults.

Syntax

password-control expired-user-login delay *delay* **times** *times*

undo password-control expired-user-login

Default

A user can use an expired password to log in three times within 30 days after the password expires. If all the three attempts fail or the user makes a login attempt after 30 days, the system prompts the user to set a new password.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

delay *delay*: Specifies the maximum number of days during which a user can log in using an expired password. The value range for the *delay* argument is 1 to 90.

times *times*: Specifies the maximum number of times a user can log in after the password expires. The value range is 0 to 10. For a user to set a new password at the system prompt immediately after the password expires, set the value to 0.

Usage guidelines

This command is effective only on non-FTP login users. An FTP user cannot continue to log in after its password expires.

Examples

Allow a user to log in five times within 60 days after the password expires.

```
<Sysname> system-view
[Sysname] password-control expired-user-login delay 60 times 5
```

Related commands

display password-control

password-control history

Use **password-control history** to set the maximum number of history password records for each user.

Use **undo password-control history** to restore the default.

Syntax

password-control history *max-record-number*

undo password-control history

Default

The maximum number of history password records for each user is 4.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

max-record-number: Specifies the maximum number of history password records for each user. The value range is 2 to 15.

Usage guidelines

The global password control feature enables the system to record history passwords. When the number of history password records of a user reaches the maximum number, the newest history record overwrites the earliest one.

To delete the existing records, use one of the following methods:

- Use the **undo password-control enable** command to disable the password control feature globally.
- Use the **reset password-control history-record** command to clear the passwords manually.

Examples

Set the maximum number of history password records for each user to 10.

```
<Sysname> system-view
[Sysname] password-control history 10
```

Related commands

display password-control

password-control history enable

reset password-control blacklist

password-control length

Use **password-control length** to set the minimum password length.

Use **undo password-control length** to restore the default.

Syntax

password-control length *length*

undo password-control length

Default

The global minimum password length is 10 characters.The minimum password length for a user group equals the global setting. The minimum password length for a local user equals that of the user group to which the local user belongs.

Views

System view

User group view

Local user view

Predefined user roles

network-admin

context-admin

Parameters

length: Specifies the minimum password length in characters. The value range for this argument is 4 to 32.

Usage guidelines

The minimum length setting depends on the view:

- The setting in system view has global significance and applies to all user groups.

- The setting in user group view applies to all local users in the user group.
- The setting in local user view applies only to the local user.

A minimum password length with a smaller application scope has higher priority. The system prefers to use the minimum password length in local user view for a local user.

- If no minimum password length is configured for the local user, the system uses the minimum password length for the user group to which the local user belongs.
- If no minimum password length is configured for the user group, the system uses the global minimum password length.

Examples

Set the global minimum password length to 16 characters.

```
<Sysname> system-view
[Sysname] password-control length 16
```

Set the minimum password length to 16 characters for the user group **test**.

```
[Sysname] user-group test
[Sysname-ugroup-test] password-control length 16
[Sysname-ugroup-test] quit
```

Set the minimum password length to 16 characters for the device management user **abc**.

```
[Sysname] local-user abc class manage
[Sysname-luser-manage-abc] password-control length 16
```

password-control length enable

password-control login idle-time

Use **password-control login idle-time** to set the maximum account idle time.

Use **undo password-control login idle-time** to restore the default.

Syntax

password-control login idle-time *idle-time*

undo password-control login idle-time

Default

The maximum account idle time is 90 days.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

idle-time: Specifies the maximum account idle time in days. The value range is 0 to 365. 0 means no restriction for account idle time.

Usage guidelines

If a user account is idle for this period of time, the account becomes invalid and can no longer be used to log in to the device.

The account might become invalid if the system time changes after your last successful login. You cannot use an invalid account to log in. To disable the account idle time restriction, set the idle time value to 0.

Examples

Set the maximum account idle time to 30 days.

```
<Sysname> system-view
[Sysname] password-control login idle-time 30
```

Related commands

display password-control

password-control login-attempt

Use **password-control login-attempt** to configure the login attempt limit. The settings include the maximum number of consecutive login failures and the action to be taken when the maximum number is reached.

Use **undo password-control login-attempt** to restore the default.

Syntax

password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

undo password-control login-attempt

Default

The global login-attempt settings:

- The maximum number of consecutive login failures is 3.
- The locking period is 1 minute.

The login-attempt settings for a user group equal the global settings.

The login-attempt settings for a local user equal those for the user group to which the local user belongs.

Views

System view

User group view

Local user view

Predefined user roles

network-admin

context-admin

Parameters

login-times: Specifies the maximum number of consecutive login failures. The value range is 2 to 10.

exceed: Specifies an action if the user fails the maximum number of consecutive login attempts.

- **lock**: Locks the user account and the user's IP address permanently. No one can use this user account to log in from this locked IP address.

- **lock-time** *time*: Locks the user account and the user's IP address for a period of time. When the locking timer expires, users can use this user account to log in from the IP address. The value range for the *time* argument is 1 to 360 minutes.
- **unlock**: Does not lock the user account. The user can continue using this account to make login attempts from the current IP address.

Usage guidelines

The login-attempt policy depends on the view:

- The policy in system view has global significance and applies to all user groups.
- The policy in user group view applies to all local users in the user group.
- The policy in local user view applies only to the local user.

A login-attempt policy with a smaller application scope has higher priority. The system prefers to use the login-attempt policy in local user view for a local user.

- If no policy is configured for the local user, the system uses the policy for the user group to which the local user belongs.
- If no policy is configured for the user group, the system uses the global policy.

If an FTP, Web, or VTY user fails to log in, the system adds the user account and the user's IP address to the password control blacklist. When the maximum number of consecutive login failures is reached, the login attempt limit feature is triggered.

Whether a blacklisted user and user account are locked depends on the locking setting:

- If a user account is permanently locked for a user, the user cannot use this account unless this account is removed from the password control blacklist. To remove the user account, use the **reset password-control blacklist** command.
- To use a temporarily locked user account, the user can perform either of the following tasks:
  - Wait until the locking timer expires.
  - Remove the user account from the password control blacklist.
- If the user account and the user are blacklisted but not locked, the user can continue using this account to log in. The account and the user's IP address are removed from the password control blacklist when the user uses the account to successfully log in to the device.

NOTE:

This account is locked only for the user at the locked IP address. A user from an unlocked IP address can still use this account, and the user at the locked IP address can use other unlocked user accounts.

The **password-control login-attempt** command takes effect immediately after being executed, and can affect the users already in the password control blacklist.

Examples

Allow a maximum of four consecutive login failures on a user account, and lock the user account and the user's IP address permanently if the limit is reached.

```
<Sysname> system-view
[Sysname] password-control login-attempt 4 exceed lock
```

Use the user account **test** to log in to the device, and enter incorrect password for four times.

Display the password control blacklist. The output shows that the user account is on the blacklist, and its status is **lock**.

```
[Sysname] display password-control blacklist
 Per-user blacklist limit: 100.
 Blacklist items matched: 1.
```

```
 Username                    IP address          Login failures   Lock flag
 test                        192.168.44.1        4                lock
```

Verify that the user at 192.168.44.1 cannot use this user account to log in.

Allow a maximum of two consecutive login failures on a user account, and lock the account for 3 minutes if the limit is reached.

```
<Sysname> system-view
[Sysname] password-control login-attempt 2 exceed lock-time 3
```

Use the user account **test** to log in to the device, and enter incorrect password for two attempts.

Display the password control blacklist. The output shows that the user account is on the blacklist and its status is **lock**.

```
[Sysname] display password-control blacklist
 Per-user blacklist limit: 100.
 Blacklist items matched: 1.
 Username                    IP address          Login failures   Lock flag
 test                        192.168.44.1        2                lock
```

Verify that after 3 minutes, the user account is removed from the password control blacklist and the user at 192.168.44.1 can use this account.

reset password-control blacklist

password-control per-user blacklist-limit

Use **password-control per-user blacklist-limit** to set the maximum number of blacklist entries for a user account.

Use **undo password-control per-user blacklist-limit** to restore the default.

Syntax

password-control per-user blacklist-limit *max-number*

undo password-control per-user blacklist-limit

Default

The maximum number of blacklist entries for a user account is 32.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Maximum number of blacklist entries that the device can record for a single user account. The value range is 1 to 4294967295.

Usage guidelines

When the console users fail login, their user accounts are added to the password control blacklist. When FTP, Web, or virtual terminal line (VTY) users fail login, their IP addresses and user accounts are added to the password control blacklist.

If such a user uses the same user account to log in to the device from different IP addresses and fails the logins, the device will create a blacklist entry for each IP address for the user account. When the maximum number of blacklist entries for the user account is reached, a blacklist entry for a new IP address of the user account will overwrite the earliest blacklist entry for the user account.

Examples

Set the maximum number of blacklist entries for a user account to 100.

```
<Sysname> system-view
[Sysname] password-control per-user blacklist-limit 100
```

password-control super composition

Use **password-control super composition** to configure the composition policy for super passwords.

Use **undo password-control super composition** to restore the default.

Syntax

password-control super composition type-number *type-number* [**type-length** *type-length*]

undo password-control super composition

Default

A super password must contain a minimum of two character types and a minimum of one character for each type.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

type-number *type-number*: Specifies the minimum number of character types that a super password must contain. The value range for the *type-number* argument is 1 to 4.

type-length *type-length*: Specifies the minimum number of characters that are from each character type. The value range for the *type-length* argument is 1 to 63.

Usage guidelines

The product of the minimum number of character types and minimum number of characters for each type cannot be greater than the maximum length of the super password.

Examples

Specify that a super password must contain a minimum of four character types and a minimum of five characters for each type.

```
<Sysname> system-view
[Sysname] password-control super composition type-number 4 type-length 5
```

password-control length

password-control update-interval

Use **password-control update-interval** to set the minimum password update interval, which is the minimum interval at which users can change their passwords.

Use **undo password-control update-interval** to restore the default.

Syntax

password-control update-interval *interval*

undo password-control update-interval

Default

The minimum password update interval is 24 hours.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the minimum password update interval in hours, in the range of 0 to 168. 0 means no requirements for password update interval.

Usage guidelines

The set minimum interval is not effective on a user who is prompted to change the password at the first login or after the password expires.

Examples

Set the minimum password update interval to 36 hours.

```
<Sysname> system-view
[Sysname] password-control update-interval 36
```

Related commands

display password-control

reset password-control blacklist

Use **reset password-control blacklist** to remove blacklisted users.

Syntax

reset password-control blacklist [**user-name** *user-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

user-name *user-name*: Specifies the username of a user account to be removed from the password control blacklist. The username is a string of 1 to 55 characters. You can specify a pure username or specify a pure username and its domain name in the format of *pure usernname@domain name*. The pure username is case sensitive. The domain name is case-insensitive.

Usage guidelines

You can use this command to remove a user account and the user's IP address that are blacklisted due to excessive login failures. Then the user at this IP address can use this user account to log in.

Examples

Remove the user account named **test** from the password control blacklist.

```
<Sysname> reset password-control blacklist user-name test
Are you sure to delete the specified user in blacklist? [Y/N]:
```

Related commands

display password-control blacklist

reset password-control history-record

Use **reset password-control history-record** to delete history password records.

Syntax

reset password-control history-record [**super** [**role** *role name*] | **user-name** *user-name* | **network-class** [**user-name** *user-name*]]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

super: Deletes the history records of the specified super password or all super passwords.

role *role name*: Specifies a user role name, a case-sensitive string of 1 to 63 characters. If you do not specify this option, the command deletes the history records of all super passwords.

network-class: Deletes the history password records of network access users. If you do not specify this keyword, the command deletes the history password records of device management users.

user-name *user-name*: Specifies the username of the user whose password records are to be deleted. The *user-name* argument is a case-sensitive string of 1 to 55 characters. If you do not specify this option, the command deletes all history password records of the specified user type.

Usage guidelines

If you do not specify any parameters, this command deletes the history password records of all device management users.

Examples

Clear the history password records of all device management users.

```
<Sysname> reset password-control history-record
Are you sure to delete all local user's history records? [Y/N]:y
```

Delete the history password records of all network access users.

```
<Sysname> reset password-control history-record network-class
Are you sure you want to delete all network access users' history records? [Y/N]:y
```

Portal commands

aaa-fail nobinding enable

Use **aaa-fail nobinding enable** to enable AAA failure unbinding.

Use **undo aaa-fail nobinding enable** to restore the default.

Syntax

aaa-fail nobinding enable

undo aaa-fail nobinding enable

Default

AAA failure unbinding is disabled.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Usage guidelines

If a portal user fails AAA in MAC-trigger authentication, the user cannot trigger authentication before the MAC-trigger entry of the user ages out. After the MAC-trigger entry ages out, the user triggers MAC-trigger authentication when it accesses the network.

After AAA failure unbinding is enabled, the device sets the MAC-trigger entry state for a user to unbound immediately after the user fails AAA in MAC-trigger authentication. Before the user's MAC-trigger entry ages out, the user can trigger normal portal authentication.

Examples

Enable AAA failure unbinding for MAC binding server **mts**.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
[Sysname-portal-mac-trigger-server-mts] aaa-fail nobinding enable
```

Related commands

display portal mac-trigger-server

ad-url

Use **ad-url** to configure an advertisement URL in an advertisement group.

Use **undo ad-url** to delete an advertisement URL from an advertisement group.

Syntax

ad-url *url-string* [**time-range** *time-range-name*]

undo ad-url *url-string*

Default

No advertisement URLs are configured in an advertisement group.

Views

Advertisement group view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the URL of an advertisement, a case-sensitive string of 1 to 256 characters. The URL must begin with **http://**.

time-range *time-range-name*: Specifies a time range for portal advertisement push. The *time-range-name* argument represents the name of the time range, a case-insensitive string of 1 to 32 characters. The time range name must begin with a letter and cannot be **all**. For more information about time ranges, see time range configuration in *ACL and QoS Configuration Guide*.

Usage guidelines

You can configure a maximum of 16 advertisement URLs in an advertisement group.

If the advertisement push method is time range-based, you must specify a time range for each advertisement URL. The time ranges for all advertisement URLs in an advertisement group must be different from each other.

Examples

Configure advertisement URLs in advertisement group **test**.

```
<Sysname> system-view
[Sysname] portal ad-url-group test method interval
[Sysname-portal-ad-url-group-test] ad-url http://www.qq.com
[Sysname-portal-ad-url-group-test] ad-url http://www.sina.com
[Sysname-portal-ad-url-group-test] ad-url http://www.baidu.com
```

Related commands

ad-url-group

ad-url-group

Use **ad-url-group** to set the time interval or traffic threshold for portal advertisement push in an advertisement group.

Use **undo ad-url-group** to restore the default.

Syntax

ad-url-group { **interval** *interval* | **traffic-threshold** *traffic-threshold* }

undo ad-url-group

Default

The interval is 360 minutes and the traffic threshold is 100 MB for portal advertisement push in an an advertisement group.

Views

Advertisement group view

Predefined user roles

network-admin

context-admin

Parameters

interval *interval*: Specifies the advertisement push interval, in the range of 5 to 1440 minutes. The interval begins when a portal user comes online.

traffic-threshold *traffic-threshold*: Specifies the traffic threshold for portal advertisement push in the range of 1 to 1024 MB.

Usage guidelines

This command takes effect only when the advertisement push method is time-based or traffic-based. The advertisement push interval is applicable to time-based advertisement push. The traffic threshold is applicable to traffic-based advertisement push.

Each time the interval for a user ends or the user's consumed traffic since the last push reaches the traffic threshold, the device pushes an advertisement to the user. The advertisements in the advertisement group are pushed to the portal user in the order they are configured.

Examples

Set the advertisement push interval to 100 minutes in advertisement group **test**.

```
<Sysname> system-view
[Sysname] portal ad-url-group test
[Sysname-portal-ad-url-group-test] ad-url-group interval 100
```

Related commands

ad-url

portal ad-url-group

aging-time

Use **aging-time** to set the aging time for MAC-trigger entries.

Use **undo aging-time** to restore the default.

Syntax

aging-time *seconds*

undo aging-time

Default

The aging time for MAC-trigger entries is 300 seconds.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the aging time for MAC-trigger entries. The value range is 60 to 7200 seconds.

Usage guidelines

With MAC-based quick portal authentication enabled, the device generates a MAC-trigger entry for a user when the device detects traffic from the user for the first time. The MAC-trigger entry records the following information:

- MAC address of the user

- Interface index
- VLAN ID
- Traffic statistics
- Aging timer

When the aging time expires, the device deletes the MAC-trigger entry. The device re-creates a MAC-trigger entry for the user when it detects the user's traffic again.

Examples

Specify the aging time as 300 seconds for MAC-trigger entries.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
[Sysname-portal-mac-trigger-server-mts] aging-time 300
```

Related commands

app-id (Facebook authentication server view)

Use **app-id** to specify the app ID for Facebook authentication.

Use **undo app-id** to restore the default.

Syntax

app-id *app-id*

undo app-id

Default

No app ID is specified for Facebook authentication.

Views

Facebook authentication server view

Predefined user roles

network-admin

context-admin

Parameters

app-id: Specifies the app ID for Facebook authentication.

Usage guidelines

If a portal user uses Facebook authentication, the Facebook server authenticates and authorizes the user and sends an authorization code to the device after the authentication and authorization succeed. Then, the device sends the authorization code, app ID, and app key to the Facebook server to determine whether the user has passed authentication and authorization.

Examples

Specify **123456789** as the app ID for Facebook authentication.

```
<Sysname> system-view
[Sysname] portal extend-auth-server facebook
[Sysname-portal-extend-auth-server-fb] app-id 123456789
```

Related commands

display portal extend-auth-server

app-id (QQ authentication server view)

Use **app-id** to specify the app ID for QQ authentication.

Use **undo app-id** to restore the default.

Syntax

app-id *app-id*

undo app-id

Default

An app ID for QQ authentication exists.

Views

QQ authentication server view

Predefined user roles

network-admin

context-admin

Parameters

app-id: Specifies the app ID for QQ authentication.

Usage guidelines

To use QQ authentication for portal users, you must go to Tencent Open Platform (**http://connect.qq.com/intro/login**) to finish the following tasks:

1. Register as a developer by using a valid QQ account.
2. Apply the access to the platform for your website. The website is the webpage to which users are redirected after passing QQ authentication.

You will obtain the app ID and app key from the Tencent Open Platform after your application succeeds.

After a portal user passes QQ authentication, the QQ authentication server sends the authorization code of the user to the portal Web server. After the portal Web server receives the authorization code, it sends the authorization code of the user, the app ID, and the app key to the QQ authentication server for verification. If the information is verified as correct, the device determines that the user passes QQ authentication.

Examples

Specify **101235509** as the app ID for QQ authentication.

```
<Sysname> system-view
[Sysname] portal extend-auth-server qq
[Sysname-portal-extend-auth-server-qq] app-id 101235509
```

Related commands

display portal extend-auth-server

app-id (WeChat authentication server view)

Use **app-id** to specify the app ID for WeChat authentication.

Use **undo app-id** to restore the default.

Syntax

app-id *app-id*

undo app-id

Default

No app ID is specified for WeChat authentication.

Views

WeChat authentication server view

Predefined user roles

network-admin

context-admin

Parameters

app-id: Specifies the app ID for WeChat authentication.

Usage guidelines

The app ID specified in this command must be the same as the app ID obtained from the WeChat Official Account Admin Platform.

This configuration is required for the device to provide local WeChat authentication for portal users.

To obtain the app ID for WeChat authentication, you must perform the following tasks:

1. Go to the WeChat Official Account Admin Platform (**https://mp.weixin.qq.com**) to apply a WeChat official account.
2. Use the account to log in to the platform and enable the WeChat WiFi hotspot feature.
3. Click the device management tab, add the device: select the shop where the device is deployed, select the **portal** device type, and enter the deviec settings.

   After the previous configurations, you will obtain the credentials (app ID, app key, and shop ID) for WeChat authentication.

When a WeChat user attempts to connect to the WiFi network provided in the specified shop, the device sends the credentials to the WeChat Official Account Platform for verification. After the credentials are verified, the device continues the portal authentication and allows the user to use the WiFi network after the authentication.

Examples

Specify **wx23fb4aaf04b8491e** as the app ID for WeChat authentication.

```
<Sysname> system-view
[Sysname] portal extend-auth-server wechat
[Sysname-portal-extend-auth-server-wechat] app-id wx23fb4aaf04b8491e
```

No app key is specified for Facebook authentication.

Views

Facebook authentication server view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies the app key in encrypted form.

simple: Specifies the app key in plaintext form.

app-key: Specifies the app key string. Its plaintext form is a case-sensitive string of 1 to 64 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

If a portal user uses Facebook authentication, the Facebook server authenticates and authorizes the user and sends an authorization code to the device after the authentication and authorization succeed. Then, the device sends the authorization code, app ID, and app key to the Facebook server to determine whether the user has passed authentication and authorization.

Examples

Specify **123** in plaintext form as the app key for Facebook authentication.

```
<Sysname> system-view
[Sysname] portal extend-auth-server facebook
[Sysname-portal-extend-auth-server-fb] app-key simple 123
```

Related commands

display portal extend-auth-server

app-key (QQ authentication server view)

Use **app-key** to specify the app key for QQ authentication.

Use **undo app-key** to restore the default.

Syntax

app-key { **cipher** | **simple** } *app-key*

undo app-key

Default

An app key for QQ authentication exists.

Views

QQ authentication server view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies the app key in encrypted form.

simple: Specifies the app key in plaintext form.

app-key: Specifies the app key string. Its plaintext form is a case-sensitive string of 1 to 64 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

To use QQ authentication for portal users, you must go to Tencent Open Platform (**http://connect.qq.com/intro/login**) to finish the following tasks:

1. Register as a developer by using a valid QQ account.
2. Apply the access to the platform for your website. The website is the webpage to which users are redirected after passing QQ authentication.

You will obtain the app ID and app key from the Tencent Open Platform after your application succeeds.

After a portal user passes QQ authentication, the QQ authentication server sends the authorization code of the user to the portal Web server. After the portal Web server receives the authorization code, it sends the authorization code of the user, the app ID, and the app key to the QQ authentication server for verification. If the information is verified as correct, the device determines that the user passes QQ authentication.

Examples

Specify **8a5428e6afdc3e2a2843087fe73f1507** in plaintext form as the app key for QQ authentication.

```
<Sysname> system-view
[Sysname] portal extend-auth-server qq
[Sysname-portal-extend-auth-server-qq] app-key simple 8a5428e6afdc3e2a2843087fe73f1507
```

Related commands

display portal extend-auth-server

app-key (WeChat authentication server view)

Use **app-key** to specify the app key for WeChat authentication.

Use **undo app-key** to restore the default.

Syntax

app-key { **cipher** | **simple** } *app-key*

undo app-key

Default

No app key is specified for WeChat authentication.

Views

WeChat authentication server view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies the app key in encrypted form.

simple: Specifies the app key in plaintext form.

app-key: Specifies the app key string. Its plaintext form is a case-sensitive string of 1 to 64 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

This configuration is required for the device to provide local WeChat authentication for portal users. The app key specified in this command must be the same as the app key obtained from the WeChat Official Account Admin Platform.

To obtain the app key for WeChat authentication, you must perform the following tasks:

1. Go to the WeChat Official Account Admin Platform (**https://mp.weixin.qq.com**) to apply a WeChat official account.
2. Use the account to log in to the platform and enable the WeChat WiFi hotspot feature.
3. Click the device management tab, add the device: select the shop where the device is deployed, select the **portal** device type, and enter the device settings.

   After the previous configurations, you will obtain the credentials (app ID, app key, and shop ID) for WeChat authentication.

When a WeChat user attempts to connect to the WiFi network provided in the specified shop, the device sends the credentials to the WeChat Official Account Platform for verification. After the credentials are verified, the device continues the portal authentication and allows the user to use the WiFi network after the authentication.

Examples

Specify **nqduqg4816689geruhq3** in plaintext form as the app key for WeChat authentication.

```
<Sysname> system-view
[Sysname] portal extend-auth-server wechat
[Sysname-portal-extend-auth-server-wechat] app-key simple nqduqg4816689geruhq3
```

Related commands

display portal extend-auth-server

app-secret

Use **app-secret** to specify the app secret for WeChat authentication.

Use **undo app-secret** to restore the default.

Syntax

app-secret { **cipher** | **simple** } *string*

undo app-secret

Default

No app secret is specified for WeChat authentication.

Views

WeChat authentication server view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies the app secret in encrypted form.

simple: Specifies the app secret in plaintext form.

app-key: Specifies the app secret string. Its plaintext form is a case-sensitive string of 1 to 64 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

When the subscribe-required feature is enabled, you must specify the app secret for WeChat authentication on the device.

To obtain the app secret for WeChat authentication, perform the following tasks:

1. Use a WeChat official account to log in to the WeChat Official Account Admin Platform.

   For more information about the WeChat official account, see WeChat authentication configuration in *Security Configuration Guide*.
2. From the navigation tree, select **Developer Centers**.

   In the **Configuration Items** area, you can see the app secret for the WeChat Official account.

Examples

Specify **nqduqg4816689geruhq3** in plaintext form as the app secret for WeChat authentication.

```
<Sysname> system-view
[Sysname] portal extend-auth-server wechat
[Sysname-portal-extend-auth-server-wechat] app-secret simple nqduqg4816689geruhq3
```

authentication-timeout

Use **authentication-timeout** to set the authentication timeout, which is the maximum amount of time the device waits for portal authentication to complete after receiving the MAC binding query response.

Use **undo authentication-timeout** to restore the default.

Syntax

authentication-timeout *minutes*

undo authentication-timeout

Default

The authentication timeout time is 3 minutes.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Parameters

minutes: Specifies the authentication timeout in the range of 1 to 15 minutes.

Usage guidelines

Upon receiving the MAC binding query response of a user from the MAC binding server, the device starts an authentication timeout timer for the user. When the timer expires, the device deletes the MAC-trigger entry of the user.

Examples

Set the authentication timeout to 10 minutes.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
```

```
[Sysname-portal-mac-trigger-server-mts] authentication-timeout 10
```

Related commands

display portal mac-trigger-server

auth-url

Use **auth-url** to specify the URL of the QQ or Facebook authentication server.

Use **undo auth-url** to delete the URL of the QQ or Facebook authentication server.

Syntax

auth-url *url-string*

undo auth-url

Default

The URL of QQ authentication server is **https://graph.qq.com**.

The URL of Facebook authentication server is **https://graph.facebook.com**.

Views

QQ authentication server view

Facebook authentication server view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the URL of the QQ or Facebook authentication server, a case-sensitive string of 1 to 256 characters. Make sure that you specify the actual URL of the QQ or Facebook authentication server. The URL string can include question marks (?). If you enter a question mark (?) in the place of this argument, the CLI does not display help information for this argument.

Examples

Specify **http://oauth.qq.com/** as the URL of the QQ authentication server.

```
<Sysname> system-view
[Sysname] portal extend-auth-server qq
[Sysname-portal-extend-auth-server-qq] auth-url http://oauth.qq.com
```

Specify **http://oauth.facebook.com** as the URL of the Facebook authentication server.

```
<Sysname> system-view
[Sysname] portal extend-auth-server facebook
[Sysname-portal-extend-auth-server-fb] auth-url http://oauth.facebook.com
```

Related commands

display portal extend-auth-server

binding-retry

Use **binding-retry** to specify the maximum number of attempts and the interval for sending MAC binding queries to the MAC binding server.

Use **undo binding-retry** to restore the default.

Syntax

binding-retry { *retries* | **interval** *interval* } *

undo binding-retry

Default

The maximum number of query attempts is 3 and the query interval is 1 second.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Parameters

retries: Specifies the maximum number of MAC binding query attempts, in the range of 1 to 10.

interval *interval*: Specifies the query interval in the range of 1 to 60 seconds.

Usage guidelines

If the device does not receive a response from the MAC binding server after the maximum number is reached, the device determines that the MAC binding server is unreachable. The device performs normal portal authentication for the user. The user needs to enter the username and password for authentication.

If you execute this command multiple times in the same MAC binding server view, the most recent configuration takes effect.

Examples

Set the maximum number of MAC binding query attempts to 3 and the query interval to 60 seconds.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
[Sysname-portal-mac-trigger-server-mts] binding-retry 3 interval 60
```

Related commands

display portal mac-trigger-server

captive-bypass enable

Use **captive-bypass enable** to enable the captive-bypass feature.

Use **undo captive-bypass enable** to disable the captive-bypass feature.

Syntax

captive-bypass [**android** | **ios** [**optimize**]] **enable**

undo captive-bypass [**android** | **ios** [**optimize**]] **enable**

Default

The captive-bypass feature is disabled. The device automatically pushes the portal authentication page to the iOS devices and some Android devices when they are connected to the network.

Views

Portal Web server view

Predefined user roles

network-admin

context-admin

Parameters

android: Enables the captive-bypass feature for Android users.

ios: Enables the captive-bypass feature for iOS users.

optimize: Enables the optimized captive-bypass feature.

Usage guidelines

With the captive-bypass feature enabled, the device does not automatically push the portal authentication page to iOS devices and some Android devices when they are connected to the network. The device pushes the portal authentication page only when the user accesses the Internet by using a browser.

The optimized captive-bypass feature applies only to iOS mobile devices. The device automatically pushes the portal authentication page to iOS mobile devices when they are connected to the network. Users can press the home button to return to the desktop without triggering portal authentication, and the Wi-Fi connection is not terminated.

If you do not specify any parameters, this command enables the captive-bypass feature for both Android and iOS users.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Enable the captive-bypass feature.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] captive-bypass enable
```

Enable the optimized captive-bypass feature for iOS users.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] captive-bypass ios optimize enable
```

Enable the captive-bypass feature for Android users.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] captive-bypass android enable
```

Related commands

display portal captive-bypass statistics

display portal web-server

cloud-binding enable

Use **cloud-binding enable** to enable cloud MAC-trigger authentication.

Use **undo cloud-binding enable** to disable cloud MAC-trigger authentication.

Syntax

cloud-binding enable

undo cloud-binding enable

Default

Cloud MAC-trigger authentication is disabled.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Usage guidelines

The cloud MAC-trigger authentication feature enables the cloud server to provide automated authentication to users as a unified portal authentication, portal Web, and MAC binding server. Users are required to perform manual authentication (entering the username and password) only for the first network access. They are automatically connected to the network without manual authentication for subsequent network access attempts.

Examples

Enable cloud MAC-trigger authentication for MAC binding server **mts**.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
[Sysname-portal-mac-trigger-server-mts] cloud-binding enable
```

Related commands

display portal mac-trigger-server

cloud-server url

Use **cloud-server url** to specify the URL of the cloud portal authentication server.

Use **undo cloud-server url** to restore the default.

Syntax

cloud-server url *url-string*

undo cloud-server url

Default

The URL of the cloud portal authentication server is not specified. The device uses the URL of the portal Web server as the URL of the cloud portal authentication server.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the URL of a cloud portal authentication server. The specified URL must be a complete URL starting with **http://** or **https://**, a case-sensitive string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of this argument, the CLI does not display help information for this argument.

Usage guidelines

To separate portal authentication and Web servers, specify the cloud portal authentication server URL by using this command, and specify a different URL for the portal Web server. In this way, you can use a different portal Web server to provide customized authentication pages to users.

Examples

In the view of MAC binding server **mts**, specify **http://lvzhou.nsfocus.com.cn** as the URL of the cloud portal authentication server.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
[Sysname-portal-mac-trigger-server-mts] cloud-server url http://lvzhou.nsfocus.com.cn
```

Related commands

display portal mac-trigger-server

default-logon-page

Use **default-logon-page** to specify the default authentication page file for a local portal Web service.

Use **undo default-logon-page** to restore the default.

Syntax

default-logon-page *file-name*

undo default-logon-page

Default

Models	Default
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	The device does not provide a default authentication page file for a local portal Web service.
NFNX3-HDB680, NFNX3-HDB1080	The device provides a default authentication page file for a local portal Web service.

Views

Local portal Web service view

Predefined user roles

network-admin

context-admin

Parameters

file-name: Specifies the default authentication page file by the file name (without the file storage directory). The file name is a case-sensitive string of 1 to 91 characters. Valid characters are letters, digits, dots (.) and underscores (_).

Usage guidelines

You must edit the default authentication pages, compress them to a .zip file, and then upload the file to the root directory of the storage medium of the device.

After you use the **default-logon-page** command to specify the file, the device decompresses the file to get the authentication pages. The device then sets them as the default authentication pages for local portal authentication.

Examples

Specify file **pagefile1.zip** as the default authentication page file for local portal authentication.

```
<Sysname> system-view
[Sysname] portal local-web-server http
[Sysname-portal-local-websvr-http] default-logon-page pagefile1.zip
```

```

Table 1 Command output

Field	Description
Portal information of interface	Portal configuration on the interface.
NAS-ID profile	NAS-ID profile on the interface.
Authorization	Authorization information type: .
Strict checking	Whether strict checking is enabled on portal authorization information.
Dual stack	Status of the portal dual-stack feature on the interface: • Disabled. • Enabled.
Dual IP	Status of the dual IP feature, disabled or enabled. This feature enables the device to carry both an IPv4 address and an IPv6 address in RADIUS packets for single-stack users in remote portal authentication.
Dual traffic-separate	Status of separate IPv4 and IPv6 traffic statistics for dual-stack portal users on the interface: • Disabled. • Enabled.
Advertisement-push	Status of portal advertisement push: • Disabled. • Enabled.
Embedded advertisement	Status of embedded portal advertisement push: • Disabled. • Enabled.
IPv4	IPv4 portal configuration.
IPv6	IPv6 portal configuration.
Portal status	Portal authentication status on the interface: • **Disabled**—Portal authentication is disabled. • **Enabled**—Portal authentication is enabled. • **Authorized**—The portal authentication server or portal Web server is unreachable. The interface allows users to have network access without authentication.
Portal authentication method	Type of authentication enabled on the interface: • **Direct**—Direct authentication. • **Redhcp**—Re-DHCP authentication. • **Layer3**—Cross-subnet authentication.
Portal Web server	Name of the primary portal Web server specified on the interface. This field displays the **(active)** flag next to the server name if the server is being used.
Secondary portal Web server	Name of the backup portal Web server specified on the interface. This field displays the **(active)** flag next to the server name if the server is being used.
Portal mac-trigger-server	Name of the MAC binding server specified on the interface.
Authentication domain	Mandatory authentication domain on the interface.
Pre-auth domain	Preauthentication domain for portal users on the interface.
Extend-auth domain	Authentication domain configured for third-party authentication on an

Field	Description
	interface.
User-dhcp-only	Status of the user-dhcp-only feature: • **Enabled**—Only users with IP addresses obtained through DHCP can perform portal authentication. • **Disabled**—Both users with IP addresses obtained through DHCP and users with static IP addresses can pass authentication to get online.
Pre-auth ip-pool	Name of the IP address pool specified for portal users before authentication.
Max portal users	Maximum number of portal users allowed on an interface.
Bas-ip	BAS-IP attribute of the portal packets sent to the portal authentication server.
Bas-ipv6	BAS-IPv6 attribute of the portal packets sent to the portal authentication server.
User detection	Configuration for online detection of portal users on the interface, including detection method (ARP, ICMP, ND, or ICMPv6), detection interval, maximum number of detection attempts, and user idle time.
Portal temp-pass	Status of the temporary pass feature: • **Enabled**—The temporary pass feature is enabled. • **Disabled**—The temporary pass feature is disabled. • **Period**—Temporary pass period during which a user can access the Internet temporarily. This field is displayed only if the temporary pass feature is enabled.
Action for server detection	Portal server detection configuration on the interface: • **Server type**—Type of the server. **Portal server** represents the portal authentication server, and **Web server** represents the portal Web server. • **Server name**—Name of the server. • **Action**—Action triggered by the result of server detection. This field displays **fail-permit** when the portal fail-permit feature is enabled.
Layer3 source network	Information of the portal authentication source subnet.
Destination authentication subnet	Information of the portal authentication destination subnet.
IP address	IP address of the portal authentication subnet.
Mask	Subnet mask of the portal authentication subnet.
Prefix length	Prefix length of the IPv6 portal authentication subnet address.
Advertisement push URL	URL of the advertisement to be pushed to portal users and the push method related setting: Possible settings include: • **Interval**—Interval for time-based advertisement push, in minutes. • **Traffic**—Traffic threshold for traffic-based advertisement push, in MB. • **Time-range**—Time range for time range-based advertisement push.
Advertisement push url-group	Name of an advertisement group. The advertisements in the group are pushed to portal users.

display portal ad-push statistics

Use **display portal ad-push statistics** to display statistics about portal advertisement push.

Syntax

display portal ad-push statistics { **ad-url-group** | **url** }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ad-url-group: Displays statistics on an advertisement group basis.

url: Displays statistics on an advertisement URL basis.

Examples

Display URL-based statistics about portal advertisement push.

```
<Sysname> display portal ad-push statistics url
PV = Page View        IP = IP        UV = Unique Visitor
   URL                    PV    IP   UV
   www.sina.com.cn        10    5    5
   www.baidu.com.cn       1     1    1
```

Display advertisement group-based statistics about portal advertisement push.

```
<Sysname> display portal ad-push statistics ad-url-group
PV = Page View        IP = IP        UV = Unique Visitor
URL-group name: group1
   URL                    PV    IP    UV
   www.sina.com.cn        1     1     1
   www.dianying.com       2     1     1
URL-group name: group2
   URL                    PV    IP    UV
   www.sina.com.cn        1     1     1
   www.qq.com             2     1     1
```

Table 2 Command output

Field	Description
Url-group name	Name of an advertisement group.
URL	URL of an advertisement.
PV	Number of times that a portal user visits the advertisement page. This value increases by 1 each time the page is refreshed.
IP	Number of IP addresses from which portal users visit the advertisement page.

Field	Description
UV	Number of portal users with different usernames that visit the advertisement page.

reset portal ad-push statistic

display portal auth-error-record

Use **display portal auth-error-record** to display portal authentication error records.

Syntax

display portal auth-error-record { **all** | **ipv4** *ipv4-address* | **ipv6** *ipv6-address* | **start-time** *start-date start-time* **end-time** *end-date end-time* }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

all: Specifies all portal authentication error records.

ipv4 *ipv4-address*: Specifies the IPv4 address of a portal user.

ipv6 *ipv6-address*: Specifies the IPv6 address of a portal user.

start-time *start-date start-time* **end-time** *end-date end-time*: Specifies a time range. The start date and end date must be in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for MM is 1 to 12. The value range for DD varies with the specified month. The value range for YYYY is 1970 to 2037. The start time and end time must be in the format of hh:mm. The value range for the start time and end time is 00:00 to 23:59.

Examples

Display all portal authentication error records.

```
<Sysname> display portal auth-error-record all
Total authentication error records: 2
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 192.168.0.188
Auth error time        : 2016-03-04 16:49:07
Auth error reason      : The maximum number of users already reached.

User MAC               : 0016-ecb7-a235
Interface              : Vlan-interface100
User IP address        : 192.168.0.10
Auth error time        : 2016-03-04 16:51:07
```

```
Auth error reason      : The maximum number of users already reached.
```

Display portal authentication error records for the portal user whose IPv4 address is **192.168.0.188**.

```
<Sysname> display portal auth-error-record ip 192.168.0.188
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 192.168.0.188
Auth error time        : 2016-03-04 16:49:07
Auth error reason      : The maximum number of users already reached.
```

Display portal authentication error records for the portal user whose IPv6 address is **2000::2**.

```
<Sysname> display portal auth-error-record ipv6 2000::2
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 2000::2
Auth error time        : 2016-03-04 16:49:07
Auth error reason      : The maximum number of users already reached.
```

Display portal authentication error records with the error time in the range of 2016/3/4 14:20 to 2016/3/4 14:23.

```
<Sysname> display portal auth-error-record start-time 2016/3/4 14:20 end-time 2016/3/4
14:23
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 192.168.0.188
Auth error time        : 2016-03-04 14:22:25
Auth error reason      : The maximum number of users already reached.
```

Table 3 Command output

Field	Description
Total authentication error records	Total number of portal authentication error records.
User MAC	MAC address of the portal user.
Interface	Access interface of the portal user.
User IP address	IP address of the portal user.
Auth error time	Time when the portal user encountered an authentication error, in the format of YYYY-MM-DD hh:mm:ss.
Auth error reason	Reason for the authentication error: • The maximum number of users already reached. • Failed to obtain user physical information. • Failed to receive the packet because packet length is 0. • Packet source unknown. Server IP:X.X.X.X, VRF index:0. • Packet validity check failed because packet length and version don't match. • Packet type invalid. • Packet validity check failed due to invalid authenticator. • Memory insufficient. • Portal is disabled on the interface. • The maximum number of users on the interface already reached. • Failed to get the access token of the cloud user.

Field	Description
	• Failed to get the user information of the cloud user. • Failed to get the access token of the QQ user. • Failed to get the openID of the QQ user. • Failed to get the user information of the QQ user. • Email authentication failed.

Related commands

portal auth-error-record enable

context-admin

context-operator

Parameters

all: Specifies all portal authentication failure records.

ipv4 *ipv4-address*: Specifies the IPv4 address of a portal user.

ipv6 *ipv6-address*: Specifies the IPv6 address of a portal user.

start-time *start-date start-time* **end-time** *end-date end-time*: Specifies a time range. The start date and end date must be in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for MM is 1 to 12. The value range for DD varies with the specified month. The value range for YYYY is 1970 to 2037. The start time and end time must be in the format of hh:mm. The value range for the start time and end time is 00:00 to 23:59.

username *username*: Specifies the username of a portal user, a case-sensitive string of 1 to 253 characters. The username cannot contain the domain name.

Examples

Display all portal authentication failure records.

```
<Sysname> display portal auth-fail-record all
Total authentication fail records: 2
User name              : test@abc
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 192.168.0.188
```

```
Auth failure time      : 2016-03-04 16:49:07
Auth failure reason    : Authorization information does not exist.

User name              : coco
User MAC               : 0016-ecb7-a235
Interface              : Vlan-interface100
User IP address        : 192.168.0.10
Auth failure time      : 2016-03-04 16:50:07
Auth failure reason    : Authorization information does not exist.
```

Display portal authentication failure records for the portal user whose IPv4 address is **192.168.0.8**.

```
<Sysname> display portal auth-fail-record ip 192.168.0.188
User name              : test@abc
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 192.168.0.188
Auth failure time      : 2016-03-04 16:49:07
Auth failure reason    : Authorization information does not exist.
```

Display portal authentication failure records for the portal user whose IPv6 address is **2000::2**.

```
<Sysname> display portal auth-fail-record ipv6 2000::2
User name              : test@abc
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 2000::2
Auth failure time      : 2016-03-04 16:49:07
Auth failure reason    : Authorization information does not exist.
```

Display portal authentication failure records for the portal user whose username is **chap1**.

```
<Sysname> display portal auth-fail-record username chap1
User name              : chap1
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 192.168.0.188
Auth failure time      : 2016-03-04 16:49:07
Auth failure reason    : Authorization information does not exist.
```

Display portal authentication failure records with the failure time in the range of 2016/3/4 14:20 to 2016/3/4 14:23.

```
<Sysname> display portal auth-fail-record start-time 2016/3/4 14:20 end-time 2016/3/4
14:23
User name              : chap1
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 192.168.0.188
Auth failure time      : 2016-03-04 14:22:25
Auth failure reason    : Authorization information does not exist.
```

Table 4 Command output

Field	Description
Total authentication fail records	Total number of portal authentication failure records.

Field	Description
User name	Username of the portal user.
User MAC	MAC address of the portal user.
Interface	Access interface of the portal user.
User IP address	IP address of the portal user.
Auth failure time	Time when the portal user failed authentication, in the format of YYYY/MM/DD hh:mm:ss.
Auth failure reason	Reason why the user failed portal authentication.

display portal captive-bypass statistics

Use **display portal captive-bypass statistics** to display packet statistics for portal captive-bypass.

Syntax

display portal captive-bypass statistics [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays portal captive-bypass packet statistics on all member devices.

Examples

Display portal captive-bypass packets on the specified slot.

```
<Sysname> display portal captive-bypass statistics slot 1
Slot 1:
User type       Packets
iOS             1
Android         0
```

Table 5 Command output

Field	Description
User type	Type of users: • iOS.

Field	Description
	• Android.
Packets	Number of portal captive-bypass packets sent to the users.

Related commands

captive-bypass enable

display portal dns free-rule-host

Use **display portal dns free-rule-host** to display IP addresses corresponding to host names in destination-based portal-free rules.

Syntax

display portal dns free-rule-host [*host-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

host-name: Specifies a host by its name, a case-insensitive string of 1 to 253 characters. Valid characters are letters, digits, hyphens (-), underscores (_), dots (.), and wildcards (asterisks *). The host name cannot be **ip** or **ipv6**. If you do not specify a host name, this command displays IP addresses corresponding to all host names in destination-based portal-free rules.

Examples

Display IP addresses corresponding to host name **http://www.baidu.com/** in a destination-based portal-free rule.

```
<Sysname> display portal dns free-rule-host www.baidu.com
 Host name                      IP
 www.baidu.com                  10.10.10.10
```

Display IP addresses corresponding to host name ***abc.com** in a destination-based portal-free rule.

```
<Sysname> display portal dns free-rule-host *abc.com
 Host name                      IP
 *abc.com                       12.12.12.12
                                111.8.33.100
                                3.3.3.3
```

Table 6 Command output

Field	Description
Host name	Host name specified in a destination-based portal-free rule.
IP	IP address corresponding to the host name.

display portal dns redirect-rule-host

Use **display portal dns redirect-rule-host** to display IP addresses resolved by host names in destination-based portal redirection rules.

Syntax

display portal dns redirect-rule-host [*host-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

host-name: Specifies a host name, a case-insensitive string of 1 to 253 characters. Valid characters include letters, digits, hyphens (-), underscores (_), and dots (.). If you do not specify a host name, this command displays IP addresses resolved by all host names in all destination-based portal redirection rules.

Usage guidelines

For destination-based portal redirection rules that specify host names, the device will resolve the host names to IP addresses. Use this command to display IP addresses that are resolved by the host names in redirection rules.

The system can save a maximum of 16 resolved IPv4 addresses and 16 resolved IPv6 addresses. If the maximum number is reached, the new resolved IP address will override the oldest resolved IP address.

Examples

Display IP addresses resolved by host name **www.baidu.com** in a destination-based portal redirection rule.

```
<Sysname> display portal dns redirect-rule-host www.baidu.com
 Host name                      IP
 www.baidu.com                  10.10.10.10
```

Display IP addresses resolved by host name **www.abc.com** in a destination-based portal redirection rule.

```
<Sysname> display portal dns redirect-rule-host www.abc.com
 Host name                      IP
 www.abc.com                    12.12.12.12
                                111.8.33.100
                                3.3.3.3
```

Display IP addresses resolved by all host names in all destination-based portal redirection rules.

```
<Sysname> display portal dns redirect-rule-host
 Host name                      IP
www.baidu.com                   10.10.10.10
 www.abc.com                    12.12.12.12
                                111.8.33.100
                                3.3.3.3
```

Table 7 Command output

Field	Description
Host name	Host name in a destination-based portal redirection rule.
IP	IP address resolved by the host name.

display portal extend-auth-server

Use **display portal extend-auth-server** to display information about third-party authentication servers.

Syntax

display portal extend-auth-server { **all** | **facebook** | **mail** | **qq** | **wechat** }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

all: Specifies all third-party authentication servers.

facebook: Specifies the Facebook authentication server.

mail: Specifies the email authentication server.

qq: Specifies the QQ authentication server.

wechat: Specifies the WeChat authentication server.

Examples

Display information about all third-party authentication servers.

```
<Sysname> display portal extend-auth-server all
Portal extend-auth-server: qq
   Authentication URL : http://graph.qq.com
   APP ID             : 101235509
   APP key            : ******
   Redirect URL       : http://oauthindev.nsfocus.com.cn/portal/qqlogin.html
Portal extend-auth-server: mail
   Mail protocol      : POP3
   Mail domain name   : @qq.com
Portal extend-auth-server: wechat
  App ID              : wx23fb4aaf04b8491e
  App key             : ******
  App secret          : ******
```

```
  Subscribe-required : Enabled
  Shop ID            : 6747662
Portal extend-auth-server: facebook
   Authentication URL : https://graph.facebook.com
   APP ID             : 123456789
   APP key            : ******
   Redirect URL       : http://oauthindev.nsfocus.com.cn/portal/fblogin.html
```

Table 8 Command output

Field	Description
Portal extend-auth-server	Type of the third-party authentication server.
Authentication URL	URL of the third-party authentication server.
APP ID	App ID for the third-party authentication.
APP key	App key for the third-party authentication.
APP secret	App secret for WeChat authentication.
Subscribe-required	Status of the subscribe-required feature: • Enabled. • Disabled.
Redirect URL	URL to which portal users are redirected after they pass third-party authentication.
Mail protocol	Protocols of the email authentication service.
Mail domain name	Email domain name of the email authentication service.
Shop ID	ID of the shop where the device is deployed as a portal device for WeChat authentication.

Related commands

display portal local-binding mac-address

Use **display portal local-binding mac-address** to display information about local MAC-account binding entries on the local MAC binding server.

Syntax

display portal local-binding mac-address { *mac-address* | **all** }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

mac-address: Specifies the MAC address of a portal user, in the format H-H-H.

all: Specifies all local MAC-account binding entries.

Examples

Display information about all local MAC-account binding entries.

```
<Sysname> display portal local-binding mac-address all
Total MAC addresses: 5
MAC address               Username            Aging(hh:mm:ss)
0015-e9a6-7cfe            wlan_user1          00:41:38
0000-e27c-6e80            wlan_user2          00:41:38
000f-e212-ff01            wlan_user3          00:41:38
001c-f08f-f804            wlan_user4          00:41:38
000f-e233-9000            wlan_user5          00:41:38
```

Display information about the local MAC-account binding entry for the user with MAC address 0015-e9a6-7cfe.

```
<Sysname> display portal local-binding mac-address 0015-e9a6-7cfe
Total MAC addresses: 1
MAC address               Username            Aging(hh:mm:ss)
0015-e9a6-7cfe            wlan_user1          00:41:38
```

Table 9 Command output

Field	Description
MAC address	MAC address of a portal user.
Username	Username of a portal user.
Aging	Remaining lifetime of the local MAC-account binding entry.

display portal logout-record

Use **display portal logout-record** to display portal user offline records.

Syntax

display portal logout-record { **all** | **ipv4** *ipv4-address* | **ipv6** *ipv6-address* | **start-time** *start-date start-time* **end-time** *end-date end-time* | **username** *username* }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

all: Specifies all portal user offline records.

ipv4 *ipv4-address*: Specifies the IPv4 address of a portal user.

ipv6 *ipv6-address*: Specifies the IPv6 address of a portal user.

start-time *start-date start-time* **end-time** *end-date end-time*: Specifies a time range. The start date and end date must be in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for MM is 1 to 12. The value range for DD varies with the specified month. The value range for YYYY is 1970 to 2037. The start time and end time must be in the format of hh:mm. The value range for the start time and end time is 00:00 to 23:59.

username *username*: Specifies the username of a portal user, a case-sensitive string of 1 to 253 characters. The username cannot contain the domain name.

Examples

Display all portal user offline records.

```
<Sysname> display portal logout-record all
Total logout records: 2
User name              : test@abc
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 192.168.0.8
User login time        : 2016-03-04 14:20:19
User logout time       : 2016-03-04 14:22:05
Logout reason          : Admin Reset

User name              : coco
User MAC               : 0016-ecb7-a235
Interface              : Vlan-interface100
User IP address        : 192.168.0.10
User login time        : 2016-03-04 14:10:15
User offline time      : 2016-03-04 14:22:05
Offline reason         : Admin Reset
```

Display offline records for the portal user whose IP address is **192.168.0.8**.

```
<Sysname> display portal logout-record ip 192.168.0.8
User name              : test@abc
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 192.168.0.8
User login time        : 2016-03-04 14:26:12
User logout time       : 2016-03-04 14:27:35
Logout reason          : Admin Reset
```

Display offline records for the portal user whose username is **chap1**.

```
<Sysname> display portal logout-record username chap1
User name              : chap1
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 192.168.0.8
User login time        : 2016-03-04 17:20:19
User logout time       : 2016-03-04 17:22:05
Logout reason          : Admin Reset
```

Display portal user offline records with the logout time in the range of 2016/3/4 14:20 to 2016/3/4 14:23.

```
<Sysname> display portal logout-record start-time 2016/3/4 14:20 end-time 2016/3/4 14:23
User name              : test@abc
User MAC               : 0016-ecb7-a879
Interface              : Vlan-interface100
User IP address        : 192.168.0.8
User login time        : 2016-03-04 14:20:19
User logout time       : 2016-03-04 14:22:05
Logout reason          : Admin Reset
```

Table 10 Command output

Field	Description
Total logout records	Total number of portal user offline records.
User name	Username of the portal user.
User MAC	MAC address of the portal user.
Interface	Access interface of the portal user.
User IP address	IP address of the portal user.
User login time	Time when the portal user came online, in the format of YYYY-MM-DD hh:mm:ss.
User logout time	Time when the portal user went offline, in the format of YYYY-MM-DD hh:mm:ss.
Logout reason	Reason why the portal user went offline: • User Request. • Carrier Lost. • Service Lost. • Admin Reset. • NAS Request. • Idle Timeout. • Port Suspended. • Port Error. • Admin Reboot. • Session Timeout. • User Error. • Service Unavailable. • NAS Error. • Other Errors.

Related commands

portal logout-record enable

display portal mac-trigger user

Use **display portal mac-trigger user** to display information about MAC-trigger authentication users (portal users that perform MAC-trigger authentication).

Syntax

display portal mac-trigger user { **all** | **ip** *ipv4-address* | **mac** *mac-address* }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

all: Specifies all MAC-trigger authentication users.

ip *ipv4-address*: Specifies a MAC-trigger authentication user by its IP address.

mac *mac-address*: Specifies a MAC-trigger authentication user by its MAC address, in the format of H-H-H.

Examples

Display information about all MAC-trigger authentication users.

```
<Sysname> display portal mac-trigger user all
Total portal mac-trigger users: 8
MAC address      IP address     VLAN ID   Interface          Traffic(Bytes)  State
0050-ba50-732a   1.1.1.6        1         Vlan-interface1    0               NOBIND
0050-ba50-7328   1.1.1.4        1         Vlan-interface1    0               NOBIND
0050-ba50-7326   1.1.1.2        1         Vlan-interface1    0               NOBIND
0050-ba50-732c   1.1.1.8        1         Vlan-interface1    0               NOBIND
0050-ba50-7329   1.1.1.5        1         Vlan-interface1    0               NOBIND
```

Display information about the MAC-trigger authentication user whose MAC address is 0050-ba50-7777.

```
<Sysname> display portal mac-trigger user mac 0050-ba50-7777
MAC address      IP address     VLAN ID   Interface          Traffic(Bytes)  State
0050-ba50-777    1.1.5.83       1         Vlan-interface1    0               NOBIND
```

Display information about the MAC-trigger authentication user whose IP address is 1.1.2.126.

```
<Sysname> display portal mac-trigger user ip 1.1.2.126
MAC address      IP address     VLAN ID   Interface          Traffic(Bytes)  State
0050-ba50-74a2   1.1.2.126      1         Vlan-interface1    0               NOBIND
```

Table 11 Command output

Field	Description
MAC address	MAC address of the user.
IP address	IP address of the user.
VLAN ID	ID of the VLAN to which the user belongs.
Interface	Interface through which the user accesses the network.
Traffic(Bytes)	Traffic of the user, in bytes.
State	Status of the user: • **DEFAULT**—The user's traffic is below the free-traffic

Field	Description
	threshold and the user can access the network without authentication. • **WAIT**—The binding status between the user's MAC address and account is being queried. • **NOBIND**—The user's MAC address is not bound with the user's account. • **BIND**—The user's MAC address is bound with the user's account. • **DISABLE**—The MAC-trigger entry for the user is deleted on the device.

Table 12 Command output

Field	Description
Portal mac trigger server name	Name of the MAC binding server.
Version	Version of the portal protocol: • **1.0**—Version 1. • **2.0**—Version 2. • **3.0**—Version 3.
Server type	Type of the MAC binding server: • **CMCC**—CMCC server. • **IMC**—IMC server.
IP	IP address of the MAC binding server.
Port	UDP port number on which the MAC binding server listens for MAC binding query packets.
VPN instance	MPLS L3VPN where the MAC binding server resides.
Aging time	Aging time in seconds. A MAC-trigger entry is aged out when the aging time expires.
Free-traffic threshold	Free-traffic threshold in bytes. If a user's traffic is below the threshold, the user can access the network without authentication.
NAS-Port-Type	NAS-Port-Type attribute value in RADIUS request packets sent to the RADIUS server.
Binding retry times	Maximum number of attempts for sending MAC binding queries to the MAC binding server.
Binding retry interval	Interval at which the device sends MAC binding queries to the MAC binding server.
Authentication timeout	Maximum amount of time that the device waits for portal authentication to complete after receiving the MAC binding query response.
Excluded attribute list	Numbers of attributes excluded from portal protocol packets.
Local-binding	Status of local MAC-trigger authentication: • Disabled. • Enabled.
Local-binding aging-time	Aging time for local MAC-account binding entries, in minutes.
Cloud-binding	Status of cloud MAC-trigger authentication: • Disabled. • Enabled.
Cloud server URL	URL of the cloud portal authentication server.
aaa-fail nobinding	Status of the AAA failure unbinding feature: • Disabled. • Enabled.

display portal packet statistics

Use **`display portal packet statistics`** to display packet statistics for portal authentication servers and MAC binding servers.

Syntax

display portal packet statistics [**extend-auth-server** { **cloud** | **facebook** | **mail** | **qq** | **wechat** } | **mac-trigger-server** *server-name* | **server** *server-name*] *

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

extend-auth-server: Specifies a third-party authentication server.

cloud: Specifies the cloud authentication server.

facebook: Specifies the Facebook authentication server.

mail: Specifies the email authentication server.

qq: Specifies the QQ authentication server.

wechat: Specifies the WeChat authentication server.

mac-trigger-server *server-name*: Specifies a MAC binding server by its name, a case-sensitive string of 1 to 32 characters.

server *server-name*: Specifies a portal authentication server by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

If you do not specify any parameters, this command displays packet statistics for all third-party authentication servers, portal authentication servers, and MAC binding servers.

Examples

Display packet statistics for portal authentication server **pts**.

```
<Sysname> display portal packet statistics server pts
 Portal server :  pts
 Invalid packets: 0
 Pkt-Type                          Total    Drops    Errors
 REQ_CHALLENGE                     3        0        0
 ACK_CHALLENGE                     3        0        0
 REQ_AUTH                          3        0        0
 ACK_AUTH                          3        0        0
 REQ_LOGOUT                        1        0        0
 ACK_LOGOUT                        1        0        0
 AFF_ACK_AUTH                      3        0        0
 NTF_LOGOUT                        1        0        0
 REQ_INFO                          6        0        0
 ACK_INFO                          6        0        0
 NTF_USERDISCOVER                  0        0        0
 NTF_USERIPCHANGE                  0        0        0
```

```
 AFF_NTF_USERIPCHAN                  0        0        0
 ACK_NTF_LOGOUT                      1        0        0

Table 13 Command output

Field	Description
Portal server	Name of the portal authentication server.
Invalid packets	Number of invalid packets.
Pkt-Type	Packet type.
Total	Total number of packets.
Drops	Number of dropped packets.
Errors	Number of packets that carry error information.
REQ_CHALLENGE	Challenge request packet the portal authentication server sent to the

Field	Description
	access device.
ACK_CHALLENGE	Challenge acknowledgment packet the access device sent to the portal authentication server.
REQ_AUTH	Authentication request packet the portal authentication server sent to the access device.
ACK_AUTH	Authentication acknowledgment packet the access device sent to the portal authentication server.
REQ_LOGOUT	Logout request packet the portal authentication server sent to the access device.
ACK_LOGOUT	Logout acknowledgment packet the access device sent to the portal authentication server.
AFF_ACK_AUTH	Affirmation packet the portal authentication server sent to the access device after receiving an authentication acknowledgment packet.
NTF_LOGOUT	Forced logout notification packet the access device sent to the portal authentication server.
REQ_INFO	Information request packet.
ACK_INFO	Information acknowledgment packet.
NTF_USERDISCOVER	User discovery notification packet the portal authentication server sent to the access device.
NTF_USERIPCHANGE	User IP change notification packet the access device sent to the portal authentication server.
AFF_NTF_USERIPCHAN	User IP change success notification packet the portal authentication server sent to the access device.
ACK_NTF_LOGOUT	Forced logout acknowledgment packet the portal authentication server sent to the access device.
NTF_HEARTBEAT	Server heartbeat packet the portal authentication server periodically sent to the access device.
NTF_USER_HEARTBEAT	User synchronization packet the portal authentication server sent to the access device.
ACK_NTF_USER_HEARTBEAT	User synchronization acknowledgment packet the access device sent to the portal authentication server.
NTF_CHALLENGE	Challenge request packet the access device sent to the portal authentication server.
NTF_USER_NOTIFY	User information notification packet the access device sent to the portal authentication server.
AFF_NTF_USER_NOTIFY	NTF_USER_NOTIFY acknowledgment packet the portal authentication server sent to the access device.
MAC-trigger server	Name of the MAC binding server.
REQ MACBIND	MAC binding request packet the access device sent to the MAC binding server.
ACK_MACBIND	MAC binding acknowledgment packet the MAC binding server sent to the access device.
NTF_MTUSER_LOGON	User logon notification packet the access device sent to the MAC binding server.
NTF_MTUSER_LOGOUT	User logout notification packet the access device sent to the MAC

Field	Description
	binding server.
REQ_MTUSER_OFFLINE	Forced offline request packet the MAC binding server sent to the access device.
Extend-auth server	Type of the third-party authentication server: • **qq**—QQ authentication server. • **mail**—Email authentication server. • **wechat**—WeChat authentication server. • **cloud**—Cloud authentication server. • **facebook**—Facebook authentication server.
Update interval	Interval at which the device sends online user information to the Oasis cloud server, in seconds. This field is displayed only if the third-party authentication server is the Oasis cloud authentication server.
Success	Number of packets that have been successfully sent or received.
Timeout	Number of packets that timed out of establishing a connection to the third-party authentication server.
Conn-failure	Number of packets that failed to establish a connection to the third-party authentication server.
Deny	Number of packets denied access to the third-party authentication server. This field is displayed only if the third-party authentication server is the email authentication server.
REQ_ACCESSTOKEN	Access token request packet the access device sent to the third-party authentication server. This field is displayed only if the third-party authentication server is QQ, Facebook, Oasis cloud, or WeChat authentication server.
REQ_OPENID	Open ID request packet the access device sent to the third-party authentication server. This field is displayed only if the third-party authentication server is the QQ authentication server.
REQ_USERINFO	User information request packet the access device sent to the third-party authentication server. This field is displayed only if the third-party authentication server is the QQ, Facebook, Oasis cloud, or WeChat authentication server.
RESP_ACCESSTOKEN	Access token response packet the access device received from the third-party authentication server. This field is displayed only if the third-party authentication server is the QQ, Facebook, Oasis cloud, or WeChat authentication server.
RESP_OPNEID	Open ID response packet the access device received from the third-party authentication server. This field is displayed only if the third-party authentication server is the QQ authentication server.
RESP_USERINFO	User information response packet the access device received from the third-party authentication server. This field is displayed only if the third-party authentication server is the QQ, Facebook, Oasis cloud, or WeChat authentication server.
REQ_POP3	POP3 authentication request packet the access device sent to the third-party authentication server.

Field	Description
	This field is displayed only if the third-party authentication server is the email authentication server.
REQ_IMAP	IMAP authentication request packet the access device sent to the third-party authentication server. This field is displayed only if the third-party authentication server is the email authentication server.
POST_ONLINEDATA	Cloud user information request packet the access device sent to the third-party authentication server. This field is displayed only if the third-party authentication server is the Oasis cloud authentication server.
RESP_ONLINEDATA	Cloud user information response packet the access device received from the third-party authentication server. This field is displayed only if the third-party authentication server is the Oasis cloud authentication server.
POST_OFFLINEUSER	Cloud user offline packet the access device sent to the third-party authentication server. This field is displayed only if the third-party authentication server is the Oasis cloud or WeChat authentication server.
REPORT_ONLINEUSER	Cloud user online packet the access device sent to the third-party authentication server. This field is displayed only if the third-party authentication server is Oasis cloud or WeChat authentication server.
REQ_CLOUDBIND	Cloud user binding status query request that the access device sent to the third-party authentication server. This field is displayed only if the third-party authentication server is Oasis cloud authentication server.
RESP_CLOUDBIND	Cloud user binding status query response that the access device received from the third-party authentication server. This field is displayed only if the third-party authentication server is Oasis cloud authentication server.
REQ_BINDUSERINFO	Cloud user information request packet that the access device sent to the third-party authentication server. This field is displayed only if the third-party authentication server is the Oasis cloud authentication server.
RESP_BINDUSERINFO	Cloud user information response packet that the access device received from the third-party authentication server. This field is displayed only if the third-party authentication server is the Oasis cloud authentication server.
AUTHENTICATION	Result of third-party authentication.

Related commands

`reset portal packet statistics`

display portal permit-rule statistics

Use **`display portal permit-rule statistics`** to display statistics for portal permit rules.

Syntax

`display portal permit-rule statistics`

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Usage guidelines

Portal permit rules refer to category-1 and category-2 portal filtering rules, which permit user packets to pass.

Examples

Display statistics for portal permit rules.

```
<Sysname> display portal permit-rule statistics
Interface            Free rules          Fuzzy rules           User rules
Vlan-interface30     2                   5                     10
Vlan-interface30     2                   3                     6
```

Table 14 Command output

Field	Description
Interface	Interface on which portal permit rules are used.
Free rules	Number of permit rules generated based on configured portal-free rules, excluding permit rules generated based on fuzzy matches of destination-based portal-free rules.
Fuzzy rules	Number of permit rules generated based on fuzzy matches of destination-based portal-free rules.
User rules	Number of permit rules generated after portal users pass authentication.

display portal redirect session

Use **display portal redirect session** to display redirect session statistics for online portal users.

Syntax

display portal redirect session [**ip** *ipv4-address* | **ipv6** *ipv6-address*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ip *ipv4-address*: Specifies a portal user by its IPv4 address.

ipv6 *ipv6-address*: Specifies a portal user by its IPv6 address.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays redirect session statistics for online portal users on all member devices.

Usage guidelines

If you do not specify a user IPv4 or IPv6 address, this command displays redirect session statistics for all online portal users.

Examples

Display redirect session statistics for all online portal users on the specified slot.

```
<Sysname> display portal redirect session slot 0
Total HTTP sessions: 40
Total HTTP rejected: 2542
Total HTTPS sessions: 40
Total HTTPS rejected: 0
IP: 192.168.0.1
  HTTP sessions: 20
  HTTP rejected: 10
  HTTPS sessions: 20
  HTTPS rejected: 40
IP: 192.168.0.2
  HTTP sessions: 20
  HTTP rejected: 8
  HTTPS sessions: 20
  HTTPS rejected: 40
```

Display redirect session statistics for online portal user at 192.168.0.2 on the specified slot.

```
<Sysname> display portal redirect session ip 192.168.0.2 slot 0
IP: 192.168.0.2
  HTTP sessions: 128
  HTTP rejected: 10
  HTTPS sessions: 0
  HTTPS rejected: 0
```

Table 15 Command output

Field	Description
Total HTTP sessions	Total number of HTTP redirect sessions.
Total HTTP rejected	Total number of discarded HTTP redirect session requests.
Total HTTPS sessions	Total number of HTTPS redirect sessions.
Total HTTPS rejected	Total number of discarded HTTPS redirect session requests.
IP	IP address of the online portal user.
HTTP sessions	Number of HTTP redirect sessions for the user.
HTTP rejected	Number of discarded HTTP redirect requests for the user.
HTTPS sessions	Number of HTTPS redirect sessions for the user.

Field	Description
HTTPS rejected	Number of discarded HTTPS redirect requests for the user.

Related commands

portal redirect max-session

portal redirect max-session per-user

display portal redirect session-record

Use **display portal redirect session-record** to display history records about portal redirect sessions.

Syntax

display portal redirect session-record [**start-time** *start-date start-time*] [**end-time** *end-date end-time*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

start-time *start-date start-time*: Specifies the start time of a time range. The start date must be in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for MM is 1 to 12. The value range for DD varies with the specified month. The value range for YYYY is 1970 to 2037. The start time must be in the format of hh:mm. The value range for the start time is 00:00 to 23:59. If you do not specify a start time, the time range starts when portal authentication was enabled.

end-time *end-date end-time*: Specifies the end time of a time range. The end date must be in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for MM is 1 to 12. The value range for DD varies with the specified month. The value range for YYYY is 1970 to 2037. The end time must be in the format of hh:mm. The value range for the end time is 00:00 to 23:59. If you do not specify an end time, the time range ends with the current time.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays history records about portal redirect sessions on all member devices.

Usage guidelines

The device records statistics about portal redirect sessions on a per minute basis since portal authentication is enabled. The device only keeps records generated within the most recent 24 hours. Twenty-four hours later, a new record will override the oldest record.

Examples

Display history records about portal redirect sessions in the time range from 2019/3/20 14:40 to now.

```
<Sysname> display portal redirect session-record start-time 2019/3/20 14:40 slot 0

Time              HTTP sessions  HTTP rejected  HTTPS sessions  HTTPS rejected
```

```
2019/03/20 14:40   1             0             21            1
2019/03/20 14:41   2             0             21            1
2019/03/20 14:42   13            1             31            1

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays summary statistics about portal redirect sessions on all member devices.

Examples

Display summary statistics about portal redirect sessions on the specified slot.

```
<Sysname> display portal redirect session-statistics slot 0
  HTTP sessions  HTTP rejected  HTTPS sessions  HTTPS rejected
  30             2              73              3
```

Table 17 Command output

Field	Description
HTTP sessions	Number of HTTP redirect sessions for all portal users.
HTTP rejected	Number of rejected HTTP redirect session requests for all portal users.

HTTPS sessions	Number of HTTPS redirect sessions for all portal users.
HTTPS rejected	Number of rejected HTTPS redirect session requests for all portal users.

display portal rule

Use **display portal rule** to display portal filtering rules.

Syntax

display portal rule { **all** | **dynamic** | **static** } **interface** *interface-type interface-number* [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

all: Displays all portal filtering rules, including dynamic and static portal filtering rules.

dynamic: Displays dynamic portal filtering rules, which are generated after users pass portal authentication. These rules allow packets with specific source IP addresses to pass the interface.

static: Displays static portal filtering rules, which are generated after portal authentication is enabled. The interface filters packets by these rules when portal authentication is enabled.

interface *interface-type interface-number*: Specifies an interface by its type and number.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays portal filtering rules on all member devices.

Examples

Table 19 Command output

Field	Description
Rule	Number of the portal rule. IPv4 portal filtering rules and IPv6 portal filtering rules are numbered separately.
Type	Type of the portal filtering rule: • **Static**—Static portal rule. • **Dynamic**—Dynamic portal rule.
Action	Action triggered by the portal filtering rule: • **Permit**—The interface allows packets to pass. • **Forbid**—The interface forbids packets to pass. • **Redirect**—The interface redirects packets. • **Deny**—The interface denies packets. • **Match pre-auth ACL**—The interface matches packets against the authorized ACL rules in the preauthentication domain.
Protocol	Transport layer protocol permitted by the portal filtering rule: • **Any**—Permits any transport layer protocol. • **TCP**—Permits TCP. • **UDP**—Permits UDP.
Status	Status of the portal filtering rule: • **Active**—The portal rule is effective. • **Unactuated**—The portal rule is not activated.
Source	Source information of the portal filtering rule.

Field	Description
IP	Source IPv4 or IPv6 address. If the IPv6 address of a portal user changes after the user has come online, this field displays colons (**::**). This value indicates that no IP address is specified in the portal filtering rule.
Mask	Subnet mask of the source IPv4 address.
Prefix length	Prefix length of the source IPv6 address.
Port	Source transport layer port number.
MAC	Source MAC address.
Interface	Layer 2 or Layer 3 interface on which the portal rule is implemented.
VLAN	Source VLAN ID.
Protocol	Transport layer protocol of the portal redirect rule. This field always displays **TCP**.
Destination	Destination information of the portal filtering rule.
IP	Destination IP address.
Port	Destination transport layer port number.
Mask	Subnet mask of the destination IPv4 address.
Prefix length	Prefix length of the destination IPv6 address.
Author ACL	Authorized ACL assigned to authenticated portal users. This field is displayed only for a dynamic portal filtering rule.
Pre-auth ACL	Authorized ACL assigned to preauthentication portal users. This field is displayed only for the **Match pre-auth ACL** action.
Number	Number of the authorized ACL. This field displays **N/A** if the AAA server does not assign an ACL.

display portal safe-redirect statistics

Use **display portal safe-redirect statistics** to display portal safe-redirect packet statistics.

Syntax

display portal safe-redirect statistics [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays statistics on all member devices.

Examples

Display portal safe-redirect packet statistics on the specified slot.

```
<Sysname> display portal safe-redirect statistics slot 1
Slot 1:
Redirect statistics:
  Success: 7
  Failure: 8
  Total  : 15

Method statistics:
  Get    : 11
  Post   : 1
  Others : 3

Default-action statistics:
  Permit: 1
  Forbid: 0

User agent statistics:
  Safari: 3
  Chrome: 2

Forbidden User URL statistics:
  www.qq.com: 4

Forbidden filename extension statistics:
  .jpg: 0
```

Table 20 Command output

Field	Description
Success	Number of packets redirected successfully.
Failure	Number of packets failed redirection.
Total	Total number of packets.
Method statistics	Statistics of HTTP request methods.
Get	Number of packets with the **GET** request method.
Post	Number of packets with the **POST** request method.
Other	Number of packets with other request methods.
User agent statistics	Browser types (in HTTP User Agent) allowed by portal safe-redirect, and packet statistics for the browsers.
Forbidden URL statistics	URLs forbidden by portal safe-redirect, and statistics for packets dropped by forbidden URL filtering.
Forbidden filename extension statistics	Filename extension forbidden by portal safe-redirect, and statistics for packets dropped by forbidden filename extension filtering.
Permit user URL statistics	URLs permitted by portal safe-redirect, and packet statistics for the URLs.
Default-action statistics	Statistics on packets processed by the default actions of portal

Field	Description
	safe-redirect.

Related commands

reset portal safe-redirect statistics

display portal server

Use **display portal server** to display information about portal authentication servers.

Syntax

display portal server [*server-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

server-name: Specifies a portal authentication server by its name, a case-sensitive string of 1 to 32 characters. If you do not specify the *server-name* argument, this command displays information about all portal authentication servers.

Examples

Display information about portal authentication server **pts**.

```
<Sysname> display portal server pts
Portal server: pts
  Type                  : IMC
  IP                    : 192.168.0.111
  VPN instance          : Not configured
  Port                  : 50100
  Server detection      : Timeout 60s  Action: log, trap
  User synchronization  : Timeout 200s
  Status                : Up
  Exclude-attribute     : Not configured
  Logout notification   : Retry 3 interval 5s
```

Table 21 Command output

Field	Description
Type	Portal authentication server type: • **CMCC**—CMCC server. • **IMC**—IMC server.
Portal server	Name of the portal authentication server.
IP	IP address of the portal authentication server.

Field	Description
VPN instance	MPLS L3VPN where the portal authentication server resides.
Port	Listening port on the portal authentication server.
Server detection	Parameters for portal authentication server detection: • Detection timeout in seconds. • Actions (**log** and **trap**) triggered by the reachability status change of the portal authentication server.
User synchronization	User idle timeout in seconds for portal user synchronization.

Status	Reachability status of the portal authentication server:
	• **Up**—This value indicates one of the following conditions:
	  ◦ Portal authentication server detection is disabled.
	  ◦ Portal authentication server detection is enabled and the server is reachable.
	• **Down**—Portal authentication server detection is enabled and the server is unreachable.

Exclude-attribute	Attributes that are not carried in portal protocol packets sent to the portal authentication server.
Logout notification	Maximum number of times and the interval (in seconds) for retransmitting a logout notification packet.

display portal user

Use **`display portal user`** to display information about portal users.

Syntax

`display portal user` { **`all`** | **`auth-type`** { **`cloud`** | **`email`** | **`facebook`** | **`local`** | **`mac-trigger`** | **`normal`** | **`qq`** | **`wechat`** } | **`interface`** *`interface-type interface-number`* | **`ip`** *`ipv4-address`* | **`ipv6`** *`ipv6-address`* | **`mac`** *`mac-address`* | **`pre-auth`** [**`interface`** *`interface-type interface-number`* | **`ip`** *`ipv4-address`* | **`ipv6`** *`ipv6-address`*] | **`username`** *`username`* } [**`brief`** | **`verbose`**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`all`: Displays information about all portal users.

auth-type: Specifies an authentication type.

cloud: Specifies the cloud authentication (a cloud portal authentication server performs portal authentication on portal users).

email: Specifies the email authentication.

facebook: Specifies the Facebook authentication.

local: Specifies the local authentication (a local portal authentication server performs portal authentication on portal users).

mac-trigger: Specifies the MAC-trigger authentication.

normal: Specifies the normal authentication (a remote portal authentication server performs portal authentication on portal users).

qq: Specifies QQ authentication.

wechat: Specifies WeChat authentication.

interface *interface-type interface-number*: Displays information about portal users on the specified interface.

ip *ipv4-address*: Specifies the IPv4 address of a portal user.

ipv6 *ipv6-address*: Specifies the IPv6 address of a portal user.

mac *mac-address*: Specifies the MAC address of a portal user, in the format of H-H-H.

username *username*: Specifies the username of a portal user, a case-sensitive string of 1 to 253 characters. The username cannot contain the domain name.

pre-auth: Displays information about preauthentication portal users. A preauthentication user is a user who is authorized with the authorization attributes in a preauthentication domain before portal authentication. If you do not specify the **pre-auth** keyword, this command displays information about authenticated portal users.

brief: Displays brief information about portal users.

verbose: Displays detailed information about portal users.

Usage guidelines

If you specify neither the **brief** nor the **verbose** keyword, this command displays portal authentication-related information for portal users.

Examples

Display information about all portal users.

```
<Sysname> display portal user all
Total portal users: 2
Username: abc
  Portal server: pts
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  000d-88f8-0eab    2.2.2.2           --     GigabitEthernet1/0/1
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number/name: N/A
    Inbound CAR: N/A
```

```
    Outbound CAR: N/A

Username: def
  Portal server: pts
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  000d-88f8-0eac    3.3.3.3           --     GigabitEthernet1/0/2
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number/name: 3000
    Inbound CAR: CIR 9000       bps PIR 20500      bps
                 CBS 20500      bit (active)
    Outbound CAR: CIR 9000       bps PIR 20400      bps
                  CBS 20400      bit (active)
```

Display information about portal users whose authentication type is normal portal authentication.

```
<Sysname> display portal user auth-type normal
Total normal users: 1
Username: abc
  Portal server: pts
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  000d-88f8-0eab    2.2.2.2           --     GigabitEthernet1/0/1
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number/name: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
```

Display information about the portal user whose MAC address is **000d-88f8-0eab**.

```
<Sysname> display portal user mac 000d-88f8-0eab
Username: abc
  Portal server: pts
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  000d-88f8-0eab    2.2.2.2           --     GigabitEthernet1/0/1
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number/name: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
```

Display information about the portal user whose username is **abc**.

```
<Sysname> display portal user username abc
Username: abc
  Portal server: pts
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  000d-88f8-0eab    2.2.2.2           --     GigabitEthernet1/0/1
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number/name: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
```

Table 22 Command output

Field	Description
Total portal users	Total number of portal users.
Total normal users	Total number of portal users whose authentication type is normal authentication.
Total local users	Total number of portal users whose authentication type is local authentication.
Total email users	Total number of portal users whose authentication type is email authentication.
Total cloud users	Total number of portal users whose authentication type is cloud authentication.
Total QQ users	Total number of portal users whose authentication type is QQ authentication.
Total WeChat users	Total number of portal users whose authentication type is WeChat authentication.
Total facebook users	Total number of portal users whose authentication type is Facebook authentication.
Total MAC-trigger users	Total number of portal users whose authentication type is MAC-trigger authentication.
Username	Name of the user.
Portal server	Name of the portal authentication server.
State	Current state of the portal user: • **Initialized**—The user is initialized and ready for authentication. • **Authenticating**—The user is being authenticated. • **Waiting SetRule**—Deploying portal rules to the user. • **Authorizing**—The user is being authorized. • **Online**—The user is online. • **Waiting Traffic**—Waiting for traffic from the user. • **Stop Accounting**—Stopping accounting for the user. • **Done**—The user is offline.
VPN instance	Name of the authorization VPN instance. If no VPN instance is authorized for the portal user, this field displays the MPLS L3VPN that the portal user belongs to. If the portal user is on a public network, this field displays **N/A**.

Field	Description
MAC	MAC address of the portal user.
IP	IP address of the portal user.
VLAN	VLAN where the portal user resides.
Interface	Access interface of the portal user.
Authorization information	Authorization information for the portal user.
DHCP IP pool	Name of the authorized IP address pool. If no IP address pool is authorized for the portal user, this field displays **N/A**.
User profile	This field is not supported in the current software version. Authorized user profile: • **N/A**—The AAA server authorizes no user profile. • **active**—The AAA server has authorized the user profile successfully. • **inactive**—The AAA server failed to authorize the user profile or the user profile does not exist on the device.
Session group profile	This field is not supported in the current software version. Authorized session group profile: • **N/A**—The AAA server authorizes no session group profile. • **active**—The AAA server has authorized the session group profile successfully. • **inactive**—The AAA server failed to authorize the session group profile or the session group profile does not exist on the device.
ACL number/name	Number or name of the authorized ACL: • **N/A**—The AAA server authorizes no ACL. • **active**—The AAA server has authorized the ACL successfully. • **inactive**—The AAA server failed to authorize the ACL or the ACL does not exist on the device.
Inbound CAR	Authorized inbound CAR information: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps. • **CBS**—Committed burst size in bits. • **active**—The AAA server has authorized the inbound CAR successfully. • **inactive**—The AAA server failed to authorize the inbound CAR. If no inbound CAR is authorized, this field displays **N/A**.
Outbound CAR	Authorized outbound CAR information: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps. • **CBS**—Committed burst size in bits. • **active**—The AAA server has authorized the outbound CAR successfully. • **inactive**—The AAA server failed to authorize the outbound CAR. If no outbound CAR is authorized, this field displays **N/A**.

Display detailed information about the portal user with IP address 50.50.50.3.

```
<Sysname> display portal user ip 50.50.50.3 verbose
Basic:
  Current IP address: 50.50.50.3
  Original IP address: 30.30.30.2
```

```
  Username: user1@hrss
  User ID: 0x18000002
  Access interface: GE1/0/2
  Service-VLAN/Customer-VLAN: -/-
  MAC address: 0000-0000-0001
  Authentication type: Normal
  Domain: hrss
  VPN instance: 123
  Status: Online

            Uplink   packets/bytes: 3/200
            Downlink packets/bytes: 0/0
  IPv6 address: 2001::2
            Uplink   packets/bytes: 4/346
```

```
            Downlink packets/bytes: 0/0
```

Table 23 Command output

Field	Description
Current IP address	IP address of the portal user after passing authentication.
Original IP address	IP address of the portal user during authentication.
Username	Name of the portal user.
User ID	Portal user ID.
Access interface	Access interface of the portal user.
Service-VLAN/Customer-VLAN	Public VLAN/Private VLAN to which the portal user belongs. If no VLAN is configured for the portal user, this field displays **-/-**.
MAC address	MAC address of the portal user.
Authentication type	Type of portal authentication: • **Normal**—Normal authentication. • **Local**—Local authentication. • **Email**—Email authentication. • **Cloud**—Cloud authentication. • **QQ**—QQ authentication. • **WeChat**—WeChat authentication. • **Facebook**—Facebook authentication. • **MAC-trigger**—MAC-trigger authentication.
Domain	ISP domain name for portal authentication.
VPN instance	Name of the authorized VPN instance. If no VPN instance is authorized, this field displays the MPLS L3VPN to which the portal user belongs. If the portal user is on a public network, this field displays **N/A**.
Status	Status of the portal user: • **Authenticating**—The user is being authenticated. • **Authorizing**—The user is being authorized. • **Waiting SetRule**—Deploying portal rules to the user. • **Online**—The user is online. • **Waiting Traffic**—Waiting for traffic from the user. • **Stop Accounting**—Stopping accounting for the user. • **Done**—The user is offline.
Portal server	Name of the portal server.
Vendor	Vendor name of the endpoint.
Portal authentication method	Portal authentication method on the access interface: • **Direct**—Direct authentication. • **Re-Dhcp**—Re-DHCP authentication. • **Layer3**—Cross-subnet authentication.
AAA	AAA information about the portal user.
Realtime accounting interval	Interval for sending real-time accounting updates, and the maximum number of accounting attempts. If the real-time accounting is not authorized, this field displays **N/A**.
Idle-cut	Idle timeout period and the minimum traffic threshold. If idle-cut is not authorized, this field displays **N/A**.
Session duration	Session duration and the remaining session time. If the session duration is

Field	Description
	not authorized, this field displays **N/A**.
Remaining traffic	Remaining traffic for the portal user. If the remaining traffic is not authorized, this field displays **N/A**.
Login time	Time when the user logged in. The field uses the device time format, for example, 2023-1-19 2:42:30 UTC.
ITA policy name	Name of the intelligent target accounting policy.
DHCP IP pool	Authorized DHCP IP address pool. If no DHCP IP address pool is authorized for the portal user, this field displays **N/A**.
Inbound CAR	Authorized inbound CAR information: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps. • **CBS**—Committed burst size in bits. • **active**—The AAA server has authorized the inbound CAR successfully. • **inactive**—The AAA server failed to authorize the inbound CAR. If no inbound CAR is authorized, this field displays **N/A**.
Outbound CAR	Authorized outbound CAR information: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps. • **CBS**—Committed burst size in bits. • **active**—The AAA server has authorized the outbound CAR successfully. • **inactive**—The AAA server failed to authorize the outbound CAR. If no outbound CAR is authorized, this field displays **N/A**.
ACL number/name	Number or name of the authorized ACL: • **N/A**—The AAA server authorizes no ACL. • **active**—The AAA server has authorized the ACL successfully. • **inactive**—The AAA server failed to authorize the ACL or the ACL does not exist on the device.
User profile	This field is not supported in the current software version. Authorized user profile: • **N/A**—The AAA server authorizes no user profile. • **active**—The AAA server has authorized the user profile successfully. • **inactive**—The AAA server failed to authorize the user profile or the user profile does not exist on the device.
Session group profile	This field is not supported in the current software version. Authorized session group profile: • **N/A**—The AAA server authorizes no session group profile. • **active**—The AAA server has authorized the session group profile successfully. • **inactive**—The AAA server failed to authorize the session group profile or the session group profile does not exist on the device.
Max multicast addresses	Maximum number of multicast groups the portal user can join.
NAT444	NAT444 mapping information for the portal user. This field is displayed only when portal is used in conjunction with NAT444.
Global IP address	Public IP address.
Port block	Port block: start port-end port.

Field	Description
Multicast address list	Multicast group list the portal user can join. If no multicast group is authorized, this field displays **N/A**.
Traffic statistic	Traffic statistics for the portal user.
Uplink packets/bytes	Packet and byte statistics of the upstream traffic.
Downlink packets/bytes	Packet and byte statistics of the downstream traffic.
ITA	ITA statistics for the portal user.
level-*n* uplink packets/bytes	Packet and byte statistics of the upstream traffic in accounting level n. Number *n* is in the range of 1 to 8.
level-*n* downlink packets/bytes	Packet and byte statistics of the downstream traffic in accounting level n. Number *n* is in the range of 1 to 8.
Dual-stack traffic statistic	IPv4 and IPv6 traffic statistics for the dual-stack user.
IPv4 address	IPv4 address of the portal user.
IPv6 address	IPv6 address of the portal user.
Uplink packets/bytes	Packet and byte statistics of the upstream traffic.
Downlink packets/bytes	Packet and byte statistics of the downstream traffic.

Display brief information about all portal users.

```
<Sysname> display portal user all brief
IP address       MAC address       Online duration       Username
2.2.2.2          000d-88f8-0eab    1:53:7                abc
3.3.3.3          000d-88f8-0eac    1:53:7                def
```

Table 24 Command output

Field	Description
IP address	IP address of the portal user.
MAC address	MAC address of the portal user.
Online duration	Online duration of the portal user, in hh:ss:mm.
Username	Username of the portal user.

Related commands

portal enable

display portal user-block

Use **display portal user-block** to display information about portal users blocked for portal authentication failure.

Syntax

display portal user-block [**ip** *ipv4-address* | **ipv6** *ipv6-address* | **mac** *mac-address* | **username** *username*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ip *ipv4-address*: Specifies a blocked portal user by its IPv4 address.

ipv6 *ipv6-address*: Specifies a blocked portal user by its IPv6 address.

mac *mac-address*: Specifies a blocked portal user by its MAC address in the format of H-H-H.

username *username*: Specifies a blocked portal user by its username, a case-insensitive string of 1 to 253 characters.

Usage guidelines

If you do not specify any parameters, this command displays information about all blocked portal users.

Examples

Display information about all blocked portal users.

```
<Sysname> display portal user-block
Total blocked users: 2

IP address: 10.2.33.2
MAC address: E0A5-66BB-B2AA
Remaining block time: 01h:38m:44s
Username: test

IP address: 19.19.0.4
MAC address: B577-CDCB-D49C
Remaining block time: 01h:26m:44s
Username: school
```

Display information about the blocked portal user at IPv4 address 10.2.33.2.

```
<Sysname> display portal user-block ip 10.2.33.2
IP address: 10.2.33.2
MAC address: E0A5-66BB-B2AA
Remaining block time: 01h:38m:44s
Username: test
```

Display information about the blocked portal user at IPv6 address 20::0:2.

```
<Sysname> display portal user-block ipv6 20::0:2
IP address: 20::0:2
MAC address: E0A5-66BB-B2AA
Remaining blocking time: 01h:38m:44s
Username: test
```

Display information about the blocked portal user at MAC address E0-A5-66-BH.

```
<Sysname> display portal user-block mac E0-A5-66-BH
IP address: 10.2.33.2
MAC address: E0A5-66BB-B2AA
```

```
Remaining block time: 01h:38m:44s
Username: test
```

Display information about the blocked portal user whose username is **test**.

```
<Sysname> display portal user-block username test
IP address: 10.2.33.2
MAC address: E0A5-66BB-B2AA
Remaining block time: 01h:38m:44s
Username: test
```

Table 25 Command output

Field	Description
IP address	IP address of the blocked portal user.
MAC address	MAC address of the blocked portal user.
Username	Username of the blocked portal user.
Remaining block time(hh:mm:ss)	Remaining blocking timeout time, in the format of hh:mm:ss.

Parameters

ipv4 *ipv4-address*: Specify an IPv4 portal user by its IPv4 address. If you do not specify an IPv4 portal user, this command displays DHCP lease information about all IPv4 portal users.

Usage guidelines

Use this command only when DHCP packet capture is enabled to detect online status of portal users. To enable the DHCP packet capture feature, use the **portal idle-cut dhcp-capture enable** command.

Examples

Display DHCP lease information for all IPv4 portal users.

```
<Sysname> display portal user dhcp-lease
Total DHCP lease entries: 2
IPv4 address      MAC address           Lease time          Remaining time
1.1.1.1           AABB-CCDD-1122        02h 00m 00s         01h 10m 46s
1.1.1.2           AABB-CCDD-1133        01h 00m 00s         00h 08m 46s
```

Display DHCP lease information for an IPv4 portal user.

```
<Sysname> display portal user dhcp-lease ip 1.1.1.1
IPv4 address      MAC address           Lease time          Remaining time
1.1.1.1           AABB-CCDD-1122        02h 00m 00s         01h 10m 46s
```

Table 26 Command output

Field	Description
Total DHCP lease entries	Total number of DHCP lease entries of IPv4 portal users.
IPv4 address	IPv4 address of an IPv4 portal user.
MAC	MAC address of the IPv4 portal user.
Lease time	Lease time period for the IPv4 address. • If the time period is less than one day, this field is displayed in the *xx*h *xx*m *xx*s format. • If the time period is less than one week, this field is displayed in the *x*d *xx*h format.

Field	Description
	• If the time period is greater than one week, this field is displayed in the *x*w *x*d *xx*h format. The **w**, **d**, **h**, **m**, and **s** represent weeks, days, hours, minutes, and seconds, respectively.
Remaining time	Remaining lease time period for the IPv4 address. • If the time period is less than one day, this field is displayed in the *xx*h *xx*m *xx*s format. • If the time period is less than one week, this field is displayed in the *x*d *xx*h format. • If the time period is greater than one week, this field is displayed in the *x*w *x*d *xx*h format. The **w**, **d**, **h**, **m**, and **s** represent weeks, days, hours, minutes, and seconds, respectively.

context-operator

Parameters

server-name: Specifies a portal Web server by its name, a case-sensitive string of 1 to 32 characters. If you do not specify a portal Web server, this command displays information about all portal Web servers.

Examples

Display information about portal Web server **wbs**.

```
<Sysname> display portal web-server wbs
Portal Web server: wbs
    Type IMC
    URL: http://www.test.com/portal
    URL parameters:
       userurl=http://www.test.com/welcome
       userip=source-address
    VPN instance: Not configured
    Server detection:
      Interval: 120s
      Attempts: 5
      Action: log, trap
      Detection URL: http://www.test.com/portal
      Detection type: TCP
    IPv4 status: Up
    IPv6 status: Up
    Captive-bypass: Disabled
    If-match: original-url:  http://2.2.2.2, redirect-url:  http://192.168.56.2
              original-url:   http://1.1.1.1, temp-pass redirect-url:
              http://192.168.1.1
```

Table 28 Command output

Field	Description
Type	Portal Web server type: • **CMCC**—CMCC server. • **IMC**—IMC server. • **ISE**—ISE sever. • **OAuth**—Cloud server. • **WiFiDog**—WiFiDog server.
Portal Web server	Name of the portal Web server.
URL	URL of the portal Web server.
URL parameters	URL parameters for the portal Web server.
VPN instance	Name of the MPLS L3VPN where the portal Web server resides.
Server detection	Parameters for portal Web server detection.
Interval	Detection interval in seconds.
Attempts	Maximum number of detection attempts.
Action	Actions (**log** and **trap**) to take when a reachability status change of the portal Web server is detected.
Detection URL	Portal Web server detection URL.

Field	Description
Detection type	Type of portal Web server detection: • TCP. • HTTP.

IPv4 status	Current state of the IPv4 portal Web server:
	• **Up**—This value indicates one of the following conditions:
	  ◦ Portal Web server detection is disabled.
	  ◦ Portal Web server detection is enabled and the server is reachable.
	• **Down**—Portal Web server detection is enabled and the server is unreachable.

IPv6 status	Current state of the IPv6 portal Web server:
	• **Up**—This value indicates one of the following conditions:
	  ◦ Portal Web server detection is disabled.
	  ◦ Portal Web server detection is enabled and the server is reachable.
	• **Down**—Portal Web server detection is enabled and the server is unreachable.

Captive-bypass	Status of the captive-bypass feature: • **Disabled**—Captive-bypass is disabled. • **Enabled**—Captive-bypass is enabled. • **Optimize Enabled**—Optimized captive-bypass is enabled.
If-match	Match rules configured for URL redirection. This field displays **Not configured** if no match rules for URL redirection are configured.

display web-redirect rule

Use **display web-redirect rule** to display information about Web redirect rules.

Syntax

display web-redirect rule interface *interface-type interface-number* [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays Web redirect rules for the master device.

Examples

Display all Web redirect rules on GigabitEthernet 1/0/1.

```
<Sysname> display web-redirect rule interface gigabitethernet 1/0/1
IPv4 web-redirect rules on GigabitEthernet1/0/1:
Rule 1:
 Type                : Dynamic
 Action              : Permit
 Status              : Active
 Source:
    IP             : 192.168.2.114
    VLAN           : Any

Rule 2:
 Type                : Static
 Action              : Redirect
 Status              : Active
 Source:
    VLAN           : Any
    Protocol       : TCP
 Destination:
    Port           : 80

IPv6 web-redirect rules on GigabitEthernet1/0/1:
Rule 1:
 Type                : Static
 Action              : Redirect
 Status              : Active
 Source:
    VLAN           : Any
    Protocol       : TCP
 Destination:
    Port           : 80
```

Table 29 Command output

Field	Description
Rule	Number of the Web redirect rule.
Type	Type of the Web redirect rule: • **Static**—Static Web redirect rule, generated when the Web redirect feature takes effect. • **Dynamic**—Dynamic Web redirect rule, generated when a user visits a redirect webpage.
Action	Action in the Web redirect rule: • **Permit**—Allows packets to pass. • **Redirect**—Redirects the packets.
Status	Status of the Web redirect rule:

Field	Description
	• **Active**—The Web redirect rule is effective. • **Inactive**—The Web redirect rule is not effective.
Source	Source information in the Web redirect rule.
IP	Source IP address.
Mask	Subnet mask of the source IPv4 address.
Prefix length	Prefix length of the source IPv6 address.
VLAN	Source VLAN. If not specified, this field displays **Any**.
Protocol	Transport layer protocol in the Web redirect rule: • **Any**—No transport layer protocol is limited. • **TCP**—Transmission Control Protocol.
Destination	Destination information in the Web redirect rule.
Port	Destination transport layer port number. The default port number is 80.

exclude-attribute (MAC binding server view)

Use **exclude-attribute** to exclude an attribute from portal protocol packets.

Use **undo exclude-attribute** to not exclude an attribute from portal protocol packets.

Syntax

exclude-attribute *attribute-number*

undo exclude-attribute *attribute-number*

Default

No attributes are excluded from portal protocol packets.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Parameters

attribute-number: Specifies an attribute by its number in the range of 1 to 255.

Usage guidelines

Support of the portal authentication server for portal protocol attributes varies by the server type. During MAC-trigger authentication, the device and the server cannot communicate if the device sends the portal authentication server a packet that contains an attribute unsupported by the server.

To address this issue, you can configure this command to exclude the unsupported attributes from portal protocol packets sent to the portal authentication server.

You can specify multiple excluded attributes.

Table 30 describes all attributes of the portal protocol.

Table 30 Portal attributes

Name	Number	Description
UserName	1	Name of the user to be authenticated.
PassWord	2	User password in plaintext form.
Challenge	3	Random challenge for CHAP authentication.
ChapPassWord	4	CHAP password encrypted by MD5.
TextInfo	5	The device uses this attribute to transparently transport prompt information of a RADIUS server or packet error information to the portal authentication server. The attribute value can be any string excluding the end character '\0'. This attribute can exist in any packet from the device to the portal server. A packet can contain multiple TextInfo attributes. As a best practice, carry only one TextInfo attribute in a packet.
UpLinkFlux	6	Uplink (output) traffic of the user, an 8-byte unsigned integer, in KB.
DownLinkFlux	7	Downlink (input) traffic of the user, an 8-byte unsigned integer, in KB.
Port	8	Port information, a string excluding the end character '\0'.
IP-Config	9	This attribute has different meanings in different types of packets. • The device uses this attribute in ACK _AUTH (Type=0x04) packets to notify the portal server that the user requires re-DHCP. • The device uses this attribute in ACK_LOGOUT (Type=0x06) and NTF_LOGOUT (Type=0x08) packets to indicate that the current user IP address must be released. The portal server must notify the user to release the public IP address through DHCP. The device will reallocate a private IP address to the user.
BAS-IP	10	IP address of the access device. For re-DHCP portal authentication, the value of this attribute is the public IP address of the access device.
Session-ID	11	Identification of a portal user. Generally, the value of this attribute is the MAC address of the portal user.
Delay-Time	12	Delay time for sending a packet. This attributes exists in NTF_LOGOUT (Type=0x08) packets.
User-List	13	List of IP addresses of an IPv4 portal user.
EAP-Message	14	An EAP attribute that needs to be transported transparently. This attribute is applicable to EAP TLS authentication. Multiple EAP-Message attributes can exist in a portal authentication packet.
User-Notify	15	Value of the hw_User_Notify attribute in a RADIUS accounting response. This attribute needs to be transported transparently.
BAS-IPv6	100	IPv6 address of the access device.
UserIPv6-List	101	List of IPv6 addresses of an IPv6 portal user.

Examples

Exclude the BAS-IP attribute (number 10) from portal packets sent to MAC binding server 123.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server 123
[Sysname-portal-mac-trigger-server-123] exclude-attribute 10
```

exclude-attribute (portal authentication server view)

Use **exclude-attribute** to exclude an attribute from portal protocol packets.

Use **undo exclude-attribute** to not exclude an attribute from portal protocol packets.

Syntax

exclude-attribute *number* { **ack-auth** | **ack-logout** | **ntf-logout** }

undo exclude-attribute *number* { **ack-auth** | **ack-logout** | **ntf-logout** }

Default

No attributes are excluded from portal protocol packets.

Views

Portal authentication server view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies an attribute by its number in the range of 1 to 255.

ack-auth: Excludes the attribute from ACK_AUTH packets.

ack-logout: Excludes the attribute from ACK_LOGOUT packets.

ntf-logout: Excludes the attribute from NTF_LOGOUT packets.

Usage guidelines

Support of the portal authentication server for portal protocol attributes varies by the server type. If the device sends the portal authentication server a packet that contains an attribute unsupported by the server, the device and the server cannot communicate.

To address this issue, you can configure this command to exclude the unsupported attributes from specific portal protocol packets sent to the portal authentication server.

You can specify multiple excluded attributes. For an excluded attribute, you can specify multiple types of portal protocol packets (**ack-auth**, **ntf-logout**, and **ack-logout**).

Table 31 describes all attributes of the portal protocol.

Table 31 Portal attributes

Name	Number	Description
UserName	1	Name of the user to be authenticated.
PassWord	2	User password in plaintext form.
Challenge	3	Random challenge for CHAP authentication.
ChapPassWord	4	CHAP password encrypted by MD5.
TextInfo	5	The device uses this attribute to transparently transport prompt information of a RADIUS server or packet error information to the portal authentication server. The attribute value can be any string excluding the end character '\0'. This attribute can exist in any packet from the device to the portal server. A packet can contain multiple TextInfo attributes. As a best practice, carry only one TextInfo attribute in a packet.

Name	Number	Description
UpLinkFlux	6	Uplink (output) traffic of the user, an 8-byte unsigned integer, in KB.
DownLinkFlux	7	Downlink (input) traffic of the user, an 8-byte unsigned integer, in KB.
Port	8	Port information, a string excluding the end character '\0'.
IP-Config	9	This attribute has different meanings in different types of packets. • The device uses this attribute in ACK _AUTH (Type=0x04) packets to notify the portal server that the user requires re-DHCP. • The device uses this attribute in ACK_LOGOUT (Type=0x06) and NTF_LOGOUT (Type=0x08) packets to indicate that the current user IP address must be released. The portal server must notify the user to release the public IP address through DHCP. The device will reallocate a private IP address to the user.
BAS-IP	10	IP address of the access device. For re-DHCP portal authentication, the value of this attribute is the public IP address of the access device.
Session-ID	11	Identification of a portal user. Generally, the value of this attribute is the MAC address of the portal user.
Delay-Time	12	Delay time for sending a packet. This attributes exists in NTF_LOGOUT (Type=0x08) packets.
User-List	13	List of IP addresses of an IPv4 portal user.
EAP-Message	14	An EAP attribute that needs to be transported transparently. This attribute is applicable to EAP TLS authentication. Multiple EAP-Message attributes can exist in a portal authentication packet.
User-Notify	15	Value of the hw_User_Notify attribute in a RADIUS accounting response. This attribute needs to be transported transparently.
BAS-IPv6	100	IPv6 address of the access device.
UserIPv6-List	101	List of IPv6 addresses of an IPv6 portal user.

Examples

Exclude the UpLinkFlux attribute (number 6) from portal ACK_AUTH packets.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] exclude-attribute 6 ack-auth
```

Related commands

display portal server

free-traffic threshold

Use **free-traffic threshold** to set the free-traffic threshold for portal users.

Use **undo free-traffic threshold** to restore the default.

Syntax

free-traffic threshold *value*

undo free-traffic threshold

Default

The free-traffic threshold is 0 bytes.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies the free-traffic threshold in the range of 0 to 10240000 bytes. If the free-traffic threshold is set to 0, the device immediately triggers MAC-based quick portal authentication for a user once the user's traffic is detected.

Usage guidelines

After MAC-based quick portal authentication is configured, the device monitors a user's network traffic (sent and received) in real time before the MAC-trigger entry for the user ages out. A user can access the network without authentication if the user's network traffic is below the free-traffic threshold. When the user's network traffic reaches the threshold, the device triggers MAC-based quick portal authentication for the user.

If the user passes portal authentication, the device deletes the MAC-trigger entry and clears the user traffic statistics. If the user fails authentication, the device does not trigger MAC-based quick authentication for the user before the MAC-trigger entry ages out. When the MAC-trigger entry ages out, the device clears the user traffic statistics.

When traffic is detected from the user again, the device re-creates a MAC-trigger entry for the user and repeats the previous procedure.

Examples

Set the free-traffic threshold for portal users to 10240 bytes.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
[Sysname-portal-mac-trigger-server-mts] free-traffic threshold 10240
```

Related commands

display portal mac-trigger-server

if-match

Use **if-match** to configure a match rule for URL redirection.

Use **undo if-match** to delete a URL redirection match rule.

Syntax

if-match { **original-url** *url-string* **redirect-url** *url-string* [**url-param-encryption** { **aes** | **des** } **key** { **cipher** | **simple** } *string*] | **user-agent** *string* **redirect-url** *url-string* }

undo if-match { **original-url** *url-string* | **user-agent** *user-agent* }

Default

No URL redirection match rules exist.

Views

Portal Web server view

Predefined user roles

network-admin

context-admin

Parameters

original-url *url-string*: Specifies the user-requested URL to be matched. The specified URL must be a complete URL starting with **http://** or **https://**, a case-sensitive string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of the *url-string* argument, the CLI does not display help information for this argument.

redirect-url *url-string*: Specifies the URL to which the user is redirected. The specified URL must be a complete URL starting with **http://** or **https://**, a case-sensitive string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of the *url-string* argument, the CLI does not display help information for this argument.

url-param-encryption: Specifies an encryption algorithm to encrypt the parameters carried in the redirection URL. If you do not specify an encryption algorithm, the parameters carried in the redirection URL are not encrypted.

aes: Specifies the AES algorithm.

des: Specifies the DES algorithm.

key: Specifies a key for encryption.

cipher: Specifies a key in encrypted form.

simple: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the case-sensitive key string. The string length varies by the selected encryption method:

- If **des cipher** is specified, the string length is 41 characters.
- If **des simple** is specified, the string length is 8 characters.
- If **aes cipher** is specified, the string length is 1 to 73 characters.
- If **aes simple** is specified, the string length is 1 to 31 characters.

user-agent *user-agent*: Specifies a user agent string to match the User-Agent string in HTTP/HTTPS requests. The user agent string is a case-sensitive string of 1 to 255 characters. The User-Agent string in HTTP or HTTPS requests includes information about hardware manufacturer, operating system, browser, and search engine.

Usage guidelines

A URL redirection match rule matches Web requests (HTTP or HTTPS requests) by user-requested URL or User-Agent information, and redirects the matching Web requests to the specified redirection URL.

For a user to successfully access a redirection URL, configure a portal-free rule to allow HTTP or HTTPS requests destined for the redirection URL to pass. For information about configuring portal-free rules, see the **portal free-rule** command.

For a portal Web server, you can configure the **url** command and the **if-match** command for URL redirection. The **url** command redirects all Web requests from unauthenticated users to the portal Web server for authentication. The **if-match** command allows for flexible URL redirection by redirecting specific Web requests to specific redirection URLs. If both commands are executed, the **if-match** command takes priority to perform URL redirection.

If both portal safe-redirect and URL redirection match rules are configured, the device preferentially uses URL redirection match rules to perform URL redirection.

If you configure encryption for parameters in the redirection URL, you must add an encryption prompt field after the redirection URL address. For example, to redirect HTTP requests to URL 10.1.1.1 with encrypted URL parameters, specify the redirection URL as **http://10.1.1.1?yyyy=**. The

value of yyyy depends on the portal Web server configuration. For more information, see the portal Web server configuration guide.

You can configure a URL in a URL redirection match rule in one of the following ways:

- **For exact match**—Specify a complete URL. For example, if you configure the URL as **abc.com.cn**, only Web requests that contain URL **abc.com.cn** match the rule.
- **For fuzzy match**—Specify a URL by placing the asterisk (*) wildcard character at the beginning or end of the URL string. For example, if you configure the URL as ***abc.com.cn**, **abc***, or ***abc***, Web requests that carry the URL ending with **abc.com.cn**, starting with **abc**, or including **abc** match the rule.
  - The asterisk (*) wildcard character represents any characters. The device treats multiple consecutive asterisks as one.
  - The configured URL cannot contain only asterisks (*).

You cannot configure two URL redirection match rules with the same user-requested URL.

Examples

Configure a match rule to redirect HTTP requests destined for the URL **http://www.abc.com.cn** to the URL **http://192.168.0.1**.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] if-match original-url http://www.abc.com.cn redirect-url
http://192.168.0.1
```

Configure a match rule to redirect HTTP requests that carry the user agent string **5.0(WindowsNT6.1)AppleWebKit/537.36(KHTML,likeGecko)Chrome/36.0.1985.125Safari/537.36** to the URL **http://192.168.0.1.**

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] if-match user-agent
5.0(WindowsNT6.1)AppleWebKit/537.36(KHTML,likeGecko)Chrome/36.0.1985.125Safari/537.36
redirect-url http://192.168.0.1
```

url-parameter

if-match temp-pass

Use **if-match temp-pass** to configure a match rule for temporary pass.

Use **undo if-match temp-pass** to restore the default.

Syntax

if-match { **original-url** *url-string* | **user-agent** *user-agent* } * **temp-pass** [**redirect-url** *url-string* | **original**]

undo if-match { **original-url** *url-string* | **user-agent** *user-agent* } * **temp-pass**

Default

No match rules for temporary pass are configured.

Views

Portal Web server view

Predefined user roles

network-admin

context-admin

Parameters

original-url *url-string*: Specifies a URL string to match the URL in HTTP/HTTPS requests of portal users. The specified URL must be a complete URL starting with **http://** or **https://**, a case-sensitive string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of the *url-string* argument, the CLI does not display help information for this argument.

user-agent *user-agent*: Specifies a user agent string to match the User-Agent string in HTTP/HTTPS requests. The user agent string is a case-sensitive string of 1 to 255 characters. The User-Agent string in HTTP or HTTPS requests includes information about hardware manufacturer, operating system, browser, and search engine.

redirect-url *url-string*: Redirects the matching Web requests to the specified URL. The specified URL must be a complete URL starting with **http://** or **https://**, a case-sensitive string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of the *url-string* argument, the CLI does not display help information for this argument.

original: Redirects the matching Web requests to the originally requested URLs.

Usage guidelines

A match rule for temporary pass matches Web requests by URL or User-Agent information. Only the matching Web requests are temporarily permitted to pass.

A permitted request can be redirected to the specified redirection URL or to the originally requested URL, depending on the redirection action in the match rule. If you do not configure a redirection action (by using the **redirect-url** *url-string* option or the **original** keyword), the device permits the matching requests to pass without redirection.

For the match rules to take effect, make sure the portal temporary pass feature is enabled.

If you configure the same match criteria but different redirection actions in two match rules, the new configuration overwrites the existing one.

If both portal safe-redirect and portal temporary pass match rules are configured, portal temporary pass match rules take precedence.

Examples

Configure a temporary pass match rule to temporarily allow user packets that access URL **http://www.abc.com.cn** to pass.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] if-match original-url http://www.abc.com.cn temp-pass
```

Configure a temporary pass match rule to temporarily allow user packets that access the URL **http://www.abc.com.cn/** to pass and then redirect the packets to the originally requested URL.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] if-match original-url http://www.abc.com.cn temp-pass
original
```

Configure a temporary pass match rule to allow user packets that contain user agent information **5.0(WindowsNT6.1)AppleWebKit/537.36(KHTML,likeGecko)Chrome/36.0.1985.125Safari/537.36** to pass and then redirect the packets to URL **http://192.168.0.1**.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] if-match user-agent
5.0(WindowsNT6.1)AppleWebKit/537.36(KHTML,likeGecko)Chrome/36.0.1985.125Safari/537.36
temp-pass redirect-url http://192.168.0.1
```

Configure a temporary pass match rule. This rule allows user packets that access the URL **http://www.abc.com.cn/** and contain user agent information **5.0(WindowsNT6.1)AppleWebKit/537.36(KHTML,likeGecko)Chrome/36.0.1985.125Safari/537.36** to pass and then redirects the packets to URL **http://192.168.0.1**.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] if-match original-url http://www.123.com.cn user-agent
5.0(WindowsNT6.1)AppleWebKit/537.36(KHTML,likeGecko)Chrome/36.0.1985.125Safari/537.36
temp-pass redirect-url http://192.168.0.1
```

ip (MAC binding server view)

Use **ip** to specify the IP address of a MAC binding server.

Use **undo ip** to restore the default.

Syntax

ip *ipv4-address* [**vpn-instance** *vpn-instance-name*] [**key** { **cipher** | **simple** } *string*]

undo ip

Default

The IP address of the MAC binding server is not specified.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies the IP address of a MAC binding server.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the MAC binding server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the MAC binding server belongs to the public network, do not specify this option.

key: Specifies a shared key to be used to authenticate packets between the device and the MAC binding server. Portal packets exchanged between the device and MAC binding server carry an authenticator that is generated with the shared key. The receiver uses the authenticator to verify the correctness of the received portal packets. If you do not specify a shared key, the device and MAC binding server do not authenticate the packets between them.

cipher: Specifies a shared key in encrypted form.

simple: Specifies a shared key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the shared key. Its plaintext form is a case-sensitive string of 1 to 64 characters. Its encrypted form is a case-sensitive string of 33 to 117 characters.

Usage guidelines

If you execute this command multiple times in the same MAC binding server view, the most recent configuration takes effect.

Examples

Specify the IP address of the MAC binding server as **192.168.0.111** and the plaintext key as **portal**.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
[Sysname-portal-mac-trigger-server-mts] ip 192.168.0.111 key simple portal
```

Related commands

display portal mac-trigger-server

ip (portal authentication server view)

Use **ip** to specify the IPv4 address of a portal authentication server.

Use **undo ip** to restore the default.

Syntax

ip *ipv4-address* [**vpn-instance** *vpn-instance-name*] [**key** { **cipher** | **simple** } *string*]

undo ip

Default

The IPv4 address of the portal authentication server is not specified.

Views

Portal authentication server view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies the IPv4 address of the portal authentication server.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN where the portal authentication server resides by the VPN instance name, a case-sensitive string of 1 to 31 characters. If the portal authentication server is on the public network, do not specify this option.

key: Specifies a shared key for communication with the portal authentication server. Portal packets exchanged between the access device and the portal authentication server carry an authenticator

that is generated with the shared key. The receiver uses the authenticator to check the correctness of the received portal packets.

cipher: Specifies a key in encrypted form.

simple: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. Its plaintext form is a case-sensitive string of 1 to 64 characters. Its encrypted form is a case-sensitive string of 33 to 117 characters.

Usage guidelines

A portal authentication server has only one IPv4 address. Therefore, in portal authentication server view, only one IPv4 address exists. If you execute this command multiple times, the most recent configuration takes effect.

Do not configure the same IPv4 address and VPN instance for different portal authentication servers.

Examples

Specify **192.168.0.111** as the IPv4 address of portal authentication server **pts** and plaintext key **portal** as the shared key for communication with the portal authentication server.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] ip 192.168.0.111 key simple portal
```

local-binding aging-time

Use **local-binding aging-time** to set the aging time for local MAC-account binding entries.

Use **undo local-binding aging-time** to restore the default.

Syntax

local-binding aging-time *minutes*

undo local-binding aging-time

Default

The aging time for local MAC-account binding entries is 720 minutes.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Parameters

minutes: Specifies the aging time for local MAC-account binding entries. The value range for this argument is 1 to 129600 minutes.

Usage guidelines

The local MAC binding server uses a local MAC-account binding entry to record the MAC address and portal account information (username and password) of a portal user.

The local MAC-account binding entry of a portal user is deleted when the entry ages out. The device creates a local MAC-account binding entry for the user again when the user triggers and passes a new portal authentication.

If you disable local MAC-trigger authentication, the device does not delete existing local MAC-account binding entries. These entries are automatically deleted when they age out.

Examples

Set the aging time for local MAC-account binding entries to 240 minutes in the view of MAC binding server **mts**.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
[Sysname-portal-mac-trigger-server-mts] local-binding aging-time 240
```

Related commands

`display portal mac-trigger-server`

local-binding enable

Use **`local-binding enable`** to enable local MAC-trigger authentication.

Use **`undo local-binding enable`** to disable local MAC-trigger authentication.

Syntax

`local-binding enable`

`undo local-binding enable`

Default

Local MAC-trigger authentication is disabled.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the device to act as a local MAC binding server to provide MAC-trigger authentication for local portal authentication users.

After a user passes portal authentication for the first time, the access device (local MAC binding server) generates a local MAC-account binding entry for the user. The local MAC binding-account entry records the MAC address and portal account information (username and password) of the user. Then, the user can automatically connect to the network without manual authentication for subsequent network access attempts.

Examples

Enable local MAC-trigger authentication in the view of MAC binding server **mts**.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
```

```
[Sysname-portal-mac-trigger-server-mts] local-binding enable
```

login failed-url

Use **login failed-url** to configure the redirect URL for authentication failure.

Use **undo login failed-url** to restore the default.

Syntax

login failed-url *url-string*

undo login failed-url

Default

No redirection URL for authentication failure is configured.

Views

Local portal Web service view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the redirect URL for authentication failure, a case-sensitive string of 1 to 256 characters.

Usage guidelines

The device redirects portal users to the specified URL after they fail authentication.

Examples

Configure the redirect URL for authentication failure as **https://1.1.1.1/portal/iselogin.html**.

```
<Sysname> system-view
[Sysname] portal local-web-server https
[Sysname-portal-local-websvr-https] login failure-url
https://1.1.1.1/portal/iselogin.html
```

login success-url

Use **login success-url** to configure the redirect URL for authentication success.

Use **undo login success-url** to restore the default.

Syntax

login success-url *url-string*

undo login success-url

Default

No redirection URL for authentication success is configured.

Views

Local portal Web service view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the redirect URL for authentication success, a case-sensitive string of 1 to 256 characters.

Usage guidelines

The device redirects portal users to the specified URL after they pass authentication.

Examples

Configure the redirect URL for authentication success as **https://1.1.1.1/portal/islogin.html**.

```
<Sysname> system-view
[Sysname] portal local-web-server https
[Sysname-portal-local-websvr-https] login success-url
https://1.1.1.1/portal/islogin.html
```

logon-page bind

Use **logon-page bind** to bind an endpoint name or endpoint type to an authentication page file.

Use **undo logon-page bind** to unbind the endpoint name or endpoint type from the authentication page file.

Syntax

logon-page bind { **device-type** { **computer** | **pad** | **phone** } | **device-name** *device-name* } * **file** *file-name*

undo logon-page bind { **all** | **device-type** { **computer** | **pad** | **phone** } | **device-name** *device-name* } *

Default

No endpoint name or endpoint type is bound to an authentication page file.

Views

Local portal Web service view

Predefined user roles

network-admin

context-admin

Parameters

all: Specifies all endpoint names and endpoint types.

device-type *type-name*: Specifies an endpoint type.

computer: Specifies the endpoint type as computer.

pad: Specifies the endpoint type as tablet.

phone: Specifies the endpoint type as mobile phone.

device-name *device-name*: Specify an endpoint by its name, a case-sensitive string of 1 to 127 characters. The specified endpoint name must have been predefined on the device. Otherwise, the bound authentication page file does not take effect.

file *file-name*: Specifies an authentication page file by the file name (without the file storage directory). A file name is a string of 1 to 91 characters, and can contain letters, digits, and underscores (_). You must edit the authentication pages, compress them to a .zip file, and then upload the file to the root directory of the storage medium of the device.

Usage guidelines

This command implements customized authentication page pushing for portal users. After you configure this command, the device pushes authentication pages to users according to the user's, endpoint name and endpoint type.

When a Web user triggers local portal authentication, the device searches for a binding that matches the user's endpoint name and endpoint type.

- If the binding exists, the device pushes the bound authentication pages to the user.
- If multiple matching binding entries are found, the device selects an entry in the following order:
  a. The entry that specifies the endpoint name and endpoint type.
  b. The entry that specifies only the endpoint name.
  c. The entry that specifies only the endpoint type.
- If the binding does not exist, the device pushes the default authentication pages to the user.

When you configure this command, follow these restrictions and guidelines:

- If the name or content of the file in a binding entry is changed, you must reconfigure the binding.
- To reconfigure or modify a binding, you can simply re-execute this command without canceling the existing binding.
- If you execute this command multiple times to bind an endpoint name or endpoint type to different authentication page files, the most recent configuration takes effect.
- You can configure multiple binding entries on the device.

Examples

Create an HTTP-based local portal Web service.

```
<Sysname> system-view
[Sysname] portal local-web-server http
```

Bind endpoint type **phone** to authentication page file **file2.zip**.

```
[Sysname-portal-local-websvr-http] logon-page bind device-type phone file file2.zip
```

Related commands

default-logon-page

portal local-web-server

logout-notify

Use **logout-notify** to set the maximum number of times and the interval for retransmitting a logout notification packet.

Use **undo logout-notify** to restore the default.

Syntax

logout-notify retry *retries* **interval** *interval*

undo logout-notify

Default

The device does not retransmit a logout notification packet.

Views

Portal authentication server view

Predefined user roles

network-admin

context-admin

Parameters

retry *retries*: Specifies the maximum number of retries, in the range of 1 to 5.

interval *interval*: Specifies the retry interval, in the range of 1 to 10 seconds.

Usage guidelines

A logout notification packet is a UDP packet that the device sends to the portal authentication server for forcibly logging out a portal user. To increase the delivery reliability, you can set the maximum number of times and the interval for retransmitting a logout notification packet.

After the device sends a logout notification packet for logging out a portal user, it waits for a response from the portal authentication server. If the device receives a response within the specified period of time (maximum number of retries × retry interval), it logs out and deletes the user immediately. If the device does not receive a response within the period of time, the device logs out and deletes the user when the period of time elapses.

Examples

Set the maximum number of times for retransmitting a logout notification packet to 3 and the retry interval to 5 seconds.

```
<Sysname> system-view
[Sysname] portal server pt
[Sysname-portal-server-pt] logout-notify retry 3 interval 5
```

Related commands

mail-domain-name

Use **mail-domain-name** to specify an email domain name for email authentication.

Use **undo mail-address** to remove an email domain name for email authentication.

Syntax

mail-domain-name *string*

undo mail-domain-name [*string*]

Default

No email domain names are specified for email authentication.

Views

Email authentication server view

Predefined user roles

network-admin

context-admin

Parameters

string: Specifies an email domain name for email authentication, a case-sensitive string of 1 to 255 characters, in the format of @XXX.XXX.

Usage guidelines

If you do not specify an email domain name in the **undo** form of this command, this command removes all email domain names for email authentication.

After you configure this command, the device performs email authentication only on portal users that use the specified email domain names.

You can specify a maximum of 16 email domain names for email authentication.

Examples

Specify **@qq.com** and **@sina.com** email domain names for email authentication.

```
<Sysname> system-view
[Sysname] portal extend-auth-server mail
[Sysname-portal-extend-auth-server-mail] mail-domain-name @qq.com
[Sysname-portal-extend-auth-server-mail] mail-domain-name @Sina.com
```

portal ad-push

Use **portal ad-push** to specify an advertisement URL or advertisement group for portal advertisement push.

Use **undo portal ad-push** to restore the default.

Syntax

portal [**ipv6**] **ad-push** { **url** *url-string* [**interval** *interval* | **time-range** *time-range-name* | **traffic-threshold** *traffic-threshold*] | **url-group** *group-name* }

undo portal [**ipv6**] **ad-push** { **url** | **url-group** }

Default

No advertisement URL or advertisement group is specified for portal advertisement push.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies IPv6 URLs. To specify IPv4 URLs, do not specify this keyword.

url *url-string*: Specifies the URL of an advertisement to be pushed to portal users. The URL is a case-sensitive string of 1 to 256 characters and must begin with **http://**. If you specify the **ipv6** keyword, the URL of the advertisement must be an IPv6 URL.

url-group *group-name*: Specifies an advertisement group by its name, a case-sensitive string of 1 to 32 characters. The device will push advertisements in this group to portal users. If you specify the **ipv6** keyword, the URLs of advertisements in this group must be IPv6 URLs.

interval *interval*: Specifies the advertisement push interval, in the range of 5 to 1440 minutes. The interval begins when a portal user comes online.

time-range *time-range-name*: Specifies a time range for portal advertisement push. The *time-range-name* argument represents the name of the time range, a case-insensitive string of 1 to 32 characters. The time range name must begin with a letter and cannot be **all**. For more information about time ranges, see time range configuration in *ACL and QoS Configuration Guide*.

traffic-threshold *traffic-threshold*: Specifies the traffic threshold for portal advertisement push. The value range for the argument is 1 to 1024, in MB.

Usage guidelines

If you specify an advertisement group for portal advertisement push, the device uses the group advertisement push method specified by using the **portal ad-url-group** command.

If you specify an advertisement URL without configuring a push method, the device only pushes the advertisement to the portal user five seconds after the user comes online.

Examples

Configure the device to push the advertisement on URL **http://192.168.56.1/welcome** every 60 minutes to portal users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal ad-push url http://192.168.56.1/welcome interval
60
```

Configure the device to push advertisements in advertisement group **test** to portal users on GigabitEthernet 1/0/2.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] portal ad-push url-group test
```

undo portal ad-push embedded

Default

Embedded portal advertisement push is disabled. The advertisements that the device pushes to portal users are independent of the user visited webpages.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the device to embed advertisements in webpages that portal users visit.

Examples

Enable embedded portal advertisement push on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal ad-push embedded
```

Related commands

portal ad-push enable

portal ad-push enable

Use **portal ad-push enable** to enable portal advertisement push.

Use **undo portal ad-push enable** to disable portal advertisement push.

Syntax

portal ad-push enable

undo portal ad-push enable

Default

Portal advertisement push is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the device to push advertisements to portal users after they pass portal authentication.

Examples

Enable portal advertisement push on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal ad-push enable
```

Related commands

portal ad-push url

portal ad-push whitelist

Use **portal ad-push whitelist** to add a portal user to a portal advertisement whitelist.

Use **undo ad-push whitelist** to remove portal users from the portal advertisement whitelist.

Syntax

portal ad-push whitelist { **ip** *ipv4-address* | **ipv6** *ipv6-address* | **mac-address** *mac-address* }

undo portal ad-push whitelist { **all** | **ip** *ipv4-address* | **ipv6** *ipv6-address* | **mac-address** *mac-address* }

Default

No portal advertisement whitelist exists.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

all: Specifies all portal users.

ip *ipv4-address*: Specifies a portal user by its IPv4 address.

ipv6 *ipv6-address*: Specifies a portal user by its IPv6 address.

mac-address *mac-address*: Specifies a portal user by its MAC address in the format of H-H-H.

Usage guidelines

If a portal user has been added to the portal advertisement whitelist, the device does not push advertisements to the portal user.

You can execute this command multiple times to add multiple portal users to the portal advertisement whitelist. A maximum of 1024 portal users can be added to the whitelist.

Examples

Add portal user at IPv4 address 20.20.20.3 to the portal advertisement whitelist.

```
<Sysname> system-view
[Sysname] portal ad-push whitelist ip 20.20.20.3
```

Add portal user at IPv6 address 2000::0:3 to the portal advertisement whitelist.

```
<Sysname> system-view
[Sysname] portal ad-push whitelist ipv6 2000::0:3
```

portal ad-push url

portal ad-url-group

Use **portal ad-url-group** to create an advertisement group and enter its view, or enter the view of an existing advertisement group.

Use **undo portal ad-url-group** to delete an advertisement group.

Syntax

portal ad-url-group *group-name* [**method** { **interval** | **time-range** | **traffic** }]

undo portal ad-url-group *group-name*

Default

No advertisement groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies an advertisement group name, a case-sensitive string of 1 to 32 characters.

method: Specifies the advertisement push method. If you do not specify a method, the device uses the time-based advertisement push method.

interval: Specifies the time-based advertisement push method.

time-range: Specifies the time range-based advertisement push method. For more information about time ranges, see time range configuration in *ACL and QoS Configuration Guide*.

traffic: Specifies the traffic-based advertisement push method.

Usage guidelines

If you have specified an advertisement push method for an advertisement group, you cannot directly change the method. To change the method, use the **undo** form of this command to delete the advertisement group and then recreate it with the new method specified.

Examples

Create an advertisement group named **test** and specify the time-based advertisement push method.

```
<Sysname> system-view
[Sysname] portal ad-url-group test method interval
[Sysname-portal-ad-url-group-test]
```

portal apply mac-trigger-server

Use **portal apply mac-trigger-server** to specify a MAC binding server.

Use **undo portal apply mac-trigger-server** to restore the default.

Syntax

portal apply mac-trigger-server *server-name*

undo portal apply mac-trigger-server

Default

No MAC binding server is specified.

Views

VLAN interface view

Predefined user roles

network-admin

context-admin

Parameters

server-name: Specifies a MAC binding server by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

Only direct IPv4 portal authentication supports MAC-based quick portal authentication.

For MAC-based quick portal authentication to take effect, perform the following tasks:

- Configure normal portal authentication.
- Configure a MAC binding server.
- Specify the MAC binding server on a portal-enabled VLAN interface.

Examples

Specify the MAC binding server **mts** on VLAN-interface 2.

```
<Sysname> system-view
[Sysname] interface vlan-interface 2
[Sysname-Vlan-interface2] portal apply mac-trigger-server mts
```

Related commands

portal mac-trigger-server

portal apply web-server

Use **portal apply web-server** to specify a portal Web server. The device redirects the HTTP or HTTPS requests sent by unauthenticated portal users to the portal Web server.

Use **undo portal apply web-server** to delete a portal Web server.

Syntax

portal [**ipv6**] **apply web-server** *server-name* [**secondary**]

undo portal [**ipv6**] **apply web-server** [*server-name*]

Default

No portal Web servers are specified.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies an IPv6 portal Web server. If the server is an IPv4 portal Web server, do not specify this keyword.

secondary: Specifies the backup portal Web server. If you do not specify this keyword, the specified server is the primary portal Web server.

server-name: Specifies a portal Web server to be specified on the interface by its name, a case-sensitive string of 1 to 32 characters. The name must already exist. If you do not specify a server name in the **undo** form of this command, all portal Web servers on the interface are removed.

Usage guidelines

IPv4 and IPv6 portal authentication can both be enabled on an interface.

You can specify both a primary portal Web server and a backup portal Web server after enabling each type (IPv4 or IPv6) of portal authentication.

The device first uses the primary portal Web server for portal authentication. When the primary portal Web server is unreachable but the backup portal Web server is reachable, the device uses the backup portal Web server. When the primary portal Web server becomes reachable, the device switches back to the primary portal Web server for portal authentication.

To automatically switch between the primary portal Web server and the backup portal Web server, configure portal Web server detection on both servers.

Examples

Specify portal Web server **wbs** as the backup portal Web server on GigabitEthernet 1/0/1 for portal authentication.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal apply web-server wbs secondary
```

Use **portal auth-error-record export** to export portal authentication error records to a path.

Syntax

portal auth-error-record export url *url-string* [**start-time** *start-date start-time* **end-time** *end-date end-time*]

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

url *url-string*: Specifies the URL to which portal authentication error records are exported. The URL is a case-insensitive string of 1 to 255 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of the *url-string* argument, the CLI does not display help information for this argument.

start-time *start-date start-time* **end-time** *end-date end-time*: Specifies a time range. The start date and end date must be in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for MM is 1 to 12. The value range for DD varies with the specified month. The value range for YYYY is 1970 to 2037. The start time and end time must be in the format of hh:mm. The value range for the start time and end time is 00:00 to 23:59.

Usage guidelines

The device supports FTP, TFTP, and HTTP file transfer methods. Table 32 describes the valid URL format for each method.

Table 32 URL formats

Protocol	URL format	Remarks
FTP	ftp://*username*[:*password*]@*server-address*[:*port-number*]/*file-path* Example: **ftp://a:1@1.1.1.1/authfail/**	The username and password must be the same as those on the server. If the server authenticates only the username, no password is required.
TFTP	tftp://*server-address*[:*port-number*]/*file-path* Example: **tftp://1.1.1.1/ autherror/**	N/A
HTTP	http://*username*[:*password*]@*server-address*[:*port-number*]/*file-path* Example: **http://1.1.1.1/autherror/**	The username and password must be the same as those on the server. If the server authenticates only the username, no password is required.

If the server address is an IPv6 address, bracket the IPv6 address to distinguish the IPv6 address from the port number. For example, if the server address is **2001::1** and the port number is 21, the URL is **ftp://test:test@[2001::1]/test/**.

Examples

Export all portal authentication error records to path **tftp://1.1.1.1/record/autherror/**.

```
<Sysname> system-view
[Sysname] portal auth-error-record export url tftp://1.1.1.1/record/autherror/
```

Export portal authentication error records in the time range from 2016/3/4 14:20 to 2016/3/4 15:00 to path **tftp://1.1.1.1/record/autherror/**.

```
<Sysname> system-view
```

```
[Sysname] portal auth-error-record export url tftp://1.1.1.1/record/autherror/
start-time 2016/3/4 14:20 end-time 2016/3/4 15:00
```

portal captive-bypass optimize delay

Use **portal captive-bypass optimize delay** to set the captive-bypass detection timeout time.

Use **undo portal captive-bypass optimize delay** to restore the default.

Syntax

portal captive-bypass optimize delay *seconds*

undo portal captive-bypass optimize delay

Default

The captive-bypass detection timeout time is 6 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the captive-bypass detection timeout time, in the range of 1 to 120 seconds.

Usage guidelines

This command applies only to iOS mobile clients.

With optimized captive-bypass enabled, the device automatically pushes the portal authentication page to iOS mobile devices when they are connected to the network. Users can perform authentication on the page or press the home button to return to the desktop without performing authentication, and the Wi-Fi connection is not terminated.

Optimized captive-bypass might fail when the network condition is poor. The device cannot detect a server reachability detection packet from an iOS mobile device within the captive-bypass detection timeout time. Therefore, the Wi-Fi connection will be terminated on the iOS mobile device. To avoid Wi-Fi disconnections caused by server reachability detection failure, you can set a longer captive-bypass detection timeout time when the network condition is poor.

Examples

Set the captive-bypass detection timeout time to 20 seconds.

```
<Sysname> system-view
[Sysname] portal captive-bypass optimize delay 20
```

Related commands

portal cloud report interval

Use **portal cloud report interval** to configure the time interval at which portal authentication information is reported to the cloud server.

Use **undo portal cloud report interval** to restore the default.

Syntax

portal cloud report interval *minutes*

undo portal cloud report interval

Default

The portal authentication information is reported to the cloud server at intervals of 5 minutes.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

minutes: Specifies the time interval at which portal authentication information is reported to the cloud server. The value range for the time interval is 0 to 60 minutes. If you set the interval to 0 minutes, the device does not report portal authentication information to the cloud server.

Usage guidelines

After you configure this command, the device reports portal authentication failure and error information to the cloud server. The first report is sent to the cloud server 30 seconds after the device is connected to the server. The subsequent reports are sent at regularly intervals as configured by the command.

If you modify the report interval, the modified interval takes effect for the next report.

Examples

Configure the device to report portal authentication failure and error information to the cloud server at intervals of 60 minutes.

```
<Sysname> system-view
[Sysname] portal cloud report interval 60
```

portal delete-user

Use **portal delete-user** to log out online portal users.

Syntax

portal delete-user { *ipv4-address* | **all** | **auth-type** { **cloud** | **email** | **facebook** | **local** | **normal** | **qq** | **wechat** } | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* | **mac** *mac-address* | **username** *username* }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies the IP address of an IPv4 online portal user.

all: Specifies IPv4 and IPv6 online portal users on all interfaces.

auth-type: Specifies online portal users by the authentication type.

cloud: Specifies the cloud authentication.

email: Specifies the email authentication.

facebook: Specifies the Facebook authentication.

local: Specifies the local authentication.

normal: Specifies the normal authentication.

qq: Specifies the QQ authentication.

wechat: Specifies the WeChat authentication.

interface *interface-type interface-number*: Specifies an interface by its type and number. If you specify this option, this command logs out all IPv4 and IPv6 online portal users on the interface.

ipv6 *ipv6-address*: Specifies the IP address of an IPv6 online portal user.

mac *mac-address*: Specifies the MAC address of an online portal user, in the format of H-H-H.

username *username*: Specifies the username of an online portal user, a case-sensitive string of 1 to 253 characters. The username cannot contain the domain name.

Examples

Log out the portal user whose IP address is **1.1.1.1**.

```
<Sysname> system-view
[Sysname] portal delete-user 1.1.1.1
```

Log out the portal user whose MAC address is **000d-88f8-0eab**.

```
<Sysname> system-view
[Sysname] portal delete-user mac 000d-88f8-0eab
```

Log out all portal users that come online through email authentication.

A device is not configured with a device ID.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

device-id: Specifies a device ID for the device, a case-sensitive string of 1 to 63 characters.

Usage guidelines

The portal authentication server uses device IDs to identify the device that sends protocol packets to the portal server.

Make sure the configured device ID is different than any other access devices communicating with the same portal authentication server.

Examples

Set the device ID of the device to 0002.0010.100.00.

```
<Sysname> system-view
[Sysname] portal device-id 0002.0010.100.00
```

portal domain

Use **portal domain** to configure a portal authentication domain. All portal users accessing through the interface must use the authentication domain.

Use **undo portal domain** to delete the configured portal authentication domain.

Syntax

portal [**ipv6**] **domain** *domain-name*

undo portal [**ipv6**] **domain**

Default

No portal authentication domain is configured.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies an authentication domain for IPv6 portal users. Do not specify this keyword for IPv4 portal users.

domain-name: Specifies an ISP authentication domain by its name, a case-insensitive string of 1 to 255 characters.

Usage guidelines

You can specify both an IPv4 portal authentication domain and an IPv6 portal authentication domain on an interface.

Do not specify the **ipv6** keyword for IPv4 portal users.

Examples

Configure the authentication domain for IPv4 portal users as **my-domain** on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname–GigabitEthernet1/0/1] portal domain my-domain
```

Related commands

portal dual-ip enable

Use **portal dual-ip enable** to enable the dual IP feature for single-stack portal users in remote portal authentication.

Use **undo portal dual-ip enable** to disable the dual IP feature for single-stack portal users in remote portal authentication.

Syntax

portal dual-ip enable

undo portal dual-ip enable

Default

The dual IP feature is disabled for single-stack portal users in remote portal authentication.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the device to carry both an IPv4 address and an IPv6 address for single-stack portal users in the authentication requests during remote portal authentication. For IPv4 portal users, the carried IPv6 address is 0. For IPv6 portal users, the carried IPv4 address is 0.

This feature is applicable only to RADIUS-based remote portal authentication.

Some RADIUS servers require that both IPv4 and IPv6 addresses of portal users must be carried in portal authentication requests. To avoid authentication failure, enable this feature for single-stack portal users when such a RADIUS server is used.

Examples

Enable the dual IP feature on VLAN-interface 100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] portal dual-ip enable
```

portal dual-stack enable

Use **portal dual-stack enable** to enable the portal dual-stack feature.

Use **undo portal dual-stack enable** to disable the portal dual-stack feature.

Syntax

portal dual-stack enable

undo portal dual-stack enable

Default

The portal dual-stack feature is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

The portal dual-stack feature enables portal users to access both IPv4 and IPv6 networks after passing one type (IPv4 or IPv6) of portal authentication.

Only direct portal authentication supports this feature.

Examples

Enable the portal dual-stack feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal dual-stack enable
```

portal dual-stack traffic-separate enable

Use **portal dual-stack traffic-separate enable** to enable separate IPv4 and IPv6 traffic statistics for dual-stack portal users.

Use **undo portal dual-stack traffic-separate enable** to disable separate IPv4 and IPv6 traffic statistics for dual-stack portal users.

Syntax

portal dual-stack traffic-separate enable

undo portal dual-stack traffic-separate enable

Default

Separate IPv4 and IPv6 traffic statistics is disabled for dual-stack portal users. The device collects IPv4 and IPv6 traffic statistics collectively.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the device to separately collect IPv4 traffic statistics and IPv6 traffic statistics for a dual-stack portal user. Then, the AAA server can separately perform accounting on IPv4 traffic and IPv6 traffic of the user.

For this feature to take effect, you must enable the portal dual-stack feature.

This command has a higher priority over the **accounting dual-stack** command in ISP domain view. For more information about the **accounting dual-stack** command, see "AAA commands."

Examples

Enable separate IPv4 and IPv6 traffic statistics for dual-stack portal users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal dual-stack traffic-separate enable
```

Related commands

accounting dual-stack

portal dual-stack enable

portal enable (interface view)

Use **portal enable** to enable portal authentication.

Use **undo portal enable** to disable portal authentication.

Syntax

portal enable method { **direct** | **layer3** | **redhcp** }

portal ipv6 enable method { **direct** | **layer3** }

undo portal [**ipv6**] **enable**

Default

Portal authentication is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Enables IPv6 portal authentication. Do not specify this keyword for IPv4 portal authentication.

method: Specifies an authentication mode.

direct: Specifies direct authentication.

layer3: Specifies cross-subnet authentication.

redhcp: Specifies re-DHCP authentication.

Usage guidelines

To modify the portal authentication mode, first execute the **undo** form of this command to disable portal authentication.

Make sure the device supports IPv6 ACL and IPv6 forwarding before you enable IPv6 portal authentication on the interface.

IPv6 portal authentication does not support the re-DHCP authentication mode.

You can enable both IPv4 portal authentication and IPv6 portal authentication on an interface.

Do not add a portal authentication-enabled Ethernet interface to an aggregation group. Otherwise, portal authentication cannot take effect on the interface.

Examples

Enable direct IPv4 portal authentication on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal enable method direct
```

Related commands

portal extend-auth domain

Use **portal extend-auth domain** to specify the authentication domain for third-party authentication.

Use **undo portal extend-auth domain** to remove the authentication domain for third-party authentication.

Syntax

portal extend-auth domain *domain-name*

undo portal extend-auth domain

Default

No authentication domain is specified for third-party authentication.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies an ISP domain by its name, a case-insensitive string of 1 to 255 characters.

Usage guidelines

The specified ISP domain takes effect only on IPv4 portal users that use third-party authentication.

Make sure the authentication, authorization, and accounting methods in the authentication domain are **none**.

Examples

Specify authentication domain **my-domain** for third-party authentication on GigabitEthernet1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname–GigabitEthernet1/0/1] portal extend-auth domain my-domain
```

portal extend-auth-server

Use **portal extend-auth-server** to create a third-party authentication server and enter its view, or enter the view of an existing third-party authentication server.

Use **undo portal extend-auth-server** to delete a third-party authentication server.

Syntax

portal extend-auth-server { **facebook** | **mail** | **qq** | **wechat** }

undo portal extend-auth-server { **facebook** | **mail** | **qq** | **wechat** }

Default

No third-party authentication servers exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

facebook: Specifies the Facebook authentication server.

mail: Specifies the email authentication server.

qq: Specifies the QQ authentication server.

wechat: Specifies the WeChat authentication server.

Usage guidelines

The device supports using a third-party portal authentication server for portal authentication. A portal user can use a third-party account instead of a portal account to perform portal authentication. If the user passes third-party authentication, the third-party server notifies the third-party authentication success of the user to the device. Then, the device interacts with the local portal Web service to complete the remaining process of portal authentication.

Only direct portal authentication that uses a local portal Web portal service supports third-party authentication.

Examples

Create a QQ authentication server and enter its view.

```
<Sysname> system-view
[Sysname] portal extend-auth-server qq
[Sysname-portal-extend-auth-server-qq]
```

Create an email authentication server and enter its view.

```
<Sysname> system-view
[Sysname] portal extend-auth-server mail
[Sysname-portal-extend-auth-server-mail]
```

Create a WeChat authentication server and enter its view.

```
<Sysname> system-view
[Sysname] portal extend-auth-server wechat
[Sysname-portal-extend-auth-server-wechat]
```

Create a Facebook authentication server and enter its view.

```
<Sysname> system-view
[Sysname] portal extend-auth-server facebook
[Sysname-portal-extend-auth-server-fb]
```

portal fail-permit server

Use **portal fail-permit server** to enable the portal fail-permit feature for a portal authentication server.

Use **undo portal fail-permit server** to disable the portal fail-permit feature for the portal authentication server.

Syntax

portal [**ipv6**] **fail-permit server** *server-name*

undo portal [**ipv6**] **fail-permit server**

Default

Portal fail-permit is disabled for the portal authentication server.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies an IPv6 portal authentication server. Do not specify this keyword for an IPv4 portal authentication server.

server-name: Specifies a portal authentication server by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

On an interface, you can enable portal fail-permit for both the portal authentication server and the portal Web servers.

On an interface enabled with portal fail-permit for a portal authentication server and portal Web servers, portal authentication on the interface is disabled in either of the following conditions:

- All portal Web servers are unreachable.
- The specified portal authentication server is unreachable.

Portal authentication resumes on the interface when the specified portal authentication server and a minimum of one portal Web server becomes reachable. After portal authentication resumes, unauthenticated portal users need to pass authentication to access network resources. Portal users who have passed authentication can continue accessing network resources.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Enable portal fail-permit for portal authentication server **pts1** on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal fail-permit server pts1
```

Related commands

portal forbidden-rule

Use **portal forbidden-rule** to configure a portal-forbidden rule.

Use **undo portal forbidden-rule** to delete portal-forbidden rules.

Syntax

portal forbidden-rule *rule-number* [**source ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*]] **destination** { *host-name* | **ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] }

portal forbidden-rule *rule-number* [**source ipv6** { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*]] **destination** { *host-name* | **ipv6** { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] }

undo portal forbidden-rule { *rule-number* | **all** }

Default

No portal-forbidden rules are configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

rule-number: Specifies the number of a portal-forbidden rule. The value range for this argument is 0 to 4294967295.

source: Specifies the source information.

ip *ipv4-address*: Specifies an IPv4 address.

{ *mask-length* | *mask* }: Specifies the subnet mask of the IPv4 address. The *mask-length* argument represents the length of a subnet mask, in the range of 0 to 32. The *mask* argument represents a subnet mask in dotted decimal notation.

ip any: Specifies any IPv4 address.

tcp *tcp-port-number*: Specifies a TCP port number in the range of 0 to 65535.

udp *udp-port-number*: Specifies a UDP port number in the range of 0 to 65535.

ipv6 *ipv6-address*: Specifies an IPv6 address.

prefix-length: Specifies the prefix length of the IPv6 address, in the range of 0 to 128.

ipv6 any: Specifies any IPv6 address.

host-name: Specifies a destination host by its name, a case-insensitive string of 1 to 253 characters. Valid characters include letters, digits, hyphens (-), underscores (_), and dots (.). The host name cannot be **i**, **ip**, **ipv**, or **ipv6**.

all: Specifies all portal-forbidden rules.

Usage guidelines

Portal-forbidden rules are used to filter user packets from the specified sources or destined for the specified destinations. The device drops user packets that match the portal-forbidden rules.

Portal-forbidden rules take effect only when portal authentication is enabled.

In a portal-forbidden rule, the source and destination IP addresses must be of the same IP type, and the source and destination ports must be of the same transport protocol type.

You can configure multiple portal-forbidden rules.

If the source or destination information in a portal-free rule and that in a portal-forbidden rule overlap, the portal-forbidden rule takes effect.

If you specify a destination host name in a portal-forbidden rule, the device drops users' DNS query packets for the specified host name. In addition, if a DNS server is correctly configured on the device, the device also drops user packets destined for the IP address resolved from the specified host name. If the DNS server is not correctly configured, the rule does not take effect on user packets destined for that IP address.

Examples

Configure portal-forbidden rule 10 to prohibit portal users from accessing website **www.xyz.com**.

```
<Sysname> system-view
[Sysname] portal forbidden-rule 10 source ip any destination www.xyz.com
```

Configure portal-forbidden rule 12 to prohibit the portal user with IP address 1.1.1.1/32 from accessing IP address 2.2.2.2/32.

```
<Sysname> system-view
[Sysname] portal forbidden-rule 12 source ip 1.1.1.1 32 destination ip 2.2.2.2 32
```

Related commands

display portal rule

portal free-all except destination

Use **portal free-all except destination** to configure an IPv4 portal authentication destination subnet on an interface.

Use **undo portal free-all except destination** to delete the IPv4 portal authentication destination subnets on the interface.

Syntax

portal free-all except destination *ipv4-network-address* { *mask-length* | *mask* }

undo portal free-all except destination [*ipv4-network-address*]

Default

No IPv4 portal authentication destination subnet is configured on the interface. Portal users must pass portal authentication to access any subnet.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-network-address: Specifies an IPv4 portal authentication subnet address.

mask-length: Specifies the subnet mask length for the authentication subnet address, in the range of 0 to 32.

mask: Specifies the subnet mask in dotted decimal format.

Usage guidelines

Portal users on the interface are authenticated when accessing the specified authentication destination subnet (except IP addresses and subnets specified in portal-free rules). The users can access other subnets without portal authentication.

If you do not specify the *ipv4-network-address* argument in the **undo portal free-all except destination** command, this commands deletes all IPv4 portal authentication destination subnets on the interface.

Re-DHCP authentication does not support authentication destination subnets.

If you configure both an authentication source subnet and an authentication destination subnet on an interface, only the authentication destination subnet takes effect.

You can repeat this command to configure multiple authentication destination subnets.

Examples

Configure an IPv4 portal authentication destination subnet of **11.11.11.0**/**24** on GigabitEthernet 1/0/1. Portal users need to pass authentication to access this subnet and can access other subnets without authentication.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname–GigabitEthernet1/0/1] portal free-all except destination 11.11.11.0 24
```

Related commands

display portal

portal free-rule

Use **portal free-rule** to configure an IP-based portal-free rule.

Use **undo portal free-rule** to delete portal-free rules.

Syntax

portal free-rule *rule-number* { **destination ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] | **source ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] } * [**interface** *interface-type interface-number*]

portal free-rule *rule-number* { **destination ipv6** { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] | **source ipv6** { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] } * [**interface** *interface-type interface-number*]

undo portal free-rule { *rule-number* | **all** }

Default

No IP-based portal-free rule is configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

rule-number: Specifies a portal-free rule number. The value range for this argument is 0 to 4294967295.

destination: Specifies the destination information.

source: Specifies the source information.

ip *ipv4-address*: Specifies an IPv4 address for the portal-free rule.

{ *mask-length* | *mask* }: Specifies the subnet mask of the IPv4 address. The value range for the *mask-length* argument is 0 to 32. The *mask* argument is in dotted decimal format.

ip any: Represents any IPv4 address.

tcp *tcp-port-number*: Specifies a TCP port number for the portal-free rule, in the range of 0 to 65535.

udp *udp-port-number*: Specifies a UDP port number for the portal-free rule, in the range of 0 to 65535.

ipv6 *ipv6-address*: Specifies an IPv6 address for the portal-free rule.

prefix-length: Specifies the prefix length of the IPv6 address, in the range of 0 to 128.

ipv6 any: Represents any IPv6 address.

all: Specifies all portal-free rules.

interface *interface-type interface-number*: Specifies a Layer 3 interface on which the portal-free rule takes effect.

Usage guidelines

You can specify both the **source** and **destination** keyword for a portal-free rule. If you specify only one keyword, the other keyword does not act as a filtering criterion.

If you specify both a source port number and a destination port number for a portal-free rule, the two port numbers must belong to the same transport layer protocol.

If you do not specify a Layer 3 interface, the portal-free rule takes effect on all portal-enabled interfaces.

You cannot configure two portal-free rules with the same filtering criteria.

Examples

Configure an IPv4-based portal-free rule numbered **1** for GigabitEthernet 1/0/1. In the rule, the source IP address is 10.10.10.1/24, the destination IP address is 20.20.20.1/32, the destination TCP port number is 23.

```
<Sysname> system-view
[Sysname] portal free-rule 1 destination ip 20.20.20.1 32 tcp 23 source ip 10.10.10.1 24
interface gigabitethernet 1/0/1
```

Configure an IPv6-based portal-free rule numbered **2** for GigabitEthernet 1/0/1. In this rule, the source IPv6 address is 2000::1/64, the destination IPv6 address is 2001::1/128, the destination TCP port number is 23.

```
<Sysname> system-view
[Sysname] portal free-rule 2 destination ipv6 2001::1 128 tcp 23 source ipv6 2000::1 64
interface gigabitethernet 1/0/1
```

Related commands

display portal rule

portal free-rule acl

Use **portal free-rule acl** to configure an ACL-based portal-free rule.

Use **undo portal free-rule acl** to delete portal-free rules.

Syntax

portal free-rule *rule-number* **acl** [**ipv6**] *acl-number*

undo portal free-rule { *rule-number* | **all** }

Default

No ACL-based portal-free rules exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

rule-number: Specifies a portal-free rule number. The value range for this argument is 0 to 4294967295.

ipv6: Specifies an IPv6 ACL-based portal-free rule. To configure an IPv4 ACL-based portal-free rule, do not specify this keyword.

acl-number: Specifies an ACL number in the range of 2000 to 3999.

all: Specifies all portal-free rules.

Usage guidelines

The ACL used by a portal-free rule can contain only IP address object groups and IP quintuples (source and destination IP addresses, source and destination port numbers, and transport layer protocol).

If an ACL has already been used by a portal-free rule, you cannot configure another portal-free rule that uses the same ACL.

If the specified ACL does not exist or does not contain rules, all users are allowed to access network resources without passing portal authentication.

If the **vpn-instance** keyword is specified in an ACL rule, the rule applies only to VPN packets. If the **vpn-instance** keyword is not specified in an ACL rule, the rule applies only to public network packets.

Examples

Configure an IPv4 ACL-based portal-free rule numbered **1**. This portal-free rule allows portal user traffic that matches ACL 3001 to pass through without authentication.

```
<Sysname> system-view
[Sysname] portal free-rule 1 acl 3001
```

Configure an IPv6 ACL-based portal-free rule numbered **2**. This portal-free rule allows portal user traffic that matches ACL 3001 to pass through without authentication.

```
<Sysname> system-view
[Sysname] portal free-rule 2 acl ipv6 3001
```

portal free-rule description

Use **portal free-rule description** to configure a description for a portal-free rule.

Use **undo portal free-rule description** to delete the description of a portal-free rule.

Syntax

portal free-rule *rule-number* **description** *text*

undo portal free-rule *rule-number* **description**

Default

No description is configured for a portal-free rule.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

rule-number: Specifies a portal-free rule by its rule number. The value range for this argument is 0 to 4294967295.

text: Specifies the description, a case-sensitive string of 1 to 255 characters.

Examples

Configure a description of **This is IT department** for portal-free rule 2.

```
<Sysname> system-view
[Sysname] portal free-rule 2 description This is IT department
```

portal free-rule destination

Use **portal free-rule destination** to configure a destination-based portal-free rule.

Use **undo portal free-rule** to delete portal-free rules.

Syntax

portal free-rule *rule-number* **destination** *host-name*

undo portal free-rule { *rule-number* | **all** }

Default

No destination-based portal-free rule is configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

rule-number: Specifies a portal-free rule number. The value range for this argument is 0 to 4294967295.

destination: Specifies the destination host.

host-name: Specifies the destination host by its name, a case-insensitive string of 1 to 253 characters. Valid characters are letters, digits, hyphens (-), underscores (_), dots (.), and asterisks (*). The host name string cannot be **i**, **ip**, **ipv**, or **ipv6**.

all: Specifies all portal-free rules.

Usage guidelines

Before you configure destination-based portal-free rules, make sure a DNS server has been deployed in the network.

You can configure a host name in one of the following ways:

- **For exact match**—Specify a complete host name. For example, if you configure the host name as **abc.com.cn** in the portal-free rule, only packets that contain the host name **abc.com.cn** match the rule. Packets that carry any other host names (such as **dfabc.com.cn**) do not match the rule.
- **For fuzzy match**—Specify a host name by placing the asterisk (*) wildcard character at the beginning or end of the host name string. For example, if you configure the host name as ***abc.com.cn, abc***, or ***abc***, packets that carry the host name ending with **abc.com.cn**, starting with **abc**, or including **abc** match the rule.

The asterisk (*) wildcard character represents any characters. The device treats multiple consecutive asterisks as one.

The configured host name cannot contain only asterisks (*).

The fuzzy match feature takes effect only on HTTP or HTTPS requests initiated by Web browsers.

You cannot configure two destination-based portal-free rules with the same destination information. Otherwise the system prompts you that the same rule already exists.

Examples

Configure a destination-based portal-free rule: specify the rule number as **4** and host name as **www.abc.com**. This rule allows the portal user who sends the HTTP/HTTPS request that carries the host name **www.abc.com** to access network resources without authentication.

```
<Sysname> system-view
[Sysname] portal free-rule 4 destination www.abc.com
```

Related commands

display portal rule

portal free-rule source

Use **portal free-rule source** to configure a source-based portal-free rule. The filtering criteria include source MAC address, source interface, and source VLAN.

Use **undo portal free-rule** to delete a specific or all portal-free rules.

Syntax

portal free-rule *rule-number* **source** { **interface** *interface-type interface-number* | **mac** *mac-address* | **object-group** *object-group-name* | **vlan** *vlan-id* } * }

undo portal free-rule { *rule-number* | **all** }

Default

No source-based portal-free rules exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

rule-number: Specifies a portal-free rule number. The value range for this argument is 0 to 4294967295.

interface *interface-type interface-number*: Specifies a source interface by its type and number for the portal-free rule.

mac *mac-address*: Specifies a source MAC address for the portal-free rule, in the form of H-H-H.

object-group *object-group-name*: Specifies a source object group by its name, a case-insensitive string of 1 to 31 characters.

vlan *vlan-id*: Specifies a source VLAN ID for the portal-free rule. This option takes effect only on portal users that access the network through VLAN interfaces.

all: Specifies all portal-free rules.

Usage guidelines

If you specify both the source VLAN and the source Layer 2 interface, the interface must be in the VLAN.

For a source-based portal-free rule to be correctly created, make sure the object group you specified already exists. Only IPv4 address groups and IPv6 address groups are supported.

Examples

Configure a source-based portal-free rule: specify the rule number as **3**, source MAC address as **1-1-1**, and source VLAN ID as **10**. This rule allows the portal user whose source MAC address is 1-1-1 from VLAN 10 to access network resources without authentication.

```
<Sysname> system-view
[Sysname] portal free-rule 3 source mac 1-1-1 vlan 10
```

portal idle-cut dhcp-capture enable

Use **`portal idle-cut dhcp-capture enable`** to enable DHCP packet capture to detect online status of portal users by capturing DHCP packets of the portal users.

Use **`undo portal idle-cut dhcp-capture enable`** to disable DHCP packet capture.

Syntax

`portal idle-cut dhcp-capture enable`

`undo portal idle-cut dhcp-capture enable`

Default

DHCP packet capture is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

context-operator

Usage guidelines

This feature enables the AC to detect the online status of portal users by capturing DHCP packets of the portal users.

When this feature is enabled, the AC captures DHCP packets between a portal user and the DHCP server and obtains the IP address lease information of the user. The AC then detects the online status of the portal user as follows:

- If the AC captures a DHCP lease renewal packet from the portal user before the lease expires, the AC determines that the portal user is online.
- If no DHCP lease renewal packet is captured before the lease expires, the AC forcibly logs out the portal user.

For more information about DHCP packets, see DHCP configuration in *Layer 3—IP Services Configuration Guide*.

The timeout time of the DHCP packet capture timer is the same as the IP address lease time in DHCP packets. This timer resets each time a DHCP packet is captured.

Examples

Enable DHCP packet capture to detect online status of portal users.

```
<Sysname> system-view
[Sysname] portal idle-cut dhcp-capture enable
```

portal ipv6 free-all except destination

Use **portal ipv6 free-all except destination** to configure an IPv6 portal authentication destination subnet on an interface.

Use **undo portal ipv6 free-all except destination** to delete IPv6 portal authentication destination subnets on the interface.

Syntax

portal ipv6 free-all except destination *ipv6-network-address prefix-length*

undo portal ipv6 free-all except destination [*ipv6-network-address*]

Default

No IPv6 portal authentication destination subnet is configured on the interface. Portal users must pass portal authentication to access any IPv6 subnet.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-network-address: Specifies an IPv6 portal authentication destination subnet.

prefix-length: Specifies the prefix length of the IPv6 subnet, in the range of 0 to 128.

Usage guidelines

Portal users on the interface are authenticated when accessing the specified authentication destination subnet (except IP addresses and subnets specified in portal-free rules). The users can access other subnets without portal authentication.

If you do not specify the *ipv6-network-address* argument in the **undo portal ipv6 free-all except destination** command, this command deletes all IPv6 portal authentication destination subnets on the interface.

Re-DHCP authentication does not support authentication destination subnets.

If you configure both an authentication source subnet and an authentication destination subnet on an interface, only the authentication destination subnet takes effect.

You can repeat this command to configure multiple authentication destination subnets.

Examples

Configure an IPv6 portal authentication destination subnet of **1::2/16** on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname–GigabitEthernet1/0/1] portal ipv6 free-all except destination 1::2 16
```

display portal

portal ipv6 layer3 source

Use **portal ipv6 layer3 source** to configure an IPv6 portal authentication source subnet on an interface.

Use **undo portal ipv6 layer3 source** to delete IPv6 portal authentication source subnets on an interface.

Syntax

portal ipv6 layer3 source *ipv6-network-address prefix-length*

undo portal ipv6 layer3 source [*ipv6-network-address*]

Default

No IPv6 portal authentication source subnet is configured on the interface. Portal users from any IPv6 subnet must pass portal authentication.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-network-address: Specifies an IPv6 portal authentication source subnet address.

prefix-length: Specifies the prefix length of the IPv6 address, in the range of 0 to 128.

Usage guidelines

With IPv6 authentication source subnets configured, only packets from IPv6 users on the authentication source subnets can trigger portal authentication. If an unauthenticated IPv6 user is not on any authentication source subnet, the access device discards all the user's packets that do not match any portal-free rule.

If you do not specify the *ipv6-network-address* argument in the **undo portal ipv6 layer3 source** command, this command deletes all IPv6 portal authentication source subnets on the interface.

Only cross-subnet authentication supports authentication source subnets.

If you configure both an authentication source subnet and an authentication destination subnet on an interface, only the authentication destination subnet takes effect.

Examples

Configure an IPv6 portal authentication source subnet of **1::1/16** on GigabitEthernet 1/0/1. Only portal users from subnet 1::1/16 trigger portal authentication.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname–GigabitEthernet1/0/1] portal ipv6 layer3 source 1::1 16
```

portal ipv6 user-detect

Use **portal ipv6 user-detect** to enable online detection of IPv6 portal users.

Use **undo ipv6 portal user-detect** to disable online detection of IPv6 portal users.

Syntax

portal ipv6 user-detect type { **icmpv6** | **nd** } [**retry** *retries*] [**interval** *interval*] [**idle** *time*]

undo portal ipv6 user-detect

Default

Online detection of IPv6 portal users is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

type: Specifies the detection type.

icmpv6: Specifies ICMPv6 detection.

nd: Specifies ND detection.

retry *retries*: Specifies the maximum number of detection attempts, in the range of 1 to 10. The default value is 3.

interval *interval*: Specifies a detection interval in the range of 1 to 1200 seconds. The default interval is 3 seconds.

idle *time*: Specifies the user idle timeout in the range of 60 to 3600 seconds. The default idle timeout is 180 seconds. When the timeout expires, online detection of portal users is started.

Usage guidelines

If the device receives no packets from a portal user within the idle time, the device detects the user's online status as follows:

- **ICMPv6 detection**—Sends ICMPv6 requests to the user at configurable intervals to detect the user status.
  - If the device receives a reply within the maximum number of detection attempts, it considers that the user is online and stops sending detection packets. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the device receives no reply after the maximum number of detection attempts, the device logs out the user.
- **ND detection**—Sends ND requests to the user and detects the ND entry status of the user at configurable intervals.
  - If the ND entry of the user is refreshed within the maximum number of detection attempts, the device considers that the user is online and stops detecting the user's ND entry. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the ND entry of the user is not refreshed after the maximum number of detection attempts, the device logs out the user.

Direct authentication and re-DHCP authentication support both ND detection and ICMPv6 detection. Cross-subnet authentication only supports ICMPv6 detection.

If the access device filters out ICMPv6 packets, ICMPv6 detection might fail and result in the logout of portal users. Make sure the access device does not block ICMPv6 packets before you enable ICMPv6 detection on an interface.

Examples

Enable online detection of IPv6 portal users on GigabitEthernet 1/0/1. Configure the detection type as **ICMPv6**, the maximum number of detection attempts as **5**, the detection interval as **10** seconds, and the user idle timeout as **300** seconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname–GigabitEthernet1/0/1] portal ipv6 user-detect type icmpv6 retry 5 interval 10
idle 300
```

Related commands

display portal

portal layer3 source

Use **portal layer3 source** to configure an IPv4 portal authentication source subnet.

Use **undo portal layer3 source** to delete IPv4 portal authentication source subnets.

Syntax

portal layer3 source *ipv4-network-address* { *mask-length* | *mask* }

undo portal layer3 source [*ipv4-network-address*]

Default

No IPv4 portal authentication source subnet is configured. Portal users from any IPv4 subnet must pass portal authentication.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-network-address: Specifies an IPv4 portal authentication source subnet address.

mask-length: Specifies the subnet mask length of the IPv4 address, in the range of 0 to 32.

mask: Specifies the subnet mask in dotted decimal format.

Usage guidelines

With IPv4 authentication source subnets configured, only packets from IPv4 users on the authentication source subnets can trigger portal authentication. If an unauthenticated IPv4 user is not on any authentication source subnet, the access device discards all the user's packets that do not match any portal-free rule.

If you do not specify the *ipv4-network-address* argument in the **undo portal layer3 source** command, this command deletes all IPv4 portal authentication source subnets on the interface.

Only cross-subnet authentication supports authentication source subnets.

If you configure both an authentication source subnet and an authentication destination subnet on an interface, only the authentication destination subnet takes effect.

Examples

Configure an IPv4 portal authentication source subnet of **10.10.10.0/24** on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname–GigabitEthernet1/0/1] portal layer3 source 10.10.10.0 24
```

Related commands

display portal

portal free-all except destination

portal local-web-server

Use **portal local-web-server** create an HTTP- or HTTPS-based local portal Web service and enter its view, or enter the view of the existing HTTP- or HTTPS-based local portal Web service.

Use **undo portal local-web-server** to delete the HTTP- or HTTPS-based local portal Web service.

Syntax

portal local-web-server { **http** | **https** [**ssl-server-policy** *policy-name*] [**tcp-port** *port-number*] }

undo portal local-web-server { **http** | **https** }

Default

No local portal Web services exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

http: Specifies the HTTP-based local portal Web service, which uses HTTP to exchange authentication information with clients.

https: Specifies the HTTPS-based local portal Web service, which uses HTTPS to exchange authentication information with clients.

ssl-server-policy *policy-name*: Specifies an existing SSL server policy for HTTPS. The policy name is a case-insensitive string of 1 to 31 characters.

tcp-port *port-number*: Specifies the listening TCP port number for the HTTPS-based local portal Web service. The value range for the *port-number* argument is 1 to 65535. The default port number is 443.

Usage guidelines

In the local portal Web service, the access device also acts as the portal Web server and the portal authentication server. No external portal Web server and portal authentication server are needed.

For an interface to use the local portal Web service, the URL of the portal Web server specified for the interface must meet the following requirements:

- The IP address in the URL must be a local IP address on the device.
- The URL must be ended with **/portal/**. For example: **http://1.1.1.1/portal/**.

You cannot delete an SSL server policy by using the **undo ssl server-policy** command when the policy is associated with HTTPS.

To specify a new SSL server policy for HTTPS, first execute the **undo** form of this command to delete the existing HTTPS-based local portal Web service.

When you specify the listening TCP port number for the HTTPS-based local portal Web service, follow these restrictions and guidelines:

- For HTTPS-based local portal Web service and other services that use HTTPS:
  - If they use the same SSL server policy, they can use the same TCP port number to listen to HTTPS.
  - If they use different SSL server policies, they cannot use the same TCP port number to listen to HTTPS.
- Do not configure the HTTPS listening TCP port number as the port number used by a known protocol (except HTTPS) or other service.
- Do not configure the same TCP port number for HTTP-based local portal Web service and HTTPS-based local portal Web service.

Examples

Create an HTTP-based local portal Web service and enter its view.

```
<Sysname> system-view
[Sysname] portal local-web-server http
[Sysname-portal-local-websvr-http] quit
```

Create an HTTPS-based local portal Web service and associate SSL server policy **policy1** with the service.

```
<Sysname> system-view
[Sysname] portal local-web-server https ssl-server-policy policy1
[Sysname-portal-local-websvr-https] quit
```

Change the SSL server policy to **policy2**.

```
[Sysname] undo portal local-web-server https
[Sysname] portal local-web-server https ssl-server-policy policy2
[Sysname-portal-local-websvr-https] quit
```

Create an HTTPS-based local portal Web service. In the service, the associated SSL server policy is **policy1** and the listening port number is 442.

```
<Sysname> system-view
[Sysname] portal local-web-server https ssl-server-policy policy1 tcp-port 442
[Sysname-portal-local-websvr-https] quit
```

portal logout-record enable

Use **portal logout-record enable** to enable portal user offline recording.

Use **undo portal logout-record enable** to disable portal user offline recording.

Syntax

portal logout-record enable

undo portal logout-record enable

Default

Portal user offline recording is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the device to save all portal user offline records and to periodically send the records to the authentication server.

Examples

Enable portal user offline recording.

```
<Sysname> system-view
[Sysname] portal logout-record enable
```

Related commands

display portal logout-record

portal logout-record export

Use **portal logout-record export** to export portal user offline records to a path.

Syntax

portal logout-record export url *url-string* [**start-time** *start-date start-time* **end-time** *end-date end-time*]

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

url *url-string*: Specifies the URL to which portal user offline records are exported. The URL is a case-insensitive string of 1 to 255 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of the *url-string* argument, the CLI does not display help information for this argument.

start-time *start-date start-time* **end-time** *end-date end-time*: Specifies a time range. The start date and end date must be in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for MM is 1 to 12. The value range for DD varies with the specified month. The value range for YYYY is 1970 to 2037. The start time and end time must be in the format of hh:mm. The value range for the start time and end time is 00:00 to 23:59.

Usage guidelines

The device supports FTP, TFTP, and HTTP file transfer methods. Table 34 describes the valid URL format for each method.

Table 34 URL formats

Protocol	URL format	Remarks
FTP	ftp://*username*[:*password*]@*server-address*[:*port-number*]/*file-path* Example: **ftp://a:1@1.1.1.1/authfail/**	The username and password must be the same as those on the server. If the server authenticates only the username, no password is required.
TFTP	tftp://*server-address*[:*port-number*]/*file-path* Example: **tftp://1.1.1.1/ autherror/**	N/A
HTTP	http://*username*[:*password*]@*server-address*[:*port-number*]/*file-path* Example: **http://1.1.1.1/autherror/**	The username and password must be the same as those on the server. If the server authenticates only the username, no password is required.

If the server address is an IPv6 address, bracket the IPv6 address to distinguish the IPv6 address from the port number. For example, if the server address is **2001::1** and the port number is 21, the URL is **ftp://test:test@[2001::1]/test/**.

Examples

Export all portal user offline records to path **tftp://1.1.1.1/record/logout/**.

```
<Sysname> system-view
[Sysname] portal logout-record export url tftp://1.1.1.1/record/logout/
```

Export portal user offline records in the time rang of 2016/3/4 14:20 to 2016/3/4 15:00 to path **tftp://1.1.1.1/record/logout/**.

```
<Sysname> system-view
[Sysname] portal logout-record export url tftp://1.1.1.1/record/logout/ start-time
2016/3/4 14:20 end-time 2016/3/4 15:00
```

Related commands

display portal logout-record

portal logout-record enable

reset portal logout-record

portal logout-record max

Use **portal logout-record max** to set the maximum number of portal user offline records.

Use **undo portal logout-record max** to restore the default.

Syntax

portal logout-record max *number*

undo portal logout-record max

Default

Models	Default
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280	The device supports a maximum of 60000 portal user offline records.
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480,	The device supports a maximum of 24000 portal user offline records.

Models	Default
NFNX3-HDB680, NFNX3-HDB1080	

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the maximum number of portal user offline records.

The following compatibility matrixes show the value ranges for this argument:

Models	Value range
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280,	1 to 60000
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	1 to 24000

Usage guidelines

When the maximum number of portal user offline records is reached, a new record overwrites the oldest one.

Examples

Set the maximum number of portal user offline records to 50.

```
<Sysname> system-view
[Sysname] portal logout-record max 50
```

Related commands

display portal logout-record

portal mac-trigger-server

Use **portal mac-trigger-server** to create a MAC binding server and enter its view, or enter the view of an existing MAC binding server.

Use **undo portal mac-trigger-server** to delete the MAC binding server.

Syntax

portal mac-trigger-server *server-name*

undo portal mac-trigger-server *server-name*

Default

No MAC binding servers exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

server-name: Specifies a MAC binding server name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

After you create a MAC binding server, you can configure MAC binding server parameters, such as the server's IP address and port number.

Examples

Create the MAC binding server **mts** and enter its view.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
[Sysname-portal-mac-trigger-server-mts]
```

Related commands

display portal mac-trigger-server

portal max-user

Use **portal max-user** to set the maximum number of total portal users allowed in the system.

Use **undo portal max-user** to restore the default.

Syntax

portal max-user *max-number*

undo portal max-user

Default

No limit is placed on the total number of portal users allowed in the system.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of total portal users in the system. The value range for this argument is 1 to 4294967295.

Usage guidelines

If you configure the maximum total number smaller than the number of current online portal users on the device, this command still takes effect. The online users are not affected by this command, but the system forbids new portal users to log in.

This command sets the maximum number of online IPv4 and IPv6 portal users in all.

Make sure the maximum combined number of IPv4 and IPv6 portal users specified on all interfaces does not exceed the system-allowed maximum number. Otherwise, the exceeding portal users will not be able to log in to the device.

Examples

Set the maximum number of online portal users allowed in the system to 100.

```
<Sysname> system-view
```

```
[Sysname] portal max-user 100
```

Related commands

display portal user

portal { **ipv4-max-user** | **ipv6-max-user** }

portal nas-id profile

Use **portal nas-id-profile** to specify a NAS-ID profile for an interface.

Use **undo portal nas-id-profile** to restore the default.

Syntax

portal nas-id-profile *profile-name*

undo portal nas-id-profile

Default

No NAS-ID profile is specified for an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

profile-name: Specifies the name of a NAS-ID profile, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A NAS-ID profile defines the binding relationship between VLANs and NAS-IDs. To configure a NAS-ID profile, use the **aaa nas-id profile** command. For more information about the **aaa nas-id profile** command, see "AAA commands."

If an interface is specified with a NAS-ID profile, the interface prefers to use the bindings defined in the profile.

If no NAS-ID profile is specified for an interface or no matching binding is found in the specified profile, the device uses the device name as the interface NAS-ID.

Examples

Specify the NAS-ID profile **aaa** for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname–GigabitEthernet1/0/1] portal nas-id-profile aaa
```

Related commands

aaa nas-id profile

portal nas-port-id format

Use **portal nas-port-id format** to specify the NAS-Port-Id attribute format.

Use **undo portal nas-port-id format** to restore the default.

Syntax

portal nas-port-id format { **1** | **2** | **3** | **4** }

undo portal nas-port-id format

Default

The format for the NAS-Port-Id attribute is format 2.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

1: Uses format 1 for the NAS-Port-Id attribute.

2: Uses format 2 for the NAS-Port-Id attribute.

3: Uses format 3 for the NAS-Port-Id attribute.

4: Uses format 4 for the NAS-Port-Id attribute.

Usage guidelines

The NAS-Port-Id format supported by RADIUS servers varies by vendor. Use this command to specify the format of the NAS-Port-Id attribute in the RADIUS packets sent for portal users to the RADIUS server. The device then automatically constructs a value for the NAS-Port-Id attribute in the specified format to meet the RADIUS server requirements.

Format 1 contains three space-separated strings: *interface-type port-location access-node-id*. Spaces are not allowed within a string.

- The *interface-type* string specifies the interface type of the NAS port. Available options include:
  - **eth**—Common Ethernet interface.
  - **trunk**—Ethernet trunk interface.
  - **0**—The interface type information will be reported by the access node to the BRAS.
- The *port-location* string represents the location of the access line on the BRAS. Its format is NAS_slot/NAS_subslot/NAS_port:XPI.XCI.

Field	Description
NAS_slot	Slot number of the BRAS, in the range of 0 to 31.
NAS_subslot	Subslot number of the BRAS, in the range of 0 to 31.
NAS_Port	Port number of the BRAS, in the range of 0 to 63.
XPI.XCI	For Ethernet interfaces or Ethernet trunk interfaces: • XPI is PVLAN in the range of 0 to 4095. This field is set to 4096 if there is no PVLAN. • XCI is CVLAN in the range of 0 to 4095. This field is set to 4096 if the user is not assigned to a VLAN as in the situation where the end user device is directly connected to a BRAS port.

For the access node to report its access line information to the BRAS, all fields will be set to 0s except for the XPI and XCI fields.

- The *access-node-id* string specifies the attributes the of BRAS. Its format is AccessNodeIdentifier/ANI_rack/ANI_frame/ANI_slot/ANI_subslot/ANI_port:ANI_XPI.ANI_XCI, in which the :ANI_XPI.ANI_XCI portion is optional.

AccessNodeIdentifier	Identifier description of the access node, a string not longer than 50 characters without spaces.
ANI_rack	Rack number of the access node, in the range of 0 to 15.
ANI_frame	Frame number of the access node, in the range of 0 to 31.
ANI_slot	Slot number of the access node, in the range of 0 to 127.
ANI_subslot	Subslot number of the access node, in the range of 0 to 31.
ANI_port	Port number of the access node, in the range of 0 to 255.
ANI_XPI.ANI_XCI	Optional. This field is mainly used to carry CPE-side service information, identifying the further service type requirement. For example, use this field to identify specific services in a multi-PVC scenario. For Ethernet interfaces or Ethernet trunk interfaces: • ANI_XPI is PVLAN in the range of 0 to 4095. This field is set to 4096 if there is no PVLAN. • ANI_XCI is CVLAN in the range of 0 to 4095. This field is set to 4096 if the user is not assigned to a VLAN as in the situation where the end user device is directly connected to a BRAS port.

  If the device does not have rack, frame, or subslot information, 0 is padded in the corresponding field.

- Examples of format 1:

NAS-Port-Id	Description
eth 31/31/7:1234.2345 0/0/0/0/0/0	The subscriber interface type is an Ethernet interface. The slot number is 31, the subslot number is 31, the port number is 7, the PVLAN is 1234, and the CVLAN is 2345. If there is no PVLAN, 1234 will be replaced with 4096.
eth 31/31/7:4096.2345 0/0/0/0/0/0	The subscriber interface type is Ethernet. The slot number is 31, the subslot number is 31, the port number is 7, and the VLAN ID is 2345.
eth 31/31/7:4096.2345 guangzhou001/1/31/63/31/127	The subscriber interface type is Ethernet. The slot number is 31, the subslot number is 31, the port number is 7, and the VLAN ID is 2345. The access node identifier of the DSLAM is guangzhou001, the rack number is 1, the frame number is 31, the slot number is 63, the subslot number is 31, and the port number is 127.

Format 2 is SlotID00IfNOVlanID.

- **SlotID**—Slot number, a string of 2 characters.
- **IfNO**—Slot number, a string of 3 characters.
- **VlanID**—VLAN ID, a string of 9 characters.

Format 3 is SlotID00IfNOVlanIDDHCPoption.

- **SlotID**—Slot number, a string of 2 characters.
- **IfNO**—Interface number, a string of 3 characters.
- **VlanID**—VLAN ID, a string of 9 characters.
- **DHCPoption**—DHCP option 82 is appended for IPv4 users and DHCP option 1 is appended for IPv6 users.

Format 4 is slot=**;subslot=**;port=**;vlanid=**;vlanid2=**.

- For non-VLAN interfaces, the slot=**;subslot=**;port=**;vlanid=0 format is used.
- For interfaces that terminate only the outermost VLAN tag, the slot=**;subslot=**;port=**;vlanid=** format is used.

Examples

Set the format of the NAS-Port-Id attribute to format 1.

```
<Sysname> system-view
[Sysname] portal nas-port-id format 1
```

portal oauth user-sync interval

Use **portal oauth user-sync interval** to set the user synchronization interval for portal authentication using OAuth.

Use **undo portal oauth user-sync interval** to restore the default.

Syntax

portal oauth user-sync interval *interval*

undo portal oauth user-sync interval

Default

The user synchronization interval is 60 seconds for portal authentication using OAuth.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the user synchronization interval, in seconds. The value for this argument can be 0 or in the range of 60 to 3600.

Usage guidelines

If portal authentication uses OAuth, the device periodically reports user information to the portal authentication server for user synchronization on the server. To disable user synchronization from the device to the portal authentication server, set the user synchronization interval to 0 seconds on the device.

Examples

Set the user synchronization interval to 120 seconds for portal authentication using OAuth.

```
<Sysname> system-view
[Sysname] portal oauth user-sync interval 120
```

portal outbound-filter enable

Use **portal outbound-filter enable** to enable outgoing packets filtering.

Use **undo portal outbound-filter enable** to disable outgoing packets filtering.

Syntax

portal [**ipv6**] **outbound-filter enable**

undo portal [**ipv6**] **outbound-filter enable**

Default

Outgoing packets filtering is disabled. A portal-enabled interface can send any packets.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies outgoing IPv6 packets. If you do not specify this keyword, the command is for outgoing IPv4 packets.

Usage guidelines

When you enable this feature on a portal-enabled interface, the device permits the interface to send the following packets:

- Packets whose destination IP addresses are IP addresses of authenticated portal users.
- Packets that match portal-free rules.

Other outgoing packets on the interface are dropped.

Examples

Enable outgoing packets filtering on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal outbound-filter enable
```

portal packet log enable

Use **portal packet log enable** to enable logging for portal protocol packets.

Use undo **portal packet log enable** to disable logging for portal protocol packets.

Syntax

portal packet log enable

undo portal packet log enable

Default

Portal protocol packet logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature logs information about portal protocol packets, including the username, IP address, authentication type, and packet type. For portal log messages to be sent correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Examples

Enable logging for portal protocol packets.

```
<Sysname> system-view
[Sysname] portal packet log enable
```

Related commands

portal redirect log enable

portal user log enable

portal pre-auth domain

Use **portal pre-auth domain** to specify a preauthentication domain for portal users.

Use **undo portal pre-auth domain** to restore the default.

Syntax

portal [**ipv6**] **pre-auth domain** *domain-name*

undo portal [**ipv6**] **pre-auth domain**

Default

No preauthentication domain is specified for portal users.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies IPv6 portal users. Do not specify this keyword for IPv4 portal users.

domain-name: Specifies an existing ISP domain by its name, a case-insensitive string of 1 to 255 characters. The string cannot contain the following characters: slashes (/), backslashes (\), vertical bars (|), quotation marks ("), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), and at signs (@).

Usage guidelines

After you configure a preauthentication domain on a portal-enabled interface, the device authorizes users on the interface as follows:

1. After an unauthenticated user obtains an IP address, the user is assigned with authorization attributes configured for the preauthentication domain.

   The authorization attributes in a preauthentication domain include ACL and CAR.

An unauthenticated user who is authorized with the authorization attributes in a preauthentication domain is called a preauthentication user.

2. After the user passes portal authentication, the user is assigned with new authorization attributes from the AAA server.
3. After the user goes offline, the user is reassigned with the authorization attributes in the preauthentication domain.

Make sure you specify an existing ISP domain as a preauthentication domain. If the specified ISP domain does not exist, the device might operate incorrectly. You must delete a preauthentication domain (by using the **undo portal** [**ipv6**] **pre-auth domain** command) and reconfigure it in the following situations:

- You create the ISP domain after specifying it as the preauthentication domain.
- You delete the specified ISP domain and then re-create it.

The preauthentication domain takes effect only on portal users with IP addresses assigned by DHCP or DHCPv6.

If you change the preauthentication domain on an interface, the interface uses the new preauthentication domain for both new and existing preauthentication users.

If authorization attributes in the preauthentication domain are modified, the modified attributes take effect only on new preauthentication users. Existing preauthentication users use the original authorization attributes.

If both a preauthentication domain and MAC-trigger authentication are configured on the device, set the free-traffic threshold for MAC-trigger authentication to 0 bytes.

Examples

Create preauthentication domain **abc** for VLAN-interface 2.

```
<Sysname> system-view
[Sysname] interface vlan-interface 2
[Sysname-Vlan-interface2] portal pre-auth domain abc
```

Related commands

display portal

portal pre-auth ip-pool

Use **portal pre-auth ip-pool** to specify a preauthentication IP address pool for portal users.

Use **undo portal pre-auth ip-pool** to restore the default.

Syntax

portal [**ipv6**] **pre-auth ip-pool** *pool-name*

undo portal [**ipv6**] **pre-auth ip-pool**

Default

No preauthentication IP address pool is specified for portal users.

Views

Interface view

Parameters

ipv6: Specifies IPv6 portal users. Do not specify this keyword for IPv4 portal users.

pool-name: Specifies an IP address pool by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

You must use this command to specify a preauthentication IP address pool on a portal-enabled Layer 3 interface in the following situation:

- Portal users access the network through a subinterface of the portal-enabled Layer 3 interface.
- The subinterface does not have an IP address.
- Portal users need to obtain IP addresses through DHCP.

DHCP assigns an IP address from the specified IP address pool to a user. Then, the user can use this IP address to perform portal authentication.

The specified IP address pool takes effect only when the direct portal authentication mode is used on the interface.

For the preauthentication IP address pool to take effect, make sure the specified IP address pool exists and has been correctly configured.

Examples

Specify IPv4 address pool **abc** as the preauthentication IP address pool for portal users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal pre-auth ip-pool abc
```

portal redirect log enable

Use **portal redirect log enable** to enable logging for portal redirect.

Use **undo portal redirect log enable** to disable logging for portal redirect.

Syntax

portal redirect log enable

undo portal redirect log enable

Default

Portal redirect logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature logs information about portal redirect packets, including the user IP address, MAC address, BAS IP, and Web server IP address. For portal log messages to be sent correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Examples

Enable logging for portal redirect.

```
<Sysname> system-view
[Sysname] portal redirect log enable
```

Related commands

portal packet log enable

portal user log enable

portal redirect max-session per-user

Use **portal redirect max-session per-user** to set the maximum number of portal redirect sessions for a single user.

Use **undo portal redirect max-session per-user** to disable logging for portal redirect.

Syntax

portal redirect max-session per-user *number*

undo redirect max-session per-user

Default

No limit is set on the number of portal redirect sessions for a single user.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the maximum number of portal redirect sessions for a single user, in the range of 1 to 128.

Usage guidelines

If a user client is attacked by malicious software or viruses, it might initiate a large number of portal redirect sessions. You can configure this command to limit the number of portal redirect sessions that can be established for that user.

The value set by this command applies to the HTTP redirect sessions and HTTPS redirect sessions separately. For example, assume you set the maximum value to 50. Then, a portal user can establish a maximum of 50 HTTP redirect sessions and a maximum of 50 HTTPS redirect sessions.

Examples

Set the maximum number of portal redirect sessions for a single user to 128.

```
<Sysname> system-view
[Sysname] portal redirect max-session per-user 128
```

Related commands

portal redirect max-session

display portal redirect

portal redirect-rule

Use **portal redirect-rule destination** to configure a destination-based portal redirection rule.

Use **undo portal redirect-rule destination** to delete a destination-based portal redirection rule.

Syntax

portal redirect-rule destination { **host** { *host-name* | *ip-address* } | **ipv6** *ipv6-address* } [**redirect-url** *url*]

undo portal redirect-rule destination { **host** { *host-name* | *ip-address* } | **ipv6** *ipv6-address* | **all** }

Default

No destination-based portal redirection rules are configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

host *host-name*: Specifies a destination host by its host name, a case-insensitive string of 1 to 253 characters. Valid characters include letters, digits, hyphens (-), underscores (_), and dots (.).

host *ip-address*: Specifies a destination IPv4 address.

ipv6 *ipv6-address*: Specifies a destination IPv6 address.

redirect-url *url*: Specifies the redirection URL. The device will redirect Web requests destined for the specified destination to the specified redirection URL. The specified URL must be a complete URL starting with http:// or https://, a case-sensitive string of 1 to 256 characters. If you do not specify a redirection URL, the device redirects the user to the redirection URL in a URL redirection match rule (**if-match** rule) that matches the user's Web request. If no matching **if-match** rule is found, the device redirects the user to the URL of the portal Web server.

all: Specifies all destination-based portal redirection rules.

Usage guidelines

The device uses destination-based portal redirection rules to perform URL redirection. If the Web request of a portal user matches the specified destination in a redirection rule, the device redirects the user to the URL specified in the redirection rule.

If the Web request of a portal user matches a destination-based portal redirection rule and a URL redirection match rule (configured by using the **if-match** command), the redirection rule takes effect.

If you specify a host name or IP address in a destination-based portal redirection rule, do not specify a URL that includes the host name or IP address as the redirection URL in another rule. A violation will cause redirect loops.

The system supports a maximum of 10 destination-based portal redirection rules. For the same host or IP address, only one destination-based portal redirection rule is supported.

Examples

Configure a destination-based portal redirection rule to redirect Web requests destined for host **http://www.abc.com.cn** to **http://192.168.0.1**.

```
<Sysname> system-view
[Sysname] portal redirect-rule destination host www.abc.com.cn redirect-url
http://192.168.0.1
```

Related commands

display portal dns redirect-rule-host

portal refresh enable

Use **portal refresh enable** to enable the Rule ARP or ND entry feature for portal clients.

Use **undo portal refresh enable** to disable the Rule ARP or ND entry feature for portal clients.

Syntax

portal refresh { **arp** | **nd** } **enable**

undo portal refresh { **arp** | **nd** } **enable**

Default

The Rule ARP or ND entry feature is disabled for portal clients.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

arp: Enables the Rule ARP entry feature.

nd: Enables the Rule ND entry feature.

Usage guidelines

When the Rule ARP or ND entry feature is enabled for portal clients, ARP or ND entries for portal clients are Rule entries after the clients come online. These entries will not age out and will be deleted immediately after the portal clients go offline. If portal clients go offline and then try to come online before these entries are relearned for them, the clients will fail the authentication. In this case, disable this feature so that ARP or ND entries are dynamic entries after the clients come online. The dynamic ARP or ND entries are deleted only when they age out.

Enabling or disabling of this feature does not affect existing Rule ARP or ND entries for portal users.

Examples

Disable the Rule ARP entry feature for portal clients.

```
<Sysname> system-view
[Sysname] undo portal refresh arp enable
```

portal roaming enable

Use **portal roaming enable** to enable intra-VLAN roaming for portal users.

Use **undo portal roaming enable** to disable intra-VLAN roaming for portal users.

Syntax

portal roaming enable

undo portal roaming enable

Default

Intra-VLAN roaming is disabled for portal users.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

If intra-VLAN roaming is enabled for portal users, an online portal user can access network resources from any Layer 2 port in its local VLAN. If intra-VLAN roaming is disabled for portal users, the portal user can access network resources only from the Layer 2 port on which it passes authentication.

For intra-VLAN roaming for portal users to take effect, you must disable the Rule ARP or ND entry feature by using the **undo portal refresh** { **arp** | **nd** } **enable** command.

Intra-VLAN roaming applies only to portal users that log in from VLAN interfaces.

This command cannot be executed when online users or preauthentication portal users are present on the device.

Examples

Enable intra-VLAN roaming for portal users.

```
<Sysname> system-view
[Sysname] portal roaming enable
```

Related commands

portal refresh enable

portal safe-redirect default-action

Use **portal safe-redirect default-action** to configure the default action for portal safe-redirect.

Use **undo portal safe-redirect default-action** to restore the default.

Syntax

portal safe-redirect default-action { **forbidden** | **permit** }

undo portal safe-redirect default-action

Default

No default action is configured for portal safe-redirect.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

`forbidden`: Sets the default action to forbid, which drops a packet.

`permit`: Sets the default action to permit, which permits a packet.

Usage guidelines

The portal safe-redirect default action rule matches URLs that are not permitted or forbidden by portal safe-redirect, and applies the default action to packets containing the matching URLs.

For this command to take effect, make sure portal safe-redirect is enabled.

Portal safe-redirect matches URL information of a Web request packet in the following order:

1. Matches the HTTP request methods specified for portal safe-redirect.
   - If the packet does not match a specified HTTP request method, the packet is dropped.
   - If the packet matches a specified method or no HTTP request methods are specified for portal safe-redirect, the next step applies.
2. Matches the browser types specified for portal safe-redirect.
   - If the packet does not match a specified browser type, the packet is dropped.
   - If the packet matches a specified browser type or no browser types are specified for portal sate-redirect, the next step applies.
3. Matches the forbidden URLs configured for portal safe-redirect.
   - If the packet matches a forbidden URL, the packet is dropped.
   - If the packet does not match a forbidden URL or no forbidden URLs are configured, the next step applies.
4. Matches the forbidden filename extensions configured for portal safe-redirect.
   - If the packet matches a forbidden filename extension, the packet is dropped.
   - If the packet does not match a forbidden filename extension or no forbidden filename extensions are configured for portal safe-redirect, the next step applies.
5. Matches the permitted URLs configured for portal safe-redirect.
   - If the packet matches a permitted URL, the packet is permitted.
   - If the packet does not match a permitted URL or no permitted URLs are configured for portal safe-redirect, the packet is dropped.
6. Matches the default HTTP request method of portal safe-redirect.
   - If the packet does not match the default HTTP request method, the packet is dropped.
   - If the packet matches the default HTTP request method, the next step applies.
7. Identifies whether browser types are specified portal safe-redirect.
   - If browser types are specified for portal safe-redirect, the packet is permitted.
   - If no browser types are specified for portal safe-redirect, the next step applies.
8. Matches the portal safe-redirect default action rule.
   - If the packet matches the default action rule, the packet is processed according to the default action.
   - If the packet does not match the default action rule or the default action is not configured, the next step applies.

9. Matches the default browser types of portal safe-redirect.
    - If the packet matches a default browser type, the packet is permitted.
    - If the packet does not match a default browser type, the packet is dropped.

Examples

Configure the default action as permit for portal safe-redirect.

```
<Sysname> system-view
[Sysname] portal safe-redirect default-action permit
```

Syntax

portal safe-redirect enable

undo portal safe-redirect enable

Default

The portal safe-redirect feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Portal redirects all HTTP requests except HTTP requests that match portal-free rules to the portal Web server, which might overload the server.

Portal safe-redirect filters HTTP requests by HTTP request method, browser type (in HTTP User Agent), and destination URL, and redirects only the permitted HTTP requests.

As a best practice to avoid server overload and improve security, enable portal safe-redirect on the device.

Examples

Enable the portal safe-redirect feature.

```
<Sysname> system-view
[Sysname] portal safe-redirect enable
```

Related commands

portal safe-redirect forbidden-url

portal safe-redirect method

portal safe-redirect user-agent

portal safe-redirect forbidden-keyword

Use **portal safe-redirect forbidden-keyword** to configure a URL keyword forbidden by portal safe-redirect.

Use **undo portal safe-redirect forbidden-keyword** to delete a portal safe-redirect forbidden URL keyword.

Syntax

portal safe-redirect forbidden-keyword *keyword*

undo portal safe-redirect forbidden-keyword *keyword*

Default

No forbidden URL keywords are configured. The device redirects HTTP requests regardless of the keywords in the URL.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

keyword: Specifies a URL keyword forbidden by portal safe-redirect, a case-insensitive string of 1 to 16 characters.

Usage guidelines

If the URL in an HTTP request of a portal user contains a specified forbidden URL keyword, the device drops the HTTP request.

- If the HTTP request comes from an unauthenticated user, the device does not redirect the user to the portal Web server for authentication.
- If the HTTP request comes from an authenticated user, the device does not redirect the user to the specified redirection webpages (such as an advertisement webpage configured by using the **ad-url** command).

For this command to take effect, make sure portal safe-redirect is enabled.

You can configure multiple portal safe-redirect forbidden URL keywords.

Examples

Specify **.jpg** as a portal safe-redirect forbidden URL keywords.

```
<Sysname> system-view
[Sysname] portal safe-redirect forbidden-keyword .jpg
```

Related commands

display portal safe-redirect statistics

portal safe-redirect enable

portal safe-redirect forbidden-url

Use **portal safe-redirect forbidden-url** to configure a URL forbidden by portal safe-redirect.

Use **undo portal safe-redirect forbidden-url** to delete a portal safe-redirect forbidden URL.

Syntax

portal safe-redirect forbidden-url *user-url-string*

undo portal safe-redirect forbidden-url *user-url-string*

Default

No forbidden URLs are configured. The device can redirect HTTP requests with any URLs.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

user-url-string: Specifies a URL forbidden by portal safe-redirect, a case sensitive string of 1 to 256 characters. Valid characters are letters, digits, hyphens (-), underscores (_), and wildcards (asterisks *). The URL string can include question marks (?). If you enter a question mark (?) in the place of this argument, the CLI does not display help information for this argument.

Usage guidelines

For this command to take effect, make sure portal safe-redirect is enabled.

You can repeat this command to configure multiple portal safe-redirect forbidden URLs. The device does not redirect HTTP requests destined for the specified URLs to the portal Web server.

You can configure a forbidden URL in one of the following ways:

- **For exact match**—Specify a complete URL. For example, if you configure the URL as **abc.com.cn**, only Web requests that contain URL **abc.com.cn** match the rule.
- **For fuzzy match**—Specify a URL by placing the asterisk (*) wildcard character at the beginning or end of the URL string. For example, if you configure the URL as ***abc.com.cn**, **abc***, or ***abc***, Web requests that carry the URL ending with **abc.com.cn**, starting with **abc**, or including **abc** match the rule.
  - The asterisk (*) wildcard character represents any characters. The device treats multiple consecutive asterisks as one.
  - The configured URL cannot contain only asterisks (*).

Examples

Specify **http://www.abc.com** as a portal safe-redirect forbidden URL.

```
<Sysname> system-view
[Sysname] portal safe-redirect forbidden-url http://www.abc.com
```

Related commands

portal safe-redirect enable

portal safe-redirect method

Use **portal safe-redirect method** to specify HTTP request methods permitted by portal safe-redirect.

Use **undo portal safe-redirect method** to delete HTTP request methods permitted by portal safe-redirect.

Syntax

portal safe-redirect method { **get** | **post** }*

undo portal safe-redirect method { **get** | **post** }*

Default

After portal safe-redirect is enabled, the device redirects only HTTP requests with the GET method.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

get: Specifies the GET request method.

post: Specifies the POST request method.

Usage guidelines

After you specify HTTP request methods for portal safe-redirect, the device redirects only the HTTP requests with the specified methods to the portal Web server.

For this command to take effect, make sure portal safe-redirect is enabled.

If you configure this command multiple times, the most recent configuration takes effect.

Examples

Specify the GET request method for portal safe-redirect.

```
<Sysname> system-view
[Sysname] portal safe-redirect method get
```

portal safe-redirect action

portal safe-redirect user-agent

Use **portal safe-redirect user-agent** to specify a browser type for portal safe-redirect.

Use **undo portal safe-redirect user-agent** to delete a browser type for portal safe-redirect.

Syntax

portal safe-redirect user-agent *user-agent-string*

undo portal safe-redirect user-agent *user-agent-string*

Default

After portal safe-redirect is enabled, the device redirects the HTTP packets matching any browser types in Table 35.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

user-agent-string: Specifies a browser type in HTTP User Agent, a case-sensitive string of 1 to 255 characters. You can specify the browser types as shown in Table 35.

Table 35 Browser type and description

Browser type	Description
Safari	Apple browser
Chrome	Google browser
Firefox	Firefox browser
UC	UC browser
QQBrowser	QQ browser
LBBROWSER	Cheetah browser
TaoBrowser	Taobao browser
Maxthon	Maxthon browser
BIDUBrowser	Baidu browser
MSIE 10.0	Microsoft IE 10.0 browser
MSIE 9.0	Microsoft IE 9.0 browser
MSIE 8.0	Microsoft IE 8.0 browser
MSIE 7.0	Microsoft IE 7.0 browser
MSIE 6.0	Microsoft IE 6.0 browser
MetaSr	Sogou browser

Usage guidelines

You can execute this command for multiple times to specify multiple browser types. The device redirects an HTTP request only when its User-Agent string contains a specified browser type.

For this command to take effect, make sure portal safe-redirect is enabled.

Examples

Specify browser types **Chrome** and **Safari** for portal safe-redirect.

```
<Sysname> system-view
[Sysname] portal safe-redirect user-agent Chrome
[Sysname] portal safe-redirect user-agent Safari
```

Related commands

portal safe-redirect enable

portal server

Use **portal server** to create a portal authentication server and enter its view, or enter the view of an existing portal authentication server.

Use **undo portal server** to delete the specified portal authentication server.

Syntax

portal server *server-name*

undo portal server *server-name*

Default

No portal authentication servers exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

server-name: Specifies a portal authentication server by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

In portal authentication server view, you can configure the following parameters and features for the portal authentication server:

- IP address of the server.
- Destination UDP port number used by the device to send unsolicited portal packets to the portal authentication server.
- Pre-shared key for communication between the access device and the server.
- Server detection feature.

You can configure multiple portal authentication servers for an access device.

Examples

Create the portal authentication server **pts** and enter its view.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts]
```

Related commands

display portal server

portal temp-pass enable

Use **portal temp-pass enable** to enable portal temporary pass and set the temporary pass period.

Use **undo portal temp-pass enable** to disable portal temporary pass.

Syntax

portal temp-pass [**period** *period-value*] **enable**

undo portal temp-pass enable

Default

Portal temporary pass is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

period *period-value*: Specifies the temporary pass period. The value range for the *period-value* argument is 10 to 3600 seconds, and the default is 30 seconds.

Usage guidelines

This command is available only for direct portal authentication mode.

Typically, a portal user cannot access the network before passing portal authentication. This feature allows a user to access the Internet temporarily if the user uses a WeChat account to perform portal authentication. During the temporary pass period, the user provides WeChat authentication information to the WeChat server for the server to interact with the access device to finish portal authentication.

Examples

On GigabitEthernet1/0/1, enable portal temporary pass and set the temporary pass period to 25 seconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal temp-pass period 25 enable
```

portal traffic-accounting disable

Use **portal traffic-accounting disable** to disable traffic accounting for portal users.

Use **undo portal traffic-accounting disable** to restore the default.

Syntax

portal traffic-accounting disable

undo portal traffic-accounting disable

Default

Traffic accounting for portal users is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The accounting server might perform time-based or traffic-based accounting, or it might not perform accounting. If the accounting server does not perform traffic-based accounting, disable traffic accounting for portal users on the device. The device will provide quick accounting for portal users, and the traffic statistics will be imprecise. If the accounting server performs traffic-based accounting, enable traffic accounting for portal users. The device will provide precise traffic statistics for portal users.

Examples

Disable traffic accounting for portal users.

```
<Sysname> system-view
[Sysname] portal traffic-accounting disable
```

portal traffic-backup threshold

Use **portal traffic-backup threshold** to set the user traffic backup threshold.

Use **undo portal traffic-backup threshold** to restore the default.

Syntax

portal traffic-backup threshold *value*

undo portal traffic-backup threshold

Default

The user traffic backup threshold is 10 MB.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies the user traffic backup threshold, in MB. The value range for this argument is 0 to 100000. If you set the threshold to 0 MB, the device backs up user traffic in real time.

Usage guidelines

The device backs up traffic for a user when the user's traffic reaches the user traffic backup threshold. A smaller threshold provides more accurate backup for user traffic. However, when a large number of users exist, a small threshold results in frequent user traffic backups, affecting the user online, offline, and accounting processes. Set a proper threshold to balance between service performance and traffic backup accuracy.

Examples

Set the user traffic backup threshold to 10240 MB.

```
<Sysname> system-view
[Sysname] portal traffic-backup threshold 10240
```

portal user log enable

Use **portal user log enable** to enable logging for portal user logins and logouts.

Use **undo portal user log enable** to disable logging for portal user logins and logouts.

Syntax

portal user log enable

undo portal user log enable

Default

Portal user login and logout logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature logs information about portal user login and logout events, including the username, IP address, user's MAC address, interface name, VLAN, and reason for login failure. For portal log messages to be sent correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Examples

Enable logging for portal user logins and logouts.

```
<Sysname> system-view
[Sysname] portal user log enable
```

Related commands

portal user-block failed-times

Use **portal user-block failed-times** to configure the device to block portal users that fail portal authentication.

Use **undo portal user-block failed-times** to configure the device not to block portal users that fail portal authentication.

Syntax

portal user-block failed-times *failed-times* **period** *period* [**method** { **ip** | **mac** | **username** }]

undo portal user-block failed-times

Default

The device does not block portal users that fail portal authentication.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

failed-times: Specifies the maximum number of consecutive authentication failures allowed for a portal user in the specified failure detection period. The value range for this argument is 0 to 10. If you specify value 0 for this argument, the device does not block portal users that fail portal authentication.

period *period*: Specifies the authentication failure detection period, in the range of 1 to 120 minutes.

method: Specifies the method to block portal users that fail portal authentication. If you do not specify this keyword, the device blockes portal users that fail portal authentication by IP address.

ip: Blocks portal users by IP address. If portal users at the same IP address consecutively fail portal authentication for the specified times within the failure detection period, the device blocks the IP address.

mac: Blocks portal users by MAC address. If portal users at the same MAC address consecutively fail portal authentication for the specified times within the failure detection period, the device blocks the MAC address.

username: Blocks portal users by username. If portal users using the same username consecutively fail portal authentication for the specified times within the failure detection period, the device blocks the username.

Usage guidelines

This feature prevents exhaustive password cracking. It blocks a portal user if the user consecutively fails authentication for the specified times within the failure detection period. All authentication requests from the user are dropped by the device till the blocking times out. To set the blocking timeout time, use the **portal user-block reactive** command.

This feature does not block preauthentication portal users.

Examples

Configure the device to block portal users at a MAC address if the users consecutively fail portal authentication twice within 100 minutes.

```
<Sysname> system-view
[Sysname] portal user-block failed-times 2 period 100 method mac
```

Related commands

portal user-block reactive

portal user-block reactive

Use **portal user-block reactive** to set the portal user blocking timeout time.

Use **undo portal user-block reactive** to restore the default.

Syntax

portal user-block reactive *period*

undo portal user-block reactive

Default

The portal user blocking timeout time is 30 minutes.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

period: Specifies the blocking timeout time, in the range of 0 to 1000 minutes. If you specify value 0 for this argument, blocked portal users cannot perform portal authentication again.

Usage guidelines

A portal user is blocked after the user consecutively fails portal authentication for the specified times within the specified failure detection period (set by using the **portal user-block failed-times** command). This user can perform portal authentication again only after the portal user blocking timeout time expires.

Examples

Set the portal user blocking timeout time to 20 minutes.

```
<Sysname> system-view
[Sysname] portal user-block reactive 20
```

Related commands

portal user-block failed-times

portal user-detect

Use **portal user-detect** to enable online detection of IPv4 portal users.

Use **undo portal user-detect** to disable online detection of IPv4 portal users.

Syntax

portal user-detect type { **arp** | **icmp** } [**retry** *retries*] [**interval** *interval*] [**idle** *time*]

undo portal user-detect

Default

Online detection of IPv4 portal users is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

type: Specifies the detection type.

arp: Specifies ARP detection.

icmp: Specifies ICMP detection.

retry *retries*: Specifies the maximum number of detection attempts, in the range of 1 to 10. The default value is 3.

interval *interval*: Specifies a detection interval in the range of 1 to 1200 seconds. The default interval is 3 seconds.

idle *time*: Specifies a user idle timeout in the range of 60 to 3600 seconds. The default idle timeout is 180 seconds. When the timeout expires, online detection of IPv4 portal users is started.

Usage guidelines

If the device receives no packets from a portal user within the configured idle time, the device detects the user's online status as follows:

- **ICMP detection**—Sends ICMP requests to the user at configurable intervals to detect the user status.
  - If the device receives a reply within the maximum number of detection attempts, it considers that the user is online and stops sending detection packets. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the device receives no reply after the maximum number of detection attempts, the device logs out the user.
- **ARP detection**—Sends ARP requests to the user and detects the ARP entry status of the user at configurable intervals.
  - If the ARP entry of the user is refreshed within the maximum number of detection attempts, the device considers that the user is online and stops detecting the user's ARP entry. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the ARP entry of the user is not refreshed after the maximum number of detection attempts, the device logs out the user.

Direct authentication and re-DHCP authentication support both ARP detection and ICMP detection. Cross-subnet authentication only supports ICMP detection.

If the access device filters out ICMP packets, ICMP detection might fail and result in the logout of portal users. Make sure the access device does not block ICMP packets before you enable ICMP detection on an interface.

Examples

Enable online detection of IPv4 portal users on GigabitEthernet 1/0/1. Configure the detection type as **ICMP**, the maximum number of detection attempts as **5**, the detection interval as **10** seconds, and the user idle timeout as **300** seconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname–GigabitEthernet1/0/1] portal user-detect type icmp retry 5 interval 10 idle 300
```

Related commands

display portal

portal user-dhcp-only

Use **portal user-dhcp-only** to allow only users with DHCP-assigned IP addresses to pass portal authentication.

Use **undo portal user-dhcp-only** to restore the default.

Syntax

portal [**ipv6**] **user-dhcp-only**

undo portal [**ipv6**] **user-dhcp-only**

Default

Both users with DHCP-assigned IP addresses and users with static IP addresses can pass portal authentication to come online.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies IPv6 portal users. Do not specify this keyword for IPv4 portal users.

Usage guidelines

CAUTION:

- With this feature enabled, users with static IP addresses cannot pass portal authentication to come online.

Examples

Allow only users with DHCP-assigned IP addresses on GigabitEthernet 1/0/1 to pass portal authentication.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal user-dhcp-only
```

Related commands

display portal

portal user-log traffic-separate

Use **portal user-log traffic-separate** to enable separate IPv4 and IPv6 traffic statistics in portal user offline logs.

Use **undo portal user-log traffic-separate** to restore the default.

Syntax

portal user-log traffic-separate

undo portal user-log traffic-separate

Default

IPv4 and IPv6 traffic statistics of portal users are collectively counted as IPv4 traffic statistics in portal user offline logs. No IPv6 traffic statistics is displayed in portal user offline logs.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

For single-stack users:

- If this feature is enabled, both IPv4 and IPv6 traffic statistics are displayed in user offline logs. For IPv4 users, the IPv6 traffic statistics is displayed as 0. For IPv6 users, the IPv4 traffic statistics is displayed as 0.

- If this feature is disabled, traffic statistics of both IPv4 users and IPv6 users are displayed as IPv4 traffic statistics in portal user offline logs.

For dual-stack users:

- If this feature is enabled, IPv4 and IPv6 traffic statistics of a user are displayed separately in the user offline logs.
- If this feature is disabled, IPv4 and IPv6 traffic statistics of a user are collectively counted as IPv4 traffic statistics in portal user offline logs.

Examples

Enable separate IPv4 and IPv6 traffic statistics in portal user offline logs.

```
<Sysname> system-view
[Sysname] portal user-log traffic-separate
```

portal web-proxy port

Use **portal web-proxy port** to specify the port number of a Web proxy server.

Use **undo portal web-proxy port** to delete port numbers of Web proxy servers.

Syntax

portal web-proxy { **http** | **https** } **port** *port-number*

undo portal web-proxy { { **http** | **https** } **port** *port-number* | **all-port** }

Default

No port numbers of Web proxy servers are specified. Proxied HTTP and HTTPS requests are dropped.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

http: Specifies the HTTP service.

https: Specifies the HTTPS service.

port-number: Specifies the TCP port number of a Web proxy server. The value range for this argument is 1 to 65535. Do not specify TCP port number 80 or 443 because 80 and 443 are port numbers reserved for portal.

all-port: Specifies all port numbers of Web proxy servers.

Usage guidelines

To allow HTTP or HTTPS requests proxied by Web proxy servers to trigger portal authentication, specify the port numbers of the Web proxy servers on the device. If a Web proxy server port is not specified on the device, HTTP or HTTPS requests proxied by the Web proxy server are dropped, and portal authentication cannot be triggered.

You can configure this command multiple times to specify a maximum of 64 Web proxy server ports for HTTP and HTTPS.

Do not specify the same Web proxy server port for HTTP and HTTPS.

If a user's browser uses the Web Proxy Auto-Discovery (WPAD) protocol to discover Web proxy servers, you must perform the following tasks on the device:

- Specify the port numbers of the Web proxy servers on the device.
- Configure portal-free rules to allow user packets destined for the IP address of the WPAD server to pass without authentication.

If portal users enable Web proxy in their browsers, the users must add the IP address of the portal authentication server as a proxy exception in their browsers. Then, HTTP or HTTPS packets that the users send to the portal authentication server will not be sent to Web proxy servers.

Examples

Specify TCP port number 8080 as a Web proxy server port that allows HTTP requests to trigger portal authentication.

```
<Sysname> system-view
[Sysname] portal web-proxy http port 8080
```

Related commands

portal enable method

portal web-server

Use **portal web-server** to create a portal Web server and enter its view, or enter the view of an existing portal Web server.

Use **undo portal web-server** to delete a portal Web server.

Syntax

portal web-server *server-name*

undo portal web-server *server-name*

Default

No portal Web servers exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

server-name: Specifies a portal Web server by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

The portal Web server pushes portal authentication pages to portal users during authentication. The access device redirects HTTP requests of unauthenticated portal users to the portal Web server. In portal Web server view, you can configure the URL and URL parameters for the portal Web server and the portal Web server detection feature.

Examples

Create the portal Web server **wbs** and enter its view.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs]
```

Related commands

portal wifidog user-sync interval

Use **portal wifidog user-sync interval** to enable user information synchronization and set the synchronization interval for portal authentication using WiFiDog.

Use **undo portal wifidog user-sync interval** to disable user information synchronization and cancel the synchronization interval setting for portal authentication using WiFiDog.

Syntax

portal wifidog user-sync interval *interval*

undo portal wifidog user-sync interval

Default

User information synchronization is disabled for portal authentication using WiFiDog.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the user information synchronization interval, in the range of 60 to 1440 minutes.

Usage guidelines

Use this feature when users perform portal authentication using the WiFiDog protocol. This feature enables the device to periodically synchronize user information with the portal server to ensure user information consistency between the device and the portal server.

For this feature to take effect, make sure the type of the portal Web server is Wifidog before you perform this task. To specify the type of the portal Web server, use the **server-type** command.

Examples

Enable user information synchronization and set the synchronization interval to 61 minutes for portal authentication using WiFiDog.

```
<Sysname> system-view
[Sysname] portal wifidog user-sync interval 61
```

Related commands

server-type

portal { bas-ip | bas-ipv6 }

Use **portal** { **bas-ip** | **bas-ipv6** } to configure the BAS-IP or BAS-IPv6 attribute carried in the portal packets sent to the portal authentication server.

Use **undo portal** { **bas-ip** | **bas-ipv6** } to delete the BAS-IP or BAS-IPv6 attribute setting.

Syntax

portal { **bas-ip** *ipv4-address* | **bas-ipv6** *ipv6-address* }

undo portal { **bas-ip** | **bas-ipv6** }

Default

The BAS-IP attribute of an IPv4 portal reply packet sent to the portal authentication server is the source IPv4 address of the packet. The BAS-IPv6 attribute of an IPv6 portal reply packet sent to the portal authentication server is the source IPv6 address of the packet.

The BAS-IP attribute of an IPv4 portal notification packet sent to the portal authentication server is the IPv4 address of the packet's outgoing interface. The BAS-IPv6 attribute of an IPv6 portal notification packet sent to the portal authentication server is the IPv6 address of the packet's outgoing interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

bas-ip *ipv4-address*: Specifies BAS-IP for portal packets sent to the portal authentication server. The *ipv4-address* argument must be the IPv4 address of an interface on the device. It cannot be 0.0.0.0, 1.1.1.1, a class D address, a class E address, or a loopback address.

bas-ipv6 *ipv6-address*: Specifies BAS-IPv6 for portal packets sent to the portal authentication server. The *ipv6-address* argument must be the IPv6 address of an interface on the device. It cannot be a multicast address, an all 0 address, or a link-local address.

Usage guidelines

If the device runs Portal 2.0, unsolicited portal packets (such as a logout notification packet) sent to the portal authentication server must carry the BAS-IP attribute. If the device runs Portal 3.0, unsolicited portal packets sent to the portal authentication server must carry the BAS-IP or BAS-IPv6 attribute.

After this command takes effect, the source IP address for unsolicited notification portal packets the device sends to the portal authentication server is the configured BAS-IP or BAS-IPv6. If the BAS IP address is not configured, the source IP address of the packets is the IP address of the packet output interface.

You must configure the BAS-IP or BAS-IPv6 attribute on a portal authentication-enabled interface if the following conditions are met:

- The portal authentication server is an IMC server or the portal authentication mode on the interface is re-DHCP.
- The portal device IP address specified on the portal authentication server is not the IP address of the portal packet output interface.

Examples

On GigabitEthernet 1/0/1, configure the BAS-IP attribute as **2.2.2.2** for portal packets sent to the portal authentication server.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal bas-ip 2.2.2.2
```

Related commands

display portal

portal { ipv4-max-user | ipv6-max-user }

Use **portal** { **ipv4-max-user** | **ipv6-max-user** } to set the maximum number of portal users allowed on an interface.

Use **undo portal** { **ipv4-max-user** | **ipv6-max-user** } to restore the default.

Syntax

portal { **ipv4-max-user** | **ipv6-max-user** } *max-number*

undo portal { **ipv4-max-user** | **ipv6-max-user** }

Default

No limit is placed on the maximum number of portal users allowed.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of IPv4 or IPv6 portal users allowed on an interface. The value range for this argument is 1 to 4294967295.

Usage guidelines

If the specified maximum number is smaller than the number of current online portal users on the interface, the limit can be set successfully. The limit does not impact the online portal users. However, the device does not allow new portal users to log in from the interface until the number drops down below the limit.

Make sure the maximum combined number of IPv4 and IPv6 portal users specified on all interfaces does not exceed the system-allowed maximum number. Otherwise, the exceeding portal users will not be able to log in to the device.

Examples

Set the maximum number of IPv4 portal users to 100 on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] portal ipv4-max-user 100
```

Related commands

display portal user

portal max-user

redirect-url

Use **redirect-url** to specify the URL to which portal users are redirected after they pass QQ or Facebook authentication.

Use **undo redirect-url** to restore the default.

Syntax

redirect-url *url-string*

undo redirect-url

Default

Portal users are redirected to URLs **http://lvzhou.nsfocus.com.cn/portal/qqlogin.html** and **http://oauthindev.nsfocus.com.cn/portal/fblogin.html** after they pass QQ authentication and Facebook authentication, respectively.

Views

QQ authentication server view

Facebook authentication server view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the URL to which portal users are redirected after they pass QQ or Facebook authentication. The URL is a case-sensitive string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of this argument, the CLI does not display help information for this argument.

Usage guidelines

After a portal user passes QQ or Facebook authentication, the user is redirected to the specified webpage to complete portal authentication.

You must enable DNS proxy and specify the IP address of an interface on the device as the DNS server.

Examples

Configure the device to redirect portal users to URL **http://www.abc.com/portal/qqlogin.html** after they pass QQ authentication.

```
<Sysname> system-view
[Sysname] portal extend-auth-server qq
[Sysname-portal-extend-auth-server-qq] redirect-url
http://www.abc.com/portal/qqlogin.html
```

Configure the device to redirect portal users to URL **http://www.abc.com/portal/qqlogin.html** after they pass Facebook authentication.

```
<Sysname> system-view
[Sysname] portal extend-auth-server qq
[Sysname-portal-extend-auth-server-qq] redirect-url
http://www.abc.com/portal/qqlogin.html
```

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

all: Specifies all portal authentication error records.

ipv4 *ipv4-address*: Specifies the IPv4 address of a portal user.

ipv6 *ipv6-address*: Specifies the IPv6 address of a portal user.

start-time *start-date start-time* **end-time** *end-date end-time*: Specifies a time range. The start date and end date must be in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for MM is 1 to 12. The value range for DD varies with the specified month. The value range for YYYY is 1970 to 2037. The start time and end time must be in the format of hh:mm. The value range for the start time and end time is 00:00 to 23:59.

Examples

Clear all portal authentication error records.

```
<Sysname> reset portal auth-error-record all
```

Clear portal authentication error records of the portal user whose IPv4 address is **11.1.0.1**.

```
<Sysname> reset portal auth-error-record ipv4 11.1.0.1
```

Clear portal authentication error records of the portal user whose IPv6 address is **2000::2**.

```
<Sysname> reset portal auth-error-record ipv6 2000::2
```

Clear portal authentication error records with the error time in the range of 2016/3/4 14:20 to 2016/3/4 16:23.

```
<Sysname> reset portal auth-error-record start-time 2016/3/4 14:20 end-time 2016/3/4 16:23

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

all: Specifies all portal authentication failure records.

ipv4 *ipv4-address*: Specifies the IPv4 address of a portal user.

ipv6 *ipv6-address*: Specifies the IPv6 address of a portal user.

start-time *start-date start-time* **end-time** *end-date end-time*: Specifies a time range. The start date and end date must be in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for MM is 1 to 12. The value range for DD varies with the specified month. The value range for YYYY is 1970 to 2037. The start time and end time must be in the format of hh:mm. The value range for the start time and end time is 00:00 to 23:59.

username *username*: Specifies the username of a portal user, a case-sensitive string of 1 to 253 characters. The username cannot contain the domain name.

Examples

Clear all portal authentication failure records.

```
<Sysname> reset portal auth-fail-record all
```

Clear portal authentication failure records of the portal user whose IPv4 address is **11.1.0.1**.

```
<Sysname> reset portal auth-fail-record ipv4 11.1.0.1
```

Clear portal authentication failure records of the portal user whose IPv6 address is **2000::2**.

```
<Sysname> reset portal auth-fail-record ipv6 2000::2
```

Clear portal authentication failure records of the portal user whose username is **abc**.

```
<Sysname> reset portal auth-fail-record username abc

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

extend-auth-server: Specifies a third-party authentication server by its type.

facebook: Specifies the Facebook authentication server.

cloud: Specifies the cloud authentication server.

mail: Specifies the email authentication server.

qq: Specifies the QQ authentication server.

wechat: Specifies the WeChat authentication server.

mac-trigger-server: Specify a MAC binding server by its name, a case-sensitive string of 1 to 32 characters. If you do not specify a MAC binding server, this command clears packet statistics for the specified portal authentication server.

server *server-name*: Specifies a normal portal authentication server by its name, a case-sensitive string of 1 to 32 characters. If you do not specify this parameter, this command clears packet statistics for the specified MAC binding server.

Usage guidelines

If you do not specify any parameters, this command clears packet statistics for all portal authentication servers and MAC binding servers.

Examples

Clear packet statistics for portal authentication server **pts**.

```
<Sysname> reset portal packet statistics server pts
```

Clear packet statistics for MAC binding server **newps**.

```
<Sysname> reset portal packet statistics mac-trigger-server newpt

server-detect (portal authentication server view)

Use **server-detect** to enable portal authentication server detection. After server detection is enabled for a portal authentication server, the device periodically detects portal packets from the server to identify its reachability status.

Use **undo server-detect** to disable portal authentication server detection.

Syntax

server-detect [**timeout** *timeout*] { **log** | **trap** } *

undo server-detect

Default

Portal authentication server detection is disabled.

Views

Portal authentication server view

Predefined user roles

network-admin

context-admin

Parameters

timeout *timeout*: Specifies the detection timeout in the range of 10 to 3600 seconds. The default is 60 seconds.

log: Enables the device to send a log message when reachability status of the portal authentication server changes. The log message contains the name, the original state, and the current state of the portal authentication server.

trap: Enables the device to send a trap message to the NMS when reachability status of the portal authentication server changes. The trap message contains the name and the current state of the portal authentication server.

Usage guidelines

The portal authentication server detection feature takes effect only when the device has a portal-enabled interface.

To test server reachability by detecting heartbeat packets, you must enable the server heartbeat feature on the portal authentication server. Only the IMC portal authentication server supports sending heartbeat packets.

The detection timeout configured on the device must be greater than the server heartbeat interval configured on the portal authentication server.

If the device receives portal packets from the portal authentication server before the detection timeout expires and verifies the correctness of the packets, the device considers the portal authentication server is reachable. Otherwise, the device considers the portal authentication server is unreachable.

Examples

Enable server detection for the portal authentication server **pts**:

- Set the detection timeout to **600** seconds.
- Configure the device to send a log message if the server reachability status changes.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] server-detect timeout 600 log
```

Related commands

portal server

server-detect (portal Web server view)

Use **server-detect** to enable portal Web server detection.

Use **undo server-detect** to disable portal Web server detection.

Syntax

server-detect [**interval** *interval*] [**retry** *retries*] { **log** | **trap** } *

undo server-detect

Default

Portal Web server detection is disabled.

Views

Portal Web server view

Predefined user roles

network-admin

context-admin

Parameters

interval *interval*: Specifies a detection interval in the range of 1 to 1200 seconds. The default is 5 seconds. As a best practice, set the detection interval to a value no less than 5.

retry *retries*: Specifies the maximum number of consecutive detection failures, in the range of 1 to 10. The default is 3. If the number of consecutive failed detections reaches this threshold, the device considers the server as unreachable.

log: Enables the device to send a log message when reachability status of the portal Web server changes. The log message contains the name, the original state, and the current state of the portal Web server.

trap: Enables the device to send a trap message to the NMS when reachability status of the portal Web server changes. The trap message contains the name and the current state of the portal Web server.

Usage guidelines

The access device performs server detection independently. No configuration on the portal Web server is required for the detection.

The portal Web server detection feature takes effect only when the URL of the portal Web server is specified and the device has a portal-enabled interface.

Examples

Enable server detection for the portal Web server **wbs**:

- Set the detection interval to **600** seconds.
- Set the maximum number of consecutive detection failures to 2.
- Configure the device to send a log message and a trap massage after server reachability status changes.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] server-detect interval 600 retry 2 log trap
```

Related commands

portal web-server

server-detect url

Use **server-detect url** to configure the URL and the type for portal Web server detection.

Use **undo server-detect url** to restore the default.

Syntax

server-detect url *string* [**detect-type** { http | tcp }]

undo server-detect url

Default

The URL for portal Web server detection is the URL of the portal Web server. The type of portal Web server detection is TCP detection.

Views

Portal Web server view

Predefined user roles

network-admin

context-admin

Parameters

string: Specifies a URL to detect the reachability of the portal Web server. The URL is a case-sensitive string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of this argument, the CLI does not display help information for this argument.

detect-type: Specifies the type of portal Web server detection. If this keyword is not specified, TCP detection is used.

tcp: Specifies the TCP detection.

http: Specifies the HTTP detection.

Usage guidelines

This configuration takes effect only when portal Web server detection is enabled.

Examples

Configure **http://www.test.com/portal** as the portal Web server detection URL.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] server-detect url http://www.test.com/portal
```

Configure **http://www.test.com/portal** as the portal Web server detection URL and specify TCP as the detection type.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] server-detect url http://www.test.com/portal detect-type tcp
```

Configure **http://www.test.com/portal** as the portal Web server detection URL and specify HTTP as the detection type.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] server-detect url http://www.test.com/portal detect-type
http
```

server-detect (portal Web server view)

server-register

Use **server-register** to configure the device to periodically send register packets to the portal authentication server.

Use **undo server-register** to restore the default.

Syntax

server-register [**interval** *interval*]

undo server-register

Default

The device does not send register packets to a portal authentication server.

Views

Portal authentication server view

Predefined user roles

network-admin

context-admin

Parameters

interval *interval*: Specifies the interval at which the device sends register packets to the portal authentication server, in seconds. The value range for the *interval* argument is 1 to 3600, and the default value is 600.

Usage guidelines

This feature is typically used in scenarios where a NAT device exists between a portal authentication server and a large number of access devices.

Before this feature is used, you must configure a static NAT mapping for each access device on the NAT device, causing much workload. After this feature is enabled on an access device, the access device automatically sends a register packet to the portal authentication server. When the server receives the register packet, it records register information for the access device, including the device name, and the IP address and port number after NAT. The register information is used for subsequent authentication information exchanges between the server and the access device. The access device updates its register information on the server by sending register packets at regular intervals.

Only CMCC portal authentication servers support this feature.

Examples

Configure the device to send register packets to portal authentication server **pts** at intervals of 120 seconds.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] server-register interval 120
```

Related commands

server-type (portal authentication server view/portal Web server view)

server-type (MAC binding server view)

Use **server-type** to specify the type of a MAC binding server.

Use **undo server-type** to restore the default.

Syntax

server-type { **cmcc** | **imc** }

undo server-type

Default

The type of the MAC binding server is IMC.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Parameters

cmcc: Specifies the MAC binding server type as CMCC.

imc: Specifies the MAC binding server type as IMC.

Examples

Specify the type of the MAC binding server as **cmcc**.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
[Sysname-portal-mac-trigger-server-mts] server-type cmcc
```

server-type (portal authentication server view/portal Web server view)

Use **server-type** to specify the type of a portal authentication server or portal Web server.

Use **undo server-type** to restore the default.

Syntax

server-type { **cmcc** | **imc** | **ise** | **oauth** | **wifidog** }

undo server-type

Default

The type of the portal authentication server and portal Web server is IMC.
