ise: Specifies the portal server type as ISE. This keyword is supported only in portal Web server view.

oauth: Specifies the portal server type as the cloud platform. This keyword is supported only in portal Web server view.

wifidog: Specifies the server type as WiFiDog. This keyword is supported only in portal Web server view.

Usage guidelines

Specify the portal server type on the device with the server type the device actually uses.

Examples

Specify the type of the portal authentication server as **cmcc**.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] server-type cmcc
```

Specify the type of the portal Web server as **cmcc**.

```
<Sysname> system-view
[Sysname] portal web-server pts
[Sysname-portal-websvr-pts] server-type cmcc
```

Related commands

display portal server

shop-id

Use **shop-id** to specify the shop ID for WeChat authentication.

Use **undo shop-id** to restore the default.

Syntax

shop-id *shop-id*

undo shop-id

Default

No shop ID is specified for WeChat authentication.

Views

WeChat authentication server view

Predefined user roles

network-admin

context-admin

Parameters

shop-id: Specifies the ID of the shop where the device is deployed as a portal device for WeChat authentication.

Usage guidelines

This configuration is required for the device to provide local WeChat authentication for portal users.

To obtain the shop ID for WeChat authentication, you must perform the following tasks:

1. Go to the WeChat Official Account Admin Platform (**https://mp.weixin.qq.com**) to apply a WeChat official account.
2. Use the account to log in to the platform and enable the WeChat WiFi hotspot feature.
3. Click the device management tab, add the device: select the shop where the device is deployed, select the **portal** device type, and enter the device settings.

After the previous configurations, you will obtain the credentials (app ID, app key, and shop ID) for WeChat authentication.

When a WeChat user attempts to connect to the WiFi network provided in the specified shop, the device sends the credentials to the WeChat Official Account Platform for verification. After the credentials are verified, the device continues the portal authentication and allows the user to use the WiFi network after the authentication.

The shop ID specified in this command must be the same as the shop ID obtained from the WeChat Official Account Admin Platform.

Examples

Specify **6747662** as the shop ID for WeChat authentication.

```
<Sysname> system-view
[Sysname] portal extend-auth-server wechat
[Sysname-portal-extend-auth-server-wechat] shop-id 6747662
```

Related commands

display portal extend-auth-server

subscribe-required enable

Use **subscribe-required enable** to enable the subscribe-required feature for WeChat authentication.

Use **undo subscribe-required enable** to disable the subscribe-required feature for WeChat authentication.

Syntax

subscribe-required enable

undo subscribe-required enable

Default

The subscribe-required feature is disabled for WeChat authentication.

Views

WeChat authentication server view

Predefined user roles

network-admin

context-admin

Usage guidelines

When the subscribe-required feature is enabled, portal users must follow WeChat official accounts to pass WeChat authentication.

This feature must be used with the portal temporary pass feature. As a best practice, set the temporary pass period to 600 seconds.

Examples

Enable the subscribe-required feature for WeChat authentication.

```
<Sysname> system-view
[Sysname] portal extend-auth-server wechat
[Sysname-portal-extend-auth-server-wechat] subscribe-required enable
```

tcp-port

Use **tcp-port** to configure a listening TCP port for a local portal Web service.

Use **undo tcp-port** to restore the default.

Syntax

tcp-port *port-number*

undo tcp-port

Default

The listening TCP port number for HTTP is 80 and that for HTTPS is the TCP port number set by using the **portal local-web-server** command.

Views

Local portal Web service view

Predefined user roles

network-admin

context-admin

Parameters

port-number: Specifies the listening TCP port number in the range of 1 to 65535.

Usage guidelines

To use the local portal Web service, make sure the port number in the portal Web server URL and the port number configured in this command are the same.

For successful local portal authentication, follow these guidelines:

- Do not configure the listening TCP port number for a local portal Web service as the port number used by a known protocol. For example, do not specify port numbers 21 and 23, which are used by FTP and Telnet, respectively.
- Do not configure the HTTP listening port number as the default HTTPS listening port number 443.
- Do not configure the HTTPS listening port number as the default HTTP listening port number 80.
- Do not configure the same listening port number for HTTP and HTTPS.
- For the HTTPS-based local portal Web service and other services that use HTTPS:
  - If they use the same SSL server policy, they can use the same TCP port number to listen to HTTPS.
  - If they use different SSL server policies, they cannot use the same TCP port number to listen to HTTPS.

Examples

Set the listening port number to 2331 for the HTTP-based local portal Web service.

```
<Sysname> system-view
[Sysname] portal local-web-server http
[Sysname-portal-local-websvr-http] tcp-port 2331
```

Related commands

portal local-web-server

url

Use **url** to specify a URL for a portal Web server.

Use **undo url** to restore the default.

Syntax

url *url-string*

undo url

Default

No URL is specified for a portal Web server.

Views

Portal Web server view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies a URL for the portal Web server, a case-sensitive string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of this argument, the CLI does not display help information for this argument.

Usage guidelines

This command specifies a URL that can be accessed through standard HTTP or HTTPS. The URL should start with **http://** or **https://**. If the URL you specify does not start with **http://** or **https://**, the system considers the URL begins with **http://** by default.

Examples

Configure the URL for the portal Web server **wbs** as **http://www.test.com/portal**.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] url http://www.test.com/portal
```

Related commands

display portal web-server

url-parameter

Use **url-parameter** to configure the parameters carried in the URL of a portal Web server. The access device redirects a portal user by sending the URL with the parameters to the user.

Use **undo url-parameter** to delete the parameters carried in the URL of the portal Web server.

Syntax

url-parameter *param-name* { **nas-id** | **nas-port-id** | **original-url** | **source-address** | **source-mac** [**format section** { **1** | **3** | **6** } { **lowercase** | **uppercase** }] [**encryption** { **aes** | **des** } **key** { **cipher** | **simple** } *string*] | **value** *expression* | **vlan** }

undo url-parameter *param-name*

Default

No URL parameters are configured for a portal Web server.

Views

Portal Web server view

Predefined user roles

network-admin

context-admin

Parameters

param-name: Specifies a URL parameter name, a case-sensitive string of 1 to 32 characters. Content of the parameter is determined by the following keyword you specify.

nas-id: Specifies the NAS-ID.

nas-port-id: Specifies the NAS-Port-ID.

original-url: Specifies the URL of the original webpage that a portal user visits.

source-address: Specifies the user IP address.

source-mac: Specifies the user MAC address.

format: Specifies the format of the MAC address.

section: Specifies the number of sections that a MAC address contains.

1: Specifies the one-section format XXXXXXXXXXXX.

3: Specifies the three-section format XXXX-XXXX-XXXX.

6: Specifies the six-section format XX-XX-XX-XX-XX-XX.

lowercase: Specifies the letters in a MAC address to be in lower case.

uppercase: Specifies the letters in a MAC address to be in upper case.

encryption: Specifies the encryption algorithm to encrypt the MAC address of the device oruser.

aes: Specifies the AES algorithm.

des: Specifies the DES algorithm.

key: Specifies a key for encryption.

cipher: Specifies a key in encrypted form.

simple: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the case-sensitive key string. The string length varies by the selected encryption method:

- If **des cipher** is specified, the string length is 41 characters.
- If **des simple** is specified, the string length is 8 characters.
- If **aes cipher** is specified, the string length is 1 to 73 characters.
- If **aes simple** is specified, the string length is 1 to 31 characters.

value *expression*: Specifies a custom case-sensitive string of 1 to 256 characters. The string can include question marks (?). If you enter a question mark (?) in the place of the *expression* argument, the CLI does not display help information for this argument.

vlan: Specifies the user VLAN ID.

Usage guidelines

You can configure multiple URL parameters.

To avoid redirection failure, add only necessary URL parameters to the portal Web server URL. Ensure that the total length of the portal Web server URL is no longer than 2048 bytes.

If you execute this command multiple times to configure the same URL parameter, the most recent configuration takes effect.

After you configure the URL parameters, the access device sends the portal Web server URL with these parameters to portal users. For example, assume that the URL of a portal Web server is **http://www.test.com/portal**, and you execute the **url-parameter userip source-address** and **url-parameter userurl value http://www.abc.com/welcome** commands. Then, the access device sends to the user whose IP address is 1.1.1.1 the URL **http://www.test.com/portal?userip=1.1.1.1&userurl=http://www.abc.com/welcome**.

When you configure the *param-name* argument in this command, you must use the URL parameter name supported by the actual portal server. Different portal server types support different URL parameter names.

For example, the IMC server supports parameter names **userurl**, **userip**, and **usermac** for the keywords **original-url**, **source-address**, and **source-mac**, respectively. To carry the user IP information in the portal Web server URL, you must configure the parameter name as **userip** and specify the **source-address** keyword.

If you specify the encryption algorithm for a parameter, the redirection URL carries the encrypted value for the parameter. Execute the **url-parameter usermac source-mac encryption des key simple 12345678** command. Then, the access device sends to the user with MAC address 1111-1111-1111 the URL **http://www.test.com/portal?usermac=xxxxxxxxx&userip=1.1.1.1&userurl= http://www.test.com/welcome**, where xxxxxxxxx represents the encrypted user MAC address.

Examples

Configure URL parameters **userip** and **userurl** for portal Web server **wbs**. Configure the value of the **userip** parameter as **source-address** (the IP addresses of users) and that of the **userurl** parameter as **http://www.abc.com/welcome**.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] url-parameter userip source-address
[Sysname-portal-websvr-wbs] url-parameter userurl value http://www.abc.com/welcome
```

Configure URL parameter **usermac** for portal Web server **wbs**. Configure the value of the **usermac** parameter as **source-mac** (the MAC addresses of users) and specify DES to encrypt the MAC addresses.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] url-parameter usermac source-mac encryption des key simple
12345678
```

Configure URL parameter **uservlan** for portal Web server **wbs**. Configure the value of the **uservlan** parameter as **vlan** (the VLAN IDs of users.)

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] url-parameter uservlan vlan
```

Related commands

url

user-agent

Use **user-agent** to configure the User-Agent match string.

Use **undo user-agent** to restore the default.

Syntax

user-agent *user-agent-string*

undo user-agent

Default

The User-Agent match string is **MicroMessenger**.

Views

Local portal Web service view

Predefined user roles

network-admin

context-admin

Parameters

user-agent-string: Specifies the User-Agent match string, a case-sensitive string of 1 to 255 characters.

Examples

Configure the User-Agent match string as **text**.

```
<Sysname> system-view
[Sysname] portal local-web-server http
[Sysname-portal-local-websvr-http] user-agent text
```

user-password modify enable

Use **user-password modify enable** to enable local portal user password modification.

Use **undo user-password modify enable** to disable local portal user password modification.

Syntax

user-password modify enable

undo user-password modify enable

Default

Local portal user password modification is disabled.

Views

Local portal Web service view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the local portal Web service to display the password modification button on the portal authentication page. Local portal users can change their passwords through this button.

If global password control is enabled by using the **password-control enable network-class** command, the new password of a local portal user must meet the password control requirements. For more information about password control, see password control configuraiton in *Security Configuration Guide*.

Examples

In local portal Web service view, enable local portal user password modification.

```
<Sysname> system-view
[Sysname] portal local-web-server http
[Sysname-portal-local-websvr-http] user-password modify enable
```

Related commands

password-control enable network-class

portal local-web-server

user-sync

Use **user-sync** to enable portal user synchronization for a portal authentication server.

Use **undo user-sync** to disable portal user synchronization for a portal authentication server.

Syntax

user-sync timeout *timeout*

undo user-sync

Default

Portal user synchronization is disabled for a portal authentication server.

Views

Portal authentication server view

Predefined user roles

network-admin

context-admin

Parameters

timeout *timeout*: Specifies a detection timeout for synchronization packets, in the range of 60 to 18000 seconds.

Usage guidelines

This feature enables the device to reply to and periodically detect the synchronization packets from the portal authentication server. In this way, information about online portal users on the device and on the portal authentication server remains consistent.

- For information of the users considered as nonexistent on the portal authentication server, the device deletes the information after the configured detection timeout expires.
- If the user information from the portal authentication server does not exist on the device, the device encapsulates IP addresses of the users in user heartbeat reply packets to the server. The portal authentication server then deletes the users.

Portal user synchronization requires that the portal authentication server support the portal user heartbeat feature. Now, only the IMC portal authentication server supports portal user heartbeat. To implement portal user synchronization, you need to configure the user heartbeat feature on the portal authentication server. Make sure the user heartbeat interval configured on the portal authentication server is not greater than the synchronization detection timeout configured on the access device.

Deleting a portal authentication server on the device also deletes the user synchronization configuration for the server.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Enable portal user synchronization for the portal authentication server **pts** and set the detection timeout to **600** seconds. If a use has not appeared in the synchronization packets sent by the portal authentication server for 600 seconds, the access device logs out the user.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] user-sync timeout 600
```

Related commands

portal server

version

Use **version** to specify the version of the portal protocol.

Use **undo version** to restore the default.

Syntax

version *version-number*

undo version

Default

The version of the portal protocol is 1.

Views

MAC binding server view

Predefined user roles

network-admin

context-admin

Parameters

version-number: Specifies the portal protocol version in the range of 1 to 3.

Usage guidelines

The specified portal protocol version must be the that required by the MAC binding server.

Examples

Configure the device to use portal protocol version 2 to communicate with the MAC binding server **mts**.

```
<Sysname> system-view
[Sysname] portal mac-trigger-server mts
[Sysname-portal-mac-trigger-server-mts] version 2
```

Related commands

vpn-instance

Use **vpn-instance** to specify the MPLS L3VPN where a portal Web server resides.

Use **undo vpn-instance** to restore the default.

Syntax

vpn-instance *vpn-instance-name*

undo vpn-instance

Default

A portal Web server is on the public network.

Views

Portal Web server view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance-name: Specifies the name of the MPLS L3VPN where the portal Web server resides, a case-sensitive string of 1 to 31 characters.

Usage guidelines

A portal Web server belongs to only one MPLS L3VPN.

Examples

Configure the MPLS L3VPN for the portal Web server **wbs** as **abc**.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] vpn-instance abc
```

web-redirect url

Use **web-redirect url** to enable the Web redirect feature.

Use **undo web-redirect url** to disable the Web redirect feature.

Syntax

web-redirect [**ipv6**] **url** *url-string* [**interval** *interval*]

undo web-redirect [**ipv6**]

Default

The Web redirect feature is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies the IPv6 Web redirect feature. Do not specify this keyword for the IPv4 Web redirect feature.

url *url-string*: Specifies the URL to which the user is redirected, a string of 1 to 256 characters. The URL must exist and must be a complete URL beginning with **http://** or **https://**. The URL string can include question marks (?). If you enter a question mark (?) in the place of the *url-string* argument, the CLI does not display help information for this argument.

interval *interval*: Specifies the time interval at which the user is redirected to the specified URL. It is in the range of 60 to 86400 seconds. The default interval is 86400 seconds.

Usage guidelines

This feature redirects a user on an interface to the specified URL before the user can access an external network through a Web browser. After the specified interval, the user is redirected to the specified URL again.

The Web redirect feature takes effect only on HTTP packets that use the default port number 80.

To use the device URL as the Web redirect URL or allow users to successfully access the device URL, you must enable the HTTP service. To enable the HTTP service, use the **ip http enable** command.

To push different advertisement pages to different users, you can carry parameters in the redirect URL (by using the **url** *url-string* option) as needed. The following parameters are available:

- **userip=%c**—IP address of the user.
- **usermac=%m**—MAC address of the user.
- **nasid=%n**—NAS identifier of the device.
- **ssid=%E**—SSID with which the user associates.
- **originalurl=%o**—Original URL that the user enters in the browser.

Make sure the arrangement of the parameters conforms to the format of http://XXXX/index.html?userip=%c&usermac=%m&nasid=%n&ssid=%E&originalurl=%o.

Examples

Configure IPv4 Web redirect on GigabitEthernet 1/0/1. Set the redirect URL to **http://192.0.0.1 /index.html?userip=%c&usermac=%m&nasid=%n&ssid=%E&originalurl=%o** and the interval to 3600 seconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] web-redirect url http://192.0.0.1
/index.html?userip=%c&usermac=%m&nasid=%n&ssid=%E&originalurl=%o interval 3600
```

MAC authentication commands

display mac-authentication

Use **display mac-authentication** to display MAC authentication settings and statistics.

Syntax

display mac-authentication [**ap** *ap-name* [**radio** *radio-id*] | **interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ap *ap-name*: Specifies an AP by its name, a case-sensitive string of 1 to 64 characters. The string can contain letters, digits, underscores (_), dots (.), left brackets ([), right brackets (]), forward slashes (/), and hyphens (-).

radio *radio-id*: Specifies a radio by its ID. The value range for the *radio-id* argument varies by AP model. If you do not specify a radio, this command displays MAC authentication information for all radios on the specified AP.

interface *interface-type interface-number*: Specifies a port by its type and number. If the specified port is not enabled with MAC authentication, this command displays only global MAC authentication information.

Usage guidelines

If you do not specify any parameters, this command displays all MAC authentication information including the global settings, port-specific settings, MAC authentication statistics, and online user statistics.

Examples

Display all MAC authentication settings and statistics.

```
<Sysname> display mac-authentication
Global MAC authentication parameters:
   MAC authentication     : Enabled
   User name format       : MAC address in lowercase(xx-xx-xx-xx-xx-xx)
           Username       : mac
           Password       : Not configured
   Offline detect period  : 300 s

Table 1 Command output

Field	Description
MAC authentication	Whether MAC authentication is enabled globally. Support for MAC authentication depends on the device model. The MAC authentication configuration does not take effect on some device models.
User name format	User account type: MAC-based or shared. • If MAC-based accounts are used, this field displays the format settings for the username. For example, **MAC address in lowercase(xx-xx-xx-xx-xx-xx)** indicates that the MAC address is in six-section format, and letters are in lower case. • If a shared account is used, this field displays **Fixed account**.
Username	Username for MAC authentication. • If MAC-based accounts are used, this field displays **mac**. The device uses the MAC address of each user as the username

Field	Description
	and password for MAC authentication. • If a shared account is used, this field displays the username of the shared account for MAC authentication users. By default, the username is **mac**.
Password	Password for MAC authentication. • If MAC-based accounts are used or if a shared account is used but no password is configured, this field displays **Not configured**. • If a shared account is used and a password is configured, this field displays a string of asterisks (******).
Offline detect period	Offline detect timer.
Quiet period	Quiet timer.
Server timeout	Server timeout timer.
Authentication domain	MAC authentication domain specified in system view. If no authentication domain is specified in system view, this field displays **Not configured, use default domain**.
Online MAC-auth wired users	Number of wired online MAC authentication users, including users that have passed MAC authentication and users that are performing MAC authentication.
Silent MAC users	Information about silent MAC addresses.
MAC address	Silent MAC address.
VLAN ID	ID of the VLAN to which the silent MAC address belongs.
From port	Name of the port that marks the MAC address as a silent MAC address.
Port index	Index of the port that marks the MAC address as a silent MAC address.
GigabitEthernet1/0/1 is link-up	Status of the link on GigabitEthernet 1/0/1. In this example, the link is up.
MAC authentication	Whether MAC authentication is enabled on the port.
Carry User-IP	This field is not supported in the current software version. Whether user IP addresses are included in MAC authentication requests.
Authentication domain	MAC authentication domain specified for the port.
Auth-delay timer	Whether MAC authentication delay is enabled on the port.
Auth-delay period	MAC authentication delay timer.
Re-auth server-unreachable	Action taken when no server is reachable for MAC reauthentication: • **Logoff**—Logs off online MAC authentication users. • **Online**—Keeps MAC authenticated users online.
Guest VLAN	MAC authentication guest VLAN configured on the port. If no MAC authentication guest VLAN is configured, this field displays **Not configured**.
Guest VLAN auth-period	Authentication interval for users in the MAC authentication guest VLAN on the port.
Critical VLAN	MAC authentication critical VLAN configured on the port.

Field	Description
	If no MAC authentication critical VLAN is configured, this field displays **Not configured**.
Critical voice VLAN	This field is not supported in the current software version. Whether the MAC authentication critical voice VLAN feature is enabled on the port.
Host mode	• If multi-VLAN mode is enabled, this field displays **Multiple VLAN**. • If multi-VLAN mode is disabled, this field displays **Single VLAN**.
Max online users	Maximum number of concurrent online users allowed on the port.
Authentication attempts: successful 1, failed 0	MAC authentication statistics, including the number of successful and unsuccessful authentication attempts.
MAC address	MAC address of the online user.
Auth state	User status: • **Authenticated**—The user has passed MAC authentication. • **Unauthenticated**—The user failed MAC authentication.

display mac-authentication connection

Use **display mac-authentication connection** to display information about online MAC authentication users.

Syntax

display mac-authentication connection [**interface** *interface-type interface-number* | **slot** *slot-number* | **user-mac** *mac-addr* | **user-name** *user-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number. If you do not specify a port, this command displays information about online MAC authentication users for all ports.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about online MAC authentication users for all member devices.

user-mac *mac-address*: Specifies an online MAC authentication user by its MAC address. The *mac-address* argument represents the MAC address of the user, in the form of H-H-H. If you do not specify an online MAC authentication user, this command displays online user information for all MAC authentication users.

user-name *user-name*: Specifies an online MAC authentication user by its username. The user name is a case-sensitive string of 1 to 55 characters, and it can include the domain name. If you do not specify an online MAC authentication user, this command displays online user information for all MAC authentication users.

Usage guidelines

If you do not specify any parameters, this command displays information about online MAC authentication users for all ports.

If you do not specify any parameters, this command displays information about online MAC authentication users for all member devices.

Examples

Display all online MAC authentication user information.

```
<Sysname> display mac-authentication connection
Total connections: 1

Table 2 Command output

Field	Description
Total connections	Total number of online MAC authentication users.
User MAC address	MAC address of the user.
Access interface	Interface through which the user accesses the device.
Authentication domain	MAC authentication domain to which the user belongs.
IPv4 address	IPv4 address of the user. If no user IPv4 address is available, this field is not displayed.
IPv6 address	IPv6 address of the user. If no user IPv6 address is available, this field is not displayed.
Initial VLAN	VLAN that holds the user before MAC authentication.
Authorization untagged VLAN	Untagged VLAN authorized to the user.
Authorization tagged VLAN	Tagged VLAN authorized to the user.
Authorization VLAN	VLAN authorized to the user.
Authorization ACL number/name	This field is not supported in the current software version. Number or name of the ACL authorized to the user. If no ACL is authorized, this field displays **N/A**. If ACL authorization fails, this field displays **(NOT effective)** after the ACL number or name.
Authorization user profile	User profile authorized to the user.
Authorization CAR	Authorization CAR attributes assigned by the server. • **Average input rate**—Average rate of inbound traffic in bps. • **Average output rate**—Average rate of outbound traffic in bps. If no authorization CAR attributes are assigned, this field displays **N/A**.
Authorization URL	URL authorized to the user.
Termination action	Action attribute assigned by the server to terminate the user session: • **Default**—Logs off the online authenticated user when the session timeout timer expires. • **Radius-request**—Reauthenticates the online user when the session timeout timer expires. If the device performs local authentication, this field displays **N/A**.
Session timeout period	Session timeout timer assigned by the server. If the device performs local authentication, this field displays **N/A**.
Online from	Time from which the MAC authentication user came online.
Online duration	Online duration of the MAC authentication user.

mac-authentication

Use **mac-authentication** to enable MAC authentication globally or on a port.

Use **undo mac-authentication** to disable MAC authentication globally or on a port.

Syntax

mac-authentication

undo mac-authentication

Default

MAC authentication is disabled globally or on any port.

Views

System view

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

To use MAC authentication on a port, you must enable the feature both globally and on the port.

Support for MAC authentication depends on the device model. MAC authentication does not take effect on some device models.

Examples

Enable MAC authentication globally.

```
<Sysname> system-view
[Sysname] mac-authentication
```

Enable MAC authentication on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication
```

Related commands

display mac-authentication

mac-authentication access-user log enable

Use **mac-authentication access-user log enable** to enable MAC authentication user logging.

Use **undo mac-authentication access-user log enable** to disable MAC authentication user logging.

Syntax

mac-authentication access-user log enable [**failed-login** | **logoff** | **successful-login**] *

undo mac-authentication access-user log enable [**failed-login** | **logoff** | **successful-login**] *

Default

MAC authentication user logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

`failed-login`: Logs MAC authentication user login failures.

`logoff`: Logs MAC authentication user logoffs.

`successful-login`: Logs successful MAC authentication user logins.

Usage guidelines

To prevent excessive MAC authentication user log entries, use this feature only if you need to analyze abnormal MAC authentication user logins or logouts.

If you do not specify any parameters, this command enables all types of MAC authentication user logs.

Examples

Enable logging MAC authentication user login failures.

```
<Sysname> system-view
[Sysname] mac-authentication access-user log enable failed-login
```

Related commands

`info-center source maca logfile deny` (*Network Management and Monitoring Command Reference*)

mac-authentication critical vlan

Use **`mac-authentication critical vlan`** to configure a MAC authentication critical VLAN on a port.

Use **`undo mac-authentication critical vlan`** to restore the default.

Syntax

`mac-authentication critical vlan` *`critical-vlan-id`*

`undo mac-authentication critical vlan`

Default

No MAC authentication critical VLAN exists on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

`critical-vlan-id`: Specifies a VLAN as the MAC authentication critical VLAN. The value range for the VLAN ID is 1 to 4094. Make sure the VLAN has been created.

Usage guidelines

The MAC authentication critical VLAN accommodates users that have failed MAC authentication because all the servers in their ISP domains are unreachable. Users in the critical VLAN can access network resources in the critical VLAN.

The critical VLAN feature takes effect when MAC authentication is performed only through RADIUS servers. If a MAC authentication user fails local authentication after RADIUS authentication, the user is not assigned to the critical VLAN.

Before you delete a VLAN that has been set as a MAC authentication critical VLAN, use the **undo mac-authentication critical vlan** command to remove the critical VLAN configuration.

Examples

Configure VLAN 100 as the MAC authentication critical VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication critical vlan 100
```

Related commands

display mac-authentication

reset mac-authentication critical-vlan

mac-authentication domain

Use **mac-authentication domain** to specify a global or port-specific authentication domain.

Use **undo mac-authentication domain** to restore the default.

Syntax

mac-authentication domain *domain-name*

undo mac-authentication domain

Default

The system default authentication domain is used. For more information about the default authentication domain, see the **domain default enable** command in "AAA commands."

Views

System view

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies the name of an ISP domain, a case-insensitive string of 1 to 255 characters.

Usage guidelines

The global authentication domain applies to all MAC authentication-enabled ports. An authentication domain specified in Layer 2 Ethernet interface view applies only to the port. You can specify different authentication domains on different ports.

A port chooses an authentication domain for MAC authentication users in the following order:

1. Authentication domain specified on the port.
2. Global authentication domain specified in system view.
3. Default authentication domain.

Examples

Specify ISP domain **domain1** as the global MAC authentication domain.

```
<Sysname> system-view
[Sysname] mac-authentication domain domain1
```

Specify ISP domain **aabbcc** as the MAC authentication domain on GigabitEthernet 1/0/1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication domain aabbcc
```

Related commands

display mac-authentication

domain default enable

mac-authentication guest-vlan

Use **mac-authentication guest-vlan** to configure a MAC authentication guest VLAN on a port.

Use **undo mac-authentication guest-vlan** to restore the default.

Syntax

mac-authentication guest-vlan *guest-vlan-id*

undo mac-authentication guest-vlan

Default

No MAC authentication guest VLAN exists on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

guest-vlan-id: Specifies a VLAN as the MAC authentication guest VLAN. The value range for the VLAN ID is 1 to 4094. Make sure the VLAN has been created.

Usage guidelines

The MAC authentication guest VLAN accommodates users that have failed MAC authentication for any reason other than server unreachable. For example, the VLAN accommodates users with invalid passwords entered. You can deploy a limited set of network resources in the MAC authentication guest VLAN. For example, a software server for downloading software and system patches.

Before you delete a VLAN that has been set as a MAC authentication guest VLAN, use the **undo mac-authentication guest-vlan** command to remove the guest VLAN configuration.

Examples

Configure VLAN 100 as the MAC authentication guest VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication guest-vlan 100
```

Related commands

display mac-authentication

reset mac-authentication guest-vlan

mac-authentication guest-vlan auth-period

Use **mac-authentication guest-vlan auth-period** to set the interval at which the device authenticates users in the MAC authentication guest VLAN.

Use **undo mac-authentication guest-vlan auth-period** to restore the default.

Syntax

mac-authentication guest-vlan auth-period *period-value*

undo mac-authentication guest-vlan auth-period

Default

The device authenticates users in the MAC authentication guest VLAN every 30 seconds.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

period-value: Specifies the authentication interval for users in the MAC authentication guest VLAN. The value range is 1 to 3600, in seconds.

Examples

Set the authentication interval to 150 seconds for users in the MAC authentication guest VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication guest-vlan auth-period 150
```

Related commands

display mac-authentication

mac-authentication guest-vlan

mac-authentication host-mode multi-vlan

Use **mac-authentication host-mode multi-vlan** to enable MAC authentication multi-VLAN mode on a port.

Use **undo mac-authentication host-mode** to restore the default.

Syntax

mac-authentication host-mode multi-vlan

undo mac-authentication host-mode

Default

MAC authentication multi-VLAN mode is disabled on a port. When the port receives a packet sourced from an authenticated MAC address in a VLAN not matching the existing MAC-VLAN mapping, the device logs off and reauthenticates the user.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

The MAC authentication multi-VLAN mode prevents an authenticated online user from service interruption caused by VLAN changes on a port. When the port receives a packet sourced from the user in a VLAN not matching the existing MAC-VLAN mapping, the device neither logs off the user nor reauthenticates the user. The device creates a new MAC-VLAN mapping for the user, and traffic transmission is not interrupted. The original MAC-VLAN mapping for the user remains on the device until it dynamically ages out. As a best practice, configure this feature on hybrid or trunk ports.

Examples

Enable MAC authentication multi-VLAN mode on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication host-mode multi-vlan
```

Related commands

display mac-authentication

mac-authentication max-user

Use **mac-authentication max-user** to set the maximum number of concurrent MAC authentication users on a port.

Use **undo mac-authentication max-user** to restore the default.

Syntax

mac-authentication max-user *max-number*

undo mac-authentication max-user

Default

The default is 4294967295.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Sets the maximum number of concurrent MAC authentication users on the port. The value range for this argument is 1 to 4294967295.

Usage guidelines

Set the maximum number of concurrent MAC authentication users on a port to prevent the system resources from being overused. When the maximum number is reached, the port denies subsequent MAC authentication users.

Examples

Configure GigabitEthernet 1/0/1 to support a maximum of 32 concurrent MAC authentication users.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication max-user 32
```

Related commands

display mac-authentication

mac-authentication re-authenticate server-unreachable keep-online

Use **mac-authentication re-authenticate server-unreachable keep-online** to enable the keep-online feature on a port.

Use **undo mac-authentication re-authenticate server-unreachable** to restore the default.

Syntax

mac-authentication re-authenticate server-unreachable keep-online

undo mac-authentication re-authenticate server-unreachable

Default

The keep-online feature is disabled on a port. The device logs off online MAC authentication users if no server is reachable for MAC reauthentication.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

The keep-online feature keeps authenticated MAC authentication users online when no server is reachable for MAC reauthentication.

Examples

Enable the keep-online feature for authenticated MAC authentication users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication re-authenticate server-unreachable
keep-online
```

Related commands

display mac-authentication

mac-authentication timer

Use **mac-authentication timer** to configure a MAC authentication timer.

Use **undo mac-authentication timer** to restore the default of a MAC authentication timer.

Syntax

mac-authentication timer { **offline-detect** *offline-detect-value* | **quiet** *quiet-value* | **server-timeout** *server-timeout-value* }

undo mac-authentication timer { **offline-detect** | **quiet** | **server-timeout** }

Default

The following MAC authentication timers apply:

- The offline detect timer is 300 seconds.
- The quiet timer is 60 seconds.
- The server timeout timer is 100 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

offline-detect *offline-detect-value*: Sets the offline detect timer in seconds, in the range of 60 to 2147483647.

quiet *quiet-value*: Sets the quiet timer in seconds, in the range of 1 to 3600.

server-timeout *server-timeout-value*: Sets the server timeout timer in seconds, in the range of 100 to 300.

Usage guidelines

MAC authentication uses the following timers:

- **Offline detect timer**—Sets the interval that the device waits for traffic from a user before the device determines that the user is idle. If the device has not received traffic from a user before the timer expires, the device logs off that user and requests the accounting server to stop accounting for the user.
- **Quiet timer**—Sets the interval that the device must wait before the device can perform MAC authentication for a user that has failed MAC authentication. All packets from the MAC address are dropped during the quiet time. This quiet mechanism prevents repeated authentication from affecting system performance.
- **Server timeout timer**—Sets the interval that the device waits for a response from a RADIUS server before the device determines that the RADIUS server is unavailable. If the timer expires during MAC authentication, the user cannot access the network.

Examples

Set the server timeout timer to 150 seconds.

```
<Sysname> system-view
[Sysname] mac-authentication timer server-timeout 150
```

Related commands

display mac-authentication

mac-authentication user-name-format

Use **mac-authentication user-name-format** to configure the type of user accounts for MAC authentication users.

Use **undo mac-authentication user-name-format** to restore the default.

Syntax

mac-authentication user-name-format { **fixed** [**account** *name*] [**password** { **cipher** | **simple** } *string*] | **mac-address** [{ **with-hyphen** [**six-section** | **three-section**] | **without-hyphen** } [**lowercase** | **uppercase**]] }

undo mac-authentication user-name-format

Default

Each user's MAC address is used as the username and password for MAC authentication. The MAC addresses are in hexadecimal notation without hyphens, and letters are in lower case.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

fixed: Uses a shared account for all MAC authentication users.

account *name*: Specifies the username for the shared account. The name is a case-sensitive string of 1 to 55 characters, excluding the at sign (@). If you do not specify a username, the default name **mac** applies.

password: Specifies the password for the shared user account. If you do not specify a password for the shared account, the shared account does not have a password.

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 63 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

mac-address: Uses MAC-based user accounts for MAC authentication users. You can also specify the format of username and password by using the following keywords:

- **with-hyphen**: Includes hyphens in the MAC address.
  - **six-section**: Hyphenates the MAC address into six groups of two hexadecimal digits, for example, xx-xx-xx-xx-xx-xx or XX-XX-XX-XX-XX-XX.
  - **three-section**: Hyphenates the MAC address into three groups of four hexadecimal digits, for example, xxxx-xxxx-xxxx or XXXX-XXXX-XXXX.

  If you do not specify the **six-section** or **three-section** keyword, the MAC address is in six-section format.
- **without-hyphen**: Excludes hyphens from the MAC address, for example, xxxxxxxxxxxx or XXXXXXXXXXXX.
- **lowercase**: Specifies letters in lower case.
- **uppercase**: Specifies letters in upper case.

Usage guidelines

If you specify the MAC-based user account, the device uses the MAC address of a user as the username and password for MAC authentication of the user. This user account type ensures high authentication security. However, you must create on the authentication server a user account for each user, using the MAC address of the user as both the username and password.

If you specify a shared user account, the device uses the specified username and password for MAC authentication of all users. Because all MAC authentication users use a single account for authentication, you only need to create one account on the authentication server. This user account type is suitable for trusted networks.

Examples

Configure a shared account for MAC authentication users, and set the username to **abc** and password to plaintext string of **xyz**.

```
<Sysname> system-view
[Sysname] mac-authentication user-name-format fixed account abc password simple xyz
```

Use MAC-based user accounts for MAC authentication users. The MAC addresses must be in hexadecimal notation without hyphens, and letters are in upper case.

```
<Sysname> system-view
[Sysname] mac-authentication user-name-format mac-address without-hyphen uppercase
```

Related commands

display mac-authentication

reset mac-authentication access-user

Use **reset mac-authentication access-user** to log off MAC authentication users.

Syntax

reset mac-authentication access-user [**interface** *interface-type interface-number* | **mac** *mac-address* | **username** *username* | **vlan** *vlan-id* | **vsi** *vsi-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number.

mac *mac-address*: Specifies a MAC authentication user by its MAC address. The *mac-address* argument is in the format of H-H-H.

username *username*: Specifies a MAC authentication user by its name. The *username* argument is a case-sensitive string of 1 to 253 characters.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID. The value range for the *vlan-id* argument is 1 to 4094.

vsi *vsi-name*: Specifies a VSI by its name. The *vsi-name* argument is a case-sensitive string of 1 to 31 characters.

Usage guidelines

Use this command to log off the specified MAC authentication users and clear information about these users from the device. These users must perform MAC authentication to come online again.

With a VSI specified, this command logs off a MAC authentication user if that user has passed authentication and its authorization VSI is the specified VSI.

With a VLAN specified, this command logs off the following MAC authentication users:

- Users that have passed MAC authentication and have been assigned the specified VLAN as their authorization VLAN by the server.
- Users that stay in the specified VLAN after they have passed MAC authentication, because they have not been assigned an authorization VLAN yet.
- Users that are performing MAC authentication in the specified VLAN.

To identify the VLAN in which a user is staying, use the **display mac-address** command.

If you do not specify any parameters, the **reset mac-authentication access-user** command logs off all MAC authentication users on the device.

Examples

Log off all MAC authentication users on GigabitEthernet 1/0/1.

```
<Sysname> reset mac-authentication access-user interface gigabitethernet 1/0/1
```

Syntax

reset mac-authentication critical-vlan interface *interface-type interface-number* [**mac-address** *mac-address*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number.

mac-address *mac-address*: Specifies a user by its MAC address. If you do not specify this option, the command removes all users from the MAC authentication critical VLAN on the port.

Examples

Remove the user with MAC address **1-1-1** from the MAC authentication critical VLAN on GigabitEthernet 1/0/1.

```
<Sysname> reset mac-authentication critical-vlan interface gigabitethernet 1/0/1
mac-address 1-1-1
```

Related commands

reset mac-authentication guest-vlan

Use **reset mac-authentication guest-vlan** to remove users from the MAC authentication guest VLAN on a port.

Syntax

reset mac-authentication guest-vlan interface *interface-type interface-number* [**mac-address** *mac-address*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number.

mac-address *mac-address*: Specifies a user by its MAC address. If you do not specify this option, the command removes all users from the MAC authentication guest VLAN on the port.

Examples

Remove the user with MAC address **1-1-1** from the MAC authentication guest VLAN on GigabitEthernet 1/0/1.

```
<Sysname> reset mac-authentication guest-vlan interface gigabitethernet 1/0/1 mac-address 1-1-1
```

Related commands

display mac-authentication

mac-authentication guest-vlan

reset mac-authentication statistics

Use **reset mac-authentication statistics** to clear MAC authentication statistics.

Syntax

reset mac-authentication statistics [**ap** *ap-name* [**radio** *radio-id*] | **interface** *interface-type interface-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

ap *ap-name*: Specifies an AP by its name, a case-sensitive string of 1 to 64 characters. The string can contain letters, digits, underscores (_), dots (.), left brackets ([), right brackets (]), forward slashes (/), and hyphens (-). If you do not specify an AP, this command clears MAC authentication statistics for all APs.

radio *radio-id*: Specifies a radio by its ID. The value range for the *radio-id* argument varies by AP model. If you do not specify a radio, this command clears MAC authentication statistics for all radios on the specified AP.

interface *interface-type interface-number*: Specifies a port by its type and number. If you do not specify a port, this command clears both global and port-specific MAC authentication statistics.

Usage guidelines

If you do not specify any parameters, this command clears all MAC authentication statistics.

Examples

Clear MAC authentication statistics on GigabitEthernet 1/0/1.

```
<Sysname> reset mac-authentication statistics interface gigabitethernet 1/0/1
```

Table 1 Command output

Field	Description
Basic	Basic session information.
Access interface	Interface that connects the user.
VPN instance	MPLS L3VPN instance of the user. If the user is not in a VPN, this field displays **N/A**.
Username	Username for authentication.
User ID	User ID assigned after the user came online. If no user ID is assigned, this field displays **0xffffffff**.
State	User state: • **Init**—The user is being initiated. • **Offline**—The user is going offline. • **Auth**—The user is being authenticated. • **AuthFail**—The user failed authentication. • **AuthPass**—The user passed authentication. • **AssignedIP**—The user has an IP address. • **Online**—The user is online. • **Backup**—Backup information about the user on the primary BRAS.
Service node	Slot number and CPU number of the card that connects the user.
Domain	ISP domain.
Online time (hh:mm:ss)	Online duration for the user.
Login time	Time when the user passed authentication and logged in, in the format of MM-DD hh:mm:ss YYYY.
AAA	AAA authorization information.
IP pool	AAA-authorized DHCP address pool. If no DHCP address pool is authorized, this field displays **N/A**.

Field	Description
Session idle time	Idle time in seconds specified for online users. If the idle time expires, the user is logged out. If no idle time is specified, this field displays **N/A** and the user can remain idle without being logged out.
Session duration	AAA-authorized IPoE session duration in seconds: • **N/A**—No IPoE session duration is authorized. • **Unlimited**—The IPoE session duration is unlimited.
remaining	Remaining AAA-authorized IPoE session duration. If no session duration is authorized, this field displays **N/A**. ◦ For users on Layer 3 Ethernet interfaces and subinterfaces, this field displays the remaining time or **Unlimited**. ◦ For users on Layer 3 aggregate interfaces and subinterfaces, this field displays the remaining time or **Unlimited** only when the slot or interface is specified. If you do not specify the slot or interface, this field displays **N/A**.
Remaining traffic	Remaining AAA-authorized traffic in bytes. If no traffic is authorized, this field displays **N/A**.
Max multicast addresses	Maximum number of AAA-authorized multicast groups that a user can join.
Multicast address list	List of AAA-authorized multicast group addresses. If no multicast group is authorized, this field displays **N/A**.
QoS	QoS information.
User profile	AAA-authorized user profile: • **N/A**—No user profile is authorized. • **inactive**—User profile authorization failed or the user profile does not exist on the BRAS. • **active**—The user profile is authorized successfully. If the authorization result has not been updated, nothing is displayed.
Session group profile	AAA-authorized session group profile: • **N/A**—No session group profile is authorized. • **inactive**—Session group profile authorization failed or the session group profile does not exist on the BRAS. • **active**—The session group profile is authorized successfully. If the authorization result has not been updated, nothing is displayed.
Inbound CAR	Inbound CIR and PIR in bps and CBS in bits: • **N/A**—Inbound CAR is not authorized. • **inactive**—Inbound CAR is not authorized successfully. • **active**—Inbound CAR is authorized successfully.
Outbound CAR	Outbound CIR and PIR in bps and CBS in bits: • **N/A**—Outbound CAR is not authorized. • **inactive**—Outbound CAR is not authorized successfully. • **active**—Outbound CAR is authorized successfully.
Flow statistic	Session flow statistics.
Uplink packets/bytes	Total number and size of uplink packets.
Downlink packets/bytes	Total number and size of downlink packets.
ITA	Intelligent target accounting (ITA) information.
Level-*n* Uplink packets/bytes	Number and size of uplink packets for level *n* accounting ($1 \le n \le 8$).

Field	Description
Downlink packets/bytes	Number and size of downlink packets for level *n* accounting (1 ≤ *n* ≤ 8).

Related commands

ip subscriber enable

display ip subscriber interface-leased statistics

Use **display ip subscriber interface-leased statistics** to display IPoE session statistics for IPv4 interface-leased users.

Syntax

display ip subscriber interface-leased statistics [**interface** *interface-type interface-number*] [**slot** *slot-number*]

Views

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays IPoE session statistics for IPv4 interface-leased users for all interfaces.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPoE session statistics for IPv4 interface-leased users for all member devices.

Examples

Display IPoE session statistics for IPv4 interface-leased users on the BRAS.

```
<Sysname> display ip subscriber interface-leased statistics
Total                : 100
Init                 : 0
Authenticating       : 20
Authenticate fail    : 0
Authenticate pass    : 20
Assigned IP          : 10
Online               : 50
Backup               : 0
```

Table 2 Command output

Field	Description
Total	Total number of hosts on the interface.
Init	Number of users who initiated sessions.
Authenticating	Number of users being authenticated.

Field	Description
Authenticate fail	Number of users who failed authentication.
Authenticate pass	Number of users who passed authentication.
Assigned IP	Number of users who have IP addresses.
Online	Number of online users.
Backup	Number of users whose information was backed up.

display ip subscriber offline statistics

Use **display ip subscriber offline statistics** to display offline statistics for IPv4 users.

Syntax

display ip subscriber offline statistics [**interface** *interface-type interface-number*]

Views

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays offline statistics for IPv4 users for all interfaces.

Examples

Display offline statistics for IPv4 users on GigabitEthernet 1/0/1.

```
<Sysname> display ip subscriber offline statistics interface gigabitethernet 1/0/1
Total               : 100
User request        : 0
DHCP lease expire   : 0
AAA lease expire    : 0
Command cut         : 80
AAA terminate       : 0
Authenticate fail   : 0
Authorization fail  : 0
Idle timeout        : 10
Detect fail         : 10
Not enough resource : 0
Interface down      : 0
Interface shutdown  : 0
VSRP event          : 0
DHCP notify         : 0
```

```
Other               : 0
```

Table 3 Command output

Field	Description
Total	Total number of offline users.
User request	Number of users requesting to go offline.
DHCP lease expire	Number of users with expired DHCP leases.
AAA lease expire	Number of users with expired AAA leases.
Command cut	Number of users logged out by commands.
AAA terminate	Number of users logged out by AAA.
Authenticate fail	Number of users who failed authentication.
Authorization fail	Number of users who failed authorization.
Idle timeout	Number of users with an expired idle timeout timer.
Detect fail	Number of users who failed online detection.
Not enough resource	Number of users with insufficient hardware resources.
Interface down	Number of users on an interface that went down.
Interface shutdown	Number of users on an interface that was shut down.
VSRP event	Number of users disconnected by the VSRP event.
DHCP notify	Number of users disconnected by DHCP.
Other	Number of users disconnected from the network because of unknown causes.

Related commands

reset ip subscriber offline statistics

display ip subscriber session

Use **display ip subscriber session** to display session information for IPv4 individual users.

Syntax

display ip subscriber session [**interface** *interface-type interface-number*] [**domain** *domain-name* | **ip** *ip-address* [**vpn-instance** *vpn-instance-name*] | **mac** *mac-address* | **static** | **username** *name*] [**slot** *slot-number*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays session information for IPv4 individual users for all interfaces.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

ip *ip-address*: Specifies the source IP address of the IPv4 individual user.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays session information for IPv4 individual users on the public network.

mac *mac-address*: Specifies the MAC address of an IPv4 individual user, in the format of H-H-H.

static: Specifies static IPoE sessions. If this parameter is not specified, this command displays information about static and dynamic sessions for IPv4 individual users.

username *name*: Specifies a username for authentication, a case-sensitive string of 1 to 255 characters.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays session information for IPv4 individual users for all member devices.

verbose: Displays detailed session information for IPv4 individual users. If this parameter is not specified, this command displays general session information.

Examples

Display general session information for the IPv4 individual user with an IP address of **1.1.1.1** in **vpn1**.

```
<Sysname> display ip subscriber session ip 1.1.1.1 vpn-instance vpn1
  Type: D-DHCP   S-Static     U-Unclassified-IP
Interface            IP address                MAC address    Type  State

```

Table 4 Command output

Field	Description
Basic	Basic session information.
Description	Description of the IPoE session. If the IPoE session does not have a description, this field displays a hyphen (-).
Username	Username for authentication.
Domain	ISP domain of the user.
VPN instance	MPLS L3VPN instance of the user. If the user is not in a VPN, this field displays **N/A**.
IP address	IP address of the user.
MAC address	MAC address of the user.
Service-VLAN/Customer-VLAN	Public and private VLANs of the user. If the user is not a VLAN user, this field displays **-**.
Access interface	Interface that connects the user.
User ID	User ID assigned after the user came online. If no user ID is assigned, this field displays **0xffffffff**.
VPI/VCI(for ATM)	PVC information about the ATM.
DHCP lease	DHCP-authorized IP lease in seconds: • **N/A**—No IP lease is authorized.

Field	Description
	• **Unlimited**—The IP lease is unlimited.
DHCP remain lease	Remaining DHCP-authorized IP lease. This field is valid only on the card that connects the user. On other cards, this field displays **N/A**.
Login time	Time when the user passed authentication and logged in, in the format of MM-DD hh:mm:ss YYYY.
Online time (hh:mm:ss)	Online duration for the user.
Service node	Slot number and CPU number of the card that connects the user.
Type	IPoE session types: • **DHCP**—Dynamic IPoE sessions for DHCP users. • **Unclassified-IP**—Dynamic IPoE sessions for unclassified-IP users. • **Static**—Static sessions.
State	User state: • **Init**—The user is being initiated. • **Offline**—The user is going offline. • **Auth**—The user is being authenticated. • **AuthFail**—The user failed authentication. • **AuthPass**—The user passed authentication. • **AssignedIP**—The user has an IP address. • **Online**—The user is online. • **Backup**—Backup information about the user on the primary BRAS.
AAA	AAA authorization information.
IP pool	AAA-authorized DHCP address pool. If no DHCP address pool is authorized, this field displays **N/A**.
Session idle time	Idle time in seconds specified for online users. If the idle time expires, the user is logged out. If no idle time is specified, this field displays **N/A** and the user can remain idle without being logged out.
Session duration	AAA-authorized IPoE session duration in seconds: • **N/A**—No IPoE session duration is authorized. • **Unlimited**—The IPoE session duration is unlimited.
remaining	Remaining AAA-authorized IPoE session duration. If no session duration is authorized, this field displays **N/A**. ◦ For users on Layer 3 Ethernet interfaces and subinterfaces, this field displays the remaining time or **Unlimited**. ◦ For users on Layer 3 aggregate interfaces and subinterfaces, this field displays the remaining time or **Unlimited** only when the slot or interface is specified. If you do not specify the slot or interface, this field displays **N/A**.
Remaining traffic	Remaining AAA-authorized traffic in bytes. If no traffic is authorized, this field displays **N/A**.
Max multicast addresses	Maximum number of AAA-authorized multicast groups that a user can join.
Multicast address list	List of AAA-authorized multicast group addresses. If no multicast group is authorized, this field displays **N/A**.
QoS	QoS information.
User profile	AAA-authorized user profile:

Field	Description
	• **N/A**—No user profile is authorized. • **inactive**—User profile authorization failed or the user profile does not exist on the BRAS. • **active**—The user profile is authorized successfully. If the authorization result has not been updated, nothing is displayed.
Session group profile	AAA-authorized session group profile: • **N/A**—No session group profile is authorized. • **inactive**—Session group profile authorization failed or the session group profile does not exist on the BRAS. • **active**—The session group profile is authorized successfully. If the authorization result has not been updated, nothing is displayed.
Inbound CAR	Inbound CIR and PIR in bps and CBS in bits: • **N/A**—Inbound CAR is not authorized. • **inactive**—Inbound CAR is not authorized successfully. • **active**—Inbound CAR is authorized successfully.
Outbound CAR	Outbound CIR and PIR in bps and CBS in bits: • **N/A**—Outbound CAR is not authorized. • **inactive**—Outbound CAR is not authorized successfully. • **active**—Outbound CAR is authorized successfully.
Flow statistic	Session flow statistics.
Uplink packets/bytes	Total number and size of uplink packets.
Downlink packets/bytes	Total number and size of downlink packets.
ITA	Intelligent target accounting (ITA) information.
Level-*n* Uplink packets/bytes	Number and size of uplink packets for level *n* accounting (1 ≤ *n* ≤ 8).
Downlink packets/bytes	Number and size of downlink packets for level *n* accounting (1 ≤ *n* ≤ 8).

display ip subscriber session statistics

Use **display ip subscriber session statistics** to display IPoE session statistics for IPv4 individual users.

Syntax

display ip subscriber session statistics [**session-type** { **dhcp** | **static** | **unclassified-ip** }] [**interface** *interface-type interface-number*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

session-type: Specifies a user type. If you do not specify a user type, this command displays IPoE session statistics for all types of IPv4 individual users.

dhcp: Specifies DHCP users.

static: Specifies static users.

unclassified-ip: Specifies unclassified-IP users.

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays IPoE session statistics for IPv4 individual users for all interfaces.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPoE session statistics for IPv4 individual users for all member devices.

Examples

Display IPoE session statistics for IPv4 individual users on GigabitEthernet 1/0/1.

```
<Sysname> display ip subscriber session statistics session-type dhcp interface
gigabitethernet 1/0/1
Total                : 100
Init                 : 0
Authenticating       : 20
Authenticate fail    : 0
Authenticate pass    : 20
Assigned IP          : 10
Online               : 50
Backup               : 0
```

Table 5 Command output

Field	Description
Total	Total number of users on the interface.
Init	Number of users who initiated sessions.
Authenticating	Number of users being authenticated.
Authenticate fail	Number of users who failed authentication.
Authenticate pass	Number of users who passed authentication.
Assigned IP	Number of users who have IP addresses.
Online	Number of online users.
Backup	Number of users whose information was backed up.

ip subscriber 8021p

Use **ip subscriber 8021p** to bind an ISP domain to an 802.1p list for IPv4 unclassified-IP users, static individual users, and leased users.

Use **undo ip subscriber 8021p** to remove the binding between an ISP domain and an 802.1p list.

Syntax

ip subscriber 8021p *8021p-list* **domain** *domain-name*

undo ip subscriber 8021p *8021p-list*

Default

No ISP domain is bound to an 802.1p list for IPv4 unclassified-IP users, static individual users, and leased users.

Views

Layer 3 aggregate subinterface view

Layer 3 Ethernet subinterface view

Predefined user roles

network-admin

context-admin

Parameters

8021p-list: Specifies a space-separated list of up to eight 802.1p value items. Each item specifies a 802.1p value or a range of 802.1p values in the form of start-802.1p-value to end-802.1p-value. The 802.1p value is in the range of 0 to 7.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

Usage guidelines

This command configures an ISP domain for IPv4 unclassified-IP users, static individual users, and leased users who send IP packets with the specified 802.1p values.

Examples

Configure ISP domain **1pdm** for IPv4 unclassified-IP users, static individual users, and leased users who send IP packets with the specified 802.1p values on GigabitEthernet 1/0/1.100. The specified 802.1p values are in the range of 2 to 5.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1.100
[Sysname-GigabitEthernet1/0/1.100] ip subscriber service-identify 8021p second-vlan
[Sysname-GigabitEthernet1/0/1.100] ip subscriber 8021p 2 to 5 domain 1pdm
```

Related commands

ip subscriber service-identify

ip subscriber access-user log enable

Use **ip subscriber access-user log enable** to enable IPv4 IPoE user logging.

Use **undo ip subscriber access-user log enable** to disable IPv4 IPoE user logging.

Syntax

ip subscriber access-user log enable [**successful-login** | **failed-login** | **logout** [**normal**] [**abnormal**]] *

undo ip subscriber access-user log enable [**successful-login** | **failed-login** | **logout** [**normal**] [**abnormal**]] *

Default

IPv4 IPoE user logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

successful-login: Specifies login success logs.

failed-login: Specifies login failure logs.

logout: Specifies logout logs.

normal: Specifies normal logout logs.

abnormal: Specifies abnormal logout logs.

Usage guidelines

IMPORTANT:

Typically, disable this feature to prevent excessive IPv4 IPoE log output.

The IPv4 IPoE user logging feature enables the device to generate IPv4 IPoE logs and send them to the information center. Logs are generated after a user comes online successfully, fails to come online, normally goes offline, or abnormally goes offline. A log entry contains information such as the username, IP address, interface name, inner VLAN, outer VLAN, MAC address, and failure causes. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

When you execute this command without specifying any keyword, this command enables or disables logging for login successes, login failures, normal logouts, and abnormal logouts.

Examples

Enable IPv4 IPoE user logging.

```
<Sysname> system-view
[Sysname] ip subscriber access-user log enable
```

ip subscriber dhcp domain

Use **ip subscriber dhcp domain** to configure an ISP domain for DHCPv4 users.

Use **undo ip subscriber dhcp domain** to restore the default.

Syntax

ip subscriber dhcp domain *domain-name*

undo ip subscriber dhcp domain

Default

DHCPv4 users use the default system domain.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

Usage guidelines

This command configures an ISP domain for DHCPv4 users. The specified ISP domain must exist on the BRAS.

If multiple ISP domains are available for an DHCPv4 user, the ISP domains are used in the following order:

1. Domain specified in Option 60 if the BRAS trusts Option 60 and Option 60 does not include null terminators and non-printable characters.
2. Domain specified by this command.
3. Default system domain.

Examples

Configure ISP domain **ipoe** for DHCPv4 users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber dhcp domain ipoe
```

Related commands

ip subscriber initiator dhcp enable

ip subscriber trust

ip subscriber dhcp max-session

Use **ip subscriber dhcp max-session** to configure the maximum number of IPoE sessions for DHCPv4 users on an interface.

Use **undo ip subscriber dhcp max-session** to restore the default.

Syntax

ip subscriber dhcp max-session *max-number*

undo ip subscriber dhcp max-session

Default

The maximum number of IPoE sessions for DHCPv4 users on an interface is not configured.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of IPoE sessions for DHCPv4 users. The value range for this argument is 1 to 64000

Usage guidelines

If IPoE sessions for DHCPv4 users reach the maximum, no more IPoE session can be established for DHCPv4 users.

Examples

Set the maximum number of IPoE sessions to **100** for DHCPv4 users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber dhcp max-session 100
```

Related commands

display ip subscriber session

ip subscriber initiator dhcp enable

reset ip subscriber session

ip subscriber dhcp password option60

Use **ip subscriber dhcp password option60** to specify a string from Option 60 as the password for DHCPv4 users.

Use **undo ip subscriber dhcp password option60** to restore the default.

Syntax

ip subscriber dhcp password option60 [**offset** *offset*] [**length** *length*]

undo ip subscriber dhcp password option60

Default

The BRAS does not use the password specified in Option 60 for DHCPv4 users.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

offset *offset*: Specifies an offset for the password starting byte, in the range of 1 to 63. If you do not specify this option, the first byte of the option is the starting byte.

length *length*: Specifies the length of the password string, in the range of 1 to 63. If you do not specify this option, all bytes following the starting byte are used as the password.

Usage guidelines

Passwords configured by this command are used for authentication, and must be the same as those configured on the AAA server.

A DHCPv4 user can obtain a password in various ways. If multiple passwords are available for an DHCPv4 user, the passwords are used in the following order:

1. Password configured by this command if the BRAS trusts Option 60 and Option 60 does not contain null terminators or non-printable characters.
2. Password configured by using the **ip subscriber password** command.
3. Default password: **vlan**.

Examples

Specify the string with an offset of 10 and a length of 20 bytes from Option 60 as the password for DHCPv4 users.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber dhcp password option60 offset 10 length 20
```

Related commands

ip subscriber password

ip subscriber trust

ip subscriber dhcp username

ip subscriber dhcp username

Use **ip subscriber dhcp username** to configure an authentication user naming convention for DHCPv4 users.

Use **undo ip subscriber dhcp username** to restore the default.

Syntax

ip subscriber dhcp username include { **circuit-id** [**separator** *separator*] | **client-id** [**separator** *separator*] | **nas-port-id** [**separator** *separator*] | **port** [**separator** *separator*] | **remote-id** [**separator** *separator*] | **second-vlan** [**separator** *separator*] | **slot** [**separator** *separator*] | **source-mac** [**address-separator** *address-separator*] [**separator** *separator*] | **subslot** [**separator** *separator*] | **sysname** [**separator** *separator*] | **vendor-class** [**separator** *separator*] | **vendor-specific** [**separator** *separator*] | **vlan** [**separator** *separator*] } *

undo ip subscriber dhcp username

Default

A DHCPv4 user uses its source MAC address as the authentication username.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

circuit-id: Includes the Option 82 sub-option 1 information in a username.

client-id: Includes the Option 61 information in a username.

nas-port-id: Includes the NAS-Port-ID attribute carried in the authentication request packet in a username.

port: Includes the number of the port that receives the user packets in a username.

remote-id: Includes the Option 82 sub-option 2 information in a username.

second-vlan: Includes the inner VLAN ID in a username.

slot: Includes the number of the slot that receives the user packets in a username.

source-mac: Includes the source MAC address in a username.

address-separator *address-separator*: Specifies any printable character as the separator for the MAC address. For example, if you specify a hyphen (-) as the separator, the username is the hyphen-separated MAC address (xxxx-xxxx-xxxx). If you do not specify a separator, the username is the non-separated MAC address (xxxxxxxxxxxx). Do not use the at sign (@) as the separator. The AAA server cannot parse a username containing the at sign (@).

subslot: Includes the number of the subslot that receives the user packets in a username.

sysname: Includes the name of the device that receives the user packets in a username.

vendor-class: Includes the Option 60 information in a username.

vendor-specific: Includes the Option 82 sub-option 9 information in a username.

vlan: Includes the outer VLAN ID in a username.

separator *separator*: Specifies a character for separating an option and the option that follows. Do not use the at sign (@) as the separator. The AAA server cannot parse a username containing the at sign (@).

Usage guidelines

Usernames obtained based on the naming convention are used for authentication, authorization, and accounting, and must be the same as those configured on the AAA server.

You can specify one or more keywords in a naming convention. If you use a combination of keywords, a username obtained based on the naming convention includes the specified options in the configuration order.

Options used as the username information cannot include null terminators or non-printable characters.

Examples

Configure information carried in the Client Identifier Option as the authentication usernames for DHCPv4 users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber dhcp username include client-id
```

Configure an authentication user naming convention for DHCPv4 users on GigabitEthernet 1/0/1. Each username contains the device name, slot number, subslot number, port number, and outer VLAN, separated by the pound sign (#).

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber dhcp username include sysname separator #
slot separator # subslot separator # port separator # vlan
```

Related commands

ip subscriber initiator dhcp enable

ip subscriber password

ip subscriber dscp

Use **ip subscriber dscp** to bind an ISP domain to a DSCP list for IPv4 unclassified-IP users, static individual users, and leased users.

Use **undo ip subscriber dscp** to remove the binding between an ISP domain and a DSCP list.

Syntax

ip subscriber dscp *dscp-value-list* **domain** *domain-name*

undo ip subscriber dscp *dscp-value-list*

Default

No ISP domain is bound to a DSCP list for IPv4 unclassified-IP users, static individual users, and leased users.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value-list: Specifies a space-separated list of up to eight DSCP value items. Each item specifies a DSCP value or a range of DSCP values in the form of start-DSCP-value to end-DSCP-value. The DSCP value is in the range of 0 to 63.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

Usage guidelines

This command configures an ISP domain for IPv4 unclassified-IP users, static individual users, and leased users who send IP packets with the specified DSCP values.

Examples

Configure ISP domain **dscpdm** for IPv4 unclassified-IP users, static individual users, and leased users who send IP packets with the specified DSCP values on GigabitEthernet 1/0/1. The specified DSCP values are in the range of 1 to 4.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber service-identify dscp
[Sysname-GigabitEthernet1/0/1] ip subscriber dscp 1 to 4 domain dscpdm
```

Related commands

ip subscriber service-identify

ip subscriber enable

Use **ip subscriber enable** to enable IPoE and configure an IPoE access mode for IPv4 users.

Use **undo ip subscriber enable** to disable IPoE for IPv4 users.

Syntax

ip subscriber { **l2-connected** | **routed** } **enable**

undo ip subscriber { **l2-connected** | **routed** } **enable**

Default

IPoE is disabled for IPv4 users.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

l2-connected: Specifies the Layer 2 access mode.

routed: Specifies the Layer 3 access mode.

Usage guidelines

All IPoE configurations take effect on an interface only when IPoE is enabled on the interface.

To change the IPoE access mode on an interface, you must disable IPoE, and then enable IPoE with a new IPoE access mode.

To ensure successful traffic statistics in aggregate interface view, use the **service** command to specify a service card for traffic statistics. For more information about the **service** command, see *Layer 2—LAN Switching Command Reference*.

Examples

Enable IPoE and configure the Layer 2 access mode for IPv4 users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber l2-connected enable
```

Related commands

service (*Layer 2—LAN Switching Command Reference*)

ip subscriber initiator dhcp enable

Use **ip subscriber initiator dhcp enable** to enable the DHCPv4 user.

Use **undo ip subscriber initiator dhcp enable** to disable the DHCPv4 user.

Syntax

ip subscriber initiator dhcp enable

undo ip subscriber initiator dhcp enable

Default

The DHCPv4 user is disabled.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Usage guidelines

If you enable the DHCP user, the first DHCP Discover or the DHCP Request packet initiates the IPoE session. If you disable the DHCP user, DHCP packets cannot initiate IPoE sessions, but existing IPoE sessions for DHCP are not affected.

You can enable the DHCP user and unclassified-IP user on the same interface.

Examples

Enable the DHCPv4 user on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber initiator dhcp enable
```

reset ip subscriber session

ip subscriber initiator unclassified-ip enable

Use **ip subscriber initiator unclassified-ip enable** to enable the IPv4 unclassified-IP user.

Use **undo ip subscriber initiator unclassified-ip enable** to disable the IPv4 unclassified-IP user.

Syntax

ip subscriber initiator unclassified-ip enable

undo ip subscriber initiator unclassified-ip enable

Default

The IPv4 unclassified-IP user is disabled.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Usage guidelines

If you enable the unclassified-IP user, the first IPv4 packet from a host initiates an IPoE session. If you disable the unclassified-IP user, IPv4 packets cannot initiate IPoE sessions, but existing IPoE sessions for unclassified-IP are not affected.

You can enable the DHCP user and unclassified-IP user on the same interface.

Examples

Enable the IPv4 unclassified-IP user on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber initiator unclassified-ip enable
```

display ip subscriber session

ip subscriber enable

ip subscriber initiator dhcp enable

reset ip subscriber session

ip subscriber interface-leased

Use **ip subscriber interface-leased** to configure IPv4 interface-leased users.

Use **undo ip subscriber interface-leased** to restore the default.

Syntax

ip subscriber interface-leased username *name* **password** { **ciphertext** | **plaintext** } *string* [**domain** *domain-name*]

undo ip subscriber interface-leased

Default

No IPv4 interface-leased user exists.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

username *name*: Specifies a username for authentication, a case-sensitive string of 1 to 255 characters.

password ciphertext *string*: Specifies a ciphertext password, a case-sensitive string of 1 to 117 characters.

password plaintext *string*: Specifies a plaintext password, a case-sensitive string of 1 to 63 characters. For security purposes, the password specified in plaintext form will be stored in encrypted form.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@). If you do not specify an ISP domain, the default system domain is used. For more information about the default system domain, see *Security Configuration Guide*.

Usage guidelines

An IPv4 interface-leased user is a group of IPv4 hosts that rent the same interface and share the same IPoE session. The BRAS authenticates, authorizes, and bills all hosts of the same interface-leased user.

You can configure only one IPv4 interface-leased user on one interface. To change the parameters of an existing IPv4 interface-leased user, use the undo form of the command to delete the user, and then reconfigure it with new parameter settings.

You cannot configure an interface-leased user on an interface configured with individual users or subnet-leased users.

Examples

Configure an IPv4 interface-leased user with a username of **intuser** and a plaintext password of **pw123** on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber interface-leased username intuser password plaintext pw123
```

Related commands

ip subscriber nas-port-id format

Use **ip subscriber nas-port-id format** to configure NAS-Port-ID formats for IPv4 users.

Use **undo ip subscriber nas-port-id format** to restore the default.

Syntax

ip subscriber nas-port-id format cn-telecom { **version1.0** | **version2.0** }

undo ip subscriber nas-port-id format

Default

NAS-Port-ID for IPv4 users is encapsulated in the format of version 1.0.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

version 1.0: Specifies the China Telecom format.

- The version 1.0 encapsulation format varies by interface type.

  Table 8 Version 1.0 encapsulation formats

Interface type	Encapsulation format
Layer 3 Ethernet interface and Layer 3 aggregate interface	slot=*slot_num*;subslot=*subslot_num*;port=*port_num*;vlanid=0
Layer 3 Ethernet subinterface and Layer 3 aggregate subinterface (single VLAN tag)	slot=*slot_num*;subslot=*subslot_num*;port=*port_num*;vlanid=*vlan_id*
Layer 3 Ethernet subinterface and Layer 3 aggregate subinterface (Dual VLAN tags)	*slot*=*slot_num*;subslot=*subslot_num*;port=*port_num*;vlanid=*inner-vlan*;vlanid2=*outer-vlan*
ATM-based virtual Layer 3 Ethernet interface (IPoEoA)	slot=*slot_num*;subslot=*subslot_num*;port=*port_num*;vpi=*vpi*;vci=*vci*

- Version 1.0 format parameters

  Table 9 Version 1.0 format parameter description

Parameter	Description
slot_num	Specifies the slot number of the access interface on the BRAS.
subslot_num	Specifies the subslot number of the access interface on the BRAS.
port_num	Specifies the port number of the access interface on the BRAS.
vlan_id	Specifies the ID of the user's VLAN.
inner-vlan	Specifies the ID of the inner VLAN.
outer-vlan	Specifies the ID of the outer VLAN.
vpi	Specifies the VPI of the access interface on the BRAS.
vci	Specifies the VCI of the access interface on the BRAS.

`version 2.0`: Specifies the format described in *`YDT 2275-2011`* Subscriber Access Loop (Port) Identification in Broadband Access Networks.

- Version 2.0 encapsulation format:

  {eth | trunk | atm} NAS_slot/NAS_subslot/NAS_port:svlan.cvlan AccessNodeIdentifier/ANI_rack/ANI_frame/ANI_slot/ANI_subslot/ANI_port

- Version 2.0 format parameters:

  Table 10 Version 2.0 format parameter description

Parameter	Description
{eth|trunk|atm}	Specifies the type of the access interface on the BRAS as Ethernet, trunk, or ATM.
NAS_slot	Specifies the slot number of the access interface on the BRAS.
NAS_subslot	Specifies the subslot number of the access interface on the BRAS.
NAS_port	Specifies the port number of the access interface on the BRAS.
svlan	Specifies the ID of the user's SVLAN.
cvlan	Specifies the ID of the user's CVLAN.
AccessNodeIdentifier	Specifies the identifier of the access node.
ANI_rack	Specifies the rack number of the access node.

Parameter	Description
ANI_frame	Specifies the frame number of the access node.
ANI_slot	Specifies the slot number of the access node.
ANI_subslot	Specifies the subslot number of the access node.
ANI_port	Specifies the port number of the access node.

Examples

Configure version 2.0 as the format for encapsulating NAS-Port-ID on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber nas-port-id format cn-telecom version2.0
```

Related commands

ip subscriber trust

ip subscriber nas-port-id nasinfo-insert

ip subscriber nas-port-id nasinfo-insert

Use **ip subscriber nas-port-id nasinfo-insert** to include NAS information and information obtained from DHCPv4 Option 82 in NAS-Port-ID.

Use **undo ip subscriber nas-port-id nasinfo-insert** to restore the default.

Syntax

ip subscriber nas-port-id nasinfo-insert

undo ip subscriber nas-port-id nasinfo-insert

Default

The BRAS uses information obtained from DHCPv4 Option 82 as NAS-Port-ID.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Usage guidelines

Configure version 2.0 format and the trusted DHCP option before you use this command.

- If DHCP packets contain Option 82 Suboption Circuit-ID, this command includes NAS information and the obtained option information in NAS-Port-ID. Suboption Circuit-ID is not affected.
- If DHCP packets do not contain Option 82 Suboption Circuit-ID, this command includes NAS information in NAS-Port-ID and sets non-NAS parts to zeros in the following format:

  NAS_slot/NAS_subslot/NAS_port:svlan.cvlan 0/0/0/0/0/0

Examples

Include NAS information and the obtained Option 82 information in NAS-Port-ID on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber nas-port-id nasinfo-insert
```

ip subscriber nas-port-type

Use **ip subscriber nas-port-type** to configure NAS-Port-Type for an IPv4 interface.

Use **undo ip subscriber nas-port-type** to restore the default.

Syntax

ip subscriber nas-port-type { **802.11** | **adsl-cap** | **adsl-dmt** | **async** | **cable** | **ethernet** | **g.3-fax** | **hdlc** | **idsl** | **isdn-async-v110** | **isdn-async-v120** | **isdn-sync** | **piafs** | **sdsl** | **sync** | **virtual** | **wireless-other** | **x.25** | **x.75** | **xdsl** }

undo ip subscriber nas-port-type

Default

NAS-Port-Type for an IPv4 interface is Ethernet.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

802.11: Specifies the port type complying with Wireless-IEEE 802.11. The type ID is 19.

adsl-cap: Specifies the ADSL-CAP port type, including Asymmetric DSL and Carrierless Amplitude Phase Modulation. The type ID is 12.

adsl-dmt: Specifies the ADSL-DMT port type, including Asymmetric DSL and Discrete Multi-Tone. The type ID is 13.

async: Specifies the Async port type with a type ID of 0.

cable: Specifies the Cable port type with a type ID of 17.

ethernet: Specifies the Ethernet port type with a type ID of 15.

g.3-fax: Specifies the G.3 Fax port type with a type ID of 10.

hdlc: Specifies the HDLC port type with a type ID of 7.

idsl: Specifies the IDSL port type with a type ID of 14.

isdn-async-v110: Specifies the ISDN Async V.110 port type with a type ID of 4.

ISDN Async V.110: Specifies the ISDN Async V.120 port type with a type ID of 3.

isdn-sync: Specifies the ISDN Sync port type with a type ID of 2.

piafs: Specifies the port type complying with PIAFS. The type ID is 6.

sdsl: Specifies the SDSL port type with a type ID of 11.

sync: Specifies the Sync port type with a type ID of 1.

virtual: Specifies the Virtual port type with a type ID of 5.

wireless-other: Specifies the Wireless-other port type with a type ID of 18.

x.25: Specifies the X.25 port type with a type ID of 8.

x.75: Specifies the X.75 port type with a type ID of 9.

xdsl: Specifies the XDSL port type with a type ID of 16.

Usage guidelines

The NAS-Port-Type attribute carries information about the access interface. The BRAS includes the configured NAS-Port-Type in RADIUS requests sent to the RADIUS server.

Examples

Configure the port type as **sdsl** for IPv4 interface GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber nas-port-type sdsl
```

ip subscriber password

Use **ip subscriber password** to configure passwords for IPv4 individual users.

Use **undo ip subscriber password** to restore the default.

Syntax

ip subscriber password { **ciphertext** | **plaintext** } *string*

undo ip subscriber password

Default

The password for IPv4 individual users is **vlan**.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

ciphertext *string*: Specifies a ciphertext password, a case-sensitive string of 1 to 117 characters.

plaintext *string*: Specifies a plaintext password, a case-sensitive string of 1 to 63 characters. For security purposes, the password specified in plaintext form will be stored in encrypted form.

Usage guidelines

Passwords configured by this command are used for authentication, and must be the same as those configured on the AAA server.

A DHCPv4 user can obtain a password in various ways. For password priority, see "ip subscriber dhcp password option60."

Examples

Configure the plaintext password as **123** for IPv4 individual users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber password plaintext 123
```

Related commands

ip subscriber dhcp username

ip subscriber unclassified-ip username

ip subscriber dhcp password option60

ip subscriber service-identify

Use **ip subscriber service-identify** to configure service identifiers for IPv4 unclassified-IP users, static individual users, and leased users.

Use **undo ip subscriber service-identify** to restore the default.

Syntax

Layer 3 Ethernet interface view, Layer 3 aggregate interface view, L3VE interface view, VEth interface view:

ip subscriber service-identify dscp

undo ip subscriber service-identify

Layer 3 Ethernet subinterface view, Layer 3 aggregate subinterface view, L3VE subinterface view, VEth subinterface view:

ip subscriber service-identify { **8021p** { **second-vlan** | **vlan** } | **dscp** | **second-vlan** | **vlan** }

undo ip subscriber service-identify

VLAN interface view:

ip subscriber service-identify { **8021p vlan** } | **dscp** | **vlan** }

undo ip subscriber service-identify

Default

No service identifier is configured for IPv4 unclassified-IP users, static individual users, and leased users.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

8021p second-vlan: Specifies the 802.1p value of the inner VLAN tag in QinQ mode as the service identifier.

8021p vlan: Specifies the 802.1p value of the VLAN tag or the 802.1p value of the outer VLAN tag in QinQ mode as the service identifier.

dscp: Specifies the DSCP value as the service identifier.

second-vlan: Specifies the inner VLAN ID in QinQ mode as the service identifier.

vlan: Specifies the VLAN ID or the outer VLAN ID in QinQ mode as the service identifier.

Usage guidelines

You must specify an identifier for a service before you bind an ISP domain to the service. Otherwise, the binding does not take effect.

IPv4 unclassified-IP users, static individual users, and leased users whose IP packets containing the specified service identifier will be assigned a service-specific ISP domain.

You can configure only one service identifier on each interface.

Examples

Configure **dscp** as the service identifier on GigabitEthernet 1/0/1 for IPv4 unclassified-IP users, static individual users, and leased users.

```
<Sysname> system-view

ip subscriber session static

Use **ip subscriber session static** to configure IPv4 static IPoE sessions.

Use **undo ip subscriber session static** to delete IPv4 static IPoE sessions.

Syntax

ip subscriber session static ip *ip-address* [**vlan** *vlan-id* [**second-vlan** *vlan-id*]] [**mac** *mac-address*] [**domain** *domain-name*] [**description** *string*]

undo ip subscriber session static ip *ip-address* [**vlan** *vlan-id* [**second-vlan** *vlan-id*]]

Default

No IPv4 static IPoE session exists.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

ip *ip-address*: Specifies a user IPv4 address.

vlan *vlan-id*: Specifies an outer VLAN ID of the user packet, in the range of 1 to 4094. This option is available only for subinterfaces.

second-vlan *vlan-id*: Specifies an inner VLAN ID of the user packet, in the range of 1 to 4094. This option is available only for subinterfaces.

mac *mac-address*: Specifies a user MAC address in the form of H-H-H.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@). If you do not specify an ISP domain, the default system domain is used. For more information about the default system domain, see *Security Configuration Guide*.

description *string*: Specifies the static session description, a case-insensitive string of 1 to 31 characters. If this option is not specified, the static session does not have a description. The description cannot contain the following characters: forward slashes (/), backslashes (\), vertical bars (|), quotation marks ("), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), and at signs (@).

Usage guidelines

Static IPoE sessions have higher priority than dynamic IPoE sessions. If a user IP or DHCP packet matches a static IPoE session, the static IPoE session overwrites the existing dynamic IPoE session.

When the IP address specified in a static session overlaps with the assignable IP addresses in the DHCP address pool, you must use the **dhcp server forbidden-ip** or **forbidden-ip** command to exclude the overlapping IP address in the DHCPv4 address pool from dynamic address allocation. For more information about excluding IP addresses from dynamic allocation, see DHCP configuration in *Layer 3—IP Services Configuration Guide*.

You can configure multiple static IPoE sessions on an interface. Static IPv4 IPoE sessions include the following types:

- A session with a specified IPv4 address.
- A session with a specified IPv4 address and outer VLAN ID.
- A session with a specified IPv4 address, outer VLAN ID, and inner VLAN ID.

For each session type, configuration fails if the settings are identical to the settings of an existing session.

To change the parameters of an existing IPoE session, use the undo form of the command to delete the session, and then reconfigure it with new parameter settings.

You cannot configure a static IPoE session on an interface configured with dedicated-interface or subnet-leased users.

Examples

Configure an IPv4 static IPoE session with an IP address of 1.1.1.1 and an ISP domain of **dm1** on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber session static ip 1.1.1.1 domain dm1
```

Related commands

undo ip subscriber subnet-leased ip *ip-address* { *mask* | *mask-length* }

Default

No IPv4 subnet-leased user exists.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

ip *ip-address*: Specifies a user IPv4 address.

mask: Specifies an IP address mask in dotted decimal notation.

mask-length: Specifies a mask length, an integer in the range of 0 to 32.

username *name*: Specifies a username for authentication, a case-sensitive string of 1 to 255 characters.

password: Specifies a password for authentication.

ciphertext *string*: Specifies a ciphertext password, a case-sensitive string of 1 to 117 characters.

plaintext *string*: Specifies a plaintext password, a case-sensitive string of 1 to 63 characters. For security purposes, the password specified in plaintext form will be stored in encrypted form.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@). If you do not specify an ISP domain, the default system domain is used. For more information about the default system domain, see *Security Configuration Guide*.

Usage guidelines

An IPv4 subnet-leased user is a group of IPv4 hosts that rent the same subnet of an interface and share the same IPoE session. The BRAS authenticates, authorizes, and bills all hosts of the same subnet-leased user.

You can configure only one IPv4 subnet-leased user on each subnet.

You cannot configure a subnet-leased user on an interface configured with individual users or interface-leased users.

Examples

Configure an IPv4 subnet-leased user for subnet **1.1.1.1/24** with a username of **netuser** and a plaintext password of **pw123** on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber subnet-leased ip 1.1.1.1 24 username netuser
password plaintext pw123
```

Related commands

display ip subscriber subnet-leased

ip subscriber timer quiet

Use **ip subscriber timer quiet** to configure a quiet timer for IPv4 users.

Use **undo ip subscriber timer quiet** to restore the default.

Syntax

ip subscriber timer quiet *time*

undo ip subscriber timer quiet

Default

No quite timer is configured for IPv4 users.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the quiet timer in the range of 10 to 3600 seconds.

Usage guidelines

IPoE starts the quiet timer after a user fails authentication. It discards packets from the user during the quiet time. After the quiet timer expires, IPoE performs authentication upon receiving a packet from the user.

Examples

Set the quiet time to **100** seconds for IPv4 users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber timer quiet 100
```

ip subscriber trust

Use **ip subscriber trust** to configure a trusted option for DHCPv4 users.

Use **undo ip subscriber trust** to cancel a trusted option.

Syntax

ip subscriber trust { **option60** | **option82** }

undo ip subscriber trust { **option60** | **option82** }

Default

No trusted options are configured for DHCPv4 users.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

option60: Specifies Option 60 as the trusted option.

option82: Specifies Option 82 as the trusted option.

Usage guidelines

If the BRAS trusts DHCPv4 Option 60, the following option information is used as the ISP domain:

- All information in Option 60 if the option does not contain invalid characters or the at sign (@).

  Invalid characters include the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), and right angle bracket (>).
- Information that follows the last at sign (@) if the option contains at signs (@) and does not contain invalid characters.

If the BRAS does not trust DHCPv4 Option 60, the ISP domains are used in the following order:

1. Domain specified in the **ip subscriber dhcp domain** command.
2. Default system domain.

If the BRAS trusts DHCPv4 Option 82, it obtains the following information from the option and uses the information to encapsulate RADIUS attributes:

- Obtains the Circuit-ID information and uses it to encapsulate NAS-Port-ID that adopts version 2.0 as the encapsulation format.
- Obtains the Circuit-ID information and uses it to encapsulate DSL_AGENT_CIRCUIT_ID.
- Obtains the Remote-ID information and uses it to encapsulate DSL_AGENT_REMOTE_ID.

If the BRAS does not trust DHCPv4 Option 82, it does not use the Option 82 to encapsulate RADIUS attributes.

Examples

Configure DHCPv4 Option 82 as a trusted option on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber trust option82
```

ip subscriber unclassified-ip domain

Use **ip subscriber unclassified-ip domain** to configure an ISP domain for IPv4 unclassified-IP users, static individual users, and leased users.

Use **undo ip subscriber unclassified-ip domain** to restore the default.

Syntax

ip subscriber unclassified-ip domain *domain-name*

undo ip subscriber unclassified-ip domain

Default

IPv4 unclassified-IP users, static individual users, and leased users use the default system ISP domain.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

Usage guidelines

This command configures an ISP domain for IPv4 unclassified-IP users, static individual users, and leased users. The configured ISP domain must exist on the BRAS.

The BRAS selects an ISP domain for an IPv4 unclassified-IP user, static individual user, or leased user in the following order:

1. Service-specific domain.
2. Domain specified by this command.
3. Default system domain.

Examples

Configure ISP domain **ipoe** for IPv4 unclassified-IP users, static individual users, and leased users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber unclassified-ip domain ipoe
```

Use **ip subscriber unclassified-ip max-session** to configure the maximum number of IPoE sessions for IPv4 unclassified-IP users on an interface.

Use **undo ip subscriber unclassified-ip max-session** to restore the default.

Syntax

ip subscriber unclassified-ip max-session *max-number*

undo ip subscriber unclassified-ip max-session

Default

The maximum number of IPoE sessions for IPv4 unclassified-IP users on an interface is not configured.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of IPoE sessions for IPv4 unclassified-IP users. The value range for this argument is 1 to 64000.

Usage guidelines

If IPoE sessions for IPv4 unclassified-IP users reach the maximum, no more IPoE session can be initiated for IPv4 unclassified-IP users.

Examples

Set the maximum number of IPoE sessions to **100** for IPv4 unclassified-IP users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber unclassified-ip max-session 100
```

Related commands

ip subscriber unclassified-ip username

Use **ip subscriber unclassified-ip username** to configure an authentication user naming convention for IPv4 unclassified-IP users and static individual users.

Use **undo ip subscriber unclassified-ip username** to restore the default.

Syntax

ip subscriber unclassified-ip username include { **nas-port-id** [**separator** *separator*] | **port** [**separator** *separator*] | **second-vlan** [**separator** *separator*] | **slot** [**separator** *separator*] | **source-ip** [**address-separator** *address-separator*] [**separator** *separator*] | **source-mac** [**address-separator** *address-separator*] [**separator** *separator*] | **subslot** [**separator** *separator*] | **sysname** [**separator** *separator*] | **vlan** [**separator** *separator*] } *

undo ip subscriber unclassified-ip username

Default

An IPv4 unclassified-IP user or static individual user uses its source IPv4 address as the authentication username.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

nas-port-id: Includes the NAS-Port-ID attribute in a username.

port: Includes the number of the port that receives the user packets in a username.

second-vlan: Includes the inner VLAN ID in a username.

slot: Includes the number of the slot that receives the user packets in a username.

source-ip: Includes the source IP address in a username.

address-separator *address-separator*: Specifies any printable character as the separator for the IPv4 address. For example, if you specify a hyphen (-) as the separator, the username is the hyphen-separated IP address (xxxx-xxxx-xxxx). If you do not specify a separator, the username is the dot-separated IP address (x.x.x.x). Do not use the at sign (@) as the separator. The AAA server cannot parse a username containing the at sign (@).

source-mac: Includes the source MAC address in a username.

address-separator *address-separator*: Specifies any printable character as the separator for the MAC address. For example, if you specify a hyphen (-) as the separator, the username is the hyphen-separated MAC address (xxxx-xxxx-xxxx). If you do not specify a separator, the username is the non-separated MAC address (xxxxxxxxxxxx). Do not use the at sign (@) as the separator. The AAA server cannot parse a username containing the at sign (@).

subslot: Includes the number of the subslot that receives the user packets in a username.

sysname: Includes the name of the device that receives the user packets in a username.

vlan: Includes the outer VLAN ID in a username.

separator *separator*: Specifies a character for separating an option and the option that follows. Do not use the at sign (@) as the separator. The AAA server cannot parse a username containing the at sign (@).

Usage guidelines

Usernames obtained based on the naming convention are used for authentication and must be the same as those configured on the AAA server.

You can specify one or more keywords in a naming convention. If you use a combination of keywords, a username obtained based on the naming convention includes the specified options in the configuration order.

Examples

Configure the source IPv4 address as the authentication usernames for IPv4 unclassified-IP users and static individual users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
```

```
[Sysname-GigabitEthernet1/0/1] ip subscriber unclassified-ip username include source-ip
```

Configure an authentication user naming convention for IPv4 unclassified-IP users and static individual users on GigabitEthernet 1/0/1. Each username contains the device name, slot number, subslot number, port number, and outer VLAN, separated by the pound sign (#).

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber unclassified-ip username include sysname
separator # slot separator # subslot separator # port separator # vlan
```

Related commands

ip subscriber initiator unclassified-ip enable

ip subscriber password

ip subscriber user-detect

Use **ip subscriber user-detect** to configure online detection for IPv4 individual users.

Use **undo ip subscriber user-detect** to restore the default.

Syntax

ip subscriber user-detect { **arp** | **icmp** } **retry** *retries* **interval** *interval*

undo ip subscriber user-detect

Default

Online detection for IPv4 individual users is disabled.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

arp: Specifies the ARP request packet as detection packets.

icmp: Specifies the ICMP request packet as detection packets.

retry *retries*: Specifies the maximum number of detection attempts following the first detection attempt, in the range of 2 to 5.

interval *interval*: Configures the detection timer for each attempt, in the range of 30 to 1200 seconds.

Usage guidelines

Online detection enables the BRAS to periodically detect the status of an IPv4 individual user. It uses ARP and ICMP requests to detect IPv4 individual users. If IPv4 individual users and the interface are in different subnets, only ICMP request packets can be used for detection.

After you configure online detection, the BRAS starts a detection timer to detect online users. If the BRAS does not receive user packets before the detection timer expires, it sends a detection packet to the user.

- If the BRAS receives user packets within the maximum detection attempts, the BRAS assumes that the user is online. It resets the detection timer, and starts the next detection attempt.

- If the BRAS does not receive user packets after detection attempts reach the maximum, the BRAS assumes that the user is offline and deletes the user session.

Examples

Configure online detection on GigabitEthernet 1/0/1. The maximum number of detection attempts is **5**, the detection timer is **100** seconds, and the detection packet type is **ARP.**

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber user-detect arp retry 5 interval 100
```

Related commands

ip subscriber enable

ip subscriber vlan

Use **ip subscriber vlan** to bind an ISP domain to a VLAN list for IPv4 unclassified-IP users, static individual users, and leased users.

Use **undo ip subscriber vlan** to remove the binding between an ISP domain and a VLAN list.

Syntax

ip subscriber vlan *vlan-list* **domain** *domain-name*

undo ip subscriber vlan *vlan-list*

Default

No ISP domain is bound to a VLAN list for IPv4 unclassified-IP users, static individual users, and leased users.

Views

Layer 3 aggregate subinterface view

Layer 3 Ethernet subinterface view

Predefined user roles

network-admin

context-admin

Parameters

vlan-list: Specifies a space-separated list of up to 10 VLAN ID items. Each item specifies a VLAN by its ID or a range of VLANs in the form of start-VLAN-ID to end-VLAN-ID. The VLAN ID is in the range of 1 to 4094.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

Usage guidelines

This command configures an ISP domain for IPv4 unclassified-IP users, static individual users, and leased users who send IP packets with the specified VLAN IDs.

Examples

Configure an ISP domain for IPv4 unclassified-IP users, static individual users, and leased users who send IP packets with the specified VLAN IDs on GigabitEthernet 1/0/1.100. The specified VLAN IDs are in the range of 2 to 100.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1.100
```

```
[Sysname-GigabitEthernet1/0/1.100] ip subscriber service-identify second-vlan
[Sysname-GigabitEthernet1/0/1.100] ip subscriber vlan 2 to 100 domain vlandm
```

Related commands

ip subscriber whitelist enable

Use **ip subscriber whitelist enable** to enable the IPv4 IPoE whitelist feature.

Use **undo ip subscriber whitelist enable** to disable the IPv4 IPoE whitelist feature.

Syntax

ip subscriber whitelist enable

undo ip subscriber whitelist enable

Default

The IPv4 IPoE whitelist feature is disabled.

Views

Layer 3 Ethernet interface/subinterface view

Layer 3 aggregate interface/subinterface view

Predefined user roles

network-admin

context-admin

Usage guidelines

With this feature enabled, only IPv4 traffic matching static IPv4 IPoE sessions can initiate IPoE authentication, and IPoE directly permits the other traffic without any processing.

In some scenarios, an interface might need to have both IPoE and portal authentication enabled. For example, both dumb terminals and broadband dial-up users exist on an interface. Dumb terminals (for example, monitoring cameras) need to come online through IPoE without portal authentication, and broadband dial-up users need to come online through portal Web authentication. In this case, you can enable the IPv4 IPoE whitelist feature on the interface. When both the IPv4 IPoE whitelist feature and portal authentication are enabled on an interface, the following rules apply:

- If the IPv4 traffic of a user matches a static IPv4 IPoE session, the user is processed by the static IPv4 IPoE authentication flow. For an IPoE user to bypass authentication, specify the authentication and authorization modes as **none** in the ISP domain of the IPoE user.
- If the IPv4 traffic of a user does not match any IPv4 IPoE session, the user is processed by portal authentication.

Examples

Enable the IPv4 IPoE whitelist feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip subscriber whitelist enable
```

reset ip subscriber offline statistics

Use **reset ip subscriber offline statistics** to remove offline statistics for IPv4 users.

Syntax

reset ip subscriber offline statistics [**interface** *interface-type interface-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command removes offline statistics for IPv4 users for all interfaces.

Examples

Remove offline statistics for all IPv4 users on GigabitEthernet 1/0/1.

```
<Sysname> reset ip subscriber offline statistics interface gigabitethernet 1/0/1
```

Related commands

display ip subscriber offline statistics

reset ip subscriber session

Use **reset ip subscriber session** to delete dynamic IPv4 IPoE sessions and log out the users.

Syntax

reset ip subscriber session [**interface** *interface-type interface-number*] [**domain** *domain-name* | **ip** *ip-address* [**vpn-instance** *vpn-instance-name*] | **mac** *mac-address* | **username** *name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command deletes dynamic IPv4 IPoE sessions for all interfaces.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters.

ip *ip-address*: Specifies the IP address of the IPoE session to be deleted.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command deletes IPv4 IPoE sessions on the public network.

mac *mac-address*: Specifies the MAC address of an IPv4 IPoE session to be deleted, in the format of H-H-H.

username *name*: Specifies the username of the IPv4 IPoE session to be deleted, a case-sensitive string of 1 to 255 characters.

Usage guidelines

If you do not specify any parameters, this command deletes all dynamic IPv4 IPoE sessions.

To delete static IPoE sessions for static users and leased users, use the **undo** commands.

Examples

Delete dynamic IPv4 IPoE sessions and log out the users on GigabitEthernet 1/0/1.

```
<Sysname> reset ip subscriber session interface gigabitethernet 1/0/1
```

Table 11 Command output

Field	Description
Basic	Basic session information.
Access interface	Interface that connects the user.
VPN instance	MPLS L3VPN instance of the user. If the user is not in a VPN, this field displays **N/A**.
Username	Username for authentication.
User ID	User ID assigned after the user came online. If no user ID is assigned, this field displays **0xffffffff**.
State	User state: • **Init**—The user is being initiated. • **Offline**—The user is going offline. • **Auth**—The user is being authenticated. • **AuthFail**—The user failed authentication. • **AuthPass**—The user passed authentication. • **AssignedIP**—The user has an IP address. • **Online**—The user is online. • **Backup**—Backup information about the user on the primary BRAS.

Field	Description
Service node	Slot number and CPU number of the card that connects the user.
Domain	ISP domain.
Login time	Time when the user passed authentication and logged in, in the format of MM-DD hh:mm:ss YYYY.
Online time (hh:mm:ss)	Online duration for the user.
AAA	AAA authorization information.
IP pool	AAA-authorized DHCP address pool. If no DHCP address pool is authorized, this field displays **N/A**.
Session idle time	Idle time in seconds specified for online users. If the idle time expires, the user is logged out. If no idle time is specified, this field displays **N/A** and the user can remain idle without being logged out.
Session duration	AAA-authorized IPoE session duration in seconds: • **N/A**—No IPoE session duration is authorized. • **Unlimited**—The IPoE session duration is unlimited.
remaining	Remaining AAA-authorized IPoE session duration. If no session duration is authorized, this field displays **N/A**. ○ For users on Layer 3 Ethernet interfaces and subinterfaces, this field displays the remaining time or **Unlimited**. ○ For users on Layer 3 aggregate interfaces and subinterfaces, this field displays the remaining time or **Unlimited** only when the slot or interface is specified. If you do not specify the slot or interface, this field displays **N/A**.
Remaining traffic	Remaining AAA-authorized traffic in bytes. If no traffic is authorized, this field displays **N/A**.
Max multicast addresses	Maximum number of AAA-authorized multicast groups that a user can join.
Multicast address list	List of AAA-authorized multicast group addresses. If no multicast group is authorized, this field displays **N/A**.
QoS	QoS information.
User profile	AAA-authorized user profile: • **N/A**—No user profile is authorized. • **inactive**—User profile authorization failed or the user profile does not exist on the BRAS. • **active**—The user profile is authorized successfully. If the authorization result has not been updated, nothing is displayed.
Session group profile	AAA-authorized session group profile: • **N/A**—No session group profile is authorized. • **inactive**—Session group profile authorization failed or the session group profile does not exist on the BRAS. • **active**—The session group profile is authorized successfully. If the authorization result has not been updated, nothing is displayed.
Inbound CAR	Inbound CIR and PIR in bps and CBS in bits: • **N/A**—Inbound CAR is not authorized. • **inactive**—Inbound CAR is not authorized successfully. • **active**—Inbound CAR is authorized successfully.
Outbound CAR	Outbound CIR and PIR in bps and CBS in bits: • **N/A**—Outbound CAR is not authorized.

Field	Description
	• **inactive**—Outbound CAR is not authorized successfully. • **active**—Outbound CAR is authorized successfully.
Flow statistic	Session flow statistics.
Uplink packets/bytes	Total number and size of uplink packets.
Downlink packets/bytes	Total number and size of downlink packets.
ITA	Intelligent target accounting (ITA) information.
Level-*n* Uplink packets/bytes	Number and size of uplink packets for level *n* accounting (1 ≤ *n* ≤ 8).
Downlink packets/bytes	Number and size of downlink packets for level *n* accounting (1 ≤ *n* ≤ 8).

Related commands

ipv6 subscriber enable

display ipv6 subscriber interface-leased statistics

Use **display ipv6 subscriber interface-leased statistics** to display IPoE session statistics for IPv6 interface-leased users.

Syntax

display ipv6 subscriber interface-leased statistics [**interface** *interface-type interface-number*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays IPoE session statistics for IPv6 interface-leased users for all interfaces.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPoE session statistics for IPv6 interface-leased users for all member devices.

Examples

Display IPoE session statistics for IPv6 interface-leased users on the BRAS.

```
<Sysname> display ipv6 subscriber interface-leased statistics
Total                : 100
Init                 : 0
Authenticating       : 20
Authenticate fail    : 0
Authenticate pass    : 20
Assigned IP          : 10
```

```
Online               : 50
Backup               : 0
```

Table 12 Command output

Field	Description
Total	Total number of users on the interface.
Init	Number of users who initiated sessions.
Authenticating	Number of users being authenticated.
Authenticate fail	Number of users who failed authentication.
Authenticate pass	Number of users who passed authentication.
Assigned IP	Number of users who have IP addresses.
Online	Number of online users.
Backup	Number of users whose information was backed up.

display ipv6 subscriber offline statistics

Use **display ipv6 subscriber offline statistics** to display offline statistics for IPv6 users.

Syntax

display ipv6 subscriber offline statistics [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays offline statistics for IPv6 users for all interfaces.

Examples

Display offline statistics for IPv6 users on GigabitEthernet 1/0/1.

```
<Sysname> display ipv6 subscriber offline statistics interface gigabitethernet 1/0/1
Total               : 100
User request        : 0
DHCP lease expire   : 0
AAA lease expire    : 0
Command cut         : 80
AAA terminate       : 0
Authenticate fail   : 0
Authorization fail  : 0
```

```
Idle timeout        : 10
Detect fail         : 10
Not enough resource : 0
Interface down      : 0
Interface shutdown  : 0
VSRP event          : 0
DHCP notify         : 0
Other               : 0
```

Table 13 Command output

Field	Description
Total	Total number of offline users.
User request	Number of users requesting to go offline.
DHCP lease expired	Number of users with expired DHCP leases.
AAA lease expired	Number of users with expired AAA leases.
Command cut	Number of users logged out by commands.
AAA terminate	Number of users logged out by AAA.
Authenticate fail	Number of users who failed authentication.
Authorization fail	Number of users who failed authorization.
Idle timeout	Number of users with an expired idle timeout timer.
Detect fail	Number of users who failed online detection.
Not enough resource	Number of users with insufficient hardware resources.
Interface down	Number of users on an interface that went down.
Interface shutdown	Number of users on an interface that was shut down.
VSRP event	Number of users disconnected as requested by the VSRP event.
DHCP notify	Number of users disconnected by DHCP.
Other	Number of users disconnected from the network because of unknown causes.

Related commands

reset ipv6 subscriber offline statistics

display ipv6 subscriber session

Use **display ipv6 subscriber session** to display session information for IPv6 individual users.

Syntax

display ipv6 subscriber session [**interface** *interface-type interface-number*] [**domain** *domain-name* | **ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] | **mac** *mac-address* | **static** | **username** *name*] [**slot** *slot-number*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays session information for IPv6 individual users for all interfaces.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

ip *ip-address*: Specifies the source IP address of the IPv6 individual user.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays session information for IPv6 individual users on the public network.

mac *mac-address*: Specifies the MAC address of an IPv6 individual user, in the format of H-H-H.

static: Specifies static IPoE sessions. If this parameter is not specified, this command displays information about static and dynamic sessions for IPv6 individual users.

username *name*: Specifies the username of the IPv6 individual user, a case-sensitive string of 1 to 255 characters.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays session information for IPv6 individual users for all member devices.

verbose: Displays detailed session information for IPv6 individual users. If this parameter is not specified, this command displays general session information.

Examples

Display general session information for the IPv6 individual user with an IP address of **2000::1** in **vpn1**.

```
<Sysname> display ipv6 subscriber session ipv6 2000::1 vpn-instance vpn1
Type: D-DHCP   S-Static     U-Unclassified-IP   N-NDRS

```

Figure 1 Command output

Field	Description
Basic	Basic session information.
Description	Description of the IPoE session. If the IPoE session does not have a description, this field displays a hyphen (-).
Username	Username for authentication.
Domain	ISP domain of the user.
VPN instance	MPLS L3VPN instance of the user. If the user is not in a VPN, this field displays **N/A**.
IP address	IP address of the user.
MAC address	MAC address of the user.
Service-VLAN/Customer-VLAN	Public and private VLANs of the user. If the user is not a VLAN user, this field displays **-**.

Field	Description
Access interface	Interface that connects the user.
User ID	User ID assigned after the user came online. If no user ID is assigned, this field displays **0xffffffff**.
VPI/VCI(for ATM)	PVC information about the ATM.
DHCP lease	DHCP-authorized IP lease in seconds: • **N/A**—No IP lease is authorized. • **Unlimited**—The IP lease is unlimited.
DHCP remain lease	Remaining DHCP-authorized IP lease. This field is valid only on the card that connects the user. On other cards, this field displays **N/A**.
Login time	Time when the user passed authentication and logged in, in the format of MM-DD hh:mm:ss YYYY.
Online time (hh:mm:ss)	Online duration for the user.
Service node	Slot number and CPU number of the card that connects the user.
Type	IPoE session types: • **DHCP**—Dynamic IPoE sessions for DHCP users. • **Unclassified-IP**—Dynamic IPoE sessions for unclassified-IP users. • **Static**—Static sessions. • **NDRS**—Dynamic sessions for IPv6-ND-RS users.
State	User state: • **Init**—The user is being initiated. • **Offline**—The user is going offline. • **Auth**—The user is being authenticated. • **AuthFail**—The user failed authentication. • **AuthPass**—The user passed authentication. • **AssignedIP**—The user has an IP address. • **Online**—The user is online. • **Backup**—Backup information about the user on the primary BRAS.
AAA	AAA authorization information.
IP pool	AAA-authorized DHCP address pool. If no DHCP address pool is authorized, this field displays **N/A**.
Session idle time	Idle time in seconds specified for online users. If the idle time expires, the user is logged out. If no idle time is specified, this field displays **N/A** and the user can remain idle without being logged out.
Session duration	AAA-authorized IPoE session duration in seconds: • **N/A**—No IPoE session duration is authorized. • **Unlimited**—The IPoE session duration is unlimited.
remaining	Remaining AAA-authorized IPoE session duration. If no session duration is authorized, this field displays **N/A**. ◦ For users on Layer 3 Ethernet interfaces and subinterfaces, this field displays the remaining time or **Unlimited**. ◦ For users on Layer 3 aggregate interfaces and subinterfaces, this field displays the remaining time or **Unlimited** only when the slot or interface is specified. If you do not specify the slot or interface, this field displays **N/A**.

Field	Description
Remaining traffic	Remaining AAA-authorized traffic in bytes. If no traffic is authorized, this field displays **N/A**.
Max multicast addresses	Maximum number of AAA-authorized multicast groups that a user can join.
Multicast address list	List of AAA-authorized multicast group addresses. If no multicast group is authorized, this field displays **N/A**.
QoS	QoS information.
User profile	AAA-authorized user profile: • **N/A**—No user profile is authorized. • **inactive**—User profile authorization failed or the user profile does not exist on the BRAS. • **active**—The user profile is authorized successfully. If the authorization result has not been updated, nothing is displayed.
Session group profile	AAA-authorized session group profile: • **N/A**—No session group profile is authorized. • **inactive**—Session group profile authorization failed or the session group profile does not exist on the BRAS. • **active**—The session group profile is authorized successfully. If the authorization result has not been updated, nothing is displayed.
Inbound CAR	Inbound CIR and PIR in bps and CBS in bits: • **N/A**—Inbound CAR is not authorized. • **inactive**—Inbound CAR is not authorized successfully. • **active**—Inbound CAR is authorized successfully.
Outbound CAR	Outbound CIR and PIR in bps and CBS in bits: • **N/A**—Outbound CAR is not authorized. • **inactive**—Outbound CAR is not authorized successfully. • **active**—Outbound CAR is authorized successfully.
Flow statistic	Session flow statistics.
Uplink packets/bytes	Total number and size of uplink packets.
Downlink packets/bytes	Total number and size of downlink packets.
ITA	Intelligent target accounting (ITA) information.
Level-*n* Uplink packets/bytes	Number and size of uplink packets for level *n* accounting (1 ≤ *n* ≤ 8).
Downlink packets/bytes	Number and size of downlink packets for level *n* accounting (1 ≤ *n* ≤ 8).

network-admin

network-operator

context-admin

context-operator

Parameters

session-type: Specifies a user type. If you do not specify a user type, this command displays IPoE session statistics for all types of IPv6 individual users.

dhcp: Specifies DHCP users.

ndrs: Specifies IPv6-ND-RS users.

static: Specifies static users.

unclassified-ip: Specifies unclassified-IP users.

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays IPoE session statistics for IPv6 individual users for all interfaces.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPoE session statistics for IPv6 individual users for all member devices.

Examples

Display IPoE session statistics for IPv6 individual users on GigabitEthernet 1/0/1.

```
<Sysname> display ipv6 subscriber session statistics session-type dhcp interface
gigabitethernet 1/0/1
Total                : 100
Init                 : 0
Authenticating       : 20
Authenticate fail    : 0
Authenticate pass    : 20
Assigned IP          : 10
Online               : 50
Backup               : 0
```

Table 14 Command output

Field	Description
Total	Total number of users on the interface.
Init	Number of users who initiated sessions.
Authenticating	Number of users being authenticated.
Authenticate fail	Number of users who failed authentication.

Field	Description
Authenticate pass	Number of users who passed authentication.
Assigned IP	Number of users who have IP addresses.
Online	Number of online users.
Backup	Number of users whose information was backed up.

ipv6 subscriber 8021p

Use **ipv6 subscriber 8021p** to bind an ISP domain to an 802.1p list for IPv6 unclassified-IP users, static individual users, and leased users.

Use **undo ipv6 subscriber 8021p** to remove the binding between an ISP domain and an 802.1p list.

Syntax

ipv6 subscriber 8021p *8021p-list* **domain** *domain-name*

undo ipv6 subscriber 8021p *8021p-list*

Default

No ISP domain is bound to an 802.1p list for IPv6 unclassified-IP users, static individual users, and leased users.

Views

Layer 3 aggregate subinterface view

Layer 3 Ethernet subinterface view

Predefined user roles

network-admin

context-admin

Parameters

8021p-list: Specifies a space-separated list of up to eight 802.1p value items. Each item specifies a 802.1p value or a range of 802.1p values in the form of start-802.1p-value to end-802.1p-value. The 802.1p value is in the range of 0 to 7.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

Usage guidelines

This command configures an ISP domain for IPv6 unclassified-IP users, static individual users, and leased users who send IP packets with the specified 802.1p values.

Examples

Configure ISP domain **1pdm** for IPv6 unclassified-IP users, static individual users, and leased users who send IP packets with the specified 802.1p values on GigabitEthernet 1/0/1.100. The specified 802.1p values are in the range of 2 to 5.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1.100
[Sysname-GigabitEthernet1/0/1.100] ipv6 subscriber service-identify 8021p second-vlan
[Sysname-GigabitEthernet1/0/1.100] ipv6 subscriber 8021p 2 to 5 domain 1pdm
```

Related commands

ipv6 subscriber service-identify

ipv6 subscriber access-user log enable

Use **ipv6 subscriber access-user log enable** to enable IPv6 IPoE user logging.

Use **undo ipv6 subscriber access-user log enable** to disable IPv6 IPoE user logging.

Syntax

ipv6 subscriber access-user log enable [**successful-login** | **failed-login** | **logout** [**normal**] [**abnormal**]] *

undo ipv6 subscriber access-user log enable [**successful-login** | **failed-login** | **logout** [**normal**] [**abnormal**]] *

Default

IPv6 IPoE user logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

successful-login: Specifies login success logs.

failed-login: Specifies login failure logs.

logout: Specifies logout logs.

normal: Specifies normal logout logs.

abnormal: Specifies abnormal logout logs.

Usage guidelines

IMPORTANT:

Typically, disable this feature to prevent excessive IPoE log output.

The IPv6 IPoE user logging feature enables the device to generate IPv6 IPoE logs and send them to the information center. Logs are generated after a user comes online successfully, fails to come online, normally goes offline, or abnormally goes offline. A log entry contains information such as the username, IP address, interface name, inner VLAN, outer VLAN, MAC address, and failure causes. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

When you execute this command without specifying any keyword, this command enables or disables logging for login successes, login failures, normal logouts, and abnormal logouts.

Examples

Enable IPv6 IPoE user logging.

```
<Sysname> system-view
[Sysname] ip subscriber access-user log enable
```

ipv6 subscriber dhcp domain

Use **ipv6 subscriber dhcp domain** to configure an ISP domain for DHCPv6 users.

Use **undo ipv6 subscriber dhcp domain** to restore the default.

Syntax

ipv6 subscriber dhcp domain *domain-name*

undo ipv6 subscriber dhcp domain

Default

DHCPv6 users use the default system domain.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

Usage guidelines

This command specifies an ISP domain for DHCPv6 users. The specified ISP domain must exist on the BRAS.

If multiple ISP domains are available for an DHCPv6 user, the ISP domains are used in the following order:

1. Domain specified in Option 16 if the BRAS trusts Option 16 and Option 16 does not include null terminators and non-printable characters.
2. Domain specified by this command.
3. Default system domain.

Examples

Configure ISP domain **ipoe** for DHCPv6 users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber dhcp domain ipoe
```

Related commands

ipv6 subscriber dhcp username

ipv6 subscriber initiator dhcp enable

ipv6 subscriber trust

ipv6 subscriber dhcp max-session

Use **ipv6 subscriber dhcp max-session** to configure the maximum number of IPoE sessions for DHCPv6 users on an interface.

Use **undo ip subscriber dhcp max-session** to restore the default.

Syntax

ipv6 subscriber dhcp max-session *max-number*

undo ipv6 subscriber dhcp max-session

Default

The maximum number of IPoE sessions for DHCPv6 users on an interface is not configured.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of IPoE sessions for DHCPv6 users. The value range for this argument is 1 to 64000.

Usage guidelines

If IPoE sessions for DHCPv6 users reach the maximum, no more IPoE session can be established for DHCPv6 users.

Examples

Set the maximum number of IPoE sessions to **100** for DHCPv6 users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber dhcp max-session 100
```

Related commands

display ipv6 subscriber session

ipv6 subscriber initiator dhcp enable

reset ipv6 subscriber session

ipv6 subscriber dhcp password option16

Use **ipv6 subscriber dhcp password option16** to specify a string from Option 16 as the password for DHCPv6 users.

Use **undo ipv6 subscriber dhcp password option16** to restore the default.

Syntax

ipv6 subscriber dhcp password option16 [**offset** *offset*] [**length** *length*]

undo ipv6 subscriber dhcp password option16

Default

The BRAS does not use the password specified in Option 16 for DHCPv6 users.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

offset *offset*: Specifies an offset for the password starting byte, in the range of 1 to 63. If you do not specify this option, the first byte of the option is the starting byte.

length *length*: Specifies the length of the password string, in the range of 1 to 63. If you do not specify this option, all bytes following the starting byte are used as the password.

Usage guidelines

Passwords configured by using this command are used for authentication, and must be the same as those configured on the AAA server.

A DHCPv6 user can obtain a password in various ways. If multiple passwords are available for an DHCPv6 user, the passwords are used in the following order:

1. Password configured by using this command if the BRAS trusts Option 16 and Option 16 does not contain null terminators or non-printable characters.
2. Password configured by using the **ipv6 subscriber password** command.
3. Default password: **vlan**.

Examples

Specify the string with an offset of 10 and a length of 20 bytes from Option 16 as the password for DHCPv6 users.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber dhcp password option16 offset 10 length
20
```

ipv6 subscriber dhcp username

ipv6 subscriber dhcp username

Use **ipv6 subscriber dhcp username** to configure an authentication user naming convention for DHCPv6 users.

Use **undo ipv6 subscriber dhcp username** to restore the default.

Syntax

ipv6 subscriber dhcp username include { **circuit-id** [**separator** *separator*] | **client-id** [**separator** *separator*] | **nas-port-id** [**separator** *separator*] | **port** [**separator** *separator*] | **remote-id** [**separator** *separator*] | **second-vlan** [**separator** *separator*] | **slot** [**separator** *separator*] | **source-mac** [**address-separator** *address-separator*] [**separator** *separator*] | **subslot** [**separator** *separator*] | **sysname** [**separator** *separator*] | **vendor-class** [**separator** *separator*] | **vendor-specific** [**separator** *separator*] | **vlan** [**separator** *separator*] } *

undo ipv6 subscriber dhcp username

Default

A DHCPv6 user uses its source MAC address as the authentication username.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

circuit-id: Includes the Option 18 information in a username.

client-id: Includes the Option 1 information in a username.

nas-port-id: Includes the NAS-Port-ID attribute carried in the authentication request packet in a username.

port: Includes the number of the port that receives the user packets in a username.

remote-id: Includes the Option 37 information in a username.

second-vlan: Includes the inner VLAN ID in a username.

slot: Includes the number of the slot that receives the user packets in a username.

source-mac: Includes the source MAC address in a username.

address-separator *address-separator*: Specifies any printable character as the separator for the MAC address. For example, if you specify a hyphen (-) as the separator, the username is the hyphen-separated MAC address (xxxx-xxxx-xxxx). If you do not specify a separator, the username is the non-separated MAC address (xxxxxxxxxxxx). Do not use the at sign (@) as the separator. The AAA server cannot parse a username containing the at sign (@).

subslot: Includes the number of the subslot that receives the user packets in a username.

sysname: Includes the name of the device that receives the user packets in a username.

vendor-class: Includes the Option 16 information in a username.

vendor-specific: Includes the Option 17 information in a username.

vlan: Includes the outer VLAN ID in a username.

separator *separator*: Specifies a character for separating an option and the option that follows. Do not use the at sign (@) as the separator. The AAA server cannot parse a username containing the at sign (@).

Usage guidelines

Usernames obtained based on the naming convention are used for authentication, authorization, and accounting, and must be the same as those configured on the AAA server.

You can specify one or more keywords in a naming convention. If you use a combination of keywords, a username obtained based on the naming convention includes the specified options in the configuration order.

Options used as the username information cannot include null terminators or non-printable characters.

Examples

Configure information carried in the **client-id** option as the authentication usernames for DHCPv6 users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber dhcp username include client-id
```

Configure an authentication user naming convention for DHCPv6 users on GigabitEthernet 1/0/1. Each username contains the device name, slot number, subslot number, port number, and outer VLAN, separated by the pound sign (#).

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber dhcp username include sysname separator
# slot separator # subslot separator # port separator # vlan
```

ipv6 subscriber dscp

Use **ipv6 subscriber dscp** to bind an ISP domain to a DSCP list for IPv6 unclassified-IP users, static individual users, and leased users.

Use **undo ipv6 subscriber dscp** to remove the binding between an ISP domain and a DSCP list.

Syntax

ipv6 subscriber dscp *dscp-value-list* **domain** *domain-name*

undo ipv6 subscriber dscp *dscp-value-list*

Default

No ISP domain is bound to a DSCP list for IPv6 unclassified-IP users, static individual users, and leased users.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value-list: Specifies a space-separated list of up to eight DSCP value items. Each item specifies a DSCP value or a range of DSCP values in the form of start-DSCP-value to end-DSCP-value. The DSCP value is in the range of 0 to 63.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

Usage guidelines

This command configures an ISP domain for IPv6 unclassified-IP users, static individual users, and leased users who send IP packets with the specified DSCP values.

Examples

Configure ISP domain **dscpdm** for IPv6 unclassified-IP users, static individual users, and leased users who send IP packets with the specified DSCP values on GigabitEthernet 1/0/1. The specified DSCP values are in the range of 1 to 4.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber service-identify dscp
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber dscp 1 to 4 domain dscpdm
```

Related commands

ipv6 subscriber service-identify

ipv6 subscriber enable

Use **ipv6 subscriber enable** to enable IPoE and configure an IPoE access mode for IPv6 users.

Use **undo ipv6 subscriber enable** to disable IPoE.

Syntax

ipv6 subscriber { **l2-connected** | **routed** } **enable**

undo ipv6 subscriber { **l2-connected** | **routed** } **enable**

Default

IPoE is disabled for IPv6 users.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

l2-connected: Specifies the Layer 2 access mode.

routed: Specifies the Layer 3 access mode.

Usage guidelines

All IPoE configurations take effect on an interface only when IPoE is enabled on the interface.

To change the IPoE access mode on an interface, you must disable IPoE, and then enable IPoE with a new IPoE access mode.

To ensure successful traffic statistics in aggregate interface view, use the **service** command to specify a service card for traffic statistics. For more information about the **service** command, see *Layer 2—LAN Switching Command Reference*.

Examples

Enable IPoE and configure the Layer 2 access mode for IPv6 users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber l2-connected enable
```

Related commands

service (*Layer 2—LAN Switching Command Reference*)

ipv6 subscriber initiator dhcp enable

Use **ipv6 subscriber initiator dhcp enable** to enable the DHCPv6 user.

Use **undo ipv6 subscriber initiator dhcp enable** to disable the DHCPv6 user.

Syntax

ipv6 subscriber initiator dhcp enable

undo ipv6 subscriber initiator dhcp enable

Default

The DHCPv6 user is disabled.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Usage guidelines

If you enable the DHCP user, the first DHCP Solicitor or the DHCP Request packet initiates the IPoE session. If you disable the DHCP user, DHCP packets cannot initiate IPoE sessions, but existing IPoE sessions for DHCPv6 are not affected.

You can enable the DHCP user, IPv6-ND-RS user, and unclassified-IP user on the same interface.

Examples

Enable the DHCPv6 user on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber initiator dhcp enable
```

Use **ipv6 subscriber initiator ndrs enable** to enable the IPv6-ND-RS user.

Use **undo ipv6 subscriber initiator ndrs enable** to disable the IPv6-ND-RS user.

Syntax

ipv6 subscriber initiator ndrs enable

undo ipv6 subscriber initiator ndrs enable

Default

The IPv6-ND-RS user is disabled.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Usage guidelines

If you enable the IPV6-ND-RS user, the first IPv6 ND RS packet initiates the IPoE session. If you disable the IPV6-ND-RS user, IPv6 ND RS packets cannot initiate IPoE sessions, but existing IPoE sessions for IPv6-ND-RS are not affected.

You can enable the DHCP user, IPv6-ND-RS user, and unclassified-IP user on the same interface.

Examples

Enable the IPv6-ND-RS user on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber initiator ndrs enable
```

reset ipv6 subscriber session

ipv6 subscriber interface-leased

Use **ipv6 subscriber interface-leased** to configure IPv6 interface-leased users.

Use **undo ipv6 subscriber interface-leased** to restore the default.

Syntax

ipv6 subscriber interface-leased username *name* **password** { **ciphertext** | **plaintext** } *string* [**domain** *domain-name*]

undo ipv6 subscriber interface-leased

Default

No IPv6 interface-leased user exists.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

username *name*: Specifies a username for authentication, a case-sensitive string of 1 to 255 characters.

password ciphertext *string*: Specifies a ciphertext password, a case-sensitive string of 1 to 117 characters.

password plaintext *string*: Specifies a plaintext password, a case-sensitive string of 1 to 63 characters. For security purposes, the password specified in plaintext form will be stored in encrypted form.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@). If you do not specify an ISP domain, the default system domain is used. For more information about the default system domain, see *Security Configuration Guide*.

Usage guidelines

An IPv6 interface-leased user is a group of IPv6 hosts that rent the same interface and share the same IPoE session. The BRAS authenticates, authorizes, and bills all hosts of the same interface-leased user.

You can configure only one IPv6 interface-leased user on each interface. To change the parameters of an existing IPv6 interface-leased user, use the undo form of the command to delete the user, and then reconfigure it with new parameter settings.

You cannot configure an interface-leased user on an interface configured with individual users or subnet-leased users.

Examples

Configure an IPv6 interface-leased user with a username of **intuser** and a plaintext password of **pw123** on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber interface-leased username intuser
password plaintext pw123
```

Related commands

ipv6 subscriber nas-port-id format

Use **ipv6 subscriber nas-port-id format** to configure NAS-Port-ID formats for IPv6 users.

Use **undo ipv6 subscriber nas-port-id format** to restore the default.

Syntax

ipv6 subscriber nas-port-id format cn-telecom { **version1.0** | **version2.0** }

undo ipv6 subscriber nas-port-id format

Default

NAS-Port-ID for IPv6 users is encapsulated in the format of version 1.0.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

`version 1.0`: Specifies the China Telecom format.

- The version 1.0 encapsulation format varies by interface type.

  Table 17 Version 1.0 encapsulation formats

Interface type	Encapsulation format
Layer 3 Ethernet interface and Layer 3 aggregate interface	slot=*slot_num*;subslot=*subslot_num*;port=*port_num*;vlanid=0
Layer 3 Ethernet subinterface and Layer 3 aggregate subinterface (single VLAN tag)	slot=*slot_num*;subslot=*subslot_num*;port=*port_num*;vlanid=*vlan_id*
Layer 3 Ethernet subinterface and Layer 3 aggregate subinterface (Dual VLAN tags)	*slot*=*slot_num*;subslot=*subslot_num*;port=*port_num*;vlanid=*inner-vlan*;vlanid2=*outer-vlan*
ATM-based virtual Layer 3 Ethernet interface (IPoEoA)	slot=*slot_num*;subslot=*subslot_num*;port=*port_num*;vpi=*vpi*;vci=*vci*

- Version 1.0 format parameters

  Table 18 Version 1.0 format parameter description

Parameter	Description
slot_num	Specifies the slot number of the access interface on the BRAS.
subslot_num	Specifies the subslot number of the access interface on the BRAS.
port_num	Specifies the port number of the access interface on the BRAS.
vlan_id	Specifies the ID of the user's VLAN.
inner-vlan	Specifies the ID of the inner VLAN.
outer-vlan	Specifies the ID of the outer VLAN.
vpi	Specifies the VPI of the access interface on the BRAS.
vci	Specifies the VCI of the access interface on the BRAS.

`version 2.0`: Specifies the format described in *`YDT 2275-2011 Subscriber Access Loop (Port) Identification in Broadband Access Networks`*.

- Version 2.0 encapsulation format:

  {eth | trunk | atm} NAS_slot/NAS_subslot/NAS_port:svlan.cvlan AccessNodeIdentifier/ANI_rack/ANI_frame/ANI_slot/ANI_subslot/ANI_port

- Version 2.0 format parameters:

Table 19 Version 2.0 format parameter description

Parameter	Description
{eth|trunk|atm}	Specifies the type of the access interface on the BRAS as Ethernet, trunk, or ATM.
NAS_slot	Specifies the slot number of the access interface on the BRAS.
NAS_subslot	Specifies the subslot number of the access interface on the BRAS.
NAS_port	Specifies the port number of the access interface on the BRAS.
svlan	Specifies the ID of the user's SVLAN.
cvlan	Specifies the ID of the user's CVLAN.
AccessNodeIdentifier	Specifies the identifier of the access node.
ANI_rack	Specifies the rack number of the access node.
ANI_frame	Specifies the frame number of the access node.
ANI_slot	Specifies the slot number of the access node.
ANI_subslot	Specifies the subslot number of the access node.
ANI_port	Specifies the port number of the access node.

Examples

Configure version 2.0 as the format for encapsulating NAS-Port-ID on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber nas-port-id format cn-telecom version2.0
```

Related commands

ipv6 subscriber nas-port-id nasinfo-insert

Use **ipv6 subscriber nas-port-id nasinfo-insert** to include NAS information and information obtained from DHCPv6 Option 18 in NAS-Port-ID.

Use **undo ipv6 subscriber nas-port-id nasinfo-insert** to restore the default.

Syntax

ipv6 subscriber nas-port-id nasinfo-insert

undo ipv6 subscriber nas-port-id nasinfo-insert

Default

The BRAS uses information obtained from DHCPv6 Option 18 as NAS-Port-ID.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Usage guidelines

Configure version 2.0 format and the trusted DHCP option before you use this command.

- If DHCP packets contain Option 18, this command includes NAS information and the obtained option information in NAS-Port-ID. Option 18 is not affected.
- If DHCP packets do not contain Option 18, this command includes NAS information in NAS-Port-ID and sets non-NAS parts to zeros in the following format:

  NAS_slot/NAS_subslot/NAS_port:svlan.cvlan 0/0/0/0/0/0

Examples

Include NAS information and the obtained Option 18 information in NAS-Port-ID on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber nas-port-id format cn-telecom version2.0

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

802.11: Specifies the port type complying with Wireless-IEEE 802.11. The type ID is 19.

adsl-cap: Specifies the ADSL-CAP port type, including Asymmetric DSL and Carrierless Amplitude Phase Modulation. The type ID is 12.

adsl-dmt: Specifies the ADSL-DMT port type, including Asymmetric DSL and Discrete Multi-Tone. The type ID is 13.

async: Specifies the Async port type with a type ID of 0.

cable: Specifies the Cable port type with a type ID of 17.

ethernet: Specifies the Ethernet port type with a type ID of 15.

g.3-fax: Specifies the G.3 Fax port type with a type ID of 10.

hdlc: Specifies the HDLC port type with a type ID of 7.

idsl: Specifies the IDSL port type with a type ID of 14.

isdn-async-v110: Specifies the ISDN Async V.110 port type with a type ID of 4.

ISDN Async V.110: Specifies the ISDN Async V.120 port type with a type ID of 3.

isdn-sync: Specifies the ISDN Sync port type with a type ID of 2.

piafs: Specifies the port type complying with PIAFS. The type ID is 6.

sdsl: Specifies the SDSL port type with a type ID of 11.

sync: Specifies the Sync port type with a type ID of 1.

virtual: Specifies the Virtual port type with a type ID of 5.

wireless-other: Specifies the Wireless-other port type with a type ID of 18.

x.25: Specifies the X.25 port type with a type ID of 8.

x.75: Specifies the X.75 port type with a type ID of 9.

xdsl: Specifies the XDSL port type with a type ID of 16.

Usage guidelines

The NAS-Port-Type attribute carries information about the access interface. The BRAS includes the configured NAS-Port-Type in RADIUS requests sent to the RADIUS server.

Examples

Configure the port type as **sdsl** for IPv6 interface GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber nas-port-type sdsl
```

ipv6 subscriber ndrs domain

Use **ipv6 subscriber ndrs domain** to configure an ISP domain for IPv6-ND-RS users.

Use **undo ipv6 subscriber ndrs domain** to restore the default.

Syntax

ipv6 subscriber ndrs domain *domain-name*

undo ipv6 subscriber ndrs domain

Default

IPv6-ND-RS users use the default system ISP domain.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

Usage guidelines

This command specifies an ISP domain for IPv6-ND-RS users. The specified ISP domain must exist on the BRAS.

If you do not use this command to configure the ISP domain, the default system domain is used.

Examples

Configure ISP domain **ipoe** for IPv6-ND-RS users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber ndrs domain ipoe
```

Related commands

ipv6 subscriber initiator ndrs enable

ipv6 subscriber ndrs max-session

Use **ipv6 subscriber ndrs max-session** to configure the maximum number of IPoE sessions for IPv6-ND-RS users on an interface.

Use **undo ipv6 subscriber ndrs max-session** to restore the default.

Syntax

ipv6 subscriber ndrs max-session *max-number*

undo ipv6 subscriber ndrs max-session

Default

The maximum number of IPoE sessions for IPv6-ND-RS users on an interface is not configured.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of IPoE sessions for IPv6-ND-RS users. The value range for this argument is 1 to 64000.

Usage guidelines

If IPoE sessions for IPv6-ND-RS user reach the maximum, no more IPoE session can be initiated IPv6 ND RS packets.

Examples

Set the maximum number of IPoE sessions to **100** for IPv6-ND-RS users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber ndrs max-session 100
```

Related commands

display ipv6 subscriber session

ipv6 subscriber initiator ndrs enable

reset ipv6 subscriber session

ipv6 subscriber ndrs username

Use **ipv6 subscriber ndrs username** to configure an authentication user naming convention for IPv6-ND-RS users.

Use **undo ipv6 subscriber ndrs username** to restore the default.

Syntax

ipv6 subscriber ndrs username include { **nas-port-id** [**separator** *separator*] | **port** [**separator** *separator*] | **second-vlan** [**separator** *separator*] | **slot** [**separator** *separator*] | **source-mac** [**address-separator** *address-separator*] [**separator** *separator*] | **subslot** [**separator** *separator*] | **sysname** [**separator** *separator*] | **vlan** [**separator** *separator*] } *

undo ipv6 subscriber ndrs username

Default

An IPv6-ND-RS user uses its source MAC address as the authentication username.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

nas-port-id: Includes the NAS-Port-ID attribute in a username.

port: Includes the number of the port that receives the user packets in a username.

second-vlan: Includes the inner VLAN ID in a username.

slot: Includes the number of the slot that receives the user packets in a username.

source-mac: Includes the source MAC address in a username.

separator *separator*: Specifies any printable character as the separator for the MAC address. For example, if you specify a hyphen (-) as the separator, the username is the hyphen-separated MAC address (xxxx-xxxx-xxxx). If you do not specify a separator, the username is the non-separated MAC address (xxxxxxxxxxxx). Do not use the at sign (@) as the separator. The AAA server cannot parse a username containing the at sign (@).

subslot: Includes the number of the subslot that receives the user packets in a username.

sysname: Includes the name of the device that receives the user packets in a username.

vlan: Includes the outer VLAN ID in a username.

separator *separator*: Specifies a character for separating an option and the option that follows. Do not use the at sign (@) as the separator. The AAA server cannot parse a username containing the at sign (@).

Usage guidelines

Usernames obtained based on the naming convention are used for authentication and must be the same as those configured on the AAA server.

You can specify one or more keywords in a naming convention. If you use a combination of keywords, a username obtained based on the naming convention includes the specified options in the configuration order.

Examples

Configure the source MAC addresses as the authentication usernames for IPv6-ND-RS users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber ndrs username include source-mac
```

Configure an authentication user naming convention for IPv6-ND-RS users on GigabitEthernet 1/0/1. Each username contains the device name, slot number, subslot number, port number, and outer VLAN, separated by the pound sign (#).

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber ndrs username include sysname separator
# slot separator # subslot separator # port separator # vlan
```

Related commands

ipv6 subscriber initiator ndrs enable

ipv6 subscriber password

ipv6 subscriber password

Use **ipv6 subscriber password** to configure passwords for IPv6 individual users.

Use **undo ipv6 subscriber password** to restore the default.

Syntax

ipv6 subscriber password { **ciphertext** | **plaintext** } *string*

undo ipv6 subscriber password

Default

The password for IPv6 individual users is **vlan**.

Views

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Usage guidelines

Passwords configured by this command are used for authentication, and must be the same as those configured on the AAA server.

A DHCPv6 user can obtain a password in various ways. For password priority, see "ipv6 subscriber dhcp password option16."

Parameters

ciphertext *string*: Specifies a ciphertext password, a case-sensitive string of 1 to 117 characters.

plaintext *string*: Specifies a plaintext password, a case-sensitive string of 1 to 63 characters. For security purposes, the password specified in plaintext form will be stored in encrypted form.

Examples

Configure the plaintext password as **123** for IPv6 individual users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber password plaintext 123
```

ipv6 subscriber service-identify

Use **ip subscriber service-identify** to configure service identifier for IPv6 unclassified-IP users, static individual users, and leased users.

Use **undo ipv6 subscriber service-identify** to restore the default.

Syntax

Layer 3 Ethernet interface view, Layer 3 aggregate interface view, L3VE interface view, VEth interface view:

ipv6 subscriber service-identify dscp

undo ipv6 subscriber service-identify

Layer 3 Ethernet subinterface view, Layer 3 aggregate subinterface view, L3VE subinterface view, VEth subinterface view:

ipv6 subscriber service-identify { **8021p** { **second-vlan** | **vlan** } | **dscp** | **second-vlan** | **vlan** }

undo ipv6 subscriber service-identify

VLAN interface view:

ipv6 subscriber service-identify { **8021p vlan** } | **dscp** | **vlan** }

undo ipv6 subscriber service-identify

Default

No service identifier is configured for IPv6 unclassified-IP users, static individual users, and leased users.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

8021p second-vlan: Specifies the 802.1p value of the inner VLAN tag in QinQ mode as the service identifier.

8021p vlan: Specifies the 802.1p value of the VLAN tag or the 802.1p value of the outer VLAN tag in QinQ mode as the service identifier.

dscp: Specifies the DSCP value as the service identifier.

second-vlan: Specifies the inner VLAN ID in QinQ mode as the service identifier.

vlan: Specifies the VLAN ID or the outer VLAN ID in QinQ mode as the service identifier.

Usage guidelines

You must specify an identifier for a service before you bind an ISP domain to the service. Otherwise, the binding does not take effect.

IPv6 unclassified-IP users, static individual users, and leased users whose IP packets containing the specified service identifier will be assigned a service-specific ISP domain.

You can configure only one service identifier on each interface.

Examples

Configure **dscp** as the service identifier on GigabitEthernet 1/0/1 for IPv6 unclassified-IP users, static individual users, and leased users.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber service-identify dscp
```

ipv6 subscriber session static

Use **ipv6 subscriber session static** to configure IPv6 static IPoE sessions.

Use **undo ipv6 subscriber session static** to delete IPv6 static IPoE sessions.

Syntax

ipv6 subscriber session static ipv6 *ipv6-address* [**vlan** *vlan-id* [**second-vlan** *vlan-id*]] [**mac** *mac-address*] [**domain** *domain-name*] [**description** *string*]

undo ipv6 subscriber session static ipv6 *ipv6-address* [**vlan** *vlan-id* [**second-vlan** *vlan-id*]]

Default

No IPv6 static IPoE session exists.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

ip *ip-address*: Specifies a user IPv6 address.

vlan *vlan-id*: Specifies an outer VLAN ID of the user packet, in the range of 1 to 4094. This option is available only for subinterfaces.

second-vlan *vlan-id*: Specifies an inner VLAN ID of the user packet, in the range of 1 to 4094. This option is available only for subinterfaces.

mac *mac-address*: Specifies a user MAC address in the form of H-H-H.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@). If you do not specify an ISP domain, the default system domain is used. For more information about the default system domain, see *Security Configuration Guide*.

description *string*: Specifies the static session description, a case-insensitive string of 1 to 31 characters. If this option is not specified, the static session does not have a description. The description cannot contain the following characters: forward slashes (/), backslashes (\), vertical bars (|), quotation marks ("), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), and at signs (@).

Usage guidelines

Static IPoE sessions have higher priority than dynamic IPoE sessions. If a user IP, DHCP, or ND RS packet matches a static IPoE session, the static IPoE session overwrites the existing dynamic IPoE session.

When the IPv6 address specified in a static session overlaps with the assignable IPv6 addresses in the DHCP address pool, you must use the **ipv6 dhcp server forbidden-address** command to exclude the overlapping IPv6 address in the DHCPv6 address pool from dynamic address allocation. For more information about excluding IPv6 addresses from dynamic allocation, see DHCPv6 configuration in *Layer 3—IP Services Configuration Guide*.

You can configure multiple static IPoE sessions on an interface. Static IPv6 IPoE sessions include the following types:

- A session with a specified IPv6 address.
- A session with a specified IPv6 address and outer VLAN ID.
- A session with a specified IPv6 address, outer VLAN ID, and inner VLAN ID.

For each session type, configuration fails if the settings are identical to the settings of an existing session.

To change the parameters of an existing IPoE session, use the undo form of the command to delete the session, and then reconfigure it with new parameter settings.

You cannot configure a static IPoE session on an interface configured with dedicated-interface or subnet-leased users.

Examples

Configure an IPv6 static IPoE session with an IP address of 2000::1 and an ISP domain of **dm1** on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber session static ipv6 2000::1 domain dm1
```

Related commands

undo ipv6 subscriber subnet-leased ipv6 *ipv6-address prefix-length*

Default

No IPv6 subnet-leased user exists.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

ip *ip-address*: Specifies a user IPv6 address.

prefix-length: Specified the IPv6 prefix length in the range of 1 to 127.

username *name*: Specifies a username for authentication, a case-sensitive string of 1 to 255 characters.

password: Specifies a password for authentication.

ciphertext *string*: Specifies a ciphertext password, a case-sensitive string of 1 to 117 characters.

plaintext *string*: Specifies a plaintext password, a case-sensitive string of 1 to 63 characters. For security purposes, the password specified in plaintext form will be stored in encrypted form.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@). If you do not specify an ISP domain, the default system domain is used. For more information about the default system domain, see *Security Configuration Guide*.

Usage guidelines

An IPv6 subnet-leased user is a group of IPv6 hosts that rent the same subnet of an interface and share the same IPoE session. The BRAS authenticates, authorizes, and bills all hosts of the same subnet-leased user.

You can configure only one IPv6 subnet-leased user on each subnet.

You cannot configure a subnet-leased user on an interface configured with individual users or interface-leased users.

Examples

Configure an IPv6 subnet-leased user with an IPv6 prefix of **2001:10::100**, prefix length of **64**, a username of **netuser,** and a plaintext password of **pw123** on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber subnet-leased ipv6 2001:10::100 64
username netuser password plaintext pw123
```

Related commands

ipv6 subscriber timer quiet

Use **ipv6 subscriber timer quiet** to configure a quiet timer for IPv6 users.

Use **undo ipv6 subscriber timer quiet** to restore the default.

Syntax

ipv6 subscriber timer quiet *time*

undo ipv6 subscriber timer quiet

Default

No quite timer is configured for IPv6 users.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the quiet timer in the range of 10 to 3600 seconds.

Usage guidelines

IPoE starts the quiet timer after a user fails authentication. It discards packets from the user during the quiet time. After the quiet timer expires, IPoE performs authentication upon receiving a packet from the user.

Examples

Set the quiet time to **100** seconds for IPv6 users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber timer quiet 100
```

ipv6 subscriber trust

Use **ipv6 subscriber trust** to configure a trusted option for DHCPv6 users.

Use **undo ipv6 subscriber trust** to cancel a trusted option.

Syntax

ipv6 subscriber trust { **option16** | **option18** | **option37** }

undo ipv6 subscriber trust { **option16** | **option18** | **option37** }

Default

No trusted options are configured for DHCPv6 users.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

option16: Specifies Option 16 as the trusted option.

option18: Specifies Option 18 as the trusted option.

option37: Specifies Option 37 as the trusted option.

Usage guidelines

If the BRAS trusts DHCPv6 Option 16, the following option information is used as the ISP domain:

- All information in Option 16 if the option does not contain invalid characters or the at sign (@).

  Invalid characters include the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), and right angle bracket (>).
- Information that follows the last at sign (@) if the option contains at signs (@) and does not contain invalid characters.

If the BRAS does not trust DHCPv6 Option 16, the ISP domains are used in the following order:

1. Domain specified in the **ipv6 subscriber dhcp domain** command.
2. Default system domain.

If the BRAS trusts DHCPv6 Option 18 or Option 37, it obtains the following information from the option and uses the information to encapsulate RADIUS attributes:

- Obtains information from Option 18 and uses it to encapsulate NAS-Port-ID that adopts version 2.0 as the encapsulation format.
- Obtains information from Option 18 and uses it to encapsulate DSL_AGENT_CIRCUIT_ID.
- Obtains information from Option 37 and uses it to encapsulate DSL_AGENT_REMOTE_ID.

Examples

Configure DHCPv6 Option 18 as a trusted option on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber trust option18
```

Syntax

ipv6 subscriber unclassified-ip domain *domain-name*

undo ipv6 subscriber unclassified-ip domain

Default

IPv6 unclassified-IP users, static individual users, and leased users use the default system ISP domain.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

Usage guidelines

This command configures an ISP domain for IPv6 unclassified-IP users, static individual users, and leased users. The configured ISP domain must exist on the BRAS.

The BRAS selects an ISP domain for an IPv6 unclassified-IP user, static individual user, or leased user in the following order:

1. Service-specific domain.
2. Domain specified by this command.
3. Default system domain.

Examples

Configure ISP domain **ipoe** for IPv6 unclassified-IP users, static individual users, and leased users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1

ipv6 subscriber initiator unclassified-ip enable

ipv6 subscriber password

ipv6 subscriber user-detect

Use **ipv6 subscriber user-detect** to configure online detection for IPv6 individual users.

Use **undo ipv6 subscriber user-detect** to restore the default.

Syntax

ipv6 subscriber user-detect { **icmpv6** | **nd** } **retry** *retries* **interval** *interval*

undo ipv6 subscriber user-detect

Default

Online detection for IPv6 individual users is disabled.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

icmpv6: Specifies the ICMPv6 request packet as detection packets.

nd: Specifies the NS packet of the ND protocol as detection packets.

retry *retries*: Specifies the maximum number of detection attempts following the first detection attempt, in the range of 2 to 5.

interval *interval*: Configures the detection timer in the range of 30 to 1200 seconds.

Usage guidelines

Online detection enables the BRAS to periodically detect the status of an IPv6 individual user. It uses NS requests of the ND protocol and ICMPv6 requests to detect IPv6 individual users. If IPv6 individual users and the interface are in different subnets, only ICMPv6 request packets can be used for detection.

After you configure online detection, the BRAS starts a detection timer to detect online users. If the BRAS does not receive user packets before the detection timer expires, it sends a detection packet to the user.

- If the BRAS receives user packets within the maximum detection attempts, the BRAS assumes that the user is online. It resets the detection timer, and starts the next detection attempt.
- If the BRAS does not receive user packets after detection attempts reach the maximum, the BRAS assumes that the user is offline and deletes the user session.

Examples

Configure online detection on GigabitEthernet 1/0/1. The maximum number of detection attempts is **3**, the detection timer is **50** seconds, and the detection packet type is **ND.**

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber user-detect nd retry 3 interval 50
```

Related commands

ipv6 subscriber enable

ipv6 subscriber vlan

Use **ipv6 subscriber vlan** to bind an ISP domain to a VLAN list for IPv6 unclassified-IP users, static individual users, and leased users.

Use **undo ipv6 subscriber vlan** to remove the binding between an ISP domain and a VLAN list.

Syntax

ipv6 subscriber vlan *vlan-list* **domain** *domain-name*

undo ipv6 subscriber vlan *vlan-list*

Default

No ISP domain is bound to a VLAN list for IPv6 unclassified-IP users, static individual users, and leased users.

Views

Layer 3 Ethernet subinterface view

L3VE subinterface view

VEth subinterface view

VLAN interface view

Predefined user roles

network-admin

context-admin

Parameters

vlan-list: Specifies a space-separated list of up to 10 VLAN ID items. Each item specifies a VLAN by its ID or a range of VLANs in the form of start-VLAN-ID to end-VLAN-ID. The VLAN ID is in the range of 1 to 4094.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

Usage guidelines

This command configures an ISP domain for IPv6 unclassified-IP users, static individual users, and leased users who send IP packets with the specified VLAN IDs.

Examples

Configure ISP domain **vlandm** for IPv6 users who send IP packets with the specified VLAN IDs on GigabitEthernet 1/0/1.100. The specified VLAN IDs are in the range of 2 to 100.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1.100
[Sysname-GigabitEthernet1/0/1.100] ipv6 subscriber service-identify second-vlan
[Sysname-GigabitEthernet1/0/1.100] ipv6 subscriber vlan 2 to 100 domain vlandm
```

Syntax

ipv6 subscriber whitelist enable

undo ipv6 subscriber whitelist enable

Default

The IPv6 IPoE whitelist feature is disabled.

Views

Layer 3 aggregate interface/subinterface view

Layer 3 Ethernet interface/subinterface view

Predefined user roles

network-admin

context-admin

Usage guidelines

With this feature enabled, only IPv6 traffic matching static IPv6 IPoE sessions can initiate IPoE authentication, and IPoE directly permits the other traffic without any processing.

In some scenarios, an interface might need to have both IPoE and portal authentication enabled. For example, both dumb terminals and broadband dial-up users exist on an interface. Dumb terminals

(for example, monitoring cameras) need to come online through IPoE without portal authentication, and broadband dial-up users need to come online through portal Web authentication. In this case, you can enable the IPv6 IPoE whitelist feature on the interface. When both the IPv6 IPoE whitelist feature and portal authentication are enabled on an interface, the following rules apply:

- If the IPv6 traffic of a user matches a static IPv6 IPoE session, the user is processed by the static IPv6 IPoE authentication flow. For an IPoE user to bypass authentication, specify the authentication and authorization modes as **none** in the ISP domain of the IPoE user.
- If the IPv6 traffic of a user does not match any IPv6 IPoE session, the user is processed by portal authentication.

Examples

Enable the IPv6 IPoE whitelist feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 subscriber whitelist enable
```

reset ipv6 subscriber offline statistics

Use **reset ipv6 subscriber offline statistics** to remove offline statistics for IPv6 users.

Syntax

reset ipv6 subscriber offline statistics [**interface** *interface-type interface-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command removes offline statistics for IPv6 users for all interfaces.

Examples

Remove offline statistics for all IPv6 users on GigabitEthernet1/0/1.

```
<Sysname> reset ipv6 subscriber offline statistics
```

Related commands

display ipv6 subscriber offline statistics

reset ipv6 subscriber session

Use **reset ipv6 subscriber session** to delete dynamic IPv6 IPoE sessions and log out users.

Syntax

reset ipv6 subscriber session [**interface** *interface-type interface-number*] [**domain** *domain-name* | **ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] | **mac** *mac-address* | **username** *name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command deletes dynamic IPv6 IPoE sessions for all interfaces.

domain *domain-name*: Specifies an ISP domain name, a case-insensitive string of 1 to 255 characters. The name cannot contain the slash (/), back slash (\), vertical bar (|), quotation mark ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

ipv6 *ipv6-address*: Specifies the IPv6 address of the IPoE session to be deleted.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command deletes IPv6 IPoE sessions on the public network.

mac *mac-address*: Specifies the MAC address of an IPv6 IPoE session to be deleted, in the format of H-H-H.

username *name*: Specifies the username of the IPv6 IPoE session to be deleted, a case-sensitive string of 1 to 255 characters.

Usage guidelines

If you do not specify any parameters, this command deletes all dynamic IPv6 IPoE sessions.

To delete static IPoE sessions for static users and leased users, use the **undo** commands.

Examples

Delete dynamic IPv6 IPoE sessions and log out users on GigabitEthernet 1/0/1.

```
<Sysname> reset ipv6 subscriber session interface gigabitethernet 1/0/1
```

Related commands

display ipv6 subscriber session

Contents

Public key management commands

display public-key local public

Use **display public-key local public** to display local public keys.

Syntax

display public-key local { **dsa** | **ecdsa** | **rsa** | **sm2** } **public** [**name** *key-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

dsa: Specifies the DSA key pair type.

ecdsa: Specifies the ECDSA key pair type.

rsa: Specifies the RSA key pair type.

sm2: Specifies the SM2 key pair type.

name *key-name*: Specifies a local key pair by its name, a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not specify a key pair, this command displays the public keys of all local key pairs of the specified type.

Usage guidelines

You can copy and distribute the public key of a local key pair to peer devices.

You cannot display a host public key that has the default key pair name by specifying the **name** *key-name* option. To view a host public key that has the default key pair name, display all local public keys by using this command without specifying a key pair name.

Examples

Display all local RSA public keys.

```
<Sysname> display public-key local rsa public

Table 1 Command output

Field	Description
Key name	Name of the local key pair. If you did not specify a name when creating the key pair, the default name is used followed by the word **default** in brackets. The following is the default key pair name for each key algorithm: • **hostkey**—Default RSA host key pair name. • **serverkey**—Default RSA server key pair name. • **dsakey**—Default DSA host key pair name. • **ecdsakey**—Default ECDSA host key pair name. • **sm2key**—Default SM2 host key pair name.
Key type	Options include: • RSA. • DSA. • ECDSA. • SM2.
Key length	Key length in bits.

Field	Description
Storage device serial number	Serial number of the crypto device that generated the key pair. This field is not displayed if the key pair is created by a software algorithm.
Time when key pair created	Date and time when the local key pair was created.
Key code	Public key string.

Related commands

public-key local create

display public-key peer

Use **display public-key peer** to display information about peer host public keys.

Syntax

display public-key peer [**brief** | **name** *publickey-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

brief: Displays brief information about all peer host public keys. The brief information includes only the key type, key modulus, and key name.

name *publickey-name*: Displays detailed information about a peer host public key, including its key code. The *publickey-name* argument specifies a peer host public by its name, a case-sensitive string of 1 to 64 characters.

Usage guidelines

If you do not specify any keywords, this command displays detailed information about all peer host public keys configured on the local device.

You can use the **public-key peer** command or the **public-key peer import sshkey** command to configure a peer host public key on the local device.

Examples

Display detailed information about peer host public key **idrsa**.

```
<Sysname> display public-key peer name idrsa

=========================================
Key name: idrsa
Key type: RSA
Key length: 1024
Key code:
   30819F300D06092A864886F70D010101050003818D0030818902818100C5971581A78B5388

```

Table 2 Command output

Field	Description
Key name	Name of the peer host public key.
Key type	Key type: RSA, DSA or ECDSA.
Key length	Key length in bits.
Key code	Public key string.

Display brief information about all peer host public keys.

```
<Sysname> display public-key peer brief
Type  Modulus  Name
--------------------------
RSA   1024    idrsa
DSA   1024    10.1.1.1
```

Table 3 Command output

Field	Description
Type	Key type: RSA, DSA or ECDSA.
Modulus	Key modulus length in bits.
Name	Name of the peer host public key.

Related commands

public-key peer

public-key peer import sshkey

peer-public-key end

Use **peer-public-key end** to return from public key view to system view and save the configured peer host public key.

Syntax

peer-public-key end

Views

Public key view

Predefined user roles

network-admin

context-admin

Usage guidelines

After you type the peer host public key on the local device, use this command to exit public key view and to save the peer host public key.

The system verifies the public key before saving it. If the key is not in the correct format, the system discards the key and displays an error message. If the key is valid, for example, the key was displayed by the **display public-key local public** command, the system saves the key.

Examples

Exit public key view and save the configured peer host public key.

```
<Sysname> system-view
[Sysname] public-key peer key1
Enter public key view. Return to system view with "peer-public-key end" command.
[Sysname-pkey-public-key-key1]30819F300D06092A864886F70D010101050003818D0030818902818

[Sysname-pkey-public-key-key1] peer-public-key end
[Sysname]
```

Related commands

display public-key local public

display public-key peer

public-key peer

public-key local create

Use **public-key local create** to create local key pairs.

Syntax

public-key local create { **dsa** | **ecdsa** [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**] | **rsa** } [**name** *key-name*]

public-key local create sm2 [**name** *key-name*] [**on** *device-name*]

Default

No local key pairs exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dsa: Specifies the DSA key pair type.

ecdsa: Specifies the ECDSA key pair type.

- **secp192r1**: Uses the secp192r1 curve to create a 192-bit ECDSA key pair.
- **secp256r1**: Uses the secp256r1 curve to create a 256-bit ECDSA key pair.

- **secp384r1**: Uses the secp384r1 curve to create a 384-bit ECDSA key pair.
- **secp521r1**: Uses the secp521r1 curve to create a 521-bit ECDSA key pair.

By default, the secp192r1 curve is used.

rsa: Specifies the RSA key pair type.

sm2: Specifies the SM2 key pair type.

name *key-name*: Assigns a name to the key pair. The *key-name* argument is a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not assign a name to the key pair, the key pair takes the default name (see Table 4).

on *device-name*: Specifies the crypto device to be used to generate the SM2 key pair. The *device-name* argument specifies the device name, a case-sensitive string of 1 to 31 characters. If you do not specify a crypto device, the SM2 key pair will be created by a software algorithm. You can view the names of available crypto devices by entering a question mark (?) after the **on** keyword.

Table 4 Default local key pair names

Type	Default name
RSA	• Host key pair: **hostkey** • Server key pair: **serverkey**
DSA	**dsakey**
ECDSA	**ecdsakey**
SM2	**sm2key**

Usage guidelines

The key algorithm must be the same as required by the security application.

When you create an RSA or DSA key pair, enter an appropriate key modulus length at the prompt. The longer the key modulus length, the higher the security, and the longer the key generation time.

When you create an ECDSA key pair, choose the appropriate elliptic curve. The elliptic curve determines the ECDSA key length. The longer the key length, the higher the security, and the longer the key generation time.

When you create an SM key pair, you do not need to specify the key length. Only a 256-bit SM2 key pair can be created.

See Table 5 for more information about key modulus lengths and key lengths.

If you do not assign the key pair a name, the system assigns the default name to the key pair and marks the key pair as **default**. You can also assign the default name to another key pair, but the system does not mark the key pair as **default**. The name of a key pair must be unique among all manually named key pairs that use the same key algorithm. If a name conflict occurs, the system asks whether you want to overwrite the existing key pair.

The key pairs are automatically saved and can survive system reboots.

Table 5 A comparison of different types of asymmetric key algorithms

Type	Generated key pairs	Modulus/key length
RSA	• One host key pair, if you specify a key pair name. • One server key pair and one host key pair, if you do not specify a key pair name. Both key pairs use their default names. **NOTE:** Only SSH 1.5 uses the RSA server key pair.	Key modulus length: 512 to 2048 bits. Default: 1024 bits. To ensure security, use a minimum of 768 bits.
DSA	One host key pair.	Key modulus length: 512 to 2048 bits. Default: 1024 bits. To ensure security, use a minimum of 768 bits.
ECDSA	One host key pair.	Key length: 192, 256, 384, or 521 bits.
SM2	One host key pair.	Key length: 256 bits.

Examples

Create local RSA key pairs with default names.

```
<Sysname> system-view
[Sysname] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
...++++++
.++++++
..++++++++
....++++++++
Create the key pair successfully.
```

Create a local DSA key pair with the default name.

```
<Sysname> system-view
[Sysname] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+..+.............
.......+..........+............+............+...+.....+.............+..+...
...+................+.........+...+....+.......+.....+...........+.........+.
.......................+........+.........+............+.....+...+..........
..............+.........+.........+...........+........+....+.................
.....++++++++++++++++++++++++++++++++++++++++++++++++++*
Create the key pair successfully.
```

Create a local ECDSA key pair with the default name.

```
<Sysname> system-view
[Sysname] public-key local create ecdsa
Generating Keys...
Create the key pair successfully.
```

Create a local SM2 key pair with the default name.

```
<Sysname> system-view
[Sysname] public-key local create sm2
Generating Keys...
Create the key pair successfully.
```

Create a local RSA key pair named **rsa1**.

```
<Sysname> system-view
[Sysname] public-key local create rsa name rsa1
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
...++++++
..............................++++++
Create the key pair successfully.
```

Create a local DSA key pair named **dsa1**.

```
<Sysname> system-view
[Sysname] public-key local create dsa name dsa1
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+..+.............

..............+.........+..........+...........+........+....+.................
.....++++++++++++++++++++++++++++++++++++++++++++++++++*
Create the key pair successfully.
```

Create a local ECDSA key pair named **ecdsa1**.

```
<Sysname> system-view
[Sysname] public-key local create ecdsa name ecdsa1
Generating Keys...
Create the key pair successfully.
```

Create a local SM2 key pair named **sm2**.

```
<Sysname> system-view
[Sysname] public-key local create sm2 name sm2
Generating Keys...
Create the key pair successfully.
```

Related commands

display public-key local public

public-key local destroy

public-key local destroy

Use **public-key local destroy** to destroy local key pairs.

Syntax

public-key local destroy { **dsa** | **ecdsa** | **rsa** | **sm2** } [**name** *key-name*]

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dsa: Specifies the DSA key pair type.

ecdsa: Specifies the ECDSA key pair type.

rsa: Specifies the RSA key pair type.

sm2: Specifies the SM2 key pair type.

name *key-name*: Specifies a local key pair by its name, a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not specify a key pair, this command destroys all key pairs of the specified type.

Usage guidelines

To avoid key compromise, destroy the local key pair and generate a new pair after in any of the following situations:

- An intrusion event has occurred.
- The storage media of the device is replaced.
- The key pair has been used for a long time and there is a risk of key compromise or decryption.
- The local certificate has expired. For more information about local certificates, see PKI configuration in *Security Configuration Guide*.

Examples

Destroy the local RSA key pairs with the default names.

```
<Sysname> system-view
[Sysname] public-key local destroy rsa
Confirm to destroy the key pair? [Y/N]:y
```

Destroy the local DSA key pair with the default name.

```
<Sysname> system-view
[Sysname] public-key local destroy dsa
Confirm to destroy the key pair? [Y/N] :y
```

Destroy the local ECDSA key pair with the default name.

```
<Sysname> system-view
[Sysname] public-key local destroy ecdsa
Confirm to destroy the key pair? [Y/N]:y
```

Destroy the local SM2 key pair with the default name.

```
<Sysname> system-view
[Sysname] public-key local destroy sm2
Confirm to destroy the key pair? [Y/N]:y
```

Destroy local RSA key pair **rsa1**.

```
<Sysname> system-view
[Sysname] public-key local destroy rsa name rsa1
Confirm to destroy the key pair? [Y/N]:y
```

Destroy local DSA key pair **dsa1**.

```
<Sysname> system-view
[Sysname] public-key local destroy dsa name dsa1
Confirm to destroy the key pair? [Y/N] :y
```

Destroy local ECDSA key pair **ecdsa1**.

```
<Sysname> system-view
[Sysname] public-key local destroy ecdsa name ecdsa1
Confirm to destroy the key pair? [Y/N]:y
```

Destroy local SM2 key pair **sm2**.

```
<Sysname> system-view
[Sysname] public-key local destroy sm2 name sm2
Confirm to destroy the key pair? [Y/N]:y
```

Related commands

public-key local create

public-key local export dsa

Use **public-key local export dsa** to export a local DSA host public key.

Syntax

public-key local export dsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

name *key-name*: Specifies a local DSA key pair by its name, a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not specify a key pair, this command exports the host public key of the local DSA key pair with the default name.

openssh: Exports the host public key in OpenSSH format.

ssh2: Exports the host public key in SSH 2.0 format.

filename: Specifies the name of the file for saving the DSA host public key. The name cannot be all dots (.), hostkey, serverkey, dsakey, ecdsakey, or sm2key, and cannot start with a slash (/) or contain **./** or **../**. The file name is a case-insensitive string of 1 to 128 characters. For more information about file names, see file system management in *Fundamentals Configuration Guide*. If you do not specify a file name, this command displays the key on the monitor screen.

Usage guidelines

You can use this command to export a local DSA host public key before distributing it to a peer device.

To distribute a local DSA host public key to a peer device:

1. Save the exported local host public key to a file by using one of the following methods:
   - Use the **public-key local export dsa** [**name** *key-name*] { **openssh** | **ssh2** } command to export the local host public key, and then copy and paste the key to a file.
   - Use the **public-key local export dsa** [**name** *key-name*] { **openssh** | **ssh2** } *filename* command to export the key to a file. You cannot export the key to the **pkey** folder or its subfolders.
2. Transfer a copy of the file to the peer device, for example, by using FTP in binary mode or TFTP. For more information about FTP and TFTP, see *Fundamentals Configuration Guide*.
3. On the peer device, use the **public-key peer import sshkey** command to import the host public key from the file.

SSH 2.0 and OpenSSH are different public key formats. Choose the correct format that is supported on the device where you import the host public key.

Examples

Export the host public key of the local DSA key pair with the default name in OpenSSH format to a file named **key.pub**.

```
<Sysname> system-view
[Sysname] public-key local export dsa openssh key.pub
```

Display the host public key of the local DSA key pair with the default name in SSH 2.0 format.

```
<Sysname> system-view
[Sysname] public-key local export dsa ssh2

Related commands

public-key local create

public-key peer import sshkey

public-key local export ecdsa

Use **public-key local export ecdsa** to export a local ECDSA host public key.

Syntax

public-key local export ecdsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

name *key-name*: Specifies a local ECDSA key pair by its name, a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not specify a key pair, this command exports the host public key of the local ECDSA key pair with the default name.

openssh: Exports the host public key in OpenSSH format.

ssh2: Exports the host public key in SSH 2.0 format.

filename: Specifies the name of the file for saving the local host public key. The name cannot be all dots (.), hostkey, serverkey, dsakey, ecdsakey, or sm2key, and cannot start with a slash (/) or contain **./** or **../**.The file name is a case-insensitive string of 1 to 128 characters. For more information

about file names, see file system management in *Fundamentals Configuration Guide*. If you do not specify a file name, this command displays the key on the monitor screen.

Usage guidelines

You can use this command to export a local ECDSA host public key before distributing it to a peer device.

To distribute a local ECDSA host public key to a peer device:

1. Save the exported ECDSA host public key to a file by using one of the following methods:
   - Use the **public-key local export ecdsa** [**name** *key-name*] { **openssh** | **ssh2** } command to export the local host public key, and then copy and paste it to a file.
   - Use the **public-key local export ecdsa** [**name** *key-name*] { **openssh** | **ssh2** } *filename* command to export the host public key to a file. You cannot export the key to the **pkey** folder or its subfolders.
2. Transfer a copy of the file to the peer device, for example, by using FTP in binary mode or TFTP. For more information about FTP and TFTP, see *Fundamentals Configuration Guide*.
3. On the peer device, use the **public-key peer import sshkey** command to import the host public key from the file.

SSH 2.0 and OpenSSH are different public key formats. Choose the correct format that is supported by the device where you import the host public key.

Only the ECDSA host public key generated by using the secp256r1 curve can be exported.

Examples

Export the host public key of the local ECDSA key pair with the default name in OpenSSH format to file **key.pub**.

```
<Sysname> system-view
[Sysname] public-key local export ecdsa openssh key.pub
```

Display the host public key of the local ECDSA key pair with the default name in SSH 2.0 format.

```
<Sysname> system-view
[Sysname] public-key local export ecdsa ssh2
---- BEGIN SSH2 PUBLIC KEY ----
Comment: "ecdsa-sha2-nistp256-2014/07/06"

public-key peer import sshkey

public-key local export rsa

Use **public-key local export rsa** to export a local RSA host public key.

Syntax

public-key local export rsa [**name** *key-name*] { **openssh** | **ssh1** | **ssh2** } [*filename*]

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

name *key-name*: Specifies a local RSA key pair by its name, a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not specify a key pair, this command exports the host public key of the local RSA key pair with the default name.

openssh: Exports the host public key in OpenSSH format.

ssh1: Exports the host public key in SSH 1.5 format.

ssh2: Exports the host public key in SSH 2.0 format.

filename: Specifies the name of the file for saving the local host public key. The name cannot be all dots (.), hostkey, serverkey, dsakey, ecdsakey, or sm2key, and cannot start with a slash (/) or contain **./** or **../**. The file name is a case-insensitive string of 1 to 128 characters. For more information about file names, see file system management in *Fundamentals Configuration Guide*. If you do not specify a file name, this command displays the key on the monitor screen.

Usage guidelines

You can use this command to export a local RSA host public key before distributing it to a peer device.

To distribute a local RSA host public key to a peer device:

1. Save the exported local host public key to a file by using one of the following methods:
   - Use the **public-key local export rsa** [**name** *key-name*] { **openssh** | **ssh2** } command to export the key, and then copy and paste it to a file.
   - Use the **public-key local export rsa** [**name** *key-name*] { **openssh** | **ssh2** } *filename* command to export key to a file. You cannot export the key to the **pkey** folder or its subfolders.
2. Transfer a copy of the file to the peer device, for example, by using FTP in binary mode or TFTP. For more information about FTP and TFTP, see *Fundamentals Configuration Guide*.
3. On the peer device, use the **public-key peer import sshkey** command to import the host public key from the file.

Choose the correct public key format that is supported on the device where you import the host public key.

Examples

Export the host public key of the local RSA key pair with the default name in OpenSSH format to file **key.pub**.

```
<Sysname> system-view
[Sysname] public-key local export rsa openssh key.pub
```

Display the host public key of the local RSA key pair with the default name in SSH 2.0 format.

```
<Sysname> system-view
[Sysname] public-key local export rsa ssh2
---- BEGIN SSH2 PUBLIC KEY ----
```

Related commands

public-key local create

public-key peer import sshkey

public-key local export sm2

Use **public-key local export sm2** to export a local SM2 host public key.

Syntax

public-key local export sm2 [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

name *key-name*: Specifies a local SM2 key pair by its name, a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not specify a key pair, this command exports the host public key of the local SM2 key pair with the default name.

openssh: Exports the host public key in OpenSSH format.

ssh2: Exports the host public key in SSH2.0 format.

filename: Specifies the name of the file for saving the local host public key. The name cannot be all dots (.), hostkey, serverkey, dsakey, sm2key, or ecdsakey, and cannot start with a slash (/) or contain **./** or **../**. The file name is a case-insensitive string of 1 to 128 characters. For more information about file names, see file system management in *Fundamentals Configuration Guide*. If you do not specify a file name, this command displays the key on the monitor screen.

Usage guidelines

You can use this command to export a local SM2 host public key before distributing it to a peer device.

To distribute a local SM2 host public key to a peer device:

1. Save the exported local host public key to a file by using one of the following methods:
   - Use the **public-key local export sm2** [**name** *key-name*] { **openssh** | **ssh2** } command to export the key, and then copy and paste it to a file.
   - Use the **public-key local export sm2** [**name** *key-name*] { **openssh** | **ssh2** } *filename* command to export key to a file. You cannot export the key to the **pkey** folder or its subfolders.
2. Transfer a copy of the file to the peer device, for example, by using FTP in binary mode or TFTP. For more information about FTP and TFTP, see *Fundamentals Configuration Guide*.
3. On the peer device, use the **public-key peer import sshkey** command to import the host public key from the file.

SSH2.0 and OpenSSH are different public key formats. Choose the correct public key format that is supported on the device where you import the host public key.

Examples

Export the host public key of the local SM2 key pair with the default name in OpenSSH format to file **key.pub**.

```
<Sysname> system-view
[Sysname] public-key local export sm2 openssh key.pub
```

Display the host public key of the local SM2 key pair with the default name in SSH2.0 format.

```
<Sysname> system-view
[Sysname] public-key local export sm2 ssh2
---- BEGIN SSH2 PUBLIC KEY ----
Comment: "sm2-key-2016/09/12"
AAAAB3NtMi1rZXkAAABBBJo0XIySNcZiJq/N81QQozLcdBneur2w/E1gIRAfHM5SwDspD22aMdg5dRQr
IFrN6XMXdftV5vwI9qWX/tGMH0g=
---- END SSH2 PUBLIC KEY ----
```

Display the host public key of the local SM2 key pair with the default name in OpenSSH format.

```
<Sysname> system-view
[Sysname] public-key local export sm2 openssh
ssh-sm2 AAAAB3NtMi1rZXkAAABBBJo0XIySNcZiJq/N81QQozLcdBneur2w/E1gIRAfHM5SwDspD22a
Mdg5dRQrIFrN6XMXdftV5vwI9qWX/tGMH0g= sm2-key
```

Related commands

public-key local create

public-key peer import sshkey

public-key local import

Use **public-key local import** to import local key pairs.

Syntax

public-key local import { **ecdsa** | **rsa** } [*key-name*] **filename** *filename*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ecdsa: Specifies the ECDSA key pair type.

rsa: Specifies the RSA key pair type.

key-name: Assigns a name to the key pair. The *key-name* argument is a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not assign a name to the key pair, the RSA and ECDSA key pairs take the default name **hostkey** and **ecdsakey**, respectively.

filename *filename*: Specifies the name of the file that stores the key pair to be imported. The file name is a case-sensitive string of 1 to 128 characters. The key pair file must already exist on the device and must be in PEM format.

Usage guidelines

If the certificate and the key pair are saved in separate files, the device cannot import the key pair by importing the certificate. In this case, you can execute this command to import the key pair from the key pair file to the device. Before executing this command, upload the key pair file to the device through FTP or other methods.

The key pairs imported by using this command are automatically saved and can survive system reboots.

The device supports importing the RSA host key pair but not the RSA server key pair.

If you do not assign the key pair a name, the system assigns the default name to the key pair and marks the key pair as **default**. You can also assign the default name to another key pair, but the system does not mark the key pair as **default**. The name of a key pair must be unique among all manually named key pairs that use the same key algorithm. If a name conflict occurs, the system asks whether you want to overwrite the existing key pair.

To import the encrypted key pair into the device successfully, provide the decryption password.

See Table 6 for information about the supported key modulus lengths and key lengths.

Table 6 Length of key pair

Type	Modulus/key length
RSA	Key modulus length: 512 to 2048 bits.
ECDSA	Key length: 192, 256, 384, or 521 bits.

Examples

Import the encrypted local RSA key pair **rsa1** from the **private_key.pem** file.

```
<Sysname> system-view
[Sysname] public-key local import rsa rsa1 filename private_key.pem
Please input the password:
Importing Keys...
Key pair imported successfully.
```

Related commands

display public-key local public

public-key peer

Use **public-key peer** to assign a name to a peer host public key and enter public key view, or enter the view of an existing peer host public key.

Use **undo public-key peer** to delete a peer host public key.

Syntax

public-key peer *keyname*

undo public-key peer *keyname*

Default

No peer host public keys exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

keyname: Specifies a key name, a case-sensitive string of 1 to 64 characters.

Usage guidelines

After you execute this command to enter the public key view, type the public key. Spaces and carriage returns are allowed, but are not saved.

To configure a peer host public key on the local device, first obtain the peer public key in hexadecimal notation, and then perform the following tasks on the local device:

1. Execute the **public-key peer** command to enter public key view.
2. Type the public key.
3. Execute the **peer-public-key end** command to save the public key and return to system view.

The public key you type in the public key view must be in a correct format. If the peer device is an NSFOCUS device, use the **display public-key local public** command to display and record its public key.

Examples

Assign name **key1** to the peer host public key and enter public key view.

```
<Sysname> system-view
```

```
[Sysname] public-key peer key1
Enter public key view. Return to system view with "peer-public-key end" command.
[Sysname-pkey-public-key-key1]
```

Related commands

public-key peer import sshkey

Use **public-key peer import sshkey** to import a peer host public key from a public key file.

Use **undo public-key peer** to remove a peer host public key.

Syntax

public-key peer *keyname* **import sshkey** *filename*

undo public-key peer *keyname*

Default

No peer host public keys exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

keyname: Specifies a name for a peer host public key, a case-sensitive string of 1 to 64 characters.

filename: Specifies a public key file by its name. The name cannot be all dots (.), hostkey, serverkey, dsakey, ecdsakey, or sm2key, and cannot start with a slash (/) or contain **./** or **../**. The file name is a case-insensitive string of 1 to 128 characters. For more information about file names, see file system management in *Fundamentals Configuration Guide*.

Usage guidelines

After you configure this command, the system automatically transforms the host public key to the PKCS format, and saves the key.

Before you use this command, make sure you have got a copy of the public key file from the peer device through FTP in binary mode or through TFTP.

The device supports importing public keys in the format of SSH 1.5, SSH 2.0 and OpenSSH.

Examples

Import peer host public key **key2** from public key file **key.pub**.

```
<Sysname> system-view
[Sysname] public-key peer key2 import sshkey key.pub
```

Related commands

display public-key peer

PKI commands

attribute

Use **attribute** to configure a rule to filter certificates based on an attribute in the certificate issuer name, subject name, or alternative subject name field.

Use **undo attribute** to remove an attribute rule.

Syntax

attribute *id* { **alt-subject-name** { **fqdn** | **ip** } | { **issuer-name** | **subject-name** } { **dn** | **fqdn** | **ip** } } { **ctn** | **equ** | **nctn** | **nequ** } *attribute-value*

undo attribute *id*

Default

No attribute rules exist.

Views

Certificate attribute group view

Predefined user roles

network-admin

context-admin

Parameters

id: Specifies a rule ID in the range of 1 to 16.

alt-subject-name: Specifies the alternative subject name field.

fqdn: Specifies the FQDN attribute.

ip: Specifies the IP address attribute.

dn: Specifies the DN attribute.

issuer-name: Specifies the issuer name field.

subject-name: Specifies the subject name field.

ctn: Specifies the contain operation.

equ: Specifies the equal operation.

nctn: Specifies the not-contain operation.

nequ: Specifies the not-equal operation.

attribute-value: Sets an attribute value, a case-insensitive string of 1 to 128 characters.

Usage guidelines

Different certificate fields support different attributes.

- The subject name field and the issuer name field can contain a single DN, multiple FQDNs, and multiple IP addresses.
- The alternative subject name field can contain multiple FQDNs and IP addresses but zero DNs.

An attribute rule is a combination of an attribute-value pair with an operation keyword, as listed in Table 1.

Table 1 Combinations of attribute-value pairs and operation keywords

Operation	DN	FQDN/IP
ctn	The DN contains the specified attribute value.	Any FQDN or IP address contains the specified attribute value.
nctn	The DN does not contain the specified attribute value.	None of the FQDNs or IP addresses contain the specified attribute value.
equ	The DN is the same as the specified attribute value.	Any FQDN or IP address is the same as the specified attribute value.
nequ	The DN is not the same as the specified attribute value.	None of the FQDNs or IP addresses are the same as the specified attribute value.

A certificate matches an attribute rule if it contains an attribute that matches the criterion defined in the rule. For example, a certificate matches the **attribute 1 subject-name dn ctn abc** rule if it meets the following conditions:

- The subject name field of the certificate contains the DN attribute.
- The DN attribute value contains the **abc** string.

A certificate matches an attribute group if it matches all attribute rules in the group.

Examples

Create a certificate attribute group and enter its view.

```
<Sysname> system-view
[Sysname] pki certificate attribute-group mygroup
```

Configure an attribute rule to match certificates that contain the **abc** string in the subject DN.

```
[Sysname-pki-cert-attribute-group-mygroup] attribute 1 subject-name dn ctn abc
```

Configure an attribute rule to match certificates that do not contain FQDN **abc** in the issuer name field.

```
[Sysname-pki-cert-attribute-group-mygroup] attribute 2 issuer-name fqdn nequ abc
```

Configure an attribute rule to match certificates that do not contain IP address **10.0.0.1** in the alternative subject name field.

```
[Sysname-pki-cert-attribute-group-mygroup] attribute 3 alt-subject-name ip nequ 10.0.0.1
```

Related commands

display pki certificate attribute-group

rule

ca identifier

Use **ca identifier** to specify the trusted CA.

Use **undo ca identifier** to restore the default.

Syntax

ca identifier *name*

undo ca identifier

Default

No trusted CA is specified.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

name: Specifies the trusted CA by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

To obtain a CA certificate in a PKI domain, you must specify the trusted CA name. The trusted CA name uniquely identifies the CA to be used if multiple CAs exist on the CA server specified for the PKI domain.

Make sure the specified CA name is consistent with the name of the CA that owns the CA certificate to be obtained.

Examples

Set the name of the trusted CA to **new-ca**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] ca identifier new-ca
```

certificate request entity

Use **certificate request entity** to specify the PKI entity for certificate request.

Use **undo certificate request entity** to restore the default.

Syntax

certificate request entity *entity-name*

undo certificate request entity

Default

No PKI entity is specified for certificate request.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

entity-name: Specifies a PKI entity by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A PKI entity describes the identity attributes of an entity for certificate request, including the following information:

- Common name.
- Organization.
- Unit in the organization.
- Locality.
- State and country where the entity resides.
- FQDN.

- IP address.

You can specify only one PKI entity for a PKI domain. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify PKI entity **en1** for certificate request in PKI domain **aaa**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] certificate request entity en1
```

Related commands

pki entity

certificate request from

Use **certificate request from** to specify the type of certificate request reception authority.

Use **undo certificate request from** to restore the default.

Syntax

certificate request from { **ca** | **ra** }

undo certificate request from

Default

The type of certificate request reception authority is not specified.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

ca: Sends certificate requests to the CA.

ra: Sends certificate requests to the RA.

Usage guidelines

The CA server determines whether the CA or RA accepts certificate requests. This authority setting must be consistent with the setting on the CA server.

Examples

Sends certificate requests to the RA.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] certificate request from ra
```

certificate request mode

Use **certificate request mode** to set the certificate request mode.

Use **undo certificate request mode** to restore the default.

Syntax

certificate request mode { **auto** [**password** { **cipher** | **simple** } *string* | **renew-before-expire** *days* [**reuse-public-key**] [**automatic-append common-name**]] * | **manual** }

undo certificate request mode

Default

The certificate request mode is manual.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

auto: Specifies the auto certificate request mode.

password: Specifies a password for certificate revocation.

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 31 characters. Its encrypted form is a case-sensitive string of 1 to 73 characters.

renew-before-expire *days*: Configures the system to automatically request a new certificate the specified number of days before the current certificate expires. The value range for the *days* argument is 0 to 365. Value 0 indicates that the request for a new certificate is made when the old certificate expires, which might cause service interruptions.

reuse-public-key: Reuses the key pair in the old certificate for the new certificate. If you do not specify this keyword, the system generates a new key pair for the new certificate. The old key pair is replaced with the new one when the new certificate is received from the CA.

automatic-append common-name: Automatically appends random data to the common name of the PKI entity for the new certificate. If you do not specify this keyword, the common name of the PKI entity will be unchanged in the new certificate.

manual: Specifies the manual certificate request mode.

Usage guidelines

A certificate request can be submitted to a CA in offline or online mode. In online mode, a certificate request can be automatically or manually submitted:

- **Auto request mode**—A PKI entity automatically obtains the CA certificate and submits a certificate request to the CA when both of the following conditions exist:
  - An associated application (IKE, for example) performs identity authentication.
  - No certificate is available for the application on the device.

  In auto request mode, specify the password for certificate revocation as required by the CA policy.
- **Manual request mode**—You must manually obtain the CA certificate and submit certificate requests.

To avoid service interruptions caused by certificate expiration, specify the **renew-before-expire** *days* option to enable certificate auto-renewal in auto certificate request

mode. Certificate auto-renewal allows the system to automatically request a new certificate the specified number of days before the old certificate expires. The old certificate is replaced immediately when the new certificate is received.

Examples

Set the certificate request mode to **auto**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] certificate request mode auto
```

Set the certificate request mode to **auto**, and set the certificate revocation password in plain text to **123456**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] certificate request mode auto password simple 123456
```

Set the certificate request mode to **auto**, and set the certificate revocation password in plain text to **123456**. Configure the system to automatically request a new certificate by using a new key pair 60 days before the certificate expires.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] certificate request mode auto password simple 123456
renew-before-expire 60
```

Related commands

pki request-certificate

certificate request polling

Use **certificate request polling** to set the polling interval and the maximum number of attempts to query certificate request status.

Use **undo certificate request polling** to restore the defaults.

Syntax

certificate request polling { **count** *count* | **interval** *interval* }

undo certificate request polling { **count** | **interval** }

Default

The polling interval is 20 minutes, and the maximum number of attempts is 50.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

count *count*: Specifies the maximum number of query attempts. The value range is 1 to 100.

interval *interval*: Specifies a polling interval in minutes. The value range is 5 to 168.

Usage guidelines

After a PKI entity submits a certificate request, it might take the CA server a while to issue the certificate if the CA administrator must manually approve the certificate request. During this period,

the PKI entity periodically queries the CA server for the certificate request status. The periodic query operation stops until the PKI entity obtains the certificate or the maximum number of query attempts is reached. If the maximum number of query attempts is reached, the certificate request fails.

If the CA server automatically approves certificate requests, the PKI entity can obtain the certificate immediately after it submits a certificate request. In this case, the PKI entity does not send queries to the CA server.

Examples

Set the polling interval to 15 minutes, and the maximum number of query attempts to 40.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] certificate request polling interval 15
[Sysname-pki-domain-aaa] certificate request polling count 40
```

Related commands

display pki certificate request-status

certificate request url

Use **certificate request url** to specify the URL of the certificate request reception authority (CA or RA) to which the device should send SCEP certificate requests.

Use **undo certificate request url** to restore the default.

Syntax

certificate request url *url-string*

undo certificate request url

Default

The URL of the certificate request reception authority is not specified.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the URL of the certificate request reception authority, a case-sensitive string of 1 to 511 characters. The URL length is restricted by the CLI string limitation or the *url-string* parameter, whichever is smaller.

Usage guidelines

The certificate request URL contains the location of the certificate request reception authority server and the path of the application script on the server, in the format http*://server_location/cgi_script_location*.

Examples

Set the certificate request URL to **http://169.254.0.1/certsrv/mscep/mscep.dll**.

```
<Sysname> system-view
[Sysname] pki domain a
[Sysname-pki-domain-a] certificate request url
http://169.254.0.1/certsrv/mscep/mscep.dll
```

common-name

Use **common-name** to set the common name for a PKI entity.

Use **undo common-name** to restore the default.

Syntax

common-name *common-name-sting*

undo common-name

Default

No common name is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

context-admin

Parameters

common-name-sting: Specifies a common name, a case-sensitive string of 1 to 63 characters. No comma can be included. You can set the username of the PKI entity as the common name.

Examples

Set the common name to **test** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] common-name test
```

country

Use **country** to set the country code of a PKI entity.

Use **undo country** to restore the default.

Syntax

country *country-code-string*

undo country

Default

No country code is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

context-admin

Parameters

country-code-string: Specifies a country code, a case-sensitive string of two characters. For example, CN is the country code for China.

Examples

Set the country code to **CN** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] country CN
```

crl check enable

Use **crl check enable** to enable CRL checking.

Use **undo crl check enable** to disable CRL checking.

Syntax

crl check enable

undo crl check enable

Default

CRL checking is enabled.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Usage guidelines

A CRL is a list of revoked certificates signed and published by a CA. Revoked certificates should no longer be trusted.

Enable CRL checking to ensure that the device only accepts certificates that have not been revoked by the issuing CA.

Examples

Disable CRL checking.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] undo crl check enable
```

Related commands

pki import

pki retrieve-certificate

crl update-period

Use **crl update-period** to enable automatic CRL update and set the update interval.

Use **undo crl update-period** to restore the default.

Syntax

crl update-period *hours*

undo crl update-period

Default

The device does not update the CRL automatically.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

hours: Specifies the CRL update interval, in the range of 1 to 720 hours.

Usage guidelines

In scenarios that require strict certificate verification (such as bank systems), the device must be able to obtain the latest CRL in time. This command enables the device to automatically connect to the CRL repository at the specified intervals to obtain the latest CRL.

The device uses HTTP, LDAP, or SCEP to obtain the CRL, depending on the URL configuration for the CRL repository in the PKI domain (by using the **crl url** command):

- If an HTTP URL is specified for the CRL repository, the device uses HTTP to obtain the CRL.
- If an LDAP URL is specified, the device uses LDAP to obtain the CRL.

  If an LDAP URL is specified, the device must connect to the LDAP server to obtain the CRL. If the LDAP URL does not contain the hostname of the LDAP server, such as **ldap:///CN=8088,OU=test,U=rd,C=cn**, use the **ldap-server** command to configure the server hostname in the PKI domain.
- If no CRL repository URL is specified in the PKI domain, the device looks up the CRL repository from the local certificates and CA certificate in turn. If a CRL repository is found, the device obtains the CRL from the CRL repository. If no CRL repository is found, the device obtains the CRL through SCEP.

  In this case, the CA certificate and the local certificates must have been obtained.

Using automatic CRL update, the device might not be able to update the CRL immediately when the CRL expires. This is because the device must wait for the specified interval of time to perform a next update. Set the CRL update interval to a proper value to ensure the timeliness of CRL update.

You can also execute the **pki retrieve-crl** command to perform an immediate CRL update as needed.

Examples

Set the CRL update interval to 24 hours.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] crl update-period 24
```

Related commands

Parameters

url-string: Specifies the URL of the CRL repository, a case-sensitive string of 1 to 511 characters. The URL format is ldap://*server_location* or http://*server_location*, where *server_location* can be the IP address or domain name of the CRL repository server. The URL length is restricted by the CLI string limitation or the *url-string* parameter, whichever is smaller.

Usage guidelines

To use CRL checking, a CRL must be obtained from a CRL repository.

The device selects a CRL repository in the following order:

1. CRL repository specified in the PKI domain by using this command.
2. CRL repository in the certificate that is being verified.
3. CRL repository in the CA certificate or CRL repository in the upper-level CA certificate if the CA certificate is the certificate being verified.

After the previous selection process, if the CRL repository is not found, the device obtains the CRL through SCEP. In this scenario, the CA certificate and the local certificates must have been obtained.

If an LDAP URL is specified, the device must connect to the LDAP server to obtain the CRL. If the LDAP URL does not contain the address of the LDAP server, use the **ldap-server** command to configure the server address in the PKI domain.

Examples

Set the URL of the CRL repository to **http://169.254.0.30**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] crl url http://169.254.0.30
```

Related commands

ldap-server

pki retrieve-crl

display pki certificate access-control-policy

Use **display pki certificate access-control-policy** to display information about certificate-based access control policies.

Syntax

display pki certificate access-control-policy [*policy-name*]

Views

context-operator

Parameters

policy-name: Specifies a certificate-based access control policy by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

If you do not specify a policy name, this command displays information about all certificate-based access control policies.

Examples

Display information about certificate-based access control policy **mypolicy**.

```
<Sysname> display pki certificate access-control-policy mypolicy
 Access control policy name: mypolicy
     Rule 1  deny    mygroup1
     Rule 2  permit  mygroup2
```

Display information about all certificate-based access control policies.

```
<Sysname> display pki certificate access-control-policy
 Total PKI certificate access control policies: 2
 Access control policy name: mypolicy1
     Rule 1  deny    mygroup1
     Rule 2  permit  mygroup2
 Access control policy name: mypolicy2
     Rule 1  deny    mygroup3
     Rule 2  permit  mygroup4
```

Table 2 Command output

Field	Description
Total PKI certificate access control policies	Total number of certificate-based access control policies.
permit	Permit certificates that match the attribute group in the access control rule.
deny	Deny certificates that match the attribute group in the access control rule.

Related commands

Parameters

group-name: Specifies a certificate attribute group by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

If you do not specify a certificate attribute group, this command displays information about all certificate attribute groups.

Examples

Display information about certificate attribute group **mygroup**.

```
<Sysname> display pki certificate attribute-group mygroup
 Attribute group name: mygroup
      Attribute  1 subject-name     dn    ctn   abc
      Attribute  2 issuer-name      fqdn  nctn  app
```

Display information about all certificate attribute groups.

```
<Sysname> display pki certificate attribute-group
 Total PKI certificate attribute groups: 2.
 Attribute group name: mygroup1
      Attribute  1 subject-name     dn    ctn   abc
      Attribute  2 issuer-name      fqdn  nctn  app
Attribute group name: mygroup2
      Attribute  1 subject-name     dn    ctn   def
      Attribute  2 issuer-name      fqdn  nctn  fqd
```

Table 3 Command output

Field	Description
Total PKI certificate attribute groups	Total number of certificate attribute groups.
ctn	Contain operation.
nctn	Not-contain operation.
equ	Equal operation.
nequ	Not-equal operation.

Field	Description
Attribute 1 subject-name dn ctn abc	Attribute rule contents: • **alt-subject-name**—Alternative subject name. • **issuer-name**—Certificate issuer name. • **subject-name**—Certificate subject name. • **fqdn**—FQDN of the PKI entity. • **ip**—IP address of the PKI entity. • **dn**—DN of the PKI entity. • **ctn**—Indicates the contain operation. • **equ**—Indicates the equal operation. • **nctn**—Indicates the not-contain operation. • **nequ**—Indicates the not-equal operation.

display pki certificate domain

Use **`display pki certificate domain`** to display information about certificates.

Syntax

`display pki certificate domain` *`domain-name`* { **`ca`** | **`local`** | **`peer`** [**`serial`** *`serial-num`*] }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`domain-name`: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 4.

Table 4 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

`ca`: Specifies the CA certificate.

`local`: Specifies the local certificates.

peer: Specifies the peer certificates.

serial *serial-num*: Specifies the serial number of a peer certificate.

Usage guidelines

If you specify the **CA** keyword, this command displays information about all CA certificates in the domain. If the domain has RA certificates, the RA certificates are also displayed.

If you specify the **local** keyword, this command displays information about all local certificates in the domain.

If you specify the **peer** keyword without a serial number, this command displays brief information about all peer certificates. If you specify a serial number, this command display detailed information about the specified peer certificate.

Examples

Display information about the CA certificate in PKI domain **aaa**.

```

Related commands

pki domain

pki retrieve-certificate

display pki certificate renew-status

Use **display pki certificate renew-status** to display the certificate renewal status for a PKI domain.

Syntax

display pki certificate renew-status [**domain** *domain-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 5. If you do not specify a domain name, this command displays the certificate renewal status for all PKI domains.

Table 5 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

Examples

Display the certificate renewal status for all PKI domains.

```
<Sysname> display pki certificate renew-status
Domain Name: domain1
Renew Time : 03:12:05 2016-06-13
Renew public key:
  Key type: RSA
  Time when key pair created: 15:40:48 2016/06/13
  Key code:
    30819F300D06092A864886F70D010101050003818D0030818902818100DAA4AAFEFE04C2C9
    667269BB8226E26331E30F41A8FF922C7338208097E84332610632B49F75DABF6D871B80CE
    C1BA2B75020077C74745C933E2F390DC0B39D35B88283D700A163BB309B19F8F87216A44AB
    FBF6A3D64DEB33E5CEBF2BCF26296778A26A84F4F4C5DBF8B656ACFA62CD96863474899BC1
    2DA4C04EF5AE0835090203010001
```

The command output indicates that the **reuse-public-key** keyword was not configured for PKI domain **domain1** and a new key pair was created for the new certificate.

Display the certificate renewal status for PKI domain **domain1**.

```
<Sysname> display pki certificate renew-status domain domain1
Domain Name: domain1
Renew Time : 03:12:05 2016-06-13
Renew public key:
  Key type: RSA
```

```
Time when  key pair created: 15:40:48 2016/06/13
Key code:
  30819F300D06092A864886F70D010101050003818D0030818902818100DAA4AAFEFE04C2C9

  C1BA2B75020077C74745C933E2F390DC0B39D35B88283D700A163BB309B19F8F87216A44AB
  FBF6A3D64DEB33E5CEBF2BCF26296778A26A84F4F4C5DBF8B656ACFA62CD96863474899BC1
  2DA4C04EF5AE0835090203010001
```

Table 6 Command output

Field	Description
Renew Time	Time when a new certificate will be requested.
Renew public key	Information about the new key pair created for the certificate. The renewed public key information is displayed only if the certificate renewal process is slow or has failed.
Key type	Key pair type, which can be RSA, DSA, SM2, or ECDSA.
Time when key pair created	Time when the key pair was created.
Key code	Public key data.

Related commands

`certificate request mode`

`pki domain`

display pki certificate request-status

Use **`display pki certificate request-status`** to display certificate request status.

Syntax

`display pki certificate request-status` [**`domain`** *`domain-name`*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`domain-name`: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 7.

Table 7 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<

Character name	Symbol	Character name	Symbol
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

Usage guidelines

If you do not specify a PKI domain, this command displays the certificate request status for all PKI domains.

Examples

Display certificate request status for PKI domain **aaa**.

```
<Sysname> display pki certificate request-status domain aaa
Certificate Request Transaction 1
    Domain name: aaa
    Status: Pending
    Key usage: General
    Remain polling attempts: 10
    Next polling attempt after : 1191 seconds
```

Display certificate request statuses for all PKI domains.

```
<Sysname> display pki certificate request-status
Certificate Request Transaction 1
    Domain name: domain1
    Status: Pending
    Key usage: General
    Remain polling attempts: 10
    Next polling attempt after : 1191 seconds
Certificate Request Transaction 2
    Domain name: domain2
    Status: Pending
    Key usage: Signature
    Remain polling attempts: 10
    Next polling attempt after : 188 seconds
```

Table 8 Command output

Field	Description
Certificate Request Transaction *number*	Certificate request transaction number, starting from 1.
Status	Certificate request status, including only the pending status.
Key usage	Certificate purposes: • **General**—Signature and encryption. • **Signature**—Signature only. • **Encryption**—Encryption only.
Remain polling attempts	Remaining number of attempts to query certificate request status.
Next polling attempt after	Remaining seconds before the next request status polling.

pki domain

pki retrieve-certificate

display pki crl domain

Use **display pki crl domain** to display information about the CRL saved at the local for a PKI domain.

Syntax

display pki crl domain *domain-name*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 9.

Table 9 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

Usage guidelines

Use this command to determine whether a certificate has been revoked.

Examples

Display information about the CRL saved at the local for PKI domain **aaa**.

```
<Sysname> display pki crl domain aaa
Certificate Revocation List (CRL):
        Version 2 (0x1)
        Signature Algorithm: sha1WithRSAEncryption

```

Table 10 Command output

Field	Description
Version	CRL version number.
Signature Algorithm	Signature algorithm used by the CA to sign the CRL.
Issuer	Name of the CA that issued the CRL.
Last Update	Most recent CRL update time.
Next Update	Next CRL update time.
X509v3 Authority Key Identifier	X509v3 ID of the CA that issues the CRL.
keyid	Key ID. This field identifies the key pair used to sign the CRL.
Signature Algorithm:	Signature algorithm and signature data.

Related commands

`pki retrieve-crl`

fqdn

Use **`fqdn`** to set the FQDN of an entity.

Use **`undo fqdn`** to restore the default.

Syntax

fqdn *fqdn-name-string*

undo fqdn

Default

No FQDN is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

context-admin

Parameters

fqdn-name-string: Specifies an FQDN, a case-sensitive string of 1 to 255 characters in the format of *hostname@domainname*.

Usage guidelines

An FQDN uniquely identifies a PKI entity on a network.

Examples

Set the FQDN to **pki.domain-name.com** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] fqdn abc@pki.domain.com
```

ip

Use **ip** to assign an IP address to a PKI entity.

Use **undo ip** to restore the default.

Syntax

ip { *ip-address* | **interface** *interface-type interface-number* }

undo ip

Default

No IP address is assigned to the PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies an IPv4 address.

interface *interface-type interface-number*: Specifies an interface by its type and number. The primary IPv4 address of the interface will be used as the IP address of the PKI entity.

Usage guidelines

Use this command to assign an IP address to a PKI entity or specify an interface for the entity. The interface's primary IPv4 address will be used as the IP address of the PKI entity. If you specify an interface, make sure the interface is assigned an IP address before the PKI entity requests a certificate.

Examples

Assign IP address **192.168.0.2** to PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] ip 192.168.0.2
```

ldap-server

Use **ldap-server** to specify an LDAP server for a PKI domain.

Use **undo ldap-server** to restore the default.

Syntax

ldap-server host *hostname* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]

undo ldap-server

Default

No LDAP server is specified for a PKI domain.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

host *hostname*: Specifies an LDAP server by its IPv4 address, IPv6 address, or domain name. The domain name is a case-sensitive string of 1 to 255 characters.

port *port-number*: Specifies the port number of the LDAP server. The value range is 1 to 65535, and the default is 389.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If the LDAP server is on the public network, do not specify this option.

Usage guidelines

You must specify an LDAP server for a PKI domain in the following situations:

- The certificate repository uses LDAP for certificate distribution.
- The CRL repository uses LDAP for CRL distribution. However, the CRL repository URL configured for the PKI domain does not contain the IP address or host name of the LDAP server.

You can specify only one LDAP server for a PKI domain. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify LDAP server **10.0.0.1** for PKI domain **aaa**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] ldap-server host 10.0.0.1
```

Specify LDAP server **10.0.0.11** in VPN instance **vpn1** for PKI domain **aaa**. Set the port number to **333**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] ldap-server host 10.0.0.11 port 333 vpn-instance vpn1
```

Related commands

pki retrieve-certificate

pki retrieve-crl

locality

Use **locality** to set the locality of a PKI entity.

Use **undo locality** to restore the default.

Syntax

locality *locality-name*

undo locality

Default

No locality is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

context-admin

Parameters

locality-name: Specifies a locality, a case-sensitive string of 1 to 63 characters. No comma can be included. You can set a city name as the locality.

Examples

Set the locality to **pukras** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] locality pukras
```

organization

Use **organization** to set an organization name for a PKI entity.

Use **undo organization** to restore the default.

Syntax

organization *org-name*

undo organization

Default

No organization name is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

context-admin

Parameters

org-name: Specifies an organization name, a case-sensitive string of 1 to 63 characters. No comma can be included.

Examples

Set the organization name to **abc** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] organization abc
```

organization-unit

Use **organization-unit** to set an organization unit name for a PKI entity.

Use **undo organization-unit** to restore the default.

Syntax

organization-unit *org-unit-name*

undo organization-unit

Default

No organization unit name is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

context-admin

Parameters

org-unit-name: Specifies an organization unit name, a case-sensitive string of 1 to 63 characters. No commas can be included.

Examples

Set the organization unit name to **rdtest** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] organization-unit rdtest
```

pkcs7-encryption-algorithm

Use **pkcs7-encryption-algorithm** to specify the encryption algorithm for certificate files in PKCS#7 format.

Use **undo pkcs7-encryption-algorithm** to restore the default.

Syntax

pkcs7-encryption-algorithm { **3des-cbc** | **aes-cbc-128** | **des-cbc** | **sm4-cbc** }

undo pkcs7-encryption-algorithm

Default

The DES-CBC encryption algorithm is used.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

3des-cbc: Specifies the 3DES algorithm in CBC mode, which uses a 168-bit key.

des-cbc: Specifies the DES algorithm in CBC mode, which uses a 56-bit key.

sm4-cbc: Specifies SM4 algorithm in CBC mode, which uses a 128-bit key.

aes-cbc-128: Specifies the AES algorithm in CBC mode, which uses a 128-bit key.

Usage guidelines

During online certificate request, the device uses the specified encryption algorithm to encrypt the certificate signing request in PKCS#7 format before sending the request to the CA. After obtaining the certificate issued by the CA, the device uses the encryption algorithm to decrypt the certificate file in PKCS#7 format. Make sure the specified encryption algorithm is supported on the CA server.

Examples

Specify the 3DES algorithm in CBC mode as the encryption algorithm for certificate files in PKCS#7 format.

```
<Sysname> system-view
[Sysname] pki domain 1
[Sysname-pki-domain-1] pkcs7-encryption-algorithm 3des-cbc
```

pki abort-certificate-request

Use **pki abort-certificate-request** to abort the certificate request for a PKI domain.

Syntax

pki abort-certificate-request domain *domain-name*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 11.

Table 11 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

Usage guidelines

You can abort a certificate request and change some parameters, such as common name, country code, or FQDN, in the certificate request before the CA issues the certificate. Use the **display pki certificate request-status** command to display the certificate request status.

Examples

Abort the certificate request for PKI domain 1.

```
<Sysname> system-view
[Sysname] pki abort-certificate-request domain 1
The certificate request is in process.
Confirm to abort it? [Y/N]:y
```

Related commands

display pki certificate request-status

pki request-certificate domain

pki certificate access-control-policy

Use **pki certificate access-control-policy** to create a certificate-based access control policy and enter its view, or enter the view of an existing certificate-based access control policy.

Use **undo pki certificate access-control-policy** to remove a certificate-based access control policy.

Syntax

pki certificate access-control-policy *policy-name*

undo pki certificate access-control-policy *policy-name*

Default

No certificate-based access control policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies a policy name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A certificate-based access control policy contains a set of access control rules that permit or deny access to the device based on the attributes in the requesting client's certificate.

Examples

Create a certificate-based access control policy named **mypolicy** and enter its view.

```
<Sysname> system-view
[Sysname] pki certificate access-control-policy mypolicy
[Sysname-pki-cert-acp-mypolicy]
```

Related commands

display pki certificate access-control-policy

rule

pki certificate attribute-group

Use **pki certificate attribute-group** to create a certificate attribute group and enter its view, or enter the view of an existing certificate attribute group.

Use **undo pki certificate attribute-group** to remove a certificate attribute group.

Syntax

pki certificate attribute-group *group-name*

undo pki certificate attribute-group *group-name*

Default

No certificate attribute groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a group name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A certificate attribute group is a set of attribute rules configured by using the **attribute** command. Each attribute rule defines a matching criterion for an attribute in the issuer name, subject name, or alternative subject name field of certificates.

A certificate attribute group must be associated with an access control rule (a permit or deny statement configured by using the **rule** command). If a certificate attribute group does not have any attribute rules, the system determines that the all certificates match the associated access control rule.

Examples

Create a certificate attribute group named **mygroup** and enter its view.

```
<Sysname> system-view
```

```
[Sysname] pki certificate attribute-group mygroup
[Sysname-pki-cert-attribute-group-mygroup]
```

Related commands

attribute

display pki certificate attribute-group

rule

pki certificate logging enable

Use **pki certificate logging enable** to enable local certificate expiration notification.

Use **undo pki certificate logging enable** to disable local certificate expiration notification.

Syntax

pki certificate logging { **local-will-expire** | **local-has-expired** } **enable**

undo pki certificate logging { **local-will-expire** | **local-has-expired** } **enable**

Default

Local certificate expiration notification is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

local-will-expire: Sends expiration notifications for local certificates every other day starting from 30 days prior to expiration.

local-has-expired: Sends expiration notifications for local certificates every other day starting from the expiration day.

Usage guidelines

After this feature is enabled, the system checks the validity date for local certificates every other hour. When a local certificate is about to expire in 30 days (included) or has expired, the system sends a notification log message for the certificate every other day.

Examples

Enable the device to send expiration notifications for local certificates every other day starting from 30 days prior to expiration.

```
<Sysname> system-view
[Sysname] pki certificate logging local-will-expire enable
```

pki delete-certificate

Use **pki delete-certificate** to remove certificates from a PKI domain.

Syntax

pki delete-certificate domain *domain-name* { **ca** | **local** | **peer** [**serial** *serial-num*] }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 12.

Table 12 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

ca: Specifies the CA certificate.

local: Specifies the local certificates.

peer: Specifies the peer certificates.

serial *serial-num*: Specifies a peer certificate by its serial number, a case-insensitive string of 1 to 127 characters. If you do not specify a serial number, this command removes all peer certificates in the PKI domain.

Usage guidelines

When you remove the CA certificate in a PKI domain, the system also removes the local certificates, peer certificates, and the CRL in the PKI domain.

To delete a specific peer certificate in a PKI domain, perform the following steps:

1. Execute the **display pki certificate** command to determine the serial number of the peer certificate.
2. Execute the **pki delete-certificate domain** *domain-name* **peer serial** *serial-num* command.

Examples

Remove the CA certificate in PKI domain **aaa**.

```
<Sysname> system-view
[Sysname] pki delete-certificate domain aaa ca
Local certificates, peer certificates and CRL will also be deleted while deleting the CA certificate.
Confirm to delete the CA certificate? [Y/N]:y
[Sysname]
```

Remove the local certificates in PKI domain **aaa**.

```
<Sysname> system-view
[Sysname] pki delete-certificate domain aaa local
[Sysname]
```

Remove all peer certificates in PKI domain **aaa**.

```
<Sysname> system-view
[Sysname] pki delete-certificate domain aaa peer
[Sysname]
```

Display information about all peer certificates in PKI domain **aaa**, and remove a peer certificate with the specified serial number.

```
<Sysname> system-view
[Sysname] display pki certificate domain aaa peer
Total peer certificates: 1

Serial Number: 9a0337eb2156ba1f5476e4d754a5a9f7
Subject  Name: CN=abc
[Sysname] pki delete-certificate domain aaa peer serial 9a0337eb2156ba1f5476e4d754a5a9f7
```

Related commands

display pki certificate

pki domain

Use **pki domain** to create a PKI domain and enter its view, or enter the view of an existing PKI domain.

Use **undo pki domain** to remove a PKI domain.

Syntax

pki domain *domain-name*

undo pki domain *domain-name*

Default

No PKI domains exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a PKI domain name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 13.

Table 13 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>

Character name	Symbol	Character name	Symbol
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

Usage guidelines

When you remove a PKI domain, the certificates and the CRL in the domain are also removed.

Examples

Create a PKI domain named **aaa** and enter its view.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa]
```

pki entity

Use **pki entity** to create a PKI entity and enter its view, or enter the view of an existing PKI entity.

Use **undo pki entity** to remove a PKI entity.

Syntax

pki entity *entity-name*

undo pki entity *entity-name*

Default

No PKI entities exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

entity-name: Specifies a name for a PKI entity, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A PKI entity includes the identity information that can be used by a CA to identify a certificate applicant. You can configure multiple attributes for a PKI entity, such as common name, organization, organization unit, locality, state, country, FQDN, and IP address. The information will be included as subject contents in the certificate issued by the CA.

Examples

Create a PKI entity named **en** and enter its view.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en]
```

Related commands

Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

der: Specifies the DER certificate file format, including PKCS#7.

p12: Specifies the PKCS#12 certificate file format.

pem: Specifies the PEM certificate file format.

all: Specifies both CA and local certificates. The RA certificate is excluded.

ca: Specifies the CA certificate.

local: Specifies the local certificates or the local certificates and their private keys.

passphrase *p12-key*: Specifies a password for encrypting the private key of a local PKCS12 certificate.

3des-cbc: Specifies 3DES_CBC for encrypting the private key of a local certificate.

aes-128-cbc: Specifies 128-bit AES_CBC for encrypting the private key of a local certificate.

aes-192-cbc: Specifies 192-bit AES_CBC for encrypting the private key of a local certificate.

aes-256-cbc: Specifies 256-bit AES_CBC for encrypting the private key of a local certificate.

des-cbc: Specifies DES_CBC for encrypting the private key of a local certificate.

pem-key: Specifies a password for encrypting the private key of a local certificate in PEM format.

filename *filename*: Specifies the name of the file for storing the certificate. The file name is a case-insensitive string. If you do not specify a file name when you export certificates in PEM format, this command displays the certificates on the terminal.

Usage guidelines

When you export the CA certificate, the following conditions might exist:

- If the PKI domain has only one CA certificate, this command exports the CA certificate to a file or displays it on the terminal.
- If the PKI domain has a CA certificate chain, this command exports the certificate chain to a file or displays it on the terminal.

When you export a local certificate to a local file, the local file name might be different from the file name specified in the command. The file name depends on the usage of the key pair contained in the certificate.

The following example uses **certificate** as the file name for saving an exported local certificate.

- If the local certificate contains an RSA signing key pair, the local file name is **certificate-signature**.
- If the local certificate contains an RSA encryption key pair, the local file name is **certificate-encryption**.
- If the local certificate contains a general purpose RSA, ECDSA, or DSA key pair, the local file name is **certificate**.

If the PKI domain has two local certificates, the local certificates are exported as follows:

- If you specify a file name, the two local certificates are exported to two different files.
- If you do not specify a file name, the local certificates are displayed on the terminal, separated by system prompts.

When you export all certificates, the following conditions might exist:

- If the PKI domain has only the CA certificate or local certificates, the result is the same as when you export the CA certificate or local certificates separately.
- If the PKI domain has both the CA certificate and local certificates, you get the following results:
  - If you specify a file name, each local certificate is exported to a separate file with their associated CA certificate chain.
  - If you do not specify a file name, the local certificates and CA certificate or CA certificate chain are displayed on the terminal, separated by system prompts.

When you export all certificates in PKCS12 format, the PKI domain must have a local certificate. If the domain does not have a local certificate, the export operation fails. If a local certificate does not have a matching private key, the export of that local certificate fails.

When you export the local certificates or all certificates in PEM format, the local certificates are exported as follows:

- If you do not specify the cryptographic algorithm or password for encrypting a private key, this command does not export the private keys of the local certificates.
- If you specify the cryptographic algorithm and password and the local certificates have matching private keys, this command exports the local certificates with their private keys.
- If you specify the cryptographic algorithm and password but the local certificates do not have matching private keys, the export operation fails.

If the matching private key of a local certificate is an SM2 key created by a crypto device, the certificate cannot be exported in PKCS12 or PEM format.

When you export the local certificates, if the key pair in the PKI domain is changed and no longer matches the key in the local certificates, the export operation fails.

When you export the local certificates or all certificates, if the PKI domain has two local certificates, failure of exporting one local certificate does not affect export of the other.

The specified file name can contain an absolute path. If the specified path does not exist, the export operation fails.

Examples

Export the CA certificate in the PKI domain to a file named **cert-ca.der** in DER format.

```
<Sysname> system-view
[Sysname] pki export domain domain1 der ca filename cert-ca.der
```

Export the local certificates in the PKI domain to a file named **cert-lo.der** in DER format.

```
<Sysname> system-view
[Sysname] pki export domain domain1 der local filename cert-lo.der
```

Export all certificates in the PKI domain to a file named **cert-all.p7b** in DER format.

```
<Sysname> system-view
[Sysname] pki export domain domain1 der all filename cert-all.p7b
```

Export the CA certificate in the PKI domain to a file named **cacert** in PEM format.

```
<Sysname> system-view
[Sysname] pki export domain domain1 pem ca filename cacert
```

Export the local certificates and their private keys in the PKI domain to a file named **local.pem** in PEM format. For the private keys, the cryptographic algorithm is DES_CBC and the password is 111.

```
<Sysname> system-view
[Sysname] pki export domain domain1 pem local des-cbc 111 filename local.pem
```

Export the all certificates in the PKI domain to a file named **all.pem** in PEM format. No cryptographic algorithm or password is specified, and the private keys are not exported.

```
<Sysname> system-view
[Sysname] pki export domain domain1 pem all filename all.pem
```

Display the local certificates and their private keys in the PKI domain on the terminal in PEM format. For the private keys, the cryptographic algorithm is DES_CBC and the password is 111.

```
<Sysname> system-view
[Sysname] pki export domain domain1 pem local des-cbc 111

```

Export the local certificates and their private keys in the PKI domain to a file named **cert-lo.der** in PKCS12 format. The password for the private keys is 123.

```
<Sysname> system-view
[Sysname] pki export domain domain1 p12 local passphrase 123 filename cert-lo.der
```

Export all certificates in the PKI domain to a file named **cert-all.p7b** in PKCS12 format.

```
<Sysname> system-view
```

```
[Sysname] pki export domain domain1 p12 all passphrase 123 filename cert-all.p7b
```

Related commands

pki domain

pki import

Use **pki import** to import the CA certificate, local certificates, or peer certificates for a PKI domain.

Syntax

pki import domain *domain-name* { **der** { **ca** | **local** | **peer** } **filename** *filename* | **p12 local filename** *filename* | **pem** { **ca** | **local** | **peer** } [**filename** *filename*] }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 15.

Table 15 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

der: Specifies the DER certificate file format, including PKCS#7.

p12: Specifies the PKCS#12 certificate file format.

pem: Specifies the PEM certificate file format.

ca: Specifies the CA certificate.

local: Specifies the local certificates.

peer: Specifies the peer certificates.

filename *filename*: Specifies a certificate file name, a case-insensitive string. For a certificate in PEM format, you can also choose to copy and paste the certificate contents on the terminal instead of importing from a file.

Usage guidelines

Use this command to import a certificate in the following situations:

- The CRL repository is not specified or the CA server does not support SCEP.
- The certificate is packed with the server generated key pair in a single file. Only certificate files in PKCS12 or PEM format can contain key pairs.

Before you import certificates, complete the following tasks:

- Use FTP or TFTP to upload the certificate files to the storage media of the device. If FTP or TFTP is not available, display and copy the contents of a certificate to a file on the device. Make sure the certificate is in PEM format because only certificates in PEM format can be imported by this means.
- For the local certificates or peer certificates to be imported, the correct CA certificate chain must exist. The CA certificate chain can be stored on the device, or carried in the local certificates or peer certificates. If the PKI domain, the local certificates, or the peer certificates do not have the CA certificate chain, you must import the CA certificate first.

When you import the local or peer certificates:

- If the local or peer certificates contain the CA certificate chain, you can import the CA certificate and the local or peer certificates at the same time. If the CA certificate already exists in a PKI domain, the system prompts you whether to overwrite the existing CA certificate.
- If the local or peer certificates do not contain the CA certificate chain, but the CA certificate already exists in a PKI domain, you can directly import the certificates.

You can import the CA certificate to a PKI domain when either of the following conditions is met:

- The CA certificate to be imported is the root CA certificate or contains the certificate chain with the root certificate.
- The CA certificate contains a certificate chain without the root certificate, but can form a complete certificate chain with an existing CA certificate on the device.

Contact the CA administrator to get information as prompted in the following scenarios:

- The system prompts you to confirm the certificate's fingerprint in the following situation:
  - The certificate file to be imported contains the root certificate, but the root certificate does not exist in any PKI domains on the device.
  - The **root-certificate fingerprint** command is not configured in the PKI domain to which the certificate file is to be imported.
- The system prompts you to enter the challenge password used for encrypting the private key if the local certificate to be imported contains a key pair.

When you import a local certificate file that contains a key pair to a PKI domain, you can choose to update the domain with the key pair. Depending on the purpose of the key pair, the following conditions might apply:

- If the purpose of the key pair is general, the device uses the key pair to replace the local key pair that is found in this order:
  a. General-purpose key pair.
  b. Signature key pair.
  c. Encryption key pair.
- If the purpose of the key pair is signature, the device uses the key pair to replace the local key pair that is found in this order:
  a. General-purpose key pair.
  b. Signature key pair.
- If the purpose of the key pair is encryption, the device searches the PKI domain for an encryption key pair.

If a matching key pair is found, the device asks whether you want to overwrite the existing key pair on the device. If no match is found, the device asks you to enter a key pair name, which must be different from the names of any local key pairs of the same algorithm on the device. Then, it generates the key pair according to the key algorithm and the purpose defined in the certificate file. If you do not specify a key pair name, the PKI domain name will be used as the key pair name.

The import operation automatically updates or generates the correct key pair. When you perform the import operation, be sure to save the configuration file to avoid data loss.

Examples

Import CA certificate file **rootca_pem.cer** in PEM format to PKI domain **aaa**. The certificate file contains the root certificate.

```
<Sysname> system-view
[Sysname] pki import domain aaa pem ca filename rootca_pem.cer
The trusted CA's finger print is:
    MD5  fingerprint:FFFF 3EFF FFFF 37FF FFFF 137B FFFF 7535
    SHA1 fingerprint:FFFF FF7F FF2B FFFF 7618 FF4C FFFF 0A7D FFFF FF69
Is the finger print correct?(Y/N):y
[Sysname]
```

Import CA certificate file **aca_pem.cer** in PEM format to PKI domain **bbb**. The certificate file does not contain the root certificate.

```
<Sysname> system-view
[Sysname] pki import domain bbb pem ca filename aca_pem.cer
[Sysname]
```

Import local certificate file **local-ca.p12** in PKCS12 format to PKI domain **bbb**. The certificate file contains a key pair.

```
<Sysname> system-view
[Sysname] pki import domain bbb p12 local filename local-ca.p12
Please input challenge password:
******
[Sysname]
```

Import the local certificate in PEM format to PKI domain **bbb** by copying and pasting the contents of the certificate. The certificate contains the key pair and the CA certificate chain.

```
<Sysname> system-view
[Sysname] pki import domain bbb pem local
Enter PEM-formatted certificates.
End with a Ctrl+C on a line by itself.

pki request-certificate

Use **pki request-certificate** to submit a local certificate request or generate a certificate request in PKCS#10 format.

Syntax

pki request-certificate domain *domain-name* [**password** *password*] [**pkcs10** [**filename** *filename*]]

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 16.

Table 16 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

password *password*: Sets the password for certificate revocation, a case-sensitive string of 1 to 31 characters. The password is contained in the certificate request and must be provided if the certificate is revoked.

pkcs10: Displays BASE64-encoded PKCS#10 certificate request information, which can be used to request a certificate by an out-of-band means, like phone, disk, or email.

filename *filename*: Specifies a local file for saving the certificate request in PKCS#10 format. The *filename* argument is case-insensitive.

Usage guidelines

If SCEP fails, you can perform one of the following tasks:

- Use the **pkcs10** keyword to print the BASE64-encoded request information.
- Use the **pkcs10 filename** *filename* option to save the request information to a local file and transfer the file to the CA by using an out-of-band means. The file name can contain an absolute path. If the specified path does exist, the request information cannot be saved.

This command is not saved in the configuration file.

Examples

Display information about the certificate request in PKCS#10 format.

```
<Sysname> system-view
[Sysname] pki request-certificate domain aaa pkcs10

display pki certificate

pki retrieve-certificate

Use **pki retrieve-certificate** to obtain a certificate from the certificate distribution server.

Syntax

pki retrieve-certificate domain *domain-name* { **ca** | **local** | **peer** *entity-name* }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 17.

Table 17 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

ca: Specifies the CA certificate.

local: Specifies the local certificates.

peer *entity-name*: Specifies a peer entity by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

In online mode:

- You can obtain the CA certificate through the SCEP protocol. If a CA certificate already exists locally, do not obtain the CA certificate again. To obtain a new CA certificate, use the **pki delete-certificate** command to remove the CA certificate and local certificates, and then obtain the CA certificate again.
- You can obtain local certificates or peer certificates through the LDAP protocol. If a PKI domain already has local certificates or peer certificates, you can still perform the obtain operation and the obtained local certificates or peer certificates overwrite the existing ones. If RSA or SM2 is used, a PKI domain can have two local certificates, one for signing and the other for encryption. Certificates for different purposes do not overwrite each other.

The obtained CA certificate, local certificates, and peer certificates are automatically verified before they are saved locally. If the verification fails, they are not saved.

This command is not saved in the configuration file.

Examples

Obtain the CA certificate from the certificate distribution server. (This operation requires the user to confirm the fingerprint of the root CA certificate.)

```
<Sysname> system-view
[Sysname] pki retrieve-certificate domain aaa ca
The trusted CA's finger print is:
    MD5  fingerprint:5C41 E657 A0D6 ECB4 6BD6 1823 7473 AABC
    SHA1 fingerprint:1616 E7A5 D89A 2A99 9419 1C12 D696 8228 87BC C266
Is the finger print correct?(Y/N):y
```

Obtain the local certificates from the certificate distribution server.

```
<Sysname> system-view
[Sysname] pki retrieve-certificate domain aaa local
```

Obtain the certificate of the peer entity **en1** from the certificate distribution server.

```
<Sysname> system-view
[Sysname] pki retrieve-certificate domain aaa peer en1
```

Related commands

display pki certificate

pki delete-certificate

pki retrieve-crl

Use **pki retrieve-crl** to obtain CRLs and save them locally.

Syntax

pki retrieve-crl domain *domain-name*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 18.

Table 18 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

Usage guidelines

CRLs are used to verify the validity of the local certificates and the peer certificates in a PKI domain. To obtain CRLs, a PKI domain must have the correct CA certificate.

The URL of the CRL repository is specified by using the **crl url** command.

The device can obtain CRLs from the CRL repository through the HTTP, LDAP, or SCEP protocol. Which protocol is used depends on the configuration of the CRL repository in the PKI domain:

- If the specified URL of the CRL repository is in HTTP format, the device obtains CRLs through the HTTP protocol.
- If the specified URL of the CRL repository is in LDAP format, the device obtains CRLs through the LDAP protocol. If the specified URL does not have a host name, for example, **ldap:///CN=8088,OU=test,U=rd,C=cn**, you must specify the LDAP server's URL for the PKI domain by using the **ldap server** command. The device can obtain the complete URL of the LDAP repository by combining the URLs of the LDAP server and of the CRL repository.
- If the PKI domain is not configured with the CRL repository, the device looks up the local certificates and then the CA certificate for the CRL repository. If a CRL repository is found, the device obtains CRLs from the CRL repository. If no CRL repository is found, the device obtains CRLs through the SCEP protocol.

Examples

Obtain CRLs from the CRL repository.

```
<Sysname> system-view
[Sysname] pki retrieve-crl domain aaa
```

Related commands

crl url

ldap server

pki storage

Use **pki storage** to specify the storage path for the certificates or CRLs.

Use **undo pki storage** to restore the default.

Syntax

pki storage { **certificates** | **crls** } *dir-path*

undo pki storage { **certificates** | **crls** }

Default

Certificates and CRLs are stored in the **PKI** directory on the storage media of the device. The **PKI** directory is automatically created when a certificate is successfully requested, obtained, or imported for the first time.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

certificates: Specifies a storage path for certificates.

crls: Specifies a storage path for CRLs.

dir-path: Specifies a storage path, a case-sensitive string, which cannot start with a slash (/) or contain two dots plus a slash (../). The *dir-path* argument specifies an absolute path or a relative path, and the path must exist.

Usage guidelines

The specified storage path must be on the master device.

If the path to be specified does not exist, use the **mkdir** command to create the path first.

Certificate files use the .cer or .p12 file extension. CRL files use the .crl file extension. After you change the storage path for certificates or CRLs, the certificate files and CRL files in the original path are moved to the new path.

Examples

Specifies **flash:/pki-new** as the storage path for certificates.

```
<Sysname> system-view
[Sysname] pki storage certificates flash:/pki-new
```

Specifies **pki-new** as the storage path for CRLs.

```
<Sysname> system-view
```

```
[Sysname] pki storage crls pki-new
```

pki validate-certificate

Use **pki validate-certificate** to verify the validity of certificates.

Syntax

pki validate-certificate domain *domain-name* { **ca** | **local** }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 19.

Table 19 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

ca: Specifies the CA certificate.

local: Specifies the local certificates.

Usage guidelines

Generally, certificates are automatically verified when you request, obtain, or import them, or when an application uses PKI.

You can also use this command to manually verify a certificate in the following aspects:

- Whether the certificate is issued by a trusted CA.
- Whether the certificate has expired.
- Whether the certificate is revoked. This check is performed only if CRL checking is enabled.

When CRL checking is enabled:

- To verify the local certificates, if the PKI domain has no CRLs, the device looks up the locally saved CRLs. If a correct CRL is found, the device loads the CRL to the PKI domain. If no correct CRL is found locally, the device obtains a correct CRL from the CA server and saves it locally.
- To verify the CA certificate, CRL checking is performed for the CA certificate chain from the current CA to the root CA.

Examples

Verify the validity of the CA certificate in PKI domain **aaa**.

```
<Sysname> system-view
[Sysname] pki validate-certificate domain aaa ca
```

```

pki domain

public-key dsa

Use **public-key dsa** to specify a DSA key pair for certificate request.

Use **undo public-key** to restore the default.

Syntax

public-key dsa name *key-name* [**length** *key-length*]

undo public-key

Default

No key pair is specified for certificate request.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

name *key-name*: Specifies a key pair by its name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

length *key-length*: Specifies the key length, in bits. The value range is 512 to 2048, and the default is 1024. A longer key means higher security but more public key calculation time.

Usage guidelines

You can specify a nonexistent key pair in this command. A key pair can be obtained in any of the following ways:

- Use the **public-key local create** command to generate a key pair.
- An application, like IKE using digital signature authentication, triggers the device to generate a key pair.
- Use the **pki import** command to import a certificate containing a key pair.

A PKI domain can have key pairs using only one type of cryptographic algorithm (DSA, ECDSA, RSA, or SM2).

- If DSA or ECDSA is used, a PKI domain can have only one key pair. If you configure a DSA or ECDSA key pair multiple times, the most recent configuration takes effect.
- If RSA or SM2 is used, a PKI domain can have two key pairs of different purposes: one is the signing key pair, and the other is the encryption key pair.

  If you configure an RSA signing key pair or RSA encryption key pair multiple times, the most recent configuration takes effect. The RSA signing key pair and encryption key pair do not overwrite each other. The same is true for SM2 key pairs.

The **length** *key-length* option takes effect only if you specify a nonexistent key pair. The device will automatically create the key pair by using the specified name and length before submitting a certificate request. The **length** *key-length* option is ignored if the specified key pair already exists or is already contained in an imported certificate.

Examples

Specify 2048-bit DSA key pair **abc** for certificate request.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] public-key dsa name abc length 2048
```

Related commands

pki import

public-key local create

public-key ecdsa

Use **public-key ecdsa** to specify an ECDSA key pair for certificate request.

Use **undo public-key** to restore the default.

Syntax

public-key ecdsa name *key-name* [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**]

undo public-key

Default

No key pair is specified for certificate request.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

name *key-name*: Specifies a key pair by its name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

secp192r1: Uses the secp192r1 curve to generate the key pair.

secp256r1: Uses the secp256r1 curve to generate the key pair.

secp384r1: Uses the secp384r1 curve to generate the key pair.

secp521r1: Uses the secp521r1 curve to generate the key pair.

Usage guidelines

You can specify a nonexistent key pair for a PKI domain.

A key pair can be obtained in any of the following ways:

- Use the **public-key local create** command to generate a key pair.
- An application, like IKE using digital signature authentication, triggers the device to generate a key pair.
- Use the **pki import** command to import a certificate containing a key pair.

A PKI domain can have key pairs using only one type of cryptographic algorithm (DSA, ECDSA, RSA, or SM2).

- If DSA or ECDSA is used, a PKI domain can have only one key pair. If you configure a DSA or ECDSA key pair multiple times, the most recent configuration takes effect.
- If RSA or SM2 is used, a PKI domain can have two key pairs of different purposes: one is the signing key pair, and the other is the encryption key pair.

  If you configure an RSA signing key pair or RSA encryption key pair multiple times, the most recent configuration takes effect. The RSA signing key pair and encryption key pair do not overwrite each other. The same is true for SM2 key pairs.

The specified elliptic curve takes effect only if you specify a nonexistent key pair. The device will automatically create the key pair by using the specified name and curve before submitting a certificate request. The curve parameter is ignored if the specified key pair already exists or is already contained in an imported certificate.

If you do not specify an elliptic curve, the secp192r1 curve is used by default.

Examples

Specify 384-bit ECDSA key pair **abc** for certificate request.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] public-key ecdsa name abc secp384r1
```

Parameters

encryption: Specifies a key pair for encryption.

name *encryption-key-name*: Specifies a key pair name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

signature: Specifies a key pair for signing.

name *signature-key-name*: Specifies a key pair name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

general: Specifies a key pair for both signing and encryption.

name *key-name*: Specifies a key pair name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

length *key-length*: Specifies the key length, in bits. The value range is 512 to 2048, and the default is 1024. A longer key means higher security but more public key calculation time.

Usage guidelines

You can specify a nonexistent key pair in this command. You can get a key pair in any of the following ways:

- Use the **public-key local create** command to generate a key pair.
- An application, like IKE using digital signature authentication, triggers the device to generate a key pair.
- Use the **pki import** command to import a certificate containing a key pair.

A PKI domain can have key pairs using only one type of cryptographic algorithm (DSA, ECDSA, RSA, or SM2).

- If DSA or ECDSA is used, a PKI domain can have only one key pair. If you configure a DSA or ECDSA key pair multiple times, the most recent configuration takes effect.
- If RSA or SM2 is used, a PKI domain can have two key pairs of different purposes: one is the signing key pair, and the other is the encryption key pair.

  If you configure an RSA signing key pair or RSA encryption key pair multiple times, the most recent configuration takes effect. The RSA signing key pair and encryption key pair do not overwrite each other. The same is true for SM2 key pairs.

If you specify a signing key pair and an encryption key pair separately, their key lengths can be different.

The **length** *key-length* option takes effect only if you specify a nonexistent key pair. The device will automatically create the key pair by using the specified name and length before submitting a certificate request. The **length** *key-length* option is ignored if the specified key pair already exists or is already contained in an imported certificate.

Examples

Specify 2048-bit general purpose RSA key pair **abc** for certificate request.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] public-key rsa general name abc length 2048
```

Specify the following RSA key pairs for certificate request:

- 2048-bit RSA encryption key pair **rsa1**.
- 2048-bit RSA signing key pair **sig1**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] public-key rsa encryption name rsa1 length 2048
[Sysname-pki-domain-aaa] public-key rsa signature name sig1 length 2048
```

Related commands

pki import

public-key local create

public-key sm2

Use **public-key sm2** to specify an SM2 key pair for certificate request.

Use **undo public-key** to restore the default.

Syntax

public-key sm2 { { **encryption name** *encryption-key-name* | **signature name** *signature-key-name* } * | **general name** *key-name* }

undo public-key

Default

No key pair is specified for certificate request.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

encryption name *encryption-key-name*: Specifies a key pair for encryption by its name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

signature name *signature-key-name*: Specifies a key pair for signing by its name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

general name *key-name*: Specifies a key pair for both signing and encryption. The **name** *key-name* option specifies the key pair name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

Usage guidelines

You can specify a nonexistent key pair in this command. You can get a key pair in any of the following ways:

- Use the **public-key local create** command to generate a key pair.
- An application, like IKE using digital signature authentication, triggers the device to generate a key pair.

A PKI domain can have key pairs using only one type of cryptographic algorithm (DSA, ECDSA, RSA, or SM2).

If you configure an SM2 key pair for a PKI domain multiple times, the most recent configuration takes effect.

A CA server that uses double certificate templates always issues both a signing certificate and an encryption certificate to a requesting applicant. When such a CA server is used, follow these guidelines when you specify SM2 key pairs for certificate request:

- Specify different names for the encryption key pair and the signing key pair. If you specify the same name for the two key pairs, request of the signing certificate will fail.
- If you do not specify an encryption key pair, the device will save the key pair in the issued encryption certificate with the PKI domain name. Do not use the PKI domain name as the name of the SM2 signing key pair.

If you configure this command for a PKI domain multiple times, the most recent configuration takes effect.

Examples

Specify SM2 signing key pair **sm21** and SM2 encryption key pair **sm22** for certificate request.

```
<Sysname> system-view
[Sysname] pki domain 1
[Sysname-pki-domain-1] public-key sm2 signature name sm21 encryption name sm22
```

Related commands

pki import

public-key local create

revocation-check method

Use **revocation-check method** to specify the certificate revocation checking methods.

Use **undo revocation-check method** to restore the default.

Syntax

revocation-check method *method1* [*method2*]

undo revocation-check method

Default

The CRL is used for certificate revocation checking.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

method1 [*method2*]: Specifies an ordered list of certificate revocation checking methods. Supported methods are:

- **crl**: Uses the CRL for certificate revocation checking.
- **none**: Performs no revocation checking and treats all certificates as not revoked. If you specify **none** as method 1, you cannot specify method 2 because no revocation checking is required.

Usage guidelines

If you configure the **revocation-check method crl none** command, the device will first check the CRL to identify whether the certificate has been revoked during certificate verification. If the device cannot obtain a CRL, it will treat the certificate as not revoked.

The CRL method takes effect only if CRL checking is enabled in the PKI domain (by using the **crl check enable** command). If CRL checking is disabled in the PKI domain, no CRL checking will be performed and all certificates will be treated as not revoked.

If the **revocation-check method none** command is configured in the PKI domain, the **crl check enable** command does not take effect.

Examples

Specify the CRL certificate revocation checking method for PKI domain **abc**.

```
<Sysname> system
[Sysname] pki domain abc
[Sysname-pki-domain-abc] revocation-check method crl
```

Related commands

crl check enable

root-certificate fingerprint

Use **root-certificate fingerprint** to set the fingerprint for verifying the root CA certificate.

Use **undo root-certificate fingerprint** to restore the default.

Syntax

root-certificate fingerprint { **md5** | **sha1** } *string*

undo root-certificate fingerprint

Default

No fingerprint is set for verifying the root CA certificate.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

md5: Sets an MD5 fingerprint.

sha1: Sets an SHA1 fingerprint.

string: Sets the fingerprint in hexadecimal notation. If you specify the **MD5** keyword, the fingerprint is a string of 32 characters. If you specify the **SHA1** keyword, the fingerprint is a string of 40 characters.

Usage guidelines

If you set the certificate request mode to auto for a PKI domain that does not have a CA certificate, you must configure the fingerprint for root CA certificate verification. When an application (for example, IKE) triggers the device to request local certificates, the device automatically performs the following operations:

1. Obtains the CA certificate from the CA server.
2. Compares the fingerprint contained in the root CA certificate with the fingerprint configured in the PKI domain, if either of the following conditions exists:
   - The obtained CA certificate is a root certificate.
   - The obtained CA certificate is a certificate chain and contains a root certificate that does not exist on the device.

   If the two fingerprints do not match, or if no fingerprint is configured in the PKI domain, the device rejects the CA certificate and the local certificate request fails.

The fingerprint configured by this command is also used for root CA certificate verification when the device performs the following operations:

- Imports the CA certificate as requested by the **pki import** command.
- Obtains the CA certificate as requested by the **pki retrieve-certificate** command.

The device compares the fingerprint contained in the root CA certificate with the fingerprint configured in the PKI domain, if either of the following conditions exists:

- The CA certificate to be imported or obtained is a root certificate that does not exist on the device.
- The CA certificate to be imported or obtained is a certificate chain and contains a root certificate that does not exist on the device.

If the two fingerprints do not match, the device rejects the CA certificate. If no fingerprint is configured in the PKI domain, the device prompts you to manually verify the fingerprint of the root CA certificate.

Examples

Specify an MD5 fingerprint for verifying the root CA certificate.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] root-certificate fingerprint md5
12EF53FA355CD23E12EF53FA355CD23E
```

Specify an SHA1 fingerprint for verifying the root CA certificate.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] root-certificate fingerprint sha1
D1526110AAD7527FB093ED7FC037B0B3CDDDAD93
```

rule

Use **rule** to create an access control rule.

Use **undo rule** to remove an access control rule.

Syntax

rule [*id*] { **deny** | **permit** } *group-name*

undo rule *id*

Default

No access control rules exist.

Views

Certificate-based access control policy view

Predefined user roles

network-admin

context-admin

Parameters

id: Assigns an ID to the access control rule, in the range of 1 to 16. The default setting is the smallest unused ID in this range.

deny: Denies the certificates that match the associated attribute group.

permit: Permits the certificates that match the associated attribute group.

group-name: Specifies a certificate attribute group by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

When you create an access control rule, you can associate it with a nonexistent certificate attribute group.

The system determines that a certificate matches an access control rule when either of the following conditions exists:

- The associated certificate attribute group does not exist.
- The associated certificate attribute group does not contain any attribute rules.
- The certificate matches all attribute rules in the associated certificate attribute group.

You can configure multiple access control rules for an access control policy. A certificate matches the rules one by one, starting with the rule with the smallest ID. When a match is found, the match process stops, and the system performs the access control action defined in the access control rule.

Examples

Create rule 1 to permit all certificates that match certificate attribute group **mygroup**.

```
<Sysname> system-view
[Sysname] pki certificate access-control-policy mypolicy
[Sysname-pki-cert-acp-mypolicy] rule 1 permit mygroup
```

Related commands

source

Use **source** to specify the source IP address for PKI protocol packets.

Use **undo source** to restore the default.

Syntax

source { **ip** | **ipv6** } { *ip-address* | **interface** *interface-type interface-number* }

undo source

Default

The source IP address of PKI protocol packets is the IP address of their outgoing interface.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

ip *ip-address*: Specifies a source IPv4 address.

ipv6 *ip-address*: Specifies a source IPv6 address.

interface *interface-type interface-number*: Specifies an interface by its type and number. The interface's primary IP address or the lowest IPv6 address will be used as the source IP address for PKI protocol packets.

Usage guidelines

Use this command to specify the source IP address for PKI protocol packets. You can also specify a source interface if the IP address is dynamically obtained.

Make sure there is a route between the source IP address and the CA server.

You can specify only one source IP address in a PKI domain. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify **111.1.1.8** as the source IP address for PKI protocol packets.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] source ip 111.1.1.8
```

Specify **1::8** as the source IPv6 address for PKI protocol packets.

```
<Sysname> system-view
[Sysname] pki domain 1
[Sysname-pki-domain-1] source ipv6 1::8
```

Use the IP address of GigabitEthernet 1/0/1 as the source IP address for PKI protocol packets.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] source ip interface gigabitethernet 1/0/1
```

Use the IPv6 address of GigabitEthernet 1/0/1 as the source IPv6 address for PKI protocol packets.

```
<Sysname> system-view
[Sysname] pki domain 1
[Sysname-pki-domain-1] source ipv6 interface gigabitethernet 1/0/1
```

state

Use **state** to set the state or province name for a PKI entity.

Use **undo state** to restore the default.

Syntax

state *state-name*

undo state

Default

No state name or province name is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

context-admin

Parameters

state-name: Specifies a state or province by its name, a case-sensitive string of 1 to 63 characters. No comma can be included.

Examples

Set the state name to **countryA** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] state countryA
```

subject-dn

Use **subject-dn** to configure the DN for a PKI entity.

Use **undo subject-dn** to restore the default.

Syntax

subject-dn *dn-string*

undo subject-dn

Default

No DN is configured for a PKI entity.

Views

PKI entity view

Default command level

network-admin

context-admin

Parameters

dn-string: Specifies the DN for the PKI entity, a case-insensitive string of 1 to 255 characters.

Usage guidelines

The subject DN string is a sequence of *attribute=value* pairs separated by commas. Each attribute can be specified multiple times with different values. Supported DN attributes are:

- **CN**—Common-name.
- **C**—Country code.
- **L**—Locality.
- **O**—Organization.
- **OU**—Organization unit.
- **ST**—State or province.

After this command is configured, the following commands do not take effect:

- **common-name**
- **country**
- **locality**
- **organization**
- **organization-unit**
- **state**

If you configure this command multiple times, the most recent configuration takes effect.

Examples

Configure the DN for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] subject-dn
CN=test,C=CN,O=abc,OU=rdtest,OU=rstest,ST=countryA,L=pukras
```

usage

Use **usage** to specify the extensions for certificates.

Use **undo usage** to remove certificate extensions.

Syntax

usage { **ike** | **ssl-client** | **ssl-server** } *

undo usage [**ike** | **ssl-client** | **ssl-server**] *

Default

No extensions for certificates are specified. A certificate can be used by IKE, SSL clients, and SSL servers.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

ike: Specifies the IKE certificate extension so IKE peers can use the certificates.

ssl-client: Specifies the SSL client certificate extension so the SSL client can use the certificates.

ssl-server: Specifies the SSL server certificate extension so the SSL server can use the certificates.

Usage guidelines

If you do not specify any keywords for the **undo usage** command, this command removes all certificate extensions.

The extension options contained in a certificate depends on the CA policy, and might be different from those specified in the PKI domain.

Examples

Specify the SSL client certificate extension.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] usage ssl-client
```

vpn-instance

Use **vpn-instance** to specify the VPN instance where the certificate request reception authority and the CRL repository belong.

Use **undo vpn-instance** to restore the default.

Syntax

vpn-instance *vpn-instance-name*

undo vpn-instance

Default

The certificate request reception authority and the CRL repository belong to the public network.

Views

PKI domain view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance-name: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters.

Examples

Specify **vpn1** as the VPN instance where the certificate request reception authority and the CRL repository belong.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] vpn-instance vpn1
```

Syntax

display ssh server { **session** [**slot** *slot-number*] | **status** }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

session: Specifies the SSH server sessions.

status: Specifies the SSH server status.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays SSH server session information for the master device.

Examples

Display the SSH server status.

```
<Sysname> display ssh server status
 Stelnet server: Disable
 SSH version : 2.0
 SSH authentication-timeout : 60 second(s)
 SSH server key generating interval : 0 hour(s)
 SSH authentication retries : 3 time(s)
 SFTP server: Disable
 SFTP server Idle-Timeout: 10 minute(s)
 NETCONF server: Disable
 SCP server: Disable
 SSH Server PKI domain name: aaa
```

Table 1 Command output

Field	Description
Stelnet server	Whether the Stelnet server is enabled.
SSH version	SSH protocol version. When the SSH supports SSH1, the protocol version is 1.99. Otherwise, the protocol version is 2.

Field	Description
SSH authentication-timeout	Authentication timeout timer.
SSH server key generating interval	Minimum interval for updating the RSA server key pair.
SSH authentication retries	Maximum number of authentication attempts for SSH users.
SFTP server	Whether the SFTP server is enabled.
SFTP server Idle-Timeout	SFTP connection idle timeout timer.
NETCONF server	Whether NETCONF over SSH is enabled.
SCP server	Whether the SCP server is enabled.
SSH Server PKI domain name	Name of the PKI domain specified for the SSH server.

Display the SSH server sessions.

```
<Sysname> display ssh server session
UserPid   SessID Ver   Encrypt    State          Retries  Serv     Username   Idx
 184      0     2.0   aes128-cbc Established    1        Stelnet  abc@123
```

Table 2 Command output

Field	Description
UserPid	User process ID.
SessID	Session ID.
Ver	Protocol version of the SSH server.
Encrypt	Encryption algorithm used on the SSH server.
State	Session state: • **Init**—Initialization. • **Ver-exchange**—Version negotiation. • **Keys-exchange**—Key exchange. • **Auth-request**—Authentication request. • **Serv-request**—Session service request. • **Established**—The session is established. • **Disconnected**—The session is terminated.
Retries	Number of authentication failures.
Serv	Service type: • SCP. • SFTP. • Stelnet. • NETCONF.
Username	Username that the client uses to log in to the server.
Idx	Absolute number of the user line. The value for this field is empty if the SSH connection for the user is not redirected.

display ssh user-information

Use **display ssh user-information** to display information about SSH users on an SSH server.

Syntax

display ssh user-information [*username*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

username: Specifies an SSH username, a case-sensitive string of 1 to 80 characters. If you do not specify an SSH user, this command displays information about all SSH users.

Usage guidelines

This command displays information only about SSH users that are configured by using the **ssh user** command on the SSH server.

Examples

Display information about all SSH users.

```
<Sysname> display ssh user-information
 Total ssh users:2
 Username            Authentication-type  User-public-key-name  Service-type
 yemx                password                                   Stelnet|SFTP
 test                publickey            pubkey                SFTP
```

Table 3 Command output

Field	Description
Total ssh users	Total number of SSH users.
Authentication-type	Authentication methods: • Password authentication. • Publickey authentication. • Password-publickey authentication. • Any authentication.
User-public-key-name	Public key name of the user. This field is empty if the authentication method is password authentication.
Service-type	Service types: • Stelnet. • SFTP. • SCP. • NETCONF. If multiple service types are available for an SSH user, they are separated by vertical bars (|).

sftp server idle-timeout

Use **sftp server idle-timeout** to set the idle timeout timer for SFTP connections on an SFTP server.

Use **undo sftp server idle-timeout** to restore the default.

Syntax

sftp server idle-timeout *time-out-value*

undo sftp server idle-timeout

Default

The idle timeout timer is 10 minutes for SFTP connections.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

time-out-value: Specifies an idle timeout timer in the range of 1 to 35791 minutes.

Usage guidelines

If an SFTP connection is idle when the idle timeout timer expires, the system automatically terminates the connection. To promptly release connection resources, set the idle timeout timer to a small value when many SFTP connections concurrently exist.

Examples

Set the idle timeout timer to 500 minutes for SFTP connections.

```
<Sysname> system-view
[Sysname] sftp server idle-timeout 500
```

Related commands

display ssh server

ssh server acl

Use **ssh server acl** to specify an ACL to control IPv4 SSH connections to the server.

Use **undo ssh server acl** to restore the default.

Syntax

ssh server acl { *advanced-acl-number* | *basic-acl-number* | **mac** *mac-acl-number* }

undo ssh server acl

Default

No ACLs are specified and all IPv4 SSH clients can initiate SSH connections to the server.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

advanced-acl-number: Specifies an IPv4 advanced ACL number in the range of 3000 to 3999.

basic-acl-number: Specifies an IPv4 basic ACL number in the range of 2000 to 2999.

mac *mac-acl-number:* Specifies a Layer 2 ACL by its number in the range of 4000 to 4999.

Usage guidelines

The ACL specified in this command filters IPv4 SSH clients' connection requests. Only the IPv4 SSH clients that the ACL permits can access the device. If the specified ACL does not exist or contains no rules, IPv4 SSH clients are not allowed to access the device.

If the **vpn-instance** keyword is specified in an ACL rule, the rule applies only to VPN packets. If the **vpn-instance** keyword is not specified in an ACL rule, the rule applies only to public network packets.

This command takes effect only on SSH connections that are initiated after the configuration of this command.

This command does not take effect on NETCONF-over-SSH connections initiated by IPv4 SSH clients. To control IPv4 clients to establish NETCONF-over-SSH connections to the server, use the **netconf ssh acl** command. For more information about the **netconf ssh acl** command, see NETCONF commands in *Network Management and Monitoring Command Reference*.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure ACL 2001 and permit only the users at 1.1.1.1 to initiate SSH connections to the server.

```
<Sysname> system-view
[Sysname] acl basic 2001
[Sysname-acl-ipv4-basic-2001] rule permit source 1.1.1.1 0
[Sysname-acl-ipv4-basic-2001] quit
[Sysname] ssh server acl 2001
```

Related commands

display ssh server

ssh server acl-deny-log enable

Use **ssh server acl-deny-log enable** to enable logging for SSH login attempts that are denied by the SSH login control ACL.

Use **undo ssh server acl-deny-log enable** to disable logging for SSH login attempts that are denied by the SSH login control ACL.

Syntax

ssh server acl-deny-log enable

undo ssh server acl-deny-log enable

Default

Logging is disabled for SSH login attempts that are denied by the SSH login control ACL.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Only SSH clients permitted by the SSH login control ACL can access the SSH server. The logging feature generates log messages for SSH login attempts that are denied by the SSH login control ACL, and sends the messages to the information center.

For information about log message output, see the information center in *Network Management and Monitoring Configuration Guide*. For information about configuring an SSH login control ACL, see the **ssh server acl** or **ssh server ipv6 acl** command.

Examples

Enable logging for SSH login attempts that are denied by the SSH login control ACL.

```
<Sysname> system-view
[Sysname] ssh server acl-deny-log enable
```

Related commands

ssh server acl

ssh server ipv6 acl

ssh server authentication-retries

Use **ssh server authentication-retries** to set the maximum number of authentication attempts for SSH users.

Use **undo ssh server authentication-retries** to restore the default.

Syntax

ssh server authentication-retries *retries*

undo ssh server authentication-retries

Default

The maximum number of authentication attempts is 3 for SSH users.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

retries: Specifies the maximum number of authentication attempts for SSH users, in the range of 1 to 5.

Usage guidelines

Setting the maximum number of authentication attempts prevents malicious hacking of usernames and passwords.

If the total number of authentication attempts exceeds the upper limit specified in this command, further authentication is not allowed.

- For **any** authentication, an authentication attempt is a publickey or password authentication process.
- For **password-publickey** authentication, an authentication attempt contains both a publickey authentication process and a password authentication process. The server first uses publickey authentication, and then uses password authentication to authenticate the SSH user.

This configuration does not affect logged-in users. It affects only users that attempt to log in after the configuration.

Examples

Set the maximum number of authentication attempts to 4 for SSH users.

```
<Sysname> system-view
[Sysname] ssh server authentication-retries 4
```

Related commands

display ssh server

ssh server authentication-timeout

Use **ssh server authentication-timeout** to set the SSH user authentication timeout timer on the SSH server.

Use **undo ssh server authentication-timeout** to restore the default.

Syntax

ssh server authentication-timeout *time-out-value*

undo ssh server authentication-timeout

Default

The SSH user authentication timeout timer is 60 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

time-out-value: Specifies an authentication timeout timer in the range of 1 to 120 seconds.

Usage guidelines

If a user does not finish the authentication when the timeout timer expires, the connection cannot be established.

To prevent malicious occupation of TCP connections, set the authentication timeout timer to a small value.

Examples

Set the authentication timeout timer to 10 seconds for SSH users.

```
<Sysname> system-view
[Sysname] ssh server authentication-timeout 10
```

Related commands

display ssh server

ssh server compatible-ssh1x enable

Use **ssh server compatible-ssh1x enable** to enable the SSH server to support SSH1 clients.

Use **undo ssh server compatible-ssh1x** [**enable**] to restore the default.

Syntax

ssh server compatible-ssh1x enable

undo ssh server compatible-ssh1x [**enable**]

Default

The SSH server does not support SSH1 clients.

Views

System view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Usage guidelines

The **undo** form of this command restores the default setting whether you specify the **enable** keyword or not.

This configuration does not affect logged-in users. It affects only users that attempt to log in after the configuration.

Examples

Enable the SSH server to support SSH1 clients.

```
<Sysname> system-view
[Sysname] ssh server compatible-ssh1x enable
```

Related commands

display ssh server

ssh server dscp

Use **ssh server dscp** to set the DSCP value in the IPv4 SSH packets that the SSH server sends to SSH clients.

Use **undo ssh server dscp** to restore the default.

Syntax

ssh server dscp *dscp-value*

undo ssh server dscp

Default

The DSCP value is 48 in IPv4 SSH packets.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Specifies the DSCP value in the IPv4 SSH packets, in the range of 0 to 63. A bigger DSCP value represents a higher priority.

Usage guidelines

The DSCP value of a packet specifies the priority of the packet and affects the transmission priority of the packet.

Examples

Set the DSCP value to 30 for IPv4 SSH packets.

```
<Sysname> system-view
[Sysname] ssh server dscp 30
```

ssh server enable

Use **ssh server enable** to enable the Stelnet server.

Use **undo ssh server enable** to disable the Stelnet server.

Syntax

ssh server enable

undo ssh server enable

Default

The Stelnet server is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Examples

Enable the Stelnet server.

```
<Sysname> system-view
[Sysname] ssh server enable
```

display ssh server

ssh server ipv6 acl

Use **ssh server ipv6 acl** to specify an ACL to control IPv6 SSH connections to the server.

Use **undo ssh server ipv6 acl** to restore the default.

Syntax

ssh server ipv6 acl { **ipv6** { *advanced-acl-number* | *basic-acl-number* } | **mac** *mac-acl-number* }

undo ssh server ipv6 acl

Default

No ACLs are specified and all IPv6 SSH clients can initiate SSH connections to the server.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies the IPv6 ACL type.

advanced-acl-number: Specifies an IPv6 advanced ACL number in the range of 3000 to 3999.

basic-acl-number: Specifies an IPv6 basic ACL number in the range of 2000 to 2999.

mac *mac-acl-number:* Specifies a Layer 2 ACL by its number in the range of 4000 to 4999.

Usage guidelines

The ACL specified in this command filters IPv6 SSH clients' connection requests. Only the IPv6 SSH clients that the ACL permits can access the device. If the specified ACL does not exist or contains no rules, IPv6 SSH clients are not allowed to access the device.

If the **vpn-instance** keyword is specified in an ACL rule, the rule applies only to VPN packets. If the **vpn-instance** keyword is not specified in an ACL rule, the rule applies only to public network packets.

This command takes effect only on SSH connections that are initiated after the configuration of this command.

This command does not take effect on NETCONF-over-SSH connections initiated by IPv6 SSH clients.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure ACL 2001 and permit only the users on the subnet 1::1/64 to initiate SSH connections to the server.

```
<Sysname> system-view
[Sysname] acl ipv6 basic 2001
[Sysname-acl-ipv6-basic-2001] rule permit source 1::1 64
[Sysname-acl-ipv6-basic-2001] quit
[Sysname] ssh server ipv6 acl ipv6 2001
```

Related commands

display ssh server

ssh server ipv6 dscp

Use **ssh server ipv6 dscp** to set the DSCP value in the IPv6 SSH packets that the SSH server sends to SSH clients.

Use **undo ssh server ipv6 dscp** to restore the default.

Syntax

ssh server ipv6 dscp *dscp-value*

undo ssh server ipv6 dscp

Default

The DSCP value is 48 in IPv6 SSH packets.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Specifies the DSCP value in the IPv6 SSH packets, in the range of 0 to 63. A bigger DSCP value represents a higher priority.

Usage guidelines

The DSCP value of an IPv6 packet specifies the priority of the packet and affects the transmission priority of the packet.

Examples

Set the DSCP value to 30 for IPv6 SSH packets.

```
<Sysname> system-view
[Sysname] ssh server ipv6 dscp 30
```

ssh server pki-domain

Use **ssh server pki-domain** to specify a PKI domain for an SSH server.

Use **undo ssh server pki-domain** to restore the default.

Syntax

ssh server pki-domain *domain-name*

undo ssh server pki-domain

Default

No PKI domain is specified for an SSH server.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies the name of the PKI domain used to verify the SSH server. The PKI domain name is a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

Examples

Specify PKI domain **serverpkidomain** for the SSH server.

```
<Sysname> system-view
[Sysname] ssh server pki-domain serverpkidomain
```

ssh server port

Use **ssh server port** to specify the SSH service port.

Use **undo ssh server port** to restore the default.

Syntax

ssh server port *port-number*

undo ssh server port

Default

The SSH service port is 22.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

port-number: Specifies a port number in the range of 1 to 65535.

Usage guidelines

CAUTION:

- If you modify the SSH port number when the SSH server is enabled, the SSH service is restarted and all SSH connections are terminated after the modification. SSH users must reconnect to the SSH server to access the server.
- If you set the SSH port to a well-known port number, the service that uses the well-known port number might fail to start. Well-known port numbers are in the range of 1 to 1024.

When the device acts as an SSH redirect server, modifying the SSH service port on the device affects existing SSH redirect connections as follows:

- If an SSH user accesses the destination device by specifying the SSH redirect listening port, modifying the SSH service port does not affect the existing SSH redirect connection.
- If an SSH user accesses the destination device by specifying the absolute number of the user line, modifying the SSH service port terminates the SSH redirect connection. The SSH user must reconnect to the SSH redirect server to access the destination device.

Examples

Set the SSH service port to 1025.

```
<Sysname> system-view
```

```
[Sysname] ssh server port 1025
```

ssh server rekey-interval

Use **ssh server rekey-interval** to set the minimum interval for updating the RSA server key pair.

Use **undo ssh server rekey-interval** to restore the default.

Syntax

ssh server rekey-interval *interval*

undo ssh server rekey-interval

Default

The minimum interval for updating the RSA server key pair is 0 hours. The system does not update the RSA server key pair.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the minimum interval for updating the RSA server key pair, in the range of 1 to 24 hours.

Usage guidelines

Periodically updating the RSA server key pair prevents malicious hacking to the key pair and enhances security of the SSH connections.

The system starts to count down the configured minimum update interval after the first SSH1 user logs in to the server. If a new SSH1 user logs in to the server after the interval, the system performs the following operations:

1. Updates the RSA server key pair.
2. Uses the updated RSA server key pair for key pair negotiation with the new user.
3. Resets the interval and starts to count down the interval again.

This command takes effect only on SSH1 clients.

Examples

Set the minimum interval to 3 hours for updating the RSA server key pair.

```
<Sysname> system-view
[Sysname] ssh server rekey-interval 3
```

Related commands

display ssh server

ssh user

Use **ssh user** to create an SSH user and specify the service type and authentication method.

Use **undo ssh user** to delete an SSH user.

Syntax

ssh user *username* **service-type** { **all** | **netconf** | **scp** | **sftp** | **stelnet** } **authentication-type** { **password** | { **any** | **password-publickey** | **publickey** } [**assign** { **pki-domain** *domain-name* | **publickey** *keyname* }] }

undo ssh user *username*

Default

No SSH users exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

username: Specifies an SSH username, a case-sensitive string of 1 to 80 characters. The username cannot be **a**, **al**, or **all**. In addition, the username cannot include vertical bars (|), colons (:), asterisks (*), question marks (?), or angle brackets (< >). The at sign (@), slash (/), and backslash (\) can only be used to append ISP domain names to usernames in the *pureusername@domain*, *pureusername*/*domain*, and *domain**pureusername* format. Do not include hyphens (-) in the username of an SCP user. Otherwise, SCP logins using that username will fail.

service-type: Specifies a service type for the SSH user.

- **all**: Specifies service types Stelnet, SFTP, SCP, and NETCONF.
- **scp**: Specifies the service type SCP.
- **sftp**: Specifies the service type SFTP.
- **stelnet**: Specifies the service type Stelnet.
- **netconf**: Specifies the service type NETCONF.

authentication-type: Specifies an authentication method for the SSH user.

- **password**: Specifies password authentication. This authentication method provides easy and fast encryption, but it is vulnerable. It can work with AAA to implement user authentication, authorization, and accounting.
- **any**: Specifies either password authentication or publickey authentication.
- **password-publickey**: Specifies both password authentication and publickey authentication for SSH2 clients. In SSH2, the password-publickey authentication method provides higher security. If the client runs SSH1, this keyword specifies either password authentication or publickey authentication.
- **publickey**: Specifies publickey authentication. This authentication method has complicated and slow encryption, but it provides strong authentication that can defend against brute-force attacks. This authentication method is easy to use. If this method is configured, the authentication process completes automatically without entering any password.

assign: Specifies parameters used for client verification.

- **pki-domain** *domain-name*: Specifies the PKI domain that verifies the client's digital certificate. The *domain-name* argument is a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes ('). The server uses the CA certificate that is saved in the PKI domain to verify the client's digital certificate. In this scenario, the server does not need to save clients' public keys in advance.

- **publickey** *keyname*: Specifies the public key of the SSH client. The *keyname* argument represents the name of the SSH client's public key configured on the server. It is a case-insensitive string of 1 to 64 characters. The server uses the client's public key to check the validity of the client. If the public key file of the client is changed, you must update the client's public key on the server promptly.

Usage guidelines

Use this command to configure an SSH user depending on the authentication method.

- If the authentication method is **publickey**, you must create an SSH user and a local user on the SSH server. The two users must have the same username, so that the SSH user can be assigned the correct working directory and user role.
- If the authentication method is **password**, you must perform one of the following tasks:
  - For local authentication, configure a local user on the SSH server.
  - For remote authentication, configure an SSH user on a remote authentication server, for example, a RADIUS server.

  You do not need to create an SSH user by using the **ssh user** command. However, if you want to display all SSH users, including the password-only SSH users, for centralized management, you can use this command to create them. If such an SSH user has been created, make sure you have specified the correct service type and authentication method.
- If the authentication method is **password-publickey** or **any**, you must create an SSH user on the SSH server and perform one of the following tasks:
  - For local authentication, configure a local user on the SSH server.
  - For remote authentication, configure an SSH user on a remote authentication server, for example, a RADIUS server.

  In either case, the local user or the SSH user configured on the remote authentication server must have the same username as the SSH user.

For an SFTP or SCP user, the working directory depends on the authentication method.

- If the authentication method is **publickey** or **password-publickey**, the working directory is specified by the **authorization-attribute** command in the associated local user view.
- If the authentication method is **password**, the working directory is authorized by AAA.

For an SSH user, the user role also depends on the authentication method.

- If the authentication method is **publickey** or **password-publickey**, the user role is specified by the **authorization-attribute** command in the associated local user view.
- If the authentication method is **password**, the user role is authorized by AAA.

If you use this command to specify a host public key or a PKI domain for a user multiple times, the most recent configuration takes effect. If neither a host public key nor a PKI domain is specified for the user, the user uses certificate authentication for login. The server uses the PKI domain of its own certificate to verify the client's certificate.

The command configuration does not affect logged-in users. It affects only users that attempt to log in after the configuration.

Examples

Create an SSH user named **user1**. Specify the service type as **sftp** and the authentication method as **password-publickey** for the user. Assign the host public key **key1** to the user.

```
<Sysname> system-view
[Sysname] ssh user user1 service-type sftp authentication-type password-publickey assign publickey key1
```

Create a local device management user named **user1**. Specify the password as **123456TESTplat&!** in plain text and the service type as **ssh** for the user. Assign the working directory **flash:** and the **network-admin** user role to the user.

```
[Sysname] local-user user1 class manage
[Sysname-luser-manage-user1] password simple 123456TESTplat&!
[Sysname-luser-manage-user1] service-type ssh
[Sysname-luser-manage-user1] authorization-attribute work-directory flash: user-role
network-admin
```

Parameters

remote-file: Specifies a file by its name.

Usage guidelines

This command has the same function as the **remove** command.

Examples

Delete file **temp.c** from the SFTP server.

```
sftp> delete temp.c
Removing /temp.c
```

dir

Use **dir** to display information about the files and subdirectories under a directory.

Syntax

dir [**-a** | **-l**] [*remote-path*]

Views

SFTP client view

Predefined user roles

network-admin

context-admin

Parameters

-a: Displays detailed information about files and subdirectories under a directory in a list, including the files and subdirectories with names starting with dots (.).

-l: Displays detailed information about the files and subdirectories under a directory in a list, excluding the files and subdirectories with names starting with dots (.).

remote-path: Specifies the name of the directory to be queried. If you do not specify this argument, the command displays information about the files and subdirectories under the current working directory.

Usage guidelines

If you do not specify both of the **-a** and **-l** keywords, this command displays the names of the files and subdirectories under a directory.

This command has the same function as the **ls** command.

Examples

Display detailed information about the files and subdirectories under the current directory, including the files and subdirectories with names starting with dots (.).

```
sftp> dir -a
drwxrwxrwx    2 1        1               512 Dec 18 14:12 .
drwxrwxrwx    2 1        1               512 Dec 18 14:12 ..

  delete path                  Delete remote file
  dir [-a|-l][path]            Display remote directory listing
       -a                        List all filenames
       -l                        List filename including the specific
                                 information of the file
  exit                         Quit sftp
  get remote-path [local-path] Download file
  help                         Display this help text
  ls [-a|-l][path]             Display remote directory
       -a                          List all filenames
       -l                          List filename including the specific
                                   information of the file
  mkdir path                   Create remote directory
  put local-path [remote-path] Upload file
  pwd                          Display remote working directory
  quit                         Quit sftp
  rename oldpath newpath       Rename remote file
  remove path                  Delete remote file
```

```
rmdir path                    Delete remote empty directory
?                             Synonym for help
```

ls

Use **ls** to display information about the files and subdirectories under a directory.

Syntax

ls [**-a** | **-l**] [*remote-path*]

Views

SFTP client view

Predefined user roles

network-admin

context-admin

Parameters

-a: Displays detailed information about files and subdirectories under a directory in a list, including the files and subdirectories with names starting with dots (.).

-l: Displays detailed information about the files and subdirectories under a directory in a list, excluding the files and subdirectories with names starting with dots (.).

remote-path: Specifies the name of the directory to be queried. If you do not specify this argument, the command displays information about the files and subdirectories under the current working directory.

Usage guidelines

If you do not specify both of the **-a** and **-l** keywords, this command displays the names of the files and subdirectories under a directory.

This command has the same function as the **dir** command.

Examples

Display detailed information about the files and subdirectories under the current directory, including the files and subdirectories with names starting with dots (.).

```
sftp> ls -a
drwxrwxrwx    2 1        1               512 Dec 18 14:12 .
drwxrwxrwx    2 1        1               512 Dec 18 14:12 ..
-rwxrwxrwx    1 1        1               301 Dec 18 14:11 010.pub
-rwxrwxrwx    1 1        1               301 Dec 18 14:12 011.pub
-rwxrwxrwx    1 1        1               301 Dec 18 14:12 012.pub
```

Display detailed information about the files and subdirectories under the current working directory, excluding the files and subdirectories with names starting with dots (.).

```
sftp> ls -l
-rwxrwxrwx    1 1        1               301 Dec 18 14:11 010.pub
-rwxrwxrwx    1 1        1               301 Dec 18 14:12 011.pub
-rwxrwxrwx    1 1        1               301 Dec 18 14:12 012.pub
```

mkdir

Use **mkdir** to create a directory on the SFTP server.

Syntax

mkdir *remote-path*

Views

SFTP client view

Predefined user roles

network-admin

context-admin

Parameters

remote-path: Specifies the name of a directory.

Examples

Create a directory named **test** on the SFTP server.

```
sftp> mkdir test
```

put

Use **put** to upload a local file to the SFTP server.

Syntax

put *local-file* [*remote-file*]

Views

SFTP client view

Predefined user roles

network-admin

context-admin

Parameters

local-file: Specifies the name of a local file.

remote-file: Specifies the name of a file on an SFTP server. If you do not specify this argument, the file will be remotely saved with the same name as the local file.

Examples

Upload the local file **startup.bak** to the SFTP server and save it as **startup01.bak**.

```
sftp> put startup.bak startup01.bak
Uploading startup.bak to /startup01.bak
startup01.bak                                 100% 1424     1.4KB/s   00:00
```

pwd

Use **pwd** to display the current working directory of the SFTP server.

Syntax

pwd

Views

SFTP client view

Predefined user roles

network-admin

context-admin

Examples

Display the current working directory of the SFTP server.

```
sftp> pwd
Remote working directory: /
```

The output shows that the current working directory is the root directory.

quit

Use **quit** to terminate the SFTP connection and return to user view.

Syntax

quit

Views

SFTP client view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command has the same function as the **bye** and **exit** commands.

Examples

Terminate the SFTP connection.

```
sftp> quit
<Sysname>
```

remove

Use **remove** to delete a file from the SFTP server.

Syntax

remove *remote-file*

Views

SFTP client view

Predefined user roles

network-admin

context-admin

Parameters

remote-file: Specifies a file by its name.

Usage guidelines

This command has the same function as the **delete** command.

Examples

Delete file **temp.c** from the SFTP server.

```
sftp> remove temp.c
Removing /temp.c
```

rename

Use **rename** to change the name of a file or directory on the SFTP server.

Syntax

rename *old-name new-name*

Views

SFTP client view

Predefined user roles

network-admin

context-admin

Parameters

oldname: Specifies the name of an existing file or directory.

newname: Specifies a new name for the existing file or directory.

Examples

Change the name of a file on the SFTP server from **temp1.c** to **temp2.c**.

```
sftp> dir
aa.pub  temp1.c
sftp> rename temp1.c temp2.c
sftp> dir
aa.pub  temp2.c
```

rmdir

Use **rmdir** to delete a directory from the SFTP server.

Syntax

rmdir *remote-path*

Views

SFTP client view

Predefined user roles

network-admin

context-admin

Parameters

remote-path: Specifies a directory.

Examples

Delete subdirectory **temp1** under the current directory on the SFTP server.

```
sftp> rmdir temp1
```

scp

Use **scp** to establish a connection to an IPv4 SCP server and transfer files with the server.

Syntax

scp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] { **get** | **put** } *source-file-name* [*destination-file-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [{ **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

server: Specifies a server by its IPv4 address or host name, a case-insensitive string of 1 to 253 characters.

port-number: Specifies the port number of the server, in the range of 1 to 65535. The default is 22.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters.

get: Downloads the file.

put: Uploads the file.

source-file-name: Specifies the name of the source file, a case-sensitive string of 1 to 255 characters.

destination-file-name: Specifies the name of the target file, a case-sensitive string of 1 to 255 characters. If you do not specify this argument, the target file uses the same file name as the source file.

identity-key: Specifies a public key algorithm for publickey authentication of the client. The default is DSA. If the server uses publickey authentication, you must specify this keyword. The client generates the digital signature or certificate by using the local private key that is associated with the specified algorithm.

- **dsa**: Specifies public key algorithm DSA.
- **ecdsa-sha2-nistp256**: Specifies the ECDSA algorithm with 256-bit key strength.
- **ecdsa-sha2-nistp384**: Specifies the ECDSA algorithm with 384-bit key strength.
- **rsa**: Specifies public key algorithm RSA.

- **x509v3-ecdsa-sha2-nistp256**: Specifies public key algorithm x509v3-ecdsa-sha2-nistp256.
- **x509v3-ecdsa-sha2-nistp384**: Specifies public key algorithm x509v3-ecdsa-sha2-nistp384.
- **pki-domain** *domain-name*: Specifies the PKI domain of the client's certificate. The *domain-name* argument is a case-insensitive string of 1 to 31 characters. When the x509v3 public key algorithm is used, you must specify this option for the client to get the correct local certificate.

prefer-compress: Specifies the preferred compression algorithm for data compression between the server and the client. By default, compression is not supported.

zlib: Specifies compression algorithm zlib.

prefer-ctos-cipher: Specifies the preferred client-to-server encryption algorithm. The default is AES128-CTR. Supported algorithms are DES-CBC, 3DES-CBC, AES128-CBC, AES128-CTR, AES128-GCM, AES192-CTR, AES256-CBC, AES256-CTR, and AES256-GCM, in ascending order of security strength and computation time.

- **3des-cbc**: Specifies encryption algorithm 3DES-CBC.
- **aes128-cbc**: Specifies encryption algorithm AES128-CBC.
- **aes128-ctr**: Specifies encryption algorithm AES128-CTR.
- **aes128-gcm**: Specifies encryption algorithm AES128-GCM.
- **aes192-ctr**: Specifies encryption algorithm AES192-CTR.
- **aes256-cbc**: Specifies encryption algorithm AES256-CBC.
- **aes256-ctr**: Specifies encryption algorithm AES256-CTR.
- **aes256-gcm**: Specifies encryption algorithm AES256-GCM.
- **des-cbc**: Specifies encryption algorithm DES-CBC.

prefer-ctos-hmac: Specifies the preferred client-to-server HMAC algorithm. The default is SHA2-256. Supported algorithms are MD5, MD5-96, SHA1, SHA1-96, SHA2-256, and SHA2-512, in ascending order of security strength and computation time.

- **md5**: Specifies HMAC algorithm HMAC-MD5.
- **md5-96**: Specifies HMAC algorithm HMAC-MD5-96.
- **sha1**: Specifies HMAC algorithm HMAC-SHA1.
- **sha1-96**: Specifies HMAC algorithm HMAC-SHA1-96.
- **sha2-256**: Specifies HMAC algorithm HMAC-SHA2-256.
- **sha2-512**: Specifies HMAC algorithm HMAC-SHA2-512.

prefer-kex: Specifies the preferred key exchange algorithm. The default is ecdh-sha2-nistp256. Supported algorithms are diffie-hellman-group-exchange-sha1, diffie-hellman-group1-sha1, diffie-hellman-group14-sha1, ecdh-sha2-nistp256, and ecdh-sha2-nistp384, in ascending order of security strength and computation time.

- **dh-group-exchange-sha1**: Specifies key exchange algorithm diffie-hellman-group-exchange-sha1.
- **dh-group1-sha1**: Specifies key exchange algorithm diffie-hellman-group1-sha1.
- **dh-group14-sha1**: Specifies key exchange algorithm diffie-hellman-group14-sha1.
- **ecdh-sha2-nistp256**: Specifies key exchange algorithm ecdh-sha2-nistp256.
- **ecdh-sha2-nistp384**: Specifies key exchange algorithm ecdh-sha2-nistp384.

prefer-stoc-cipher: Specifies the preferred server-to-client encryption algorithm. The default is AES128-CTR. Supported algorithms are the same as the client-to-server encryption algorithms (see the **prefer-ctos-cipher** keyword).

prefer-stoc-hmac: Specifies the preferred server-to-client HMAC algorithm. The default is SHA2-256. Supported algorithms are the same as the client-to-server HMAC algorithms (see the **prefer-ctos-hmac** keyword).

public-key *keyname*: Specifies the server's host public key that the client uses to authenticate the server. The *keyname* argument is a case-insensitive string of 1 to 64 characters.

server-pki-domain *domain-name*: Specifies the PKI domain for verifying the server's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

source: Specifies a source IPv4 address or source interface for SCP packets. By default, the device uses the primary IPv4 address of the output interface in the routing entry as the source address of SCP packets. As a best practice to ensure successful SCP connections, specify a loopback interface as the source interface or specify the IPv4 address of a loopback or dialer interface as the source address.

- **interface** *interface-type interface-number*: Specifies a source interface by its type and number. The IPv4 address of this interface is the source IPv4 address of the SCP packets.
- **ip** *ip-address*: Specifies a source IPv4 address.

Usage guidelines

If the client uses certificate authentication, the client must verify the server's certificate. For the client to correctly get the server's certificate, use the **server-pki-domain** *domain-name* option to specify the server's PKI domain on the client. The client uses the CA certificate stored in the specified PKI domain to verify the server's certificate and does not need to save the server's public key before authentication. If you do not specify the server's PKI domain, the client uses the PKI domain of its own certificate to verify the server's certificate.

Examples

Connect the SCP client to SCP server **200.1.1.1**. Specify the public key of the server as **svkey**, and download file **abc.txt** from the server. The SCP client uses publickey authentication. Use the following algorithms:

- Preferred key exchange algorithm: **dh-group14-sha1**.
- Preferred server-to-client encryption algorithm: **aes128-cbc**.
- Preferred client-to-server HMAC algorithm: **sha1**.
- Preferred server-to-client HMAC algorithm: **sha1-96**.
- Preferred compression algorithm: **zlib**.

```
<Sysname> scp 200.1.1.1 get abc.txt prefer-kex dh-group14-sha1 prefer-stoc-cipher
aes128-cbc prefer-ctos-hmac sha1 prefer-stoc-hmac sha1-96 prefer-compress zlib public-key
svkey
Username:
```

scp ipv6

Use **scp ipv6** to establish a connection to an IPv6 SCP server and transfer files with the server.

Syntax

scp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] { **get** | **put** } *source-file-name*

[*destination-file-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [{ **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Parameters

server: Specifies a server by its IPv6 address or host name, a case-insensitive string of 1 to 253 characters.

port-number: Specifies the port number of the server, in the range of 1 to 65535. The default is 22.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters.

-i *interface-type interface-number:* Specifies an output interface by its type and number for SCP packets. This option is used only when the server uses a link-local address to provide the SCP service for the client. The specified output interface on the SCP client must have a link-local address.

get: Downloads the file.

put: Uploads the file.

source-file-name: Specifies the name of the source file, a case-sensitive string of 1 to 255 characters.

destination-file-name: Specifies the name of the target file, a case-sensitive string of 1 to 255 characters. If you do not specify this argument, the target file uses the same file name as the source file.

identity-key: Specifies a public key algorithm for publickey authentication of the client. The default is DSA. If the server uses publickey authentication, you must specify this keyword. The client generates the digital signature or certificate by using the local private key that is associated with the specified algorithm.

- **dsa**: Specifies public key algorithm DSA.
- **ecdsa-sha2-nistp256**: Specifies the ECDSA algorithm with 256-bit key strength.
- **ecdsa-sha2-nistp384**: Specifies the ECDSA algorithm with 384-bit key strength.
- **rsa**: Specifies public key algorithm RSA.
- **x509v3-ecdsa-sha2-nistp256**: Specifies public key algorithm x509v3-ecdsa-sha2-nistp256.

x509v3-ecdsa-sha2-nistp384: Specifies public key algorithm x509v3-ecdsa-sha2-nistp384.

- **pki-domain** *domain-name*: Specifies the PKI domain of the client's certificate. The *domain-name* argument is a case-insensitive string of 1 to 31 characters. When the x509v3 public key algorithm is used, you must specify this option for the client to get the correct local certificate.

prefer-compress: Specifies the preferred compression algorithm for data compression between the server and the client. By default, compression is not supported.

zlib: Specifies compression algorithm zlib.

prefer-ctos-cipher: Specifies the preferred client-to-server encryption algorithm. The default is AES128-CTR. Supported algorithms are DES-CBC, 3DES-CBC, AES128-CBC, AES128-CTR, AES128-GCM, AES192-CTR, AES256-CBC, AES256-CTR, and AES256-GCM, in ascending order of security strength and computation time.

- **3des-cbc**: Specifies encryption algorithm 3DES-CBC.
- **aes128-cbc**: Specifies encryption algorithm AES128-CBC.
- **aes128-ctr**: Specifies encryption algorithm AES128-CTR.
- **aes128-gcm**: Specifies encryption algorithm AES128-GCM.
- **aes192-ctr**: Specifies encryption algorithm AES192-CTR.
- **aes256-cbc**: Specifies encryption algorithm AES256-CBC.
- **aes256-ctr**: Specifies encryption algorithm AES256-CTR.
- **aes256-gcm**: Specifies encryption algorithm AES256-GCM.
- **des-cbc**: Specifies encryption algorithm DES-CBC.

prefer-ctos-hmac: Specifies the preferred client-to-server HMAC algorithm. The default is SHA2-256. Supported algorithms are MD5, MD5-96, SHA1, SHA1-96, SHA2-256, and SHA2-512 in ascending order of security strength and computation time.

- **md5**: Specifies HMAC algorithm HMAC-MD5.
- **md5-96**: Specifies HMAC algorithm HMAC-MD5-96.
- **sha1**: Specifies HMAC algorithm HMAC-SHA1.
- **sha1-96**: Specifies HMAC algorithm HMAC-SHA1-96.
- **sha2-256**: Specifies HMAC algorithm HMAC-SHA2-256.
- **sha2-512**: Specifies HMAC algorithm HMAC-SHA2-512.

prefer-kex: Specifies the preferred key exchange algorithm. The default is ecdh-sha2-nistp256. Supported algorithms are diffie-hellman-group-exchange-sha1, diffie-hellman-group1-sha1, diffie-hellman-group14-sha1, ecdh-sha2-nistp256, and ecdh-sha2-nistp384, in ascending order of security strength and computation time.

- **dh-group-exchange-sha1**: Specifies key exchange algorithm diffie-hellman-group-exchange-sha1.
- **dh-group1-sha1**: Specifies key exchange algorithm diffie-hellman-group1-sha1.
- **dh-group14-sha1**: Specifies key exchange algorithm diffie-hellman-group14-sha1.
- **ecdh-sha2-nistp256**: Specifies key exchange algorithm ecdh-sha2-nistp256.
- **ecdh-sha2-nistp384**: Specifies key exchange algorithm ecdh-sha2-nistp384.

prefer-stoc-cipher: Specifies the preferred server-to-client encryption algorithm. The default is AES128-CTR. Supported algorithms are the same as the client-to-server encryption algorithms (see the **prefer-ctos-cipher** keyword).

prefer-stoc-hmac: Specifies the preferred server-to-client HMAC algorithm. The default is SHA2-256. Supported algorithms are the same as the client-to-server HMAC algorithms (see the **prefer-ctos-hmac** keyword).

public-key *keyname*: Specifies the server's host public key that the client uses to authenticate the server. The *keyname* argument is a case-insensitive string of 1 to 64 characters.

server-pki-domain *domain-name*: Specifies the PKI domain for verifying the server's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

source: Specifies a source IPv6 address or source interface for IPv6 SCP packets. By default, the device automatically selects a source address for IPv6 SCP packets in compliance with RFC 3484. As a best practice to ensure successful SCP connections, specify a loopback interface as the source interface or specify the IPv6 address of a loopback or dialer interface as the source address.

- **interface** *interface-type interface-number*: Specifies a source interface by its type and number. The IPv6 address of this interface is the source IPv6 address of the IPv6 SCP packets.
- **ipv6** *ipv6-address*: Specifies a source IPv6 address.

Usage guidelines

If the client uses certificate authentication, the client must verify the server's certificate. For the client to correctly get the server's certificate, use the **server-pki-domain** *domain-name* option to specify the server's PKI domain on the client. The client uses the CA certificate stored in the specified PKI domain to verify the server's certificate and does not need to save the server's public key before authentication. If you do not specify the server's PKI domain, the client uses the PKI domain of its own certificate to verify the server's certificate.

Examples

Connect an SCP client to SCP server **2000::1**. Specify the public key of the server as **svkey**, and download file **abc.txt** from the server. The SCP client uses publickey authentication. Use the following algorithms:

- Preferred key exchange algorithm: **dh-group14-sha1**.
- Preferred server-to-client encryption algorithm: **aes128-cbc**.
- Preferred client-to-server HMAC algorithm: **sha1**.
- Preferred server-to-client HMAC algorithm: **sha1-96**.
- Preferred compression algorithm: **zlib**.

```
<Sysname> scp ipv6 2000::1 get abc.txt prefer-kex dh-group14-sha1 prefer-stoc-cipher
aes128-cbc prefer-ctos-hmac sha1 prefer-stoc-hmac sha1-96 prefer-compress zlib public-key
svkey
Username:
```

scp ipv6 suite-b

Use **scp ipv6 suite-b** to establish a connection to an IPv6 SCP server based on Suite B algorithms and transfer files with the server.

Syntax

scp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] { **get** | **put** } *source-file-name* [*destination-file-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }]

Parameters

server: Specifies a server by its IPv6 address or host name, a case-insensitive string of 1 to 253 characters.

port-number: Specifies the port number of the server, in the range of 1 to 65535. The default is 22.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters.

-i *interface-type interface-number:* Specifies an output interface by its type and number for SCP packets. Specify this option when the server uses a link-local address to provide the SCP service for the client. The specified output interface on the SCP client must have a link-local address.

get: Downloads the file.

put: Uploads the file.

source-file-name: Specifies the name of the source file, a case-sensitive string of 1 to 255 characters.

destination-file-name: Specifies the name of the target file, a case-sensitive string of 1 to 255 characters. If you do not specify this argument, the target file uses the same file name as the source file.

suite-b: Specifies the Suite B algorithms. If neither the 128-bit keyword nor the 192-bit keyword is specified, all algorithms in Suite B are used. For more information about the Suite B algorithms, see Table 4.

128-bit: Specifies the 128-bit Suite B security level.

192-bit: Specifies the 192-bit Suite B security level.

pki-domain *domain-name*: Specifies the PKI domain of the client's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

server-pki-domain *domain-name*: Specifies the PKI domain for verifying the server's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes ('). If you do not specify the server's PKI domain, the client uses the PKI domain of its own certificate to verify the server's certificate.

prefer-compress: Specifies the preferred compression algorithm for data compression between the server and the client. By default, compression is not supported.

zlib: Specifies compression algorithm zlib.

source: Specifies a source IPv6 address or source interface for IPv6 SCP packets. By default, the device automatically selects a source address for IPv6 SCP packets in compliance with RFC 3484. As a best practice to ensure successful SCP connections, specify a loopback interface as the source interface or specify the IPv6 address of a loopback or dialer interface as the source address.

- **interface** *interface-type interface-number*: Specifies a source interface by its type and number. The IPv6 address of this interface is the source IPv6 address of the IPv6 SCP packets.
- **ipv6** *ipv6-address*: Specifies a source IPv6 address.

Usage guidelines

Table 4 Suite B algorithms

Security level	Key exchange algorithm	Encryption algorithm and HMAC algorithm	Public key algorithm
128-bit	ecdh-sha2-nistp256	AES128-GCM	x509v3-ecdsa-sha2-nistp256
192-bit	ecdh-sha2-nistp384	AES256-GCM	x509v3-ecdsa-sha2-nistp384
Both	ecdh-sha2-nistp256 ecdh-sha2-nistp384	AES128-GCM AES256-GCM	x509v3-ecdsa-sha2-nistp256 x509v3-ecdsa-sha2-nistp384

Examples

Use the 192-bit Suite B algorithms to establish a connection to SCP server **2000::1** and download the file **abc.txt** from the server. Specify the client's PKI domain and the server's PKI domain as **clientpkidomain** and **serverpkidomain**, respectively.

```
<Sysname> scp ipv6 2000::1 get abc.txt suite-b 192-bit pki-domain clientpkidomain
server-pki-domain serverpkidomain
Username:
```

scp suite-b

Use **scp suite-b** to establish a connection to an SCP server based on Suite B algorithms and transfer files with the server.

Syntax

scp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] { **get** | **put** } *source-file-name* [*destination-file-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**source** { **interface** *interface-type interface-number* | **ip** *ip-address* }]

Parameters

server: Specifies a server by its IPv4 address or host name, a case-insensitive string of 1 to 253 characters.

port-number: Specifies the port number of the server, in the range of 1 to 65535. The default is 22.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters.

get: Downloads the file.

put: Uploads the file.

source-file-name: Specifies the name of the source file, a case-sensitive string of 1 to 255 characters.

destination-file-name: Specifies the name of the target file, a case-sensitive string of 1 to 255 characters. If you do not specify this argument, the target file uses the same file name as the source file.

suite-b: Specifies the Suite B algorithms. If neither the 128-bit keyword nor the 192-bit keyword is specified, all algorithms in Suite B are used. For more information about the Suite B algorithms, see Table 5.

128-bit: Specifies the 128-bit Suite B security level.

192-bit: Specifies the 192-bit Suite B security level.

pki-domain *domain-name*: Specifies the PKI domain of the client's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

server-pki-domain *domain-name*: Specifies the PKI domain for verifying the server's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes ('). If you do not specify the server's PKI domain, the client uses the PKI domain of its own certificate to verify the server's certificate.

prefer-compress: Specifies the preferred compression algorithm for data compression between the server and the client. By default, compression is not supported.

zlib: Specifies compression algorithm zlib.

source: Specifies a source IP address or source interface for SCP packets. By default, the device uses the primary IPv4 address of the output interface in the routing entry as the source address of SCP packets. As a best practice to ensure successful SCP connections, specify a loopback interface as the source interface or specify the IPv4 address of a loopback or dialer interface as the source address.

- **interface** *interface-type interface-number*: Specifies a source interface by its type and number. The IPv4 address of this interface is the source IPv4 address of the SCP packets.
- **ip** *ip-address*: Specifies a source IPv4 address.

Usage guidelines

Table 5 Suite B algorithms

Security level	Key exchange algorithm	Encryption algorithm and HMAC algorithm	Public key algorithm
128-bit	ecdh-sha2-nistp256	AES128-GCM	x509v3-ecdsa-sha2-nistp256
192-bit	ecdh-sha2-nistp384	AES256-GCM	x509v3-ecdsa-sha2-nistp384
Both	ecdh-sha2-nistp256 ecdh-sha2-nistp384	AES128-GCM AES256-GCM	x509v3-ecdsa-sha2-nistp256 x509v3-ecdsa-sha2-nistp384

Examples

Use the 128-bit Suite B algorithms to establish a connection to SCP server **200.1.1.1** and download the file **abc.txt** from the server. Specify the client's PKI domain and the server's PKI domain as **clientpkidomain** and **serverpkidomain**, respectively.

```
<Sysname> scp 200.1.1.1 get abc.txt suite-b 128-bit pki-domain clientpkidomain
server-pki-domain serverpkidomain
Username
```

sftp

Use **sftp** to establish a connection to an IPv4 SFTP server and enter SFTP client view.

Syntax

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

Parameters

server: Specifies a server by its IPv4 address or host name, a case-insensitive string of 1 to 253 characters.

port-number: Specifies the port number of the server, in the range of 1 to 65535. The default is 22.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters.

identity-key: Specifies a public key algorithm for publickey authentication of the client. The default is DSA. If the server uses publickey authentication, you must specify this keyword. The client generates the digital signature or certificate by using the local private key that is associated with the specified algorithm.

- **dsa**: Specifies public key algorithm DSA.
- **ecdsa-sha2-nistp256**: Specifies the ECDSA algorithm with 256-bit key strength.
- **ecdsa-sha2-nistp384**: Specifies the ECDSA algorithm with 384-bit key strength.
- **rsa**: Specifies public key algorithm RSA.
- **x509v3-ecdsa-sha2-nistp256**: Specifies public key algorithm x509v3-ecdsa-sha2-nistp256.
- **x509v3-ecdsa-sha2-nistp384**: Specifies public key algorithm x509v3-ecdsa-sha2-nistp384.

- **pki-domain** *domain-name*: Specifies the PKI domain of the client's certificate. The *domain-name* argument is a case-insensitive string of 1 to 31 characters. When the x509v3 public key algorithm is used, you must specify this option for the client to get the correct local certificate.

prefer-compress: Specifies the preferred compression algorithm for data compression between the server and the client. By default, compression is not supported.

zlib: Specifies compression algorithm zlib.

prefer-ctos-cipher: Specifies the preferred client-to-server encryption algorithm. The default is AES128-CTR. Supported algorithms are DES-CBC, 3DES-CBC, AES128-CBC, AES128-CTR, AES128-GCM, AES192-CTR, AES256-CBC, AES256-CTR, and AES256-GCM, in ascending order of security strength and computation time.

- **3des-cbc**: Specifies encryption algorithm 3DES-CBC.
- **aes128-cbc**: Specifies encryption algorithm AES128-CBC.
- **aes128-ctr**: Specifies encryption algorithm AES128-CTR.
- **aes128-gcm**: Specifies encryption algorithm AES128-GCM.
- **aes192-ctr**: Specifies encryption algorithm AES192-CTR.
- **aes256-cbc**: Specifies encryption algorithm AES256-CBC.
- **aes256-ctr**: Specifies encryption algorithm AES256-CTR.
- **aes256-gcm**: Specifies encryption algorithm AES256-GCM.
- **des-cbc**: Specifies encryption algorithm DES-CBC.

prefer-ctos-hmac: Specifies the preferred client-to-server HMAC algorithm. The default is SHA2-256. Supported algorithms are MD5, MD5-96, SHA1, SHA1-96, SHA2-256, and SHA2-512 in ascending order of security strength and computation time.

- **md5**: Specifies HMAC algorithm HMAC-MD5.
- **md5-96**: Specifies HMAC algorithm HMAC-MD5-96.
- **sha1**: Specifies HMAC algorithm HMAC-SHA1.
- **sha1-96**: Specifies HMAC algorithm HMAC-SHA1-96.
- **sha2-256**: Specifies HMAC algorithm HMAC-SHA2-256.
- **sha2-512**: Specifies HMAC algorithm HMAC-SHA2-512.

prefer-kex: Specifies the preferred key exchange algorithm. The default is ecdh-sha2-nistp256. Supported algorithms are diffie-hellman-group-exchange-sha1, diffie-hellman-group1-sha1, diffie-hellman-group14-sha1, ecdh-sha2-nistp256, and ecdh-sha2-nistp384, in ascending order of security strength and computation time.

- **dh-group-exchange-sha1**: Specifies key exchange algorithm diffie-hellman-group-exchange-sha1.
- **dh-group1-sha1**: Specifies key exchange algorithm diffie-hellman-group1-sha1.
- **dh-group14-sha1**: Specifies key exchange algorithm diffie-hellman-group14-sha1.
- **ecdh-sha2-nistp256**: Specifies key exchange algorithm ecdh-sha2-nistp256.
- **ecdh-sha2-nistp384**: Specifies key exchange algorithm ecdh-sha2-nistp384.

prefer-stoc-cipher: Specifies the preferred server-to-client encryption algorithm. The default is AES128-CTR. Supported algorithms are the same as the client-to-server encryption algorithms (see the **prefer-ctos-cipher** keyword).

prefer-stoc-hmac: Specifies the preferred server-to-client HMAC algorithm. The default is SHA2-256. Supported algorithms are the same as the client-to-server HMAC algorithms (see the **prefer-ctos-hmac** keyword).

dscp *dscp-value*: Specifies the DSCP value in the IPv4 SFTP packets. The value range for the *dscp-value* argument is 0 to 63, and the default value is 48. The DSCP value determines the transmission priority of the packet.

public-key *keyname*: Specifies the server's host public key that the client uses to authenticate the server. The *keyname* argument is a case-insensitive string of 1 to 64 characters.

server-pki-domain *domain-name*: Specifies the PKI domain for verifying the server's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

source: Specifies a source IPv4 address or source interface for the SFTP packets. By default, the device uses the primary IPv4 address of the output interface in the routing entry as the source address of SFTP packets. As a best practice to ensure successful SFTP connections, specify a loopback interface as the source interface or specify the IPv4 address of a loopback or dialer interface as the source address.

- **interface** *interface-type interface-number*: Specifies a source interface by its type and number. The primary IPv4 address of this interface is the source IPv4 address of the SFTP packets.
- **ip** *ip-address*: Specifies a source IPv4 address.

Usage guidelines

If the client uses certificate authentication, the client must verify the server's certificate. For the client to correctly get the server's certificate, use the **server-pki-domain** *domain-name* option to specify the server's PKI domain on the client. The client uses the CA certificate stored in the specified PKI domain to verify the server's certificate and does not need to save the server's public key before authentication. If you do not specify the server's PKI domain, the client uses the PKI domain of its own certificate to verify the server's certificate.

Examples

Connect an SFTP client to SFTP server **10.1.1.2** and specify the public key of the server as **svkey**. The SFTP client uses publickey authentication. Use the following algorithms:

- Preferred key exchange algorithm: **dh-group14-sha1**.
- Preferred server-to-client encryption algorithm: **aes128-cbc**.
- Preferred client-to-server HMAC algorithm: **sha1**.
- Preferred server-to-client HMAC algorithm: **sha1-96**.
- Preferred compression algorithm: **zlib**.

```
<Sysname> sftp 10.1.1.2 prefer-kex dh-group14-sha1 prefer-stoc-cipher aes128-cbc
prefer-ctos-hmac sha1 prefer-stoc-hmac sha1-96 prefer-compress zlib public-key svkey
```

sftp client ipv6 source

Use **sftp client ipv6 source** to configure the source IPv6 address for SFTP packets that are sent by the SFTP client.

Use **undo sftp client ipv6 source** to restore the default.

Syntax

sftp client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

undo sftp client ipv6 source

Default

The source IPv6 address for outgoing SFTP packets is not configured. The SFTP client automatically selects an IPv6 address for outgoing SFTP packets in compliance with RFC 3484.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies a source interface by its type and number. The SFTP client selects the interface's address that most specifically matches the destination address of outgoing SFTP packets as the source address of the SFTP packets.

ipv6 *ipv6-address*: Specifies a source IPv6 address.

Usage guidelines

This command takes effect on all IPv6 SFTP connections. The source IPv6 address specified in the **sftp ipv6** command takes effect only on the current IPv6 SFTP connection. If you specify the source IPv6 address both in this command and the **sftp ipv6** command, the source IPv6 address specified in the **sftp ipv6** command takes effect.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify **2:2::2:2** as the source IPv6 address for SFTP packets.

```
<Sysname> system-view
[Sysname] sftp client ipv6 source ipv6 2:2::2:2
```

Related commands

display sftp client source

sftp client source

Use **sftp client source** to configure the source IPv4 address for SFTP packets that are sent by the SFTP client.

Use **undo sftp client source** to restore the default.

Syntax

sftp client source { **interface** *interface-type interface-number* | **ip** *ip-address* }

undo sftp client source

Default

The source IPv4 address for outgoing SFTP packets is not configured. The SFTP client uses the primary IPv4 address of the output interface in the matching route as the source IPv4 address of outgoing SFTP packets.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies a source interface by its type and number. The SFTP client uses the primary IPv4 address of the interface as the source address of outgoing SFTP packets.

ip *ip-address*: Specifies a source IPv4 address.

Usage guidelines

This command takes effect on all SFTP connections. The source IPv4 address specified in the **sftp** command takes effect only on the current SFTP connection. If you specify the source IPv4 address both in this command and the **sftp** command, the source IPv4 address specified in the **sftp** command takes effect.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify **192.168.0.1** as the source IPv4 address for SFTP packets.

```
<Sysname> system-view
[Sysname] sftp client source ip 192.168.0.1
```

Related commands

display sftp client source

sftp ipv6

Use **sftp ipv6** to connect an SFTP client to an IPv6 SFTP server and enter SFTP client view.

Syntax

sftp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Parameters

server: Specifies a server by its IPv6 address or host name, a case-insensitive string of 1 to 253 characters.

port-number: Specifies the port number of the server, in the range of 1 to 65535. The default is 22.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters.

-i *interface-type interface-number:* Specifies an output interface by its type and number for IPv6 SFTP packets. This option is used only when the server uses a link-local address to provide the SFTP service for the client. The specified output interface on the SFTP client must have a link-local address.

identity-key: Specifies a public key algorithm for publickey authentication of the client. The default is DSA. If the server uses publickey authentication, you must specify this keyword. The client generates the digital signature or certificate by using the local private key that is associated with the specified algorithm.

- **dsa**: Specifies public key algorithm DSA.
- **ecdsa-sha2-nistp256**: Specifies the ECDSA algorithm with 256-bit key strength.
- **ecdsa-sha2-nistp384**: Specifies the ECDSA algorithm with 384-bit key strength.
- **rsa**: Specifies public key algorithm RSA.
- **x509v3-ecdsa-sha2-nistp256**: Specifies public key algorithm x509v3-ecdsa-sha2-nistp256.
- **x509v3-ecdsa-sha2-nistp384**: Specifies public key algorithm x509v3-ecdsa-sha2-nistp384.
- **pki-domain** *domain-name*: Specifies the PKI domain of the client's certificate. The *domain-name* argument is a case-insensitive string of 1 to 31 characters. When the x509v3 public key algorithm is used, you must specify this option for the client to get the correct local certificate.

prefer-compress: Specifies the preferred compression algorithm for data compression between the server and the client. By default, compression is not supported.

zlib: Specifies compression algorithm zlib.

prefer-ctos-cipher: Specifies the preferred client-to-server encryption algorithm. The default is AES128-CTR. Supported algorithms are DES-CBC, 3DES-CBC, AES128-CBC, AES128-CTR, AES128-GCM, AES192-CTR, AES256-CBC, AES256-CTR, and AES256-GCM, in ascending order of security strength and computation time.

- **3des-cbc**: Specifies encryption algorithm 3DES-CBC.
- **aes128-cbc**: Specifies encryption algorithm AES128-CBC.
- **aes128-ctr**: Specifies encryption algorithm AES128-CTR.
- **aes128-gcm**: Specifies encryption algorithm AES128-GCM.
- **aes192-ctr**: Specifies encryption algorithm AES192-CTR.
- **aes256-cbc**: Specifies encryption algorithm AES256-CBC.
- **aes256-ctr**: Specifies encryption algorithm AES256-CTR.
- **aes256-gcm**: Specifies encryption algorithm AES256-GCM.
- **des-cbc**: Specifies encryption algorithm DES-CBC.

prefer-ctos-hmac: Specifies the preferred client-to-server HMAC algorithm. The default is SHA2-256. Supported algorithms are MD5, MD5-96, SHA1, SHA1-96, SHA2-256, and SHA2-512 in ascending order of security strength and computation time.

- **md5**: Specifies HMAC algorithm HMAC-MD5.
- **md5-96**: Specifies HMAC algorithm HMAC-MD5-96.
- **sha1**: Specifies HMAC algorithm HMAC-SHA1.
- **sha1-96**: Specifies HMAC algorithm HMAC-SHA1-96.
- **sha2-256**: Specifies HMAC algorithm HMAC-SHA2-256.
- **sha2-512**: Specifies HMAC algorithm HMAC-SHA2-512.

prefer-kex: Specifies the preferred key exchange algorithm. The default is ecdh-sha2-nistp256. Supported algorithms are diffie-hellman-group-exchange-sha1, diffie-hellman-group1-sha1, diffie-hellman-group14-sha1, ecdh-sha2-nistp256, and ecdh-sha2-nistp384, in ascending order of security strength and computation time.

- **dh-group-exchange-sha1**: Specifies key exchange algorithm diffie-hellman-group-exchange-sha1.
- **dh-group1-sha1**: Specifies key exchange algorithm diffie-hellman-group1-sha1.
- **dh-group14-sha1**: Specifies key exchange algorithm diffie-hellman-group14-sha1.
- **ecdh-sha2-nistp256**: Specifies key exchange algorithm ecdh-sha2-nistp256.
- **ecdh-sha2-nistp384**: Specifies key exchange algorithm ecdh-sha2-nistp384.

prefer-stoc-cipher: Specifies the preferred server-to-client encryption algorithm. The default is AES128-CTR. Supported algorithms are the same as the client-to-server encryption algorithms (see the **prefer-ctos-cipher** keyword).

prefer-stoc-hmac: Specifies the preferred server-to-client HMAC algorithm. The default is SHA2-256. Supported algorithms are the same as the client-to-server HMAC algorithms (see the **prefer-ctos-hmac** keyword).

dscp *dscp-value*: Specifies the DSCP value in the IPv6 SFTP packets. The value range for the *dscp-value* argument is 0 to 63, and the default value is 48. The DSCP value determines the transmission priority of the packet.

public-key *keyname*: Specifies the host public key of the server that the client uses to authenticate the server. The *keyname* argument is a case-insensitive string of 1 to 64 characters.

server-pki-domain *domain-name*: Specifies the PKI domain for verifying the server's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

source: Specifies a source IPv6 address or source interface for IPv6 SFTP packets. By default, the device automatically selects a source address for IPv6 SFTP packets in compliance with RFC 3484. As a best practice to ensure successful SFTP connections, specify a loopback interface as the source interface or specify the IPv6 address of a loopback or dialer interface as the source address.

- **interface** *interface-type interface-number*: Specifies a source interface by its type and number. The IPv6 address of this interface is the source IPv6 address of the IPv6 SFTP packets.
- **ipv6** *ipv6-address*: Specifies a source IPv6 address.

Usage guidelines

If the client uses certificate authentication, the client must verify the server's certificate. For the client to correctly get the server's certificate, use the **server-pki-domain** *domain-name* option to specify the server's PKI domain on the client. The client uses the CA certificate stored in the

specified PKI domain to verify the server's certificate and does not need to save the server's public key before authentication. If you do not specify the server's PKI domain, the client uses the PKI domain of its own certificate to verify the server's certificate.

Examples

Connect an SFTP client to SFTP server **2000::1** and specify the public key of the server as **svkey**. The SFTP client uses publickey authentication. Use the following algorithms:

- Preferred key exchange algorithm: **dh-group14-sha1**.
- Preferred server-to-client encryption algorithm: **aes128-cbc**.
- Preferred client-to-server HMAC algorithm: **sha1**.
- Preferred server-to-client HMAC algorithm: **sha1-96**.
- Preferred compression algorithm: **zlib**.

```
<Sysname> sftp ipv6 2000::1 prefer-kex dh-group14-sha1 prefer-stoc-cipher aes128-cbc
prefer-ctos-hmac sha1 prefer-stoc-hmac sha1-96 prefer-compress zlib public-key svkey
Username:
```

sftp ipv6 suite-b

Use **sftp ipv6 suite-b** to establish a connection to an IPv6 SFTP server based on Suite B algorithms and enter SFTP client view.

Syntax

sftp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Parameters

server: Specifies a server by its IPv6 address or host name, a case-insensitive string of 1 to 253 characters.

port-number: Specifies the port number of the server, in the range of 1 to 65535. The default is 22.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters.

-i *interface-type interface-number:* Specifies an output interface by its type and number for IPv6 SFTP packets. The specified outgoing interface must have a link-local address. This option is used only when the server uses a link-local address to provide the SFTP service for the client.

suite-b: Specifies the Suite B algorithms. If neither the 128-bit keyword nor the 192-bit keyword is specified, all algorithms in Suite B are used. For more information about the Suite B algorithms, see Table 6.

128-bit: Specifies the 128-bit Suite B security level.

192-bit: Specifies the 192-bit Suite B security level.

pki-domain *domain-name*: Specifies the PKI domain of the client's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

server-pki-domain *domain-name*: Specifies the PKI domain for verifying the server's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes ('). If you do not specify the server's PKI domain, the client uses the PKI domain of its own certificate to verify the server's certificate.

prefer-compress: Specifies the preferred compression algorithm for data compression between the server and the client. By default, compression is not supported.

zlib: Specifies compression algorithm zlib.

dscp *dscp-value*: Specifies the DSCP value in the IPv6 SFTP packets. The value range for the *dscp-value* argument is 0 to 63, and the default value is 48. The DSCP value determines the transmission priority of the packet.

source: Specifies a source IP address or source interface for IPv6 SFTP packets. By default, the device automatically selects a source address for IPv6 SFTP packets in compliance with RFC 3484. As a best practice to ensure successful SFTP connections, specify a loopback interface as the source interface or specify the IPv6 address of a loopback or dialer interface as the source address.

- **interface** *interface-type interface-number*: Specifies a source interface by its type and number. The IPv6 address of this interface is the source IP address of the IPv6 SFTP packets.
- **ipv6** *ipv6-address*: Specifies a source IPv6 address.

Usage guidelines

Table 6 Suite B algorithms

Security level	Key exchange algorithm	Encryption algorithm and HMAC algorithm	Public key algorithm
128-bit	ecdh-sha2-nistp256	AES128-GCM	x509v3-ecdsa-sha2-nistp256
192-bit	ecdh-sha2-nistp384	AES256-GCM	x509v3-ecdsa-sha2-nistp384
Both	ecdh-sha2-nistp256 ecdh-sha2-nistp384	AES128-GCM AES256-GCM	x509v3-ecdsa-sha2-nistp256 x509v3-ecdsa-sha2-nistp384

Examples

Use the 192-bit Suite B algorithms to establish a connection to SFTP server **2000::1**. Specify the client's PKI domain and the server's PKI domain as **clientpkidomain** and **serverpkidomain**, respectively.

```
<Sysname> sftp ipv6 2000::1 suite-b 192-bit pki-domain clientpkidomain server-pki-domain
serverpkidomain
Username:
```

sftp suite-b

Use **sftp suite-b** to establish a connection to an IPv4 SFTP server based on Suite B algorithms and enter SFTP client view.

Syntax

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress** **zlib**] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

Parameters

server: Specifies a server by its IPv4 address or host name, a case-insensitive string of 1 to 253 characters.

port-number: Specifies the port number of the server, in the range of 1 to 65535. The default is 22.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters.

suite-b: Specifies the Suite B algorithms. If neither the 128-bit keyword nor the 192-bit keyword is specified, all algorithms in Suite B are used. For more information about the Suite B algorithms, see Table 7.

128-bit: Specifies the 128-bit Suite B security level.

192-bit: Specifies the 192-bit Suite B security level.

pki-domain *domain-name*: Specifies the PKI domain of the client's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

server-pki-domain *domain-name*: Specifies the PKI domain for verifying the server's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes ('). If you do not specify the server's PKI domain, the client uses the PKI domain of its own certificate to verify the server's certificate.

prefer-compress: Specifies the preferred compression algorithm for data compression between the server and the client. By default, compression is not supported.

zlib: Specifies compression algorithm zlib.

dscp *dscp-value*: Specifies the DSCP value in the IPv4 SFTP packets. The value range for the *dscp-value* argument is 0 to 63, and the default value is 48. The DSCP value determines the transmission priority of the packet.

source: Specifies a source IP address or source interface for the SFTP packets. By default, the device uses the primary IPv4 address of the output interface in the routing entry as the source address of SFTP packets. As a best practice to ensure successful SFTP connections, specify a loopback interface as the source interface or specify the IPv4 address of a loopback or dialer interface as the source address.

- **interface** *interface-type interface-number*: Specifies a source interface by its type and number. The primary IPv4 address of this interface is the source IPv4 address of the SFTP packets.

- **ip** *ip-address*: Specifies a source IPv4 address.

Usage guidelines

Table 7 Suite B algorithms

Security level	Key exchange algorithm	Encryption algorithm and HMAC algorithm	Public key algorithm
128-bit	ecdh-sha2-nistp256	AES128-GCM	x509v3-ecdsa-sha2-nistp256
192-bit	ecdh-sha2-nistp384	AES256-GCM	x509v3-ecdsa-sha2-nistp384
Both	ecdh-sha2-nistp256 ecdh-sha2-nistp384	AES128-GCM AES256-GCM	x509v3-ecdsa-sha2-nistp256 x509v3-ecdsa-sha2-nistp384

Examples

Use the 128-bit Suite B algorithms to establish a connection to SFTP server **10.1.1.2**. Specify the client's PKI domain and the server's PKI domain as **clientpkidomain** and **serverpkidomain**, respectively.

```
<Sysname> sftp 10.1.1.2 suite-b 128-bit pki-domain clientpkidomain server-pki-domain
serverpkidomain
Username
```

ssh client ipv6 source

Use **ssh client ipv6 source** to configure the source IPv6 address for SSH packets that are sent by the Stelnet client.

Use **undo ssh client ipv6 source** to restore the default.

Syntax

ssh client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

undo ssh client ipv6 source

Default

The source IPv6 address for outgoing SSH packets is not configured. The Stelnet client automatically selects an IPv6 address for outgoing SSH packets in compliance with RFC 3484.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies a source interface by its type and number. The Stelnet client selects the interface's address that most specifically matches the destination address of outgoing SSH packets as the source address of the SSH packets.

ipv6 *ipv6-address*: Specifies a source IPv6 address.

Usage guidelines

This command takes effect on all IPv6 Stelnet connections. The source IPv6 address specified in the **ssh2 ipv6** command takes effect only on the current IPv6 Stelnet connection. If you specify the

source IPv6 address both in this command and the **ssh2 ipv6** command, the source IPv6 address specified in the **ssh2 ipv6** command takes effect.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify **2:2::2:2** as the source IPv6 address for SSH packets that are sent by the Stelnet client.

```
<Sysname> system-view
[Sysname] ssh client ipv6 source ipv6 2:2::2:2
```

Related commands

display ssh client source

ssh client source

Use **ssh client source** to configure the source IPv4 address for SSH packets that are sent by the Stelnet client.

Use **undo ssh client source** to restore the default.

Syntax

ssh client source { **interface** *interface-type interface-number* | **ip** *ip-address* }

undo ssh client source

Default

The source IPv4 address for outgoing SSH packets is not configured. The Stelnet client uses the primary IPv4 address of the output interface in the matching route as the source address of outgoing SSH packets.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies a source interface by its type and number. The Stelnet client uses the primary IPv4 address of the interface as the source address of outgoing SSH packets.

ip *ip-address*: Specifies a source IPv4 address.

Usage guidelines

This command takes effect on all Stelnet connections. The source IPv4 address specified in the **ssh2** command takes effect only on the current Stelnet connection. If you specify the source IPv4 address both in this command and the **ssh2** command, the source IPv4 address specified in the **ssh2** command takes effect.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify **192.168.0.1** as the source IPv4 address for SSH packets.

```
<Sysname> system-view
[Sysname] ssh client source ip 192.168.0.1
```

Related commands

display ssh client source

ssh2

Use **ssh2** to establish a connection to an IPv4 Stelnet server.

Syntax

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

context-admin

Parameters

server: Specifies a server by its IPv4 address or host name, a case-insensitive string of 1 to 253 characters.

port-number: Specifies the port number of the server, in the range 1 to 65535. The default is 22.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters.

identity-key: Specifies a public key algorithm for publickey authentication of the client. The default is DSA. If the server uses publickey authentication, you must specify this keyword. The client generates the digital signature or certificate by using the local private key that is associated with the specified algorithm.

- **dsa**: Specifies public key algorithm DSA.
- **ecdsa-sha2-nistp256**: Specifies the ECDSA algorithm with 256-bit key strength.
- **ecdsa-sha2-nistp384**: Specifies the ECDSA algorithm with 384-bit key strength.
- **rsa**: Specifies public key algorithm RSA.
- **x509v3-ecdsa-sha2-nistp256**: Specifies public key algorithm x509v3-ecdsa-sha2-nistp256.
- **x509v3-ecdsa-sha2-nistp384**: Specifies public key algorithm x509v3-ecdsa-sha2-nistp384.

- **pki-domain** *domain-name*: Specifies the PKI domain of the client's certificate. The *domain-name* argument is a case-insensitive string of 1 to 31 characters. When the x509v3 public key algorithm is used, you must specify this option for the client to get the correct local certificate.

prefer-compress: Specifies the preferred compression algorithm for data compression between the server and the client. By default, compression is not supported.

zlib: Specifies compression algorithm zlib.

prefer-ctos-cipher: Specifies the preferred client-to-server encryption algorithm. The default is AES128-CTR. Supported algorithms are DES-CBC, 3DES-CBC, AES128-CBC, AES128-CTR, AES128-GCM, AES192-CTR, AES256-CBC, AES256-CTR, and AES256-GCM, in ascending order of security strength and computation time.

- **3des-cbc**: Specifies encryption algorithm 3DES-CBC.
- **aes128-cbc**: Specifies encryption algorithm AES128-CBC.
- **aes128-ctr**: Specifies encryption algorithm AES128-CTR.
- **aes128-gcm**: Specifies encryption algorithm AES128-GCM.
- **aes192-ctr**: Specifies encryption algorithm AES192-CTR.
- **aes256-cbc**: Specifies encryption algorithm AES256-CBC.
- **aes256-ctr**: Specifies encryption algorithm AES256-CTR.
- **aes256-gcm**: Specifies encryption algorithm AES256-GCM.
- **des-cbc**: Specifies encryption algorithm DES-CBC.

prefer-ctos-hmac: Specifies the preferred client-to-server HMAC algorithm. The default is SHA2-256. Supported algorithms are MD5, MD5-96, SHA1, SHA1-96, SHA2-256, and SHA2-512 in ascending order of security strength and computation time.

- **md5**: Specifies HMAC algorithm HMAC-MD5.
- **md5-96**: Specifies HMAC algorithm HMAC-MD5-96.
- **sha1**: Specifies HMAC algorithm HMAC-SHA1.
- **sha1-96**: Specifies HMAC algorithm HMAC-SHA1-96.
- **sha2-256**: Specifies HMAC algorithm HMAC-SHA2-256.
- **sha2-512**: Specifies HMAC algorithm HMAC-SHA2-512.

prefer-kex: Specifies the preferred key exchange algorithm. The default is ecdh-sha2-nistp256. Supported algorithms are diffie-hellman-group-exchange-sha1, diffie-hellman-group1-sha1, diffie-hellman-group14-sha1, ecdh-sha2-nistp256, and ecdh-sha2-nistp384, in ascending order of security strength and computation time.

- **dh-group-exchange-sha1**: Specifies key exchange algorithm diffie-hellman-group-exchange-sha1.
- **dh-group1-sha1**: Specifies key exchange algorithm diffie-hellman-group1-sha1.
- **dh-group14-sha1**: Specifies key exchange algorithm diffie-hellman-group14-sha1.
- **ecdh-sha2-nistp256**: Specifies key exchange algorithm ecdh-sha2-nistp256.
- **ecdh-sha2-nistp384**: Specifies key exchange algorithm ecdh-sha2-nistp384.

prefer-stoc-cipher: Specifies the preferred server-to-client encryption algorithm. The default is AES128-CTR. Supported algorithms are the same as the client-to-server encryption algorithms (see the **prefer-ctos-cipher** keyword).

prefer-stoc-hmac: Specifies the preferred server-to-client HMAC algorithm. The default is SHA2-256. Supported algorithms are the same as the client-to-server HMAC algorithms (see the **prefer-ctos-hmac** keyword).

dscp *dscp-value*: Specifies the DSCP value in the IPv4 SSH packets. The value range for the *dscp-value* argument is 0 to 63, and the default value is 48. The DSCP value determines the transmission priority of the packet.

escape *character*: Specifies a case-sensitive escape character. By default, the escape character is a tilde (~).

public-key *keyname*: Specifies the host public key of the server that the client uses to authenticate the server. The *keyname* argument is a case-insensitive string of 1 to 64 characters.

server-pki-domain *domain-name*: Specifies the PKI domain for verifying the server's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

source: Specifies a source IPv4 address or source interface for SSH packets. By default, the device uses the primary IPv4 address of the output interface in the routing entry as the source address of SSH packets. As a best practice to ensure successful Stelnet connections, specify a loopback interface as the source interface or specify the IPv4 address of a loopback or dialer interface as the source address.

- **interface** *interface-type interface-number*: Specifies a source interface by its type and number. The primary IPv4 address of this interface is the source IPv4 address of the SSH packets.
- **ip** *ip-address*: Specifies a source IPv4 address.

Usage guidelines

The combination of an escape character and a dot (.) works as an escape sequence. This escape sequence is typically used to quickly terminate an SSH connection when the server reboots or malfunctions.

For the escape sequence to take effect, you must enter it at the very beginning of a line. If you have entered other characters or performed operations in a line, enter the escape sequence in the next line.

As a best practice, use the default escape character (~). Do not use any character in SSH usernames as the escape character.

If the client uses certificate authentication, the client must verify the server's certificate. For the client to correctly get the server's certificate, use the **server-pki-domain** *domain-name* option to specify the server's PKI domain on the client. The client uses the CA certificate stored in the specified PKI domain to verify the server's certificate and does not need to save the server's public key before authentication. If you do not specify the server's PKI domain, the client uses the PKI domain of its own certificate to verify the server's certificate.

Examples

Establish a connection to Stelnet server **3.3.3.3** and specify the public key of the server as **svkey**. The Stelnet client uses publickey authentication. Specify the dollar sign ($) as the escape character. Use the following algorithms:

- Preferred key exchange algorithm: **dh-group14-sha1**.
- Preferred server-to-client encryption algorithm: **aes128-cbc**.
- Preferred client-to-server HMAC algorithm: **sha1**.
- Preferred server-to-client HMAC algorithm: **sha1-96**.
- Preferred compression algorithm: **zlib**.

```
<Sysname> ssh2 3.3.3.3 prefer-kex dh-group14-sha1 prefer-stoc-cipher aes128-cbc
prefer-ctos-hmac sha1 prefer-stoc-hmac sha1-96 prefer-compress zlib public-key svkey
escape $
```

ssh2 ipv6

Use **ssh2 ipv6** to establish a connection to an IPv6 Stelnet server.

Syntax

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Parameters

server: Specifies a server by its IPv6 address or host name, a case-insensitive string of 1 to 253 characters.

port-number: Specifies the port number of the server, in the range 1 to 65535. The default is 22.

vpn-instance *vpn-instance-name:* Specifies the MPLS L3VPN instance to which the server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters.

-i *interface-type interface-number:* Specifies an output interface by its type and number for IPv6 SSH packets. This option is used only when the server uses a link-local address to provide the Stelnet service for the client. The specified output interface on the Stelnet client must have a link-local address.

identity-key: Specifies a public key algorithm for publickey authentication of the client. The default is DSA. If the server uses publickey authentication, you must specify this keyword. The client generates the digital signature or certificate by using the local private key that is associated with the specified algorithm.

- **dsa**: Specifies public key algorithm DSA.
- **ecdsa-sha2-nistp256**: Specifies the ECDSA algorithm with 256-bit key strength.
- **ecdsa-sha2-nistp384**: Specifies the ECDSA algorithm with 384-bit key strength.
- **rsa**: Specifies public key algorithm RSA.

- **x509v3-ecdsa-sha2-nistp256**: Specifies public key algorithm x509v3-ecdsa-sha2-nistp256.
- **x509v3-ecdsa-sha2-nistp384**: Specifies public key algorithm x509v3-ecdsa-sha2-nistp384.
- **pki-domain** *domain-name*: Specifies the PKI domain of the client's certificate. The *domain-name* argument is a case-insensitive string of 1 to 31 characters. When the x509v3 public key algorithm is used, you must specify this option for the client to get the correct local certificate.

prefer-compress: Specifies the preferred compression algorithm for data compression between the server and the client. By default, compression is not supported.

zlib: Specifies compression algorithm zlib.

prefer-ctos-cipher: Specifies the preferred client-to-server encryption algorithm. The default is AES128-CTR. Supported algorithms are DES-CBC, 3DES-CBC, AES128-CBC, AES128-CTR, AES128-GCM, AES192-CTR, AES256-CBC, AES256-CTR, and AES256-GCM, in ascending order of security strength and computation time.

- **3des-cbc**: Specifies encryption algorithm 3DES-CBC.
- **aes128-cbc**: Specifies encryption algorithm AES128-CBC.
- **aes128-ctr**: Specifies encryption algorithm AES128-CTR.
- **aes128-gcm**: Specifies encryption algorithm AES128-GCM.
- **aes192-ctr**: Specifies encryption algorithm AES192-CTR.
- **aes256-cbc**: Specifies encryption algorithm AES256-CBC.
- **aes256-ctr**: Specifies encryption algorithm AES256-CTR.
- **aes256-gcm**: Specifies encryption algorithm AES256-GCM.
- **des-cbc**: Specifies encryption algorithm DES-CBC.

prefer-ctos-hmac: Specifies the preferred client-to-server HMAC algorithm. The default is SHA2-256. Supported algorithms are MD5, MD5-96, SHA1, SHA1-96, SHA2-256, and SHA2-512 in ascending order of security strength and computation time.

- **md5**: Specifies HMAC algorithm HMAC-MD5.
- **md5-96**: Specifies HMAC algorithm HMAC-MD5-96.
- **sha1**: Specifies HMAC algorithm HMAC-SHA1.
- **sha1-96**: Specifies HMAC algorithm HMAC-SHA1-96.
- **sha2-256**: Specifies HMAC algorithm HMAC-SHA2-256.
- **sha2-512**: Specifies HMAC algorithm HMAC-SHA2-512.

prefer-kex: Specifies the preferred key exchange algorithm. The default is ecdh-sha2-nistp256. Supported algorithms are diffie-hellman-group-exchange-sha1, diffie-hellman-group1-sha1, diffie-hellman-group14-sha1, ecdh-sha2-nistp256, and ecdh-sha2-nistp384, in ascending order of security strength and computation time.

- **dh-group-exchange-sha1**: Specifies key exchange algorithm diffie-hellman-group-exchange-sha1.
- **dh-group1-sha1**: Specifies key exchange algorithm diffie-hellman-group1-sha1.
- **dh-group14-sha1**: Specifies key exchange algorithm diffie-hellman-group14-sha1.
- **ecdh-sha2-nistp256**: Specifies key exchange algorithm ecdh-sha2-nistp256.
- **ecdh-sha2-nistp384**: Specifies key exchange algorithm ecdh-sha2-nistp384.

prefer-stoc-cipher: Specifies the preferred server-to-client encryption algorithm. The default is AES128-CTR. Supported algorithms are the same as the client-to-server encryption algorithms (see the **prefer-ctos-cipher** keyword).

prefer-stoc-hmac: Specifies the preferred server-to-client HMAC algorithm. The default is SHA2-256. Supported algorithms are the same as the client-to-server HMAC algorithms (see the **prefer-ctos-hmac** keyword).

dscp *dscp-value*: Specifies the DSCP value in the IPv6 SSH packets. The value range for the *dscp-value* argument is 0 to 63, and the default value is 48. The DSCP value determines the transmission priority of the packet.

escape *character*: Specifies a case-sensitive escape character. By default, the escape character is a tilde (~).

public-key *keyname*: Specifies the server by its host public key that the client uses to authenticate the server. The *keyname* argument is a case-insensitive string of 1 to 64 characters.

server-pki-domain *domain-name*: Specifies the PKI domain for verifying the server's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

source: Specifies a source IPv6 address or source interface for IPv6 SSH packets. By default, the device automatically selects a source address for IPv6 SSH packets in compliance with RFC 3484. As a best practice to ensure successful Stelnet connections, specify a loopback interface as the source interface or specify the IPv6 address of a loopback or dialer interface as the source address.

- **interface** *interface-type interface-number*: Specifies a source interface by its type and number. The IPv6 address of this interface is the source IPv6 address of the IPv6 SSH packets.
- **ipv6** *ipv6-address*: Specifies a source IPv6 address.

Usage guidelines

The combination of an escape character and a dot (.) works as an escape sequence. This escape sequence is typically used to quickly terminate an SSH connection when the server reboots or malfunctions.

For the escape sequence to take effect, you must enter it at the very beginning of a line. If you have entered other characters or performed operations in a line, enter the escape sequence in the next line.

As a best practice, use the default escape character (~). Do not use any characters in SSH usernames as the escape character.

If the client uses certificate authentication, the client must verify the server's certificate. For the client to correctly get the server's certificate, use the **server-pki-domain** *domain-name* option to specify the server's PKI domain on the client. The client uses the CA certificate stored in the specified PKI domain to verify the server's certificate and does not need to save the server's public key before authentication. If you do not specify the server's PKI domain, the client uses the PKI domain of its own certificate to verify the server's certificate.

Examples

Establish a connection to Stelnet server **2000::1** and specify the public key of the server as **svkey**. The SSH client uses publickey authentication. Specify the dollar sign ($) as the escape character. Use the following algorithms:

- Preferred key exchange algorithm: **dh-group14-sha1**.
- Preferred server-to-client encryption algorithm: **aes128-cbc**.
- Preferred client-to-server HMAC algorithm: **sha1**.
- Preferred server-to-client HMAC algorithm: **sha1-96**.

- Preferred compression algorithm: **zlib**.

```
<Sysname> ssh2 ipv6 2000::1 prefer-kex dh-group14-sha1 prefer-stoc-cipher aes128-cbc
prefer-ctos-hmac sha1 prefer-stoc-hmac sha1-96 prefer-compress zlib public-key svkey
escape $
```

ssh2 ipv6 suite-b

Use **ssh2 ipv6 suite-b** to establish a connection to an IPv6 Stelnet server based on Suite B algorithms.

Syntax

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Parameters

server: Specifies a server by its IPv6 address or host name, a case-insensitive string of 1 to 253 characters.

port-number: Specifies the port number of the server, in the range 1 to 65535. The default is 22.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters.

-i *interface-type interface-number:* Specifies an output interface by its type and number for IPv6 SSH packets. Specify this option when the server uses a link-local address to provide the Stelnet service for the client. The specified output interface on the Stelnet client must have a link-local address.

suite-b: Specifies the Suite B algorithms. If neither the 128-bit keyword nor the 192-bit keyword is specified, all algorithms in Suite B are used. For more information about the Suite B algorithms, see Table 8.

128-bit: Specifies the 128-bit Suite B security level.

192-bit: Specifies the 192-bit Suite B security level.

pki-domain *domain-name*: Specifies the PKI domain of the client's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

server-pki-domain *domain-name*: Specifies the PKI domain for verifying the server's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes ('). If you do not specify the server's PKI domain, the client uses the PKI domain of its own certificate to verify the server's certificate.

prefer-compress: Specifies the preferred compression algorithm for data compression between the server and the client. By default, compression is not supported.

zlib: Specifies compression algorithm zlib.

dscp *dscp-value*: Specifies the DSCP value in the IPv6 SSH packets. The value range for the *dscp-value* argument is 0 to 63, and the default value is 48. The DSCP value determines the transmission priority of the packet.

escape *character*: Specifies a case-sensitive escape character. By default, the escape character is a tilde (~).

source: Specifies a source IP address or source interface for IPv6 SSH packets. By default, the device automatically selects a source address for IPv6 SSH packets in compliance with RFC 3484. As a best practice to ensure successful Stelnet connections, specify a loopback interface as the source interface or specify the IPv6 address of a loopback or dialer interface as the source address.

- **interface** *interface-type interface-number*: Specifies a source interface by its type and number. The IPv6 address of this interface is the source IP address of the IPv6 SSH packets.
- **ipv6** *ipv6-address*: Specifies a source IPv6 address.

Usage guidelines

Table 8 Suite B algorithms

Security level	Key exchange algorithm	Encryption algorithm and HMAC algorithm	Public key algorithm
128-bit	ecdh-sha2-nistp256	AES128-GCM	x509v3-ecdsa-sha2-nistp256
192-bit	ecdh-sha2-nistp384	AES256-GCM	x509v3-ecdsa-sha2-nistp384
Both	ecdh-sha2-nistp256 ecdh-sha2-nistp384	AES128-GCM AES256-GCM	x509v3-ecdsa-sha2-nistp256 x509v3-ecdsa-sha2-nistp384

The combination of an escape character and a dot (.) works as an escape sequence. This escape sequence is typically used to quickly terminate an SSH connection when the server reboots or malfunctions.

For the escape sequence to take effect, you must enter it at the very beginning of a line. If you have entered other characters or performed operations in a line, enter the escape sequence in the next line. As a best practice, use the default escape character (~). Do not use any character in SSH usernames as the escape character.

Examples

Use the 192-bit Suite B algorithms to establish a connection to Stelnet server **2000::1**. Specify the client's PKI domain and the server's PKI domain as **clientpkidomain** and **serverpkidomain**, respectively.

```
<Sysname> ssh2 ipv6 2000::1 suite-b 192-bit pki-domain clientpkidomain server-pki-domain
serverpkidomain
Username
```

ssh2 suite-b

Use **ssh2 suite-b** to establish a connection to an IPv4 Stelnet server based on Suite B algorithms.

Syntax

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress** **zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

Parameters

server: Specifies a server by its IPv4 address or host name, a case-insensitive string of 1 to 253 characters.

port-number: Specifies the port number of the server, in the range 1 to 65535. The default is 22.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the server belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters.

suite-b: Specifies the Suite B algorithms. If neither the 128-bit keyword nor the 192-bit keyword is specified, all algorithms in Suite B are used. For more information about the Suite B algorithms, see Table 9.

128-bit: Specifies the 128-bit Suite B security level.

192-bit: Specifies the 192-bit Suite B security level.

pki-domain *domain-name*: Specifies the PKI domain of the client's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes (').

server-pki-domain *domain-name*: Specifies the PKI domain for verifying the server's certificate. The *domain-name* argument represents the PKI domain name, a case-insensitive string of 1 to 31 characters. Invalid characters are tildes (~), asterisks (*), backslashes (\), vertical bars (|), colons (:), dots (.), angle brackets (< >), quotation marks ("), and apostrophes ('). If you do not specify the server's PKI domain, the client uses the PKI domain of its own certificate to verify the server's certificate.

prefer-compress: Specifies the preferred compression algorithm for data compression between the server and the client. By default, compression is not supported.

zlib: Specifies compression algorithm zlib.

dscp *dscp-value*: Specifies the DSCP value in the IPv4 SSH packets. The value range for the *dscp-value* argument is 0 to 63, and the default value is 48. The DSCP value determines the transmission priority of the packet.

escape *character*: Specifies a case-sensitive escape character. By default, the escape character is a tilde (~).

source: Specifies a source IP address or source interface for SSH packets. By default, the device uses the primary IPv4 address of the output interface in the routing entry as the source address of SSH packets. As a best practice to ensure successful Stelnet connections, specify a loopback interface as the source interface or specify the IPv4 address of a loopback or dialer interface as the source address.

- **interface** *interface-type interface-number*: Specifies a source interface by its type and number. The primary IPv4 address of this interface is the source IPv4 address of the SSH packets.
- **ip** *ip-address*: Specifies a source IPv4 address.

Usage guidelines

Table 9 Suite B algorithms

Security level	Key exchange algorithm	Encryption algorithm and HMAC algorithm	Public key algorithm
128-bit	ecdh-sha2-nistp256	AES128-GCM	x509v3-ecdsa-sha2-nistp256
192-bit	ecdh-sha2-nistp384	AES256-GCM	x509v3-ecdsa-sha2-nistp384
Both	ecdh-sha2-nistp256 ecdh-sha2-nistp384	AES128-GCM AES256-GCM	x509v3-ecdsa-sha2-nistp256 x509v3-ecdsa-sha2-nistp384

The combination of an escape character and a dot (.) works as an escape sequence. This escape sequence is typically used to quickly terminate an SSH connection when the server reboots or malfunctions.

For the escape sequence to take effect, you must enter it at the very beginning of a line. If you have entered other characters or performed operations in a line, enter the escape sequence in the next line. As a best practice, use the default escape character (~). Do not use any character in SSH usernames as the escape character.

Examples

Use the 128-bit Suite B algorithms to establish a connection to Stelnet server **3.3.3.3**. Specify the client's PKI domain and the server's PKI domain as **clientpkidomain** and **serverpkidomain**, respectively.

```
<Sysname> ssh2 3.3.3.3 suite-b 128-bit pki-domain clientpkidomain server-pki-domain
serverpkidomain
Username
```

ssh2 algorithm key-exchange

ssh2 algorithm mac

ssh2 algorithm public-key

ssh2 algorithm cipher

Use **ssh2 algorithm cipher** to specify encryption algorithms for SSH2.

Use **undo ssh2 algorithm cipher** to restore the default.

Syntax

ssh2 algorithm cipher { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } *

undo ssh2 algorithm cipher

Default

SSH2 uses encryption algorithms AES128-CTR, AES192-CTR, AES256-CTR, AES128-GCM, AES256-GCM, AES128-CBC, 3DES-CBC, AES256-CBC, and DES-CBC in descending order of priority for algorithm negotiation.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

3des-cbc: Specifies encryption algorithm 3DES-CBC.

aes128-cbc: Specifies encryption algorithm AES128-CBC.

aes128-ctr: Specifies encryption algorithm AES128-CTR.

aes128-gcm: Specifies encryption algorithm AES128-GCM.

aes192-ctr: Specifies encryption algorithm AES192-CTR.

aes256-cbc: Specifies encryption algorithm AES256-CBC.

aes256-ctr: Specifies encryption algorithm AES256-CTR.

aes256-gcm: Specifies encryption algorithm AES256-GCM.

des-cbc: Specifies encryption algorithm DES-CBC.

Usage guidelines

If you specify the encryption algorithms, SSH2 uses only the specified algorithms for algorithm negotiation. The algorithm specified earlier has a higher priority during negotiation.

Examples

Specify algorithm **aes256-cbc** as the encryption algorithm for SSH2.

```
<Sysname> system-view
[Sysname] ssh2 algorithm cipher aes256-cbc
```

Contents

SSL commands

certificate-chain-sending enable

Use **certificate-chain-sending enable** to enable the SSL server to send the complete certificate chain to the client during SSL negotiation.

Use **undo certificate-chain-sending enable** to restore the default.

Syntax

certificate-chain-sending enable

undo certificate-chain-sending enable

Default

During SSL negotiation, the SSL server sends the server certificate rather than the complete certificate chain to the client.

Views

SSL server policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature causes additional overheads in the SSL negotiation process. Enable it only when the SSL client does not have the complete certificate chain to verify the server certificate.

Examples

Enable the SSL server to send the complete certificate chain to the client during SSL negotiation.

```
<Sysname> system-view
[Sysname] ssl server-policy policy1
[Sysname-ssl-server-policy-policy1] certificate-chain-sending enable
```

ciphersuite

Use **ciphersuite** to specify the cipher suites supported by an SSL server policy.

Use **undo ciphersuite** to restore the default.

Syntax

ciphersuite { dhe_rsa_aes_128_cbc_sha | dhe_rsa_aes_128_cbc_sha256 | dhe_rsa_aes_256_cbc_sha | dhe_rsa_aes_256_cbc_sha256 | ecc_sm2_sm1_sm3 | ecc_sm2_sm4_sm3 | ecdhe_ecdsa_aes_128_cbc_sha256 | ecdhe_ecdsa_aes_128_gcm_sha256 | ecdhe_ecdsa_aes_256_cbc_sha384 | ecdhe_ecdsa_aes_256_gcm_sha384 | ecdhe_rsa_aes_128_cbc_sha256 | ecdhe_rsa_aes_128_gcm_sha256 | ecdhe_rsa_aes_256_cbc_sha384 | ecdhe_rsa_aes_256_gcm_sha384 | ecdhe_sm2_sm1_sm3 | ecdhe_sm2_sm4_sm3 | exp_rsa_des_cbc_sha | rsa_3des_ede_cbc_sha | rsa_aes_128_cbc_sha | rsa_aes_128_cbc_sha256 | rsa_aes_128_gcm_sha256 | rsa_aes_256_cbc_sha | rsa_aes_256_cbc_sha256 | rsa_aes_256_gcm_sha384 | rsa_des_cbc_sha | rsa_sm1_sha | rsa_sm1_sm3 | rsa_sm4_sha | rsa_sm4_sm3

Parameters

dhe_rsa_aes_128_cbc_sha: Specifies the cipher suite that uses key exchange algorithm DHE RSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA.

dhe_rsa_aes_128_cbc_sha256: Specifies the cipher suite that uses key exchange algorithm DHE RSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA256.

dhe_rsa_aes_256_cbc_sha: Specifies the cipher suite that uses key exchange algorithm DHE RSA, data encryption algorithm 256-bit AES_CBC, and MAC algorithm SHA.

dhe_rsa_aes_256_cbc_sha256: Specifies the cipher suite that uses key exchange algorithm DHE RSA, data encryption algorithm 256-bit AES_CBC, and MAC algorithm SHA256.

ecc_sm2_sm1_sm3: Specifies the cipher suite that uses key exchange algorithm ECC SM2, data encryption algorithm 128-bit SM1, and MAC algorithm SM3.

ecc_sm2_sm4_sm3: Specifies the cipher suite that uses key exchange algorithm ECC SM2, data encryption algorithm SM4, and MAC algorithm SM3.

ecdhe_ecdsa_aes_128_cbc_sha256: Specifies the cipher suite that uses key exchange algorithm ECDHE ECDSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA256.

ecdhe_ecdsa_aes_128_gcm_sha256: Specifies the cipher suite that uses key exchange algorithm ECDHE ECDSA, data encryption algorithm 128-bit AES_GCM, and MAC algorithm SHA256.

ecdhe_ecdsa_aes_256_cbc_sha384: Specifies the cipher suite that uses key exchange algorithm ECDHE ECDSA, data encryption algorithm 256-bit AES_CBC, and MAC algorithm SHA384.

ecdhe_ecdsa_aes_256_gcm_sha384: Specifies the cipher suite that uses key exchange algorithm ECDHE ECDSA, data encryption algorithm 256-bit AES_GCM, and MAC algorithm SHA384.

ecdhe_rsa_aes_128_cbc_sha256: Specifies the cipher suite that uses key exchange algorithm ECDHE RSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA256.

ecdhe_rsa_aes_128_gcm_sha256: Specifies the cipher suite that uses key exchange algorithm ECDHE RSA, data encryption algorithm 128-bit AES_GCM, and MAC algorithm SHA256.

ecdhe_rsa_aes_256_cbc_sha384: Specifies the cipher suite that uses key exchange algorithm ECDHE RSA, data encryption algorithm 256-bit AES_CBC, and MAC algorithm SHA384.

ecdhe_rsa_aes_256_gcm_sha384: Specifies the cipher suite that uses key exchange algorithm ECDHE RSA, data encryption algorithm 256-bit AES_GCM, and MAC algorithm SHA384.

ecdhe_sm2_sm1_sm3: Specifies the cipher suite that uses key exchange algorithm ECDHE SM2, data encryption algorithm 128-bit SM1, and MAC algorithm SM3.

ecdhe_sm2_sm4_sm3: Specifies the cipher suite that uses key exchange algorithm ECDHE SM2, data encryption algorithm SM4, and MAC algorithm SM3.

exp_rsa_des_cbc_sha: Specifies the export cipher suite that uses key exchange algorithm RSA, data encryption algorithm DES_CBC, and MAC algorithm SHA.

rsa_3des_ede_cbc_sha: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 3DES_EDE_CBC, and MAC algorithm SHA.

rsa_aes_128_cbc_sha: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA.

rsa_aes_128_cbc_ sha256: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA256.

rsa_aes_128_gcm_sha256: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 128-bit AES_GCM, and MAC algorithm SHA256.

rsa_aes_256_cbc_sha: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 256-bit AES_CBC, and MAC algorithm SHA.

rsa_aes_256_cbc_ sha256: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 256-bit AES_CBC, and MAC algorithm SHA256.

rsa_aes_256_gcm_sha384: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 256-bit AES_GCM, and MAC algorithm SHA384.

rsa_des_cbc_sha: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm DES_CBC, and MAC algorithm SHA.

rsa_sm1_sha: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 128-bit SM1, and MAC algorithm SHA.

rsa_sm1_sm3: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 128-bit SM1, and MAC algorithm SM3.

rsa_sm4_sha: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm SM4, and MAC algorithm SHA.

rsa_sm4_sm3: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm SM4, and MAC algorithm SM3.

tls_aes_128_ccm_sha256: Specifies the cipher suite that uses data encryption algorithm AES 128 CCM and MAC algorithm SHA256. This cipher suite is exclusive to TLS 1.3 and is supported only by SSL VPN.

tls_aes_128_ccm_8_sha256: Specifies the cipher suite that uses data encryption algorithm AES 128 CCM 8 and MAC algorithm SHA256. This cipher suite is exclusive to TLS 1.3 and is supported only by SSL VPN.

tls_aes_128_gcm_sha256: Specifies the cipher suite that uses data encryption algorithm 128-bit AES_GCM and MAC algorithm SHA256. This cipher suite is exclusive to TLS 1.3 and is supported only by SSL VPN.

tls_aes_256_gcm_sha384: Specifies the cipher suite that uses data encryption algorithm 256-bit AES_GCM and MAC algorithm SHA384. This cipher suite is exclusive to TLS 1.3 and is supported only by SSL VPN.

tls_chacha20_poly1305_sha256: Specifies the cipher suite that uses data encryption algorithm CHACHA20 POLY1305 and MAC algorithm SHA256. This cipher suite is exclusive to TLS 1.3 and is supported only by SSL VPN.

<1-11>: Specifies a maximum of 11 cipher suites.

Usage guidelines

SSL employs the following algorithms:

- **Data encryption algorithms**—Encrypt data to ensure privacy. Commonly used data encryption algorithms are symmetric key algorithms. When a symmetric key algorithm is used, the SSL server and the SSL client must use the same key.
- **Message Authentication Code (MAC) algorithms**—Calculate the MAC value for data to ensure integrity. Commonly used MAC algorithms include MD5 and SHA. When a MAC algorithm is used, the SSL server and the SSL client must use the same key.
- **Key exchange algorithms**—Implement secure exchange of the keys used by the symmetric key algorithm and the MAC algorithm. Commonly used key exchange algorithms are usually asymmetric key algorithms, such as RSA.

After the SSL server receives cipher suites from a client, the server compares the received cipher suites with the cipher suites it supports. If a match is found, the cipher suite negotiation succeeds. If no match is found, the negotiation fails. The cipher suite matching can use the server-preferred order or the client-preferred order, depending on the configuration of the **ciphersuite server-preferred enable** command.

The earlier a cipher suite is configured, the higher priority it has during the cipher suite negotiation.

When executing the **ciphersuite** command, you can specify a maximum of 11 cipher suites at a time. If you execute this command multiple times, the SSL server policy supports all the specified cipher suites.

Examples

Configure SSL server policy **policy1** to support the following cipher suites:

- Key exchange algorithm DHE RSA, data encryption algorithm 128-bit AES, and MAC algorithm SHA.
- Key exchange algorithm RSA, data encryption algorithm 128-bit AES, and MAC algorithm SHA.

```
<Sysname> system-view
[Sysname] ssl server-policy policy1
[Sysname-ssl-server-policy-policy1] ciphersuite dhe_rsa_aes_128_cbc_sha
rsa_aes_128_cbc_sha
```

Related commands

display ssl server-policy

prefer-cipher

ciphersuite server-preferred enable

ciphersuite server-preferred enable

Use **ciphersuite server-preferred enable** to enable the server-preferred order for the cipher suite negotiation between the SSL server and SSL client.

Use **undo ciphersuite server-preferred enable** to restore the default.

Syntax

ciphersuite server-preferred enable

undo ciphersuite server-preferred enable

Default

The SSL server uses the client-preferred order to choose a cipher suite during the cipher suite negotiation.

Views

SSL server policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

During the SSL connection negotiation process, the SSL server and client present a list of cipher suites that they each support, in order of preference. By default, the SSL server uses the order of cipher suites presented by the client to negotiate the cipher suite. That is, the SSL server chooses the first cipher suite in the client's list that matches any one of the server's cipher suites. If no match is found, the negotiation fails.

After this command is executed, the server-preferred order is used for cipher suite negotiation. That is, the SSL server chooses the first cipher suite in its list that matches any one of the client's cipher suites. If no match is found, the negotiation fails.

The earlier a cipher suite is configured, the higher priority it has during the cipher suite negotiation.

Examples

Enable the server-preferred order for cipher suite negotiation.

```
<Sysname> system-view
[Sysname] ssl server-policy policy1
[Sysname-ssl-server-policy-policy1] ciphersuite server-preferred enable
```

Related commands

prefer-cipher

client-verify

Use **client-verify** to enable mandatory or optional SSL client authentication.

Use **undo client-verify** to restore the default.

Syntax

client-verify { **enable** | **optional** }

undo client-verify

Default

SSL client authentication is disabled. The SSL server does not authenticate SSL clients based on digital certificates.

Views

SSL server policy view

Predefined user roles

network-admin

context-admin

Parameters

`enable`: Enables mandatory SSL client authentication.

`optional`: Enables optional SSL client authentication.

Usage guidelines

SSL uses digital certificates to authenticate communicating parties. For more information about digital certificates, see *Security Configuration Guide*.

Mandatory SSL client authentication—The SSL server requires an SSL client to submit its digital certificate for identity authentication. The SSL client can access the SSL server only after it passes identity authentication.

Optional SSL client authentication—The SSL server does not require an SSL client to submit its digital certificate for identity authentication.

- If an SSL client submits its certificate to the SSL server, the server authenticates the client identity. The client must pass authentication to access the server.
- If an SSL client does not submit its certificate to the SSL server, the server does not authenticate the client identity. The client can access the SSL server without authentication.

If SSL client authentication is disabled, the SSL server does not authenticate SSL clients regardless of whether the clients submit digital certificates or not. SSL clients can access the SSL server without authentication.

When authenticating a client by using the digital certificate, the SSL server performs the following operations:

- Verifies the certificate chain presented by the client.
- Checks that the certificates in the certificate chain (except the root CA certificate) are not revoked.

Examples

Enable mandatory SSL client authentication.

```
<Sysname> system-view
[Sysname] ssl server-policy policy1
[Sysname-ssl-server-policy-policy1] client-verify enable
```

Enable optional SSL client authentication.

```
<Sysname> system-view
[Sysname] ssl server-policy policy1
[Sysname-ssl-server-policy-policy1] client-verify optional
```

Disable SSL client authentication.

```
<Sysname> system-view
[Sysname] ssl server-policy policy1
[Sysname-ssl-server-policy-policy1] undo client-verify
```

context-operator

Parameters

policy-name: Specifies an SSL client policy by its name, a case-insensitive string of 1 to 31 characters. If you do not specify a policy name, this command displays information about all SSL client policies.

Examples

Display information about the SSL client policy **policy1**.

```
<Sysname> display ssl client-policy policy1
 SSL client policy: policy1
     SSL version: SSL 3.0
     PKI domain: client-domain
     Preferred ciphersuite:
         RSA_AES_128_CBC_SHA
     Server-verify: enabled
```

Display information about the SSL client policy **policy2**.

```
<Sysname> display ssl client-policy policy2
 SSL client policy: policy2
     SSL version: TLS 1.3
     PKI domain:
     Preferred ciphersuite:
         TLS_AES_128_GCM_SHA256
         TLS_CHACHA20_POLY1305_SHA256
         TLS_AES_256_GCM_SHA384
         TLS_AES_128_CCM_8_SHA256
         TLS_AES_128_CCM_SHA256
     Server-verify: enable
```

Table 1 Command output

Field	Description
Server-verify	Indicates whether the client is enabled to use digital certificates to authenticate servers.
SSL version	SSL protocol version in the SSL client policy. Possible versions include: • SSL 3.0. • TLS 1.0. • TLS 1.1. • TLS 1.2. • TLS 1.3. TLS 1.3 is supported only by SSL VPN. • GM-TLS 1.1.

display ssl server-policy

Parameters

policy-name: Specifies an SSL server policy by its name, a case-insensitive string of 1 to 31 characters. If you do not specify a policy name, this command displays information about all SSL server policies.

Examples

Display information about the SSL server policy **policy1**.

```
<Sysname> display ssl server-policy policy1
 SSL server policy: policy1
     Version info:
         SSL3.0: Disabled
         TLS1.0: Enabled
         TLS1.1: Disabled
         TLS1.2: Enabled
         TLS1.3: Enabled
         GM-TLS1.1: Disabled
     PKI domains: server-domain
     Ciphersuites:
         DHE_RSA_AES_128_CBC_SHA
         RSA_AES_128_CBC_SHA
         TLS_AES_128_GCM_SHA256
```

```
        TLS_CHACHA20_POLY1305_SHA256
        TLS_AES_256_GCM_SHA384
        TLS_AES_128_CCM_8_SHA256
        TLS_AES_128_CCM_SHA256
    Session cache size: 600
    Caching timeout: 3600 seconds
    Client-verify: Enabled
    Ciphersuite server-perferred: Disabled
```

Table 2 Command output

Field	Description
Version info	Enabling status of the SSL protocol versions in the SSL server policy. The SSL server can use only the enabled SSL protocol versions for session negotiation. Possible SSL protocol versions include: • SSL 3.0. • TLS 1.0. • TLS 1.1. • TLS 1.2. • TLS 1.3. TLS 1.3 is supported only by SSL VPN. • GM-TLS 1.1.
Caching timeout	Session cache timeout time in seconds.
Client-verify	SSL client authentication mode, including: • **Disabled**—SSL client authentication is disabled. • **Enabled**—SSL client authentication is mandatory. • **Optional**—SSL client authentication is optional.
Ciphersuite server-preferred	Enabling status of using the server-preferred order during the cipher suite negotiation between the SSL server and SSL client: • **Enabled**—The server-preferred order is used. • **Disabled**—The client-preferred order is used.

pki-domain (SSL client policy view)

Use **pki-domain** to specify a PKI domain for an SSL client policy.

Use **undo pki-domain** to restore the default.

Syntax

pki-domain *domain-name*

undo pki-domain

Default

No PKI domain is specified for an SSL client policy.

Views

SSL client policy view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

If you specify a PKI domain for an SSL client policy, the SSL client that uses the SSL client policy will obtain its digital certificate through the specified PKI domain.

Examples

Specify PKI domain **client-domain** for SSL client policy **policy1**.

```
<Sysname> system-view
[Sysname] ssl client-policy policy1
[Sysname-ssl-client-policy-policy1] pki-domain client-domain
```

Related commands

display ssl client-policy

pki domain

pki-domain (SSL server policy view)

Use **pki-domain** to specify a PKI domain for an SSL server policy.

Use **undo pki-domain** to restore the default.

Syntax

pki-domain *domain-name*

undo pki-domain

Default

No PKI domain is specified for an SSL server policy.

Views

SSL server policy view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. You must specify a minimum of one domain name. A maximum of two domain names are supported.

Usage guidelines

If you specify a PKI domain for an SSL server policy, the SSL server that uses the SSL server policy will obtain its digital certificate through the specified PKI domain.

Some services (such as SSL VPN, load balancing, and proxy policy) might require using two digital certificates on the server. To meet the requirement, you can use this command to specify two PKI domains in the SSL server policy at a time. If the two digital certificates obtained through the specified PKI domains are of the same type, only the digital certificate obtained through the first PKI domain takes effect.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify PKI domain **server-domain** for SSL server policy **policy1**.

```
<Sysname> system-view
[Sysname] ssl server-policy policy1
[Sysname-ssl-server-policy-policy1] pki-domain server-domain
```

Related commands

display ssl server-policy

pki domain

prefer-cipher

Use **prefer-cipher** to specify a preferred cipher suite for an SSL client policy.

Use **undo prefer-cipher** to restore the default.

Syntax

prefer-cipher { **dhe_rsa_aes_128_cbc_sha** | **dhe_rsa_aes_128_cbc_sha256** | **dhe_rsa_aes_256_cbc_sha** | **dhe_rsa_aes_256_cbc_sha256** | **ecc_sm2_sm1_sm3** | **ecc_sm2_sm4_sm3** | **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **ecdhe_sm2_sm1_sm3** | **ecdhe_sm2_sm4_sm3** | **exp_rsa_des_cbc_sha** | **rsa_3des_ede_cbc_sha** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_128_gcm_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_aes_256_gcm_sha384** | **rsa_des_cbc_sha** | **rsa_sm1_sha** | **rsa_sm1_sm3** | **rsa_sm4_sha** | **rsa_sm4_sm3**

tls_aes_128_ccm_8_sha256 | **tls_aes_128_ccm_sha256** | **tls_aes_128_gcm_sha256** | **tls_aes_256_gcm_sha384** | **tls_chacha20_poly1305_sha256** } *<1-11>

undo prefer-cipher

Default

The preferred cipher suites of an SSL client policy are **dhe_rsa_aes_256_cbc_sha, rsa_aes_256_cbc_sha**, **dhe_rsa_aes_128_cbc_sha**, , and **rsa_aes_128_cbc_sha**.

Views

Parameters

dhe_rsa_aes_128_cbc_sha: Specifies the cipher suite that uses key exchange algorithm DHE RSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA.

dhe_rsa_aes_128_cbc_sha256: Specifies the cipher suite that uses key exchange algorithm DHE RSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA256.

dhe_rsa_aes_256_cbc_sha: Specifies the cipher suite that uses key exchange algorithm DHE RSA, data encryption algorithm 256-bit AES_CBC, and MAC algorithm SHA.

dhe_rsa_aes_256_cbc_sha256: Specifies the cipher suite that uses key exchange algorithm DHE RSA, data encryption algorithm 256-bit AES_CBC, and MAC algorithm SHA256.

ecc_sm2_sm1_sm3: Specifies the cipher suite that uses key exchange algorithm ECC SM2, data encryption algorithm 128-bit SM1, and MAC algorithm SHA256.

ecc_sm2_sm4_sm3: Specifies the cipher suite that uses key exchange algorithm ECC SM2, data encryption algorithm SM4, and MAC algorithm SM3.

ecdhe_ecdsa_aes_128_cbc_sha256: Specifies the cipher suite that uses key exchange algorithm ECDHE ECDSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA256.

ecdhe_ecdsa_aes_128_gcm_sha256: Specifies the cipher suite that uses key exchange algorithm ECDHE ECDSA, data encryption algorithm 128-bit AES_GCM, and MAC algorithm SHA256.

ecdhe_ecdsa_aes_256_cbc_sha384: Specifies the cipher suite that uses key exchange algorithm ECDHE ECDSA, data encryption algorithm 256-bit AES_CBC, and MAC algorithm SHA384.

ecdhe_ecdsa_aes_256_gcm_sha384: Specifies the cipher suite that uses key exchange algorithm ECDHE ECDSA, data encryption algorithm 256-bit AES_GCM, and MAC algorithm SHA384.

ecdhe_rsa_aes_128_cbc_sha256: Specifies the cipher suite that uses key exchange algorithm ECDHE RSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA256.

ecdhe_rsa_aes_128_gcm_sha256: Specifies the cipher suite that uses key exchange algorithm ECDHE RSA, data encryption algorithm 128-bit AES_GCM, and MAC algorithm SHA256.

ecdhe_rsa_aes_256_cbc_sha384: Specifies the cipher suite that uses key exchange algorithm ECDHE RSA, data encryption algorithm 256-bit AES_CBC, and MAC algorithm SHA384.

ecdhe_rsa_aes_256_gcm_sha384: Specifies the cipher suite that uses key exchange algorithm ECDHE RSA, data encryption algorithm 256-bit AES_GCM, and MAC algorithm SHA384.

ecdhe_sm2_sm1_sm3: Specifies the cipher suite that uses key exchange algorithm ECDHE SM2, data encryption algorithm 128-bit SM1, and MAC algorithm SM3.

ecdhe_sm2_sm4_sm3: Specifies the cipher suite that uses key exchange algorithm ECDHE SM2, data encryption algorithm SM4, and MAC algorithm SM3.

exp_rsa_des_cbc_sha: Specifies the export cipher suite that uses key exchange algorithm RSA, data encryption algorithm DES_CBC, and MAC algorithm SHA.

rsa_3des_ede_cbc_sha: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 3DES_EDE_CBC, and MAC algorithm SHA.

rsa_aes_128_cbc_sha: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA.

rsa_aes_128_cbc_ sha256: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA256.

rsa_aes_128_gcm_sha256: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA256.

rsa_aes_256_cbc_sha: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 256-bit AES_CBC, and MAC algorithm SHA.

rsa_aes_256_cbc_ sha256: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 256-bit AES_CBC, and MAC algorithm SHA256.

rsa_aes_256_gcm_sha384: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 256-bit AES_GCM, and MAC algorithm SHA384.

rsa_des_cbc_sha: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm DES_CBC, and MAC algorithm SHA.

rsa_sm1_sha: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 128-bit SM1, and MAC algorithm SHA.

rsa_sm1_sm3: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm 128-bit SM1, and MAC algorithm SM3.

rsa_sm4_sha: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm SM4, and MAC algorithm SHA.

rsa_sm4_sm3: Specifies the cipher suite that uses key exchange algorithm RSA, data encryption algorithm SM4, and MAC algorithm SM3.

tls_aes_128_ccm_sha256: Specifies the cipher suite that uses data encryption algorithm AES 128 CCM and MAC algorithm SHA256. This cipher suite is exclusive to TLS 1.3 and is supported only by SSL VPN.

tls_aes_128_ccm_8_sha256: Specifies the cipher suite that uses data encryption algorithm AES 128 CCM 8 and MAC algorithm SHA256. This cipher suite is exclusive to TLS 1.3 and is supported only by SSL VPN.

tls_aes_128_gcm_sha256: Specifies the cipher suite that uses data encryption algorithm 128-bit AES_GCM and MAC algorithm SHA256. This cipher suite is exclusive to TLS 1.3 and is supported only by SSL VPN.

tls_aes_256_gcm_sha384: Specifies the cipher suite that uses data encryption algorithm 256-bit AES_GCM and MAC algorithm SHA384. This cipher suite is exclusive to TLS 1.3 and is supported only by SSL VPN.

tls_chacha20_poly1305_sha256: Specifies the cipher suite that uses data encryption algorithm CHACHA20 POLY1305 and MAC algorithm SHA256. This cipher suite is exclusive to TLS 1.3 and is supported only by SSL VPN.

<1-11>: Specifies a maximum of 11 cipher suites.

Usage guidelines

SSL employs the following algorithms:

- **Data encryption algorithms**—Encrypt data to ensure privacy. Commonly used data encryption algorithms are usually symmetric key algorithms. When using a symmetric key algorithm, the SSL server and the SSL client must use the same key.
- **Message Authentication Code (MAC) algorithms**—Calculate the MAC value for data to ensure integrity. Commonly used MAC algorithms include MD5 and SHA. When using a MAC algorithm, the SSL server and the SSL client must use the same key.
- **Key exchange algorithms**—Implement secure exchange of the keys used by the symmetric key algorithm and MAC algorithm. Commonly used key exchange algorithms are asymmetric key algorithms, such as RSA.

The SSL client sends the preferred cipher suites to the SSL server. The server compares the received cipher suites with the cipher suites it supports. If a match is found, the cipher suite negotiation succeeds. If no match is found, the negotiation fails. The cipher suite matching can use the server-preferred order or the client-preferred order, depending on the configuration of the **ciphersuite server-preferred enable** command.

The earlier a cipher suite is configured, the higher priority it has during the cipher suite negotiation.

When executing the **prefer-cipher** command, you can specify a maximum of 11 cipher suites at a time. If you execute this command multiple times, the SSL client policy supports all the specified cipher suites.

Examples

Configure SSL client policy **policy1** to support the key exchange algorithm RSA, data encryption algorithm 128-bit AES_CBC, and MAC algorithm SHA.

```
<Sysname> system-view
```

```
[Sysname] ssl client-policy policy1
[Sysname-ssl-client-policy-policy1] prefer-cipher rsa_aes_128_cbc_sha
```

context-admin

Parameters

cachesize *size*: Sets the maximum number of cached sessions, in the range of 100 to 20480.

timeout *time*: Sets the session cache timeout in the range of 1 to 4294967295 seconds.

Usage guidelines

The SSL server caches SSL sessions to reuse negotiated session parameters to simplify SSL handshake. Use this command to limit the maximum number and timeout time for cached sessions. When the number of cached sessions reaches the maximum, SSL does not cache new sessions. When the timeout timer for a cached session expires, SSL deletes the session.

Examples

Set the maximum number of cached sessions to 600, and the timeout time for cached sessions to 1800 seconds.

```
<Sysname> system-view
[Sysname] ssl server-policy policy1
[Sysname-ssl-server-policy-policy1] session cachesize 600 timeout 1800
```

Related commands

display ssl server-policy

ssl client-policy

Use **ssl client-policy** to create an SSL client policy and enter its view, or enter the view of an existing SSL client policy.

Use **undo ssl client-policy** to delete an SSL client policy.

Syntax

ssl client-policy *policy-name*

undo ssl client-policy *policy-name*

Default

No SSL client policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies an SSL client policy by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

This command creates an SSL client policy for which you can configure SSL parameters that the client uses to establish a connection to the server. The parameters include a PKI domain and a preferred cipher suite. An SSL client policy takes effect only after it is associated with an application such as DDNS.

Examples

Create an SSL client policy named **policy1** and enter its view.

```
<Sysname> system-view
[Sysname] ssl client-policy policy1
[Sysname-ssl-client-policy-policy1]
```

Related commands

display ssl client-policy

ssl renegotiation disable

Use **ssl renegotiation disable** to disable SSL session renegotiation.

Use **undo ssl renegotiation disable** to restore the default.

Syntax

ssl renegotiation disable

undo ssl renegotiation disable

Default

SSL session renegotiation is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The SSL session renegotiation feature enables the SSL client and server to reuse a previously negotiated SSL session for an abbreviated handshake.

Disabling session renegotiation causes more computational overhead to the system but it can avoid potential risks. Disable SSL session renegotiation only when explicitly required.

Examples

#Disable SSL session renegotiation.

```
<Sysname> system-view
[Sysname] ssl renegotiation disable
```

ssl server-policy

Use **ssl server-policy** to create an SSL server policy and enter its view, or enter the view of an existing SSL server policy.

Use **undo ssl server-policy** to delete an SSL server policy.

Syntax

ssl server-policy *policy-name*

undo ssl server-policy *policy-name*

Default

No SSL server policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies a name for the SSL server policy, a case-insensitive string of 1 to 31 characters.

Usage guidelines

This command creates an SSL server policy for which you can configure SSL parameters such as a PKI domain and supported cipher suits. An SSL server policy takes effect only after it is associated with an application such as HTTPS.

Examples

Create an SSL server policy named **policy1** and enter its view.

```
<Sysname> system-view
[Sysname] ssl server-policy policy1
[Sysname-ssl-server-policy-policy1]
```

Related commands

display ssl server-policy

ssl version disable

Use **ssl version disable** to disable the SSL server from using specific SSL protocol versions for session negotiation.

Use **undo ssl version disable** restore the default.

Syntax

ssl version { **gm-tls1.1** | **ssl3.0** | **tls1.0** | **tls1.1** | **tls1.2** | **tls1.3** } * **disable**

undo ssl version { **gm-tls1.1** | **ssl3.0** | **tls1.0** | **tls1.1** | **tls1.2** | **tls1.3** } * **disable**

Default

The SSL server supports TLS 1.1 and TLS 1.2.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

gm-tls1.1: Specifies GM-TLS 1.1.

ssl3.0: Specifies SSL 3.0.

tls1.0: Specifies TLS 1.0.

tls1.1: Specifies TLS 1.1.

tls1.2: Specifies TLS 1.2.

tls1.3: Specifies TLS 1.3. TLS 1.3 is supported only by SSL VPN.

Usage guidelines

To enhance security, you can disable the SSL server from using specific SSL protocol versions.

This command allows you to disable SSL protocol versions in system view. You can also enable or disable an SSL protocol version in SSL server policy view by using the **version disable** command. An SSL server policy prefers the policy-specific setting over the system global setting.

Make sure the SSL server is allowed to use a minimum of one SSL protocol version for session negotiation.

Disabling an SSL protocol version does not affect the availability of earlier SSL protocol versions. For example, if you execute the **ssl version tls1.1 disable** command, TLS 1.1 is disabled but TLS 1.0 is still available for the SSL server.

Examples

Disable TLS 1.0.

```
<Sysname> system-view
[Sysname] ssl version tls1.0 disable
```

Related commands

version disable

version

Use **version** to specify an SSL protocol version for an SSL client policy.

Use **undo version** to restore the default.

Syntax

version { **gm-tls1.1** | **ssl3.0** | **tls1.0** | **tls1.1** | **tls1.2** | **tls1.3** }

undo version

Default

An SSL client policy uses SSL protocol version TLS 1.2.

Views

SSL client policy view

Predefined user roles

network-admin

context-admin

Parameters

gm-tls1.1: Specifies GM-TLS 1.1.

ssl3.0: Specifies SSL 3.0.

tls1.0: Specifies TLS 1.0.

tls1.1: Specifies TLS 1.1.

tls1.2: Specifies TLS 1.2.

tls1.3: Specifies TLS 1.3. TLS 1.3 is supported only by SSL VPN.

Usage guidelines

To ensure security, do not specify SSL 3.0 for an SSL client policy.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Set the SSL protocol version to TLS 1.0 for SSL client policy **policy1**.

```
<Sysname> system-view
[Sysname] ssl client-policy policy1
[Sysname-ssl-client-policy-policy1] version tls1.0
```

Related commands

display ssl client-policy

version disable

Use **version disable** to disable SSL protocol versions for the SSL server in an SSL server policy.

Use **undo version disable** restore the default.

Syntax

version { **gm-tls1.1** | **ssl3.0** | **tls1.0** | **tls1.1** | **tls1.2** | **tls1.3** } * **disable**

undo version { **gm-tls1.1** | **ssl3.0** | **tls1.0** | **tls1.1** | **tls1.2** | **tls1.3** } * **disable**

Default

An SSL protocol version is enabled in an SSL sever policy unless it is explicitly disabled in system view by using the **ssl version disable** command.

Views

SSL server policy view

Predefined user roles

network-admin

context-admin

Parameters

gm-tls1.1: Specifies GM-TLS 1.1.

ssl3.0: Specifies SSL 3.0.

tls1.0: Specifies TLS 1.0.

tls1.1: Specifies TLS 1.1.

tls1.2: Specifies TLS 1.2.

tls1.3: Specifies TLS 1.3. TLS 1.3 is supported only by SSL VPN.

Usage guidelines

You can enable or disable an SSL protocol version in system view or in SSL server policy view. An SSL server can use an SSL protocol version for session negotiation only when the status of the SSL protocol version in the SSL server policy is **Enabled**. The status of an SSL protocol version in an SSL server policy is determined in the following sequence:

1. Configuration of the **version disable** command in SSL server policy view.
2. Configuration of the **ssl version disable** command in system view.
3. Default setting (**Enabled**).

Make sure the SSL server is allowed to use a minimum of one SSL protocol version for session negotiation.

Disabling an SSL protocol version does not affect the availability of earlier SSL protocol versions. For example, if you execute the **version tls1.1 disable** command in SSL server policy view, TLS 1.1 is disabled but TLS 1.0 is still available for the SSL server.

Examples

Disable TLS 1.0 in SSL server policy **policy1**.

```
<Sysname> system-view
[Sysname] ssl server-policy policy1
[Sysname-ssl-server-policy-policy1] version tls1.0 disable
```

Connection limit commands

connection-limit

Use **connection-limit** to create a connection limit policy and enter its view, or enter the view of an existing connection limit policy.

Use **undo connection-limit** to delete a connection limit policy.

Syntax

connection-limit { **ipv6-policy** | **policy** } *policy-id*

undo connection-limit { **ipv6-policy** | **policy** } *policy-id*

Default

No connection limit policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-policy: Specifies an IPv6 connection limit policy.

policy: Specifies an IPv4 connection limit policy.

policy-id: Specifies the ID of a connection limit policy, in the range of 1 to 32. An IPv4 or IPv6 connection limit policy has its own number.

Examples

Create IPv4 connection limit policy 1 and enter its view.

```
<Sysname> system-view
[Sysname] connection-limit policy 1
[Sysname-connlmt-policy-1]
```

Create IPv6 connection limit policy 12 and enter its view.

```
<Sysname> system-view
[Sysname] connection-limit ipv6-policy 12
[Sysname-connlmt-ipv6-policy-12]
```

Table 1 Command output

Field	Description
Limit rule list	Connection limit policy information.
Policy	Number of the connection limit policy.
Rule	Number of the connection limit rule.

Field	Description
Stat Type	Statistics types: • **Src-Dst-Port**—Limits connections by source IP, destination IP, and service combination. • **Src-Dst**—Limits connections by source IP address and destination IP address combination. • **Src-Port**—Limits connections by source IP and service combination. • **Dst-Port**—Limits connections by destination IP and service combination. • **Src**—Limits connections by source IP address. • **Dst**—Limits connections by destination IP address. • **Port**—Limits connections by service. • **Dslite**—Limits connections by B4 device of a DS-Lite tunnel. • **--**—Limits connections not by a specific IP address or service. All connections that match the ACL used by the rule are limited.
HiThres	Upper limit of the connections.
LoThres	Lower limit of the connections.
Rate	Maximum number of connections established per second.
ACL	Number or name of the ACL used by the rule.
PermitNew	Permit new connections when the connection count or connection rate exceeds the threshold.
Application list	Application list of the connection limit policy, including interface name and **Global**. **Global** indicates that the connection limit policy is applied globally.
Description	Connection limit policy description.
Description list	List of connection limit policy descriptions.

Related commands

connection-limit apply

connection-limit apply global

limit

display connection-limit ipv6-stat-nodes

Use **display connection-limit ipv6-stat-nodes** to display statistics about IPv6 connections that match connection limit rules globally or on an interface.

Syntax

display connection-limit ipv6-stat-nodes { **global** | **interface** *interface-type interface-number* } [**slot** *slot-number*] [{ **deny-new** | **permit-new** } | **destination** *destination-ip* | **service-port** *port-number* | **source** *source-ip*] * [**count**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

global: Displays statistics about IPv6 connections that match connection limit rules globally.

interface *interface-type interface-number*: Specifies an interface by its type and number.

slot *slot-number*: Specifies an IRF member device by its member ID. This option is available only when you specify the **global** keyword or specify a virtual interface, such as a VLAN-interface and tunnel interface.

deny-new: Displays limit rule-based statistics sets of which new connections are rejected.

permit-new: Displays limit rule-based statistics sets of which new connections are allowed.

destination *destination-ip*: Specifies a destination by its IP address.

service-port *port-number*: Specifies a service port by its port number.

source *source-ip*: Specifies a source by its IP address.

count: Displays only the number of limit rule-based statistics sets. Detailed information about the specified IPv6 connections is not displayed. If you do not specify this keyword, the command displays detailed information about the specified IPv6 connections that match connection limit rules.

Usage guidelines

The statistics for this command include the following information:

- Connection information, including the source/destination IP address, service port, and transport layer protocol of connections.
- Matching connection limit rules.
- Number of current connections.
- Whether or not new connections can be created.

To further filter the output statistics, specify the following options in the command:

- **source** *source-ip*.
- **destination** *destination-ip*.
- **service-port** *port-number*.
- **permit-new**.
- **deny-new**.

For example, if you specify the **source** *source-ip* and **destination** *destination-ip* combination, this command displays statistics about IPv6 connections that match connection limit rules by source IP address and destination IP address.

If you specify none of the previously mentioned parameters, this command displays statistics about all IPv6 connections that match connection limit rules.

Deleting or modifying an IPv6 connection limit policy will not delete the effective IPv6 connection limit rule-based statistics sets. An IPv6 connection limit rule-based statistics set will be automatically deleted after all the IPv6 connections for the set are disconnected.

Examples

Display statistics about IPv6 connections that match the connection limit rule on IRF member device 2.

```
<Sysname> display connection-limit ipv6-stat-nodes global slot 2
```

```
Slot 2:
 Src IP address          : Any
     VPN instance        : --
 Dst IP address          : Any
     VPN instance        : --
 DS-Lite tunnel peer     : --
 Service                 : icmp/0
 Limit rule ID           : 22(ACL: 3666)
 Sessions threshold Hi/Lo: 3500/3000
 Sessions count          : 3100
 Sessions limit rate     : 0
 New session flag        : Permit
```

Display the number of limit rule-based statistics sets on IRF member device 2.

```
<Sysname> display connection-limit ipv6-stat-nodes global slot 2 count
Slot 2:
       Current limit statistic nodes count is 0.
```

Table 2 Command output

Field	Description
Src IP address	Source IP address.
Dst IP address	Destination IP address.
VPN instance	MPLS L3VPN instance to which the IP address belongs. Two hyphens (--) indicates that the IP address is on the public network.
DS-Lite tunnel peer	Peer IP address of the DS-Lite tunnel to which the connection belongs. Two hyphens (--) indicates that the connection does not belong to a DS-Lite tunnel.
Service	Protocol name and service port number. For an unwell-known protocol, this field displays **unknown(xx)**.The cross signs (xx) indicates the protocol number. For the ICMP protocol, the protocol number is the decimal digits that are converted from the hexadecimal contents of the type and code fields.
Limit rule ID	ID of the matched rule. The ACL number of the rule is enclosed in parentheses.
Sessions threshold Hi/Lo	Upper and lower connection limits.
Sessions count	Number of current connections.
Sessions limit rate	Maximum number of connections established per second.
New session flag	Whether or not new connections can be created: • **Permit**—New connections can be created. • **Deny**—New connections cannot be created. **NOTE:** When the number of connections reaches the upper limit, this field displays **Permit** although new connections are not allowed. This field displays **Deny** only when the number of connections exceeds the upper limit.

permit-new: Displays limit rule-based statistics sets of which new connections are allowed.

destination *destination-ip*: Specifies a destination by its IP address.

service-port *port-number*: Specifies a service port by its port number.

source *source-ip*: Specifies a source by its IP address.

dslite-peer *b4-address*: Specifies a B4 device on a DS-Lite tunnel. The *b4-address* argument specifies the IPv6 address of the B4 device.

count: Displays only the number of limit rule-based statistics sets. Detailed information about the specified IPv4 connections is not displayed. If you do not specify this keyword, the command displays detailed information about the specified IPv4 connections that match connection limit rules.

Usage guidelines

The statistics for this command include the following information:

- Connection information, including the source/destination IP address, service port, and transport layer protocol of connections.
- Matching connection limit rules.
- Number of current connections.
- Whether or not new connections can be created.

To further filter the output statistics, specify the following options in the command:

- **source** *source-ip*.
- **destination** *destination-ip*.
- **service-port** *port-number*.
- **permit-new**.
- **deny-new**.

For example, if you specify the **source** *source-ip* and **destination** *destination-ip* combination, this command displays statistics about IPv4 connections that match connection limit rules by source IP address and destination IP address.

If you specify none of the previously mentioned parameters, this command displays statistics about all IPv4 connections that match connection limit rules.

Deleting or modifying an IPv4 connection limit policy will not delete the effective IPv4 connection limit rule-based statistics sets. An IPv4 connection limit rule-based statistics set will be automatically deleted after all the IPv4 connections for the set are disconnected.

Examples

Display statistics about IPv4 connections that match the connection limit rule on IRF member device 2.

```
<Sysname> display connection-limit stat-nodes global slot 2
Slot 2:
 Src IP address          : Any
     VPN instance        : Vpn1
 Dst IP address          : 202.113.16.117
     VPN instance        : Vpn2
 DS-Lite tunnel peer     : --
 Service                 : icmp/0
 Limit rule ID           : 7(ACL: 3102)
 Sessions threshold Hi/Lo: 4000/3800
 Sessions count          : 1001
 Sessions limit rate     : 0
 New session flag        : Permit
```

Display the number of limit rule-based statistics sets on IRF member device 2 by source IP address 1.1.1.1.

```
<Sysname> display connection-limit stat-nodes global slot 2 source 1.1.1.1 count
Slot 2:
       Current limit statistic nodes count is 0.
```

Table 4 Command output

Field	Description
Src IP address	Source IP address.
Dst IP address	Destination IP address.
VPN instance	MPLS L3VPN instance to which the IP address belongs. Two hyphens (--) indicates that the IP address is on the public network.
DS-Lite tunnel peer	Peer IP address of the DS-Lite tunnel to which the connection belongs. Two hyphens (--) indicates that the connection does not belong to a DS-Lite tunnel.

Field	Description
Service	Protocol name and service port number. For an unwell-known protocol, this field displays **unknown(xx)**. The cross signs (xx) represents the protocol number. For the ICMP protocol, the protocol number is the decimal digits that are converted from the hexadecimal contents of the type and code fields.
Sessions threshold Hi/Lo	Upper and lower connection limits.
Sessions count	Number of current connections.
Sessions limit rate	Maximum number of connections established per second.
New session flag	Whether or not new connections can be created: • **Permit**—New connections can be created. • **Deny**—New connections cannot be created. **NOTE:** When the number of connections reaches the upper limit, this field displays **Permit** although new connections are not allowed. This field displays **Deny** only when the number of connections exceeds the upper limit.

limit

Use **limit** to configure a connection limit rule.

Use **undo limit** to delete a connection limit rule.

Syntax

In IPv4 connection limit policy view:

limit *limit-id* **acl** { *acl-number* | **name** *acl-name* } [**per-destination** | **per-service** | **per-source**] * { **amount** *max-amount min-amount* | **rate** *rate* } * [**description** *text* | **permit-new**] *

limit *limit-id* **acl ipv6** { *acl-number* | **name** *acl-name* } **per-dslite-b4** { **amount** *max-amount min-amount* | **rate** *rate* } * [**description** *text* | **permit-new**] *

undo limit *limit-id*

In IPv6 connection limit policy view:

limit *limit-id* **acl ipv6** { *acl-number* | **name** *acl-name* } [**per-destination** | **per-service** | **per-source**] * { **amount** *max-amount min-amount* | **rate** *rate* } * [**description** *text* | **permit-new**] *

undo limit *limit-id*

Default

No connection limit rules exist.

Views

IPv4 connection limit policy view

IPv6 connection limit policy view

Predefined user roles

network-admin

context-admin

Parameters

limit-id: Specifies a connection limit rule by its ID in the range of 1 to 256.

acl: Specifies the ACL that matches the user range. Only the user connections that match the ACL are limited.

ipv6: Specifies an IPv6 ACL. If you do not specify this keyword, an IPv4 ACL is used.

acl-number: Specifies an ACL by its number in the range of 2000 to 3999.

name *acl-name*: Specifies an ACL by its name. The *acl-name* argument is a case-insensitive string of 1 to 63 characters. It must start with an English letter. To avoid confusion, it cannot be **all**.

per-destination: Limits connections by destination IP address.

per-service: Limits connections by service depending on transport layer protocol and service port.

per-source: Limits connections by source IP address.

per-dslite-b4: Limits connections by IPv6 address of a B4 device on a DS-Lite tunnel. This keyword is available only in IPv4 connection limit policy view.

amount: Limits the number of connections.

max-amount: Specifies the upper connection limit in the range of 1 to 4294967294. If the **permit-new** parameter is not specified, when user connections in a range or of a type exceed the upper limit, new connections cannot be created until the connection count drops below *min-amount*.

min-amount: Specifies the lower connection limit in the range of 1 to 4294967294. The lower connection limit cannot be greater than the upper connection limit. New connections cannot be created until the connection number goes below the lower connection limit.

rate: Limits the connection establishment rate.

rate: Specifies the maximum number of connections established per second. The value range is 5 to 10000000. If the permit-new parameter is not specified, when user connections in a range or of a type exceed this rate, new connections cannot be created until the connection rate drops below this rate.

description *text*: Specifies a description for the connection limit rule, a case-sensitive string of 1 to 127 characters. By default, a connection limit rule does not have a description.

permit-new: Permits new connections when the connection count or connection rate exceeds the threshold and generates alarm logs.

Usage guidelines

Each connection limit policy can define multiple rules, and each rule must specify the used ACL, rule type, and either of upper/lower connection limit and connection establishment rate limit. In one rule, you can specify one or multiple of the keywords **per-destination**, **per-source**, and **per-service**, but you cannot specify the **per-dslite-b4** keyword together with other keywords. For example, if the **per-destination** and **per-source** combination is specified,

connections are limited by the source IP address and destination IP address. Connections with the same source IP address and destination IP address are the same type.

When you configure a connection limit rule, follow these guidelines:

- Different rules in the same connection limit policy must use different ACLs.
- If you specify none of the **per-destination**, **per-source**, and **per-service** keywords, all connections that match the specified ACL are limited by the specified value.
- When the connections established on a device are matched against a connection limit policy, the limit rules in the policy are matched in ascending order of rule ID.
- When the specified ACL changes, the connections that have been established are limited by the new connection limit policy.
- A rule that has the **per-dslite-b4** keyword limits IPv4 connections of the DS-Lite tunnel B4 device that matches the specified IPv6 ACL in the rule. On a DS-Lite tunnel network, if the AFTR device uses the Endpoint-Independent Mapping-based NAT configuration, you must limit connections from external IPv4 networks to access the internal IPv4 network. To implement B4 device-based connection limits, perform the following tasks:
  - Add a rule that has the **per-dslite-b4** keyword to a connection limit policy.
  - Apply the policy globally or on the DS-Lite tunnel interface.

Examples

Configure connection limit rule 1 for IPv4 connection limit policy 1:

1. Configure ACL 3000.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule permit ip source 192.168.0.0 0.0.0.255
[Sysname-acl-ipv4-adv-3000] quit
```

2. Limit connections that match ACL 3000 by the source and destination IP addresses, with the upper limit 2000, lower limit 1800, and establishment rate 10 per second.

```
[Sysname] connection-limit policy 1
[Sysname-connlmt-policy-1] limit 1 acl 3000 per-destination per-source amount 2000
1800 rate 10
```

3. Verify that when the connection number exceeds 2000, new connections cannot be established until the connection number goes below 1800. (Details not shown.)

Configure connection limit rule 1 for IPv4 connection limit policy 1:

1. Configure ACL 3000.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule permit ip source 192.168.0.0 0.0.0.255
[Sysname-acl-ipv4-adv-3000] quit
```

2. Limit connections that match ACL 3000 by the source and destination IP addresses, with the upper limit 2000, lower limit 1800, and establishment rate 10 per second. Specify the **permit-new** keyword.

```
[Sysname] connection-limit policy 1
[Sysname-connlmt-policy-1] limit 1 acl 3000 per-destination per-source amount 2000
1800 rate 10 permit-new
```

3. Verify that when the connection number exceeds 2000 or the connection rate exceeds 10 per second, new connections can be established but alarm logs are generated. (Details not shown.)

Configure connection limit rule 2 for IPv6 connection limit policy 12:

1. Configure ACL 2001.

```
<Sysname> system-view
[Sysname] acl ipv6 basic 2001
[Sysname-acl-ipv6-basic-2001] rule permit source 2:1::/96
[Sysname-acl-ipv6-basic-2001] quit
```

2. Limit connections that match ACL 2001 by the source and destination IP addresses, with the upper limit 200, lower limit 100, and establishment rate 10 per second.

```
[Sysname] connection-limit ipv6-policy 12
[Sysname-connlmt-ipv6-policy-12] limit 2 acl ipv6 2001 per-destination amount 200 100 rate 10
```

3. Verify that when the connection number exceeds 200, new connections cannot be established until the connection number goes below 100. (Details not shown.)

Configure connection limit rule 2 for IPv6 connection limit policy 12:

1. Configure ACL 2001.

```
<Sysname> system-view
[Sysname] acl ipv6 basic 2001
[Sysname-acl-ipv6-basic-2001] rule permit source 2:1::/96
[Sysname-acl-ipv6-basic-2001] quit
```

2. Limit connections that match ACL 2001 by the destination IP addresses, with the upper limit 200, lower limit 100, and establishment rate 10 per second. Specify the **permit-new** keyword.

```
[Sysname] connection-limit ipv6-policy 12
[Sysname-connlmt-ipv6-policy-12] limit 2 acl ipv6 2001 per-destination amount 200 100 rate 10
```

3. Verify that when the connection number exceeds 200 or the connection rate exceeds 10 per second, new connections can be established but alarm logs are generated. (Details not shown.)

Related commands

connection-limit

display connection-limit

reset connection-limit statistics

Use **reset connection-limit statistics** to clear the connection limit statistics globally or on an interface.

Syntax

reset connection-limit statistics { **global** | **interface** *interface-type interface-number* } [**slot** *slot-number*]

Views

User view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

global: Clears the global connection limit statistics.

interface *interface-type interface-number*: Specifies an interface by its type and number.

slot *slot-number*: Specifies an IRF member device by its member ID. The *slot-number* argument represents the ID of the IRF member device. This option is available only when you specify the **global** keyword or specify a virtual interface, such as a VLAN interface or tunnel interface.

Examples

Clear the global connection limit statistics on IRF member device 2.

```
<Sysname> reset connection-limit statistics global slot 2
```

Attack detection and prevention commands

ack-flood action

Use **ack-flood action** to specify global actions against ACK flood attacks.

Use **undo ack-flood action** to restore the default.

Syntax

ack-flood action { **client-verify** | **drop** | **logging** } *

undo ack-flood action

Default

No global action is specified for ACK flood attacks.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

client-verify: Adds the victim IP addresses to the protected IP list for TCP client verification. If TCP client verification is enabled, the device provides proxy services for protected servers. This keyword does not take effect on source-based flood attack prevention.

drop: Drops subsequent ACK packets destined for the victim IP addresses in destination-based flood attack prevention, or drops subsequent ACK packets originating from the attacker IP addresses in source-based flood attack prevention.

logging: Enables logging for ACK flood attack events. The log messages will be sent to the log system.

Usage guidelines

For the ACK flood attack detection to collaborate with the TCP client verification, make sure the **client-verify** keyword is specified and the TCP client verification is enabled. To enable TCP client verification, use the **client-verify tcp enable** command.

The **logging** keyword enables the attack detection and prevention module to log ACK flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output ACK flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view ACK flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Specify **drop** as the global action against ACK flood attacks in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] ack-flood action drop
```

Related commands

ack-flood threshold

client-verify tcp enable

ack-flood detect

Use **ack-flood detect** to configure IP address-specific ACK flood attack detection.

Use **undo ack-flood detect** to remove IP address-specific ACK flood attack detection configuration.

Syntax

ack-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **drop** | **logging** } * | **none** }]

undo ack-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

Default

IP address-specific ACK flood attack detection is not configured.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies the IPv4 address to be protected. The *ip-address* argument cannot be 255.255.255.255 or 0.0.0.0.

ipv6 *ipv6-address*: Specifies the IPv6 address to be protected. The IPv6 address cannot be a multicast address or ::.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the protected IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the protected IP address is on the public network.

threshold *threshold-value*: Specifies the maximum receiving rate in pps for ACK packets that are destined for the protected IP address. The value range is 1 to 1000000.

action: Specifies the actions against a detected ACK flood attack. If no action is specified, the global actions set by the **ack-flood action** command apply.

client-verify: Adds the victim IP addresses to the protected IP list for TCP client verification. If TCP client verification is enabled, the device provides proxy services for protected servers.

drop: Drops subsequent ACK packets destined for the protected IP address.

logging: Enables logging for ACK flood attack events. The log messages will be sent to the log system.

none: Takes no action.

Usage guidelines

With ACK flood attack detection configured for an IP address, the device is in attack detection state. When the receiving rate of ACK packets destined for the IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

You can configure ACK flood attack detection for multiple IP addresses in one attack defense policy.

The **logging** keyword enables the attack detection and prevention module to log ACK flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output ACK flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view ACK flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Configure ACK flood attack detection for 192.168.1.2 in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] ack-flood detect ip 192.168.1.2 threshold 2000
```

ack-flood detect non-specific

Use **ack-flood detect non-specific** to enable global ACK flood attack detection.

Use **undo ack-flood detect non-specific** to disable global ACK flood attack detection.

Syntax

ack-flood detect non-specific

undo ack-flood detect non-specific

Default

Global ACK flood attack detection is disabled.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

The device supports the following ACK flood attack prevention types:

- **Source-based ACK flood attack prevention**—Monitors the receiving rate of ACK packets on a per-source IP basis.
- **Destination-based ACK flood attack prevention**—Monitors the receiving rate of ACK packets on a per-destination IP basis.

The global ACK flood attack detection applies to all IP addresses except those specified by the **ack-flood detect** command. The global detection uses the global trigger threshold set by the **ack-flood threshold** or **ack-flood source-threshold** command and global actions specified by the **ack-flood action** command.

Examples

Enable global ACK flood attack detection in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] ack-flood detect non-specific
```

Related commands

ack-flood action

ack-flood detect

ack-flood source-threshold

ack-flood threshold

ack-flood threshold

Use **ack-flood threshold** to set the global threshold for triggering destination-based ACK flood attack prevention.

Use **undo ack-flood threshold** to restore the default.

Syntax

ack-flood threshold *threshold-value*

undo ack-flood threshold

Default

The global threshold is 40000 for triggering destination-based ACK flood attack prevention.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the maximum receiving rate in pps for ACK packets that are destined for an IP address. The value range is 0 to 1000000. If you set the threshold value to 0, the destination-based ACK flood attack prevention is disabled.

Usage guidelines

With global ACK flood attack detection configured, the device is in attack detection state. When the receiving rate of ACK packets destined for an IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

The global threshold applies to global ACK flood attack detection. Adjust the threshold according to the application scenarios.

- If the number of ACK packets sent to a protected server, such as an HTTP or FTP server, is normally large, set a high threshold. A low threshold might affect the server services.
- For a network that is unstable or susceptible to attacks, set a low threshold.

Examples

Set the global threshold to 100 for triggering destination-based ACK flood attack prevention in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] ack-flood threshold 100
```

ack-flood action

ack-flood detect

ack-flood detect non-specific

attack-defense apply policy

Use **attack-defense apply policy** to apply an attack defense policy to a security zone.

Use **undo attack-defense apply policy** to restore the default.

Syntax

attack-defense apply policy *policy-name*

undo attack-defense apply policy

Default

No attack defense policy is applied to a security zone.

Views

Security zone view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies an attack defense policy by its name. The policy name is a case-insensitive string of 1 to 31 characters. Valid characters include uppercase and lowercase letters, digits, underscores (_), and hyphens (-).

Usage guidelines

A security zone can have only one attack defense policy applied. If you execute this command multiple times, the most recent configuration takes effect.

An attack defense policy can be applied to multiple security zones.

Examples

Apply attack defense policy **atk-policy-1** to security zone **DMZ**.

```
<Sysname> system-view
[Sysname] security-zone name DMZ
[Sysname-security-zone-DMZ] attack-defense apply policy atk-policy-1
```

attack-defense cpu-core action

Use **attack-defense cpu-core action** to specify an attack prevention action for CPU core protection.

Use **undo attack-defense cpu-core action** to restore the default.

Syntax

attack-defense cpu-core action { **drop** | **isolate** | **per-packet-balance** }

undo attack-defense cpu-core action

The following compatibility matrixes show the support of hardware platforms for this command:

Models	Command compatibility
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX5-HD6480	Yes
NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB680, NFNX3-HDB1080	No

Default

The attack prevention action for a CPU core is **drop**.

Views

System view

Predefined user roles

network-admin

Parameters

drop: Drops subsequent packets sent to a CPU core when the CPU core is attacked.

isolate: Isolates the flow that uses the most CPU time to lower its priority when a CPU core is attacked. This parameter takes effect on only one flow at a time.

The following compatibility matrixes show the support of hardware platforms for the **isolate** keyword:

Models	Parameter compatibility
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280	Yes
NFNX5-HD6480, NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB680,	No

Models	Parameter compatibility
NFNX3-HDB1080	

per-packet-balance: Distributes subsequent packets across CPU cores on a per-packet basis when a CPU core is attacked.

Usage guidelines

After the usage of a CPU core reaches the specified threshold and the shared queue of the driver is full, the system determines that an attack risk is present on the CPU core. Then, it processes the subsequent packets sent to the CPU core as follows:

- **Drop**—The CPU core uses all its available processing capability to process packets. The driver drops the packets beyond the maximum processing capability to decrease the CPU core usage. This action affects normal service processing.
- **Per-packet balance**—The CPU core uses all its available processing capability to process packets. Packets exceeding the maximum processing capability are sent to other CPU cores for load sharing on a per-packet basis. This action ensures normal service processing to some extent, but leads to risk of attacks on other CPU cores.
- **Isolate**—The driver isolates the flow that uses the most CPU time to lower the flow's processing priority. It sends the isolated packets to the CPU core for processing after the shared queue has no packets to process. This action ensures normal service processing to some extent, but it cannot significantly decrease the CPU usage because the packets in the public queue are still sent to the CPU core for processing.

To set CPU usage threshold per CPU core, execute the **context-capability inbound unicast total** command. For more information about this command, see context commands in *Virtual Technologies Command Reference*.

Examples

Specify **per-packet balance** as the attack prevention action for CPU core protection.

```
<Sysname> system-view
[Sysname] attack-defense cpu-core action per-packet-balance
```

Related commands

context-capability inbound unicast total (*Virtual Technologies Command Reference*)

display attack-defense cpu-core flow info

attack-defense ipcar action

Use **attack-defense ipcar action** to set defense actions upon threshold violations for monitored sessions.

Use **undo attack-defense ipcar action** to restore the default settings for a rate limit type.

Syntax

attack-defense ipcar { **destination** | **source** } { **ip** | **ipv6** } [**threshold** *threshold*] **action** { { **drop** | **logging** } * | **none** }

undo attack-defense ipcar { **destination** | **source** } { **ip** | **ipv6** }

Default

The packet receiving rate threshold is 5000 pps for each monitored session, and no defense actions are set.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

destination: Limits session creation rate on a per-destination basis.

source: Limits session creation rate on a per-source basis.

ip: Specifies IPv4 sessions.

ipv6: Specifies IPv6 sessions.

threshold *threshold*: Sets the packet receiving rate threshold, in pps. The value range is 1 to 500000, and the default is 5000.

logging: Enables logging upon threshold violations.

drop: Drops subsequent packets of sessions encountering threshold violations.

none: Takes no action.

Usage guidelines

The device supports limiting session creation rate based on the following criteria:

- Source IPv4 addresses.
- Source IPv6 addresses.
- Destination IPv4 addresses.
- Destination IPv6 addresses.

Make sure you define the same criteria as those defined in the **attack-defense ipcar session-rate-limit enable** command. Otherwise, the **attack-defense ipcar action** command does not take effect.

Examples

Limit sessions on a per-source IPv4 address, set the packet receiving rate threshold to 5000 pps, and set the **drop** action.

```
<Sysname> system-view
[Sysname] attack-defense ipcar source ip threshold 5000 action drop
```

Predefined user roles

network-admin

context-admin

Parameters

destination: Limits session creation rate on a per-destination basis.

source: Limits session creation rate on a per-source basis.

ip: Specifies IPv4 sessions.

ipv6: Specifies IPv6 sessions.

Usage guidelines

The device supports limiting session creation rate based on the following criteria:

- Source IPv4 addresses.
- Source IPv6 addresses.
- Destination IPv4 addresses.
- Destination IPv6 addresses.

With this feature enabled, the device enters attack detection state. It monitors the receiving rate of IP packets originating from or destined for an IP address. If the receiving rate reaches or exceeds the threshold, the device enters prevention state and takes defense actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state. To set the threshold, execute the **attack-defense ipcar action** command.

You cannot enable session creation rate limit based on both source and destination IP addresses on the same interface.

Examples

Enable session creation rate limit based on source IPv4 addresses on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] attack-defense ipcar destination ip session-rate-limit enable
```

Related commands

attack-defense ipcar action

attack-defense login block-timeout

Use **attack-defense login block-timeout** to set the block period during which a login attempt is blocked.

Use **undo attack-defense login block-timeout** to restore the default.

Syntax

attack-defense login block-timeout *minutes*

undo attack-defense login block-timeout

Default

The block period is 60 minutes.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

minutes: Specifies the block period in minutes, in the range of 1 to 2880.

Usage guidelines

After a user fails the maximum number of login attempts, login attack prevention triggers the blacklist module to add the user's IP address to the blacklist. The block period determines how long the user is on the blacklist. During the period, login attempts from the user are blocked.

Examples

Set the block period to 5 minutes.

```
<Sysname> system-view
[Sysname] attack-defense login block-timeout 5
```

attack-defense login enable

Use **attack-defense login enable** to enable login attack prevention.

Use **undo attack-defense login enable** to disable login attack prevention.

Syntax

attack-defense login enable

undo attack-defense login enable

Default

Login attack prevention is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

After a user fails the maximum number of login attempts, login attack prevention uses the blacklist to block the user from logging in during the block period.

For login attack prevention to take effect, you must enable the global blacklist feature.

Examples

Enable login attack prevention.

```
<Sysname> system-view
[Sysname] attack-defense login enable
```

Related commands

blacklist global enable

attack-defense login max-attempt

Use **attack-defense login max-attempt** to set the maximum number of successive login failures for each user.

Use **undo attack-defense login max-attempt** to restore the default.

Syntax

attack-defense login max-attempt *max-attempt*

undo attack-defense login max-attempt

Default

Login attack prevention detects a login attack if a user fails three successive login attempts.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

max-attempt: Specifies the maximum number of login failures. The value range is 1 to 60.

Usage guidelines

After a user fails the maximum number of login attempts, login attack prevention uses the blacklist to block the user from logging in during the block period.

For login attack prevention to take effect, you must enable the global blacklist feature.

The login failure counter for a user is reset after the user logs in successfully. If the device reboots, all login failure counters are reset.

Examples

Set the maximum number of successive login failures to five.

```
<Sysname> system-view
[Sysname] attack-defense login max-attempt 5
```

Related commands

attack-defense login enable

attack-defense login reauthentication-delay

Use **attack-defense login reauthentication-delay** to enable the login delay feature and set the delay period.

Use **undo attack-defense login reauthentication-delay** to restore the default.

Syntax

attack-defense login reauthentication-delay *seconds*

undo attack-defense login reauthentication-delay

Default

The login delay feature is disabled. The device does not delay accepting a login request from a user who has failed a login attempt.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the delay period in seconds, in the range of 4 to 60.

Usage guidelines

The login delay feature delays the device to accept a login request from a user after the user fails a login attempt. This feature can slow down login dictionary attacks.

The login delay feature is independent of the login attack prevention feature.

Examples

Enable the login delay feature and set the delay period to 5 seconds.

```
<Sysname> system-view
[Sysname] attack-defense login reauthentication-delay 5
```

attack-defense malformed-packet defend enable

Use **attack-defense malformed-packet defend enable** to enable malformed packet attack detection and prevention.

Use **undo attack-defense malformed-packet defend enable** to disable malformed packet attack detection and prevention.

Syntax

attack-defense malformed-packet defend enable

undo attack-defense malformed-packet defend enable

Default

Malformed packet attack detection and prevention is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature improves the single-packet attack prevention efficiency because it drops malformed packets of the following attacks without an attack defense policy match:

- IP impossible packet attack.
- TCP packet attacks that use TCP packets with different flag settings (all flags set, only the FIN flag set, invalid flags, no flags set, and both SYN and FIN flags set).
- Land attack and WinNuke attack.
- UDP fraggle attack, UDP bomb attack, and UDP snork attack.

For a single-packet attack that cannot be detected by this feature, you can use the **`signature detect`** command to enable detection and prevention specific to that attack.

Examples

Enable malformed packet attack detection and prevention.

```
<Sysname> system-view
[Sysname] attack-defense malformed-packet defend enable
```

Related commands

`signature detect`

attack-defense policy

Use **`attack-defense policy`** to create an attack defense policy and enter its view, or enter the view of an existing attack defense policy.

Use **`undo attack-defense policy`** to delete an attack defense policy.

Syntax

`attack-defense policy` *`policy-name`*

`undo attack-defense policy` *`policy-name`*

Default

No attack defense policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

`policy-name`: Assigns a name to the attack defense policy. The policy name is a case-insensitive string of 1 to 31 characters. Valid characters include uppercase and lowercase letters, digits, underscores (_), and hyphens (-).

Usage guidelines

CAUTION:

The default thresholds for triggering attack prevention might not be appropriate for your network. Set appropriate thresholds according to the actual application scenarios. Small thresholds might affect the Internet or webpage access speed. Large thresholds might make your network vulnerable to attacks.

Examples

Create attack defense policy **atk-policy-1** and enter its view.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1]
```

Related commands

attack-defense apply policy

display attack-defense policy

attack-defense signature log non-aggregate

Use **attack-defense signature log non-aggregate** to enable log non-aggregation for single-packet attack events.

Use **undo attack-defense signature log non-aggregate** to restore the default.

Syntax

attack-defense signature log non-aggregate

undo attack-defense signature log non-aggregate

Default

Log non-aggregation is disabled for single-packet attack events.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Log aggregation aggregates multiple logs generated during a period of time and sends one log. Logs that are aggregated must have the following attributes in common:

- Location where the attacks are detected: security zone.
- Attack type.
- Attack prevention action.
- Source and destination IP addresses.
- VPN instance to which the victim IP address belongs.

As a best practice, do not disable log aggregation. A large number of logs will consume the display resources of the console.

Examples

Enable log non-aggregation for single-packet attack events.

```
<Sysname> system-view
[Sysname] attack-defense signature log non-aggregate
```

Related commands

signature detect

attack-defense top-attack-statistics enable

Use **attack-defense top-attack-statistics enable** to enable the top attack statistics ranking feature.

Use **undo attack-defense top-attack-statistics enable** to disable the top attack statistics ranking feature.

Syntax

attack-defense top-attack-statistics enable

undo attack-defense top-attack-statistics enable

Default

The top attack statistics ranking feature is disabled.

Views

System view.

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature collects statistics about number of dropped attack packets based on attacker, victim, and attack type and ranks the statistics by attacker and victim.

To display the top attack statistics, use the **display attack-defense top-attack-statistics** command.

Examples

Enable the top attack statistics ranking feature.

```
<Sysname> system-view
[Sysname] attack-defense top-attack-statistics enable
```

Related commands

display attack-defense top-attack-statistics

blacklist destination-ip

Use **blacklist destination-ip** to add a destination IPv4 blacklist entry.

Use **undo blacklist destination-ip** to delete a destination IPv4 blacklist entry.

Syntax

blacklist destination-ip *destination-ip-address* [**vpn-instance** *vpn-instance-name*] [**timeout** *minutes*]

undo blacklist destination-ip *destination-ip-address* [**vpn-instance** *vpn-instance-name*]

Default

No destination IPv4 blacklist entries exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

destination-ip-address Specifies an IPv4 address for the destination blacklist entry. Packets destined for this address will be dropped.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the blacklist belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the blacklist is on the public network.

timeout *minutes*: Specifies the aging time for the destination blacklist entry, in the range of 1 to 10080 minutes. If you do not specify this option, the blacklist entry never ages out. You must delete it manually.

Usage guidelines

The **undo blacklist destination-ip** command deletes only manually added destination IPv4 blacklist entries. To delete dynamically added destination IPv4 blacklist entries, use the **reset blacklist destination-ip** command.

A destination blacklist entry with an aging time is not saved to the configuration file and cannot survive a reboot.

You can use the **display blacklist destination-ip** command to display all effective destination IPv4 blacklist entries.

Examples

Add a destination blacklist entry for IPv4 address 192.168.1.2 and set the aging time to 20 minutes for the entry.

```
<Sysname> system-view
[Sysname] blacklist ip 192.168.1.2 timeout 20
```

Syntax

blacklist logging enable

undo blacklist logging enable

Default

Logging is disabled for the blacklist feature.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

With logging enabled for the blacklist feature, the system outputs logs in the following situations:

- A blacklist entry is manually added.
- A blacklist entry is dynamically added by the scanning attack detection feature.
- A blacklist entry is manually deleted.
- A blacklist entry ages out.

A blacklist log records the following information:

- Source IP address of the blacklist entry.
- Remote IP address of the DS-Lite tunnel.
- VPN instance name.
- Reason for adding or deleting the blacklist entry.
- Aging time for the blacklist entry.

This command enables the attack detection and prevention module to log blacklist events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output blacklist logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view blacklist logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Enable logging for the blacklist feature.

```
<Sysname> system-view
[Sysname] blacklist logging enable
```

Add 192.168.1.2 to the blacklist. A log is output for the adding event.

```
[Sysname] blacklist ip 192.168.100.12
%Mar 13 03:47:49:736 2013 Sysname BLS/5/BLS_ENTRY_ADD:SrcIPAddr(1003)=192.168.100.12;
DSLiteTunnelPeer(1040)=--; RcvVPNInstance(1041)=--; TTL(1051)=;
Reason(1052)=Configuration.
```

Delete 192.168.1.2 from the blacklist. A log is output for the deletion event.

```
[Sysname] undo blacklist ip 192.168.100.12
%Mar 13 03:49:52:737 2013 Sysname BLS/5/BLS_ENTRY_DEL:SrcIPAddr(1003)=192.168.100.12;

blacklist object-group

Use **blacklist object-group** to add an address object group to the blacklist.

Use **undo blacklist object-group** to restore the default.

Syntax

blacklist object-group *object-group-name*

undo blacklist object-group

Default

No address object group is on the blacklist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

object-group-name: Specifies an address object group by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

This command must be used together with the address object group feature. For more information about address object groups, see object group configuration in *Security Configuration Guide*.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Add address object group **object-group1** to the blacklist.

```
<Sysname> system-view
[Sysname] blacklist object-group object-group1
```

blacklist user

Use **blacklist user** to add a user blacklist entry.

Use **undo blacklist user** to delete a user blacklist entry.

Syntax

blacklist user *user-name* [**domain** *domain-name*] [**timeout** *minutes*]

undo blacklist user *user-name* [**domain** *domain-name*]

Default

No user blacklist entries exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

user-name: Specifies a user by the username, a case-sensitive string of 1 to 55 characters. Packets sourced from this user will be dropped.

domain *domain-name*: Specifies a user identification domain by its name, a case-insensitive string of 1 to 255 characters. The user identification domain name cannot include question marks (?). If you do not specify a user identification domain, the user does not belong to any user identification domain.

timeout *minutes*: Specifies the aging time for the blacklist entry, in the range of 1 to 1000 minutes. If you do not specify this option, the blacklist entry never ages out. You must delete it manually.

Usage guidelines

The user blacklist feature must be used together with the user identification feature. For more information about user identification, see "Configuring user identification."

Examples

Add a user blacklist entry for user **usera** and set the aging time to 20 minutes for the entry.

```
<Sysname> system-view
[Sysname] blacklist user usera timeout 20
```

Add a user blacklist entry for user **usera** in user identification domain **domaina** and set the aging time to 20 minutes for the entry.

```

Parameters

dns: Specifies the DNS client verification feature.

dns-reply: Specifies the DNS response verification feature.

http: Specifies the HTTP client verification feature.

sip: Specifies the SIP client verification feature.

tcp: Specifies the TCP client verification feature.

destination-ip-address: Specifies the IPv4 address to be protected. All connection requests destined for this address are verified by the client verification feature.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the specified IPv4 address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the IPv4 address is on the public network.

port *port-number*: Specifies the port to be protected, in the range of 1 to 65535. If you do not specify this option, the verification feature protects ports for different protocols as follows:

- DNS client or DNS response verification protects port 53.
- HTTP client verification protects port 80.
- SIP client verification protects port 5060.
- TCP client verification protects all ports.

Usage guidelines

You can specify multiple protected IP addresses by using this command multiple times.

Examples

Configure TCP client verification to protect IPv4 address 2.2.2.5 and port 25.

```
<Sysname> system-view
[Sysname] client-verify tcp protected ip 2.2.2.5 port 25
```

Configure DNS client verification to protect IPv4 address 2.2.2.5 and port 50.

```
<Sysname> system-view
[Sysname] client-verify dns protected ip 2.2.2.5 port 50
```

Related commands

display client-verify protected ip

client-verify protected ipv6

Use **client-verify protected ipv6** to specify an IPv6 address to be protected by the client verification feature.

Use **undo client-verify protected ipv6** to remove an IPv6 address protected by the client verification feature.

Syntax

client-verify { **dns** | **dns-reply** | **http** | **sip** | **tcp** } **protected ipv6** *destination-ipv6-address* [**vpn-instance** *vpn-instance-name*] [**port** *port-number*]

undo client-verify { **dns** | **dns-reply** | **http** | **sip** | **tcp** } **protected ipv6** *destination-ipv6-address* [**vpn-instance** *vpn-instance-name*] [**port** *port-number*]

Default

The client verification feature does not protect any IPv6 addresses.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dns: Specifies the DNS client verification feature.

dns-reply: Specifies the DNS response verification feature.

http: Specifies the HTTP client verification feature.

sip: Specifies the SIP client verification feature.

tcp: Specifies the TCP client verification feature.

destination-ipv6-address: Specifies the IPv6 address to be protected. All connection requests destined for this address are verified by the client verification feature.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the specified IPv6 address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the IPv6 address is on the public network.

port *port-number*: Specifies the port to be protected, in the range of 1 to 65535. If you do not specify this option, the verification feature for different protocols protects ports as follows:

- DNS client or DNS response verification protects port 53.
- HTTP client verification protects port 80.
- SIP client verification protects port 5060.
- TCP client verification protects all ports.

Usage guidelines

You can specify multiple protected IPv6 addresses by using this command multiple times.

Examples

Configure TCP client verification to protect IPv6 address 2013::12 and port 23.

```
<Sysname> system-view
```

```
[Sysname] client-verify tcp protected ipv6 2013::12 port 23
```

Configure HTTP client verification to protect IPv6 address 2013::12.

```
<Sysname> system-view
[Sysname] client-verify http protected ipv6 2013::12
```

Related commands

display client-verify protected ipv6

client-verify tcp enable

Use **client-verify tcp enable** to enable TCP client verification on a security zone.

Use **undo client-verify tcp enable** to disable TCP client verification on a security zone.

Syntax

client-verify tcp enable [**mode** { **syn-cookie** | **safe-reset** }]

undo client-verify tcp enable

Default

TCP client verification is disabled on a security zone.

Views

Security zone view

Predefined user roles

network-admin

context-admin

Parameters

mode: Specifies a working mode for TCP client verification. If you do not specify this keyword, the SYN cookie mode is used.

syn-cookie: Specifies the SYN cookie mode. In this mode, bidirectional TCP proxy is enabled.

safe-reset: Specifies the safe reset mode. In this mode, unidirectional TCP proxy is enabled.

Usage guidelines

Enable TCP client verification on the security zone that is connected to the external network. This feature protects internal servers against TCP flood attacks, including SYN flood attacks, SYN-ACK flood attacks, RST flood attacks, FIN flood attacks, and ACK flood attacks.

For TCP client verification to collaborate with TCP flood attack prevention, specify **client-verify** as the TCP flood attack prevention action. During collaboration, the device adds the victim IP address to the protected IP list and verifies the untrusted sources if it detects a TCP flood attack. You can use the **display client-verify tcp protected ip** command to display the protected IP list for TCP client verification.

TCP client verification supports the following modes:

- **Safe reset**—Enables unidirectional TCP proxy for packets only from TCP connection initiators.
- **SYN cookie**—Enables bidirectional TCP proxy for packets from both TCP clients and TCP servers.

Choose a TCP proxy mode according to the network scenarios. If packets from clients pass through the TCP proxy device, but packets from servers do not, specify the safe reset mode. If packets from clients and servers both pass through the TCP proxy device, specify either safe reset or SYN cookie. TCP proxy must be enabled on input security zones. Otherwise, TCP connections cannot be established correctly.

Examples

Enable TCP client verification in safe reset mode on security zone **DMZ**.

```
<Sysname> system-view
[Sysname] security-zone name DMZ
[Sysname-security-zone-DMZ] client-verify tcp enable mode safe-reset
```

Table 1 Command output

Field	Description
Hardware Buffer Full	Whether the shared hardware queue of the driver is full. • **Yes**. • **No**.
TimeStamp	Time when information collection finishes.
CPU ID	ID of the CPU core to which the flow was sent.
SMAC	Source MAC address of the attack flow.
DMAC	Destination MAC address of the attack flow.
VLAN ID	ID of the VLAN to which the attack flow belongs.
Interface	Ingress interface of the attack flow.
SIP	Source IP address of the attack flow.
DIP	Destination IP address of the attack flow.
Pro	Protocol type of the attack flow.
SPort	Source port of the attack flow. This field is available only when the protocol type is TCP or UDP.
DPort	Destination port of the attack flow. This field is available only when the protocol type is TCP or UDP.
CPU Usage	Percentage of the CPU time used by the attack flow.
IfIsolate	Whether the isolation entry has been deployed to the hardware successfully. • **True**—Deployment succeeded. • **False**—Deployment failed.

context-operator

Parameters

ack-flood: Specifies ACK flood attack.

dns-flood: Specifies DNS flood attack.

dns-reply-flood: Specifies DNS response flood attack.

fin-flood: Specifies FIN flood attack.

flood: Specifies all IPv4 flood attacks.

http-flood: Specifies HTTP flood attack.

icmp-flood: Specifies ICMP flood attack.

rst-flood: Specifies RST flood attack.

sip-flood: Specifies SIP flood attack.

syn-ack-flood: Specifies SYN-ACK flood attack.

syn-flood: Specifies SYN flood attack.

udp-flood: Specifies UDP flood attack.

ip-address: Specifies a protected IPv4 address. If you do not specify an IPv4 address, this command displays flood attack detection and prevention statistics for all protected IPv4 addresses.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the protected IPv4 address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the protected IPv4 address is on the public network.

security-zone *zone-name*: Specifies a security zone by its name. The *zone-name* argument is a case-insensitive string of 1 to 31 characters. It cannot contain hyphens (-).

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv4 flood attack detection and prevention statistics for all member devices.

count: Displays the number of flood attack prevention entries.

Usage guidelines

The device collects statistics about protected IP addresses for flood attack detection and prevention. The attackers' IP addresses are not recorded.

Examples

Display all IPv4 flood attack detection and prevention statistics.

```
<Sysname> display attack-defense flood statistics ip
Slot 1:

IPv6 address     VPN             Detected on          State
1::5             asd             Local                Normal
17::14           --              GE1/0/2              Normal
```

Display the number of IPv6 HTTP slow attack prevention entries for protected IPv6 addresses.

```
<Sysname> display attack-defense http-slow-attack statistics ipv6 count
Slot 1:
Totally 5 HTTP slow attack entries.
Slot 2:
Totally 3 HTTP slow attack entries.
```

Table 6 Command output

Field	Description
IPv6 address	Destination IPv6 address.
VPN	MPLS L3VPN instance to which the destination IPv6 address belongs. If the destination IPv6 address is on the public network, this field displays hyphens (--).
Detected on	Where the attack is detected: the device (**Local**) or an interface.

Field	Description
State	Whether the interface or local device is attacked: • **Attacked**—It is being attacked. • **Normal**—It is not attacked.
Totally 2 HTTP slow attack entries	Total number of IPv6 HTTP slow attack prevention entries.

display attack-defense http-slow-attack statistics ipv6

Use **display attack-defense http-slow-attack statistics ipv6** to display statistics about IPv6 HTTP slow attack detection and prevention.

Syntax

display attack-defense http-slow-attack statistics ipv6 [*ipv6-address* [**vpn-instance** *vpn-instance-name*]] [**security-zone** *zone-name*] [**slot** *slot-number*] [**count**]

Parameters

ipv6-address: Specifies a destination IPv6 address.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the destination IPv6 address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the destination IPv6 address is on the public network.

security-zone *zone-name*: Specifies a security zone by its name. The *zone-name* argument is a case-insensitive string of 1 to 31 characters. It cannot contain hyphens (-).

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays statistics about IPv6 HTTP slow attack detection and prevention for all member devices.

count: Displays the number of IPv6 HTTP slow attack prevention entries for matching protected IPv6 addresses.

Examples

Display statistics about IPv6 HTTP slow attack detection and prevention.

```
<Sysname> display attack-defense http-slow-attack statistics ipv6
Slot 1:
IPv6 address     VPN             Detected on          State
2000::1011       asd             Trust1               Normal
1::4             --              Trust4               Normal
Slot 2:
IPv6 address     VPN             Detected on          State
```

```
2000::1011       asd             Trust1               Normal
1::4             --              Trust4               Normal
```

Display the number of IPv6 HTTP slow attack prevention entries for protected IPv6 addresses.

```
<Sysname> display attack-defense http-slow-attack statistics ipv6 count
Slot 1:
Totally 5 HTTP slow attack entries.
Slot 2:
Totally 3 HTTP slow attack entries.
```

Table 7 Command output

Field	Description
IPv6 address	Destination IPv6 address.
VPN	MPLS L3VPN instance to which the destination IPv6 address belongs. If the destination IPv6 address is on the public network, this field displays hyphens (--).
Detected on	Name of the security zone where the attack is detected.
State	Whether the security zone is attacked: • **Attacked**. • **Normal**.
Totally 5 HTTP slow attack entries	Total number of IPv6 HTTP slow attack prevention entries.

display attack-defense malformed-packet statistics

Use **display attack-defense malformed-packet statistics** to display statistics about malformed packets.

Syntax

display attack-defense malformed-packet statistics [**slot** *slot-number*]

display attack-defense policy

Use **`display attack-defense policy`** to display attack defense policy configuration.

Syntax

`display attack-defense policy` [*`policy-name`*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`policy-name`: Specifies an attack defense policy by its name. The policy name is a case-insensitive string of 1 to 31 characters. Valid characters include uppercase and lowercase letters, digits, underscores (_), and hyphens (-). If no attack defense policy is specified, this command displays brief information about all attack defense policies.

Usage guidelines

This command output includes the following configuration information about an attack defense policy:

- Whether attack detection is enabled.
- Attack prevention actions.
- Attack prevention trigger thresholds.

Examples

Display the configuration of attack defense policy **abc**.

```
<Sysname> display attack-defense policy abc
          Attack-defense Policy Information
------------------------------------------------------------------------
Policy name                       : abc
Applied list                      : Trust
------------------------------------------------------------------------
Exempt IPv4 ACL:                 : Not configured
Exempt IPv6 ACL:                 : vip
------------------------------------------------------------------------
  Actions: CV-Client verify  BS-Block source  L-Logging  D-Drop  N-None
```

Table 9 Command output

Field	Description
Policy name	Name of the attack defense policy.
Applied list	Locations to which the attack defense policy is applied.
Exempt IPv4 ACL	IPv4 ACL used for attack detection exemption.
Exempt IPv6 ACL	IPv6 ACL used for attack detection exemption.
Actions	Attack prevention actions: • **CV**—Client verification. • **BS**—Blocking sources. • **L**—Logging. • **D**—Dropping packets. • **N**—No action.
Signature attack defense configuration	Configuration information about single-packet attack detection and prevention.
Signature name	Type of the single-packet attack.
Defense	Whether attack detection is enabled.
Level	Level of the single-packet attack, **info**, **low**, **medium**, or **high**. Currently, no high-level single-packet attacks exist.
Actions	Prevention actions against the scanning attack: • **L**—Logging. • **D**—Dropping packets. • **N**—No action.
Large ICMPv6	Large ICMPv6 attack.
ICMPv6 echo request	ICMPv6 echo request attack.
ICMPv6 echo reply	ICMPv6 echo reply attack.
ICMPv6 group membership query	ICMPv6 group membership query attack.
ICMPv6 group membership report	ICMPv6 group membership report attack.
ICMPv6 group membership reduction	ICMPv6 group membership reduction attack.

Field	Description
ICMPv6 destination unreachable	ICMPv6 destination unreachable attack.
ICMPv6 time exceeded	ICMPv6 time exceeded attack.
ICMPv6 parameter problem	ICMPv6 parameter problem attack.
ICMPv6 packet too big	ICMPv6 packet too big attack.
IPv6 extension header abnormal	Abnormal IPv6 extension header attack.
IPv6 extension header exceeded	IPv6 extension header exceeded attack.
Limit	Upper limit of IPv6 extension headers.
Scan attack defense configuration	Configuration information about scanning attack detection and prevention.
Preset defense	Configuration information about predefined scanning attack detection and prevention.
Defense	Whether scanning attack detection is enabled.
Level	Level of the scanning attack detection, **low**, **medium**, or **high**.
User-defined defense	Configuration information about user-defined scanning attack detection and prevention.
Port scan defense	Status of port scan attack prevention, which can be **Enabled** or **Disabled**.
Port scan defense threshold	Threshold for triggering port scan attack prevention.
IP sweep defense	Status of IP sweep attack prevention, which can be **Enabled** or **Disabled**.
IP sweep defense threshold	Threshold for triggering IP sweep attack prevention.
Period	Scanning attack detection cycle in seconds.
Actions	Scanning attack prevention actions: • **BS**—Blocking sources. • **D**—Dropping packets. • **L**—Logging.
Flood attack defense configuration	Configuration information about flood attack detection and prevention.
Flood type	Type of the flood attack: • ACK flood. • DNS flood. • DNS reply flood. • FIN flood. • ICMP flood. • ICMPv6 flood. • SYN flood. • SYN-ACK flood. • UDP flood. • RST flood. • HTTP flood. • SIP flood.
Global dest/src thres(pps)	Global thresholds for triggering the destination-based and source-based flood attack prevention. The default is 1000 pps.

Field	Description
Global actions	Global prevention actions against the flood attack: • **D**—Dropping packets. • **L**—Logging. • **CV**—Client verification. If no actions are configured, this field displays a hyphen (**-**).
Service ports	Ports that are protected against the flood attack. This field displays port numbers only for the DNS and HTTP flood attacks. For other flood attacks, this field displays a hyphen (-).
Non-specific	Whether the global flood attack detection is enabled.
Flood attack defense for protected IP addresses	Configuration of the IP address-specific flood attack detection and prevention.
Address	Protected IP address.
VPN instance	MPLS L3VPN instance to which the protected IP address belongs. If no MPLS L3VPN instance is specified, this field does not display.
Thres(pps)	Threshold for triggering the flood attack prevention, in units of packets sent to the IP address per second. If no threshold is specified, this field displays **1000**.
Actions	Flood attack prevention actions: • **CV**—Client verification. • **BS**—Blocking sources. • **D**—Dropping packets. • **L**—Logging. • **N**—No action.
Ports	Ports that are protected against the flood attack. This field displays port numbers only for the DNS and HTTP flood attacks. For other flood attacks, this field displays a hyphen (-).
HTTP slow attack defense configuration	Configuration information about the global HTTP slow attack detection and prevention.
Non-specific	Whether global HTTP slow attack detection is enabled.
Global threshold	Global threshold settings: • **Alert-number**—HTTP concurrent connection threshold. If this threshold is not specified, the field displays **5000**. • **Content-length**—Threshold for the **Content-Length** field value. If this threshold is not specified, the field displays **10000**. • **Payload-length**—Payload size threshold. If this threshold is not specified, the field displays **50**. • **Packet-number**—Threshold of abnormal packets. If this threshold is not specified, the field displays **10**.
Global period	Global HTTP slow attack detection period.
Global action	Global HTTP slow attack prevention actions: • **BS**—Blocking sources. • **L**—Logging.
Ports	Ports protected by the global HTTP slow attack prevention. If protected no ports are specified, the field displays **80**.
HTTP slow attack defense configuration for protected IP addresses	Configuration of the IP address-specific HTTP slow attack detection and prevention.

Field	Description
Address	Protected IP address.
VPN instance	VPN instance to which the protected IP address belongs. If no VPN instance is specified, this field does not display.
Threshold (AN/CL/PL/PN)	Threshold parameter settings for IP address-specific HTTP slow attack detection. Full spellings for threshold parameters are as follows: • **AN**—Alert number. • **CL**—Content length. • **PL**—Payload length. • **PN**—Packet number. If a parameter threshold is not specified, the global threshold for this parameter is displayed.
Period	IP address-specific HTTP slow attack detection period. If this period is not specified, the field displays the global detection period.
Actions	IP address-specific HTTP slow attack prevention actions: • **BS**—Blocking sources. • **L**—Logging. If no actions are specified, this field displays the global prevention actions.
Ports	Ports protected by the IP address-specific HTTP slow attack prevention. If no ports are specified, the field displays ports protected by the global HTTP slow attack prevention.

Display brief information about all attack defense policies.

Parameters

policy-name: Specifies an attack defense policy by its name. The policy name is a case-insensitive string of 1 to 31 characters. Valid characters include uppercase and lowercase letters, digits, underscores (_), and hyphens (-).

ack-flood: Specifies ACK flood attack.

dns-flood: Specifies DNS flood attack.

dns-reply-flood: Specifies DNS response flood attack.

fin-flood: Specifies FIN flood attack.

flood: Specifies all IPv4 flood attacks.

http-flood: Specifies HTTP flood attack.

icmp-flood: Specifies ICMP flood attack.

rst-flood: Specifies RST flood attack.

sip-flood: Specifies SIP flood attack.

syn-ack-flood: Specifies SYN-ACK flood attack.

syn-flood: Specifies SYN flood attack.

udp-flood: Specifies UDP flood attack.

ip-address: Specifies a protected IPv4 address. If you do not specify an IPv4 address, this command displays information about all protected IPv4 addresses.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the IPv4 address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the IPv4 address is on the public network.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about IPv4 addresses protected by flood attack detection and prevention for all IRF member devices.

count: Displays the number of matching IPv4 addresses protected by flood attack detection and prevention.

Examples

Display information about all IPv4 addresses protected by flood attack detection and prevention in attack defense policy **abc**.

```
<Sysname> display attack-defense policy abc flood ip
Slot 1:
IP address      VPN instance     Type          Rate threshold(PPS) Dropped
123.123.123.123 --               SYN-ACK-FLOOD 100                 4294967295
```

```
201.55.7.45     --              ICMP-FLOOD    100                10
192.168.11.5    --              DNS-FLOOD     23                 100
10.168.200.5    --              SIP-FLOOD     100                102556
Slot 2:
IP address      VPN instance    Type          Rate threshold(PPS) Dropped
123.123.123.123 --              SYN-ACK-FLOOD 100                2543
201.55.7.45     --              ICMP-FLOOD    100                122
192.168.11.5    --              DNS-FLOOD     23                 0
```

Display the number of IPv4 addresses protected by flood attack detection and prevention in attack defense policy **abc**.

```
<Sysname> display attack-defense policy abc flood ip count
Slot 1:
Totally 3 flood protected IP addresses.
Slot 2:
Totally 0 flood protected IP addresses.
```

Table 11 Command output

Field	Description
Totally 3 flood protected IP addresses	Total number of the IPv4 addresses protected by flood attack detection and prevention.
IP address	Protected IPv4 address.
VPN instance	MPLS L3VPN instance to which the protected IPv4 address belongs. If the protected IPv4 address is on the public network, this field does not display.
Type	Type of the flood attack.
Rate threshold(PPS)	Threshold for triggering the flood attack prevention, in units of packets sent to the IP address per second. If no rate threshold is set, this field displays **1000**.
Dropped	Number of dropped attack packets. If the prevention action is logging, this field displays **0**.

display attack-defense policy ipv6

Use **display attack-defense policy ipv6** to display information about IPv6 addresses protected by flood attack detection and prevention.

Syntax

display attack-defense policy *policy-name* { **ack-flood** | **dns-flood** | **dns-reply-flood** | **fin-flood** | **flood** | **http-flood** | **icmpv6-flood** | **rst-flood** | **sip-flood** | **syn-ack-flood** | **syn-flood** | **udp-flood** } **ipv6** [*ipv6-address* [**vpn** *vpn-instance-name*]] [**slot** *slot-number*]] [**count**]

Slot 1:
IPv6 address    VPN instance     Type          Rate threshold(PPS) Dropped
2013::127f      --               SYN-ACK-FLOOD 100                 4294967295
2::5            --               ACK-FLOOD     100                 10
1::5            --               ACK-FLOOD     100                 23
10::15          --               SIP-FLOOD     100                 1002
Slot 2:
IPv6 address    VPN instance     Type          Rate threshold(PPS) Dropped
2013::127f      --               SYN-ACK-FLOOD 100                 5465
2::5            --               ACK-FLOOD     100                 0
1::5            --               ACK-FLOOD     100                 122
```

Display the number of IPv6 addresses protected by flood attack detection and prevention in attack defense policy **abc**.

```
<Sysname> display attack-defense policy abc flood ipv6 count
Slot 1:
Totally 3 flood protected IP addresses.
Slot 2:
Totally 0 flood protected IP addresses.
```

Table 12 Command output

Field	Description
Totally 3 flood protected IP addresses	Total number of the IPv6 addresses protected by flood attack detection and prevention.
IPv6 address	Protected IPv6 address.
VPN instance	MPLS L3VPN instance to which the protected IPv6 address belongs. If the protected IPv6 address is on the public network, this field does not display.
Type	Type of the flood attack.
Rate threshold(PPS)	Threshold for triggering the flood attack prevention, in units of packets sent to the IPv6 address per second. If no rate threshold is set, this field displays **1000**.
Dropped	Number of dropped attack packets. If the prevention action is logging, this field displays **0**.

display attack-defense scan attacker ip

Use **display attack-defense scan attacker ip** to display information about IPv4 scanning attackers.

Syntax

display attack-defense scan attacker ip [**security-zone** *zone-name* [**slot** *slot-number*]] [**count**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

security-zone *zone-name*: Specifies a security zone by its name. The *zone-name* argument is a case-insensitive string of 1 to 31 characters. It cannot contain hyphens (-).

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about IPv4 scanning attackers for all member devices.

count: Displays the number of matching IPv4 scanning attackers.

Usage guidelines

If you do not specify any parameters, this command displays information about all IPv4 scanning attackers.

Examples

Display information about all IPv4 scanning attackers.

```
<Sysname> display attack-defense scan attacker ip
Slot 1:
IP addr(DslitePeer) VPN instance     Protocol         Detected on  Duration(min)
192.168.31.2(--)    --               TCP              DMZ          1284
2.2.2.3(--)         --               UDP              DMZ          23
Slot 2:
IP addr(DslitePeer) VPN instance     Protocol         Detected on  Duration(min)
192.168.1.100(--)   --               TCP              DMZ          1586
202.2.1.172(--)     --               UDP              DMZ          258
```

Display the number of IPv4 scanning attackers.

```
<Sysname> display attack-defense scan attacker ip count
Slot 1:
Totally 3 attackers.
Slot 2:
Totally 0 attackers.
```

Table 13 Command output

Field	Description
Totally 3 attackers	Total number of IPv4 scanning attackers.
IP addr(DslitePeer)	The **IP addr** field displays the IPv4 address of the attacker. The **DslitePeer** field displays the DS-Lite tunnel source IPv6 address of the attacker in a DS-Lite network. In other situations, this field displays hyphens (**--**).
VPN instance	MPLS L3VPN instance to which the attacker's IPv4 address belongs. If the IPv4 address is on the public network, this field does not display.
Protocol	Name of the protocol.
Detected on	Name of the security zone where the attack is detected.
Duration(min)	The amount of time the attack lasts, in minutes.

```

Table 15 Command output

Field	Description
AttackType	Type of the attack.
AttackTimes	Number of times that the attack occurred. This command output displays only attacks that are detected.
Dropped	Number of dropped packets.
ICMPv6 flood	ICMPv6 flood attack. This field is not displayed when no ICMPv6 flood attack is detected.
Large ICMPv6	Large ICMPv6 attack. This field is not displayed when no large ICMPv6 attack is detected.
ICMPv6 echo request	ICMPv6 echo request attack. This field is not displayed when no ICMPv6 echo request attack is detected.
ICMPv6 echo reply	ICMPv6 echo reply attack. This field is not displayed when no ICMPv6 echo reply attack is detected.
ICMPv6 group membership query	ICMPv6 group membership query attack. This field is not displayed when no ICMPv6 group membership query attack is detected.
ICMPv6 group membership report	ICMPv6 group membership report attack. This field is not displayed when no ICMPv6 group membership report attack is detected.
ICMPv6 group membership reduction	ICMPv6 group membership reduction attack. This field is not displayed when no ICMPv6 group membership reduction attack is detected.
ICMPv6 destination unreachable	ICMPv6 destination unreachable attack. This field is not displayed when no ICMPv6 destination unreachable attack is detected.
ICMPv6 time exceeded	ICMPv6 time exceeded attack. This field is not displayed when no ICMPv6 time exceeded attack is detected.
ICMPv6 parameter problem	ICMPv6 parameter problem attack. This field is not displayed when no ICMPv6 parameter problem attack is detected.
ICMPv6 packet too big	ICMPv6 packet too big attack. This field is not displayed when no ICMPv6 packet too big attack is detected.
IPv6 extension header abnormal	Abnormal IPv6 extension header attack. This field is not displayed when no abnormal IPv6 extension header attack is detected.
IPv6 extension header exceeded	IPv6 extension header exceeded attack. This field is not displayed when no IPv6 extension header exceeded attack is detected.

`reset attack-defense statistics security-zone`

display attack-defense top-attack-statistics

Use **`display attack-defense top-attack-statistics`** to display top 10 attack statistics.

Syntax

display attack-defense top-attack-statistics { **last-1-hour** | **last-24-hours** | **last-30-days** } [**by-attacker** | **by-type** | **by-victim**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

last-1-hour: Specifies the most recent 1 hour.

last-24-hours: Specifies the most recent 24 hours.

last-30-days: Specifies the most recent 30 days.

by-attacker: Displays top 10 attack statistics by attacker.

by-type: Displays all attack statistics by attack type.

by-victim: Displays top 10 attack statistics by victim.

Usage guidelines

If you do not specify the **by-attacker**, **by-type**, or **by-victim** keyword, this command displays attack statistics by attacker, victim, attack type.

Examples

Display top 10 attack statistics in the most recent 1 hour.

```
<Sysname> display attack-defense top-attack-statistics last-1-hour
Top attackers:
No.     VPN instance   Attacker IP         Attacks
1                      200.200.200.55      21
2                      200.200.200.21      16
3                      200.200.200.133     12
4                      200.200.200.19      10
5                      200.200.200.4       8
6                      200.200.200.155     8

display blacklist destination-ip

Use **display blacklist destination-ip** to display destination IPv4 blacklist entries.

Syntax

display blacklist destination-ip [*destination-ip-address* [**vpn-instance** *vpn-instance-name*]] [**slot** *slot-number*] [**count**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

destination-ip-address: Specifies a destination IPv4 address.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the destination IPv4 address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays destination IPv4 blacklist entries for all member devices.

count: Displays the number of matching destination IPv4 blacklist entries.

Usage guidelines

If you do not specify any parameters, this command displays all destination IPv4 blacklist entries.

Examples

Display all destination IPv4 blacklist entries.

```
<Sysname> display blacklist destination-ip
Slot 1:
IP address      VPN instance   Type    Aging (sec)  Dropped
192.168.11.5    --             Dynamic 10           353452
123.123.123.123 --             Dynamic 123          4294967295
201.55.7.45     --             Manual  Never        14478
Slot 2:
IP address      VPN instance   Type    Aging (sec)  Dropped
123.55.123.7    --             Dynamic 123       164698
201.55.7.33     --             Manual  Never     845969
```

Display the total number of destination IPv4 blacklist entries.

```
<Sysname> display blacklist destination-ip count
Slot 1:
Totally 3 blacklist entries.
Slot 2:
Totally 2 blacklist entries.
```

Table 17 Command output

Field	Description
IP address	IPv4 address in the destination blacklist entry.
VPN instance	MPLS L3VPN instance to which the blacklisted IPv4 address belongs. If the blacklisted IPv4 address is on the public network, this field does not display.
Type	Type of the destination IPv4 blacklist entry: • **Dynamic**—Dynamically generated. • **Manual**—Manually configured.
Aging (sec)	Remaining aging time of the destination IPv4 blacklist entry, in seconds. If no aging time is set for the entry, this field displays **Never**.
Dropped	Number of dropped packets that are destined for the IPv4 address.
Totally 3 blacklist entries.	Total number of destination IPv4 blacklist entries.

Related commands

context-operator

Parameters

destination-ipv6-address: Specifies a destination IPv6 address.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the destination IPv6 address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays destination IPv6 blacklist entries for all member devices.

count: Displays the number of matching destination IPv6 blacklist entries.

Usage guidelines

If you do not specify any parameters, this command displays all destination IPv6 blacklist entries.

Examples

Display all destination IPv6 blacklist entries.

```
<Sysname> display blacklist destination-ipv6
Slot 1:
IPv6 address         VPN instance      Type    Aging (sec)  Dropped
1::4                 --                Manual  Never        14478
1::5                 --                Dynamic 10           353452
2013:fe07:221a:4011: --                Dynamic 123          4294967295
2013:fe07:221a:4011
Slot 2:
IPv6 address         VPN instance      Type    Aging (sec)  Dropped
1::3                 --                Manual  Never        74679
20::33               --                Dynamic 10           1697898
```

Display the total number of destination IPv6 blacklist entries.

```
<Sysname> display blacklist destination-ipv6 count
Slot 1:
Totally 3 blacklist entries.
Slot 2:
Totally 2 blacklist entries.
```

Table 18 Command output

Field	Description
IPv6 address	IPv6 address in the destination blacklist entry.

Field	Description
VPN instance	MPLS L3VPN instance to which the blacklisted IPv6 address belongs. If the blacklisted IPv6 address is on the public network, this field does not display.
Type	Type of the destination IPv6 blacklist entry: • **Dynamic**—Dynamically generated. • **Manual**—Manually configured.
Aging (sec)	Remaining aging time of the destination IPv6 blacklist entry, in seconds. If no aging time is set for the entry, this field displays **Never**.
Dropped	Number of dropped packets that are destined for the IPv6 address.
Totally 3 blacklist entries.	Total number of destination IPv6 blacklist entries.

Parameters

source-ip-address: Specifies a source IPv4 address.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the IPv4 address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the IPv4 address is on the public network.

ds-lite-peer *ds-lite-peer-address*: Specifies the IPv6 address of the B4 element of the DS-Lite tunnel that transmits packets from the blacklisted IPv4 address.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays source IPv4 blacklist entries for all member devices.

count: Displays the number of matching source IPv4 blacklist entries.

Usage guidelines

If you do not specify any parameters, this command displays all source IPv4 blacklist entries.

Examples

Display all source IPv4 blacklist entries.

```
<Sysname> display blacklist ip
Slot 1:
IP address      VPN instance   DS-Lite tunnel peer  Type    TTL(sec) Dropped
192.168.11.5    --             --                   Dynamic 10       353452
123.123.123.123 --             2013::fe07:221a:4011 Dynamic 123      4294967295
201.55.7.45     --             2013::1              Manual  Never    14478
Slot 2:
IP address      VPN instance   DS-Lite tunnel peer  Type    TTL(sec) Dropped
123.55.123.7    --             --                   Dynamic 123      164698
201.55.7.33     --             --                   Manual  Never    845969
```

Display the total number of source IPv4 blacklist entries.

```
<Sysname> display blacklist ip count
Slot 1:
Totally 3 blacklist entries.
Slot 2:
Totally 2 blacklist entries.
```

Table 19 Command output

Field	Description
IP address	IPv4 address in the source blacklist entry.
VPN instance	MPLS L3VPN instance to which the blacklisted IPv4 address belongs. If the blacklisted IPv4 address is on the public network, this field does not display.
DS-Lite tunnel peer	IPv6 address of the DS-Lite tunnel peer. If the device is the AFTR of a DS-Lite tunnel, this field displays the IPv6 address of the B4 element from which the packet comes. In other situations, this field displays hyphens (**--**).
Type	Type of the source IPv4 blacklist entry: • **Dynamic**—Dynamically generated. • **Manual**—Manually configured.
TTL(sec)	Remaining aging time of the source IPv4 blacklist entry, in seconds. If no aging time is set for the entry, this field displays **Never**.
Totally 3 blacklist entries	Total number of source IPv4 blacklist entries.

context-operator

Parameters

user-name: Specifies a user by the username, a case-sensitive string of 1 to 55 characters. If you do not specify a user, this command displays all user blacklist entries.

domain *domain-name*: Specifies a user identification domain by its name, a case-insensitive string of 1 to 255 characters. The user identification domain name cannot include question marks (?). If you do not specify a user identification domain, this command displays user blacklist entries that do not belong to any user identification domains.

count: Displays the number of matching user blacklist entries.

Examples

Display all user blacklist entries.

```
<Sysname> display blacklist user
User name    Domain name      Type       TTL(sec)  Dropped
Alex         domaina          Manual     10        353452
Bob                           Manual     123       4294967295
Cary                          Manual     Never     14478
```

Display the user blacklist entry for user **Alex** in user identification domain **domaina**.

```
<Sysname> display blacklist user Alex domain domaina
User name   Domain name      Type       TTL(sec)   Dropped
Alex        domaina          Manual     10         353452
```

Display the number of user blacklist entries.

```
<Sysname> display blacklist user count
Totally 3 blacklist entries.
```

Table 21 Command output

Field	Description
Username	Username in the user blacklist entry.
Domain name	User identification domain to which the user belongs.
Type	Type of the user blacklist entry. Only the manual mode is supported.
TTL(sec)	Remaining aging time of the user blacklist entry, in seconds. If no aging time is set for the entry, this field displays **Never**.
Dropped	Number of dropped packets sourced from the user.
Totally 3 blacklist entries	Total number of user blacklist entries.

Parameters

`dns`: Specifies the DNS client verification feature.

`dns-reply`: Specifies the DNS response verification feature.

`http`: Specifies the HTTP client verification feature.

`sip`: Specifies the SIP client verification feature.

`tcp`: Specifies the TCP client verification feature.

`ip-address`: Specifies a protected IPv4 address. If you do not specify an IPv4 address, this command displays all protected IPv4 addresses.

`vpn-instance` *`vpn-instance-name`*: Specifies the MPLS L3VPN instance to which the protected IPv4 address belongs. The *`vpn-instance-name`* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the protected IPv4 address is on the public network.

port *port-number*: Specifies a protected port in the range of 1 to 65535. If you do not specify a port, this command displays protected IPv4 addresses with default ports. The default port for DNS client verification is port 53, the default port for HTTP client verification is port 80, and the default port for TCP client verification is all ports.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays protected IPv4 addresses for all member devices.

count: Displays the number of matching protected IPv4 addresses.

Examples

Display the protected IPv4 addresses for TCP client verification.

```
<Sysname> display client-verify tcp protected ip
Slot 1:
IP address           VPN instance     Port  Type    Requested   Trusted
192.168.11.5         --               23    Dynamic 353452      555
123.123.123.123      --               65535 Dynamic 4294967295  15151
201.55.7.45          --               10    Manual  15000       222
Slot 2:
IP address           VPN instance     Port  Type    Requested   Trusted
192.168.11.5         --               23    Dynamic 46790       78578
201.55.7.45          --               10    Dynamic 2368        7237
123.123.123.123      --               65535 Manual  24587       1385
```

Display the number of protected IPv4 addresses for TCP client verification.

```
<Sysname> display client-verify tcp protected ip count
Slot 1:
Totally 3 protected IP addresses.
Slot 2:
Totally 0 protected IP addresses.
```

Table 22 Command output

Field	Description
Totally 3 protected IP addresses	Total number of protected IPv4 addresses.
IP address	Protected IPv4 address.
VPN instance	MPLS L3VPN instance to which the protected IPv4 address belongs. If the protected IPv4 address is on the public network, this field does not display.
Port	Port protected by TCP client verification. If TCP client verification protects all ports, this field displays **any**.
Type	Type of the protected IPv4 address, **Manual** or **Dynamic**.
Requested	Number of packets destined for the protected IPv4 address.
Trusted	Number of packets that passed the client verification.

TTL(sec)	Remaining aging time of the trusted IPv6 address, in seconds.

display whitelist object-group

Use **display whitelist object-group** to display statistics about packets that match the address object groups on the whitelist.

Syntax

display whitelist object-group [*object-group-name*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

object-group-name: Specifies an address object group by its name, a case-insensitive string of 1 to 63 characters. If you do not specify an address object group, this command displays statistics about packets that match all address object groups on the whitelist.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays statistics for all member devices.

Usage guidelines

If you do not specify any parameters, this command displays statistics about packets that match all address object groups on the whitelist.

Examples

Display statistics about packets that match all address object groups on the whitelist.

```
<Sysname> display whitelist object-group
Slot 1:
Object group              Type          Matching Packets
objgrp-1                  IPv4          15696
objgrp-2                  IPv4          855864455
Slot 2:
Object group              Type          Matching Packets
objgrp-1                  IPv4          353452
```

dns-flood action

Use **`dns-flood action`** to specify global actions against DNS flood attacks.

Use **`undo dns-flood action`** to restore the default.

Syntax

`dns-flood action` { **`client-verify`** | **`drop`** | **`logging`** } *

`undo dns-flood action`

Default

No global action is specified for DNS flood attacks.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

`client-verify`: Adds the victim IP addresses to the protected IP list for DNS client verification. If DNS client verification is enabled, the device provides proxy services for protected servers. This keyword does not take effect on source-based flood attack prevention.

`drop`: Drops subsequent DNS packets destined for the victim IP addresses in destination-based flood attack prevention, or drops subsequent DNS packets originating from the attacker IP addresses in source-based flood attack prevention.

`logging`: Enables logging for DNS flood attack events. The log messages will be sent to the log system.

Usage guidelines

For the DNS flood attack detection to collaborate with the DNS client verification, make sure the **`client-verify`** keyword is specified and the DNS client verification is enabled. To enable DNS client verification, use the **`client-verify dns enable`** command.

The **`logging`** keyword enables the attack detection and prevention module to log DNS flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output DNS flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view DNS flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Specify **drop** as the global action against DNS flood attacks in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] dns-flood action drop
```

dns-flood source-threshold

dns-flood threshold

dns-flood detect

Use **dns-flood detect** to configure IP address-specific DNS flood attack detection.

Use **undo dns-flood detect** to remove the IP address-specific DNS flood attack detection configuration.

Syntax

dns-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-list*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **drop** | **logging** } * | **none** }]

undo dns-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

Default

IP address-specific DNS flood attack detection is not configured.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies the IPv4 address to be protected. The *ip-address* argument cannot be 255.255.255.255 or 0.0.0.0.

ipv6 *ipv6-address*: Specifies the IPv6 address to be protected. The IPv6 address cannot be a multicast address or ::.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the protected IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the protected IP address is on the public network.

port *port-list*: Specifies a space-separated list of up to 24 port number items. Each item specifies a port by its port number or a range of ports in the form of *start-port-number* to *end-port-number*. The *end-port-number* cannot be smaller than the *start-port-number*. If you do not specify this option, the global ports apply.

threshold *threshold-value*: Specifies the maximum receiving rate in pps for DNS packets that are destined for the protected IP address. The value range is 1 to 1000000.

action: Specifies the actions against a detected DNS flood attack. If no action is specified, the global actions set by the **dns-flood action** command apply.

client-verify: Adds the victim IP addresses to the protected IP list for DNS client verification. If DNS client verification is enabled, the device provides proxy services for protected servers.

drop: Drops subsequent DNS packets destined for the protected IP address.

logging: Enables logging for DNS flood attack events. The log messages will be sent to the log system.

none: Takes no action.

Usage guidelines

With DNS flood attack detection configured for an IP address, the device is in attack detection state. When the receiving rate of DNS packets destined for the IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

You can configure DNS flood attack detection for multiple IP addresses in one attack defense policy.

The **logging** keyword enables the attack detection and prevention module to log DNS flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output DNS flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view DNS flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Configure DNS flood attack detection for 192.168.1.2 in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] dns-flood detect ip 192.168.1.2 port 53
threshold 2000
```

Use **dns-flood detect non-specific** to enable global DNS flood attack detection.

Use **undo dns-flood detect non-specific** to disable global DNS flood attack detection.

Syntax

dns-flood detect non-specific

undo dns-flood detect non-specific

Default

Global DNS flood attack detection is disabled.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

The device supports the following DNS flood attack prevention types:

- **Source-based DNS flood attack prevention**—Monitors the receiving rate of DNS packets on a per-source IP basis.
- **Destination-based DNS flood attack prevention**—Monitors the receiving rate of DNS packets on a per-destination IP basis.

The global DNS flood attack detection applies to all IP addresses except for those specified by the **dns-flood detect** command. The global detection uses the global trigger threshold set by the **dns-flood threshold** or **dns-flood source-threshold** command and global actions specified by the **dns-flood action** command.

Examples

Enable global DNS flood attack detection in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] dns-flood detect non-specific
```

dns-flood port

dns-flood source-threshold

dns-flood threshold

dns-flood port

Use **dns-flood port** to specify the global ports to be protected against DNS flood attacks.

Use **undo dns-flood port** to restore the default.

Syntax

dns-flood port *port-list*

undo dns-flood port

Default

The global DNS flood attack prevention protects port 53.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

port-list: Specifies a space-separated list of up to 32 port number items. Each item specifies a port by its port number or a range of ports in the form of *start-port-number* to *end-port-number*. The *end-port-number* cannot be smaller than the *start-port-number*.

Usage guidelines

The device detects only DNS packets destined for the specified ports.

The global ports apply to global DNS flood attack detection and IP address-specific DNS flood attack detection with no port specified.

Examples

Specify the ports 53 and 61000 as the global ports to be protected against DNS flood attacks in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] dns-flood port 53 61000
```

Related commands

dns-flood source-threshold

dns-flood threshold

dns-flood threshold

Use **dns-flood threshold** to set the global threshold for triggering destination-based DNS flood attack prevention.

Use **undo dns-flood threshold** to restore the default.

Syntax

dns-flood threshold *threshold-value*

undo dns-flood threshold

Default

The global threshold is 10000 for triggering destination-based DNS flood attack prevention.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the maximum receiving rate in pps for DNS packets that are destined for an IP address. The value range is 0 to 1000000. If you set the threshold value to 0, the destination-based DNS flood attack prevention is disabled.

Usage guidelines

With global DNS flood attack detection configured, the device is in attack detection state. When the receiving rate of DNS packets destined for an IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

The global threshold applies to global DNS flood attack detection. Adjust the threshold according to the application scenarios.

- If the number of DNS packets sent to a protected DNS server is normally large, set a high threshold. A low threshold might affect the server services.
- For a network that is unstable or susceptible to attacks, set a low threshold.

Examples

Set the global threshold to 100 for triggering destination-based DNS flood attack prevention in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] dns-flood threshold 100
```

Syntax

dns-reply-flood action { **client-verify** | **drop** | **logging** } *

undo dns-reply-flood action

Default

No global action is specified for DNS response flood attacks.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

client-verify: Adds the victim IP addresses to the protected IP list for DNS response verification. If DNS response verification is enabled, the device provides proxy services for protected clients. This keyword does not take effect on source-based flood attack prevention.

drop: Drops subsequent DNS responses destined for the victim IP addresses in destination-based flood attack prevention, or drops subsequent DNS responses originating from the attacker IP addresses in source-based flood attack prevention.

logging: Enables logging for DNS response flood attack events. The log messages will be sent to the log system.

Usage guidelines

For the DNS response flood attack detection to collaborate with the DNS response verification, make sure the **client-verify** keyword is specified and the DNS response verification is enabled. To enable DNS response verification, use the **client-verify dns-reply enable** command.

The **logging** keyword enables the attack detection and prevention module to log DNS response flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output DNS response flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view DNS response flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Specify **drop** as the global action against DNS response flood attacks in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] dns-reply-flood action drop
```

undo dns-reply-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

Default

IP address-specific DNS response flood attack detection is not configured.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies the IPv4 address to be protected. The *ip-address* argument cannot be 255.255.255.255 or 0.0.0.0.

ipv6 *ipv6-address*: Specifies the IPv6 address to be protected.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the protected IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the protected IP address is on the public network.

port *port-list*: Specifies a space-separated list of up to 24 port number items. Each item specifies a port by its port number or a range of ports in the form of *start-port-number* to *end-port-number*. The *end-port-number* cannot be smaller than the *start-port-number*. If you do not specify this option, the global ports apply.

threshold *threshold-value*: Specifies the maximum receiving rate in pps for DNS responses that are destined for the protected IP address. The value range is 1 to 1000000, and the default value is 1000.

action: Specifies the actions against a detected DNS response flood attack.

client-verify: Adds the victim IP addresses to the protected IP list for DNS response verification. If DNS response verification is enabled, the device provides proxy services for protected clients.

drop: Drops subsequent DNS responses destined for the protected IP address.

logging: Enables logging for DNS response flood attack events. The log messages will be sent to the log system.

none: Takes no action.

Usage guidelines

You can configure DNS response flood attack detection for multiple IP addresses in one attack defense policy.

With DNS response flood attack detection configured for an IP address, the device is in attack detection state. When the receiving rate of DNS responses destined for the IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

The **logging** keyword enables the attack detection and prevention module to log DNS response flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output DNS response flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view DNS response flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Configure DNS response flood attack detection for 192.168.1.2 in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] dns-reply-flood detect ip 192.168.1.2 port 53 threshold 2000
```

dns-reply-flood detect ip

dns-reply-flood detect non-specific

dns-reply-flood port

exempt acl

Use **exempt acl** to configure attack detection exemption.

Use **undo exempt acl** to restore the default.

Syntax

exempt acl [**ipv6**] { *acl-number* | **name** *acl-name* }

undo exempt acl [**ipv6**]

Default

Attack detection exemption is not configured.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies an IPv6 ACL. To specify an IPv4 ACL, do not use this keyword.

acl-number: Specifies an ACL by its number:

- 2000 to 2999 for basic ACLs.
- 3000 to 3999 for advanced ACLs.

name *acl-name*: Specifies an ACL by its name. The *acl-name* argument is a case-insensitive string of 1 to 63 characters. It must start with an English letter and to avoid confusion, it cannot be **all**.

Usage guidelines

The attack defense policy uses an ACL to identify exempted packets. The policy does not check the packets permitted by the ACL. You can configure the ACL to identify packets from trusted hosts. The exemption feature reduces the false alarm rate and improves packet processing efficiency.

If an ACL is used for attack detection exemption, only the following match criteria in the ACL permit rules take effect:

- Source IP address.
- Destination IP address.
- Source port.
- Destination port.
- Protocol.
- L3VPN instance.
- The **fragment** keyword for matching non-first fragments.

If the specified ACL does not exist or does not contain a rule, attack detection exemption does not take effect.

Examples

Configure an ACL to permit packets sourced from 1.1.1.1. Configure attack detection exemption for packets matching the ACL in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] acl basic 2001
```

```
[Sysname-acl-ipv4-basic-2001] rule permit source 1.1.1.1 0
[Sysname-acl-ipv4-basic-2001] quit
[Sysname] attack-defense policy atk-policy-1
[attack-defense-policy-atk-policy-1] exempt acl 2001
```

Parameters

ip *ipv4-address*: Specifies the IPv4 address to be protected. The *ip-address* argument cannot be 255.255.255.255 or 0.0.0.0.

ipv6 *ipv6-address*: Specifies the IPv6 address to be protected. The IPv6 address cannot be a multicast address or ::.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the protected IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the protected IP address is on the public network.

threshold *threshold-value*: Specifies the maximum receiving rate in pps for FIN packets that are destined for the protected IP address. The value range is 1 to 1000000.

action: Specifies the actions against a detected FIN flood attack. If no action is specified, the global actions set by the **fin-flood action** command apply.

client-verify: Adds the victim IP addresses to the protected IP list for TCP client verification. If TCP client verification is enabled, the device provides proxy services for protected servers.

drop: Drops subsequent FIN packets destined for the protected IP address.

logging: Enables logging for FIN flood attack events. The log messages will be sent to the log system.

none: Takes no action.

Usage guidelines

With FIN flood attack detection configured for an IP address, the device is in attack detection state. When the receiving rate of FIN packets destined for the IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

You can configure FIN flood attack detection for multiple IP addresses in one attack defense policy.

The **logging** keyword enables the attack detection and prevention module to log FIN flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output FIN flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view FIN flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Configure FIN flood attack detection for 192.168.1.2 in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] fin-flood detect ip 192.168.1.2 threshold 2000
```

fin-flood threshold

fin-flood detect non-specific

Use **fin-flood detect non-specific** to enable global FIN flood attack detection.

Use **undo fin-flood detect non-specific** to disable global FIN flood attack detection.

Syntax

fin-flood detect non-specific

undo fin-flood detect non-specific

Default

Global FIN flood attack detection is disabled.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

The device supports the following FIN flood attack prevention types:

- **Source-based FIN flood attack prevention**—Monitors the receiving rate of FIN packets on a per-source IP basis.
- **Destination-based FIN flood attack prevention**—Monitors the receiving rate of FIN packets on a per-destination IP basis.

The global FIN flood attack detection applies to all IP addresses except for those specified by the **fin-flood detect** command. The global detection uses the global trigger threshold set by the **fin-flood threshold** or **fin-flood source-threshold** command and global actions specified by the **fin-flood action** command.

Examples

Enable global FIN flood attack detection in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] fin-flood detect non-specific
```

Related commands

fin-flood detect

fin-flood source-threshold

fin-flood threshold

fin-flood threshold

Use **fin-flood threshold** to set the global threshold for triggering destination-based FIN flood attack prevention.

Use **undo fin-flood threshold** to restore the default.

Syntax

fin-flood threshold *threshold-value*

undo fin-flood threshold

Default

The global threshold is 10000 for triggering destination-based FIN flood attack prevention.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the maximum receiving rate in pps for FIN packets that are destined for an IP address. The value range is 0 to 1000000. If you set the threshold value to 0, the destination-based FIN flood attack prevention is disabled.

Usage guidelines

With global FIN flood attack detection configured, the device is in attack detection state. When the receiving rate of FIN packets destined for an IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

The global threshold applies to global FIN flood attack detection. Adjust the threshold according to the application scenarios.

- If the number of FIN packets sent to a protected server, such as an HTTP or FTP server, is normally large, set a high threshold. A low threshold might affect the server services.
- For a network that is unstable or susceptible to attacks, set a low threshold.

Examples

Set the global threshold to 100 for triggering destination-based FIN flood attack prevention in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] fin-flood threshold 100
```

undo http-flood action

Default

No global action is specified for HTTP flood attacks.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

client-verify: Adds the victim IP addresses to the protected IP list for HTTP client verification. If HTTP client verification is enabled, the device provides proxy services for protected servers. This keyword does not take effect on source-based flood attack prevention.

drop: Drops subsequent HTTP packets destined for the victim IP addresses in destination-based flood attack prevention, or drops subsequent HTTP packets originating from the attacker IP addresses in source-based flood attack prevention.

logging: Enables logging for HTTP flood attack events. The log messages will be sent to the log system.

Usage guidelines

For the HTTP flood attack detection to collaborate with the HTTP client verification, make sure the **client-verify** keyword is specified and the HTTP client verification is enabled. To enable HTTP client verification, use the **client-verify http enable** command.

The **logging** keyword enables the attack detection and prevention module to log HTTP flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output HTTP flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view HTTP flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Specify **drop** as the global action against HTTP flood attacks in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] http-flood action drop
```

undo http-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

Default

IP address-specific HTTP flood attack detection is not configured.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies the IPv4 address to be protected. The *ip-address* argument cannot be 255.255.255.255 or 0.0.0.0.

ipv6 *ipv6-address*: Specifies the IPv6 address to be protected. The IPv6 address cannot be a multicast address or ::.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the protected IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the protected IP address is on the public network.

port *port-list*: Specifies a space-separated list of up to 24 port number items. Each item specifies a port by its port number or a range of ports in the form of *start-port-number* to *end-port-number*. The *end-port-number* cannot be smaller than the *start-port-number*. If you do not specify this option, the global ports apply.

threshold *threshold-value*: Specifies the maximum receiving rate in pps for HTTP packets that are destined for the protected IP address. The value range is 1 to 1000000.

action: Specifies the actions against a detected HTTP flood attack. If no action is specified, the global actions set by the **http-flood action** command apply.

client-verify: Adds the victim IP addresses to the protected IP list for HTTP client verification. If HTTP client verification is enabled, the device provides proxy services for protected servers.

drop: Drops subsequent HTTP packets destined for the protected IP address.

logging: Enables logging for HTTP flood attack events. The log messages will be sent to the log system.

none: Takes no action.

Usage guidelines

With HTTP flood attack detection configured for an IP address, the device is in attack detection state. When the receiving rate of HTTP packets destined for the IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

You can configure HTTP flood attack detection for multiple IP addresses in one attack defense policy.

The **logging** keyword enables the attack detection and prevention module to log HTTP flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output HTTP flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view HTTP flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Syntax

http-slow-attack action { **block-source** [**timeout** *minutes*] | **logging** } *

undo http-slow-attack action

Default

No global actions are specified for HTTP slow attacks.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

block-source: Drops subsequent packets from IP addresses that launch HTTP slow attacks. When the device detects an HTTP slow attack, it adds the IP address of the attack source as a dynamic IP blacklist entry. If the blacklist feature is enabled in the security zone to which the attack defense policy applies, the device drops packets originating from this IP address.

timeout *minutes*: Specifies the aging time in minutes for dynamically added blacklist entries. The value range is 1 to 10080, and the default is 10.

logging: Enables logging for HTTP slow attack events. The log messages will be sent to the log system.

Usage guidelines

For the dynamically added IP blacklist entries to take effect, make sure the blacklist feature is enabled in the security zone to which the attack defense policy applies.

Examples

In attack defense policy **atk-policy-1**, specify **block-source** and **logging** as the global actions against HTTP slow attacks, and set the aging time to 10 minutes for dynamic blacklist entries.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] http-slow-attack action logging
block-source timeout 10
```

Syntax

http-slow-attack detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** { *start-port-number* [**to** *end-port-number*] } &<1-16>] [**threshold** { **alert-number** *alert-number* | **content-length** *content-length* | **payload-length** *payload-length* |

packet-number *packet-number* }*] [**period** *period*] [**action** { **block-source** [**timeout** *minutes*] | **logging** }*]

undo http-slow-attack detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

Default

IP address-specific HTTP slow attack detection is not configured.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies the IPv4 address to be protected. The *ip-address* argument cannot be 255.255.255.255 or 0.0.0.0.

ipv6 *ipv6-address*: Specifies the IPv6 address to be protected. The IPv6 address cannot be a multicast address or ::.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the protected IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the protected IP address is on the public network.

port *port-list*: Specifies a space-separated list of up to 16 port number items. Each item specifies a port by its port number or a range of ports in the form of *start-port-number* to *end-port-number*. The *end-port-number* cannot be smaller than the *start-port-number*. If you do not specify this option, the global ports apply.

threshold: Specifies the threshold for triggering HTTP slow attack prevention. If you do not specify this argument, the global threshold settings for triggering HTTP slow attack prevention apply.

alert-number *alert-number*: Specifies a threshold for HTTP concurrent connections. The value range is 1 to 1200000, and the default is 5000.

content-length *content-length*: Specifies a threshold for the **Content-Length** field value in an HTTP packet. The value range is 100 to 100000000, and the default is 10000.

payload-length *payload-length*: Specifies a threshold for the payload size in an HTTP packet. The value range is 1 to 1000, and the default is 50.

packet-number *packet-number*: Specifies a threshold for abnormal packets. The value range is 1 to 1000, and the default is 10.

period *period*: Specifies a detection period in the range of 1 to 1200 seconds. If you do not specify this option, the global detection period applies.

action: Specifies actions against HTTP slow attacks. If you do not specify an action, the global defensive actions apply.

block-source: Drops subsequent packets from IP addresses that launch HTTP slow attacks. When the device detects an HTTP slow attack, it adds the IP address of the attack source as a dynamic IP blacklist entry. If the blacklist feature is enabled in the security zone to which the attack defense policy applies, the device drops packets from this IP address.

timeout *minutes*: Specifies the aging time in minutes for dynamically added blacklist entries. The value range is 1 to 10080, and the default is 10. If you do not specify this option, the global setting applies.

logging: Enables logging for HTTP slow attack events. The log messages will be sent to the log system.

Usage guidelines

For the dynamically added IP blacklist entries to take effect, make sure the blacklist feature is enabled in the security zone to which the attack defense policy applies.

If you specify part of threshold parameters for IP address-specific HTTP slow attack detection, the default settings rather than the global settings apply to the unspecified threshold parameters.

Examples

Configure HTTP slow attack detection for 1.1.1.1 in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] http-slow-attack detect ip 1.1.1.1 port 80 8080 threshold alert-number 3000 content-length 10000 payload-length 20 packet-number 10 action block-source
```

http-slow-attack port

http-slow-attack threshold

http-slow-attack port

Use **http-slow-attack port** to specify global ports to be protected against HTTP slow attacks.

Use **undo http-slow-attack port** to restore the default.

Syntax

http-slow-attack port *port-list* &<1-32>

undo http-slow-attack port

Default

The global HTTP slow attack prevention protects port 80.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

port-list &<1-32>: Specifies a space-separated list of up to 32 port number items. Each item specifies a port by its port number or a range of ports in the form of *start-port-number* to *end-port-number*. The *end-port-number* cannot be smaller than the *start-port-number*.

Usage guidelines

The device detects only HTTP packets destined for the specified ports.

The global ports are used in global HTTP slow attack detection and IP address-specific HTTP slow attack detection with no protected ports specified.

As a best practice, specify port 80 as the global protected port against HTTP slow attacks. If you specify other ports, make sure these ports are used for HTTP communication. If the specified ports are not used for HTTP communication, the device resources will be wasted in inspecting non-HTTP slow attack packets.

Examples

Specify ports 80 and 8080 as the global ports to be protected against HTTP slow attacks in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] http-slow-attack port 80 8000
```

Related commands

http-slow-attack action

http-slow-attack detect

http-slow-attack detect non-specific

http-slow-attack period

http-slow-attack threshold

http-slow-attack threshold

Use **http-slow-attack threshold** to set global thresholds for triggering HTTP slow attack prevention.

Use **undo http-slow-attack threshold** to restore the default.

Syntax

http-slow-attack threshold [**alert-number** *alert-number* | **content-length** *content-length* | **payload-length** *payload-length* | **packet-number** *packet-number*]*

undo http-slow-attack threshold

Default

The device enters HTTP slow attack detection state when the number of HTTP concurrent connections exceeds 5000. An HTTP packet is a slow attack packet if its **Content-Length** field value is greater than 10000 and its payload is less than 50 bytes. When the device receives more than 10 slow attack packets within the detection period, it takes defensive actions.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

alert-number *alert-number*: Specifies a threshold for HTTP concurrent connections. The value range is 1 to 1200000, and the default is 5000.

content-length *content-length*: Specifies a threshold for the **Content-Length** field value in an HTTP packet. The value range is 100 to 100000000, and the default is 10000.

payload-length *payload-length*: Specifies a threshold for the payload size in an HTTP packet. The value range is 1 to 1000, and the default is 50.

packet-number *packet-number*: Specifies a threshold for HTTP slow attack packets. The value range is 1 to 1000, and the default is 10.

Usage guidelines

The device enters the HTTP slow attack detection state when the number of HTTP concurrent connections exceeds the threshold. An HTTP packet is a slow attack packet if its **Content-Length** field value is greater than the *content-length* value and its payload is less than the *payload-length* value. When the number of attack packets received within the detection period exceeds the threshold, the device takes defensive actions.

If you do not specify a threshold for a parameter, the default value for the parameter applies.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure global HTTP slow attack detection thresholds in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] http-slow-attack threshold alert-number

icmp-flood action

Use **icmp-flood action** to specify global actions against ICMP flood attacks.

Use **undo icmp-flood action** to restore the default.

Syntax

icmp-flood action { **drop** | **logging** } *

undo icmp-flood action

Default

No global action is specified for ICMP flood attacks.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

drop: Drops subsequent ICMP packets destined for the victim IP addresses in destination-based flood attack prevention, or drops subsequent ICMP packets originating from the attacker IP addresses in source-based flood attack prevention.

logging: Enables logging for ICMP flood attack events. The log messages will be sent to the log system.

Usage guidelines

The **logging** keyword enables the attack detection and prevention module to log ICMP flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output ICMP flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view ICMP flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Specify **drop** as the global action against ICMP flood attacks in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
```

```
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] icmp-flood action drop
```

Related commands

icmp-flood source-threshold

icmp-flood threshold

icmp-flood detect ip

Use **icmp-flood detect ip** to configure IP address-specific ICMP flood attack detection.

Use **undo icmp-flood detect ip** to remove the IP address-specific ICMP flood attack detection configuration.

Syntax

icmp-flood detect ip *ip-address* [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

undo icmp-flood detect ip *ip-address* [**vpn-instance** *vpn-instance-name*]

Default

IP address-specific ICMP flood attack detection is not configured.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IPv4 address to be protected. The *ip-address* argument cannot be 255.255.255.255 or 0.0.0.0.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the protected IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the protected IP address is on the public network.

threshold *threshold-value*: Specifies the maximum receiving rate in pps for ICMP packets that are destined for the protected IP address. The value range is 1 to 1000000.

action: Specifies the actions against a detected ICMP flood attack. If no action is specified, the global actions set by the **icmp-flood action** command apply.

drop: Drops subsequent ICMP packets destined for the protected IP address.

logging: Enables logging for ICMP flood attack events. The log messages will be sent to the log system.

none: Takes no action.

Usage guidelines

With ICMP flood attack detection configured for an IP address, the device is in attack detection state. When the receiving rate of ICMP packets destined for the IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate

drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

You can configure ICMP flood attack detection for multiple IP addresses in one attack defense policy.

The **logging** keyword enables the attack detection and prevention module to log ICMP flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output ICMP flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view ICMP flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Configure ICMP flood attack detection for 192.168.1.2 in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] icmp-flood detect ip 192.168.1.2 threshold 2000
```

Use **undo icmp-flood detect non-specific** to disable global ICMP flood attack detection.

Syntax

icmp-flood detect non-specific

undo icmp-flood detect non-specific

Default

Global ICMP flood attack detection is disabled.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

The device supports the following ICMP flood attack prevention types:

- **Source-based ICMP flood attack prevention**—Monitors the receiving rate of ICMP packets on a per-source IP basis.
- **Destination-based ICMP flood attack prevention**—Monitors the receiving rate of ICMP packets on a per-destination IP basis.

The global ICMP flood attack detection applies to all IP addresses except for those specified by the **icmp-flood detect ip** command. The global detection uses the global trigger threshold set by the **icmp-flood threshold** or **icmp-flood source-threshold** command and global actions specified by the **icmp-flood action** command.

Examples

Enable global ICMP flood attack detection in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] icmp-flood detect non-specific
```

icmp-flood source-threshold

icmp-flood threshold

icmp-flood threshold

Use **icmp-flood threshold** to set the global threshold for triggering destination-based ICMP flood attack prevention.

Use **undo icmp-flood threshold** to restore the default.

Syntax

icmp-flood threshold *threshold-value*

undo icmp-flood threshold

Default

The global threshold is 10000 for triggering destination-based ICMP flood attack prevention.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the maximum receiving rate in pps for ICMP packets that are destined for an IP address. The value range is 0 to 1000000. If you set the threshold value to 0, the destination-based ICMP flood attack prevention is disabled.

Usage guidelines

With global ICMP flood attack detection configured, the device is in attack detection state. When the receiving rate of ICMP packets destined for an IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

The global threshold applies to global ICMP flood attack detection. Adjust the threshold according to the application scenarios.

- If the number of ICMP packets sent to a protected server, such as an HTTP or FTP server, is normally large, set a high threshold. A low threshold might affect the server services.
- For a network that is unstable or susceptible to attacks, set a low threshold.

Examples

Set the global threshold to 100 for triggering destination-based ICMP flood attack prevention in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] icmp-flood threshold 100
```

rst-flood action

Use **rst-flood action** to specify global actions against RST flood attacks.

Use **undo rst-flood action** to restore the default.

Syntax

rst-flood action { **client-verify** | **drop** | **logging** } *

undo rst-flood action

Default

No global action is specified for RST flood attacks.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

client-verify: Adds the victim IP addresses to the protected IP list for TCP client verification. If TCP client verification is enabled, the device provides proxy services for protected servers. This keyword does not take effect on source-based flood attack prevention.

drop: Drops subsequent RST packets destined for the victim IP addresses in destination-based flood attack prevention, or drops subsequent RST packets originating from the attacker IP addresses in source-based flood attack prevention.

logging: Enables logging for RST flood attack events. The log messages will be sent to the log system.

Usage guidelines

For the RST flood attack detection to collaborate with the TCP client verification, make sure the **client-verify** keyword is specified and the TCP client verification is enabled. To enable TCP client verification, use the **client-verify tcp enable** command.

The **logging** keyword enables the attack detection and prevention module to log RST flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output RST flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view RST flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Specify **drop** as the global action against RST flood attacks in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] rst-flood action drop
```

Related commands

client-verify tcp enable

rst-flood detect

rst-flood detect non-specific

rst-flood source-threshold

rst-flood threshold

rst-flood detect

Use **rst-flood detect** to configure IP address-specific RST flood attack detection.

Use **undo rst-flood detect** to remove the IP address-specific RST flood attack detection configuration.

Syntax

rst-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **drop** | **logging** } * | **none** }]

undo rst-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

Default

IP address-specific RST flood attack detection is not configured.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies the IPv4 address to be protected. The *ip-address* argument cannot be 255.255.255.255 or 0.0.0.0.

ipv6 *ipv6-address*: Specifies the IPv6 address to be protected. The IPv6 address cannot be a multicast address or ::.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the protected IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the protected IP address is on the public network.

threshold *threshold-value*: Specifies the maximum receiving rate in pps for RST packets that are destined for the protected IP address. The value range is 1 to 1000000.

action: Specifies the actions against a detected RST flood attack. If no action is specified, the global actions set by the **rst-flood action** command apply.

client-verify: Adds the victim IP addresses to the protected IP list for TCP client verification. If TCP client verification is enabled, the device provides proxy services for protected servers.

drop: Drops subsequent RST packets destined for the protected IP address.

logging: Enables logging for RST flood attack events. The log messages will be sent to the log system.

none: Takes no action.

Usage guidelines

With RST flood attack detection configured for an IP address, the device is in attack detection state. When the receiving rate of RST packets destined for the IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device considers returns to the attack detection state.

You can configure RST flood attack detection for multiple IP addresses in one attack defense policy.

The **logging** keyword enables the attack detection and prevention module to log RST flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output RST flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view RST flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Configure RST flood attack detection for 192.168.1.2 in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] rst-flood detect ip 192.168.1.2 threshold
2000
```

rst-flood detect non-specific

rst-flood threshold

rst-flood detect non-specific

Use **rst-flood detect non-specific** to enable global RST flood attack detection.

Use **undo rst-flood detect non-specific** to disable global RST flood attack detection.

Syntax

rst-flood detect non-specific

undo rst-flood detect non-specific

Default

Global RST flood attack detection is disabled.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

The device supports the following RST flood attack prevention types:

- **Source-based RST flood attack prevention**—Monitors the receiving rate of RST packets on a per-source IP basis.
- **Destination-based RST flood attack prevention**—Monitors the receiving rate of RST packets on a per-destination IP basis.

The global RST flood attack detection applies to all IP addresses except for those specified by the **rst-flood detect** command. The global detection uses the global trigger threshold set by the **rst-flood threshold** or **rst-flood source-threshold** command and global actions specified by the **rst-flood action** command.

Examples

Enable global RST flood attack detection in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] rst-flood detect non-specific
```

rst-flood action

rst-flood detect

rst-flood source-threshold

rst-flood threshold

rst-flood threshold

Use **rst-flood threshold** to set the global threshold for triggering destination-based RST flood attack prevention.

Use **undo rst-flood threshold** to restore the default.

Syntax

rst-flood threshold *threshold-value*

undo rst-flood threshold

Default

The global threshold is 10000 for triggering destination-based RST flood attack prevention.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the maximum receiving rate in pps for RST packets that are destined for an IP address. The value range is 0 to 1000000. If you set the threshold value to 0, the destination-based RST flood attack prevention is disabled.

Usage guidelines

With global RST flood attack detection configured, the device is in attack detection state. When the receiving rate of RST packets destined for an IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

The global threshold applies to global RST flood attack detection. Adjust the threshold according to the application scenarios.

- If the number of RST packets sent to a protected server, such as an HTTP or FTP server, is normally large, set a high threshold. A low threshold might affect the server services.
- For a network that is unstable or susceptible to attacks, set a low threshold.

Examples

Set the global threshold to 100 for triggering destination-based RST flood attack prevention in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] rst-flood threshold 100
```

rst-flood source-threshold

Use **rst-flood source-threshold** to set the global threshold for triggering source-based RST flood attack prevention.

Use **undo rst-flood source-threshold** to restore the default.

Syntax

rst-flood source-threshold *threshold-value*

undo rst-flood source-threshold

Default

The global threshold is 10000 for triggering source-based RST flood attack prevention.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the maximum receiving rate in pps for RST packets that originate from an IP address. The value range is 0 to 1000000. If you set the threshold value to 0, the source-based RST flood attack prevention is disabled.

Usage guidelines

With global RST flood attack detection configured, the device is in attack detection state. When the receiving rate of RST packets originating from to an IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

Examples

Set the global threshold to 100 for triggering source-based RST flood attack prevention in attack defense policy **atk-policy-1**.

```
<Sysname> system-view

Related commands

rst-flood action

rst-flood detect

rst-flood detect non-specific

scan detect

Use **scan detect** to configure scanning attack detection.

Use **undo scan detect** to remove the scanning attack detection configuration.

Syntax

scan detect level { { **high** | **low** | **medium** } | **user-defined** { **port-scan-threshold** *threshold-value* | **ip-sweep-threshold** *threshold-value* } * [**period** *period-value*] } **action** { { **block-source** [**timeout** *minutes*] | **drop** } | **logging** } *

undo scan detect

Default

No scanning attack detection is configured.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

level: Specifies the level of the scanning attack detection.

high: Specifies the high level. This level can detect most of the scanning attacks, but has a high false alarm rate. Some packets from active hosts might be considered as attack packets. For high level detection, the detection cycle is 10 seconds. The threshold for triggering port scan attack prevention is 5000 packets in a detection cycle. The threshold for triggering IP sweep attack prevention is 5000 packets in a detection cycle.

low: Specifies the low level. This level provides basic scanning attack detection. It has a low false alarm rate but many scanning attacks cannot be detected. For low level detection, the detection cycle is 10 seconds. The threshold for triggering port scan attack prevention is 100000 packets in a detection cycle. The threshold for triggering IP sweep attack prevention is 100000 packets in a detection cycle.

medium: Specifies the medium level. Compared with the high and low levels, this level has medium false alarm rate and attack detection accuracy. For medium level detection, the detection cycle is 10 seconds. The threshold for triggering port scan attack prevention is 40000 packets. The threshold for triggering IP sweep attack prevention is 40000 packets.

user-defined: Specifies the user-defined level. This level allows you to set the thresholds and detection cycle for port scan and IP sweep attacks on demand.

port-scan-threshold *threshold-value*: Specifies the maximum number of packets sent from an IP address to different ports within a detection cycle. The value range is 1 to 1000000000.

ip-sweep-threshold *threshold-value*: Specifies the maximum number of packets sent from an IP address to different IP addresses within a detection cycle. The value range is 1 to 1000000000.

period *period-value*: Sets the scanning attack detection cycle in the range of 1 to 1000000000 seconds. The default value is 10.

action: Specifies the actions against scanning attacks.

block-source: Adds the attackers' IP addresses to the IP blacklist. If the blacklist feature is enabled on the receiving security zone, the device drops subsequent packets from the blacklisted IP addresses.

timeout *minutes*: Specifies the aging timer in minutes for the dynamically added blacklist entries, in the range of 1 to 10080. The default aging timer is 10 minutes.

drop: Drops subsequent packets from detected scanning attack sources. The log messages will be sent to the log system.

logging: Enables logging for scanning attack events.

Usage guidelines

To collaborate with the IP blacklist feature, make sure the blacklist feature is enabled in the security zone to which the attack defense policy is applied.

The aging timer set by the **timeout** *minutes* option must be longer than the statistics collection interval.

The **logging** keyword enables the attack detection and prevention module to log RST flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output scanning attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view scanning attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Configure low level scanning attack detection and specify the prevention action as **drop** in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] scan detect level low action drop
```

Configure scanning attack detection in attack defense policy **atk-policy-1**. Specify the detection level as **low** and the prevention actions as **block-source** and **logging**. Set the aging time for the dynamically added IP blacklist entries to 10 minutes.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] scan detect level low action logging
block-source timeout 10
```

Configure scanning attack detection in the attack defense policy **atk-policy-1**. Specify the detection level as **user-defined** and detection cycle as 30 seconds. Set the port scan attack prevention threshold and IP sweep attack prevention threshold to 6000 packets and 80000 packets, respectively. Specify the prevention action as **block-source** and **logging**. Set the aging time for the dynamically added IP blacklist entries to 10 minutes.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] scan detect level user-defined
port-scan-threshold 6000 ip-sweep-threshold 80000 period 30 action logging block-source
timeout 10
```

Related commands

blacklist enable

blacklist global enable

signature { large-icmp | large-icmpv6 } max-length

Use **signature** { **large-icmp** | **large-icmpv6** } **max-length** to set the maximum length of safe ICMP or ICMPv6 packets. A large ICMP or ICMPv6 attack occurs if an ICMP or ICMPv6 packet larger than the specified length is detected.

Use **undo signature** { **large-icmp** | **large-icmpv6** } **max-length** to restore the default.

Syntax

signature { **large-icmp** | **large-icmpv6** } **max-length** *length*

undo signature { **large-icmp** | **large-icmpv6** } **max-length**

Default

The maximum length of safe ICMP or ICMPv6 packets is 4000 bytes.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

large-icmp: Specifies large ICMP packet attack signature.

large-icmpv6: Specifies large ICMPv6 packet attack signature.

length: Specifies the maximum length of safe ICMP or ICMPv6 packets, in bytes. The value range for ICMP packets is 28 to 65534. The value range for ICMPv6 packets is 48 to 65534.

Examples

Set the maximum length of safe ICMP packets for large ICMP attack to 50000 bytes in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] signature large-icmp max-length 50000
```

Parameters

fraggle: Specifies the fraggle attack.

fragment: Specifies the IP fragment attack.

icmp-type: Specifies an ICMP packet attack by the packet type. You can specify the packet type by a number or a keyword:

- *icmp-type-value*: Specifies the ICMP packet type in the range of 0 to 255.
- **address-mask-reply**: Specifies the ICMP address mask reply type.
- **address-mask-request**: Specifies the ICMP address mask request type.
- **destination-unreachable**: Specifies the ICMP destination unreachable type.
- **echo-reply**: Specifies the ICMP echo reply type.
- **echo-request**: Specifies the ICMP echo request type.
- **information-reply**: Specifies the ICMP information reply type.
- **information-request**: Specifies the ICMP information request type.
- **parameter-problem**: Specifies the ICMP parameter problem type.
- **redirect**: Specifies the ICMP redirect type.
- **source-quench**: Specifies the ICMP source quench type.

- **time-exceeded**: Specifies the ICMP time exceeded type.
- **timestamp-reply**: Specifies the ICMP timestamp reply type.
- **timestamp-request**: Specifies the ICMP timestamp request type.

icmpv6-type: Specifies an ICMPv6 packet attack by the packet type. You can specify the packet type by a number or a keyword:

- *icmpv6-type-value*: Specifies the ICMPv6 packet type in the range of 0 to 255.
- **destination-unreachable**: Specifies the ICMPv6 destination unreachable type.
- **echo-reply**: Specifies the ICMPv6 echo reply type.
- **echo-request**: Specifies the ICMPv6 echo request type.
- **group-query**: Specifies the ICMPv6 group query type.
- **group-reduction**: Specifies the ICMPv6 group reduction type.
- **group-report**: Specifies the ICMPv6 group report type.
- **packet-too-big**: Specifies the ICMPv6 packet too big type.
- **parameter-problem**: Specifies the ICMPv6 parameter problem type.
- **time-exceeded**: Specifies the ICMPv6 time exceeded type.

impossible: Specifies the IP impossible packet attack.

ip-option: Specifies an IP option. You can specify the IP option by a number or a keyword:

- *option-code*: Specifies the IP option in the range of 1 to 255.
- **internet-timestamp**: Specifies the timestamp option.
- **loose-source-routing**: Specifies the loose source routing option.
- **record-route**: Specifies the record route option.
- **route-alert**: Specifies the route alert option.
- **security**: Specifies the security option.
- **stream-id**: Specifies the stream identifier option.
- **strict-source-routing**: Specifies the strict source route option.

ip-option-abnormal: Specifies the abnormal IP option attack.

ipv6-ext-header *ext-header-value*: Specifies an IPv6 extension header by its value in the range of 0 to 255.

ipv6-ext-header-abnormal: Specifies the abnormal IPv6 extension header attack.

ipv6-ext-header-exceed: Specifies the IPv6 extension header exceeded attack.

land: Specifies the Land attack.

large-icmp: Specifies the large ICMP packet attack.

large-icmpv6: Specifies the large ICMPv6 packet attack.

limit *limit-value*: Specifies the upper limit of IPv6 extension headers. The value range is 0 to 7, and the default is 0. An IPv6 packet is an IPv6 extension header exceeded attack packet if the number of its IPv6 extension headers exceeds the upper limit.

ping-of-death: Specifies the ping-of-death attack.

smurf: Specifies the smurf attack.

snork: Specifies the UDP snork attack.

tcp-all-flags: Specifies the attack where the TCP packet has all flags set.

tcp-fin-only: Specifies the attack where the TCP packet has only the FIN flag set.

tcp-invalid-flags: Specifies the attack that uses TCP packets with invalid flags.

tcp-null-flag: Specifies the attack where the TCP packet has no flags set.

tcp-syn-fin: Specifies the attack where the TCP packet has both SYN and FIN flags set.

teardrop: Specifies the teardrop attack.

tiny-fragment: Specifies the tiny fragment attack.

traceroute: Specifies the traceroute attack.

udp-bomb: Specifies the UDP bomb attack.

winnuke: Specifies the WinNuke attack.

action: Specifies the actions against the single-packet attack. If you do not specify this keyword, the default action of the attack level to which the single-packet attack belongs is used.

drop: Drops packets that match the specified signature.

logging: Enables logging for the specified single-packet attack.

none: Takes no action.

Usage guidelines

You can use this command multiple times to enable signature detection for multiple single-packet attack types.

When you specify a packet type by a number, if the packet type has a corresponding keyword, the keyword is displayed in command output. If the packet type does not have a corresponding keyword, the number is displayed.

In abnormal IPv6 extension header and IPv6 extension header exceeded attack detection, the device examines the ESP header and headers before it. Headers after the ESP header are not examined.

The **logging** keyword enables the attack detection and prevention module to log single-packet attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output single-packet attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view single-packet attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Enable signature detection for the IP fragment attack and specify the prevention action as **drop** in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] signature detect fragment action drop
```

Related commands

signature level action

signature level action

Use **signature level action** to specify the actions against single-packet attacks on a specific level.

Use **undo signature level action** to restore the default.

Syntax

signature level { **high** | **info** | **low** | **medium** } **action** { { **drop** | **logging** } * | **none** }

undo signature level { **high** | **info** | **low** | **medium** } **action**

Default

For informational-level and low-level single-packet attacks, the action is **logging**.

For medium-level and high-level single-packet attacks, the actions are **logging** and **drop**.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

high: Specifies the high level. None of the currently supported single-packet attacks belongs to this level.

info: Specifies the informational level. For example, large ICMP packet attack is on this level.

low: Specifies the low level. For example, the traceroute attack is on this level.

medium: Specifies the medium level. For example, the WinNuke attack is on this level.

drop: Drops packets that match the specified level.

logging: Enable logging for single-packet attacks on the specified level.

none: Takes no action.

Usage guidelines

According to their severity, single-packet attacks are divided into four levels: **info**, **low**, **medium**, and **high**. Enabling signature detection for a specific level enables signature detection for all single-packet attacks on that level.

If you enable signature detection for a single-packet attack also by using the **signature detect** command, action parameters in the **signature detect** command take effect.

The **logging** keyword enables the attack detection and prevention module to log single-packet attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output single-packet attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view single-packet attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Specify the action against informational-level single-packet attacks as **drop** in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy 1
[Sysname-attack-defense-policy-1] signature level info action drop
```

Parameters

client-verify: Adds the victim IP addresses to the protected IP list for SIP client verification. If SIP client verification is enabled, the device provides proxy services for protected servers. This keyword does not take effect on source-based flood attack prevention.

drop: Drops subsequent SIP packets destined for the victim IP addresses in destination-based flood attack prevention, or drops subsequent SIP packets originating from the attacker IP addresses in source-based flood attack prevention.

logging: Enables logging for SIP flood attack events. The log messages will be sent to the log system.

Usage guidelines

For the SIP flood attack detection to collaborate with the SIP client verification, make sure the **client-verify** keyword is specified and the SIP client verification is enabled. To enable SIP client verification, use the **client-verify sip enable** command.

The **logging** keyword enables the attack detection and prevention module to log SIP flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output SIP flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view SIP flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Specify **drop** as the global action against SIP flood attacks in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] sip-flood action drop
```

sip-flood port

sip-flood source-threshold

sip-flood threshold

sip-flood detect

Use **sip-flood detect** to configure IP address-specific SIP flood attack detection.

Use **undo sip-flood detect** to remove IP address-specific SIP flood attack detection configuration.

Syntax

sip-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-list*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **drop** | **logging** } * | **none** }]

undo sip-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

Default

IP address-specific SIP flood attack detection is not configured.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies the IPv4 address to be protected. The *ip-address* argument cannot be 255.255.255.255 or 0.0.0.0.

ipv6 *ipv6-address*: Specifies the IPv6 address to be protected. The IPv6 address cannot be a multicast address or ::.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the protected IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the protected IP address is on the public network.

port *port-list*: Specifies a space-separated list of up to 32 port number items. Each item specifies a port by its port number or a range of ports in the form of *start-port-number* to *end-port-number*. The *end-port-number* cannot be smaller than the *start-port-number*. If you do not specify this option, the global ports apply.

threshold *threshold-value*: Specifies the maximum receiving rate in pps for SIP packets that are destined for the protected IP address. The value range is 1 to 1000000, and the default value is 1000.

action: Specifies the actions against a detected SIP flood attack. If no action is specified, the global actions set by the **sip-flood action** command apply.

client-verify: Adds the victim IP addresses to the protected IP list for SIP client verification. If SIP client verification is enabled, the device provides proxy services for protected servers.

drop: Drops subsequent SIP packets destined for the protected IP address.

logging: Enables logging for SIP flood attack events. The log messages will be sent to the log system.

none: Takes no action.

Usage guidelines

With SIP flood attack detection configured for an IP address, the device is in attack detection state. When the receiving rate of SIP packets destined for the IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

You can configure SIP flood attack detection for multiple IP addresses in one attack defense policy.

The **logging** keyword enables the attack detection and prevention module to log SIP flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output SIP flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view SIP flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Configure SIP flood attack detection for 192.168.1.2 in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] sip-flood detect ip 192.168.1.2 threshold
2000
```

Usage guidelines

The device supports the following SIP flood attack prevention types:

- **Source-based SIP flood attack prevention**—Monitors the receiving rate of SIP packets on a per-source IP basis.
- **Destination-based SIP flood attack prevention**—Monitors the receiving rate of SIP packets on a per-destination IP basis.

The global SIP flood attack detection applies to all IP addresses except those specified by the **sip-flood detect** command. The global detection is configured by using the following commands:

- Global ports set by using the **sip-flood port** command.
- Global trigger threshold set by using the **sip-flood threshold** or **sip-flood source-threshold** command.
- Global actions specified by using the **sip-flood action** command.

Examples

Enable global SIP flood attack detection in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] sip-flood detect non-specific
```

sip-flood port

Use **sip-flood port** to specify the global ports to be protected against SIP flood attacks.

Use **undo sip-flood port** to restore the default.

Syntax

sip-flood port *port-list*

undo sip-flood port

Default

The global SIP flood attack prevention protects port 5060.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

port-list: Specifies a space-separated list of up to 32 port number items. Each item specifies a port by its port number or a range of ports in the form of *start-port-number* to *end-port-number*. The *end-port-number* cannot be smaller than the *start-port-number*.

Usage guidelines

The device detects only SIP packets destined for the specified ports.

The global ports apply to global SIP flood attack detection and IP address-specific SIP flood attack detection with no port specified.

Examples

Specify ports 5060 and 65530 as the global ports to be protected against SIP flood attacks in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] sip-flood port 5060 65530
```

Use **sip-flood threshold** to set the global threshold for triggering destination-based SIP flood attack prevention.

Use **undo sip-flood threshold** to restore the default.

Syntax

sip-flood threshold *threshold-value*

undo sip-flood threshold

Default

The global threshold is 10000 for triggering destination-based SIP flood attack prevention.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the maximum receiving rate in pps for SIP packets that are destined for an IP address. The value range is 0 to 1000000. If you set the threshold value to 0, the destination-based SIP flood attack prevention is disabled.

Usage guidelines

With global SIP flood attack detection configured, the device is in attack detection state. When the receiving rate of SIP packets destined for an IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

The global threshold applies to global SIP flood attack detection. Adjust the threshold according to the application scenarios.

- If the number of SIP packets sent to a protected SIP server is normally large, set a high threshold. A low threshold might affect the server services.
- For a network that is unstable or susceptible to attacks, set a low threshold.

Examples

Set the global threshold to 100 for triggering destination-based SIP flood attack prevention in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] sip-flood threshold 100

- For a network that is unstable or susceptible to attacks, set a low threshold.

Examples

Set the global threshold to 100 for triggering destination-based SYN flood attack prevention in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] syn-flood threshold 100
```

Related commands

syn-flood action

syn-flood detect

syn-flood detect non-specific

syn-flood source-threshold

Use **syn-flood source-threshold** to set the global threshold for triggering source-based SYN flood attack prevention.

Use **undo syn-flood source-threshold** to restore the default.

Syntax

syn-flood source-threshold *threshold-value*

undo syn-flood source-threshold

Default

The global threshold is 10000 for triggering source-based SYN flood attack prevention.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the maximum receiving rate in pps for SYN packets that originate from an IP address. The value range is 0 to 1000000. If you set the threshold value to 0, the source-based SYN flood attack prevention is disabled.

Usage guidelines

With global SYN flood attack detection configured, the device is in attack detection state. When the receiving rate of SYN packets originating from an IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

Examples

Set the global threshold to 100 for triggering source-based SYN flood attack prevention in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] syn-flood source-threshold 100
```

Related commands

syn-flood action

syn-flood detect

syn-flood detect non-specific

threshold-learn apply

Use **threshold-learn apply** to apply the most recent threshold that the device has learned.

Syntax

threshold-learn apply

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

You can configure this command to apply the most recent threshold that the device has learned to a flood attack defense policy that meets the following requirements:

- The threshold learning feature is enabled for the policy.
- Auto applying the learned threshold is disabled for the policy.

The learned threshold is set as the global threshold for triggering flood attack prevention. The command does not take effect when auto application of the learned threshold is enabled for the policy. If you execute this command multiple times, the most recent configuration takes effect.

Before you apply the most recently learned threshold to a flood attack defense policy, make sure global attack detection is enabled for all existing flood types in this policy.

Examples

Apply the most recent threshold that the device has learned to attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] threshold-learn apply
```

Related commands

threshold-learn enable

threshold-learn auto-apply enable

Use **threshold-learn auto-apply enable** to enable auto application of the learned threshold.

Use **undo threshold-learn auto-apply enable** to disable auto application of the learned threshold.

Syntax

threshold-learn auto-apply enable

undo threshold-learn auto-apply enable

Default

Auto application of the learned threshold is disabled.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command applies to only flood attack defense policies that are enabled with the threshold learning feature (set with the **threshold-learn enable** command). Each time the device learns a threshold, it uses the learned value to update the global threshold for triggering flood attack prevention. The formula for calculating the new global threshold is learned threshold × (1 + tolerance value). The learned threshold equals the peak packet receiving rate that the device has learned within the learning duration.

To set a tolerance value, execute the **threshold-learn tolerance-value** command. Setting a tolerance value can prevent packet loss when the network experiences a traffic spike without being attacked.

Before you apply the most recently learned threshold to a flood attack defense policy, make sure global attack detection is enabled for all existing flood types in this policy.

Examples

Enable auto application of the learned threshold for attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] threshold-learn auto-apply enable
```

Related commands

threshold-learn enable

threshold-learn tolerance-value

threshold-learn duration

Use **threshold-learn duration** to set the threshold learning duration.

Use **undo threshold-learn duration** to restore the default.

Syntax

threshold-learn duration *duration*

undo threshold-learn duration

Default

The threshold learning duration is 1440 minutes.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

duration: Specifies the threshold learning duration in the range of 1 to 1200000 minutes.

Usage guidelines

The device starts threshold learning when you apply an attack defense policy enabled with the threshold learning feature. The learned threshold equals the peak packet receiving rate learned within the duration. To ensure that the device learns the peak rate in a whole day, set a learning duration longer than 1440 minutes (24 hours). If you change the learning duration during the learning process, the device will restart threshold learning.

Examples

Set the threshold learning duration to 2880 minutes (48 hours) for attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] threshold-learn duration 2880
```

Related commands

threshold-learn enable

threshold-learn loop

threshold-learn enable

Use **threshold-learn enable** to enable the threshold learning feature for flood attack prevention.

Use **undo threshold-learn enable** to disable the threshold learning feature for flood attack prevention.

Syntax

threshold-learn enable

undo threshold-learn enable

Default

The threshold learning feature for flood attack prevention is disabled.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

An appropriate threshold can effectively prevent attacks. If the global threshold for triggering flood attack prevention is too low, false positives might occur, causing performance degradation or packet loss. If the global threshold is too high, false negatives might occur, making the network defenseless. Therefore, it is a good practice to enable the threshold learning feature. This feature allows the device to automatically learn the global threshold based on the traffic flows in the network.

Examples

Enable the threshold learning feature for attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] threshold-learn enable
```

Related commands

`threshold-learn auto-apply enable`

`threshold-learn duration`

threshold-learn interval

Use **`threshold-learn interval`** to set the threshold learning interval.

Use **`undo threshold-learn interval`** to restore the default.

Syntax

`threshold-learn interval` *`interval`*

`undo threshold-learn interval`

Default

The threshold learning interval is 1440 minutes.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

`interval`: Specifies a threshold learning interval in the range of 1 to 1200000 minutes.

Usage guidelines

The device performs periodic threshold learning when you apply an attack defense policy that meets the following requirements:

- The threshold learning feature is enabled for the policy by using the **`threshold-learn enable`** command.
- The periodic learning mode is set by using the **`threshold-learn mode periodic`** command.

Examples

Set the threshold learning interval to 120 minutes for attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] threshold-learn interval 120
```

Related commands

threshold-learn enable

threshold-learn mode

threshold-learn mode

Use **threshold-learn mode** to set the threshold learning mode.

Use **undo threshold-learn mode** to restore the default.

Syntax

threshold-learn mode { **once** | **periodic** }

undo threshold-learn mode

Default

The one-time learning mode is set.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

once: Specifies the one-time learning mode.

periodic: Specifies the periodic learning mode.

Usage guidelines

This command allows you to set the following threshold learning modes:

- **One-time learning**—The device performs threshold learning only once. This mode is applicable to stable networks.
- **Periodic learning**—The device performs threshold learning at intervals. The most recent learned threshold always takes effect. This mode is applicable to unstable networks. To set the threshold learning duration, use the **threshold-learn duration** command. To set the threshold learning interval, use the **threshold-learn interval** command.

Examples

Set the periodic learning mode for attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] threshold-learn mode periodic
```

Related commands

threshold-learn duration

threshold-learn enable

threshold-learn interval

threshold-learn tolerance-value

Use **threshold-learn tolerance-value** to set the threshold learning tolerance value.

Use **undo threshold-learn tolerance-value** to restore the default.

Syntax

threshold-learn tolerance-value *tolerance-value*

undo threshold-learn tolerance-value

Default

The threshold learning tolerance value is 50.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

tolerance-value: Specifies the threshold learning tolerance value in percentage, in the range of 0 to 4000.

Usage guidelines

When auto applying the learned threshold is enabled, the device uses the learned threshold and tolerance value to calculate the global threshold for triggering flood attack prevention. The formula for calculating the global threshold is learned threshold × (1 + tolerance value). Therefore, the calculated global threshold is larger than the learned threshold. This can prevent packet loss when the network experiences a traffic spike without being attacked.

The tolerance value takes effect only when auto applying the learned threshold is enabled.

Examples

Set the threshold learning tolerance value to 100 for attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] threshold-learn auto-apply enable
[Sysname-attack-defense-policy-atk-policy-1] threshold-learn tolerance-value 100
```

threshold-learn enable

udp-flood action

Use **udp-flood action** to specify global actions against UDP flood attacks.

Use **undo udp-flood action** to restore the default.

Syntax

udp-flood action { **drop** | **logging** } *

undo udp-flood action

Default

No global action is specified for UDP flood attacks.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

drop: Drops subsequent UDP packets destined for the victim IP addresses in destination-based flood attack prevention, or drops subsequent UDP packets originating from the attacker IP addresses in source-based flood attack prevention.

logging: Enables logging for UDP flood attack events. The log messages will be sent to the log system.

Usage guidelines

The **logging** keyword enables the attack detection and prevention module to log UDP flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output UDP flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view UDP flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Specify **drop** as the global action against UDP flood attacks in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] udp-flood action drop
```

udp-flood detect non-specific

udp-flood source-threshold

udp-flood threshold

udp-flood detect

Use **udp-flood detect** to configure IP address-specific UDP flood attack detection.

Use **undo udp-flood detect** to remove the IP address-specific UDP flood attack detection configuration.

Syntax

udp-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

undo udp-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

Default

IP address-specific UDP flood attack detection is not configured.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies the IPv4 address to be protected. The *ip-address* argument cannot be 255.255.255.255 or 0.0.0.0.

ipv6 *ipv6-address*: Specifies the IPv6 address to be protected. The IPv6 address cannot be a multicast address or ::

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the protected IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. Do not specify this option if the protected IP address is on the public network.

threshold *threshold-value*: Specifies the maximum receiving rate in pps for UDP packets that are destined for the protected IP address. The value range is 1 to 1000000.

action: Specifies the actions against a detected UDP flood attack. If no action is specified, the global actions set by the **udp-flood action** command apply.

drop: Drops subsequent UDP packets destined for the protected IP address.

logging: Enables logging for UDP flood attack events. The log messages will be sent to the log system.

none: Takes no action.

Usage guidelines

With UDP flood attack detection configured for an IP address, the device is in attack detection state. When the receiving rate of UDP packets destined for the IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

You can configure UDP flood attack detection for multiple IP addresses in one attack defense policy.

The **logging** keyword enables the attack detection and prevention module to log UDP flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output UDP flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view UDP flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Configure UDP flood attack detection for 192.168.1.2 in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] udp-flood detect ip 192.168.1.2 threshold
2000
```

Use **undo udp-flood detect non-specific** to disable global UDP flood attack detection.

Syntax

udp-flood detect non-specific

undo udp-flood detect non-specific

Default

Global UDP flood attack detection is disabled.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

The device supports the following UDP flood attack prevention types:

- **Source-based UDP flood attack prevention**—Monitors the receiving rate of UDP packets on a per-source IP basis.
- **Destination-based UDP flood attack prevention**—Monitors the receiving rate of UDP packets on a per-destination IP basis.

The global UDP flood attack detection applies to all IP addresses except for those specified by the **udp-flood detect** command. The global detection uses the global trigger threshold set by the **udp-flood threshold** or **udp-flood source-threshold** command and global actions specified by the **udp-flood action** command.

Examples

Enable global UDP flood attack detection in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] udp-flood detect non-specific
```

udp-flood threshold

Use **udp-flood threshold** to set the global threshold for triggering destination-based UDP flood attack prevention.

Use **undo udp-flood threshold** to restore the default.

Syntax

udp-flood threshold *threshold-value*

undo udp-flood threshold

Default

The global threshold is 10000 for triggering destination-based UDP flood attack prevention.

Views

Attack defense policy view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the maximum receiving rate in pps for UDP packets that are destined for an IP address. The value range is 0 to 1000000. If you set the threshold value to 0, the destination-based UDP flood attack prevention is disabled.

Usage guidelines

With global UDP flood attack detection configured, the device is in attack detection state. When the receiving rate of UDP packets destined for an IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

The global threshold applies to global UDP flood attack detection. Adjust the threshold according to the application scenarios.

- If the number of UDP packets sent to a protected server, such as an HTTP or FTP server, is normally large, set a high threshold. A low threshold might affect the server services.
- For a network that is unstable or susceptible to attacks, set a low threshold.

Examples

Set the global threshold to 100 for triggering destination-based UDP flood attack prevention in attack defense policy **atk-policy-1**.

```
<Sysname> system-view
[Sysname] attack-defense policy atk-policy-1
[Sysname-attack-defense-policy-atk-policy-1] rst-flood threshold 100

Server connection detection commands

auto-learn enable

Use **auto-learn enable** to enable server connection learning for the specified learning period.

Use **undo auto-learn enable** to disable server connection learning.

Syntax

auto-learn enable period { **one-day** | **one-hour** | **seven-day** | **twelve-hour** }

undo auto-learn enable

Default

Server connection learning is disabled.

Views

Server connection learning configuration view

Predefined user roles

network-admin

context-admin

Parameters

period: Specifies the learning period.

one-day: Specifies one day.

one-hour: Specifies one hour.

seven-day: Specifies seven days.

twelve-hour: Specifies 12 hours.

Usage guidelines

This command enables the device to learn the connections initiated by the servers specified by using the **source-ip** command for the specified learning period.

This command is configurable only when both of the following conditions are met:

- Servers are specified for the learning process to learn connections.
- The server connection learning process is not running on the device.

To change the learning period of an ongoing server connection learning process, first execute the **undo auto-learn enable** command to stop the learning process, and then execute the **auto-learn enable** command.

Examples

Enable server connection learning for one day.

```
<Sysname> system-view
[Sysname] scd learning
[Sysname-scd-learning] auto-learn enable period one-day
```

Learning status              : Active
Learning time                : One-hour
Server address object groups : 146
Progress                     : 6%
Start time                   : 2018, 03, 27 10:50
End time                     : 2018, 03, 27 11:50
```

Table 1 Command output

Field	Description
Learning status	Server connection learning status. If server connection learning is in progress, this field displays **Active**. If server connection learning is not running, this field displays a hyphen (-)..
Learning time	Learning period, which can be **One-day**, **One-hour**, **Seven-day**, or **Twelve-hour**.
Server address object groups	Number of server IP address object groups specified for server connection learning.
Progress	Progress percentage of the server connection learning.
Start time	Start time of the server connection learning.
End time	End time of the server connection learning.

display scd learning record

Use **display scd auto-learn config** to display the server-initiated connections learned by server connection learning.

Syntax

display scd learning record [**protected-server** *ip-address*] [**destination-ip** *ip-address*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

protected-server *ip-address*: Specifies the IP address of the server.

destination-ip *ip-address*: Specifies the destination IP address of the server-initiated connections.

Usage guidelines

This command displays the server connection learning results, which provides the basis for you to create SCD policies to monitor and log illegal connections initiated by servers.

If you do not specify any parameters, this command displays the connections initiated by all servers specified for server connection learning.

Examples

Display the connections initiated by all servers specified for server connection learning.

```
<Sysname> display scd learning record
Id     Protected server    Destination IPv4 address   Protocol    Port
1      192.168.102.1       192.168.101.21             TCP         443
Total entries: 1
```

Display the connections initiated by server 192.168.102.1.

```
<Sysname> display scd learning record protected-server 192.168.102.1
Id     Protected server    Destination IPv4 address   Protocol    Port
1      192.168.102.1       192.168.101.21             TCP         443
Total entries: 1
```

Display the server-initiated connections destined for 192.168.101.21.

```
<Sysname> display scd learning record destination-ip 192.168.101.21
Id     Protected server    Destination IPv4 address   Protocol    Port
1      192.168.102.1       192.168.101.21             TCP         443
Total entries: 1
```

Table 2 Command output

Field	Description
ID	ID of the server connection learning record.
Protected server	IP address of the server initiated the connection.
Destination IPv4 address	IPv4 address the connection is destined for.
Protocol	Protocol used by the connection.
Port	Destination port number of the connection.
Total entries	Total number of the learned connections.

context-admin

context-operator

Parameters

name *policy-name*: Displays detailed information about an SCD policy. The *policy-name*: argument specifies the policy name, a case-insensitive string of 1 to 63 characters. If you do not specify an SCD policy, this command displays brief information about all SCD policies.

Examples

Display brief information about all SCD policies.

```
<Sysname> display scd policy
Id     Name              Protected server  Rules       Logging     Policy status
1      policy1           1.1.1.1           0           Disabled    Disabled
Total entries: 1
```

Table 3 Command output

Field	Description
Id	Row ID of the SCD policy entry.
Name	Name of the SCD policy.
Protected server	IP address of the protected server. The SCD policy will monitor connections initiated by the server.
Rules	Number of SCD rules in the SCD policy. Each SCD rule defines a set of legal connections initiated by the server.
Logging	Enabling status of the logging for illegal connections (connections that do not match any SCD rules) initiated by the server.
Policy status	Enabling status of the SCD policy.
Total entries	Total number of the SCD policies.

Display detailed information about SCD policy **policy1**.

```
<Sysname> display scd policy name policy1
SCD policy name: policy1
 Protected server IPv4: 1.1.1.1
 Logging: Enabled
```

```
Policy status: Enabled
Rule ID: 1
 Permitted dest IPv4: 1.1.2.1
 Protocol: TCP port 1-4
 Protocol: UDP port 1,3,5,7,9,11,13,15,17,19,21,23
 Protocol: ICMP
```

Table 4 Command output

Field	Description
SCD policy name	Name of the SCD policy.
Protected server IPv4	IP address of the protected server. The SCD policy will monitor connections initiated by the server.
Rule ID	Number of an SCD rule in the SCD policy. Each SCD rule defines a set of legal connections initiated by the server.
Permitted dest IPv4	Destination IP address of the legal connections initiated by the server that match the SCD rule.
Protocol	Protocol used by the legal connections initiated by the server that match the SCD rule.
Logging	Enabling status of the logging for illegal connections (connections that do not match any SCD rules) initiated by the server.
Policy status	Enabling status of the SCD policy.

logging enable

Use **logging enable** to enable logging for illegal server-initiated connections detected by the SCD policy.

Use **undo logging enable** to disable logging for illegal server-initiated connections detected by the SCD policy.

Syntax

logging enable

undo logging enable

Default

Logging is disabled for illegal server-initiated connections detected by the SCD policy.

Views

SCD policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the device to log server-initiated connections that do not match any rules in the SCD policy and send the logs to the device information center. With the information center, you can specify log output rules to output the logs to different destinations. For more information about the information center, see information center configuration in *Network Management and Monitoring Configuration Guide*.

Examples

Enable logging for illegal server-initiated connections that are detected by SCD policy **policy1**.

```
<Sysname> system-view
[Sysname] scd policy policy1
[Sysname-scd-policy-policy1] logging enable
```

Related commands

display scd policy

permit-dest-ip

Use **permit-dest-ip** to configure the destination IP address criterion for an SCD rule.

Use **undo permit-dest-ip** to remove the destination IP address criterion from an SCD rule.

Syntax

permit-dest-ip *ip-address*

undo permit-dest-ip

Default

The destination IP address criterion is not configured in an SCD rule.

Views

SCD policy rule view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies an IPv4 address, in dotted decimal notation.

Usage guidelines

Each SCD rule contains the following criteria to identify legal connections initiated by the protected server:

- A destination IP address criterion, which specifies the destination IP address for server-initiated connections.

  In one SCD policy, each SCD rule must use a unique destination IP address.
- One or more protocol criteria. Each protocol criterion specifies a protocol and optionally a set of destination port numbers.

A connection initiated by the protected server matches the SCD rule if the connection matches both the destination IP address criterion and a protocol criterion. Connections initiated by the server that do not match any SCD rules are considered illegal connections.

If you execute the command multiple times for an SCD rule, the most recent configuration takes effect.

As a best practice, use the following procedure to configure an SCD policy for a server:

1. Enable server connection learning on the device to learn the connections initiated by the server.
2. Configure SCD rules for legal connections according to the server connection learning results. To view the learned connections, use the **display scd learning record** command.

Examples

In SCD policy **policy1**, configure SCD rule 1 to match connections destined for 1.1.1.1.

```
<Sysname> system-view
[Sysname] scd policy policy1
[Sysname-scd-policy-policy1] rule 1
[Sysname-scd-policy-policy1-1] permit-dest-ip 1.1.1.1
```

Related commands

display scd policy

policy enable

Use **policy enable** to enable an SCD policy.

Use **undo policy enable** to disable an SCD policy.

Syntax

policy enable

undo policy enable

Default

An SCD policy is disabled.

SCD policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

An SCD policy takes effect only after it is enabled.

Examples

Enable SCD policy **policy1**.

```
<Sysname> system-view
[Sysname] scd policy policy1
[Sysname-scd-policy-policy1] policy enable
```

Related commands

display scd policy

protected-server

Use **protected-server** to specify the IP address of the protected server in an SCD policy.

Use **undo protected-server** to remove the protected server IP address from an SCD policy.

Syntax

protected-server *ip-address*

undo protected-server

Default

No protected server IP address is specified.

Views

SCD policy view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IPv4 address of a protected server, in dotted decimal notation.

Usage guidelines

An SCD policy monitors only the connections initiated by the specified protected server.

The protected server IP address must be unique for each SCD policy.

If you execute this command for an SCD policy multiple times, the most recent configuration takes effect.

Examples

Configure SCD policy **policy1** to monitor connections initiated by server 192.168.1.10.

```
<Sysname> system-view
[Sysname] scd policy policy1
[Sysname-scd-policy-policy1] protected-server 192.168.1.10
```

Related commands

display scd policy

protocol

Use **protocol** to configure a protocol criterion for an SCD rule.

Use **undo protocol** to remove a protocol criterion from an SCD rule.

Syntax

protocol { **icmp** | **tcp port** *port-list* | **udp port** *port-list* }

undo protocol { **icmp** | **tcp** | **udp** }

Default

No protocol criterion is configured in an SCD rule.

Views

SCD rule view

Predefined user roles

network-admin

context-admin

Parameters

icmp: Specifies the ICMP protocol.

tcp port *port-list*: Specifies the TCP protocol and a list of up to 20 destination TCP port numbers in the range of 1 to 65535. The *port-list* argument specifies a space-separated list of port number items. Each item specifies a port by its number or specifies a range of port numbers in the form of *port-number1* **to** *port-number2*. The start port number must be identical to or lower than the end port number.

udp port *port-list*: Specifies the UDP protocol and a list of up to 20 destination UDP port numbers in the range of 1 to 65535. The *port-list* argument specifies a space-separated list of port number items. Each item specifies a port by its number or specifies a range of port numbers in the form of *port-number1* **to** *port- number2*. The start port number must be identical to or lower than the end port number.

Usage guidelines

Each SCD rule contains the following criteria to identify legal connections initiated by the protected server:

- A destination IP address criterion, which specifies the destination IP address for server-initiated connections.
- One or more protocol criteria. Each protocol criterion specifies a protocol and optionally a set of destination port numbers.

A connection initiated by the protected server matches the SCD rule if the connection matches both the destination IP address criterion and a protocol criterion. Connections initiated by the server that do not match any SCD rules are considered illegal connections.

You can use this command multiple times to specify different protocols in an SCD rule.

If you specify the TCP or UDP protocol with different port numbers in an SCD rule, the most recent configuration takes effect.

Examples

In SCD policy **policy1**, configure a protocol criterion in SCD rule 1 to match the TCP protocol with port numbers 80 and 1000 to 2000.

```
<Sysname> system-view
[Sysname] scd policy policy1
[Sysname-scd-policy-policy1] rule 1
[Sysname-scd-policy-policy1-1] protocol tcp port 80 1000 to 2000
```

rule

Use **rule** to create an SCD rule and enter its view, or enter the view of an existing SCD rule.

Use **undo rule** to remove an SCD rule.

Syntax

rule *rule-id*

undo rule [*rule-id*]

Default

No SCD rules exist in an SCD policy.

Views

SCD policy view

Predefined user roles

network-admin

context-admin

Parameters

rule-id: Specifies a rule ID in the range of 1 to 65535.

Usage guidelines

Each SCD rule contains the following criteria to identify legal connections initiated by the protected server:

- A destination IP address criterion, which specifies the destination IP address for server-initiated connections.
- One or more protocol criteria. Each protocol criterion specifies a protocol and optionally a set of destination port numbers.

A connection initiated by the protected server matches the SCD rule if the connection matches both the destination IP address criterion and a protocol criterion. Connections initiated by the server that do not match any SCD rules are considered illegal connections.

If you do not specify a rule ID for the **undo rule** command, all SCD rules in the SCD policy will be deleted.

Examples

In SCD policy **policy1**, create SCD rule 1 and enter its view.

```
<Sysname> system-view
[Sysname] scd policy policy1
[Sysname-scd-policy-policy1] rule 1
[Sysname-scd-policy-policy1-1]
```

Related commands

display scd policy

scd learning

Use **scd learning** to enter server connection learning configuration view.

Use **undo scd learning** to remove all server connection learning configurations.

Syntax

scd learning

undo scd learning

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Server connection learning allows the device to learn connections initiated by given servers. The learning results provide the basis for you to create SCD policies to monitor and log illegal connections initiated by the servers.

The **undo scd learning** command is not configurable when server connection learning is in progress.

Examples

```
<Sysname> system-view
[Sysname] scd learning
[Sysname-scd-learning]
```

scd policy

Use **scd policy** to create an SCD policy and enter its view, or enter the view of an existing SCD policy.

Use **undo scd policy** to remove an SCD policy.

Syntax

scd policy name *policy-name*

undo scd policy [**name** *policy-name*]

Default

No SCD policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

name *policy-name*: Specifies a unique name for the SCD policy. The SCD policy name is a case-insensitive string of 1 to 63 characters.

Usage guidelines

An SCD policy monitors the connections initiated by the specified protected server. You can configure the following settings in an SCD policy:

- Protected server IP address.
- SCD rules to identify legal connections initiated by the server.

- Logging for illegal connections initiated by the server.
- SCD policy enabling status.

If you do not specify an SCD policy for the **undo scd policy** command, all SCD policies will be deleted.

Examples

Create an SCD policy named **policy1** and enter its view.

```
<Sysname> system-view
[Sysname] scd policy name policy1
[Sysname-scd-policy-policy1]
```

Related commands

display scd policy

source-ip

Use **source-ip** to specify an IP address object group for server connection learning.

Use **undo source-ip** to remove an IP address object group specified for server connection learning.

Syntax

source-ip *object-group-name*

undo source-ip [*object-group-name*]

Default

No IP address object groups are specified for server connection learning.

Views

Server connection learning configuration view

Predefined user roles

network-admin

context-admin

Parameters

object-group-name: Specifies an IP address object group by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

Server connection learning will learn the connections initiated by the servers that use IP addresses in the specified IP address object groups.

You can repeat this command to specify a maximum of 1024 IP address object groups.

If you specify a nonexistent IP address object group, the system will creates an empty IP address object group with the specified name.

If you do not specify an IP address object group for the **undo source-ip** command, all IP address object groups specified for server connection learning will be removed.

The **source-ip** and **undo source-ip** commands are not configurable when sever connection learning is in progress.

For more information about address object groups, see object group configuration in *Security Configuration Guide*.

Examples

Specify IP address object group **abc** for SCD learning.

```
<Sysname> system-view
[Sysname] scd learning
[Sysname-scd-learning] source-ip abc
```

arp source-suppression limit

Use **arp source-suppression limit** to set the maximum number of unresolvable packets that can be processed per source IP address within 5 seconds.

Use **undo arp source-suppression limit** to restore the default.

Syntax

arp source-suppression limit *limit-value*

undo arp source-suppression limit

Default

The device can process a maximum of 10 unresolvable packets per source IP address within 5 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

limit-value: Specifies the limit in the range of 2 to 1024.

Usage guidelines

If unresolvable packets received from an IP address within 5 seconds exceed the limit, the device stops processing the packets from that IP address until the 5 seconds elapse.

Examples

Configure the device to process a maximum of 100 unresolvable packets per source IP address within 5 seconds.

```
<Sysname> system-view
[Sysname] arp source-suppression limit 100
```

Source MAC-based ARP attack detection commands

arp source-mac

Use **arp source-mac** to enable the source MAC-based ARP attack detection feature and specify a handling method.

Use **undo arp source-mac** to disable the source MAC-based ARP attack detection feature.

Syntax

arp source-mac { **filter** | **monitor** }

undo arp source-mac [**filter** | **monitor**]

Default

The source MAC-based ARP attack detection feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

filter: Specifies the filter handling method.

monitor: Specifies the monitor handling method.

Usage guidelines

Configure this feature on the gateways.

This feature checks the number of ARP packets delivered to the CPU. If the number of packets from the same MAC address within 5 seconds exceeds a threshold, the device generates an ARP attack entry for the MAC address. Before the entry ages out, the device handles the attack by using either of the following methods:

- **Monitor**—Only generates log messages.
- **Filter**—Generates log messages and filters out subsequent ARP packets from the MAC address.

Make sure you have enabled the ARP logging feature before enabling the source MAC-based ARP attack detection feature. For information about the ARP logging feature, see ARP configuration in *Layer 3—IP Services Configuration Guide*.

If you do not specify any handling method in the **undo arp source-mac** command, the command disables this feature.

Examples

Enable the source MAC-based ARP attack detection feature and specify the filter handling method.

```
<Sysname> system-view
[Sysname] arp source-mac filter
```

arp source-mac aging-time

Use **arp source-mac aging-time** to set the aging time for ARP attack entries.

Use **undo arp source-mac aging-time** to restore the default.

Syntax

arp source-mac aging-time *time*

undo arp source-mac aging-time

Default

The aging time for ARP attack entries is 300 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

time: Sets the aging time for ARP attack entries, in the range of 60 to 6000 seconds.

Examples

Set the aging time for ARP attack entries to 60 seconds.

```
<Sysname> system-view
[Sysname] arp source-mac aging-time 60
```

arp source-mac exclude-mac

Use **arp source-mac exclude-mac** to exclude specific MAC addresses from source MAC-based ARP attack detection.

Use **undo arp source-mac exclude-mac** to remove the excluded MAC addresses from source MAC-based ARP attack detection.

Syntax

arp source-mac exclude-mac *mac-address*&<1-n>

undo arp source-mac exclude-mac [*mac-address*&<1-n>]

Default

No MAC addresses are excluded from source MAC-based ARP attack detection.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

mac-address&<1-n>: Specifies a MAC address list. The *mac-address* argument indicates an excluded MAC address in the format of H-H-H. &<1-n> indicates the number of excluded MAC addresses that you can configure. The value for n is 10.

Usage guidelines

If you do not specify a MAC address, the **undo arp source-mac exclude-mac** command removes all excluded MAC addresses.

Examples

Exclude a MAC address from source MAC-based ARP attack detection.

```
<Sysname> system-view
[Sysname] arp source-mac exclude-mac 001e-1200-0213
```

arp source-mac threshold

Use **arp source-mac threshold** to set the threshold for source MAC-based ARP attack detection. If the number of ARP packets sent from a MAC address within 5 seconds exceeds this threshold, the device recognizes this as an attack.

Use **undo arp source-mac threshold** to restore the default.

Syntax

arp source-mac threshold *threshold-value*

undo arp source-mac threshold

Default

The threshold for source MAC-based ARP attack detection is 30.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the threshold for source MAC-based ARP attack detection. The value range for this argument is 1 to 5000.

Examples

Set the threshold for source MAC-based ARP attack detection to 30.

```
<Sysname> system-view
[Sysname] arp source-mac threshold 30
```

display arp source-mac

Use **display arp source-mac** to display ARP attack entries detected by source MAC-based ARP attack detection.

display arp source-mac { **interface** *interface-type interface-number* | **slot** *slot-number* }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number.

slot *slot-number*: Specifies an IRF member device by its ID. If you do not specify a member device, this command displays ARP attack entries for the master device.

Examples

Display the ARP attack entries detected by source MAC-based ARP attack detection on GigabitEthernet 1/0/1.

```
<Sysname> display arp source-mac interface gigabitethernet 1/0/1
Source-MAC          VLAN ID  Interface               Aging-time
23f3-1122-3344      4094     GE1/0/1                 10
```

Table 2 Command output

Field	Description
Source-MAC	Source MAC address of the attack.
VLAN ID	ID of the VLAN in which the attack was detected.
Interface	Interface on which the attack was detected.
Aging-time	Aging time for the ARP attack entry, in seconds.

ARP packet source MAC consistency check commands

arp valid-check enable

Use **arp valid-check enable** to enable ARP packet source MAC address consistency check.

Use **undo arp valid-check enable** to disable ARP packet source MAC address consistency check.

Syntax

arp detection rule

arp detection rule

Use **arp detection rule** to configure a user validity check rule.

Use **undo arp detection rule** to delete a user validity check rule.

Syntax

arp detection rule *rule-id* { **deny** | **permit** } **ip** { *ip-address* [*mask*] | **any** } **mac** { *mac-address* [*mask*] | **any** } [**vlan** *vlan-id*]

undo arp detection rule [*rule-id*]

Default

No user validity check rule is configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

rule-id: Assigns an ID to the user validity check rule. The ID value range is 0 to 511. A smaller value represents a higher priority.

deny: Denies matching ARP packets.

permit: Permits matching ARP packets.

ip { *ip-address* [*mask*] | **any** }: Specifies the sender IP address as the match criterion.

- *ip-address*: Specifies an IP address in dotted decimal notation.
- *mask*: Specifies the address mask in dotted decimal notation. If you do not specify the mask, the *ip-address* argument specifies a host IP address.
- **any**: Matches any IP address.

mac { *mac-address* [*mask*] | **any** }: Specifies the sender MAC address as the match criterion.

- *mac-address*: Specifies a MAC address in the H-H-H format.
- *mask*: Specifies the MAC address mask in the H-H-H format. If you do not specify the mask, the argument specifies the host MAC address.
- **any**: Matches any MAC address.

vlan *vlan-id*: Specifies the ID of a VLAN in the specified rule. The value range for the *vlan-id* argument is 1 to 4094. If you do not specify a VLAN, the packets' VLAN information is not checked.

Usage guidelines

A user validity check rule takes effect only when ARP attack detection is enabled.

If you do not specify a rule ID, the **undo arp detection rule** command deletes all user validity check rules.

Examples

Configure a user validity check rule and enable ARP detection for VLAN 2.

```
<Sysname> system-view
[Sysname] arp detection rule 0 permit ip 10.1.1.1 255.255.0.0 mac 0001-0203-0405

```

arp detection validate

Use **arp detection validate** to enable ARP packet validity check.

Use **undo arp detection validate** to disable ARP packet validity check.

Syntax

arp detection validate { **dst-mac** | **ip** | **src-mac** } *

undo arp detection validate [**dst-mac** | **ip** | **src-mac**] *

Default

ARP packet validity check is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dst-mac: Checks the target MAC address of ARP responses. If the target MAC address is all-zero, all-one, or inconsistent with the destination MAC address in the Ethernet header, the packet is considered invalid and discarded.

ip: Checks the sender and target IP addresses of ARP replies, and the sender IP address of ARP requests. All-one or multicast IP addresses are considered invalid and the corresponding packets are discarded.

src-mac: Checks whether the sender MAC address in the message body is identical to the source MAC address in the Ethernet header. If they are identical, the packet is forwarded. Otherwise, the packet is discarded.

Usage guidelines

You can specify more than one object to be checked in one command line.

If no keyword is specified, the **undo arp detection validate** command disables ARP packet validity check for all objects.

Examples

Enable ARP packet validity check by checking the MAC addresses and IP addresses of ARP packets.

```
<Sysname> system-view
[Sysname] arp detection validate dst-mac ip src-mac
```

arp restricted-forwarding enable

Use **arp restricted-forwarding enable** to enable ARP restricted forwarding.

Syntax

display arp detection statistics [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays dropped packet statistics for all interfaces.

Usage guidelines

This command displays numbers of packets discarded by user validity check and ARP packet validity check on interfaces.

Examples

Display statistics for packets dropped by ARP attack detection.

```
<Sysname> display arp detection statistics
State: U-Untrusted  T-Trusted
ARP packets dropped by ARP inspect checking:
Interface(State)            IP        Src-MAC   Dst-MAC   Inspect
GE1/0/1(U)                  40        0         0         78
GE1/0/2(U)                  0         0         0         0
GE1/0/3(T)                  0         0         0         0
GE1/0/4(U)                  0         0         30        0
```

Table 3 Command output

Field	Description
State	State of an interface: • **U**—ARP untrusted interface. • **T**—ARP trusted interface.
Interface(State)	Inbound interface of ARP packets. State specifies the port state, **trusted** or **untrusted**.
IP	Number of ARP packets discarded due to invalid sender and target IP addresses.
Src-MAC	Number of ARP packets discarded due to invalid source MAC address.
Dst-MAC	Number of ARP packets discarded due to invalid destination MAC address.
Inspect	Number of ARP packets that failed to pass user validity check.

context-admin

Parameters

`interface` *`interface-type interface-number`*: Specifies an interface by its type and number. If you do not specify an interface, this command clears dropped packet statistics for all interfaces.

Examples

Clear statistics for packets dropped by ARP attack detection.

```
<Sysname> reset arp detection statistics
```

Related commands

display arp detection statistics

ARP scanning and fixed ARP commands

arp fixup

Use **arp fixup** to convert existing dynamic ARP entries to static ARP entries.

Syntax

arp fixup

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The ARP conversion is a one-time operation. You can use this command again to convert the dynamic ARP entries learned later to static.

The static ARP entries converted from dynamic ARP entries have the same attributes as the manually configured static ARP entries. Due to the device's limit on the total number of static ARP entries, some dynamic ARP entries might fail the conversion.

The static ARP entries after conversion can include the following entries:

- Existing dynamic and static ARP entries before conversion.
- New dynamic ARP entries learned during the conversion.

Dynamic ARP entries that are aged out during the conversion are not converted to static ARP entries.

To delete a static ARP entry changed from a dynamic one, use the **undo arp** *ip-address* [*vpn-instance-name*] command. To delete all such static ARP entries, use the **reset arp all** or **reset arp static** command.

Examples

Convert existing dynamic ARP entries to static ARP entries.

```
<Sysname> system-view
[Sysname] arp fixup
```

arp scan

Use **arp scan** to trigger an ARP scanning in an address range.

Syntax

arp scan [*start-ip-address* **to** *end-ip-address*]

Predefined user roles

network-admin

context-admin

Parameters

start-ip-address: Specifies the start IP address of the scanning range.

end-ip-address: Specifies the end IP address of the scanning range. The end IP address must be higher than or equal to the start IP address.

Usage guidelines

CAUTION:

ARP scanning will take some time and occupy a lot of device and network resources. To stop an ongoing scan, press **Ctrl** + **C**. Dynamic ARP entries are created based on ARP replies received before the scan is terminated.

ARP scanning automatically creates ARP entries for devices in the specified address range. IP addresses already in existing ARP entries are not scanned.

If the interface's primary and secondary IP addresses are in the address range, the sender IP address in the ARP request is the address on the smallest network segment.

If no address range is specified, the device learns ARP entries for devices on the subnet where the primary IP address of the interface resides. The sender IP address in the ARP requests is the primary IP address of the interface.

The start and end IP addresses must be on the same subnet as the primary IP address or secondary IP addresses of the interface.

Examples

Configure the device to scan neighbors on the network where the primary IP address of GigabitEthernet 1/0/1 resides.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] arp scan
```

Configure the device to scan neighbors in an address range.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] arp scan 1.1.1.1 to 1.1.1.20
```

ARP gateway protection commands

arp filter source

Use **arp filter source** to enable ARP gateway protection for a gateway.

Use **undo arp filter source** to disable ARP gateway protection for a gateway.

Syntax

arp filter source *ip-address*

undo arp filter source *ip-address*

Default

ARP gateway protection is disabled.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IP address of a protected gateway.

Usage guidelines

You can enable ARP gateway protection for a maximum of eight gateways on an interface.

You cannot configure both the **arp filter source** and **arp filter binding** commands on the same interface.

Examples

Enable ARP gateway protection for the gateway with IP address 1.1.1.1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] arp filter source 1.1.1.1
```

ARP filtering commands

arp filter binding

Use **arp filter binding** to enable ARP filtering and configure an ARP permitted entry.

Use **undo arp filter binding** to remove an ARP permitted entry.

Syntax

arp filter binding *ip-address mac-address*

undo arp filter binding *ip-address*

Default

ARP filtering is disabled.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies a permitted sender IP address.

mac-address: Specifies a permitted sender MAC address.

Usage guidelines

If the sender IP and MAC addresses of an ARP packet match an ARP permitted entry, the ARP packet is permitted. If the sender IP and MAC addresses of an ARP packet do not match an ARP permitted entry, the ARP packet is discarded.

You can configure a maximum of eight ARP permitted entries on an interface.

You cannot configure both the **arp filter source** and **arp filter binding** commands on the same interface.

Examples

Enable ARP filtering and configure an ARP permitted entry.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] arp filter binding 1.1.1.1 0e10-0213-1023
```

Source MAC-based ND attack detection commands

display ipv6 nd source-mac

Use **display ipv6 nd source-mac** to display source MAC-based ND attack detection entries.

Syntax

display ipv6 nd source-mac interface *interface-type interface-number* [**slot** *slot-number*] [**verbose**]

display ipv6 nd source-mac { **mac** *mac-address* | **vlan** *vlan-id* } **slot** *slot-number* [**verbose**]

display ipv6 nd source-mac slot *slot-number* [**count** | **verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number.

mac *mac-address*: Displays the ND attack detection entry for the specified MAC address. The MAC address format is H-H-H.

vlan *vlan-id*: Displays the source MAC-based ND attack detection entries for the specified VLAN. The VLAN ID is in the range of 1 to 4094.

slot *slot-number*: Displays the ND attack entries detected by the physical interfaces that reside on the specified member device and belong to the virtual interface. If you do not specify a member device, this command displays entries detected by the physical interfaces that reside on the master device and belong to the specified virtual interface.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays source MAC-based ND attack detection entries for the master device.

verbose: Displays detailed information about source MAC-based ND attack detection entries. If you do not specify this keyword, this command displays brief information about the source MAC-based ND attack detection entries.

count: Displays the number of source MAC-based ND attack detection entries. If you do not specify this keyword, the command displays source MAC-based ND attack detection entries.

Usage guidelines

The **slot** *slot-number* option is supported only when the **interface** *interface-type interface-number* option specifies a virtual interface.

This command is supported on the following virtual interfaces: Layer 2 aggregate interfaces, Layer 3 aggregate interfaces, Layer 3 aggregate subinterfaces, and VXLAN VSI interfaces.

If you do not specify any parameters, this command displays all source MAC-based ND attack detection entries.

Examples

Display source MAC-based ND attack detection entries on GigabitEthernet 1/0/1.

```
<Sysname> display ipv6 nd source-mac interface gigabitethernet 1/0/1
Source MAC    VLAN ID Interface             Aging time (sec) Packets dropped
23f3-1122-3344 4094   GE1/0/1               10               84467
```

Displays the number of source MAC-based ND attack detection entries.

```
<Sysname> display ipv6 nd source-mac count
Total source MAC-based ND attack detection entries: 1
```

Display detailed information about source MAC-based ND attack detection entries on GigabitEthernet 1/0/1.

```
<Sysname> display ipv6 nd source-mac interface gigabitethernet 1/0/1 verbose
Source MAC: 0001-0001-0001
VLAN ID: 4094
Hardware status: Succeeded
Aging time: 10 seconds
Interface: GigabitEthernet1/0/1
Attack time: 2019/06/04 15:53:34
Packets dropped: 84467
```

Table 1 Command output

Field	Description
Source MAC	MAC address from which an ND attack is launched.
VLAN ID	ID of the VLAN where the source MAC-based ND attack is detected.
Interface	Interface where the source MAC-based ND attack is detected.
Aging time	Remaining aging time of the source MAC-based ND attack detection entry, in seconds.
Packets dropped	Total number of dropped packets. For Layer 2 Ethernet interfaces, this field is not supported and the field value is **0**.
Total source MAC-based ND attack detection entries	Total number of source MAC-based ND attack detection entries.
Hardware status	Status of the source MAC-based ND attack entry setting to hardware: • Succeeded. • Failed. • Not supported. • Not enough resources.
Attack time	Time when the source MAC-based ND attack was detected. The time format is YYYY/MM/DD HH:MM:SS.

ipv6 nd source-mac { **filter** | **monitor** }

undo ipv6 nd source-mac

Default

Source MAC-based ND attack detection is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

`filter`: Specifies the filter mode.

`monitor`: Specifies the monitor mode.

Usage guidelines

As a best practice, configure this command on gateway devices.

Source MAC-based ND attack detection checks the number of ND messages delivered to the CPU on a per source MAC basis. If the number of messages from the same MAC address within 5 seconds exceeds the threshold, the device generates an ND attack entry for the MAC address. The processing of the ND messages matching this entry depends on the detection mode. With ND logging enabled (by using the **`ipv6 nd check log enable`** command), source MAC-based ND attack detection processes the messages as follows:

- **Filter mode**—Filters out subsequent ND messages sent from the MAC address, and generates log messages.
- **Monitor mode**—Only generates log messages.

The device uses the entry aging time (fixed at 300 seconds) and the threshold to calculate a value:

The calculated value = (threshold/5) × 300

The device monitors the number of dropped packets for an entry. When the entry aging time is reached, it compares the number with the calculated value and takes actions accordingly:

- If the number of dropped packets is higher than or equal to the calculated value, the device resets the aging time for the entry.
- If the number of dropped packets is lower than the calculated value, the system deletes the entry and marks MAC address in the entry as a common MAC address.

When you change the detection mode from monitor to filter, the filter mode takes effect immediately. When you change the detection mode from filter to monitor, the device continues filtering ND messages that match existing attack entries.

Examples

Enable source MAC-based ND attack detection and set the detection mode to monitor.

```
<Sysname> system-view
[Sysname] ipv6 nd source-mac monitor
```

ipv6 nd source-mac threshold

Use **`ipv6 nd source-mac threshold`** to set the threshold for source MAC-based ND attack detection.

Use **`undo ipv6 nd source-mac threshold`** to restore the default.

Syntax

`ipv6 nd source-mac threshold` *`threshold-value`*

`undo ipv6 nd source-mac threshold`

Default

The threshold for source MAC-based ND attack detection is 30.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the threshold for source MAC-based ND attack detection. The value range is 1 to 5000.

Usage guidelines

If the number of packets from the same MAC address within 5 seconds exceeds the threshold, the device generates an ND attack entry for the MAC address.

Examples

Set the threshold to 100 for source MAC-based ND attack detection

```
<Sysname> system-view
[Sysname] ipv6 nd source-mac threshold 100
```

reset ipv6 nd source-mac

Use **reset ipv6 nd source-mac** to delete source MAC-based ND attack detection entries.

Syntax

reset ipv6 nd source-mac [**interface** *interface-type interface-number* | **mac** *mac-address* | **vlan** *vlan-id*] [**slot** *slot-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Deletes the source MAC-based ND attack entries detected on the specified interface. The *interface-type interface-number* arguments specify an interface by its type and number.

mac *mac-address*: Deletes the source MAC-based ND attack entry for the specified MAC address. The MAC address format is H-H-H.

vlan *vlan-id*: Deletes the source MAC-based ND attack entries for the specified VLAN. The value range for the *vlan-id* argument is 1 to 4094.

slot *slot-number*: Specifies an IRF member device by its member ID.

Usage guidelines

If you do not specify any parameters, this command deletes all source MAC-based ND attack detection entries.

Examples

Delete all source MAC-based ND attack detection entries.

```
<Sysname> reset ipv6 nd source-mac
```

undo ipv6 nd attack-suppression enable per-interface

Default

Interface-based ND attack suppression is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this feature to rate limit ND requests on each Layer 3 interface to prevent ND spoofing attacks. This feature monitors the number of ND requests that each Layer 3 interface received within 5 seconds. If the number on an interface exceeds the threshold, the device creates an ND attack suppression entry for the interface. During the suppression period (fixed at 300 seconds), the device drops ND messages received on this interface.

When the suppression time expires, the system examines the number of dropped ND messages on the interface within the suppression time:

- If the number is higher than or equal to a calculated value, the device resets the suppression time for the entry and continues the ND suppression on the interface.

  The calculated value = (threshold/5) × 300
- If the number is lower than the calculated value, the device deletes the suppression entry.

As a best practice, enable this feature on the gateway.

Examples

Enable interface-based ND attack suppression.

```
<Sysname> system-view
[Sysname] ipv6 nd attack-suppression enable per-interface
```

Related commands

display ipv6 nd attack-suppression per-interface

reset ipv6 nd attack-suppression per-interface statistics

Use **reset ipv6 nd attack-suppression per-interface statistics** to clear statistics for ND messages dropped by interface-based ND attack suppression.

Syntax

reset ipv6 nd attack-suppression per-interface statistics [**interface** *interface-type interface-number*] [**slot** *slot-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Clears statistics for ND messages dropped by interface-based ND attack suppression on the specified interface. The *interface-type interface-number* arguments specify an interface by its type and number.

slot *slot-number*: Specifies an IRF member device by its member ID.

Usage guidelines

After you execute this command, the value for the **Packets dropped** field from the output of the **display ipv6 nd attack-suppression per-interface** command will be cleared.

If you do not specify any parameters, this command clears all statistics for ND messages dropped by interface-based ND attack suppression.

Examples

Clear statistics for ND messages dropped by interface-based ND attack suppression.

```
<Sysname> reset ipv6 nd attack-interface per-interface statistics
```

Related commands

display ipv6 nd attack-suppression per-interface

Source MAC consistency check commands

ipv6 nd check log enable

Use **ipv6 nd check log enable** to enable the ND logging feature.

Use **undo ipv6 nd check log enable** to restore the default.

Syntax

ipv6 nd check log enable

undo ipv6 nd check log enable

Default

The ND logging feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The ND logging feature logs source MAC inconsistency events, and sends the log messages to the information center. The information center can then output log messages from different source modules to different destinations. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

As a best practice, disable the ND logging feature to avoid excessive ND logs.

Examples

Enable the ND logging feature.

```
<Sysname> system-view
[Sysname] ipv6 nd check log enable
```

Related commands

ipv6 nd mac-check enable

ipv6 nd mac-check enable

Use **ipv6 nd mac-check enable** to enable source MAC consistency check for ND messages.

Use **undo ipv6 nd mac-check enable** to disable source MAC consistency check for ND messages.

Syntax

ipv6 nd mac-check enable

undo ipv6 nd mac-check enable

Default

Source MAC consistency check for ND messages is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this command to enable source MAC consistency check on a gateway. The gateway checks the source MAC address and the source link-layer address for consistency for each ND message. If an inconsistency is found, the gateway drops the ND message.

Examples

Enable source MAC consistency check for ND messages.

```
<Sysname> system-view
[Sysname] ipv6 nd mac-check enable
```

context-admin

Parameters

loose: Enables loose uRPF check. To pass loose uRPF check, the source address of a packet must match the destination address of a FIB entry.

strict: Enables strict uRPF check. To pass strict uRPF check, the source address and receiving interface of a packet must match the destination address and output interface of a FIB entry. You can enable strict uRPF check only in VLAN interface view.

allow-default-route: Allows using the default route for uRPF check.

acl *acl-number*: Specifies an ACL by its number.

- For a basic ACL, the value range is 2000 to 2999.
- For an advanced ACL, the value range is 3000 to 3999.

link-check: Enables link layer check (Ethernet link).

Usage guidelines

uRPF can be deployed on a PE connected to a CE or an ISP, or on a CE.

Configure strict uRPF check for traffic that uses symmetric path and configure loose uRPF check for traffic that uses asymmetric path. A symmetric path exists for a session if the PE uses the same interface to receive upstream traffic and send downstream traffic. The path is asymmetric if the PE uses different interfaces to receive upstream traffic and send downstream traffic.

- Typically, symmetric path applies to traffic that goes through an ISP's PE interface connected to the CE. You can configure strict uRPF check for the security zone to which the PE interface belongs.
- Asymmetric path might exist for traffic that goes through a PE interface connected to another ISP. In this case, configure loose uRPF check for the security zone to which the PE interface belongs.

Typically, you do not need to configure the **allow-default-route** keyword on a PE device, because it has no default route pointing to a CE. If you enable uRPF on a security zone where the CE interface resides and the security zone has a default route pointing to the PE, specify the **allow-default-route** keyword.

You can use an ACL to match specific packets, so they are forwarded even if they fail to pass uRPF check.

If the specified ACL does not exist or does not contain rules, the ACL cannot match any packets.

If the **vpn-instance** keyword is specified in an ACL rule, the rule applies only to VPN packets. If the **vpn-instance** keyword is not specified in an ACL rule, the rule applies only to public network packets.

If a Layer 3 PE interface connects to a large number of PCs, configure the **link-check** keyword on the interface to enable link layer check. uRPF checks the validity of the source MAC address.

Examples

Configure strict uRPF check for security zone **Untrust**.

```
<Sysname> system-view
[Sysname] security-zone name Untrust
[Sysname-security-zone-Untrust] ip urpf strict
```

undo ipv6 urpf

Default

IPv6 uRPF is disabled.

Views

Security zone view

Predefined user roles

network-admin

context-admin

Parameters

loose: Enables loose IPv6 uRPF check. To pass loose IPv6 uRPF check, the source address of a packet must match the destination address of an IPv6 FIB entry.

strict: Enables strict IPv6 uRPF check. To pass strict IPv6 uRPF check, the source address and receiving interface of a packet must match the destination address and output interface of an IPv6 FIB entry.

allow-default-route: Allows using the default route for IPv6 uRPF check.

acl *acl-number*: Specifies an IPv6 ACL by its number.

- For a basic IPv6 ACL, the value range is 2000 to 2999.
- For an advanced IPv6 ACL, the value range is 3000 to 3999.

Usage guidelines

IPv6 uRPF can be deployed on a CE or on a PE connected to either a CE or an ISP.

Configure strict IPv6 uRPF check for traffic that uses symmetric path and configure loose IPv6 uRPF check for traffic that uses asymmetric path. A symmetric path exists for a session if the PE uses the same interface to receive upstream traffic and send downstream traffic. The path is asymmetric if the PE uses different interfaces to receive upstream traffic and send downstream traffic.

- Typically, symmetric path applies to traffic that goes through an ISP's PE interface connected to the CE. You can configure strict IPv6 uRPF check for the security zone to which the PE interface belongs.
- Asymmetric path might exist for traffic that goes through a PE interface connected to another ISP. In this case, configure loose IPv6 uRPF check for the security zone to which the PE interface belongs.

You can use an ACL to match specific packets, so they are forwarded even if they fail to pass IPv6 uRPF check.

If the specified ACL does not exist or does not contain rules, the ACL cannot match any packets.

If the **vpn-instance** keyword is specified in an ACL rule, the rule applies only to VPN packets. If the **vpn-instance** keyword is not specified in an ACL rule, the rule applies only to public network packets.

Typically, you do not need to configure the **allow-default-route** keyword on a PE device, because it has no default route pointing to a CE. If you enable uRPF on a security zone where the CE interface resides and the security zone has a default route pointing to the PE, specify the **allow-default-route** keyword.

Examples

Configure loose IPv6 uRPF check for the security zone **Untrust**.

```
<Sysname> system-view
[Sysname] security-zone name Untrust
[Sysname-security-zone-Untrust] ipv6 urpf loose
```

context-operator

Parameters

ipv4-address: Specifies an IPv4 address. The IPv4 address cannot be an all 0s, a multicast address, or a loopback address. If you do not specify an IPv4 address, this command displays IPv4-MAC binding entries for all IPv4 addresses.

mac-address *mac-address*: Specifies a MAC address in the format of H-H-H. The MAC address cannot be all 0s, all Fs (a broadcast MAC address), or a multicast address. If you do not specify a MAC address, this command displays IPv4-MAC binding entries for all MAC addresses.

vlan *vlan-id*: Specifies a VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays IPv4-MAC binding entries for all VLANs.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. The specified VPN must already exist. If you do not specify a VPN instance, this command displays IPv4-MAC binding entries for the public network.

Examples

Display IPv4-MAC binding entries.

```
<Sysname> display ip-mac binding ipv4
Total entries: 1
IP address     MAC address          VPN instance     VLAN ID
1.1.1.1        0000-0000-0001       --               N/A
```

Table 1 Command output

Field	Description
Total entries	Total number of IPv4-MAC binding entries.
IP address	IPv4 address in the IPv4-MAC binding entry.
MAC address	MAC address in the IPv4-MAC binding entry.
VPN instance	Name of the VPN instance to which the IPv4-MAC binding entry belongs. If the binding entry belongs to the public network, this field displays hyphens (**--**).

Field	Description
VLAN ID	VLAN to which the IPv4-MAC binding entry belongs.

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays statistics about packets dropped by the IP-MAC binding feature for all member devices.

Usage guidelines

When the deny action is set for packets that do not match any IP-MAC binding entries, this command displays statistics about the following packets:

- Packets that do not exactly match any IP-MAC binding entries.
- Packets that do not match any IP-MAC binding entries.

Examples

Display statistics about packets dropped by the IP-MAC binding feature on the specified slot.

```
<Sysname> display ip-mac binding statistics slot 1
Slot 1:
Statistics about dropped packets:
IPv4 drop statistics:
  IPv4 ip-mac binding dropped packets because partial match ip: 3
  IPv4 ip-mac binding dropped packets because partial match mac: 0
  IPv4 ip-mac binding dropped packets because no match entry: 12
IPv6 drop statistics:
  IPv6 ip-mac binding dropped packets because partial match ip: 0
  IPv6 ip-mac binding dropped packets because partial match mac: 0
  IPv6 ip-mac binding dropped packets because no match entry: 0
```

Table 3 Command output

Field	Description
IPv4 drop statistics	Number of IPv4 packets dropped by the IP-MAC binding feature.
IPv4 ip-mac binding dropped packets because partial match ip	Number of IPv4 packets that were dropped because no matching IPv4-MAC binding entries were found for the source MAC address.
IPv4 ip-mac binding dropped packets because partial match mac	Number of IPv4 packets that were dropped because no matching IPv4-MAC binding entry was found for the source IP address.
IPv4 ip-mac binding dropped packets because no match entry	Number of IPv4 packets that were dropped because no matching IPv4-MAC binding entry was found for the source IP address and source MAC address.
IPv6 drop statistics	Number of IPv6 packets dropped by the IP-MAC binding feature.
IPv6 ip-mac binding dropped packets because partial match ip	Number of IPv6 packets that were dropped because no matching IPv6-MAC binding entries were found for the source MAC address.
IPv6 ip-mac binding dropped packets because partial match mac	Number of IPv6 packets that were dropped because no matching IPv6-MAC binding entry was found for the source IP address.
IPv6 ip-mac binding dropped packets because no match entry	Number of IPv6 packets that were dropped because no matching IPv6-MAC binding entry was found for the source IP address and source MAC address.

context-operator

Usage guidelines

This command displays the status of the IP-MAC binding feature and the default action for packets that do not match any IP-MAC binding entries.

Examples

Display the status of the IP-MAC binding feature.

```
<Sysname> display ip-mac binding status
```

```
ip-mac binding: Disabled
ip-mac binding no-match action: Deny
```

Table 4 Command output

Field	Description
ip-mac binding	Status of the IP-MAC binding feature, **Enabled** or **Disabled**.
ip-mac binding no-match action	The default action for packets that do not match any IP-MAC binding entries: • **Permit**—Forwards packets. • **Deny**—Drops packets.

ip-mac binding enable

Use **ip-mac binding enable** to enable the IP-MAC binding feature.

Use **undo ip-mac binding enable** to disable the IP-MAC binding feature.

Syntax

ip-mac binding enable

undo ip-mac binding enable

Default

The IP-MAC binding feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The IP-MAC binding feature uses IP-MAC binding entries to match the source IP address and source MAC address in incoming packets:

- If both the source IP address and source MAC address match the same binding entry, the feature permits the packet.
- If only the source IP address or source MAC address matches a binding entry, the feature denies the packet.
- If the source IP address and the source MAC address match no binding entries, the feature processes the packet based on the specified action.

The IP-MAC binding entries are static. Therefore, this feature is applicable to only scenario that all users are statically assigned IP addresses. Using this feature in a network where users' IP addresses are dynamically assigned through DHCP might cause communication failure.

Examples

Enable the IP-MAC binding feature.

```
<Sysname> system-view
[Sysname] ip-mac binding enable
```

ip-mac binding interface

Use **ip-mac binding interface** to generate IP-MAC binding entries based on existing ARP and ND entries on an interface.

Syntax

ip-mac binding interface *interface-type interface-number*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface-type interface-number: Specifies an interface by its name and type. The interface must be a Layer 3 Ethernet interface or subinterface, Layer 3 aggregate interface or subinterface, Reth interface or subinterface, or VLAN interface.

Usage guidelines

Use this command to generate IP-MAC binding entries based on existing ARP entries and ND entries on an interface. If the newly generated IP-MAC binding entries conflict with the existing IP-MAC binding entries, the device retains the existing entries.

To generate IP-MAC binding entries based on ARP entries and ND entries newly added after the command execution, re-execute this command.

To delete IPv4-MAC binding entries generated by using this command, use the **undo ip-mac binding ipv4** command. To delete IPv6-MAC binding entries generated by using this command, use the **undo ip-mac binding ipv6** command.

IP-MAC binding entries are static. Therefore, the binding entries generated by using this command are not updated when the relevant ARP or ND entries change.

Examples

Generate IP-MAC binding entries based on existing ARP and ND entries on GigabitEthernet 0/0/1.

```
<Sysname> system-view
[Sysname] ip-mac binding interface gigabitethernet 1/0/1
```

ip-mac binding ipv4

Use **ip-mac binding ipv4** to create an IPv4-MAC binding entry.

Use **undo ip-mac binding ipv4** to delete IPv4-MAC binding entries.

Syntax

ip-mac binding ipv4 *ipv4-address* **mac-address** *mac-address* [**vlan** *vlan-id* | **vpn-instance** *vpn-instance-name*]

undo ip-mac binding ipv4 { **all** | *ipv4-address* **mac-address** *mac-address* [**vlan** *vlan-id* | **vpn-instance** *vpn-instance-name*] }

Default

No IPv4-MAC binding entries are configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies an IPv4 address. The IPv4 address cannot be all 0s, a multicast address, or a loopback address.

mac-address *mac-address*: Specifies a MAC address in the format of H-H-H. The MAC address cannot be all 0s, all Fs (a broadcast MAC address), or a multicast address.

vlan *vlan-id*: Specifies a VLAN ID in the range of 1 to 4094.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. The specified VPN must already exist. If you do not specify a VPN instance, the IPv4-MAC binding entry belongs to the public network.

all: Specifies all IPv4-MAC binding entries.

Usage guidelines

A MAC address can be bound to multiple IPv4 addresses. However, an IPv4 address can be bound to only one MAC address. To bind an IPv4 address in a binding entry to another MAC address, you must delete the existing binding entry, and then create the new binding entry.

IPv4-MAC binding entries created by using this command are globally effective.

The device supports a maximum of 1024 IPv4-MAC binding entries.

Examples

Create an IPv4-MAC binding entry to permit packets with source IPv4 address 192.168.0.1 and source MAC address 0001-0001-0001.

```
<Sysname> system-view
[Sysname] ip-mac binding ipv4 192.168.0.1 mac-address 0001-0001-0001
```

Related commands

display ip-mac binding ipv4

ip-mac binding ipv6

Use **ip-mac binding ipv6** to create an IPv6-MAC binding entry.

Use **undo ip-mac binding ipv6** to delete IPv6-MAC binding entries.

Syntax

ip-mac binding ipv6 *ipv6-address* **mac-address** *mac-address* [**vlan** *vlan-id* | **vpn-instance** *vpn-instance-name*]

undo ip-mac binding ipv6 { **all** | *ipv6-address* **mac-address** *mac-address* [**vlan** *vlan-id* | **vpn-instance** *vpn-instance-name*] }

Default

No IPv6-MAC binding entries are configured.

application statistics enable

Use **application statistics enable** to enable the application statistics feature on the specified direction of an interface.

Use **undo application statistics enable** to disable the application statistics feature on the specified direction of an interface.

Syntax

application statistics enable [**inbound** | **outbound**]

undo application statistics enable [**inbound** | **outbound**]

Default

The application statistics feature is disabled on both directions of an interface.

Views

Layer 2 interface view/Layer 3 interface view

Predefined user roles

network-admin

context-admin

Parameters

inbound: Specifies the inbound direction of the interface.

outbound: Specifies the outbound direction of the interface.

Usage guidelines

IMPORTANT:

The application statistics feature consumes a large amount of system memory. When the system generates a low-memory alarm, disable the application statistics feature on interfaces.

If no direction is specified, application statistics is enabled in both the inbound and outbound directions.

When this feature is enabled, the device separately counts the number of packets or bytes that the interface has received or sent for each application protocol. It also calculates the transmission rates of the interface for these protocols.

To display application statistics, use the **display application statistics** command.

Examples

Enable application statistics in the inbound direction of GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] application statistics enable inbound
```

Enable application statistics in the outbound direction of GigabitEthernet 1/0/2.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] application statistics enable outbound
```

Enable application statistics in the inbound and outbound directions of GigabitEthernet 1/0/3.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/3
[Sysname-GigabitEthernet1/0/3] application statistics enable
```

Enable application statistics in the inbound direction of Vlan-interface 2.

```
<Sysname> system-view
[Sysname] interface Vlan-interface 2
[Sysname-Vlan-interface2] application statistics enable inbound
```

Related commands

display application statistics

apr protocol detection-threshold application-other

Use **apr protocol detection-threshold application-other** to configure detection thresholds for categorizing an application as type **other**.

Use **undo apr protocol detection-threshold application-other** to restore the default.

Syntax

apr protocol *protocol-name* **detection-threshold** { **packet-count** *count* | **payload-length** *length* } **application-other**

undo apr protocol *protocol-name* **detection-threshold** { **packet-count** | **payload-length** } **application-other**

Default

The device uses predefined detection thresholds in the signature library for categorizing an application as type **other**.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

protocol-name: Specifies a protocol by its name, a case-insensitive string of 1 to 63 characters.

packet-count *count*: Specifies the maximum number of packets to be detected, in the range of 1 to 128.

payload-length *length*: Specify the maximum payload length to be detected, in the range of 64 to 65536 bytes.

Usage guidelines

If the device cannot identify the application to which the packets of a protocol belongs after detection thresholds are reached, it categorizes the packets as belonging to type **other**.

You can configure both the packet count threshold and the payload length threshold for the same protocol.

To display the detection threshold settings, use the **display apr protocol detection-threshold-other** command.

Examples

Configure the payload length threshold as 2500 bytes for HTTP and use the predefined packet count threshold.

```
<Sysname> system-view
[Sysname] apr protocol http detection-threshold payload-length 2500 application-other
```

Related commands

display apr protocol detection-threshold-other

apr set detectlen

Use **apr set detectlen** to set the maximum detected length for an NBAR rule.

Use **undo apr set detectlen** to restore the default.

Syntax

apr set detectlen *bytes*

undo apr set detectlen

Default

The maximum detected length is not set for an NBAR rule.

Views

NBAR rule view

Predefined user roles

network-admin

context-admin

Parameters

bytes: Specifies the maximum detected length in bytes for an NBAR rule. The value range is 0 to 4294967295.

Usage guidelines

The maximum detected length determines whether to inspect subsequent packets after the device recognizes an application:

- If the inspected byte count already reaches the maximum number, the device will not inspect subsequent packets.
- If the inspected byte count does not reach the maximum number, the device will inspect subsequent packets until the maximum number is reached.

If no maximum detected length is configured, the device continues to inspect subsequent packets for application recognition after recognizing an application. Inspection of subsequent packets affects device performance.

When you set the maximum detected length, make sure you fully understand its impact on system performance.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Set the maximum detected length to 100000 bytes for NBAR rule **abcd**.

```
<Sysname> system-view
[Sysname] nbar application abcd protocol http
[Sysname-nbar-application-abcd] apr set detectlen 100000
```

Related commands

nbar application

apr signature auto-update

Use **apr signature auto-update** to enable automatic update for the APR signature library and enter auto-update configuration view.

Use **undo apr signature auto-update** to disable automatic update for the APR signature library.

Syntax

apr signature auto-update

undo apr signature auto-update

Default

Automatic update is disabled for the APR signature library.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this command to update the APR signature library if the device can access the signature library services at the NSFOCUS website.

Examples

Enable automatic update for the APR signature library and enter auto-update configuration view.

```
<Sysname> system-view
[Sysname] apr signature auto-update
[Sysname-apr-autoupdate]
```

Related commands

override-current

update schedule

apr signature auto-update-now

Use **apr signature auto-update-now** to manually trigger an automatic update for the APR signature library.

Syntax

apr signature auto-update-now

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command starts the automatic APR signature library update process and backs up the current APR signature file. This command is independent of the **apr signature auto-update** command.

Use this command to update the APR signature library if you find a new version of APR signature library at the NSFOCUS website.

Examples

Manually trigger an automatic update for the APR signature library.

```
<Sysname> system-view
[Sysname] apr signature auto-update-now
```

apr signature rollback

Use **apr signature rollback** to roll back the APR signature library.

Syntax

apr signature rollback { **factory** | **last** }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

factory: Rolls back the APR signature library to the factory version.

last: Rolls back the APR signature library to the last version.

Usage guidelines

You can use this command if you find that high error rate or abnormality occurs when the device uses the current APR signature library for application recognition.

Each time a rollback operation is performed, the device backs up the current version of the APR signature library. If you repeat the **apr signature rollback last** command multiple times, the APR signature library will repeatedly switch between the current version and the last version.

To ensure that the APR signature library can be successfully rolled back to the last version, back up the current APR signature library each time you update the library.

Examples

Roll back the APR signature library to the last version.

```
<Sysname> system-view
[Sysname] apr signature rollback last
```

apr signature update

Use **apr signature update** to manually update the APR signature library.

Syntax

apr signature update [**override-current**] *file-path*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

override-current: Overwrites the old APR signature file. If you do not specify this keyword, the old APR signature file will be saved as a backup signature file on the device after the update.

file-path: Specifies the path of the new APR signature file, a case-insensitive string of 1 to 255 characters.

Usage guidelines

Use this command to update APR signature library if the device cannot access the signature library services at the NSFOCUS website.

You can use either of the following methods to manually update the APR signature library:

- **Local update**—By using the locally stored APR signature file.

  The APR signature file must be stored on the mater device for a successful update.

  The following table describes the formats of the *file-path* argument for different update scenarios:

Update scenario	Format of *file-path*	Remarks
The update file is stored in the current working directory.	*filename*	To display the current working directory, use the **pwd** command (see file system management in *Fundamentals Command Reference)*.
The update file is stored in a different directory on the same storage medium.	*filename*	Before updating the signature library, you must use the **cd** command to open the directory where the update file is stored. For information about the **cd** command, see file system management in *Fundamentals Command Reference.*
The update file is stored on a different storage medium.	*path/filename*	Before updating the signature library, you must first use the **cd** command to open the root directory of the storage medium where the file is stored. For information about the **cd** command, see file system management in *Fundamentals Command Reference.*

- **FTP/TFTP update**—By using the APR signature file stored on an FTP or TFTP server.

  The following table describes the formats of the *file-path* argument for different update scenarios:

Update scenario	Format of *file-path*	Remarks
The update file is stored on an FTP server.	*ftp://username:password@ server address/filename*	The *username* argument represents the FTP login username. The *password* argument represents the FTP login password. The *server address* argument represents the IP address or host name of the FTP server. If an FTP login username or password includes colons (:), at signs (@), or slashes (/), you must replace these special characters with the corresponding escape characters. • The escape character for the colon (:) character is %3A or %3a. • The escape character for the at sign (@) character is %40. • The escape character for the slash (/)

Update scenario	Format of *file-path*	Remarks
		character is %2F or %2f.
The update file is stored on a TFTP server.	*tftp://server address/filename*	The *server address* argument represents the IP address or host name of the TFTP server.

If you specify the host name, make sure the following requirements are met:

- The device can resolve the IP address of the FTP or TFTP server through static or dynamic domain name resolution.
- The device and server can reach each other.
  - For information about DNS, see *Layer 3—IP Services Configuration Guide*.

Examples

Manually update the APR signature library by using an APR signature file stored on a TFTP server.

```
<Sysname> system-view
[Sysname] apr signature update tftp://192.168.0.1/apr-1.0.2-en.dat
```

Manually update the APR signature library by using an APR signature file stored on an FTP server.

```
<Sysname> system-view
[Sysname] apr signature update
ftp://user%3A123:user%40abc%2F123@192.168.0.10/apr-1.0.2-en.dat
```

Manually update the APR signature library by using an APR signature file stored on the device, The file is stored in directory **cfa0:/apr-1.0.23-en.dat**. In this example, the working directory is **cfa0:**.

```
<Sysname> system-view
[Sysname] apr signature update apr-1.0.23-en.dat
```

Manually update the APR signature library by using an APR signature file stored on the device, The file is stored in directory **cfa0:/dpi/apr-1.0.23-en.dat**. In this example, the working directory is **cfa0:**.

```
<Sysname> cd dpi
<Sysname> system-view
[Sysname] apr signature update apr-1.0.23-en.dat
```

Manually update the APR signature library by using an APR signature file stored on the device, The file is stored in directory **cfb0:/dpi/apr-1.0.23-en.dat**. In this example, the working directory is **cfa0:**.

```
<Sysname> cd cfb0:/
<Sysname> system-view
[Sysname] apr signature update dpi/apr-1.0.23-en.dat
```

copy app-group

Use **copy app-group** to copy all application protocols in an application group to another group.

Syntax

copy app-group *group-name*

Views

Application group view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies the name of the source application group, a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed.

Usage guidelines

Execute this command multiple times to copy application protocols in different groups to the current group.

Examples

Copy application protocols in group **bcd** to group **abc**.

```
<Sysname> system-view
[Sysname] app-group abc
[Sysname-app-group-abc] copy app-group bcd
```

Related commands

app-group

include application

description (application group view)

Use **description** to configure the description of an application group.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

An application group is described as **"User-defined application group"**.

Views

Application group view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 127 characters. If the string includes spaces, use a pair of quotation marks ("") to enclose all characters.

Usage guidelines

Configure descriptions for different application groups for identification and management purposes.

Examples

Configure a description for application group **aaa**.

```
<Sysname> system-view
[Sysname] app-group aaa
```

```
[Sysname-app-group-aaa] description "User defined aaa group"
```

Related commands

app-group

description (NBAR rule view)

Use **description** to configure the description of a user-defined NBAR rule.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

A user-defined NBAR rule is described as **"User defined application"**.

Views

NBAR rule view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 127 characters.

Usage guidelines

Configure descriptions for different user-defined NBAR rules for identification and management purposes.

Examples

Configure a description for user-defined NBAR rule **abcd**.

```
<Sysname> system-view
[Sysname] nbar application abcd protocol http
[Sysname-nbar-application-abcd] description "A user-defined application based on HTTP"
```

Related commands

nbar application

destination

Use **destination** to specify a destination IP address or subnet as a match criterion in a user-defined NBAR rule.

Use **undo destination** to restore the default.

Syntax

destination ip *ipv4-address* [*mask-length*]

undo destination

Default

A user-defined NBAR rule matches packets destined for all IP addresses.

Views

NBAR rule view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies a destination IPv4 address or IPv4 subnet, in dotted decimal notation.

mask-length: Specifies the mask length for IPv4 addresses, in the range of 0 to 32. If you do not specify this argument, the default mask length is 32.

Usage guidelines

If you execute this command multiple times for the same NBAR rule, the most recent configuration takes effect.

Examples

Configure user-defined NBAR rule **abcd** to match packets destined for IPv4 subnet 192.168.1.0/24.

```
<Sysname> system-view
[Sysname] nbar application abcd protocol http
[Sysname-nbar-application-abcd] destination ip 192.168.1.0 24
```

Related commands

nbar application

detection

Use **detection** to configure a detection item for a signature.

Use **undo detection** to delete detection items for a signature.

Syntax

detection *detection-id* **field** *field-name* **match-type** { **exclude** | **include** } { **hex** *hex-vector* | **regex** *regex-pattern* | **text** *text-string* } [**offset** *offset-value* [**depth** *depth-value*] | **relative-offset** *relative-offset-value* [**relative-depth** *relative-depth-value*]]

undo detection { **all** | *detection-id* }

Default

No detection items are configured for a signature.

Views

NBAR rule signature view

Predefined user roles

network-admin

context-admin

Parameters

detection-id: Specifies a detection item ID in the range of 1 to 255.

field *field-name*: Specifies a protocol field by its name, a case-sensitive string of 1 to 31 characters. The detection item is matched in the scope of the specified protocol field. You can enter a question mark to obtain a list of supported protocol fields.

match-type { **exclude** | **include** }: Specifies the match type as **exclude** or **include**.

hex *hex-vector*: Specifies a hexadecimal vector as the match pattern. The *hex-vector* argument is a string of 8 to 256 characters. The argument must start and end with a vertical bar (|).

regex *regex-pattern*: Specifies a regular expression as the match pattern. The *regex-pattern* argument is a case-sensitive string of 3 to 253 characters.

text *text-string*: Specifies a string as the match pattern. The *string* argument is a case-sensitive string of 3 to 256 characters.

offset *offset-value*: Specifies the offset from the beginning of the specified protocol field, in the range of 0 to 65535 bytes. A packet matches the signature after the offset. If you do not specify this option, a packet matches the signature from the beginning of the specified protocol field.

depth *depth-value*: Specifies the depth of the detection item, in the range of 3 to 65535 bytes.

relative-offset *relative-offset-value*: Specifies the offset from the end of the previous detection item, in the range of -32767 to 32767 bytes. A packet matches the signature after the offset. If the offset value is minus, the detection item is before the previous detection item.

relative-depth *relative-depth-value*: Specifies the relative depth of the detection item, in the range of 3 to 65535 bytes.

all: Specifies all detection items.

Usage guidelines

You can configure multiple detection items for an NBAR rule signature. The relationship among detection items is logic AND, and the match order is the configuration order. A packet matches a signature only if all detection items are matched.

As a best practice to ensure correct detection results, configure the protocol fields in the order they appear in HTTP packets.

Examples

Configure a detection item in user-defined NBAR rule **app_http**.

```
<Sysname> system-view
[Sysname] nbar application app_http protocol http
[Sysname-nbar-application-app_http] signature 1 field uri string abcdefg
[Sysname-nbar-application-signature-app_http-1] detection 1 field uri match-type include
text abc offset 10 depth 50
```

direction

Use **direction** to specify a direction as a match criterion in a user-defined NBAR rule.

Use **undo direction** to restore the default.

Syntax

direction { **to-client** | **to-server** }

undo direction

Default

A user-defined NBAR rule matches packets in both directions.

Views

NBAR rule view

Predefined user roles

network-admin

context-admin

Parameters

to-client: Specifies the direction from server to client.

to-server: Specifies the direction from client to server.

Usage guidelines

If you execute this command multiple times for the same NBAR rule, the most recent configuration takes effect.

Examples

Configure user-defined NBAR rule **abcd** to match packets from client to server.

```
<Sysname> system-view
[Sysname] nbar application abcd protocol http
[Sysname-nbar-application-abcd] direction to-server
```

Related commands

nbar application

disable

Use **disable** to disable a user-defined NBAR rule.

Use **undo disable** to restore the default.

Syntax

disable

undo disable

Default

A user-defined NBAR rule is enabled.

Views

NBAR rule view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this command to disable a user-defined NBAR rule if the following conditions exist:

- The NBAR rule will not be used in the foreseeable future.
- You do not want to delete the NBAR rule.

Examples

Disable user-defined NBAR rule **abcd**.

```
<Sysname> system-view
[Sysname] nbar application abcd protocol http
```

```
[Sysname-nbar-application-abcd] disable
```

display app-group

Use **display app-group** to display information about the specified application groups.

Syntax

display app-group [**name** *group-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

name *group-name*: Specifies an application group by its name. The *group-name* argument is a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed. If you do not specify an application group, this command displays information about all application groups.

Examples

Display information about all application groups.

```
<Sysname> display app-group
User-defined count:3
Group Name                     Type         Group ID
 6767                          User-defined   0x00800002
 er                            User-defined   0x00800001
 hbc                           User-defined   0x00800003
```

Display information about application group **er**.

```
<Sysname> display app-group name er
 Group English name: er
 Group Chinese name: er
 Group ID:         0x00800001
 Type:            User-defined

Application count:  2
 Include application list:
 Application name               Type         App ID
 114Travel                     Pre-defined    0x0000542c
 banc                          User-defined   0x00800001

pre-defined app-group count:0
 Include pre-defined app-group list:
 App-group name                 Type         App-group ID
```

Table 1 Command output

Field	Description
User-defined count	Number of application groups.
Group Name	Name of the application group.
Group English name	English name of the application group.
Type	Application protocol attribute: • **Pre-defined**. • **User-defined**. This filed always displays **User-defined** for application groups.
Application count	Number of application protocols in the application group.
Include application list	Application protocol list.
Application name	Application protocol name.
App ID	Application protocol ID.
pre-defined app-group count	Number of predefined application groups in the application group. This field is not supported in the current software version.
Include pre-defined app-group list	List of predefined application groups. This field is not supported in the current software version.
App-group name	Name of a predefined application group. This field is not supported in the current software version.
App-group ID	ID of a predefined application group. This field is not supported in the current software version.

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

direction: Specifies the direction of the interface.

inbound: Specifies the inbound direction.

outbound: Specifies the outbound direction.

interface *interface-type interface-number*: Specifies an interface by its type and number.

slot *slot-number*: Specifies an IRF member by its member ID. This option is available only for global interfaces, such as VLAN interfaces and tunnel interfaces.

name *application-name*: Specifies an application protocol by its name, a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed.

Usage guidelines

If you do not specify any options or keywords, this command displays statistics for application protocols on all interfaces in both inbound and outbound directions.

This command displays statistics for application protocols only after the application statistics feature is enabled on the specified interfaces. Disabling the application statistics feature on the specified interfaces deletes the corresponding application statistics.

You can display statistics for application protocols based on certain criteria, including application protocol names, interface directions, interface names, or a combination of the criteria.

Examples

Display application statistics for GigabitEthernet 1/0/1.

```
<Sysname> display application statistics interface gigabitethernet 1/0/1
Interface : GigabitEthernet1/0/1
Application   In/Out  Packets          Bytes             PPS     BPS
Slot 1 :
http          IN     275             78631             0        275
              OUT    357             255251            0       101
https         IN     403             39267             0       44
              OUT    681             623501            0       32
netbios-dgm    IN     3              729               0       32
              OUT    0               0                 0       0
netbios-ns    IN     248             22816             2       1423
              OUT    0               0                 0       0
telnet         IN     801            43374             10     4509
              OUT    1519            65388             20     6774
```

Table 3 Command output

Field	Description
Interface	Interface name.
Application	Name of the application protocol.
In/Out	Interface direction: • **In**—Inbound. • **Out**—Outbound.
Packets	Number of packets received or sent by the interface.
Bytes	Number of bytes received or sent by the interface.
PPS	Packets received or sent per second.
BPS	Bytes received or sent per second.

application statistics enable

display application statistics top

Use **display application statistics top** to display statistics for application protocols on an interface in descending order, based on the specified criteria.

Syntax

display application statistics top *number* { **bps** | **bytes** | **packets** | **pps** } **interface** *interface-type interface-number* [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

number: Specifies the number of application statistics entries to be displayed. The value range is 0 to 4294967295.

bytes: Sorts application protocols by traffic size in bytes.

bps: Sorts application protocols by traffic rate in bps.

packets: Sorts application protocols by traffic size in packet count.

pps: Sorts application protocols by traffic rate in pps.

interface *interface-type interface-number*: Specifies an interface by its type and number.

slot *slot-number*: Specifies an IRF member by its member ID. This option is available only for global interfaces, such as VLAN interfaces and tunnel interfaces.

Usage guidelines

This command displays application statistics only after the application statistics feature is enabled on the specified interface. Disabling the application statistics feature on the interface deletes the existing statistics.

The system uses the sum of inbound and outbound statistics to rank the application protocols. If the sum statistics for multiple application protocols is the same, the system displays these protocols in alphabetical order.

Examples

Display the top three application protocols that have received and sent the most packets on GigabitEthernet 1/0/1.

```
<Sysname> display application statistics top 3 packets interface gigabitethernet 1/0/1
Interface : GigabitEthernet1/0/1
Application   In/Out Packets          Bytes             PPS     BPS
Slot 1 :
telnet         IN    1389            75219             0       44
               OUT   2626            112745            0       54
https          IN    468             42830             0       123
               OUT   746             626101            0       91
netbios-ns     IN    965             88780             2       1411
               OUT   0               0                 0       0
```

Table 4 Command output

Field	Description
Interface	Interface name.
Application	Name of the application protocol.
In/Out	Interface direction: • **In**—Inbound. • **Out**—Outbound.

display port-mapping user-defined

Use **display port-mapping user-defined** to display information about the user-defined port mappings.

Syntax

display port-mapping user-defined [**application** *application-name* | **port** *port-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

application *application-name*: Specifies an application protocol by its name, a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed.

port *port-number*: Specifies a port by its number, in the range of 0 to 65535.

Usage guidelines

If you do not specify an application protocol or a port number, this command displays all user-defined port mappings on the device.

Examples

Display all user-defined port mappings on the device.

```
<Sysname> display port-mapping user-defined
 Application      Port  Protocol    Match Type  Match Condition
-------------------------------------------------------------
 FTP              21    TCP         ---          ---
 FTP              21    UDP         IPv4 host   10.10.10.1(vpn1)
 FTP              2121   UDP         IPv4 host   [11.10.10.1, 11.10.10.10](vpn2)
 FTP              21    UDP         IPv4 subnet 10.10.10.1/24
 FTP              21    SCTP        IPv6 host   2000:fdb8::1:00ab:853c:39ab
 HTTP             899    TCP         IPv4 ACL    2002
```

```
HTTP            999    SCTP       IPv6 ACL    2002
```

Table 7 Command output

Field	Description
Application	Application protocol using port mapping.
Port	Port number to which the application protocol is mapped.
Protocol	Transport layer protocol.
Match Type	Match types: • **---**—No match types or match conditions are specified, and all packets that have the specified port are recognized as the packets of the specified application protocol. • **IPv4 host**—A match based on the destination IPv4 addresses of the packet. • **IPv6 host**—A match based on the destination IPv6 addresses of the packet. • **IPv4 subnet**—A match based on the destination IPv4 subnet of the packet. • **IPv6 subnet**—A match based on the destination IPv6 subnet of the packet. • **IPv4 ACL**—A match based on the IPv4 ACL. • **IPv6 ACL**—A match based on the IPv6 ACL.
Match Condition	Match conditions: • For the match type of IPv4 host or IPv6 host, the destination IP addresses of the packets are displayed. • For the match type of IPv4 subnet or IPv6 subnet, the destination subnet addresses of the packets are displayed. • For the match type of IPv4 ACL or IPv6 ACL, the correct ACL number is displayed. For IP address-based and subnet-based host-port mappings, the MPLS L3VPN instance names are also displayed if you have configured them.

include application

Use **include application** to add application protocols to an application group.

Use **undo include application** to remove application protocols from an application group.

Syntax

include application *application-name*

undo include application *application-name*

Default

No application protocols exist in an application group.

Views

Application group view

Predefined user roles

network-admin

context-admin

Parameters

application-name: Specifies an application protocol by its name, a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed.

Usage guidelines

Execute this command multiple times to add multiple predefined or user-defined application protocols to an application group. The number of application protocols in an application group is not limited.

If you add a nonexistent application protocol to the application group, the system first creates the protocol before adding it to the application group. Whether the device can recognize the packets of this protocol depends on your configuration.

Examples

Add HTTP and FTP to group **abc**.

```
<Sysname> system-view
[Sysname] app-group abc
[Sysname-app-group-abc] include application http
[Sysname-app-group-abc] include application ftp
```

Related commands

app-group

copy app-group

nbar application

Use **nbar application** to create a user-defined NBAR rule and enter its view, or enter the view of an existing NBAR rule.

Use **undo nbar application** to delete a user-defined NBAR rule.

Syntax

nbar application *application-name* **protocol** { **http** | **tcp** | **udp** }

undo nbar application *application-name*

Default

No user-defined NBAR rules exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

application-name: Specifies an application protocol by its name, a case-insensitive string of 1 to 63 characters. The following names are not allowed:

- **invalid**.
- **other**.
- Names of predefined application protocols.

http: Specifies HTTP packets to which the NBAR rule is applied.

tcp: Specifies TCP packets to which the NBAR rule is applied.

udp: Specifies UDP packets to which the NBAR rule is applied.

Usage guidelines

By default, predefined NBAR rules exist, and these NBAR rules cannot be deleted or modified. If the predefined NBAR rules cannot meet the user needs, use this command to create user-defined NBAR rules.

Examples

Create a user-defined NBAR rule named **abcd** and apply the rule to HTTP packets.

```
<Sysname> system-view
[Sysname] nbar application abcd protocol http
[Sysname-nbar-application-abcd]
```

override-current

Use **override-current** to overwrite the current signature file for an update operation if the APR signature library is automatically updated at a regular basis.

Use **undo override-current** to restore the default.

Syntax

override-current

undo override-current

Default

If the APR signature library is automatically updated at a regular basis, the current APR signature file is not overwritten for an update operation. Instead, the device will back up the current APR signature file.

Views

Auto-update configuration view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this command only if the device memory is insufficient.

This command disables the APR signature library from being rolled back to the last version. Do not use this command if the device memory is sufficient.

Examples

Overwrite the current APR signature file for a regular online auto-update operation.

```
<Sysname> system-view
[Sysname] apr signature auto-update
[Sysname-apr-autoupdate] override-current
```

Related commands

apr signatures auto-update

port-mapping

Use **port-mapping** to configure a general port mapping.

Use **undo port-mapping** to remove a general port mapping.

Syntax

port-mapping application *application-name* **port** *port-number* [**protocol** *protocol-name*]

undo port-mapping application *application-name* **port** *port-number* [**protocol** *protocol-name*]

Default

An application protocol is mapped to a common port.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

application *application-name*: Specifies an application protocol by its name, a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed.

port *port-number*: Specifies a port by its number, in the range of 0 to 65535.

protocol *protocol-name*: Specifies a transport layer protocol by its name, including:

- **dccp**: Specifies DCCP.
- **sctp**: Specifies SCTP.
- **tcp**: Specifies TCP.
- **udp**: Specifies UDP.
- **udp-lite**: Specifies UDP-Lite.

Usage guidelines

If no transport layer protocol is specified, packets that meet the following conditions are recognized as the specified application protocol's packets:

- Packets are encapsulated by any transport layer protocol.
- Packets have the specified port.

If the destination port of a packet matches a general port mapping, APR recognizes the packet as the specified application protocol's packet.

A mapping with the transport layer protocol specified has a higher priority than one without it.

If two port mappings are configured with the same port number and transport layer protocol, but with different application protocols, the most recent configuration takes effect.

To change the port number mapped to an application protocol, perform the following tasks:

1. Use the **undo port-mapping application** command to remove the existing general port mapping.
2. Use the **port-mapping application** command to specify a different port number for the application protocol.

Examples

Create a general port mapping of port 3456 to FTP.

```
<Sysname> system-view
[Sysname] port-mapping application ftp port 3456
```

Related commands

display port-mapping user-defined

port-mapping acl

Use **port-mapping acl** to configure an ACL-based host-port mapping.

Use **undo port-mapping acl** to remove an ACL-based host-port mapping.

Syntax

port-mapping application *application-name* **port** *port-number* [**protocol** *protocol-name*] **acl** [**ipv6**] *acl-number*

undo port-mapping application *application-name* **port** *port-number* [**protocol** *protocol-name*] **acl** [**ipv6**] *acl-number*

Default

An application protocol is mapped to a common port.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

application *application-name*: Specifies an application protocol by its name, a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed.

port *port-number*: Specifies a port by its number in the range of 0 to 65535.

protocol *protocol-name*: Specifies a transport layer protocol by its name, including:

- **dccp**: Specifies DCCP.
- **sctp**: Specifies SCTP.
- **tcp**: Specifies TCP.
- **udp**: Specifies UDP.
- **udp-lite**: Specifies UDP-Lite.

acl [**ipv6**] *acl-number*: Specifies the number of an ACL, in the range of 2000 to 2999. To specify an IPv6 ACL, include the **ipv6** keyword. To specify an IPv4 ACL, do not include the **ipv6** keyword. The ACL will not count traffic that matches this ACL-based host-port mapping even if match counting is enabled for the ACL.

Usage guidelines

APR uses ACL-based host-port mappings to recognize packets. A packet is recognized as an application protocol packet when it matches all the following conditions in a mapping:

- The packet's destination IP address matches the specified source IP address defined in the ACL.

- The packet's destination port matches the specified port in the mapping.
- The transport layer protocol that encapsulates the packet matches the specified transport layer protocol if you specify a transport layer protocol in the mapping.

If two port mappings are configured with the same port number, transport layer protocol, and ACL, but with different application protocols, the most recent configuration takes effect.

A mapping with the transport layer protocol specified has a higher priority than one without it.

Examples

Create a port mapping of port 3456 to FTP for the packets matching ACL 2000.

```
<Sysname> system-view
[Sysname] port-mapping application ftp port 3456 acl 2000
```

Related commands

display port-mapping user-defined

port-mapping host

Use **port-mapping host** to configure an IP address-based host-port mapping.

Use **undo port-mapping host** to remove an IP address-based host-port mapping.

Syntax

port-mapping application *application-name* **port** *port-number* [**protocol** *protocol-name*] **host** { **ip** | **ipv6** } *start-ip-address* [*end-ip-address*] [**vpn-instance** *vpn-instance-name*]

undo port-mapping application *application-name* **port** *port-number* [**protocol** *protocol-name*] **host** { **ip** | **ipv6** } *start-ip-address* [*end-ip-address*] [**vpn-instance** *vpn-instance-name*]

Default

An application protocol is mapped to a common port.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

application *application-name*: Specifies an application protocol by its name, a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed.

port *port-number*: Specifies a port by its number, in the range of 0 to 65535.

protocol *protocol-name*: Specifies a transport layer protocol by its name, including:

- **dccp**: Specifies DCCP.
- **sctp**: Specifies SCTP.
- **tcp**: Specifies TCP.
- **udp**: Specifies UDP.
- **udp-lite**: Specifies UDP-Lite.

ip: Specifies IPv4 addresses.

ipv6: Specifies IPv6 addresses.

start-ip-address [*end-ip-address*]: Specifies a range of IPv4 or IPv6 addresses. The *start-ip-address* argument represents the start IP address, and the *end-ip-address* argument represents the end IP address. To specify only one IP address, provide only the start IP address. To specify a range of IP addresses, provide both the start and end IP addresses, and make sure the end IP address is higher than the start IP address.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you configure a mapping for the public network, do not specify this option.

Usage guidelines

APR uses IP address-based host-port mappings to recognize packets. A packet is recognized as an application protocol packet when it matches all the following conditions in a mapping:

- The packet is destined for the specified IP address or IP subnet in the mapping.
- The packet's destination port matches the specified port in the mapping.
- The transport layer protocol that encapsulates the packet matches the specified transport layer protocol if you specify a transport layer protocol in the mapping.

No overlapping of IP addresses is tolerable for the host-port mappings configured with the same application protocol, port number, and transport layer protocol.

If two port mappings are configured with the same port number, transport layer protocol, and IP address or IP address ranges, but with different application protocols, the most recent configuration takes effect.

A mapping with the transport layer protocol specified has a higher priority than one without it.

Examples

Create a mapping of port 3456 to FTP for the IPv4 packets sent to the host at 1.1.1.1 to 1.1.1.10.

```
<Sysname> system-view
[Sysname] port-mapping application ftp port 3456 host ip 1.1.1.1 1.1.1.10
```

Create a mapping of port 3456 to FTP for the IPv6 packets sent to 1::1.

```
<Sysname> system-view
[Sysname] port-mapping application ftp port 3456 host ipv6 1::1
```

Related commands

display port-mapping user-defined

port-mapping subnet

Use **port-mapping subnet** to configure a subnet-based host-port mapping.

Use **undo port-mapping subnet** to remove a subnet-based host-port mapping.

Syntax

port-mapping application *application-name* **port** *port-number* [**protocol** *protocol-name*] **subnet** { **ip** *ipv4-address* { *mask-length* | *mask* } | **ipv6** *ipv6-address* *prefix-length* } [**vpn-instance** *vpn-instance-name*]

undo port-mapping application *application-name* **port** *port-number* [**protocol** *protocol-name*] **subnet** { **ip** *ipv4-address* { *mask-length* | *mask* } | **ipv6** *ipv6-address* *prefix-length* } [**vpn-instance** *vpn-instance-name*]

Default

An application protocol is mapped to a common port.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

application *application-name*: Specifies an application protocol by its name, a case-insensitive string of 1 to 63 characters. The names **invalid** and **other** are not allowed.

port *port-number*: Specifies a port by its number, in the range of 0 to 65535.

protocol *protocol-name*: Specifies a transport layer protocol by its name, including:

- **dccp**: Specifies DCCP.
- **sctp**: Specifies SCTP.
- **tcp**: Specifies TCP.
- **udp**: Specifies UDP.
- **udp-lite**: Specifies UDP-Lite.

ip *ipv4-address* { *mask-length* | *mask* }: Specifies an IPv4 subnet.

- The *ipv4-address* argument specifies the IPv4 network address.
- The *mask-length* argument specifies the mask length of the IPv4 subnet, in the range of 1 to 32.
- The *mask* argument specifies the subnet mask in dotted decimal notation.

ipv6 *ipv6-address prefix-length*: Specifies an IPv6 subnet. The *ipv6-address* argument specifies the IPv6 network address, and the *prefix-length* argument specifies the length of the IPv6 prefix, in the range of 1 to 128.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you configure a mapping for the public network, do not specify this option.

Usage guidelines

APR uses subnet-based host-port mappings to recognize packets. A packet is recognized as an application protocol packet when it matches all the following conditions in a mapping:

- The packet is destined for the specified IP subnet in the mapping.
- The packet's destination port matches the specified port in the mapping.
- The transport layer protocol that encapsulates the packet matches the specified transport layer protocol if you specify a transport layer protocol in the mapping.

If multiple subnet-based mappings are applied to packets and these subnets overlap, APR matches the packets destined for the overlapped segment with the port mapping of the subnet that has the smallest range.

If two port mappings are configured with the same port number, transport layer protocol, and subnet, but with different application protocols, the most recent configuration takes effect.

A mapping with the transport layer protocol specified has a higher priority than one without it.

Examples

Create a mapping of port 3456 to FTP for the packets sent to the IPv4 hosts on subnet 1.1.1.0/24.

```
<Sysname> system-view
[Sysname] port-mapping application ftp port 3456 subnet ip 1.1.1.0 24
```

Create a mapping of port 3456 to FTP for the packets sent to the IPv6 hosts on subnet 1:: /120.

```
<Sysname> system-view
[Sysname] port-mapping application ftp port 3456 subnet ipv6 1:: 120
```

display port-mapping user-defined

reset application statistics

Use **reset application statistics** to clear application statistics for interfaces.

Syntax

reset application statistics [**interface** *interface-type interface-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command clears application statistics for all interfaces.

Examples

Clear application statistics for GigabitEthernet 1/0/1.

```
<Sysname> reset application statistics interface gigabitethernet 1/0/1
```

Clear application statistics for all interfaces.

```
<Sysname> reset application statistics
```

Related commands

application statistics enable

display application statistics

risk type

Use **risk type** to configure a risk type for a user-defined application.

Use **undo risk type** to remove a risk type of a user-defined application.

Syntax

risk type *risk-type*

undo risk type [*risk-type*]

Default

A user-defined application does not have any risk type.

Views

User-defined application view

Predefined user roles

network-admin

context-admin

Parameters

risk-type: Specifies a risk type by its name, a case-insensitive string of 1 to 63 characters. You can enter a question mark (?) to obtain a list of supported risk types.

Usage guidelines

You can configure this command multiple times to specify multiple risk types for a user-defined application. The more risk types a user-defined application has, the higher risk level the application has. You can configure security policies according to the risk level.

If you do not specify a risk type when executing the **undo risk type** command, all risk types of the user-defined application are removed.

Examples

Configure risk types **Tunneling** and **Misoperation** for user-defined application **app1**.

```
<Sysname> system-view
[Sysname] user-defined-application app1
[Sysname-user-defined-app-app1] risk type Tunneling
[Sysname-user-defined-app-app1] risk type Misoperation
```

service-port

Use **service-port** to specify a port number or a port range as a match criterion in a user-defined NBAR rule.

Use **undo service-port** to restore the default.

Syntax

service-port { *port-num* | **range** *start-port end-port* }

undo service-port

Default

A user-defined NBAR rule matches packets of all port numbers.

Views

NBAR rule view

Predefined user roles

network-admin

context-admin

Parameters

port-num: Specifies the port number in the range of 0 to 65535.

range: Specifies a port range.

start-port: Specifies the start port number for the port range, in the range of 0 to 65535.

end-port: Specifies the end port number for the port range, in the range of 0 to 65535. The end port number cannot be smaller than the start port number.

Usage guidelines

The specified port number or port range is used to match the packets' destination ports first. If no match is found for a packet, the device continues to match its source port. A packet is determined as a matching packet as long as one of the ports is matched.

If you execute this command multiple times for the same NBAR rule, the most recent configuration takes effect.

Examples

Configure user-defined NBAR rule **abcd** to match packets with port numbers 2001 through 2004.

```
<Sysname> system-view
[Sysname] nbar application abcd protocol http
[Sysname-nbar-application-abcd] service-port range 2001 2004
```

Related commands

direction

signature

Use **signature** to create an NBAR rule signature and enter its view, or enter the view of an existing NBAR rule signature.

Use **undo signature** to cancel the signature configuration.

Syntax

signature [*signature-id*] [**field** *field-name*] [**offset** *offset-value*] { **hex** *hex-vector* | **regex** *regex-pattern* | **string** *string* }

undo signature *signature-id*

Default

No signatures are configured for a user-defined NBAR rule.

Views

NBAR rule view

Predefined user roles

network-admin

context-admin

Parameters

signature-id: Specifies the signature ID in the range of 1 to 65535. If you do not specify this argument when creating a signature, the system automatically assigns the signature a signature ID and records the signature ID. The increment of automatically assigned signature IDs is 5. A new signature ID is the nearest unassigned multiple of the increment to the latest automatically assigned signature ID. For example, if the system automatically assigns ID 5 to a signature, the next signature ID to be assigned automatically will be 10. If signature ID 10 has been assigned manually to a signature, the next signature ID to be assigned automatically will be 15.

field *field-name*: Specifies a protocol field by its name. The specified protocol field must be predefined. This option is available for configuration only if the NBAR rule is applied to HTTP packets. If you do not specify this option, the configured signature takes effect on all fields in HTTP packets.

offset *offset-value*: Specifies the offset from the beginning of the data field, in bytes. The value range for the *offset-value* argument is 0 to 65535. A packet matches the signature after

the offset. If you do not specify this option, a packet matches the signature from the beginning. If you also specify the **field** *field-name* option, the offset begins from the protocol field.

hex *hex-vector*: Specifies a hexadecimal vector as the match pattern. The *hex-vector* argument is a string of 6 to 254 characters. The argument must start and end with a vertical bar (|) and must contain an even number of characters.

regex *regex-pattern*: Specifies a regular expression as the match pattern. The *regex-pattern* argument is a case-sensitive string of 3 to 253 characters, and it must meet the following requirements:

- Contains a maximum of four branches. For example, **abc(c|d|e|\x3D)** is valid, and **abc(c|onreset|onselect|onchange|style\x3D)** is invalid.
- Nested braces are not allowed. For example, **ab((abcs*?))** is invalid.
- A branch cannot be specified after another branch. For example, **ab(a|b)(c|d)^\\r\\n]+?** is invalid.
- A minimum of four non-wildcard characters must exist before an asterisk (*) or question mark (?). For example, **abc*** is invalid and **abcd*DoS\x2d\d{5}\x20\x2bxi\\r\\nJOIN** is valid.

string *string*: Specifies a string as the match pattern. The *string* argument is a case-sensitive string of 3 to 256 characters.

Usage guidelines

You can repeat this command to configure multiple signatures of different match patterns in a user-defined NBAR rule. If the signatures have different signature IDs, all signatures take effect. The logical relation of these signatures is OR, which indicates that a packet that matches any signature matches the NBAR rule. If the signatures have the same signature ID, the most recent configuration takes effect.

Examples

Create user-defined NBAR rule **abcd**, and then add signature 1 in the NBAR rule to define packet match string **abcdefg** and enter the signature view.

```
<Sysname> system-view
[Sysname] nbar application abcd protocol http
[Sysname-nbar-application-abcd] signature 1 string abcdefg
[Sysname-nbar-application-abcd-signature-1]
```

Configure user-defined NBAR rule **ddd** to match packets with signature 2 which defines hexadecimal vector **123456**, and enter the view of the NBAR rule signature.

```
<Sysname> system-view
[Sysname] nbar application ddd protocol http
[Sysname-nbar-application-ddd] signature 2 hex |123456|
[Sysname-nbar-application-ddd-signature-2]
```

Related commands

detection

source

Use **source** to specify a source IP address or subnet as a match criterion in a user-defined NBAR rule.

Use **undo source** to restore the default.

Syntax

source ip *ipv4-address* [*mask-length*]

undo source

Default

A user-defined NBAR rule matches packets sourced from all IP addresses.

Views

NBAR rule view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies a source IPv4 address or IPv4 subnet, in dotted decimal notation.

mask-length: Specifies the mask length for IPv4 addresses, in the range of 0 to 32.

Usage guidelines

If you execute this command multiple times for the same NBAR rule, the most recent configuration takes effect.

Examples

Configure user-defined NBAR rule **abcd** to match packets sourced from IPv4 subnet 192.168.2.0/24.

```
<Sysname> system-view
[Sysname] nbar application abcd protocol http
[Sysname-nbar-application-abcd] source ip 192.168.2.0 24
```

Related commands

nbar application

update schedule

Use **update schedule** to set the update schedule for automatic update, including the update interval and update time.

Use **undo update schedule** to restore the default.

Syntax

update schedule { **daily** | **weekly** { **fri** | **mon** | **sat** | **sun** | **thu** | **tue** | **wed** } } **start-time** *time* **tingle** *minutes*

undo update schedule

Default

The device automatically updates the APR signature library between 02:01:00 to 04:01:00 every day.

Views

Auto-update configuration view

Predefined user roles

network-admin

context-admin

Parameters

daily: Specifies the daily update interval.

weekly: Specifies the weekly update interval. You can specify one day in a week for the update:

- **fri**: Specifies Friday.
- **mon**: Specifies Monday.
- **sat**: Specifies Saturday.
- **sun**: Specifies Sunday.
- **thu**: Specifies Thursday.
- **tue**: Specifies Tuesday.
- **wed**: Specifies Wednesday.

start-time *time*: Specifies the start time for the update, in the format of hh:mm:ss. The value range for the *time* argument is 00:00:00 to 23:59:59.

tingle *minutes*: Specifies the tolerance time in minutes. The value range for the *minutes* argument is 0 to 120 minutes. An automatic update will occur at a time point between the following time points:

- Start time minus half of the tolerance time.
- Start time plus half of the tolerance time.

For example, if the specified start time is 01:00:00 and the tolerance time is 60 minutes, the update starts during the period from 00:30:00 to 01:30:00.

Examples

Configure the device to automatically update the APR signature library at 23:10:00 every Monday with a tolerance time of 10 minutes.

```
<Sysname> system-view
[Sysname] apr signature auto-update
[Sysname-apr-autoupdate] update schedule weekly mon start-time 23:10:00 tingle 10
```

Related commands

apr signature auto-update

user-defined-application

Use **user-defined-application** to enter the view of a user-defined application.

Use **undo user-defined-application** to delete a user-defined application.

Syntax

user-defined-application *application-name*

undo user-defined-application *application-name*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

application-name: Specifies an application by its name, a case-insensitive string of 1 to 63 characters. The names of predefined applications and names **invalid** and **other** are not allowed.

Usage guidelines

You can configure a risk type for an NBAR or PBAR user-defined application after entering the view of the user-defined application. The user-defined application must already exist.

Examples

Enter the view of user-defined application **app1**.

```
<Sysname> system-view
[Sysname] user-defined-application app1
[Sysname-user-defined-app-app1]
```

accept-lifetime

Use **accept-lifetime** to set the receiving lifetime for a key of a keychain.

Use **undo accept-lifetime** to restore the default.

Syntax

accept-lifetime daily *start-day-time* **to** *end-day-time*

accept-lifetime date { *month-day*&<1-31> | *start-month-day* **to** *end-month-day* }

accept-lifetime day { *week-day* | *start-week-day* **to** *end-week-day* }

accept-lifetime month { *month* | *start-month* **to** *end-month* }

accept-lifetime utc *start-time start-date* { **duration** { *duration-value* | **infinite** } | **to** *end-time end-date* }

undo accept-lifetime

Default

The receiving lifetime is not configured for a key of a keychain.

Views

Key view

Predefined user roles

network-admin

context-admin

Parameters

daily: Specifies the key to be effective in the specified time range of each day.

start-day-time **to** *end-day-time*: Specifies the time range of each day. Both the start time and the end time are in the HH:MM:SS format. The value range for the *start-day-time* argument and the *end-day-time* argument is 0:0:0 to 23:59:59. You can omit the SS parameter to set a whole number of minutes, or omit both the SS and MM parameters to set a whole number of hours.

date: Specifies the key to be effective on the specified dates of each month.

month-day&<1-31>: Specifies a space-separated list of up to 31 dates of a month. The value range for the *month-day* argument is 1 to 31.

start-month-day **to** *end-month-day*: Specifies the date range of each month. The end date must be greater than the start date.

day: Specifies the key to be effective on the specified days of each week.

week-day: Specifies a day in a week. Values include **mon**, **tue**, **wed**, **thu**, **fri**, **sat**, and **sun**. You can specify this argument multiple times with different values.

start-week-day **to** *end-week-day*: Specifies the day range of each week. The end day must be greater than the start day.

month: Specifies the key to be effective in the specified months of each year.

month: Specifies a month in a year. Values include **jan**, **feb**, **mar**, **apr**, **may**, **jun**, **jul**, **aug**, **sep**, **oct**, **nov**, and **dec**. You can specify this argument multiple times with different values.

start-month **to** *end-month*: Specifies the month range of each year. The end month must be greater than the start month.

utc: Specifies the receiving lifetime in absolute time mode. The key takes effect in the specified time range, for example, from 08:00 2015/9/1 to 18:00 2015/9/3.

start-time: Specifies the start time in the HH:MM:SS format. The value range for this argument is 0:0:0 to 23:59:59. You can omit the SS parameter to set a whole number of minutes, or omit both the SS and MM parameters to set a whole number of hours.

start-date: Specifies the start date in the MM/DD/YYYY or YYYY/MM/DD format. The value range for YYYY is 2000 to 2035.

duration *duration-value*: Specifies the lifetime of the key, in the range of 1 to 2147483646 seconds.

duration infinite: Specifies that the key never expires after it becomes valid.

to: Specifies the end time and date.

end-time: Specifies the end time in the HH:MM:SS format. The value range for this argument is 0:0:0 to 23:59:59.

end-date: Specifies the end date in the MM/DD/YYYY or YYYY/MM/DD format. The value range for YYYY is 2000 to 2035.

Usage guidelines

A key becomes a valid accept key when the following requirements are met:

- A key string has been configured.
- An authentication algorithm has been specified.
- The system time is within the specified receiving lifetime.

If an application receives a packet that carries a key ID, and the key is valid, the application uses the key to authenticate the packet. If the key is not valid, packet authentication fails.

If the received packet does not carry a key ID, the application uses all valid keys in the keychain to authenticate the packet. If the packet does not pass any authentication, packet authentication fails.

An application can use multiple valid keys to authenticate packets received from a peer.

Examples

Set the receiving lifetime for key 1 of keychain **abc** in absolute time mode.

```
<Sysname> system-view
[Sysname] keychain abc mode absolute
[Sysname-keychain-abc] key 1
[Sysname-keychain-abc-key-1] accept-lifetime utc 12:30 2015/1/21 to 18:30 2015/1/21
```

Set the receiving lifetime for key 1 of keychain **123** in weekly periodic time mode.

```
<Sysname> system-view
[Sysname] keychain 123 mode periodic weekly
[Sysname-keychain-123] key 1
[Sysname-keychain-123-key-1] accept-lifetime day fri
```

Related commands

display keychain

accept-tolerance

Use **accept-tolerance** to set a tolerance time for accept keys in a keychain.

Use **undo accept-tolerance** to restore the default.

Syntax

accept-tolerance { *value* | **infinite** }

undo accept-tolerance

Default

No tolerance time is configured for accept keys in a keychain.

Views

Keychain view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies a tolerance time in the range of 1 to 8640000 seconds.

infinite: Specifies that the accept keys never expire.

Usage guidelines

After a tolerance time is configured, the start time and the end time configured in the **accept-lifetime utc** command are extended for the period of the tolerance time.

If authentication information is changed, information mismatch occurs on the local and peer devices, and the service might be interrupted. Use this command to ensure continuous packet authentication.

Examples

Set the tolerance time to 100 seconds for accept keys in keychain **abc**.

```
<Sysname> system-view
[Sysname] keychain abc mode absolute
[Sysname-keychain-abc] accept-tolerance 100
```

Configure the accept keys in keychain **abc** to never expire.

```
<Sysname> system-view
[Sysname] keychain abc mode absolute
[Sysname-keychain-abc] accept-tolerance infinite
```

Related commands

display keychain

authentication-algorithm

Use **authentication-algorithm** to specify an authentication algorithm for a key.

Use **undo authentication-algorithm** to restore the default.

Syntax

authentication-algorithm { **hmac-md5** | **hmac-sha-1** | **hmac-sha-256 | hmac-sm3** | **md5** | **sm3** }

undo authentication-algorithm

Default

No authentication algorithm is specified for a key.

Views

Key view

Predefined user roles

network-admin

context-admin

Parameters

hmac-md5: Specifies the HMAC-MD5 authentication algorithm.

hmac-sha-1: Specifies the HMAC-SHA-1 authentication algorithm.

hmac-sha-256: Specifies the HMAC-SHA-256 authentication algorithm.

hmac-sm3: Specifies the HMAC-SM3 authentication algorithm.

md5: Specifies the MD5 authentication algorithm.

sm3: Specifies the SM3 authentication algorithm.

Usage guidelines

If an application does not support the authentication algorithm specified for a key, the application cannot use the key for packet authentication.

Examples

Specify the MD5 authentication algorithm for key 1 of keychain **abc** in absolute time mode.

```
<Sysname> system-view
[Sysname] keychain abc mode absolute
[Sysname-keychain-abc] key 1
[Sysname-keychain-abc-key-1] authentication-algorithm md5
```

Related commands

display keychain

default-send-key

Use **default-send-key** to specify a key in a keychain as the default send key.

Use **undo default-send-key** to restore the default.

Syntax

default-send-key

undo default-send-key

Default

No key in a keychain is specified as the default send key.

Views

Key view

Predefined user roles

network-admin

context-admin

Usage guidelines

When send keys in a keychain are inactive, the default send key can be used for packet authentication.

A keychain can have only one default send key. The default send key must be configured with an authentication algorithm and a key string.

Examples

Specify key **1** in keychain **abc** as the default send key.

```
<Sysname> system-view
[Sysname] keychain abc mode absolute
[Sysname-keychain-abc] key 1
[Sysname-keychain-abc-key-1] default-send-key
```

  Accept status      : Active
```

Table 1 Command output

Field	Description
Mode	Time mode for the keychain: • Absolute. • Periodic daily. • Periodic weekly. • Periodic monthly. • Periodic yearly.
Accept tolerance	Tolerance time (in seconds) for accept keys of the keychain.
TCP kind value	Value for the TCP kind field. The default value is 254.
TCP algorithm value	ID of the TCP authentication algorithm. The default algorithm ID is 5 for HMAC-MD5, 7 for HMAC-SHA-256, 3 for MD5, 52 for HMAC-SM3, and 51 for SM3.
Default send key ID	ID of the default send key. The status for the key is displayed in parentheses.
Key string	Key string in encrypted form.
Algorithm	Authentication algorithm for the key: • **hmac-md5** • **hmac-sha-1** • **hmac-sha-256** • **hmac-sm3** • **md5** • **sm3**
Send lifetime	Sending lifetime for the key.

Field	Description
Send status	Status of the send key: **Active** or **Inactive**.
Accept lifetime	Receiving lifetime for the key.
Accept status	Status of the accept key: **Active** or **Inactive**.

key

Use **key** to create a key for a keychain and enter its view, or enter the view of an existing key.

Use **undo key** to delete a key and all its configurations for a keychain.

Syntax

key *key-id*

undo key *key-id*

Default

No keys exist.

Views

Keychain view

Predefined user roles

network-admin

context-admin

Parameters

key-id: Specifies a key ID in the range of 0 to 281474976710655.

Usage guidelines

The keys in a keychain must have different key IDs.

Examples

Create key 1 and enter its view.

```
<Sysname> system-view
[Sysname] keychain abc mode absolute
[Sysname-keychain-abc] key 1
[Sysname-keychain-abc-key-1]
```

Related commands

display keychain

keychain

Use **keychain** to create a keychain and enter its view, or enter the view of an existing keychain.

Use **undo keychain** to delete a keychain and all its configurations.

Syntax

keychain *keychain-name* [**mode** { **absolute** | **periodic** { **daily** | **monthly** | **weekly** | **yearly** } }]

undo keychain *keychain-name*

Default

No keychains exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

keychain-name: Specifies a keychain name, a case-sensitive string of 1 to 63 characters.

mode: Specifies a time mode.

absolute: Specifies the absolute time mode. In this mode, each time point during a key's lifetime is the UTC time and is not affected by the system's time zone or daylight saving time.

periodic: Specifies the periodic time mode. In this mode, a key's lifetime is calculated based on the local time and is affected by the system's time zone and daylight saving time.

daily: Specifies the daily periodic time mode.

monthly: Specifies the monthly periodic time mode.

weekly: Specifies the weekly periodic time mode.

yearly: Specifies the yearly periodic time mode.

Usage guidelines

You must specify the time mode when you create a keychain. You cannot change the time mode for an existing keychain.

The time mode is not required when you enter the view of an existing keychain.

Examples

Create keychain **abc**, specify the absolute time mode for it, and enter keychain view.

```
<Sysname> system-view
[Sysname] keychain abc mode absolute
[Sysname-keychain-abc]
```

Related commands

display keychain

key-string

Use **key-string** to configure a key string for a key.

Use **undo key-string** to restore the default.

Syntax

key-string { **cipher** | **plain** } *string*

undo key-string

Default

No key string is configured for a key.

Views

Key view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies a key in encrypted form.

plain: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. Its plaintext form is a case-sensitive string of 1 to 255 characters. Its encrypted form is a case-sensitive string of 33 o 373 characters.

Usage guidelines

If the length of a plaintext key exceeds the length limit supported by an application, the application uses the supported length of the key to authenticate packets.

Examples

Set the key string to **123456** in plaintext form for key 1.

```
<Sysname> system-view
[Sysname] keychain abc mode absolute
[Sysname-keychain-abc] key 1
[Sysname-keychain-abc-key-1] key-string plain 123456
```

Parameters

daily: Specifies the key to be effective in the specified time range of each day.

start-day-time **to** *end-day-time*: Specifies the time range of each day. Both the start time and the end time are in the HH:MM:SS format. The value range for the *start-day-time* argument and the *end-day-time* argument is 0:0:0 to 23:59:59. You can omit the SS parameter to set a whole number of minutes, or omit both the SS and MM parameters to set a whole number of hours.

date: Specifies the key to be effective on the specified dates of each month.

month-day&<1-31>: Specifies a space-separated list of up to 31 dates of a month. The value range for the *month-day* argument is 1 to 31.

start-month-day **to** *end-month-day*: Specifies the date range of each month. The end date must be greater than the start date.

day: Specifies the key to be effective on the specified days of each week.

week-day: Specifies a day in a week. Values include **mon**, **tue**, **wed**, **thu**, **fri**, **sat**, and **sun**. You can specify this argument multiple times with different values.

start-week-day **to** *end-week-day*: Specifies the day range of each week. The end day must be greater than the start day.

month: Specifies the key to be effective in the specified months of each year.

month: Specifies a month in a year. Values include **jan**, **feb**, **mar**, **apr**, **may**, **jun**, **jul**, **aug**, **sep**, **oct**, **nov**, and **dec**. You can specify this argument multiple times with different values.

start-month **to** *end-month*: Specifies the month range of each year. The end month must be greater than the start month.

utc: Specifies the sending lifetime in absolute time mode. The key takes effect in the specified time range, for example, from 08:00 2015/9/1 to 18:00 2015/9/3.

start-time: Specifies the start time in the HH:MM:SS format. The value range for this argument is 0:0:0 to 23:59:59. You can omit the SS parameter to set a whole number of minutes, or omit both the SS and MM parameters to set a whole number of hours.

start-date: Specifies the start date in the MM/DD/YYYY or YYYY/MM/DD format. The value range for YYYY is 2000 to 2035.

duration *duration-value*: Specifies the lifetime of the key, in the range of 1 to 2147483646 seconds.

duration infinite: Specifies that the key never expires after it becomes valid.

to: Specifies the end time and date.

end-time: Specifies the end time in the HH:MM:SS format. The value range for this argument is 0:0:0 to 23:59:59.

end-date: Specifies the end date in the MM/DD/YYYY or YYYY/MM/DD format. The value range for YYYY is 2000 to 2035.

Usage guidelines

A key becomes a valid send key when the following requirements are met:

- A key string has been configured.

- An authentication algorithm has been specified.
- The system time is within the specified sending lifetime.

To make sure only one key in a keychain is used at a time to authenticate packets to a peer, set non-overlapping sending lifetimes for the keys in the keychain.

Examples

Set the sending lifetime for key 1 of keychain **abc** in absolute time mode.

```
<Sysname> system-view
[Sysname] keychain abc mode absolute
[Sysname-keychain-abc] key 1
[Sysname-keychain-abc-key-1] send-lifetime utc 12:30 2015/1/21 to 18:30 2015/1/21
```

Set the sending lifetime for key 1 of keychain **123** in weekly periodic time mode.

```
<Sysname> system-view
[Sysname] keychain 123 mode periodic weekly
[Sysname-keychain-123] key 1
[Sysname-keychain-123-key-1] send-lifetime day fri
```

Related commands

display keychain

tcp-algorithm-id

Use **tcp-algorithm-id** to set an algorithm ID for a TCP authentication algorithm.

Use **undo tcp-algorithm-id** to restore the default.

Syntax

tcp-algorithm-id { **hmac-md5** | **hmac-sha-256** | **hmac-sm3** | **md5** | **sm3** } *algorithm-id*

undo tcp-algorithm-id { **hmac-md5** | **hmac-sha-256** | **hmac-sm3** | **md5** | **sm3** }

Default

The algorithm ID is 3 for the MD5 authentication algorithm, 5 for the HMAC-MD5 authentication algorithm, 7 for the HMAC-SHA-256 authentication algorithm, 51 for the SM3 authentication algorithm, and 52 for the HMAC-SM3 authentication algorithm.

Views

Keychain view

Predefined user roles

network-admin

context-admin

Parameters

hmac-md5: Specifies the HMAC-MD5 authentication algorithm, which provides a key length of 16 bytes.

hmac-sha-256: Specifies the HMAC-SHA-256 authentication algorithm, which provides a key length of 16 bytes.

hmac-sm3: Specifies the HMAC-SM3 authentication algorithm, which provides a key length of 32 bytes.

md5: Specifies the MD5 authentication algorithm, which provides a key length of 16 bytes.

sm3: Specifies the SM3 authentication algorithm, which provides a key length of 32 bytes.

algorithm-id: Specifies an algorithm ID in the range of 1 to 63.

Usage guidelines

If an application uses keychain authentication during TCP connection establishment, the incoming and outgoing TCP packets will carry the TCP Enhanced Authentication Option. The *algorithm-id* field in the option represents the authentication algorithm ID. The algorithm IDs are not assigned by IANA. They are vendor-specific.

To communicate with a peer device from another vendor, the local device must have the same algorithm ID as the peer device. For example, if the algorithm ID is 3 for the HMAC-MD5 algorithm on the peer device, you must execute the **tcp-algorithm-id hmac-md5** 3 command on the local device.

Examples

Create keychain **abc** and set the algorithm ID to 1 for the HMAC-MD5 authentication algorithm.

```
<Sysname> system-view
[Sysname] keychain abc mode absolute
[Sysname-keychain-abc] tcp-algorithm-id hmac-md5 1
```

Related commands

display keychain

tcp-kind

Use **tcp-kind** to set the kind value in the TCP Enhanced Authentication Option.

Use **undo tcp-kind** to restore the default.

Syntax

tcp-kind *kind-value*

undo tcp-kind

Default

The kind value is 254 in the TCP Enhanced Authentication Option.

Views

Keychain view

Predefined user roles

network-admin

context-admin

Parameters

kind-value: Specifies the kind value in the range of 28 to 255.

Usage guidelines

If an application uses keychain authentication during TCP connection establishment, the incoming and outgoing TCP packets will carry the TCP Enhanced Authentication Option. For a successful packet authentication, the local device and the peer device must have the same kind value setting in the TCP Enhanced Authentication Option.

Examples

Set the kind value to 252 for keys in keychain **abc** in absolute time mode.

```
<Sysname> system-view
```

```
[Sysname] keychain abc mode absolute
[Sysname-keychain-abc] tcp-kind 252
```

Crypto engine commands

display crypto-engine

Use **display crypto-engine** to display crypto engine information.

Syntax

display crypto-engine

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Usage guidelines

If the device does not have hardware crypto engines, this command displays information only about software crypto engines.

Examples

Display crypto engine information.

```
<Sysname> display crypto-engine
  Crypto engine name: Software crypto engine
  Crypto engine state: Enabled
  Crypto engine type: Software
  Slot ID: 1
  CPU ID: 0
  Crypto engine ID: 0
  Crypto device name: Software
  Crypto device serial number:
  Symmetric algorithms:  des-cbc des-ecb 3des-cbc aes-cbc aes-ecb aes-ctr camellia_cbc
md5 sha1 sha2-256 sha2-384 sha2-512 md5-hmac sha1-hmac sha2-256-hmac sha2-384-hmac
sha2-512-hmac aes-xcbc aes-xcbc-hmac sm3 sm3-hmac sm4-cbc
  Asymmetric algorithms:
  Random number generation function: Supported

  Crypto engine name: Cavium crypto driver
  Crypto engine state: Enabled
  Crypto engine type: Hardware
  Slot ID: 1
  CPU ID: 0
  Crypto engine ID: 1
  Crypto device name: Cavium crypto
  Crypto device serial number:
```

```
  Symmetric algorithms: des-cbc des-ecb 3des-cbc 3des-ecb aes-cbc aes-ecb aes-ctr md5 sha1
sha2-256 sha2-384 sha2-512 md5-hmac sha1-hmac sha2-256-hmac sha2-384-hmac sha2-512-hmac
aes-xcbc-hmac sm4-cbc
  Asymmetric algorithms: dh-group1 dh-group2 dh-group5 dh-group14
  Random number generation function: Supported
```

Table 1 Command output

Field	Description
Crypto engine state	Hardware crypto engine state: • Enabled. • Disabled. This field always displays **Enabled** for software crypto engines.
Crypto engine type	Crypto engine type: • Hardware. • Software.
Crypto device name	Name of the crypto device. This field displays **Software** for software crypto engines. For hardware crypto engines, the value of this field varies by device model.
Crypto device serial number	Serial number of the crypto device. This field is always empty for software crypto engines. For hardware crypto engines, the value of this field varies by device model.
Symmetric algorithms	Supported symmetric algorithms.
Asymmetric algorithms	Supported asymmetric algorithms.
Random number generation function	Whether random number generation function is supported: • Supported. • Not supported.

display crypto-engine statistics

Use **display crypto-engine statistics** to display crypto engine statistics.

Syntax

display crypto-engine statistics [**engine-id** *engine-id* **slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

engine-id *engine-id*: Specifies a crypto engine by its ID. The value range for the *engine-id* argument is 0 to 4294967295.

slot *slot-number*: Specifies an IRF member device by its member ID.

Usage guidelines

If hardware crypto engines are not enabled or the device does not have hardware crypto engines, this command displays statistics only for software crypto engines.

If you do not specify any parameters, this command displays crypto engine statistics for all member devices.

Examples

Display all crypto engine statistics.

```
<Sysname> display crypto-engine statistics
  Slot ID: 1
  CPU ID: 0
  Crypto engine ID: 0
  Submitted sessions: 0
  Failed sessions: 0
  Symmetric operations: 0
  Symmetric errors: 0
  Asymmetric operations: 0
  Asymmetric errors: 0
  Get-random operations: 0
  Get-random errors: 0
```

Display statistics for crypto engine 1 on the specified slot.

```
<Sysname> display crypto-engine statistics engine-id 1 slot 1
  Submitted sessions: 0
  Failed sessions: 0
  Symmetric operations: 0
  Symmetric errors: 0
  Asymmetric operations: 0
  Asymmetric errors: 0
  Get-random operations: 0
  Get-random errors: 0
```

Table 2 Command output

Field	Description
Submitted sessions	Number of established sessions.
Failed sessions	Number of failed sessions.
Symmetric operations	Number of operations using symmetric algorithms.
Symmetric errors	Number of failed operations using symmetric algorithms.
Asymmetric operations	Number of operations using asymmetric algorithms.
Asymmetric errors	Number of failed operations using asymmetric algorithms.
Get-random operations	Number of operations for obtaining random numbers.
Get-random errors	Number of failed operations for obtaining random numbers.

Related commands

reset crypto-engine statistics

reset crypto-engine statistics

Use **reset crypto-engine statistics** to clear crypto engine statistics.

Syntax

reset crypto-engine statistics [**engine-id** *engine-id* **slot** *slot-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

engine-id *engine-id*: Specifies a crypto engine by its ID. The value range for the *engine-id* argument is 0 to 4294967295.

slot *slot-number*: Specifies an IRF member device by its member ID.

Usage guidelines

If you do not specify any parameters, this command clears crypto engine statistics for all member devices.

Examples

Clear statistics for all crypto engines.

```
<Sysname> reset crypto-engine statistics
```

Clear statistics for crypto engine 1 on the specified slot.

```
<Sysname> reset crypto-engine statistics engine-id 1 slot 1
```

display snmp-server arp-sync table

snmp-server arp-sync { interval | timeout } *

Use **snmp-server arp-sync** { **interval** | **timeout** } * to set parameters for synchronizing APR entries through SNMP.

Use **undo snmp-server arp-sync** { **interval** | **timeout** } to restore the default.

Syntax

snmp-server arp-sync { **interval** *interval* | **timeout** *time* } *

undo snmp-server arp-sync { **interval** | **timeout** }

Default

The interval for sending SNMP requests is 5 seconds and the timeout for SNMP responses is 3 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval *interval*: Specifies the interval for sending SNMP requests in the range of 5 to 30 seconds.

timeout *time*: Specifies the timeout for SNMP responses in the range of 1 to 5 seconds.

Usage guidelines

With this feature configured, the device sends SNMP requests for ARP entry synchronization to the target Layer 3 device at the specified intervals. If the device does not receive an SNMP response before the timeout expires within the specified interval, the device re-sends SNMP requests.

Examples

Set the interval for sending SNMP requests and the timeout for SNMP responses to 10 and 2 seconds, respectively.

```
<Sysname> system-view
[Sysname] snmp-server arp-sync interval 10 timeout 2
```

snmp-server arp-sync enable

Use **snmp-server arp-sync enable** to enable ARP entry synchronization through SNMP.

Use **undo snmp-server arp-sync enable** to disable ARP entry synchronization through SNMP.

Syntax

snmp-server arp-sync enable

undo snmp-server arp-sync enable

Default

ARP entry synchronization through SNMP is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

With this feature enabled, the device acts as an NMS to learn all ARP entries on a Layer 3 device (agent) to obtain the MAC address of the Layer 3 device.

Examples

Enable ARP entry synchronization through SNMP.

```
<Sysname> system-view
[Sysname] snmp-server arp-sync enable
```

snmp-server arp-sync target-host

Use **snmp-server arp-sync target-host** to configure the target Layer 3 device for ARP synchronization through SNMP.

Use **undo snmp-server arp-sync target-host** to remove the configuration of the target Layer 3 device for ARP synchronization through SNMP.

Syntax

SNMPv2c:

snmp-server arp-sync target-host address *ip-address* **community** { **simple** | **cipher** } *community-name* **v2c**

undo snmp-server arp-sync target-host address *ip-address* **community** { **simple** | **cipher** } *community-name*

SNMPv3:

snmp-server arp-sync target-host address *ip-address* **usm-user v3** *user-name* [{ **simple** | **cipher** } **authentication-mode** { **md5** | **sha** } *auth-password* [**privacy-mode** { **aes128** | **des56** } *pri-password*]]

undo snmp-server arp-sync target-host address *ip-address* **usm-user v3** *user-name*

Default

No target Layer 3 device is configured for ARP synchronization through SNMP.

Views

System view

Predefined user roles

network-admin

contex-admin

Parameters

address *ip-address*: Specifies an IPv4 address of the target Layer 3 device.

simple: Specifies a community name in plaintext form. For security purposes, the community name specified in plaintext form will be stored in encrypted form.

cipher: Specifies a community name in encrypted form.

community-name: Specifies the community name. The plaintext form is a case-sensitive string of 1 to 32 characters. The encrypted form is a case-sensitive string of 33 to 73 characters. Input a string as escape characters after a backslash (\).

v2c: Specifies SNMPv2c.

user-name: Specifies a username, a case-sensitive string of 1 to 32 characters.

v3: Specifies SNMPv3.

simple: Specifies an authentication key and an encryption key in plaintext from. The keys will be converted to a digest in encrypted form and stored in the device.

cipher: Specifies an authentication key and an encryption key in encrypted form. The keys will be converted to a digest in encrypted form and stored in the device.

authentication-mode: Specifies an authentication algorithm. If you do not specify the keyword, the system does not perform authentication.

- **md5**: Specifies the HMAC-MD5 authentication algorithm. For information about the HMAC-MD5 algorithm, see IPsec configuration in *VPN Instance Configuration Guide*.
- **sha**: Specifies the HMAC-SHA1 authentication algorithm. For information about the HMAC-SHA1 algorithm, see IPsec configuration in *VPN Instance Configuration Guide*.

auth-password: Specifies a case-sensitive authentication key in plaintext form or encrypted form. The value is a string of 8 to 64 characters.

privacy-mode: Specifies an encryption algorithm. If you do not specify this keyword, the system does not perform encryption.

- **aes128**: Specifies the Advanced Encryption Standard (AES) algorithm that uses a 128-bit key.
- **des56**: Specifies the Data Encryption Standard (DES) algorithm that uses a 56-bit key.

priv-password: Specifies a case-sensitive encryption key in plaintext form or encrypted form. The value is a string of 8 to 64 characters.

Usage guidelines

You can configure this command multiple times to specify multiple Layer 3 devices for ARP entry synchronization.

Examples

Configure the device to use the plaintext-form community name **testCommunity** to synchronize ARP entries from Layer 3 device 10.1.1.1 through SNMPv2c.

```
<Sysname> system-view
[Sysname] snmp-server arp-sync target-host address 10.1.1.1 community simple
testCommunity v2c
```

Configure the device to use username **testUser** to synchronize ARP entries from Layer 3 device 10.1.1.1 through SNMPv3 by using authentication algorithm **HMAC-SHA1**, plaintext-form authentication key **123456TESTauth&!**, encryption algorithm **DES**, and plaintext-form encryption key **123456TESTencr&!**.

```
<Sysname> system-view
[Sysname] snmp-server arp-sync target-host address 10.1.1.1 usm-user v3 testUser simple
authentication-mode sha 123456TESTauth&! privacy-mode des56 123456TESTencr&!
```

Contents

SMS commands

app id

Use **app-id** to specify the app ID for the third-party SMS platform.

Use **undo app-id** to restore the default.

Syntax

app-id *app-id*

undo app-id

Default

No app ID is specified for the third-party SMS platform.

Views

SMS gateway view

Predefined user roles

network-admin

context-admin

Parameters

app-id: Specifies the app ID of the third-party SMS platform, a case-sensitive string of 1 to 31 characters.

Usage guidelines

The app ID is encapsulated in the header field of HTTP requests and sent to the third-party SMS platform for the identity authentication of the SMS gateway. The platform determines the secret key for decryption according to the received app ID and grants the corresponding services to the SMS gateway.

The app ID is provided by the third-party SMS platform.

Examples

Specify **abc** as the app ID of the third-party SMS platform for SMS gateway **gw1**.

```
<Sysname> system-view
[Sysname] sms-gateway gw1
[Sysname-sms-gateway-gw1] app-id abc
```

Related commands

secret-key

display sms-gateway

Use **display sms-gateway** to display SMS gateway information.

Syntax

display sms-gateway [**brief** | **name** *gateway-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

brief: Displays brief information about all SMS gateways. If you do not specify this keyword, the command displays detailed SMS gateway information.

name *gateway-name*: Specifies an SMS gateway by its name. An SMS gateway name is a case-insensitive string of 1 to 31 characters, and can contain only letters, digits, and underscores (_). If you do not specify an SMS gateway, this command displays information about all SMS gateways.

Usage guidelines

The configured secret key for SMS data encryption will be displayed in cipher text.

Examples

Display detailed information about all SMS gateways.

```
<Sysname> display sms-gateway

Total Number of SMS gateways: 2
SMS gateway name: gw1
  SMS platform: emay
  App ID: abc
  Secret key: $c$3$zvzJI1AMQ4OVHCkSnXXoAOUyd2STdtIFtQDlJETCg=
  VPN instance: vpn1

SMS gateway name: gw2
  SMS platform: emay
  App ID: 123
  Secret key: $c$3$AS4tqlnOVODYEQ5IMHJNyNTTAyBPotXgw==
  VPN instance: vpn1
```

Table 1 Command output

Field	Description
SMS platform	SMS platform used by the SMS gateway to send SMS messages.
App ID	App ID for the third-party SMS platform.
Secret key	Secret key (in cipher text) for SMS data encryption.
VPN instance	VPN instance associated with the SMS gateway.

Display brief information about all SMS gateways.

```
<Sysname> display sms-gateway brief
SMS gateway name               SMS platform     VPN instance
gw1                            emay             vpn1
gw2                            emay             vpn1
```

Table 2 Command output

Field	Description
SMS platform	SMS platform used by the SMS gateway to send SMS messages.
VPN instance	VPN instance associated with the SMS gateway.

secret-key

Use **secret-key** to specify the secret key for SMS data encryption.

Use **undo secret-key** to restore the default.

Syntax

secret-key { **cipher** | **simple** } *string*

undo secret-key

Default

No secret key is specified for SMS data encryption.

Views

SMS gateway view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies a ciphertext secret key.

simple: Specifies a plaintext secret key. A plaintext secret key is stored in cipher text.

string: Specifies a case-sensitive secret-key string. A plaintext secret key is a string of 1 to 63 characters, and a ciphertext secret key is a string of 1 to 117 characters.

Usage guidelines

The secret key is provided by the third-party SMS platform.

The secret key uniquely corresponds to the app ID configured by the **app-id** command for the third-party SMS platform.

The service module sends SMS data to the SMS gateway, and then the SMS gateway performs the following operations:

1. Parses and converts the SMS data into data that can be recognized by the third-party SMS platform.
2. Uses the secret key and algorithms to encrypt the SMS data.
3. Sends the encrypted data to the third-party SMS platform.

The third-party SMS platform performs the following operations after receiving the encrypted data:

1. Obtains the app ID in the header field of the HTTP request.
2. Uses the secret key that corresponds to the app ID to decrypt the data to plaintext data.
3. Sends the data in an SMS message to the user mobile number.

Examples

Specify the plaintext secret key as **TESTplat&!** for SMS data encryption.

```
<Sysname> system-view
[Sysname] sms-gateway gw1
[Sysname-sms-gateway-gw1] secret-key simple TESTplat&!
```

Related commands

app-id

sms-gateway

Use **sms-gateway** to create an SMS gateway and enter its view, or enter the view of an existing SMS gateway.

Use **undo sms-gateway** to remove an SMS gateway.

Syntax

sms-gateway *gateway-name*

undo sms-gateway *gateway-name*

Default

No SMS gateways exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

gateway-name: Specifies an SMS gateway by its name, a case-insensitive string of 1 to 31 characters. Valid characters are letters, digits, and underscores (_).

Usage guidelines

The device implements SMS sending through an SMS gateway as follows:

1. A service module sends SMS data to the SMS gateway.
2. The SMS gateway converts the SMS data to the data that can be recognized by the third-party SMS platform.
3. The SMS gateway sends the SMS data to the third-party SMS platform through HTTP.
4. The third-party SMS platform sends the SMS message to the user mobile number.

SMS settings are configured in SMS gateway view, including the SMS platform, app ID for logging in to the third-party SMS platform, and secret key for SMS data encryption.

An SMS gateway can be associated with multiple service modules that require SMS services.

Examples

Create an SMS gateway named **gw1** and enter its view.

```
<Sysname> system-view
[Sysname] sms-gateway gw1
[Sysname-sms-gateway-gw1]
```

Related commands

display sms-gateway

sms-platform

Use **sms-platform** to specify the SMS platform that sends messages.

Use **undo sms-platform** to restore the default.

Syntax

sms-platform emay

undo sms-platform

Default

No SMS platform is specified for sending messages.

Views

SMS gateway view

Predefined user roles

network-admin

context-admin

Parameters

emay: Specifies the Emay SMS platform.

Usage guidelines

To use the third-party SMS platform specified by this command, you must also configure **app-id** and **secret-key** for the platform on the SMS gateway.

Examples

Specify the SMS platform as **emay** for SMS gateway **gw1**.

```
<Sysname> system-view
[Sysname] sms-gateway gw1
[Sysname-sms-gateway-gw1] sms-platform emay
```

Related commands

app-id

secret-key

sms-send test-mobile

Use **sms-send test-mobile** to send a test SMS message to the specified mobile number.

Syntax

sms-send test-mobile *number*

Views

SMS gateway view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the mobile number for receiving test messages, which is a string of 1 to 31 digits.

Usage guidelines

Use this command to test whether the configured SMS gateway can operate correctly. The SMS gateway is considered to be normal if the mobile number receives an **App ID XXX verification passed** message.

Examples

Send a test message to mobile number 111111 for SMS gateway **gw1**.

```
<Sysname> system-view
[Sysname] sms-gateway gw1
[Sysname-sms-gateway-gw1] sms-send test-mobile 111111
```

Related commands

app-id

secret-key

sms-platform

vpn-instance

Use **vpn-instance** to specify the VPN instance for an SMS gateway.

Use **undo vpn-instance** to restore the default.

Syntax

vpn-instance *vpn-instance-name*

undo vpn-instance

Default

An SMS gateway belongs to the public network.

Views

SMS gateway view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance-name: Specifies the name of an MPLS L3VPN instance, a case-sensitive string of 1 to 31 characters.

Usage guidelines

After you execute this command, the resources contained by an SMS gateway will belong to the associated VPN instance.

You can specify only one VPN instance for an SMS gateway.

Examples

Specify VPN instance **vpn1** for SSL VPN gateway **gw1**.

```
<Sysname> system-view
[Sysname] sms-gateway gw1
[Sysname-sms-gateway-gw1] vpn-instance vpn1
```

NSFOCUS Firewall Series

NF DPI Command Reference

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

This command reference describes the commands for configuring DPI features, including DPI engine, IPS, URL filtering, data filtering, file filtering, anti-virus, data analysis center, proxy policy.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

DPI engine commands

app-profile

Use **app-profile** to create a deep packet inspection (DPI) application profile and enter its view, or enter the view of an existing DPI application profile.

Use **undo app-profile** to delete a DPI application profile.

Syntax

app-profile *profile-name*

undo app-profile *profile-name*

Default

No DPI application profiles exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

profile-name: Specifies a DPI application profile name. The profile name is a case-insensitive string of 1 to 63 characters. Valid characters are letters, digits, and underscores (_).

Usage guidelines

The DPI application profile is a security service template that can include DPI service policies such as URL filtering policy.

A DPI application profile takes effect after a security policy rule uses it as the action. The DPI engine inspects the packets matching the rule and submits the packets to the associated DPI service module for processing.

Examples

Create a DPI application profile named **abc** and enter its view.

```
<Sysname> system-view
[Sysname] app-profile abc
[Sysname-app-profile-abc]
```

authentication enable

Use **authentication enable** to enable email client authentication.

Use **undo authentication enable** to disable email client authentication.

Syntax

authentication enable

undo authentication enable

Default

Email client authentication is enabled.

Views

Email parameter profile view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this command when the email server specified by the **email-server** command requires client authentication.

Examples

Disable email client authentication.

```
<Sysname> system-view
[Sysname] inspect email parameter-profile c1
[Sysname-inspect-email-c1] undo authentication enable
```

block-period

Use **block-period** to set the block period during which a source IP address is blocked.

Use **undo block-period** to restore the default.

Syntax

block-period *period*

undo block-period

Default

A source IP address is blocked for 1800 seconds.

Views

Block source parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

period: Specifies the block period in the range of 1 to 86400 seconds.

Usage guidelines

For the block period to take effect, make sure the blacklist feature is enabled.

The device drops the packet that matches an inspection rule and adds the packet's source IP address to the IP blacklist.

- If the blacklist feature is enabled, the device directly drops subsequent packets from the source IP address during the block period.
- If the blacklist feature is disabled, the block period does not take effect. The device inspects all packets and drops the matching ones.

For more information about the blacklist feature, see attack detection and prevention in the *Security Configuration Guide*.

Examples

Set the block period to 3600 seconds in block source parameter profile **b1**.

```
<Sysname> system-view
[Sysname] inspect block-source parameter-profile b1
[Sysname-inspect-block-source-b1] block-period 3600
```

blacklist enable (security zone view) (*Security Command Reference*)

blacklist global enable (*Security Command Reference*)

inspect block-source parameter-profile

capture-limit

Use **capture-limit** to set the maximum volume of captured packets that can be cached.

Use **undo capture-limit** to restore the default.

Syntax

capture-limit *kilobytes*

undo capture-limit

Default

The device can cache a maximum of 512 Kilobytes of captured packets.

Views

Capture parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

kilobytes: Specifies the maximum volume in the range of 0 to 1024 Kilobytes.

Usage guidelines

The device caches captured packets locally. It exports the cached captured packets to a URL when the volume of cached captured packets reaches the maximum, and clears the cache. After the export, the device starts to capture packets again.

If you set the maximum volume of cached captured packets to 0 Kilobytes, the device immediately exports a packet to the URL after the packet is captured.

Examples

Set the maximum volume of cached captured packets to 1024 Kilobytes in the capture parameter profile **c1**.

```
<Sysname> system-view
[Sysname] inspect capture parameter-profile c1
[Sysname-inspect-capture-c1] capture-limit 1024
```

Related commands

export repeating-at

```

Table 1 Command output

Field	Description
MD5 file verification for all files	Status of the MD5 hash-based virus inspection for all files feature: **Enabled** or **Disabled**.

Related commands

inspect md5-verify all-files

display inspect status

Use **display inspect status** to display the status of the DPI engine.

Syntax

display inspect status

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display the status of the DPI engine.

```
<Sysname> display inspect status
```

```
Chassis 0 Slot 1:
 Running status: Normal
```

Table 2 Command output

Field	Description
Running status	Status of the DPI engine: • **DPI administratively disabled**. • **DPI auto-bypass for protocol xxx**. • **DPI disabled due to high CPU usage**. • **Normal**—The DPI engine is running correctly.
Usage threshold has already been reached for the following CPU cores: xxx	This sentence appears when one or more CPU cores reach the CPU core usage alarm threshold. DPI will not use these CPU cores to process services.

Related commands

monitor cpu-usage threshold core (*Fundamentals Command Reference*)

email-limit

Use **email-limit** to configure output limit for log entries sent to the email server.

Use **undo email-limit** to restore the default.

Syntax

email-limit interval *interval* **max-number** *value*

undo email-limit

Default

The device allows sending a maximum of 10 log entries within five minutes.

Views

Email parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

interval *interval*: Specifies email sending interval in the range of 1 to 10 minutes.

max-number *max-number*: Specifies the maximum number of emails per interval, in the range of 1 to 100.

Usage guidelines

This command prevents the device from frequently sending too many log entries to the email server.

The device caches the log entries and sends them when the specified interval is reached.

If the number of cached log entries has reached the upper limit, the device compares the severity level of a new log entry with the severity levels of the cached log entries. If the severity level of the new log entry is higher than that of a cached log entry, the new log entry will overwrite the most recently cached log entry with the lowest severity level. The severity level of a new log entry is the severity level of the matching IPS signatures.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Allow the device to send a maximum of 20 log entries within five minutes to the email server.

```
<Sysname> system-view
[Sysname] inspect email parameter-profile test
[Sysname-inspect-email-test] email-limit interval 5 max-number 20
```

email-server

Use **email-server** to specify the email server.

Use **undo email-server** to restore the default.

Syntax

email-server *address-string*

undo email-server

Default

No email server is specified.

Views

Email parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

address-string: Specifies the email server address, a case-sensitive string of 3 to 63 characters.

Usage guidelines

The email server address can be an IP address or a host name.

If you specify the email server by host name, make sure the device can resolve the host name into its IP address through static or dynamic DNS. Make sure the device and the email server can reach each other. For more information about DNS, see *Layer 3—IP Services Configuration Guide*.

If you execute this command multiple times for the same email parameter profile, the most recent configuration takes effect.

Examples

Specify the email server **rndcas.123.com**.

```
<Sysname> system-view
[Sysname] inspect email parameter-profile c1
[Sysname-inspect-email-c1] email-server rndcas.123.com
```

Specify the email server at 192.168.1.1.

```
<Sysname> system-view
[Sysname] inspect email parameter-profile c1
[Sysname-inspect-email-c1] email-server 192.168.1.1
```

export repeating-at

Use **export repeating-at** to set the daily export time for cached captured packets.

Use **export repeating-at** to restore the default.

Syntax

export repeating-at *time*

undo export repeating-at

Default

The system exports cached captured packets at 1:00 a.m. every day.

Views

Capture parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the daily export time in the format of hh:mm:ss in the range of 00:00:00 to 23:59:59.

Usage guidelines

The device exports cached captured packets to a URL and clears the cache at the daily export time, whether or not the volume of cached captured packets reaches the maximum.

Examples

Configure the device to export cached captured packets at 2:00 a.m. every day in the capture parameter profile **c1**.

```
<Sysname> system-view
[Sysname] inspect capture parameter-profile c1
[Sysname-inspect-capture-c1] export repeating-at 02:00:00
```

Related commands

capture-limit

export url

inspect capture parameter-profile

export url

Use **export url** to specify the URL to which the cached captured packets are exported.

Use **export url** to restore the default.

Syntax

export url *url-string*

undo export url

Default

No URL is specified for exporting the cached captured packets.

Views

Capture parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the URL, a string of 1 to 255 characters.

Usage guidelines

The device exports the cached captured packets to the specified URL at the daily export time or when the volume of cached captured packets reaches the maximum. After the captured packets are exported, the system clears the cache.

If you do not specify a URL, the device still exports the cached captured packets but the export fails.

Examples

Configure the device to export cached captured packets to URL tftp://192.168.100.100/upload in the capture parameter profile **c1**.

```
<Sysname> system-view
[Sysname] inspect capture parameter-profile c1
[Sysname-inspect-capture-c1] export url tftp://192.168.100.100/upload
```

Related commands

capture-limit

export repeating-at

inspect capture parameter-profile

import block warning-file

Use **import block warning-file** to import a user-defined alarm message from a warning file.

Syntax

import block warning-file *file-path*

Default

The device uses the default alarm message "**The site you are accessing has a security risk and thereby is blocked**."

Views

Warning parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

file-path: Specifies the warning file path, a string of 1 to 200 characters.

Usage guidelines

After you execute the **inspect warning parameter-profile** command, the system automatically generates a warning file named **av-httpDeclare-xxx** in the **dpi/av/warning** directory. The **xxx** represents the name of the warning parameter profile.

A default alarm message is predefined in the warning file. If an end-point user visits a virus-infected website, the device will block the website access and displays the alarm message on the browser of the end-point user.

You can execute the **import block warning-file** command to specify a user-defined alarm message from a file. Only HTML and TXT files are supported.

The device supports the following import methods:

- **Local import**—Imports the message from the warning file that is stored locally.

  Store the warning file on the master device for successful import.

  The format of the *file-path* argument varies by the location of the warning file to be imported.

The warning file is stored…	Format of *file-path*	Remarks
In the current working directory	*filename*	To display the current working directory, use the **pwd** command. For information about the **pwd** command, see file system management in *Fundamentals Command Reference*.
In a directory different from the working directory on the same storage medium	*filename*	Before importing the warning file, you must first use the **cd** command to open the directory where the file is stored. For information about the **cd** command, see file system management in *Fundamentals Command Reference*.
On a storage medium different from the working directory	*path/filename*	Before importing the warning file, you must first use the **cd** command to open the root directory of the storage medium where the file is stored. For information about the **cd** command, see file system management in *Fundamentals Command Reference.*

- **FTP/TFTP import**—Imports the message from the warning file that is stored on an FTP or TFTP server.

  The format of the *file-path* argument varies by the location of the warning file to be imported.

The warning file is stored on	Format of *file-path*	Remarks
An FTP server	ftp://*username*:*password*@*server*/*filename*	The *username* and *password* arguments represent the FTP login username and password, respectively. The *server* argument represents the IP address or host name of the FTP server. If a colon (:), at sign (@), or forward slash (/) exists in the username or password, you must convert it into its escape characters. The escape characters are **%3A** or **%3a** for a colon, **%40** for an at sign, and **%2F** or **%2f** for a forward slash.

A TFTP server.	tftp://*server*/*filename*	The *server* argument represents the IP address or host name of the TFTP server.

NOTE:

To specify a warning file on an FTP or TFTP server, make sure the device and the server can reach each other. If you specify the server by its host name, you must also make sure the device can resolve the host name into an IP address through static or dynamic DNS. For more information about DNS, see *Layer 3—IP Services Configuration Guide*.

Examples

Import a user-defined alarm message from the warning file on a TFTP server.

```
<Sysname> system-view
[Sysname] inspect warning parameter-profile warn
[Sysname-inspect-warning-warn] import block warning-file tftp://192.168.0.1/warning.txt
```

Import a user-defined alarm message from the warning file on an FTP server. The FTP login username and password are **user** and **password**, respectively.

```
<Sysname> system-view
[Sysname] inspect warning parameter-profile warn
[Sysname-inspect-warning-warn] import block warning-file
ftp://user:password@192.168.0.1/warning.txt
```

Import a user-defined alarm message from the warning file stored locally. The file is stored in directory **cfa0:/warning.txt**, and the current working directory is **cfa0**.

```
<Sysname> system-view
[Sysname] inspect warning parameter-profile warn
[Sysname-inspect-warning-warn] import block warning-file warning.txt
```

inspect activate

Use **inspect activate** to activate the policy and rule configurations for DPI service modules.

Syntax

inspect activate

Default

The creation, modification, and deletion of DPI service policies and rules will be activated automatically.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

CAUTION:

This command causes transient DPI service interruption. DPI-based services might also be interrupted. For example, security policies cannot control access to applications.

By default, the system will detect whether another configuration change (such as creation, modification, or deletion) occurs within a 20-second interval after a configuration change for DPI service modules such as URL filtering:

- If no configuration change occurs within the interval, the system performs an activation operation at the end of the next interval to make the configuration take effect.
- If a configuration change occurs within the interval, the system continues to periodically check whether a configuration change occurs within the interval.

To activate the policy and rule configurations for DPI service modules immediately, you can execute the **inspect activate** command.

Examples

Activate the policy and rule configurations for DPI service modules.

```
<Sysname> system-view
[Sysname] inspect activate
```

inspect auto-bypass

Use **inspect auto-bypass enable** to enable automatic bypass of the DPI engine.

Use **undo inspect auto-bypass enable** to disable automatic bypass of the DPI engine.

Syntax

inspect auto-bypass enable

undo inspect auto-bypass enable

Default

Automatic bypass of the DPI engine is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

With this feature enabled, the DPI engine automatically disables inspection on packets of the specified protocol after a device reboot caused by packet inspection errors.

Examples

Enable automatic bypass of the DPI engine.

```
<Sysname> system-view
[Sysname] inspect auto-bypass enable
This feature might cause some functions of the DPI engine to be unavailable. Continue?
[Y/N]:y
```

inspect block-source parameter-profile

Use **inspect block-source parameter-profile** to create a block source parameter profile and enter its view, or enter the view of an existing block source parameter profile.

Use **undo inspect block-source parameter-profile** to delete a block source parameter profile.

Syntax

inspect block-source parameter-profile *parameter-name*

undo inspect block-source parameter-profile *parameter-name*

Default

No block source parameter profiles exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

parameter-name: Specifies a block source parameter profile name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

In block source parameter profile view, you can set parameters for the block source action, such as the block period.

Examples

Create a block source parameter profile named **b1** and enter its view.

```
<Sysname> system-view
[Sysname] inspect block-source parameter-profile b1
[Sysname-inspect-block-source-b1]
```

Related commands

block-period

inspect bypass

Use **inspect bypass** to disable the DPI engine.

Use **undo inspect bypass** to enable the DPI engine.

Syntax

inspect bypass

undo inspect bypass

Default

The DPI engine is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

CAUTION:

This command causes packets of any protocols not to be processed by DPI. DPI-based services might also be interrupted. For example, security policies cannot control access to applications.

Packet inspection in the DPI engine is a complex and resource-consuming process. When the CPU usage is high, you can disable the DPI engine to guarantee the device performance.

Examples

Disable the DPI engine.

```
<Sysname> system-view
[Sysname] inspect bypass
```

Related commands

display inspect status

inspect bypass protocol

Use **inspect bypass protocol** to specify the protocols to bypass the DPI engine.

Use **undo inspect bypass protocol** to disable DPI engine bypass for protocols.

Syntax

inspect bypass protocol { **dns** | **ftp** | **ftp-data** | **http** | **https** | **imap** | **nfs** | **pop3** | **rtmp** | **sip** | **smb** | **smtp** | **telnet** | **tftp** } *

undo inspect bypass protocol [**dns** | **ftp** | **ftp-data** | **http** | **https** | **imap** | **nfs** | **pop3** | **rtmp** | **sip** | **smb** | **smtp** | **telnet** | **tftp**] *

Default

The DPI engine inspects all supported protocols.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dns: Specifies the DNS protocol.

ftp: Specifies the FTP protocol.

ftp-data: Specifies the FTP data protocol.

http: Specifies the HTTP protocol.

https: Specifies the HTTPS protocol.

imap: Specifies the IMAP protocol.

nfs: Specifies the NFS protocol.

pop3: Specifies the POP3 protocol.

rtmp: Specifies the RTMP protocol.

sip: Specifies the SIP protocol.

smb: Specifies the SMB protocol.

smtp: Specifies the SMTP protocol.

telnet: Specifies the Telnet protocol.

tftp: Specifies the TFTP protocol.

Usage guidelines

If you do not specify any keyword when executing the **undo inspect bypass protocol** command, the DPI engine inspects all supported protocols.

As a best practice, you can specify the protocols to bypass the DPI engine when either of the following conditions is met:

- Inspection on packets of the specified protocols is not required. You can disable the DPI engine for the specified protocols to reduce the occupation of device resources and improve the device performance.
- Inspection on packets of the specified protocols causes device reboot. You can specify the protocols to bypass the DPI engine to avoid device reboot caused by inspection error and ensure the inspection on packets of other protocols.

Examples

Specify the HTTP protocol to bypass the DPI engine.

```
<Sysname> system-view
[Sysname] inspect bypass protocol http
This feature might cause the DPI engine to be unavailable for the specified protocol.
Continue? [Y/N]:y
```

Related commands

display inspect status

inspect cache-option maximum

Use **inspect cache-option maximum** to set the maximum number of options to be cached per TCP or UDP data flow for further inspection.

Use **undo inspect cache-option** to restore the default.

Syntax

inspect cache-option maximum *max-number*

undo inspect cache-option

Default

The DPI engine can cache a maximum of 32 options per TCP or UDP data flow.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of options to be cached per TCP or UDP data flow. The value range is 1 to 254.

Usage guidelines

An inspection rule can contain multiple AC patterns, and each AC pattern can be associated with multiple options. A TCP or UDP data flow matches an inspection rule if the packets of the flow match all the AC patterns and options in the rule.

If a packet of a TCP or UDP data flow matches one AC pattern in an inspection rule, the DPI engine cannot determine whether the flow matches the rule. The DPI engine continues to match packets of the flow against the remaining options and AC patterns in the rule. For any options that cannot be matched, the DPI engine caches them to match subsequent packets. The DPI engines determines that the flow matches the rule when all options and AC patterns in the rule are matched.

The more options DPI engine caches, the more likely that DPI engine identifies the application information and the more accurate the DPI engine inspection. However, caching more options requires more memory. If the device has a high memory usage, configure the DPI engine to cache less options to improve the device performance.

Typically, the default setting is sufficient for most scenarios.

Examples

Configure the DPI engine to cache a maximum of four options per TCP or UDP data flow for further inspection.

```
<Sysname> system-view
[Sysname] inspect cache-option maximum 4
```

inspect capture parameter-profile

Use **inspect capture parameter-profile** to create a capture parameter profile and enter its view, or enter the view of an existing capture parameter profile.

Use **undo inspect capture parameter-profile** to delete a capture parameter profile.

Syntax

inspect capture parameter-profile *parameter-name*

undo inspect capture parameter-profile *parameter-name*

Default

No capture parameter profiles exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

profile-name: Specifies a capture parameter profile name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

In capture parameter profile view, you can set parameters for the packet capture action, such as the maximum volume of cached captured packets.

Only the IPS module supports the packet capture action.

Examples

Create a capture parameter profile named **c1** and enter its view.

```
<Sysname> system-view
[Sysname] inspect capture parameter-profile c1
[Sysname-inspect-capture-c1]
```

inspect cloud-server

Use **inspect cloud-server** to specify the server used by DPI services for cloud query.

Use **undo inspect cloud-server** to remove the cloud query server specified for DPI services.

Syntax

inspect cloud-server *host-name*

undo inspect cloud-server

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

host-name: Specifies the cloud query server by its host name, a case-insensitive string of 1 to 255 characters. Valid characters include letters, digits, underscores (_), hyphens (-), and dots (.)

Usage guidelines

The cloud query server supports URL filtering cloud query and anti-virus MD5 value cloud query.

For successful cloud query, make sure the device can resolve the host name of the cloud query server into an IP address through DNS. For more information about DNS, see DNS configuration in *Layer 3—IP Services Configuration Guide.*

This command is supported only on the default context. For more information about contexts, see context configuration in *Virtual Technologies Configuration Guide.*

Examples

Specify the server with host name **service.nsfocus.com.cn** for cloud query.

```
<Sysname> system-view
[Sysname] inspect cloud-server service.nsfocus.com.cn
```

Related commands

cloud-query enable (anti-virus policy view)

inspect coverage

Use **inspect coverage** to configure a DPI engine inspection mode.

Use **undo inspect coverage** to restore the default.

Syntax

inspect coverage { **balanced** | **large-coverage** | **high-performance** | **user-defined** }

undo inspect coverage

Default

The DPI engine uses the balanced mode.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

balanced: Specifies the balanced mode. This mode makes a tradeoff between the device performance and inspection coverage.

large-coverage: Specifies the large coverage mode. This mode appropriately reduces device performance to achieve the best inspection coverage.

high-performance: Specifies the high performance mode. This mode appropriately reduces the inspection coverage to ensure the best device performance.

user-defined: Specifies the user-defined mode. This mode allows you to adjust the inspection length of the DPI engine as required.

Usage guidelines

Select an inspection mode as required:

- **Balanced mode**—Applicable to most scenarios. This mode makes a tradeoff between the device performance and inspection coverage. The maximum length is 32 Kilobytes for FTP, HTTP, SMB, NFS, and email streams, and the maximum file length for MD5 inspection is 2048 Kilobytes.
- **Large coverage mode**—Applicable to the scenarios that require large inspection coverage. This mode improves the inspection coverage at the cost of device performance. The maximum length is 128 Kilobytes for FTP, HTTP, SMB, NFS, and email streams, and the maximum file length for MD5 inspection is 5120 Kilobytes.
- **High performance mode**—Applicable to the scenarios that requires high device performance. This mode improves the device performance while ensuring a certain inspection coverage. The maximum length is 32 Kilobytes for FTP, HTTP, SMB, NFS, and email streams, and the maximum file length for MD5 inspection is 32 Kilobytes.
- **User-defined mode**—Applicable to the scenarios that have specific requirements for inspection coverage and device performance. In this mode, you can execute the **inspect stream-fixed-length and inspect md5-fixed-length commands to** set the maximum stream length for inspection and maximum file length for MD5 value calculation, respectively.

Examples

Configure the user-defined mode as the DPI engine inspection mode.

```
<Sysname> system-view
[Sysname] inspect coverage user-defined
```

Related commands

inspect file-fixed-length enable

inspect stream-fixed-length enable

inspect cpu-threshold disable

Use **inspect cpu-threshold disable** to disable inspection suspension upon excessive CPU usage.

Use **undo inspect cpu-threshold disable** to enable inspection suspension upon excessive CPU usage.

Syntax

inspect cpu-threshold disable

undo inspect cpu-threshold disable

Default

Inspection suspension upon excessive CPU usage is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Packet inspection in the DPI engine is a complex and resource-consuming process.

Inspection suspension upon excessive CPU usage works as follows:

- When the device's CPU usage rises to or above the CPU usage threshold, the DPI engine suspends packet inspection to guarantee the device performance.
- When the device's CPU usage drops to or below the CPU usage recovery threshold, the DPI engine resumes packet inspection.

Do not disable inspection suspension upon excessive CPU usage if the device's CPU usage is high.

Examples

Disable inspection suspension upon excessive CPU usage.

```
<Sysname> system-view
[Sysname] inspect cpu-threshold disable
```

Related commands

display inspect status

inspect bypass

inspect dual-active enable

Use **inspect dual-active enable** to enable support for HA dual-active mode.

Use **undo inspect dual-active enable** to disable support for HA dual-active mode.

Syntax

inspect dual-active enable

undo inspect dual-active enable

Default

Support for HA dual-active mode is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The feature ensures the device in dual-active mode can correctly process DPI services in a network with asymmetric forwarding of flows.

This feature takes effect only when the device operates in HA dual-active mode.

For more information about HA dual-active mode, see RBM-based hot backup configuration in *High Availability Configuration Guide*.

Examples

Enable support for HA dual-active mode.

```
<Sysname> system-view
[Sysname] inspect dual-active enable
```

Related commands

backup-mode dual-active (*High Availability Command Reference*)

inspect email parameter-profile

Use **inspect email parameter-profile** to create an email parameter profile and enter its view, or enter the view of an existing email parameter profile.

Use **undo inspect email parameter-profile** to delete an email parameter profile.

Syntax

inspect email parameter-profile *parameter-name*

undo inspect email parameter-profile *parameter-name*

Default

No email parameter profiles exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

parameter-name: Specifies an email parameter profile name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

In email parameter profile view, you can set parameters for the email action. Email parameters include the email server, the email sender and receiver, and the username and password for logging in to the email server.

Examples

Create an email parameter profile named **c1** and enter its view.

```
<Sysname> system-view
[Sysname] inspect email parameter-profile c1
[Sysname-inspect-email-c1]
```

inspect file-fixed-length

Use **inspect file-fixed-length** to set the fixed length for file inspection.

Use **undo inspect file-fixed-length** to restore the default.

Syntax

inspect file-fixed-length { **email** | **ftp** | **http** | **nfs** | **smb** } * *length-value*

undo inspect file-fixed-length

Default

The fixed length is 32 Kilobytes for FTP, HTTP, NFS, SMB, and email files.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

email: Specifies email protocols, including SMTP, POP3 and IMAP.

ftp: Specifies the FTP protocol.

http: Specifies the HTTP protocol.

nfs: Specifies the NFS protocol.

smb: Specifies the SMB protocol.

length-value: Specifies the fixed length in the range of 1 to 2048 Kilobytes.

Usage guidelines

This command can be executed only if the DPI engine inspection mode is user-defined mode.

Typically, virus signatures are embedded in the first half of a file. Narrowing the inspection scope of each file improves the file inspection efficiency.

If a data stream contains multiple files, this feature inspects only the fixed length data of each file.

Because files are transmitted in a data stream, the fixed length of files must not be longer than that of the data stream configured by the **inspect stream-fixed-length** command.

Examples

Set the fixed length to 128 Kilobytes for inspecting each HTTP file.

```
<Sysname> system-view
[Sysname] inspect file-fixed-length http 128
```

Related commands

inspect coverage user-defined

inspect file-fixed-length enable

inspect stream-fixed-length

inspect file-fixed-length enable

Use **inspect file-fixed-length enable** to enable file fixed length inspection.

Use **undo inspect file-fixed-length enable** to disable file fixed length inspection.

Syntax

inspect file-fixed-length enable

undo inspect file-fixed-length enable

Default

The file fixed length inspection is disabled and the file inspection length is not limited.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command can be executed only if the DPI engine inspection mode is user-defined mode.

The file fixed length inspection feature enables the DPI engine to inspect only a fixed length of file data instead of the entire file in each data stream.

With this feature configured, the DPI engine cannot identify the remaining file data that exceeds the defined fixed length, affecting the data filtering service.

Examples

Enable file fixed length inspection.

```
<Sysname> system-view
[Sysname] inspect file-fixed-length enable
```

Related commands

inspect coverage user-defined

inspect file-fixed-length

inspect file-uncompr-len

Use **inspect file-uncompr-len** to set the maximum data size that can be decompressed in a file.

Use **undo inspect file-uncompr-len** to restore the default.

Syntax

inspect file-uncompr-len *max-size*

undo inspect file-uncompr-len

Default

A maximum of 100 MB data can be decompressed in a file.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

max-size: Specifies the maximum data size in the range of 1 to 200 MB.

Usage guidelines

The device can decompress .zip files for file data inspection. This command specifies the maximum data size that can be decompressed in a file. The remaining file data will be ignored.

Set an appropriate maximum data size for file decompression. A large data size might make the device get stuck in decompressing large files and the device forwarding performance might be affected. A small data size will affect the accuracy of the file inspection results for DPI services (such as anti-virus and data filtering).

Examples

Set the maximum data size that can be decompressed in a file to 150 MB.

```
<Sysname> system-view
[Sysname] inspect file-uncompr-len 150
```

inspect logging parameter-profile

Use **inspect logging parameter-profile** to create a logging parameter profile and enter its view, or enter the view of an existing logging parameter profile.

Use **undo inspect logging parameter-profile** to delete a logging parameter profile.

Syntax

inspect logging parameter-profile *parameter-name*

undo inspect logging parameter-profile *parameter-name*

Default

No logging parameter profiles exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

profile-name: Specifies a logging parameter profile name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

In logging parameter profile view, you can set parameters for the logging action, such as the log output method.

Examples

Create a logging parameter profile named **log1** and enter its view.

```
<Sysname> system-view
[Sysname] inspect logging parameter-profile log1
[Sysname-inspect-logging-log1]
```

Related commands

log

inspect md5-fixed-length

Use **inspect md5-fixed-length** to set the fixed file length for MD5 inspection.

Use **undo inspect md5-fixed-length** to restore the default.

Syntax

inspect md5-fixed-length { **email** | **ftp** | **http** | **nfs** | **smb** } * *length*

undo inspect md5-fixed-length

Default

The fixed length of FTP, HTTP, SMB, NFS, and email files for MD5 inspection is 2048 Kilobytes.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

email: Specifies email protocols, including SMTP, POP3, and IMAP.

ftp: Specifies the FTP protocol.

http: Specifies the HTTP protocol.

nfs: Specifies the NFS protocol.

smb: Specifies the SMB protocol.

length: Specifies the fixed file length for MD5 inspection, in the range of 1 to 5120 Kilobytes. Make sure the fixed file length for MD5 inspection is longer than the fixed length for stream inspection.

Usage guidelines

This command can be executed only if the DPI engine inspection mode is user-defined mode.

For some DPI services, such as anti-virus services, the DPI engine inspects the packet signatures and MD5 values at the same time. After reaching the fixed length for stream inspection, the DPI engine will stop the packet signature inspection but will not stop the MD5 inspection until the fixed MD5 inspection length is reached.

The increase of the file length for MD5 inspection will reduce the device performance but improve the success rate of the MD5 inspection. The decrease of the file length for MD5 inspection will improve the device performance but reduce the success rate of the MD5 inspection.

Examples

Set the fixed lengths of FTP and HTTP files for MD5 inspection to 1024 Kilobytes and 512 Kilobytes, respectively.

```
<Sysname> system-view
[Sysname] inspect md5-fixed-length ftp 1024 http 512
```

Related commands

inspect coverage user-defined

inspect md5-fixed-length enable

inspect md5-fixed-length enable

Use **inspect md5-fixed-length enable** to enable MD5 fixed-length file inspection.

Use **undo inspect md5-fixed-length enable** to disable MD5 fixed-length file inspection.

Syntax

inspect md5-fixed-length enable

undo inspect md5-fixed-length enable

Default

MD5 fixed-length file inspection is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command can be executed only if the DPI engine inspection mode is user-defined mode.

The MD5 fixed-length file inspection feature enables the DPI engine to calculate the MD5 values of files of fixed lengths. When a file length reaches the defined file length for MD5 inspection, the DPI engine stops calculating the MD5 value for the file.

Examples

Disable MD5 fixed-length file inspection.

```
<Sysname> system-view
[Sysname] undo inspect md5-fixed-length enable
```

Related commands

inspect coverage user-defined

inspect md5-fixed-length

inspect md5-verify all-files

Use **inspect md5-verify all-files** to enable MD5 hash-based virus inspection for all files.

Use **undo inspect md5-verify all-files** to restore the default.

Syntax

inspect md5-verify all-files

undo inspect md5-verify all-files

Default

The DPI engine performs MD5 hash-based virus inspection only for executable files, office files, and compressed files.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the DPI engine to generate MD5 hashes for all files and to compare the generated MD5 hashes with the MD5 rules in the signature library. If the MD5 hash generated for a file matches an MD5 rule in the signature library, the file is considered to contain viruses.

This feature might degrade the processing performance of other services. Enable it only when necessary.

Examples

Enable MD5 hash-based virus inspection for all files.

```
<Sysname> system-view
[Sysname] inspect md5-verify all-files
```

Related commands

display inspect md5-verify configuration

inspect optimization disable

Use **inspect optimization disable** to disable a DPI engine optimization feature.

Use **undo inspect optimization disable** to enable a DPI engine optimization feature.

Syntax

inspect optimization [**chunk** | **no-acsignature** | **raw** | **uncompress** | **url-normalization**] **disable**

undo inspect optimization [**chunk** | **no-acsignature** | **raw** | **uncompress** | **url-normalization**] **disable**

Default

All DPI engine optimization features are enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

chunk: Specifies the chunked packet decoding feature.

no-acsignature: Specifies the inspection rules that do not contain AC patterns.

raw: Specifies the application layer payload decoding feature.

uncompress: Specifies the HTTP body decompression feature.

url-normalization: Specifies the HTTP URL normalization feature.

Usage guidelines

If you do not specify any parameter, this command applies to all DPI engine optimization features.

DPI engine supports the following optimization features:

- **Chunked packet decoding**—Chunk is a packet transfer mechanism of the HTTP body. DPI engine must decode a chunked HTTP body before it inspects the HTTP body. When the device throughput is too low to ensure basic communication, you can disable DPI engine from decoding chunked packets to improve the device performance. However, when chunked packet decoding is disabled, the DPI engine cannot identify some attacks that exploit security vulnerabilities.
- **Inspection rules that do not contain AC patterns**—Inspection rules that do not contain AC patterns contain only options. These rules match packets by fields such as port numbers and error codes rather than by character strings. These rules by default are enabled to improve the inspection accuracy. However, when the device throughput is too low to ensure basic communication, you can disable these rules to improve the device performance.
- **Application layer payload decoding**—For application layer protocols featuring encoding and decoding, such as HTTP, SMTP, POP3, and IMAP4, DPI engine must decode the payload before inspection. When the device throughput is too low to ensure basic communication, you can disable DPI engine from decoding application layer payloads to improve the device performance. However, disabling application layer payload decoding affects the inspection accuracy of the DPI engine. For example, the DPI engine might fail to applications that need to be decoded, such as DingTalk. Additionally, the auditing function based on these applications cannot take effect.
- **HTTP body decompression**—If the HTTP body field is compressed, DPI engine must decompress the body before inspection. When the device throughput is too low to ensure basic communication, you can disable DPI engine from decompressing the HTTP body field to improve the device performance. However, when HTTP body decompression is disabled, the DPI engine cannot identify some attacks that exploit security vulnerabilities.
- **HTTP URL normalization**—HTTP URL normalization is the process by which the absolute path in a URL is normalized and special URLs are standardized and checked. For example, the absolute path **test/dpi/../index.html** is normalized as **test/index.html**. When the device throughput is too low to ensure basic communication, you can disable DPI engine from normalizing HTTP URLs to improve the device performance. However, when HTTP URL normalization is disabled, the DPI engine cannot identify some attacks that exploit security vulnerabilities.

Examples

Disable all DPI engine optimization features.

```
<Sysname> system-view
[Sysname] inspect all disable
```

inspect packet maximum

Use **inspect packet maximum** to set the maximum number of payload-carrying packets to be inspected per data flow.

Use **undo inspect packet** to restore the default.

Syntax

inspect packet maximum *max-number*

undo inspect packet

Default

The DPI engine can inspect a maximum of 32 payload-carrying packets per data flow.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of payload-carrying packets to be inspected per data flow, in the range of 1 to 254.

Usage guidelines

If DPI engine finds that the first payload-carrying packet of a data flow does not match any inspection rule, it continues to inspect the next payload-carrying packet, and so on. If DPI engine has inspected the maximum number of payload-carrying packets but finds no matching inspection rule, it determines the flow does not match any rule and allows the flow to pass.

The more payload-carrying packets DPI engine inspects, the more likely that DPI engine identifies the application information and the more accurate the DPI engine inspection.

Typically, the default setting is sufficient for most scenarios. You can adjust the setting according to your network condition.

- If the device throughput is high, increase the maximum number value.
- If the device throughput is low, decrease the maximum number value.

Examples

Allow the DPI engine to inspect a maximum of 16 payload-carrying packets per data flow for application identification.

```
<Sysname> system-view
[Sysname] inspect packet maximum 16
```

inspect real-ip detect-field priority

Use **inspect real-ip detect-field priority** to set the priority of an inspected field for real source IP inspection.

Use **undo inspect real-ip detect-field priority** to cancel the priority of an inspected field for real source IP inspection.

Syntax

inspect real-ip detect-field { **cdn-src-ip** | **tcp-option** | **x-real-ip** | **xff** } **priority** *priority-value*

undo inspect real-ip detect-field { **cdn-src-ip** | **tcp-option** | **x-real-ip** | **xff** } **priority**

Default

No priority is specified for any inspected field in the real source IP inspection, and all inspected fields use priority value 0. The device inspects the fields in the order of the **xff**, **cdn-src-ip**, **x-real-ip**, and **tcp-option** fields.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

cdn-src-ip: Specifies the Cdn-Src-Ip field in the HTTP header.

tcp-option: Specifies the TCP Options field.

xff: Specifies the X-Forwarded-For field in the HTTP header.

x-real-ip: Specifies the X-Real-IP field in the HTTP header.

priority *priority-value*: Specifies a priority for an inspected field, in the range of 1 to 100. The larger the priority value, the higher the priority. Each inspected filed must have a unique priority value.

Usage guidelines

With real source IP inspection enabled, the device obtains the real source IP address of the client by inspecting multiple fields in the packets by default.

When multiple IP addresses are detected, the devices uses the IP address obtained from the field with the highest priority as the final real source IP address.

Examples

Set the priority to 10 for the X-Forwarded-For field.

```
<Sysname> system-view
[Sysname] inspect real-ip detect-field xff priority 10
```

inspect real-ip detect-field tcp-option

Use **inspect real-ip detect-field tcp-option** to configure real source IP inspection for the TCP Options field.

Use **undo inspect real-ip detect-field tcp-option** to restore the default.

Syntax

inspect real-ip detect-field tcp-option hex *hex-vector* [**offset** *offset-value*] [**depth** *depth-value*] [**ip-offset** *ip-offset-value*]

undo inspect real-ip detect-field tcp-option

Default

Real source IP inspection is not configured for the TCP Options field, and the device does not obtain the real source IP address from the TCP Options field.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

hex *hex-vector*: Specifies a case-sensitive hexadecimal string of 6 to 66 characters. Specify an even number of characters, and enclose the string with two vertical bars (|), for example |1234f5b6|.

offset *offset-value*: Specifies an offset in bytes after which the hexadecimal string lookup starts, in the range of 0 to 32. If you do not specify this option, the lookup starts from the beginning of the TCP Options field.

depth *depth-value*: Specifies the number of bytes to locate the hexadecimal string, in the range of 2 to 40. If you do not specify this option, the device searches the whole TCP Options field for the hexadecimal string.

ip-offset *ip-offset-value*: Specifies an offset in bytes after which the real source IP address is, in the range of 0 to 32. If you do not specify this option, the data after the hexadecimal string is the real source IP address.

Usage guidelines

To enable the device to locate the real source IP address in the TCP Option field, you must first define a hexadecimal string. If no hexadecimal string is found, the device will stop searching the TCP Options field for the real IP address.

Examples

Configure the device to search bytes 3 to 12 for the hexadecimal string **|0102|** in the TCP Options field, and define that the real source IP address is 2 bytes away from the hexadecimal string.

```
<Sysname> system-view
[Sysname] inspect real-ip detect-field tcp-option hex |0102| offset 2 depth 10 ip-offset
2
```

inspect real-ip detect-field xff

Use **inspect real-ip detect-field xff** to configure real source IP address inspection for the X-Forwarded-For field.

Use **undo inspect real-ip detect-field xff** to restore the default.

Syntax

inspect real-ip detect-field xff { **head** | **tail** }

undo inspect real-ip detect-field xff

Default

The rightmost IP address in the X-Forwarded-For field is the real source IP address.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

head: Specifies the first IP address in the X-Forwarded-For field as the real source IP address.

tail: Specifies the last IP address in the X-Forwarded-For field as the real source IP address.

Usage guidelines

When a client connects to a Web server through an HTTP proxy, the HTTP header might contain the X-Forwarded-For field that carries multiple IP addresses. The standard syntax of the X-Forwarded-For field is <client>, <proxy1>, <proxy2>,…<proxyn>. If a request goes through multiple proxies, the IP addresses of each successive proxy are listed. The rightmost IP address is the IP address of the most recent proxy and the leftmost IP address is the IP address of the originating client.

Examples

Specify the leftmost IP address in the X-Forwarded-For field as the real source IP address.

```
<Sysname> system-view
[Sysname] inspect real-ip detect-field xff head
```

Related commands

inspect real-ip enable

inspect real-ip enable

Use **inspect real-ip enable** to enable real source IP inspection.

Use **undo inspect real-ip enable** to disable real source IP inspection.

Syntax

inspect real-ip enable

undo inspect real-ip enable

Default

Real source IP inspection is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

When a client connects to a Web server through HTTP proxies, the source IP address of the request packet will change. To identify the source IP attacks accurately, you can enable this feature to obtain the real source IP address from the corresponding fields in the request.

Examples

Enable real source IP inspection.

```
<Sysname> system-view
[Sysname] inspect real-ip enable
```

inspect real-ip record-filename nfs maximum

Use **inspect record-filename nfs maximum** to set the maximum number of NFS file names recorded.

Use **undo inspect record-filename nfs maximum** to restore the default.

Syntax

inspect record-filename nfs maximum *max-number*

undo inspect record-filename nfs maximum

Default

The maximum number of NFS file names recorded is calculated according to the actual memory size of the device.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of NFS file names recorded, in the range of 0 to 4294967295. The value 0 indicates that the number of NFS file names recorded is not limited.

Usage guidelines

The DPI engine records file names during file detection for users to obtain file information in logs. The record process occupies memory resources. The more files detected, the more memory resources occupied. In an environment using NFS to transfer a large number of files, Execute this command to limit the memory resources consumed by recording file names.

In scenarios requiring high performance, you can set a small limit to reduce memory consumption. In scenarios not requiring high performance, you can set a great limit to enable users to obtain more file information.

Examples

Set the maximum number of NFS file names recorded to 110000.

```
<Sysname> system-view
[Sysname] inspect record-filename nfs maximum 110000
```

inspect redirect parameter-profile

Use **inspect redirect parameter-profile** to create a redirect parameter profile and enter its view, or enter the view of an existing redirect parameter profile.

Use **undo inspect redirect parameter-profile** to delete a redirect parameter profile.

Syntax

inspect redirect parameter-profile *parameter-name*

undo inspect redirect parameter-profile *parameter-name*

Default

No redirect parameter profiles exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

parameter-name: Specifies a redirect parameter profile name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

In redirect parameter profile view, you can set parameters for the redirect action, such as the URL to which packets are redirected.

Examples

Create a redirect parameter profile named **r1** and enter its view.

```
<Sysname> system-view
```

```
[Sysname] inspect redirect parameter-profile r1
[Sysname-inspect-redirect-r1]
```

inspect signature auto-update proxy

Use **inspect signature auto-update proxy** to specify the proxy server used by DPI services for online signature update.

Use **undo inspect signature auto-update proxy** to restore the default.

Syntax

inspect signature auto-update proxy { **domain** *domain-name* | **ip** *ip-address* } [**port** *port-number*] [**user** *user-name* **password** { **cipher** | **simple** } *string*]

undo inspect signature auto-update proxy

Default

The proxy server used by DPI services for online signature update is not specified.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

domain *domain-name*: Specifies a proxy server by its domain name, a case-insensitive string of 3 to 63 characters.

ip *ip-address*: Specifies a proxy server by its IPv4 address.

port *port-number*: Specifies the port number used by the proxy server. The value range is 1 to 65535, and the default is 80.

user *user-name*: Specifies the username used to log in to the proxy server. The username is a case-insensitive string of 1 to 31 characters.

password: Specifies the password used to log in to the proxy server.

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password in plaintext form will be stored in encrypted form.

string: Specifies the password string. Its plaintext form is a case-sensitive string of 1 to 31 characters. Its encrypted form is a case-sensitive string of 1 to 73 characters.

Usage guidelines

The device must access the company's website for online signature update of DPI services such as URL filtering. If direct connectivity is not available, the device can access the company's website through the specified proxy server. For more information about online signature update, see *DPI Configuration Guide*.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify server **http://www.abc.com/** on port 8888 as the proxy server and set the login username and password to **admin**.

```
<Sysname> system-view
[Sysname] inspect signature auto-update proxy domain www.abc.com port 8888 user admin
password simple admin
```

inspect source-port-identify enable

Use **inspect source-port-identify enable** to enable source port-based application identification.

Use **undo inspect source-port-identify enable** to disable source port-based application identification.

Syntax

inspect source-port-identify enable

undo inspect source-port-identify enable

Default

Source port-based application identification is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

You can use this feature to identify traffic of applications that use fixed source ports when the following conditions are true:

- The types of traffic transmitted over networks are relatively unvaried and use fixed source ports.
- Destination port-based application identification or signature-based traffic content identification is not supported.

The application identification results produced by this feature might not be accurate. Configure this feature according to your live network as a best practice.

Examples

Enable source port-based application identification.

```
<sysname> system-view
[sysname] inspect source-port-identify enable
```

inspect stream-fixed-length

Use **inspect stream-fixed-length** to set the fixed length for stream inspection.

Use **undo inspect stream-fixed-length** to restore the default.

Syntax

inspect stream-fixed-length { **email** | **ftp** | **http** | **nfs** | **smb** } * *length*

undo inspect stream-fixed-length

Default

The fixed length is 32 Kilobytes for FTP, HTTP, NFS, SMB, and email streams.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

email: Specifies email protocols, including SMTP, POP3 and IMAP.

ftp: Specifies the FTP protocol.

http: Specifies the HTTP protocol.

nfs: Specifies the NFS protocol.

smb: Specifies the SMB protocol.

length: Specifies the fixed length in the range of 1 to 2048 Kilobytes.

Usage guidelines

This command can be executed only if the DPI engine inspection mode is user-defined mode.

The larger the inspection length value, the lower the device throughput, and the higher the packet inspection accuracy.

Examples

Set the fixed length to 35 Kilobytes for inspecting each FTP stream and 40 Kilobytes for inspecting each HTTP stream.

```
<Sysname> system-view
[Sysname] inspect stream-fixed-length ftp 35 http 40
```

Related commands

inspect coverage user-defined

inspect cpu-threshold disable

inspect stream-fixed-length disable

inspect stream-fixed-length disable

Use **inspect stream-fixed-length disable** to disable stream fixed length inspection.

Use **undo inspect stream-fixed-length disable** to enable stream fixed length inspection.

Syntax

inspect stream-fixed-length disable

undo inspect stream-fixed-length disable

Default

The stream fixed length inspection feature is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command can be executed only if the DPI engine inspection mode is user-defined mode.

The stream fixed length inspection feature enables the DPI engine to inspect only a fixed length of data for a stream instead of the whole packet data in a stream.

Examples

Disable stream fixed length inspection.

```
<Sysname> system-view
[Sysname] inspect stream-fixed-length disable
```

Related commands

`inspect coverage user-defined`

`inspect cpu-threshold disable`

`inspect stream-fixed-length`

inspect tcp-reassemble enable

Use **`inspect tcp-reassemble enable`** to enable the TCP segment reassembly feature.

Use **`undo inspect tcp-reassemble enable`** to disable the TCP segment reassembly feature.

Syntax

`inspect tcp-reassemble enable`

`undo inspect tcp-reassemble enable`

Default

The TCP segment reassembly feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

DPI engine inspection might fail if TCP segments arrive at the engine out of order. For example, the DPI engine searches for the keywords **this is a secret**. If the TCP segment containing **`a secret`** arrives before the one containing **`this is`**, the inspection fails.

The TCP segment reassembly feature enables the device to cache out-of-order TCP segments of the same TCP flow and reassembles the segments before submitting them to the DPI engine for inspection. This helps improve the DPI engine inspection accuracy.

The segment reassembly fails due to missing segments when the number of cached TCP segments of a flow reaches the limit. In this case, the device submits the cached segments without reassembling them and all subsequent segments of the flow to the DPI engine. This helps reduces degradation of the device performance.

Examples

Enable the TCP segment reassembly feature.

```
<Sysname> system-view
[Sysname] inspect tcp-reassemble enable
```

Related commands

inspect tcp-reassemble max-segment

inspect tcp-reassemble max-segment

Use **inspect tcp-reassemble max-segment** to set the maximum number of TCP segments that can be cached per TCP flow.

Use **undo inspect tcp-reassemble max-segment** to restore the default.

Syntax

inspect tcp-reassemble max-segment *max-number*

undo inspect tcp-reassemble max-segment

Default

A maximum of 10 TCP segments can be cached for reassembly per TCP flow.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number in the range of 10 to 50.

Usage guidelines

Set the limit for the number of TCP segments that can be cached per flow according to your network requirements. The higher the limit, the higher the inspection accuracy, and the lower the device performance.

This command takes effect only when the TCP segment reassembly feature is enabled.

Examples

Allow the device to cache a maximum of 20 TCP segments for each TCP flow.

```
<Sysname> system-view
[Sysname] inspect tcp-reassemble max-segment 20
```

Related commands

inspect tcp-reassemble enable

inspect uncompress maximum

Use **inspect uncompress maximum** to set the maximum number of file decompression operations.

Use **undo inspect uncompress maximum** to restore the default.

Syntax

inspect uncompress maximum *max-number*

undo inspect uncompress maximum

Default

The maximum number of file decompression operations is calculated according to the actual memory size of the device.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of file decompression operations, in the range of 0 to 4294967295. The value 0 indicates that the number of file decompression operations is not limited.

Usage guidelines

The DPI engine consumes memory resources each time it performs a file decompression operation. A large number of file decompression operations might consume a large number of memory resources. Execute this command to limit the memory resources consumed by file decompression operations.

This command is supported only on the default context. For more information about contexts, see *Virtual Technologies Configuration Guide*.

Examples

Set the maximum number of file decompression operations to 120000.

```
<Sysname> system-view
[Sysname] inspect uncompress maximum 120000
```

inspect warning parameter-profile

Use **inspect warning parameter-profile** to create a warning parameter profile and enter its view, or enter the view of an existing warning parameter profile.

Use **undo inspect warning parameter-profile** to delete a warning parameter profile.

Syntax

inspect warning parameter-profile *profile-name*

undo inspect warning parameter-profile *profile-name*

Default

No warning parameter profiles exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

profile-name: Specifies a warning parameter profile name, a case-insensitive string of 1 to 63 characters. Valid characters are letters, digits, underscores (_).

Usage guidelines

After you create a warning parameter profile, you can import a user-defined alarm message from a file.

Examples

Create a warning parameter profile named **w1** and enter its view.

```
<Sysname> system-view
[Sysname] inspect warning parameter-profile w1
[Sysname-inspect-warning-w1]
```

Related commands

`import block warning-file`

`reset block warning-file`

`warning parameter-profile`

log

Use **`log`** to specify the log storage method.

Use **`undo log`** to cancel the specified log storage method.

Syntax

`log` { **`email`** | **`syslog`** }

`undo log` { **`email`** | **`syslog`** }

Default

Logs are exported to the information center.

Views

Logging parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

`email`: Emails the logs to a receiver.

`syslog`: Exports the logs to the information center.

Examples

Configure the device to export logs to the information center in logging parameter profile **log1**.

```
<Sysname> system-view
[Sysname] inspect logging parameter-profile log1
[Sysname-inspect-logging-log1] log syslog
```

Related commands

`inspect logging parameter-profile`

log language

Use **`log language`** to set the language for IPS log output to Chinese.

Use **undo log language** to restore the default.

Syntax

log language chinese

undo log language chinese

Default

IPS logs are output in English.

Views

Logging parameter profile view

Predefined user roles

network-admin

context-admin

Usage guidelines

After you execute this command, only the attack name field of the IPS logs supports displaying in Chinese. For more information about IPS logs, see "IPS commands."

Examples

Set the language for IPS log output to Chinese.

```
<Sysname> system-view
[Sysname] inspect logging parameter-profile log1
[Sysname-inspect-log-para-log1] log language chinese
```

Related commands

inspect logging parameter-profile

password

Use **password** to specify the password for logging in to the email server.

Use **undo password** to restore the default.

Syntax

password { **cipher** | **simple** } *string*

undo password

Default

No password is specified for logging in to the email server.

Views

Email parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

pwd-string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 63 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

If you execute this command multiple times for the same email parameter profile, the most recent configuration takes effect.

Examples

Specify **abc123** as the plaintext password for logging in to the email server.

```
<Sysname> system-view
[Sysname] inspect email parameter-profile c1
[Sysname-inspect-email-c1] password simple abc123
```

Related commands

authentication enable

receiver

Use **receiver** to specify the email receiver address.

Use **undo receiver** to restore the default.

Syntax

receiver *address-string*

undo receiver

Default

No email receiver address is specified.

Views

Email parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

address-string: Specifies the address of the email receiver, a case-sensitive string of 3 to 502 characters.

Usage guidelines

You can specify multiple semicolon-separated email receiver addresses in one command.

Examples

Specify the email receiver addresses **123@abc.com** and **nnn@abc.com**.

```
<Sysname> system-view
[Sysname] inspect email parameter-profile c1
[Sysname-inspect-email-c1] receiver 123@abc.com;nnn@abc.com
```

redirect-url

Use **redirect-url** to specify the URL to which packets are redirected.

Use **undo redirect-url** to restore the default.

Syntax

redirect-url *url-string*

undo redirect-url

Default

No URL is specified for packet redirecting.

Views

Redirect parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

url-string: Specifies the URL, a case-sensitive string of 9 to 63 characters. The URL must start with **http://** or **https://**, for example, **http://www.example.com**.

Usage guidelines

After you specify a URL, matching packets will be redirected to the webpage that the URL identifies.

Examples

Specify **http://www.abc.com/upload** as the URL for packet redirecting.

```
<Sysname> system-view
[Sysname] inspect redirect parameter-profile r1
[Sysname-inspect-redirect-r1] redirect-url http://www.abc.com/upload
```

Related commands

inspect redirect parameter-profile

reset block warning-file

Use **reset block warning-file** to restore the default alarm message.

Syntax

reset block warning-file

Views

Warning parameter profile view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command allows you to clear the user-defined alarm message and restore the default message.

Examples

Restore the default alarm message in the warning parameter profile **w1**.

```
<Sysname> system-view
[Sysname] inspect warning parameter-profile w1
[Sysname-inspect-warning-w1] reset block warning-file
```

Related commands

import warning-file

secure-authentication enable

Use **secure-authentication enable** to enable the secure password transmission feature.

Use **undo secure-authentication enable** to disable the secure password transmission feature.

Syntax

secure-authentication enable

undo secure-authentication enable

Default

The secure password transmission feature is disabled.

Views

Email parameter profile view

Predefined user roles

network-admin

context-admin

Usage guidelines

After the secure password transmission feature is enabled, a security channel is established between the device and the email server to transmit the password for email server login.

Examples

Enable the secure password transmission feature.

```
<Sysname> system-view
[Sysname] inspect email parameter-profile c1
[Sysname-inspect-email-c1] secure-authentication enable
```

Related commands

authentication enable

sender

Use **sender** to specify the email sender address.

Use **undo sender** to restore the default.

Syntax

sender *address-string*

undo sender

Default

No email sender address is specified.

Views

Email parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

address-string: Specifies the address of the email sender, a case-sensitive string of 3 to 63 characters.

Usage guidelines

The email sender address is the source address that the device uses to send emails to destinations.

Examples

Specify the email sender address **abc@123.com**.

```
<Sysname> system-view
[Sysname] inspect email parameter-profile c1
[Sysname-inspect-email-c1] sender abc@123.com
```

username

Use **username** to specify the username for logging in to the email server.

Use **undo username** to restore the default.

Syntax

username *name-string*

undo username

Default

No username is specified for logging in to the email server.

Views

Email parameter profile view

Predefined user roles

network-admin

context-admin

Parameters

name-string: Specifies the username, a case-sensitive string of 1 to 63 characters.

Usage guidelines

If you execute this command multiple times for the same email parameter profile, the most recent configuration takes effect.

Examples

Specify **han** as the username for logging in to the email server.

```
<Sysname> system-view
[Sysname] inspect email parameter-profile c1
[Sysname-inspect-email-c1] username han
```

Related commands

authentication enable

Contents

IPS commands

action (IPS policy view)

Use **action** to configure the action criterion for IPS signature filtering in an IPS policy.

Use **undo action** to restore the default.

Syntax

action { **block-source** | **drop** | **permit** | **reset** } *

undo action

Default

The action attribute is not used for IPS signature filtering.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Parameters

block-source: Specifies the block source action.

drop: Specifies the drop action.

permit: Specifies the permit action.

reset: Specifies the reset action.

Usage guidelines

This command filters the IPS signatures that an IPS policy uses based on the actions associated with the signatures.

You can specify multiple actions in an action criterion. The IPS policy uses an IPS signature if the signature is associated with any of the specified actions.

If you execute this command in an IPS policy multiple times, the most recent configuration takes effect.

Examples

Configure IPS policy **test** to use IPS signatures associated with the drop or reset action.

```
<Sysname> system-view
[Sysname] ips policy test
[Sysname-ips-policy-test] action drop reset
```

action (IPS signature view)

Use **action** to configure the actions for a user-defined IPS signature.

Use **undo action** to restore the default.

Syntax

action { **block-source** | **drop** | **permit** | **reset** } [**capture** | **logging**] *

undo action

Default

The action for the user-defined IPS signature is **permit**.

Views

User-defined IPS signature view

Predefined user roles

network-admin

context-admin

Parameters

block-source: Specifies the block source action.

drop: Specifies the drop action.

permit: Specifies the permit action.

reset: Specifies the reset action.

logging: Specifies the logging action.

capture: Specifies the capture action.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the drop action for user-defined IPS signature **mysignature**.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] action drop
```

attack-category

Use **attack-category** to specify an attack category criterion to filter IPS signatures in an IPS policy.

Use **undo attack-category** to delete an attack category criterion.

Syntax

attack-category { *category* [*subcategory*] | **all** }

undo attack-category { *category* [*subcategory* | **all**] }

Default

The attack category attribute is not used for IPS signature filtering.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Parameters

category-name: Specifies an attack category.

subcategory: Specifies a subcategory of the attack category. If you do not specify a subcategory, this command matches any IPS signature with a subcategory of the specified attack category.

all: Specifies all attack categories.

Usage guidelines

This command filters the IPS signatures that an IPS policy uses based on the attack category attribute of the signatures.

You can execute this command multiple times to specify multiple attack category criteria in an IPS policy. The IPS policy uses an IPS signature if the signature matches any of the configured attack category criteria.

Examples

Configure IPS policy **test** to use IPS signatures with the **SQLInjection** attack subcategory of the **Vulnerability** attack category.

```
<Sysname> system-view
[Sysname] ips policy test
[Sysname-ips-policy-test] attack-category Vulnerability SQLInjection
```

description (IPS whitelist entry view)

Use **description** to configure the description for an IPS whitelist entry.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

An IPS whitelist entry does not have any description.

Views

IPS whitelist entry view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a description, a case-insensitive string of 1 to 255 characters. The description can contain spaces.

Usage guidelines

A description allows easy identification of an IPS whitelist entry.

Examples

Specify the description as **News information** for IPS whitelist entry 1.

```
<Sysname> system-view
[Sysname] ips whitelist 1
[Sysname-ips-whitelist-1] description News information
```

description (user-defined IPS signature view)

Use **description** to configure the description for a user-defined IPS signature.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

A user-defined IPS signature does not have any description.

Views

User-defined IPS signature view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a description, a case-insensitive string of 1 to 127 characters.

Usage guidelines

A description allows easy identification of a user-defined IPS signature.

Examples

Specify the description as **mydescription** for user-defined IPS signature **mysignature**.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] description mydescription
```

destination-address

Use **destination-address** to specify a destination IP address filtering criterion in a user-defined signature rule.

Use **undo destination-address** to remove a destination IP address filtering criterion from a user-defined signature rule.

Syntax

destination-address ip *ip-address*

undo destination-address

Default

No destination IP address is specified as the filtering criterion in a user-defined signature rule.

Views

User-defined IPS signature rule view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies an IPv4 address. It is used to match the packet destination IPv4 address.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

In rule 1 of user-defined IPS signature **mysignature**, specify the keyword type as the match pattern type and specify destination IP address 10.1.1.1 as a filtering criterion.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] rule 1 l4-protocol tcp l5-protocol http pattern-type keyword
[Sysname-ips-signature-mysignature-rule-1] destination-address ip 10.1.1.1
```

destination-port

Use **destination-port** to specify a destination port filtering criterion in a user-defined signature rule.

Use **undo destination-port** to restore the default.

Syntax

destination-port *start-port* [**to** *end-port*]

undo destination-port

Default

No destination ports are specified as the filtering criteria in a user-defined signature rule.

Views

User-defined IPS signature rule view

Predefined user roles

network-admin

context-admin

Parameters

start-port: Specifies the start port number of a destination port range, in the range of 1 to 65535.

to *end-port*: Specifies the end port number of a destination port range, in the range of 1 to 65535. If you do not specify this option, only the start port number is specified.

Usage guidelines

The port numbers are used to match the destination port numbers of the specified transport layer protocol.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

In rule 1 of user-defined IPS signature **mysignature**, specify the keyword type as the match pattern type and specify the destination port range as 1 to 3550.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] rule 1 l4-protocol tcp l5-protocol http pattern-type keyword
```

```
[Sysname-ips-signature-mysignature-rule-1] destination-port 1 to 3550
```

detection-integer

Use **detection-integer** to configure an integer detection item in a user-defined signature rule.

Use **undo detection-integer** to remove an integer detection item from a user-defined signature rule.

Syntax

detection-integer field *field-name* **match-type** { **eq** | **gt** | **gt-eq** | **lt** | **lt-eq** | **nequ** } *number*

undo detection-integer

Default

No integer detection items are configured in a user-defined signature rule.

Views

User-defined IPS signature rule view

Predefined user roles

network-admin

context-admin

Parameters

field-name: Specifies a protocol field by its name, a case-insensitive string. To view the names of supported protocol fields, enter a question mark (?) after the **field** keyword.

match-type { **eq** | **gt** | **gt-eq** | **lt** | **lt-eq** | **nequ** } *number*: Specifies a match operator in the detection item:

- **eq**: Matches numbers that are equal to the specified number.
- **gt**: Matches numbers that are greater than the specified number.
- **gt-eq**: Matches numbers that are greater than or equal to the specified number.
- **lt**: Matches numbers that are less than the specified number.
- **lt-eq**: Matches numbers that are less than or equal to the specified number.
- **nequ**: Matches numbers that are not equal to the specified number.

number: Specifies a number in the range of 1 to 4294967295.

Usage guidelines

A user-defined IPS signature rule can contain multiple detection items. A packet matches a rule only when the packet matches all detection items in the rule. The match order of the detection items is their configuration order. To avoid detection errors, configure the detection items based on the sequence of the protocol fields in the protocol.

Examples

In user-defined IPS signature **mysignature**, create rule 1 for UDP and SIP protocols and specify the integer match pattern type. Create a detection item in the rule to match packets whose **SIP.Content-Length** field value is 50.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] rule 1 l4-protocol UDP l5-protocol SIP pattern-type
integer
```

```
[Sysname-ips-signature-mysignature-rule-1] detection-integer field SIP.Content-Length
match-type eq 50
```

detection-keyword

Use **detection-keyword** to configure a keyword detection item in a user-defined signature rule.

Use **undo detection-keyword** to remove a keyword detection item from a user-defined signature rule.

Syntax

detection-keyword *detection-id* **field** *field-name* **match-type** { **exclude** | **include** } { **hex** *hex-string* | **regex** *regex-pattern* | **text** *text-string* } [**offset** *offset-value* [**depth** *depth-value*] | **relative-offset** *relative-offset-value* [**relative-depth** *relative-depth-value*]]

undo detection-keyword *detection-id*

Default

No keyword detection items are configured in a user-defined signature rule.

Views

User-defined IPS signature rule view

Predefined user roles

network-admin

context-admin

Parameters

detection-id: Specifies a detection item ID, in the range of 1 to 10.

field *field-name*: Specifies a protocol field by its name, in a case-insensitive string. To view the names of supported protocol fields, enter a question mark (?) after the **field** keyword.

match-type { **exclude** | **include** }: Specifies a match operator in the detection item:

- **include**: Matches contents that include the specified string.
- **exclude**: Matches contents that do not include the specified string.

hex *hex-string*: Specifies a case-sensitive hexadecimal string of 8 to 254 characters. Valid characters contain integers, and letters of A to F and a to f. An even number of characters are required, and enclose the characters with two vertical bars (|), for example |1234f5b6|.

regex *regex-pattern*: Specifies a case-sensitive regular expression string of 3 to 255 characters. The string can only start with letters, digits, and underscores (_), and must contain 3 consecutive non-wildcard characters.

text *text-string*: Specifies a case-insensitive text string of 3 to 255 characters.

offset *offset-value*: Specifies an offset in bytes after which the match operation starts, in the range of 1 to 65535. The offset starts from the beginning of the protocol field. If you do not specify the *offset-value* argument, the match operation starts from the beginning of the protocol field.

depth *depth-value*: Specifies the number of bytes to match, in the range of 3 to 65535. If you do not specify *depth-value* argument, the detection item detects the whole protocol field.

relative-offset *relative-offset-value*: Specifies an offset in bytes after which the match operation starts, in the range of –32767 to –1 and 1 to 32767. The offset starts from the end of the previous detection item. If the offset value is positive, it offsets backward. If the offset value is negative, it offsets forward.

relative-depth *relative-depth-value*: Specifies the number of bytes to be matched, in the range of 3 to 65535.

Usage guidelines

This command is available only after the detection trigger condition is configured.

A user-defined IPS signature rule can contain multiple detection items. A packet matches a rule only when the packet matches all detection items in the rule. The match order of detection items is their configuration order.

The detection item only inspects the specified protocol field range. To define the start and end positions for the match operation, use either the offset and depth, or the relative offset and relative depth.

To avoid detection errors, configure detection items based on the sequence of protocol fields in the HTTP protocol.

Examples

In user-defined IPS signature **mysignature**, create rule 1 for TCP and HTTP protocols and specify the keyword match pattern type. Create a detection item in the rule to match packets whose **http.host** field inlcudes **abc**. Specify the offset and depth as 10 bytes and 50 bytes, respectively.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] rule 1 l4-protocol tcp l5-protocol http pattern-type keyword
[Sysname-ips-signature-mysignature-rule-1] detection-keyword 1 field http.host match-type include text abc offset 10 depth 50
```

Related commands

trigger

direction

Use **direction** to specify the direction attribute in a user-defined signature.

Use **undo direction** to restore the default.

Syntax

direction { **any** | **to-client** | **to-server** }

undo direction

Default

The direction attribute of a user-defined IPS signature is **any**.

Views

User-defined IPS signature view

Predefined user roles

network-admin

context-admin

Parameters

any: Specifies both directions.

to-server: Specifies the client-to-server direction.

to-client: Specifies the server-to-client direction.

Usage guidelines

You cannot execute this command multiple times to change the direction attribute. To change the direction attribute, first execute **undo direction**. Use the **undo** command with caution because the **undo** command also deletes all rules in the signature.

Examples

In user-defined IPS signature **mysignature**, specify the server-to-client direction.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] direction to-client
```

Table 1 Command output

Field	Description
Total signatures	Total number of IPS signatures.
Pre-defined signatures	Total number of predefined IPS signatures.
User-config signatures	Total number of user-configured signatures.
Snort signatures	Total number of Snort signatures.
Type	Type of the IPS signature: • **Pre**—Predefined IPS signatures. • **User**—User-defined signatures that are manually configured. • **Snort**—Snort signatures that are imported from a Snort file.
RuleID	Signature ID.
Target	Attacked target.
SubTarget	Attacked subtarget.
Severity	Attack severity level of the signature, **Low**, **Medium**, **High**, or **Critical**.
Direction	Traffic direction to which the IPS signature applies: • **Any**—Both server to client and client to server directions. • **Client**—Server to client direction. • **Server**— Client to server direction.
Category	Attack category of the signature.
Subcategory	Attack subcategory of the signature.

Field	Description
Status	Status of the IPS signature, **Enabled** or **Disabled**.
Action	Actions for matching packets: • **Block-source**—Drops matching packets and adds the sources of the packets to the IP blacklist. • **Drop**—Drops matching packets. • **Permit**—Permits matching packets to pass. • **Reset**—Closes the TCP or UDP connections for matching packets by sending TCP reset messages or ICMP port unreachable messages. • **Redirect**—Redirects matching packets to a webpage. • **Capture**—Captures matching packets. • **Logging**—Logs matching packets.

Related commands

ips policy

display ips signature

Use **display ips signature** to display brief IPS signature information.

Syntax

display ips signature [**pre-defined** | **user-defined** { **snort** | **user-config** }] [**direction** { **any** | **to-client** | **to-server** }] [**category** *category-name* | **fidelity** { **high** | **low** | **medium** } | **protocol** { **icmp** | **ip** | **tcp** | **udp** } | **severity** { **critical** | **high** | **low** | **medium** }] *

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

pre-defined: Specifies predefined IPS signatures.

user-defined: Specifies user-defined IPS signatures.

snort: Specifies Snort signatures that are imported from a Snort file. These imported signatures are also user-defined signatures.

user-config: Specifies user-defined signatures that are manually configured.

direction { **any** | **to-client** | **to-server** }: Specifies a direction attribute. If you do not specify a direction attribute, this command displays IPS signatures with any direction attribute.

- **to-server**: Specifies the client to server direction of a session.
- **to-client**: Specifies the server to client direction of a session.
- **any**: Specifies both directions of a session.

category *category-name*: Specifies an attack category. To view the names of supported attack categories, enter a question mark (?) after the **category** keyword. If you do not specify an attack category, this command displays IPS signatures for all attack categories.

fidelity { **high** | **low** | **medium** }: Specifies a fidelity level. If you do not specify a fidelity level, this command displays IPS signatures of all fidelity levels. The fidelity level indicates the attack detection accuracy.

- **low**: Specifies the low fidelity.
- **medium**: Specifies the medium fidelity.
- **high**: Specifies the high fidelity.

protocol { **icmp** | **ip** | **tcp** | **udp** }: Specifies a protocol. If you do not specify a protocol, this command displays IPS signatures for all protocols.

severity { **critical** | **high** | **low** | **medium** }: Specifies an attack severity level. If you do not specify a severity level, this command displays IPS signatures for all severity levels of attacks.

- **low**: Specifies the low severity level.
- **medium**: Specifies the medium severity level.
- **high**: Specifies the high severity level.
- **critical**: Specifies the critical severity level.

Usage guidelines

If you do not specify any options, this command displays all IPS signatures.

Examples

Display predefined IPS signatures of the medium fidelity level for TCP.

```
<Sysname> display ips signature pre-defined protocol tcp fidelity medium
Pre-defined  signatures:465       failed:0

Flag:
  Pre: predefined   User: user-config   Snort: Snort

Type Sig-ID    Direction Severity Fidelity Category      Protocol   Sig-Name
Pre  1         To-server High     Medium   Vulnerability TCP        -
Pre  2         To-server High     Medium   Vulnerability TCP        -
Pre  3         To-client High     Medium   Vulnerability TCP        -
Pre  4         To-client High     Medium   Vulnerability TCP        -
Pre  5         To-client High     Medium   Vulnerability TCP        -
Pre  6         To-client High     Medium   Vulnerability TCP        -
Pre  7         To-client High     Medium   Vulnerability TCP        -
Pre  8         To-client High     Medium   Vulnerability TCP        -

Table 2 Command output

Field	Description
Total signatures	Total number of IPS signatures.
failed	Total number of IPS signatures that failed to be imported and loaded during signature update.
Pre-defined signatures total	Total number of predefined IPS signatures.
User-config signatures total	Total number of user-configured signatures.
Snort signatures total	Total number of Snort signatures.
Type	Type of the IPS signature: • **Pre**—Predefined IPS signatures. • **User**—User-defined signatures that are manually configured. • **Snort**—Snort signatures that are imported from a Snort file.
Sig-ID	Signature ID.
Direction	Direction attribute of the signature: • **Any**—Specifies both directions of a session. • **To-server**—Specifies the client to server direction of a session. • **To-client**—Specifies the server to client direction of a session.
Severity	Attack severity level of the signature, **Low**, **Medium**, **High**, or **Critical**.
Fidelity	Fidelity level of the signature, **Low**, **Medium**, or **High**.
Category	Attack category of the signature.
Protocol	Protocol attribute of the signature.
Sig-Name	Name of the IPS signature.

display ips signature pre-defined

Use **display ips signature pre-defined** to display detailed information about a predefined IPS signature.

Syntax

display ips signature pre-defined *signature-id*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

signature-id: Specifies the signature ID. The value range is 1 to 536870911.

Examples

Display detailed information about predefined IPS signature 1.

```
<Sysname> display ips signature pre-defined 1
 Type         : Pre-defined
 Signature ID: 1
 Status       : Enabled
 Action       : Reset & Logging
 Name         : GNU_Bash_CVE-2014-6271_Remote_Code_Execution_Vulnerability
 Protocol     : TCP
 Severity     : High
 Fidelity     : Medium
 Direction    : To-server
 Category     : Vulnerability
 Reference    : CVE-2014-6271;
 Description : GNU Bash through 4.3 processes trailing strings after function definitions
in the values of environment variables, which allows remote attackers to execute arbitrary
code via a crafted environment, as demonstrated by vectors involving the ForceCommand
feature in OpenSSH sshd, the mod_cgi and mod_cgid modules in the Apache HTTP Server, scripts
executed by unspecified DHCP clients, and other situations in which setting the environment
occurs across a privilege boundary from Bash execution, aka \"ShellShock.\" NOTE: the
original fix for this issue was incorrect; CVE-2014-7169 has been assigned to cover the
vulnerability that is still present after the incorrect fix.
```

Table 3 Command output

Field	Description
Type	Type of the IPS signature: • **Pre**—Predefined IPS signatures. • **User**—User-defined signatures.
Signature ID	Signature ID.
Status	Status of the IPS signature, **Enabled** or **Disabled**.

Field	Description
Action	Actions for matching packets: • **Block-source**—Drops matching packets and adds the sources of the packets to the IP blacklist. • **Drop**—Drops matching packets. • **Permit**—Permits matching packets to pass. • **Reset**—Closes the TCP or UDP connections for matching packets by sending TCP reset messages or ICMP port unreachable messages. • **Capture**—Captures matching packets. • **Logging**—Logs matching packets.
Name	Name of the IPS signature.
Protocol	Protocol attribute of the signature.
Severity	Attack severity, **Low**, **Medium**, **High**, or **Critical**.
Fidelity	Fidelity level of the signature, **Low**, **Medium**, or **High**.
Direction	Direction attribute of the signature: • **Any**—Specifies both directions of a session. • **To-server**—Specifies the client to server direction of a session. • **To-client**—Specifies the server to client direction of a session.
Category	Attack category of the signature.
Reference	Reference for the signature.
Description	Description for the signature.

display ips signature library

Use **`display ips signature library`** to display IPS signature library information.

Syntax

`display ips signature library`

Views

Any view

Predefined user roles

network-operator

context-admin

context-operator

Examples

Display IPS signature library information.

```
<Sysname> display ips signature library
IPS signature library information:
Type     SigVersion         ReleaseTime               Size
Current  1.02               Fri Sep 13 09:05:35 2014  71594
Last     -                  -                         -
Factory  1.00               Fri Sep 11 09:05:35 2014  71394
```

Table 4 Command output

Field	Description
Type	Version type of the IPS signature library: • **Current**—Current version. • **Last**—Previous version. • **Factory**—Factory default version.
SigVersion	Version number of the IPS signature library.
ReleaseTime	Release time of the IPS signature library.
Size	Size of the IPS signature file in bytes.

display ips signature user-defined

Use **display ips signature user-defined** to display detailed information about a user-defined IPS signature.

Syntax

display ips signature user-defined { **snort** | **user-config** } *signature-id*

Views

Any view

Predefined user roles

network-admin

context-admin

Parameters

snort: Specifies the Snort signatures.

user-config: Specifies the user-configured signatures.

signature-id: Specifies the signature ID. The value range for Snort signatures is 536870913 to 1073741823. The value range for user-configured signatures is 1073741840 to 1342177264.

Examples

Display detailed information about Snort signature 536870914.

```
<Sysname> display ips signature user-defined snort 536870914
 Type        : Snort
 Signature ID: 536870914
 Status      : Enabled
 Action      : drop
 Name        : Snort name
 Protocol    : TCP
 Severity    : High
 Fidelity    : Medium
 Direction   : To-server
 Category    : Vulnerability
 Reference   : CVE-2014-6271;
 Description : Some description.
```

Table 5 Command output

Field	Description
Type	Type of the user-defined IPS signature. **Snort** indicates that the signature is imported from a Snort file.
Signature ID	Signature ID.
Status	Status of the IPS signature, **Enabled** or **Disabled**.
Action	Actions for matching packets: • **Block-source**—Drops matching packets and adds the sources of the packets to the IP blacklist. • **Drop**—Drops matching packets. • **Permit**—Permits matching packets to pass. • **Reset**—Closes the TCP or UDP connections for matching packets by sending TCP reset messages or ICMP port unreachable messages. • **Capture**—Captures matching packets. • **Logging**—Logs matching packets.
Name	Name of the IPS signature.
Protocol	Protocol attribute of the signature.
Severity	Attack severity, **Low**, **Medium**, **High**, or **Critical**.
Fidelity	Fidelity level of the signature, **Low**, **Medium**, or **High**.
Direction	Direction attribute of the signature: • **Any**—Specifies both directions of a session. • **To-server**—Specifies the client to server direction of a session. • **To-client**—Specifies the server to client direction of a session.
Category	Attack category of the signature.
Reference	Reference for the signature.
Description	Description for the signature.

Display detailed information about user-configured IPS signature 1073741840.

```
<Sysname> display ips signature user-defined user-config 1073741840
 Type: User-config
 Signature ID: 1073741840
 Signature name: lkx
 Status:       Enable
 Action:       Permit

    Entry ID   Field                          Match-type Content-type Content

    1          HTTP.Accept                    exclude    text         ljljl

---- More --
```

Table 6 Command output

Field	Description
Type	Type of the user-defined IPS signature. **User-config** indicates that the signature is configured manually.
Signature ID	Signature ID.
Signature name	Name of the IPS signature.
Status	Status of the IPS signature, **Enabled** or **Disabled**.
Action	Actions for matching packets: • **Block-source**—Drops matching packets and adds the sources of the packets to the IP blacklist. • **Drop**—Drops matching packets. • **Permit**—Permits matching packets to pass. • **Reset**—Closes the TCP or UDP connections for matching packets by sending TCP reset messages or ICMP port unreachable messages. • **Capture**—Captures matching packets. • **Logging**—Logs matching packets.
Severity	Attack severity, **Low**, **Medium**, **High**, or **Critical**.
Fidelity	Fidelity level of the signature, **Low**, **Medium**, or **High**.
Direction	Direction attribute of the signature: • **Any**—Specifies both directions. • **To-server**—Specifies the client-to-server direction. • **To-client**—Specifies the server-to-client direction.
Rulelogic	Logical operator between rules in the IPS signature.
Description	Description for the signature.
Total rule	Total number of rules.
Rule ID	Rule ID.
L4-protocol	Transport layer protocol as a filtering criterion in the rule.
L5-protocol	Application layer protocol as a filtering criterion in the rule.
Match type	Signature match pattern type, **Keyword** or **Integer**.
Source address	Source address as a filtering criterion.
Source port	Source port as a filtering criterion.
Destination address	Destination address as a filtering criterion.
Destination port	Destination port as a filtering criterion.

Field	Description
Trigger entry	Detection trigger condition in the rule.
Field	Protocol field to inspect in the detection trigger condition.
Value	Contents to inspect in the detection trigger condition.
Offset	Offset after which the inspection starts.
Depth	Number of bytes to be inspected.
Detection entry list	Detection item list.
Entry ID	Detection item ID.
Field	Protocol field to inspect in the detection item.
Match type	Match operation in the detection item.
Content-type	Type of the match pattern: • **hex**—Specifies a hexadecimal string. • **regex**—Specifies a regular expression string. • **text**—Specifies a text string.
Content	Contents to inspect in the detection item.

display ips signature user-defined parse-failed

Use **display ips signature user-defined parse-failed** to display information about the user-defined IPS signatures that failed to be parsed during signature import.

Syntax

display ips signature user-defined parse-failed

Views

Any view

Predefined user roles

network-admin

context-admin

Examples

Display information about the user-defined IPS signatures that failed to be imported

```
<Sysname> display ips signature user-defined parse-failed
LineNo  SID         Information
1       None        Error: Invalid actions.
                    Tip: Only actions {alert|drop|pass|reject|sdrop|log} are supported
2       1010082     Error: Invalid signature ID.
                    Tip: The signature ID must be in the range of 1 to 536870912
3       1010083     Error: Invalid protocol.
                    Tip: Only protocols {tcp|udp|icmp|ip} are supported
4       1010084     Error: Invalid direction.
                    Tip: Only directions {'<>'|'->'} are supported
```

Table 7 Command output

Field	Description
LineNo	Line number where the signature is located in the Snort file.
SID	Signature ID.
Information	Signature information: • **Error**—Reason for the parse failure. • **Tip**—Tip for editing the signature rule in the file.

Related commands

`ips signature import snort`

email parameter-profile

Use **`email parameter-profile`** to specify a parameter profile for the email action.

Use **`undo email parameter-profile`** to remove the parameter profile from the email action.

Syntax

`email parameter-profile` *`parameter-profile-name`*

`undo email parameter-profile`

Default

No parameter profile is specified for the email action.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Parameters

`parameter-profile-name`: Specifies a parameter profile by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

This command takes effect only after the global parameter profile is disabled by the **`undo global-parameter enable`** command.

This command is required after you use the **`log email`** command to specify the log output method as email. For information about configuring an email parameter profile, see "DPI engine commands."

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the parameter profile **email1** for the **email** action in IPS policy **policy1**.

```
<Sysname> system-view
[Sysname] ips policy policy1
[Sysname-ips-policy-policy1] email parameter-profile email1
```

Related commands

`log`

global-parameter enable

email severity-level

Use **email severity-level** to specify the lowest severity level of the matching IPS signatures for log output via email.

Use **undo email severity-level** to restore the default.

Syntax

email severity-level { **critical** | **high** | **low** | **medium** }

undo email severity-level

Default

The lowest severity level of the matching IPS signatures for log output via email is **low**.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Parameters

critical: Specifies the critical severity level.

high: Specifies the high severity level.

low: Specifies the low severity level.

medium: Specifies the medium severity level.

Usage guidelines

This command filters logs by the severity level of an IPS signature for log output via email. The system sends emails for IPS logs only when the severity levels of the matching IPS signatures are not lower than specified severity level.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the lowest severity level of the matching IPS signatures for log output via email as **high** in IPS policy **test**.

```
<Sysname> system-view
[Sysname] ips policy test
[Sysname-ips-policy-test] email severity-level high
```

global-parameter enable

Use **global-parameter enable** to enable the global parameter profiles.

Use **undo global-parameter enable** to disable the global parameter profiles.

Syntax

global-parameter enable

undo global-parameter enable

Default

The global parameter profiles are enabled.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

The **block source**, **capture**, and **logging** actions take effect only after a parameter profile is specified. You can specify a parameter profile for an IPS action as follows:

- Specify a global parameter profile in system view. The setting takes effect in all IPS policies.
- Specify a parameter profile in IPS policy view, which is a policy-specific setting. Only the email action supports a parameter profile in IPS policy view.

The global parameter profile for an IPS action takes precedence over a policy-specific parameter profile for the action.

To have a parameter profile for an IPS action in an IPS policy take effect, make sure the global parameter profile is disabled.

As a best practice, enable the global parameter profile after the global parameter profile configuration is completed.

Examples

Enable the global parameter profiles in IPS policy **policy1**.

```
<Sysname> system-view
[Sysname] ips policy policy1
[Sysname-ips-policy-policy1] global-parameter enable
```

Related commands

email parameter-profile

ips parameter-profile

log

http-method

Use **http-method** to specify a request method filtering criterion in a user-defined signature rule.

Use **undo http-method** delete a request method filtering criterion from a user-defined signature rule.

Syntax

http-method *method-name*

undo http-method

Default

No request method filtering criterion is specified in a user-defined signature rule.

Views

User-defined IPS signature rule view

Predefined user roles

network-admin

context-admin

Parameters

method-name: Specifies the name of an HTTP request method, a case-insensitive string, such as GET and POST. To view the supported request methods, enter a question mark (?) after the **http-method** keyword.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

In rule 1 of user-defined IPS signature **mysignature**, specify the keyword type as the match pattern type and specify the GET request method as a filtering criterion.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] rule 1 l4-protocol tcp l5-protocol http pattern-type keyword
[Sysname-ips-signature-mysignature-rule-1] http-method get
```

ips apply policy

Use **ips apply policy** to apply an IPS policy to a DPI application profile.

Use **undo ips apply policy** to remove the application.

Syntax

ips apply policy *policy-name* **mode** { **alert** | **protect** }

undo ips apply policy

Default

No IPS policy is applied to a DPI application profile.

Views

DPI application profile view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies an IPS policy by its name, a case-insensitive string of 1 to 63 characters.

mode: Specifies an IPS policy mode.

alert: Only captures or logs matching packets.

protect: Takes all actions specified for signatures to process matching packets

Usage guidelines

An IPS policy takes effect only after it is applied to a DPI application profile.

You can apply only one IPS policy to a DPI application profile. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Apply IPS policy **ips1** to DPI application profile **sec**. Set the IPS policy mode to **protect**.

```
<Sysname> system-view
[Sysname] app-profile sec
[Sysname-app-profile-sec] ips apply policy ips1 mode protect
```

Related commands

app-profile

ips policy

ips capture-cache

Use **ips capture-cache** to specify the number of the captured packets to be cached for threat analysis.

Use **undo ips capture-cache** to restore the default.

Syntax

ips capture-cache *number*

undo ips capture-cache

Default

The number of the captured packets to be cached is not specified, and the device does not cache any captured packets.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the number of the captured packets to be cached, in the range of 1 to 10. If the value is set to 1, the device caches only the hit packet.

Usage guidelines

This command enables the device to cache the IPS captured packets.

The device caches the specified number of packets captured before and after the hit packet matching the IPS policy, including the hit packet. When the specified number of packets are cached, the device writes all cached packets into the capture file. The number of the cached packets will be less than the specified number in one of the following situations:

- The action, such as block or redirect on the hit packet causes the packets after the hit packet to be dropped.
- The device has no capacity to cache the specified number of packets.

Examples

Allow the device to cache a maximum of five IPS captured packets.

```
<Sysname> system-view
[Sysname] ips capture-cache 5
```

Related commands

inspect capture parameter-profile

signature override

signature override

ips parameter-profile

Use **ips parameter-profile** to specify a parameter profile for an IPS action.

Use **undo ips parameter-profile** to remove the parameter profile from an IPS action.

Syntax

ips { **block-source** | **capture** | **email** | **logging** | **redirect** } **parameter-profile** *parameter-name*

undo ips { **block-source** | **capture** | **email** | **logging** | **redirect** } **parameter-profile**

Default

No parameter profile is specified for an IPS action.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

block-source: Specifies a parameter profile for the **block-source** action.

capture: Specifies a parameter profile for the **capture** action.

email: Specifies a parameter profile for the **email** action.

logging: Specifies a parameter profile for the **logging** action.

redirect: Specifies a parameter profile for the **redirect** action.

parameter-profile *parameter-name*: Specifies a parameter profile by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

Use this command to specify the parameter profile used by an IPS action. A parameter profile is a set of parameters that determine how the action is executed. If you do not specify a parameter profile for an action, or if the specified profile does not exist, the default action parameter settings are used.

For information about configuring parameter profiles, see *DPI Configuration Guide*.

Examples

Create parameter profile **ips1**. Set the source IP address blocking period to 1111 seconds.

```
<Sysname> system-view
[Sysname] inspect block-source parameter-profile ips1
[Sysname-inspect-block-source-ips1] block-period 1111
[Sysname-inspect-block-source-ips1] quit
```

Specify the parameter profile **ips1** for the **block-source** action.

```
[Sysname] ips block-source parameter-profile ips1
```

Related commands

inspect block-source parameter-profile

inspect capture parameter-profile

inspect logging parameter-profile

inspect email parameter-profile

inspect redirect parameter-profile

ips policy

Use **ips policy** to create an IPS policy and enter its view, or enter the view of an existing IPS policy.

Use **undo ips policy** to delete an IPS policy.

Syntax

ips policy *policy-name*

undo ips policy *policy-name*

Default

An IPS policy named **default** exists.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies the IPS policy name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

An IPS policy includes all signatures on the device, whether or not the signatures are added to the device before the policy is created.

You cannot modify the signatures in the default IPS policy. In a user-defined policy, you can enable or disable a signature, or edit the actions for a signature.

Examples

Create IPS policy **ips1** and enter its view.

```
<Sysname> system-view
[Sysname] ips policy ips1
[Sysname-ips-policy-ips1]
```

ips signature auto-update

Use **ips signature auto-update** to enable automatic IPS signature library update and enter automatic IPS signature library update configuration view.

Use **undo ips signature auto-update** to disable automatic IPS signature library update.

Syntax

ips signature auto-update

undo ips signature auto-update

Default

Automatic IPS signature library update is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

After you enable automatic IPS signature library update, the device periodically accesses the NSFOCUS website to download the latest IPS signatures.

Examples

Enable automatic IPS signature library update and enter automatic IPS signature library update configuration view.

```
<Sysname> system-view
[Sysname] ips signature auto-update
[Sysname-ips-autoupdate]
```

Related commands

update schedule

ips signature auto-update-now

Use **ips signature auto-update-now** to trigger an automatic signature library update manually.

Syntax

ips signature auto-update-now

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

After you execute this command, the device immediately starts the automatic signature library update process no matter whether or not automatic signature library update is enabled. The device automatically backs up the current signature library before overwriting it.

You can execute this command anytime you find a new version of signature library on the NSFOCUS website.

Examples

Trigger an automatic signature library update manually.

```
<Sysname> system-view
[Sysname] ips signature auto-update-now
```

ips signature import snort

Use **ips signature import snort** to import Snort signatures.

Syntax

ips signature import snort *file-path*

Default

No Snort signatures exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

file-path: Specifies the path of the file where the Snort signatures to be imported are stored. The value for this argument is a string of 1 to 255 characters.

Usage guidelines

To add your own IPS signatures, create an IPS signature file in the Snort format and use this command to import the signatures.

Make sure the IPS signature file contains all user-defined signatures that you want to use. All existing user-defined signatures on the device will be overwritten by the imported signatures.

To view the imported IPS signatures, use the **display ips signature user-defined** command.

The following methods are available for Snort signature import:

- **Local method**—Imports Snort signatures from a local IPS signature file.

  The following describes the format of the *file-path* parameter for different import scenarios.

Import scenario	Format of *file-path*	Remarks
The import file is stored in the current working directory.	*filename*	To display the current working directory, use the **pwd** command. For information about the **pwd** command, see file system management in *Fundamentals Command Reference*.
The import file is stored in a different directory on the same storage medium.	*filename*	Before configuring the **ips signature import snort** command, use the **cd** command to open the directory where the file is stored. For information about the **cd** command, see file system management in *Fundamentals Command Reference.*
The import file is stored on a different storage medium.	*path/filename*	Before configuring the **ips signature import snort** command, use the **cd** command to open the root directory of the storage medium where the file is stored. For information about the **cd**

Import scenario	Format of *file-path*	Remarks
		command, see file system management in *Fundamentals Command Reference.*

- **FTP/TFTP method**—Imports Snort signatures from an IPS signature file stored on an FTP or TFTP server.

  The following describes the format of the *file-path* parameter for different import scenarios.

Import scenario	Format of *file-path*	Remarks
The import file is stored on an FTP server.	*ftp://username:password@server address/filename*	The *username* parameter represents the FTP login username. The *password* parameter represents the FTP login password. The *server address* parameter represents the IP address or host name of the FTP server. Replace the following special characters in the FTP login username and password with their respective escape characters: • **Colon (:)**—%3A or %3a. • **At sign (@)**—%40. • **Forward slash (/)**—%2F or %2f.
The import file is stored on a TFTP server.	*tftp://server address/filename*	The *server address* parameter represents the IP address or host name of the TFTP server.

When you configure a Snort rule in the IPS signature file, follow these restrictions and guidelines:

- Use the correct syntax for the rule.
- Specify an SID in the range of 1 to 536870911 for the rule. Rules with larger IDs are invalid.
- The SID of the rule must be different from the SIDs of any existing Snort rules on the device.
- Be sure to configure the **msg** field for the rule. If the **msg** field is not configured, the attack name of the rule will not be displayed in the IPS syslog message.
- Make sure the application specified in the rule is identifiable. Otherwise, no packets can match the rule.

Examples

Import Snort signatures from an IPS signature file that is stored on a TFTP server.

```
<Sysname> system-view
[Sysname] ips signature import snort tftp://192.168.0.1/snort.rules
```

Related commands

Delete all imported Snort IPS signatures.

```
<Sysname> system-view
[Sysname] ips signature remove snort
```

Related commands

ips signature import snort

ips signature rollback

Use **ips signature rollback** to roll back the IPS signature library.

Syntax

ips signature rollback { **factory** | **last** }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

factory: Rolls back the IPS signature library to the factory default version.

last: Rolls back the IPS signature library to the previous version.

Usage guidelines

If an IPS signature library update causes exceptions or a high false alarm rate, you can roll back the IPS signature library.

Before performing an IPS signature library rollback, the device backs up the current IPS signature library as the previous version. For example, the previous library version is V1 and the current library version is V2. If you perform a rollback to the previous version, library version V1 becomes the current version and library version V2 becomes the previous version. If you perform a rollback to the previous version again, the library rolls back to library version V2.

Examples

Roll back the IPS signature library to the previous version.

```
<Sysname> system-view
[Sysname] ips signature rollback last
```

ips signature update

Use **ips signature update** to manually update the IPS signature library.

Syntax

ips signature update [**override-current**] *file-path* [**vpn-instance** *vpn-instance-name*]

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

override-current: Overwrites the current IPS signature library without backing up the library. For the device to back up the current IPS signature library before overwriting the library, do not specify this keyword.

file-path: Specifies the IPS signature file path, a string of 1 to 255 characters.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the TFTP or FTP server belongs by the instance's name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the TFTP or FTP server belongs to the public network.

Usage guidelines

If the device cannot access the NSFOCUS website, use one of the following methods to manually update the IPS signature library:

- **Local update**—Updates the IPS signature library by using a locally stored update IPS signature file.

  Store the update file on the master device for successful signature library update.

  The following describes the format of the *file-path* parameter for different update scenarios.

Update scenario	Format of *file-path*	Remarks
The update file is stored in the current working directory.	*filename*	To display the current working directory, use the **pwd** command. For information about the **pwd** command, see file system management in *Fundamentals Command Reference.*
The update file is stored in a different directory on the same storage medium.	*filename*	Before configuring the **ips signature update** command, use the **cd** command to open the directory where the file is stored. For information about the **cd** command, see file system management in *Fundamentals Command Reference.*
The update file is stored on a different storage medium.	*path/filename*	Before configuring the **ips signature update** command, use the **cd** command to open the root directory of the storage medium where the file is stored. For information about the **cd** command, see file system management in *Fundamentals Command Reference.*

- **FTP/TFTP update**—Updates the IPS signature library by using the file stored on an FTP or TFTP server.

  The following describes the format of the *file-path* parameter for different update scenarios.

Update scenario	Format of *file-path*	Remarks
The update file is stored on an FTP server.	*ftp://username:password@server address/filename*	The *username* parameter represents the FTP login username. The *password* parameter represents the FTP login password. The *server address* parameter represents the IP address or host name of the FTP server. Replace the following special characters in the FTP login username and password with their respective escape characters: • **Colon (:)**—%3A or %3a. • **At sign (@)**—%40. • **Forward slash (/)**—%2F or %2f.
The update file is stored on a TFTP server.	*tftp://server address/filename*	The *server address* parameter represents the IP address or host name of the TFTP server.

NOTE:

To update the signature library successfully, make sure the device and the FTP or TFTP server can reach each other. If you specify the FTP or TFTP server by its host name, you must also make sure the device can resolve the host name into an IP address through static or dynamic DNS. For more information about DNS, see *Layer 3—IP Services Configuration Guide*.

Examples

Manually update the IPS signature library by using an IPS signature file stored on a TFTP server.

```
<Sysname> system-view
[Sysname] ips signature update tftp://192.168.0.10/ips-1.0.2-en.dat
```

Manually update the IPS signature library by using an IPS signature file stored on an FTP server. The FTP login username and password are **user:123** and **user@abc/123**, respectively.

```
<Sysname> system-view
[Sysname] ips signature update
ftp://user%3A123:user%40abc%2F123@192.168.0.10/ips-1.0.2-en.dat
```

Manually update the IPS signature library by using an IPS signature file stored on the device. The file is stored in directory **cfa0:/ips-1.0.23-en.dat**, and the current working directory is **cfa0:**.

```
<Sysname> system-view
[Sysname] ips signature update ips-1.0.23-en.dat
```

Manually update the IPS signature library by using an IPS signature file stored on the device. The file is stored in directory **cfa0:/dpi/ips-1.0.23-en.dat**, and the current working directory is **cfa0:**.

```
<Sysname> cd dpi
<Sysname> system-view
[Sysname] ips signature update ips-1.0.23-en.dat
```

Manually update the IPS signature library by using an IPS signature file stored on the device. The file is stored in directory **cfb0:/dpi/ips-1.0.23-en.dat**, and the current working directory is the **cfa0:**.

```
<Sysname> cd cfb0:/
<Sysname> system-view
[Sysname] ips signature update dpi/ips-1.0.23-en.dat
```

ips signature update-log

Use **ips signature update-log send-time** to enable logging for IPS signature library update and rollback events and daily output of the logs at the specified time.

Use **undo ips signature update-log send-time** to disable logging for IPS signature library update and rollback events.

Syntax

ips signature update-log send-time *time*

undo ips signature update-log send-time

Default

Logging for IPS signature library update and rollback events is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the daily log output time, in the format of hh:mm. The value range is 00:00 to 23:59.

Usage guidelines

This command enables the device to log successful IPS signature library update and rollback events and to output the logs at the specified time.

The device supports outputting IPS signature library update and rollback logs only as fast logs to log hosts. For the IPS logs to be output correctly, make sure the following requirements are met:

- Fast log output of IPS logs in SGCC format are enabled by using the **customlog format dpi ips sgcc** command.
- The log hosts where the IPS logs should be sent are configured by using the **customlog host** command.

For more information about the preceding commands, see fast log output commands in *Network Management and Monitoring Command Reference*.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Enable logging for IPS signature library update and rollback events and set the daily output time to 12:12.

```
<Sysname> system-view
[Sysname] ips signature update-log send-time 12:12
```

ips signature user-defined

Use **ips signature user-defined** create a user-defined IPS signature and enter its view, or enter the view of an existing user-defined IPS signature.

Use **undo ips signature user-defined** to delete user-defined IPS signatures.

Syntax

ips signature user-defined name *signature-name*

undo ips signature user-defined { **all** | **name** *signature-name* }

Default

No user-defined IPS signatures exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

signature-name: Specifies the IPS signature name, a case-insensitive string of 1 to 63 characters.

all: Deletes all user-defined signatures that are manually configured.

Usage guidelines

Repeat this command to create multiple user-defined IPS signatures, which are user-configured signatures and different from Snort signatures imported from an IPS signature file in the Snort format.

When you delete a user-configured signature, all the configurations for the signature will also be deleted.

Examples

Create user-defined IPS signature **mysignature** and enter its view.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature]
```

Related commands

display ips signature user-defined user-config

ips whitelist

Use **ips whitelist** to create an IPS whitelist entry and enter its view, or enter the view of an existing IPS whitelist entry.

Use **undo ips whitelist** to delete an IPS whitelist entry.

Syntax

ips whitelist *entry-id*

undo ips whitelist *entry-id*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

entry-id: Specifies the IPS whitelist entry ID, in the range of 1 to 2048.

Usage guidelines

If false alarms exist in IPS logs, you can enable the IPS whitelist feature, and add the detected IPS signature IDs or URLs to the IPS whitelist. The device permits packets matching the IPS signatures or URLs on the IPS whitelist to pass through, reducing false alarms.

Examples

Create IPS whitelist entry **1** and enter its view.

```
<Sysname> system-view
[Sysname] ips whitelist 1
[Sysname-ips-whitelist-1]
```

Related commands

ips whitelist activate

ips whitelist activate

Use **ips whitelist activate** to activate the IPS whitelist configuration.

Syntax

ips whitelist activate

Default

The creation and editing of an IPS whitelist entry does not take effect immediately if the entry contains a URL.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

After you create or edit an IPS whitelist entry that contains a URL, you must execute this command to have the configuration take effect.

Examples

Activate the IPS whitelist configuration.

```
<Sysname> system-view
[Sysname] ips whitelist activate
```

Related commands

url

ips whitelist enable

Use **ips whitelist enable** to enable the IPS whitelist feature.

Use **undo ips whitelist enable** to disable the IPS whitelist feature.

Syntax

ips whitelist enable

undo ips whitelist enable

Default

The IPS whitelist feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

If false alarms exist in IPS logs, you can enable the IPS whitelist feature, and add the detected IPS signature IDs or URLs to the IPS whitelist. The device permits packets matching the IPS signatures or URLs on the IPS whitelist to pass through, reducing false alarms.

Examples

Enable the IPS whitelist feature.

```
<Sysname> system-view
[Sysname] ips whitelist enable
```

log

Use **log** to specify the log output method.

Use **undo log** to restore the default.

Syntax

log { **email** | **syslog** }

undo log { **email** | **syslog** }

Default

The IPS log output method is **syslog**.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Parameters

email: Emails the IPS logs to an email receiver.

syslog: Exports the IPS logs to the information center.

Usage guidelines

This command takes effect only after the global parameter profiles are disabled by the **undo global-parameter enable** command.

If you specify the email log output method, you can specify a parameter profile used by the email action.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the log output method as **email** in IPS policy **policy1**.

```
<Sysname> system-view
[Sysname] ips policy policy1
[Sysname-ips-policy-policy1] log email
```

Related commands

email parameter-profile

global-parameter enable

object-dir

Use **object-dir** to specify a direction criterion to filter IPS signatures in an IPS policy.

Use **undo object-dir** to restore the default.

Syntax

object-dir { **client** | **server** } *

undo object-dir

Default

The direction attribute is not used for IPS signature filtering.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Parameters

client: Specifies the server to client direction.

server: Specifies the client to server direction.

Usage guidelines

Each IPS signature has a direction attribute that defines the traffic direction to which the signature applies. The direction attribute values include **To-server**, **To-client**, and **Any**.

IPS signatures with the **Any** direction attribute are always used by an IPS policy, regardless of the settings of this command. For example, if you configure the **object-dir client** command for an IPS policy, the policy will use IPS signatures with both the **To-client** and **Any** direction attributes.

If you execute this command in an IPS policy multiple times, the most recent configuration takes effect.

Examples

Configure IPS policy **test** to use IPS signatures with the **To-client** and **Any** direction attributes.

```
<Sysname> system-view
[Sysname] ips policy test
[Sysname-ips-policy-test] object-dir client
```

override-current

Use **override-current** to configure the device to overwrite the current IPS signature library without backing up the library during an automatic signature library update.

Use **undo override-current** to restore the default.

Syntax

override-current

undo override-current

Default

Before performing an automatic IPS signature library update, the device backs up the current IPS signature library as the previous version.

Views

Automatic IPS signature library update configuration view

Predefined user roles

network-admin

context-admin

Usage guidelines

Backing up the current IPS signature library requires additional storage space but enables signature library rollback. As a best practice, enable the backup function if there is sufficient storage space.

Examples

Configure the device to overwrite the current IPS signature library without backing up the library during an automatic signature library update.

```
<Sysname> system-view
[Sysname] ips signature auto-update
[Sysname-ips-autoupdate] override-current
```

Related commands

ips signature auto-update

protect-target

Use **protect-target** to set a target criterion to filter the IPS signatures in an IPS policy.

Use **undo protect-target** to remove a target criterion.

Syntax

protect-target { *target* [*subtarget*] | **all** }

undo protect-target { *target* [*subtarget*] | **all** }

Default

The protected target attribute is not used for IPS signature filtering.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Parameters

target: Specifies a target.

subtarget: Specifies a subtarget of the target. If you do not specify a subtarget, this command matches any IPS signatures with a subtarget of the specified target.

all: Specifies all targets.

Usage guidelines

This command filters the IPS signatures that an IPS policy uses based on the protected target attribute of the signatures.

You can execute this command multiple times to specify multiple target criteria in an IPS policy. The IPS policy uses an IPS signature if the signature matches any of the configured target criteria.

Examples

Configure IPS policy **test** to use IPS signatures with the **WebLogic** subtarget of the **WebServer** target.

```
<Sysname> system-view
[Sysname] ips policy test
[Sysname-ips-policy-test] protect-target WebServer WebLogic
```

rule

Use **rule** to create a user-defined IPS signature rule and enter its view, or enter the view of an existing user-defined IPS signature rule.

Use **undo rule** to delete user-defined IPS signature rules.

Syntax

rule *rule-id* **l4-protocol** *l4-protocol-name* **l5-protocol** *l5-protocol-name* **pattern-type** { **keyword** | **integer** }

undo rule { *rule-id* | **all** }

Default

No user-defined IPS signature rules exist.

Views

User-defined IPS signature view

Predefined user roles

network-admin

context-admin

Parameters

rule-id: Specifies the rule ID, in the range of 1 to 8.

l4-protocol *l4-protocol-name*: Specifies the transport layer protocol by its name. To view the names of supported protocols, enter a question mark (?) after the **l4-protocol** keyword.

l5-protocol *l5-protocol-name*: Specifies the application layer protocol by its name. To view the names of supported protocols, enter a question mark (?) after the **l5-protocol** keyword.

pattern-type: Specifies the match pattern type for the rule.

keyword: Specifies the keyword type.

integer: Specifies the integer type.

all: Deletes all user-defined IPS signature rules.

Usage guidelines

You can configure multiple rules in a user-defined signature. To configure the logical operator between rules, use the **rule-logic** command.

You cannot execute this command multiple times to change any configurations of a rule. If you want to modify the rule configuration, use the **undo rule** command to delete the rule first.

Examples

Create user-defined IPS signature rule 1 and enter its view. Set the rule to match TCP and HTTP packets, and specify the keyword match pattern type.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] rule 1 l4-protocol tcp l5-protocol http pattern-type keyword
[Sysname-ips-signature-mysignature-rule-1]
```

rule-logic

Use **rule-logic** to define the logical operator between the rules in a user-defined IPS signature.

Use **undo rule-logic** to restore the default.

Syntax

rule-logic { **and** | **or** }

undo rule-logic

Default

The logical operator between the rules in a user-defined IPS signature is **or**.

Views

User-defined IPS signature view

Predefined user roles

network-admin

context-admin

Parameters

and: Specifies the logical AND operator.

or: Specifies the logical OR operator.

Usage guidelines

If the logical AND operator is specified between rules in a user-defined signature, a packet matches the signature only when the packet matches all rules in the signature.

If the logical OR operator is specified between rules in a user-defined signature, a packet matches the signature when the packet matches any rule in the signature.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

In user-defined IPS signature **mysignature**, specify the logical AND operator between the rules.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] rule-logic and
```

severity-level (IPS policy view)

Use **severity-level** to set a severity level criterion to filter the IPS signatures in an IPS policy.

Use **undo severity-level** to restore the default.

Syntax

severity-level { **critical** | **high** | **low** | **medium** } *

undo severity-level

Default

The severity level attribute is not used for IPS signature filtering.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Parameters

critical: Specifies the critical severity level.

high: Specifies the high severity level.

low: Specifies the low severity level.

medium: Specifies the medium severity level.

Usage guidelines

Each IPS signature has a severity level attribute, which indicates the severity level of the attacks matching the signature.

This command filters the IPS signatures that an IPS policy uses based on the severity level attribute of the signatures.

You can specify multiple severity levels in a severity level criterion. The IPS policy uses an IPS signature if the signature matches any of the specified severity levels.

If you execute this command in an IPS policy multiple times, the most recent configuration takes effect.

Examples

Configure IPS policy **test** to use IPS signatures with the critical and medium severity levels.

```
<Sysname> system-view
[Sysname] ips policy test
[Sysname-ips-policy-test] severity-level critical medium
```

severity-level (IPS signature view)

Use **severity-level** to set a severity level criterion for a user-defined IPS signature.

Use **undo severity-level** to restore the default.

Syntax

severity-level { **critical** | **high** | **low** | **medium** }

undo severity-level

Default

The severity level of a user-defined IPS signature is **low**.

Views

User-defined IPS signature view

Predefined user roles

network-admin

context-admin

Parameters

critical: Specifies the critical severity level.

high: Specifies the high severity level.

low: Specifies the low severity level.

medium: Specifies the medium severity level.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Set the severity level to **medium** for user-defined IPS signature **mysignature**.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] severity-level medium
```

signature override

Use **signature override** to change the status and actions for an IPS signature in an IPS policy.

Use **undo signature override** to restore the default status and actions for an IPS signature in an IPS policy.

Syntax

signature override { **pre-defined** | **user-defined** } *signature-id* { { **disable** | **enable** } [{ **block-source** | **drop** | **permit** | **redirect** | **reset** } | **capture** | **logging**] * }

undo signature override { **pre-defined** | **user-defined** } *signature-id*

Default

Predefined IPS signatures use the actions and states defined by the system.

User-defined IPS signatures use the actions and states defined in the IPS signature file from which the signatures are imported.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Parameters

pre-defined: Specifies a predefined IPS signature.

user-defined: Specifies a user-defined IPS signature.

signature-id: Specifies an IPS signature ID. For a predefined IPS signature, the value range is 1 to 536870911. For a user-defined IPS signature, the value range is 536870913 to 1073741823.

disable: Disables the IPS signature.

enable: Enables the IPS signature.

block-source: Drops matching packets and adds the sources of the packets to the IP blacklist. If the IP blacklist feature is enabled, packets from the blacklisted sources will be blocked for a duration set by the **block-period** command. If the IP blacklist feature is not enabled, packets from the blacklisted sources are not blocked. For more information about the IP blacklist feature, see *Security Configuration Guide*. For information about configuring the block period, see "DPI engine commands."

drop: Drops matching packets.

permit: Permits matching packets to pass.

redirect: Redirects matching packets to a webpage.

reset: Closes the TCP connections for matching packets by sending TCP reset messages.

capture: Captures matching packets.

logging: Logs matching packets.

Usage guidelines

This command is available only for user-defined IPS policies. The signature actions and status in the default IPS policy cannot be modified.

If you execute this command for a signature in an IPS policy multiple times, the most recent configuration takes effect.

Examples

Enable predefined signature 2 for IPS policy **ips1**. Specify the **drop**, **capture**, and **logging** actions for the signature.

```
<Sysname> system-view
[Sysname] ips policy ips1
[Sysname-ips-policy-ips1] signature override pre-defined 2 enable drop capture logging
```

Related commands

blacklist enable (security zone view) (*Security Command Reference*)

blacklist global enable (*Security Command Reference*)

ips parameter-profile

ips policy

signature override all

signature override all

Use **signature override all** to specify the IPS actions for an IPS policy.

Use **undo signature override all** to restore the default.

Syntax

signature override all { { **block-source** | **drop** | **permit** | **redirect** | **reset** } | **capture** | **logging** } *

undo signature override all

Default

No actions are specified for an IPS policy and the default actions of IPS signatures are applied to matching packets.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Parameters

block-source: Drops matching packets and adds the sources of the packets to the IP blacklist. If the IP blacklist feature is enabled, packets from the blacklisted sources will be blocked for a duration set by the **block-period** command. If the IP blacklist feature is not enabled, packets from the blacklisted sources are not blocked. For more information about the IP blacklist feature, see *Security Configuration Guide*. For information about configuring the block period, see "DPI engine commands."

drop: Drops matching packets.

permit: Permits matching packets to pass.

redirect: Redirects matching packets to a webpage.

reset: Closes the TCP connections for matching packets by sending TCP reset messages.

capture: Captures matching packets.

logging: Logs matching packets.

Usage guidelines

Use this command to specify the global packet processing actions for an IPS policy.

Each IPS signature is defined with default actions for matching packets. You can change the default actions for individual signatures in an IPS policy.

The system selects the actions for packets matching an IPS signature in the following order:

1. Actions configured for the IPS signature in the IPS policy (by using the **signature override** command).
2. Actions configured for the IPS policy.
3. Default actions of the IPS signature.

Examples

Specify actions **drop**, **logging**, and **capture** for IPS policy **test**.

```
<Sysname> system-view
[Sysname] ips policy test
[Sysname-ips-policy-test] signature override all drop logging capture
```

Related commands

blacklist enable (security zone view) (*Security Command Reference*)

blacklist global enable (*Security Command Reference*)

ips parameter-profile

signature override

signature version-baseline

Use **signature version-baseline** to specify an IPS signature library baseline version.

Use **undo signature version-baseline** to restore the default.

Syntax

signature version-baseline *version-number*

undo signature version-baseline

Default

No IPS signature library baseline version is specified.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Parameters

version-number: Specifies an IPS signature library version number. To obtain the version number of the current version and the previous version, use the **display ips signature library** command. To obtain history signature library version numbers, access the signature database services on the company's website.

Usage guidelines

This command sets an IPS signature library version as the baseline version and enables the device to match packets only with the signatures in the baseline version. With this command, the device compares the current IPS signature library with the baseline signature library. If a signature is included in the current signature library but does not included in the baseline signature library, the device sets the signature to ineffective state. Signatures in ineffective state cannot match packets.

This command allows the device to match packets only with the signatures in the baseline version without rolling back the signature library to the baseline version.

To separately activate an ineffective signature after this command is used, perform the following tasks:

1. On the Web interface of the device, obtain the IDs of all ineffective signatures.
2. Use this command again to change the IPS signature library baseline version to the version that contains the signature.
3. Execute the **signature override** command to disable all signatures that were in ineffective state when the previous signature library baseline version was used, except the signature to be activated.

If you execute the **signature version-baseline** command multiple times, the most recent configuration takes effect.

Examples

In IPS policy test, set the signature library baseline version to 1.0.88.

```
<Sysname> system-view
[Sysname] ips policy test
[Sysname-ips-policy-test] signature version-baseline 1.0.88
```

Related commands

display ips signature library

signature-id

Use **signature-id** to add an IPS signature ID to an IPS whitelist entry.

Use **undo signature-id** to restore the default.

Syntax

signature-id *sig-id*

undo signature-id

Default

No signature ID exists in an IPS whitelist entry.

Views

IPS whitelist entry view

Predefined user roles

network-admin

context-admin

Parameters

sig-id: Specifies an IPS signature ID, in the range of 1 to 4294967294.

Usage guidelines

If false alarms exist in IPS logs, use this command to add an IPS signature ID to an IPS whitelist entry. The IPS signature ID is recorded in the IPS log. The device permits packets matching the IPS signatures on the IPS whitelist to pass through, reducing false alarms.

If both a signature ID and URL exist in the IPS whitelist entry, a packet matches the IPS whitelist entry only when both the signature ID and URL are matched.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Add IPS signature 936 to IPS whitelist entry 1.

```
<Sysname> system-view
[Sysname] ips whitelist 1
[Sysname-ips-whitelist-1] signature-id 936
```

Related commands

source-address (IPS whitelist entry view)

url

source-address (IPS whitelist entry view)

Use **source-address** to add a source IP address to an IPS whitelist entry.

Use **undo source-address** to restore the default.

Syntax

source-address { **ip** *ipv4-address* | **ipv6** *ipv6-address* }

undo source-address

Default

No source IP address exists in an IPS whitelist entry.

Views

IPS whitelist entry view

Predefined user roles

network-admin

context-admin

Parameters

ip *ipv4-address*: Specifies an IPv4 address.

ipv6 *ipv6-address*: Specifies an IPv6 address.

Usage guidelines

If false alarms exist in IPS logs, use this command to add a source IP address to an IPS whitelist entry. The source IP address is recorded in the IPS log. The device permits packets matching the source IP addresses on the IPS whitelist to pass through, reducing false alarms.

If an IPS whitelist entry contains a signature ID, URL, and source IP address, or two of them, a packet matches this entry only when it matches all configured criteria.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Add source IP address 192.168.0.1 to IPS whitelist entry 1.

```
<Sysname> system-view
[Sysname] ips whitelist 1
[Sysname-ips-whitelist-1] source-address ip 192.168.0.1
```

Related commands

signature-id
url

source-address (user-defined IPS signature rule view)

Use **source-address** to specify a source address filtering criterion in a user-defined IPS signature rule.

Use **undo source-address** to restore the default.

Syntax

source-address ip *ip-address*

undo source-address

Default

No source IP address exists.

Views

User-defined IPS signature rule view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies an IPv4 address. It is used to match the packet source IPv4 address.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

In rule 1 of user-defined IPS signature **mysignature**, specify the keyword type as the match pattern type and specify source IP address 10.1.1.1 as a filtering criterion.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] rule 1 l4-protocol tcp l5-protocol http pattern-type keyword
[Sysname-ips-signature-mysignature-rule-1] source-address ip 10.1.1.1
```

source-port

Use **source-port** to specify a source port filtering criterion in a user-defined signature rule.

Use **undo source-port** to restore the default.

Syntax

source-port *start-port* [**to** *end-port*]

undo source-port

Default

No source ports are specified as the filtering criteria in a user-defined signature rule.

Views

User-defined IPS signature rule view

Predefined user roles

network-admin

context-admin

Parameters

start-port: Specifies the start port number of a source port range, in the range of 1 to 65535.

to *end-port*: Specifies the end port number of a source port range, in the range of 1 to 65535. If you do not specify this option, only the start port number is specified.

Usage guidelines

The port numbers are used to match the source port numbers of the specified transport layer protocol.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

In rule 1 of user-defined IPS signature **mysignature**, specify the keyword type as the match pattern type and specify the source port range as 1 to 3550.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] rule 1 l4-protocol tcp l5-protocol http pattern-type keyword
[Sysname-ips-signature-mysignature-rule-1] source-port 1 to 3550
```

statistics signature-hit enable

Use **statistics signature-hit enable** to enable IPS signature hit counting.

Use **undo statistics signature-hit enable** to disable IPS signature hit counting.

Syntax

statistics signature-hit enable

undo statistics signature-hit enable

Default

IPS signature hit counting is disabled.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command enables the device to collect hit statistics for each IPS signature. You can view IPS signature hit statistics on the Web interface of the device.

Examples

Enable IPS signature hit counting in IPS policy **policy**.

```
<Sysname> system-view
[Sysname] ips policy policy
[Sysname-ips-policy-policy] statistics signature-hit enable
```

status

Use **status** to specify a default status criterion to filter IPS signatures in an IPS policy.

Use **undo status** to restore the default.

Syntax

status { **disabled** | **enabled** } *

undo status

Default

The default status attribute is not used for IPS signature filtering.

Views

IPS policy view

Predefined user roles

network-admin

context-admin

Parameters

disabled: Specifies the signatures that are not recommended in the IPS signature library by default.

enabled: Specifies the signatures that are recommended in the IPS signature library by default.

Usage guidelines

This command filters the IPS signatures that an IPS policy uses based on the default status attribute of the IPS signatures.

The default status of an IPS signature indicates whether or not the IPS signature is recommended in the IPS signature library by default.

- **Disabled IPS signatures**—Not recommended IPS signatures, which apply only to special scenarios and are not universally applied.
- **Enabled IPS signatures**—Recommended IPS signatures, which are universally applied.

You can specify both default states. The IPS policy uses an IPS signature if the IPS signature matches either of the configured default status criteria.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure IPS policy **policy** to use IPS signatures in **enabled** default status .

```
<Sysname> system-view
[Sysname] ips policy policy
[Sysname-ips-policy-policy] status enabled
```

trigger

Use **trigger** to create a detection trigger condition in a user-defined IPS signature rule.

Use **undo trigger** to delete a detection trigger condition from the user-defined IPS signature rule.

Syntax

trigger field *field-name* **include** { **hex** *hex-string* | **text** *text-string* } [**offset** *offset-value*] [**depth** *depth-value*]

undo trigger

Default

No detection trigger condition exists.

Views

User-defined IPS signature rule view

Predefined user roles

network-admin

context-admin

Parameters

field-name: Specifies a protocol field by its name, in a case-insensitive string. To view the names of supported protocol fields, enter a question mark (?) after the **field** keyword.

include: Matches contents that include the specified string.

hex *hex-string*: Specifies a case-sensitive hexadecimal string of 8 to 254 characters. Valid characters contain integers, and letters of A to F and a to f. An even number of characters are required, and enclose the characters with two vertical bars (|), for example |1234f5b6|.

text *text-string*: Specifies a case-insensitive text string of 3 to 255 characters.

offset *offset-value*: Specifies an offset in bytes after which the match operation starts, in the range of 1 to 65535. If you do not specify *offset-value* argument, the match operation starts from the beginning of the protocol field.

depth *depth-value*: Specifies the number of bytes to match, in the range of 3 to 65535. If you do not specify *depth-value* argument, the detection trigger condition detects the whole protocol field.

Usage guidelines

This command is available only for a user-defined signature rule of the keyword match pattern type. The device continues to compare a packet with detection items only after the packet matches the detection trigger condition in a rule. If a packet fails to match the detection trigger condition, the rule matching fails, and the detection items will not be compared.

In a signature rule of the keyword match pattern type, a detection trigger condition must be configured before detection item configuration.

If you delete the detection trigger condition, all detection items in the rule will also be deleted.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

In user-defined IPS signature **mysignature**, create rule 1 for TCP and HTTP protocols and specify the keyword match pattern type. Create a detection item in the rule to match packets whose **http.host** field includes **abc**. Specify the offset and depth as 10 bytes and 50 bytes, respectively.

```
<Sysname> system-view
[Sysname] ips signature user-defined name mysignature
[Sysname-ips-signature-mysignature] rule 1 l4-protocol tcp l5-protocol http pattern-type keyword
[Sysname-ips-signature-mysignature-rule-1] trigger field http.host include text abc offset 10 depth 50
```

update schedule

Use **update schedule** to schedule the time for automatic IPS signature library update.

Use **undo update schedule** to restore the default.

Syntax

update schedule { **daily** | **weekly** { **fri** | **mon** | **sat** | **sun** | **thu** | **tue** | **wed** } } **start-time** *time* **tingle** *minutes*

undo update schedule

Default

The device starts updating the IPS signature library at a random time between 01:00:00 and 03:00:00 every day.

Views

Automatic IPS signature library update configuration view

Predefined user roles

network-admin

context-admin

Parameters

daily: Updates the IPS signature library every day.

weekly: Updates the IPS signature library every week.

fri: Updates the IPS signature library every Friday.

mon: Updates the IPS signature library every Monday.

sat: Updates the IPS signature library every Saturday.

sun: Updates the IPS signature library every Sunday.

thu: Updates the IPS signature library every Thursday.

tue: Updates the IPS signature library every Tuesday.

wed: Updates the IPS signature library every Wednesday.

start-time *time*: Specifies the start time in the hh:mm:ss format. The value range is 00:00:00 to 23:59:59.

tingle *minutes*: Specifies the tolerance time in minutes. The value range is 0 to 120. An automatic library update will occur at a random time between the following time points:

- Start time minus half the tolerance time.
- Start time plus half the tolerance time.

Examples

Configure the device to automatically update the IPS signature library every Monday at a random time between 20:25:00 and 20:35:00.

```
<Sysname> system-view
[Sysname] ips signature auto-update
[Sysname-ips-autoupdate] update schedule weekly mon start-time 20:30:00 tingle 10
```

Related commands

ips signature auto-update

url

Use **url** to add a URL to an IPS whitelist entry.

Use **undo url** to restore the default.

Syntax

url match-type { **accurate** | **substring** } *url-text*

undo url

Default

No URL exists in an IPS whitelist entry.

Views

IPS whitelist entry view

Predefined user roles

network-admin

context-admin

Parameters

match-type: Specifies the match type.

accurate: Specifies the exact match. A match is found if the URL in the packet is exactly the same as the configured URL.

substring: Specifies the substring match. A match is found if the URL in the packet contains the configured URL.

url-text: Specifies a URL, a case-insensitive string of 3 to 460 characters.

Usage guidelines

If false alarms exist in IPS logs, use this command to add a URL to an IPS whitelist entry. The URL is recorded in the IPS log. The device permits packets matching the URLs on the IPS whitelist to pass through, reducing false alarms.

If both a signature ID and URL exist in the IPS whitelist entry, a packet matches the IPS whitelist entry only when both the signature ID and URL are matched.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Add URL **baidu.com** to IPS whitelist entry 1, and specify the exact match type as the match type.

```
<Sysname> system-view
[Sysname] ips whitelist 1
[Sysname-ips-whitelist-1] url match-type accurate baidu.com
```

Related commands

URL filtering commands

add

Use **add** to add a blacklist or whitelist rule to a URL filtering policy.

Use **undo add** to delete a blacklist or whitelist rule from a URL filtering policy.

Syntax

add { **blacklist** | **whitelist** } [*id*] **host** { **regex** *host-regex* | **text** *host-name* } [**uri** { **regex** *uri-regex* | **text** *uri-name* }]

undo add { **blacklist** | **whitelist** } { *id* | **all** }

Default

No blacklist or whitelist rules exist in a URL filtering policy.

Views

URL filtering policy view

Predefined user roles

network-admin

context-admin

Parameters

blacklist: Specifies the blacklist rule type.

whitelist: Specifies the whitelist rule type.

id: Specifies a rule ID. The value must be an integer in the range of 1 to 65535. The ID of a blacklist or whitelist rule must be unique among all rules of the same type. If you do not specify a rule ID, the system automatically assigns an available ID to the rule according to the largest rule ID *N* used on the device:

- If *N* is smaller than 65535, the smallest available ID that is larger than *N* is used.
- If *N* equals to 65535, the smallest available ID is used.

host: Matches the host field in the URL.

uri: Matches the URI field in the URL.

regex *regex*: Specifies a case-sensitive regular expression string pattern. The string can start with only letters, digits, or underscores (_), and it must contain a minimum of three consecutive non-wildcard characters.

- If the **host** keyword is specified, the string can contain 3 to 224 characters.
- If the **uri** keyword is specified, the string can contain 3 to 245 characters.

text *string*: Specifies a case-insensitive text string pattern, which must contain a minimum of three consecutive non-wildcard characters.

- If the **host** keyword is specified, the string can contain 3 to 224 characters. Valid characters are letters, digits, underscores (_), hyphens (-), colons (:), left square brackets ([), right square brackets (]), dots (.), and asterisk (*).
- If the **uri** keyword is specified, the string can contain 3 to 245 characters.

all: Specifies all rules of the specified type.

Usage guidelines

The device supports using URL-based whitelist and blacklist rules to filter HTTP packets. If the URL in an HTTP packet matches a blacklist rule, the packet is dropped. If the URL matches a whitelist rule, the packet is permitted to pass through.

Follow these guidelines when you use the asterisk character (*) in the text string pattern for hostname or URI matching:

- For hostname matching, the asterisk (*) can appear only at the beginning or end of the text string pattern as a wildcard character to match zero or more characters.
- For URI matching, the asterisk (*) can appear at the beginning or end of the text string pattern as a wildcard character to match zero or more characters, or appear in the middle as a non-wildcard character.

When you configure a regular expression in a blacklist or whitelist rule, follow these restrictions and guidelines:

- The regular expression pattern can contain a maximum of four branches. For example, **'abc(c|d|e|\x3D)'** is valid, and **'abc(c|onreset|onselect|onchange|style\x3D)'** is invalid.
- Nested braces are not allowed. For example, **'ab((abcs*?))'** is invalid.
- A branch cannot be specified after another branch. For example, **'ab(a|b)(c|d)^\\r\\n]+?'** is invalid.
- A minimum of four non-wildcard characters must exist before an asterisk (*) or question mark (?). For example, **'abc*'** is invalid and **'abcd*DoS\x2d\d{5}\x20\x2bxi\\r\\nJOIN'** is valid.

Examples

In URL filtering policy **news**, add a blacklist rule to match URLs with the host field starting with **games.com**.

```
<Sysname> system-view
[Sysname] url-filter policy news
[Sysname-url-filter-policy-news] add blacklist 1 host text games.com*
```

category action

Use **category action** to specify actions for a URL category.

Use **undo category** to remove the action setting from a URL category.

Syntax

category *category-name* **action** { **block-source** [**parameter-profile** *parameter-name*] | **drop** | **permit** | **redirect parameter-profile** *parameter-name* | **reset** } [**logging** [**parameter-profile** *parameter-name*]]

undo category *category-name*

Default

A URL category does not have any action specified.

Views

URL filtering policy view

Predefined user roles

network-admin

context-admin

Parameters

category-name: Specifies a URL category by its name, a case-insensitive string of 1 to 63 characters.

action: Specifies the action for the matching packets.

block-source: Drops matching packets and adds the sources of the packets to the IP blacklist. If the IP blacklist feature is enabled, packets from the blacklisted sources will be blocked for a duration set by the **block-period** command. If the IP blacklist feature is not enabled, packets from the blacklisted sources are not blocked. For more information about the IP blacklist feature, see *Security Configuration Guide*. For information about configuring the block period, see "DPI engine commands."

drop: Drops matching packets.

permit: Permits matching packets to pass.

redirect: Redirects matching packets to a webpage.

reset: Disconnects the TCP connection for matching packets.

logging: Logs matching packets.

parameter-profile *parameter-name*: Specifies a parameter profile by its name, a case-insensitive string of 1 to 63 characters. If you do not specify a profile, or if the specified profile does not exist, the URL filtering action uses the default parameter settings. For information about configuring parameter profiles, see "DPI engine commands."

Usage guidelines

If an HTTP packet matches a URL filtering rule in a URL category, the action specified for the category applies to the packet.

If the packet matches none of URL filtering rules in the URL filtering policy, the default action specified for the policy applies to the packet. If the default action is not configured, the device permits the packet to pass.

If you execute this command for a URL category multiple times, the most recent configuration takes effect.

Examples

In the URL filtering policy **news**, specify the **drop** action for the URL category **sina**.

```
<Sysname> system-view
[Sysname] url-filter policy news
[Sysname-url-filter-policy-news] category sina action drop
```

cloud-query enable

Use **cloud-query enable** to enable cloud query for URL filtering.

Use **undo cloud-query enable** to disable cloud query for URL filtering.

Syntax

cloud-query enable

undo cloud-query enable

Default

URL filtering cloud query is disabled.

Views

URL filtering policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

With cloud query enabled in a URL filtering policy, URLs that do not match any URL filtering rules in the policy are sent to the cloud server for further query. The device determines the actions for an HTTP packet based on the URL query results returned from the cloud server:

- If a matching rule is found, the rule and the name of URL category to which the rule belongs are returned. The device executes the actions specified for the URL category. If no actions are specified for the URL category, the default action of the policy is executed.
- If no matching rule is found, the device executes the default action of the policy.

Examples

Enable URL filtering cloud query in URL filtering policy **news**.

```
<Sysname> system-view
[Sysname] url-filter policy news
[Sysname-url-filter-policy-news] cloud-query enable
```

Related commands

undo default-action

Default

A URL filtering policy does not have any default action.

Views

URL filtering policy view

Predefined user roles

network-admin

context-admin

Parameters

block-source: Drops matching packets and adds the sources of the packets to the IP blacklist. If the IP blacklist feature is enabled, packets from the blacklisted sources will be blocked for a duration set by the **block-period** command. For more information about the IP blacklist feature, see *Security Configuration Guide*. For information about configuring the block period, see "DPI engine commands."

drop: Drops matching packets.

permit: Permits packets to pass.

redirect: Redirects matching packets to a webpage.

reset: Disconnects the TCP connection for matching packets.

logging: Logs matching packets.

parameter-profile *parameter-name*: Specifies a DPI action parameter profile by its name, a case-insensitive string of 1 to 63 characters. If you do not specify a profile, or if the specified profile does not exist, the DPI action uses the default parameter settings. For information about configuring parameter profiles for DPI actions, see "DPI engine commands."

Usage guidelines

The default action applies to packets that do not match any URL filtering rules.

Examples

Set the default action to **drop** for URL filtering policy **cmcc**.

```
<Sysname> system-view
[Sysname] url-filter policy cmcc
[Sysname-url-filter-policy-cmcc] default-action drop

context-operator

Parameters

category *category-name*: Specify a URL category by its name, a case-insensitive string of 1 to 63 characters.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information for all member devices.

Usage guidelines

This command displays the cached entries in the URL filtering cache and the cloud query information.

Examples

Display all URL filtering rules in the URL filtering cache.

```
<Sysname> display url-filter cache
Slot 1 :
Url-filter cache information:
Cloud-query status: Enabled
Total cached entries: 35
Min update interval: 906 seconds
Max update interval: 46760 seconds
Last query message sent: 906 seconds ago
Last query result received: 906 seconds ago
```

Slot 1 :

```
Url-filter cache verbose:
Host: 192.168.56.99
URI: /wnm/get.j?sessionid=200001a5de59aebeb0877f982e5c31f58728
Hit count: 15
Time elapsed since last update: 906 seconds
Category ID: 152
Cache query state: Query ended
```

Table 1 Command output

Field	Description
Url_filter cache information	URL filtering cache information.
Cloud-query status	Whether cloud query is enabled or disabled.
Total cached entries	Total number of cached URL entries.
Min update interval	Minimum interval that a cached entry was updated, in seconds.
Max update interval	Maximum interval that a cached entry was updated, in seconds.
Last query message sent	Number of seconds elapsed since the last query message was sent.
Last query result received	Number of seconds elapsed since the last query result was received.
Url-filter cache verbose	Detailed information about a cached URL entry.
Host	Host field of the cached URL.
URI	URI field of the cached URL.
Hit count	Number of times the URL filtering rule has been matched.
Time elapsed since last update	Number of seconds elapsed since the cached entry was last updated.
Category ID	ID of the URL category to which the matching URL filtering rule belongs. This field is empty if no matching URL filtering rule is found for the URL. If the matching URL filtering rule belongs to multiple URL categories, the URL category IDs are displayed in a space-separated list.
Cache query state	Query state of the URL: • **In the cloud query**—Cloud query is in progress. • **Query end**—Cloud query is completed.

Parameters

`category`: Specifies child URL categories.

`parent-category`: Specifies parent URL categories.

`verbose`: Display detailed URL category information. If you do not specify this keyword, this command displays the summarized URL category information.

Usage guidelines

The device supports two levels of predefined URL categories: child URL category and parent URL category. A predefined parent URL category contains only predefined child URL categories.

Examples

Display information about child URL categories.

```
<Sysname> display url-filter category
URL category statistics:
  Predefined categories: 53
  Predefined rules: 2000
  User-defined categories: 5
  User-defined rules: 4

URL categories:
  Name : 23
  Name : 24
  Name : 33
  Name : Pre-AdvertisementsAndPop-Ups
  Name : Pre-AlcoholAndTobacco
  Name : Pre-Anonymizers
  Name : Pre-Arts
  Name : Pre-Business
  Name : Pre-Chat
  Name : Pre-ComputersAndTechnology
  Name : Pre-CriminalActivity
  Name : Pre-Cults
  Name : Pre-DatingAndPersonals
  Name : Pre-DownloadSites
  Name : Pre-Education
  Name : Pre-Entertainment
  Name : Pre-FashionAndBeauty

context-operator

Examples

Display information about the URL signature library.

```
<Sysname> display url-filter signature library
URL filter signature library information:
Type      SigVersion         ReleaseTime               Size
Current   1.0.0              Wed Jan 21 06:43:53 2015  36096
(null)    -                  -                         -
Factory   1.0.0              Wed Jan 21 06:43:53 2015  36096
```

Table 4 Command output

Field	Description
Type	Version of the URL signature library: • **Current**—Current version. • **Last**—Previous version. • **Factory**—Factory default version.
SigVersion	Version number.
ReleaseTime	Time when the URL signature library was released.
Size	Size of the URL signature library, in bytes.

display url-filter statistics

Use **display url-filter statistics** to display URL filtering statistics.

Syntax

display url-filter statistics

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display URL filtering statistics.

```
<Sysname> display url-filter statistics
-------------------------------------------------------
Slot 1 :
Total HTTP requests                         : 0
Total HTTPS handshakes                      : 0
Total logged requests                       : 0
Total logging rate                          : 0/s
Total permitted requests and handshakes     : 0
Total denied requests                       : 0
Requests that matched the blacklist         : 0
Requests that matched the whitelist         : 0
Requests that matched the referer-whitelist : 0
Requests that matched a user-defined rule   : 0
Requests that matched a predefined rule     : 0
Requests that matched a cached rule         : 0
Requests that matched the default action    : 0
Predefined URL filtering rules              : 2000
-------------------------------------------------------
```

Table 5 Command output

Field	Description
Total HTTP requests	Total number of HTTP packets.
Total HTTPS handshakes	Total number of encrypted traffic hits.
Total logged HTTP requests	Total number of logged HTTP packets.
Total HTTP logging rate	Logging rate for HTTP packets.
Total permitted HTTP requests	Total number of permitted HTTP packets.
Total denied HTTP requests	Total number of denied HTTP packets.
Requests that matched the blacklist	Number of HTTP packets that matched a blacklist rule.
Requests that matched the whitelist	Number of HTTP packets that matched a whitelist rule.
Requests that matched the referer-whitelist	Number of HTTP packets with a referer header that matched a whitelist rule.
Requests that matched a user-defined rule	Number of HTTP packets that matched a user-defined URL filtering rule.
Requests that matched a predefined rule	Number of HTTP packets that matched a predefined URL filtering rule.
Requests that matched a cached rule	Number of HTTP packets that matched a cached URL filtering rule.

Field	Description
Requests that matched the default action	Number of HTTP packets on which the default action is executed.
Predefined URL filtering rules	Total number of predefined URL filtering rules.

https-filter enable

Use **`https-filter enable`** to enable HTTPS URL filtering.

Use **`undo https-filter enable`** to disable HTTPS URL filtering.

Syntax

`https-filter enable`

`undo https-filter enable`

Default

HTTPS URL filtering is disabled.

Views

URL filtering policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

By default, the device supports only the HTTP URL filtering. To enable filtering on HTTPS traffic, use either of the following methods:

- Use SSL decryption to decrypt the HTTPS traffic and then perform HTTP URL filtering on the decrypted traffic. For more information about SSL decryption, see proxy policy configuration in *DPI Configuration Guide*.

  SSL decryption involves a large number of encryption and decryption operations, which might downgrade device forwarding performance. As a best practice, use this method only when the device must perform URL filtering on HTTPS traffic.
- Enable HTTPS URL filtering. This feature performs URL filtering on undecrypted HTTPS traffic. The device directly detects the Client Hello message from the client, and extracts the server name from the Sever Name Indication (SNI) extension to match the URL filtering policy.

If SSL decryption is configured, this command does not take effect. For more information about SSL decryption, see proxy policy configuration in *DPI Configuration Guide*.

In HTTPS URL filtering, only the hostname match criterion in a URL filtering rule takes effect. The URI match criterion does not take effect.

This feature takes effect only when the hostname field in the URL is the server's domain name. This feature does not apply to the HTTPS traffic if the hostname field is an IP address.

This feature does not take effect in the following situations:

- The client browser enables TLS 1.3 downgrade enhancement mechanism, because the SNI extension will be encrypted.
- The HTTPS packets do not have the SNI extension.

Examples

Enable HTTPS URL filtering in URL filtering policy **news**.

```
<Sysname> system-view
[Sysname] url-filter policy news
[Sysname-url-filter-policy-news] https-filter enable
```

Related commands

action ssl-decrypt

include pre-defined

Use **include pre-defined** to add the URL filtering rules of a predefined URL category to a user-defined URL category.

Use **undo include pre-defined** to restore the default.

Syntax

include pre-defined *category-name*

undo include pre-defined

Default

A user-defined URL category does not contain the URL filtering rules of any predefined URL category.

Views

URL category view

Predefined user roles

network-admin

context-admin

Parameters

category-name: Specifies a predefined URL category by its name, a case-sensitive string of 1 to 63 characters. The specified URL category must exist on the device.

Usage guidelines

To simplify URL category configuration, you can use this command to add the URL filtering rules of a predefined URL category to a user-defined URL category.

You can add URL filtering rules of only one predefined URL category to a user-defined URL category. If you execute this command for a URL category multiple times, the most recent configuration takes effect.

Examples

Add the URL filtering rules of predefined URL category **Pre-Arts** to URL category **news**.

```
<Sysname> system-view
[Sysname] url-filter category news
[Sysname-url-filter-category-news] include pre-defined Pre-Arts
```

referer-whitelist enable

Use **referer-whitelist enable** to enable referer whitelist.

Use **undo referer-white enable** to disable referer whitelist.

Syntax

referer-whitelist enable

undo referer-whitelist enable

Default

Referer whitelist is enabled.

Views

URL filtering policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

The referer whitelist is useful when you want to allow users to access links on the webpages that match the whitelist rules.

If this feature is disabled, the users can visit a webpage when the URL of the webpage matches a whitelist rule, but other links on the accessed webpage are inaccessible. To solve the preceding problem, you can enable this feature. It allows the device to extract the referer header of an HTTP or HTTPS request and compare the referer header with whitelist rules. If a match is found, the device permits the HTTP or HTTPS request to pass through. If no match is found, the device drops the HTTP or HTTPS request.

Examples

Enable referer whitelist in URL filtering policy **news**.

```
<Sysname> system-view
[Sysname] url-filter policy news
[Sysname-url-filter-policy-news] referer-whitelist enable
```

Related commands

add

rename (URL category view)

Use **rename** to rename a URL category.

Syntax

rename *new-name*

Views

URL category view

Predefined user roles

network-admin

context-admin

Parameters

new-name: Specify a new name for the URL category, a case-insensitive string of 1 to 63 characters.

Usage guidelines

If you change the name for a URL category that is used by a URL filtering policy, the URL category name in the policy is also changed.

Examples

Rename URL category **news** to **hello**, and enter the view of URL category **hello**.

```
<Sysname> system-view
[Sysname] url-filter category news
[Sysname-url-filter-category-news] rename hello
[Sysname-url-filter-category-hello]
```

rename (URL filtering policy view)

Use **rename** to rename a URL filtering policy.

Syntax

rename *new-name*

Views

URL filtering policy view

Predefined user roles

network-admin

context-admin

Parameters

new-name: Specify a new name for the URL filtering policy, a case-insensitive string of 1 to 31 characters.

Usage guidelines

If you change the name of a URL filtering policy that has been assigned to a DPI application profile, the policy name in the DPI application profile is also changed.

Examples

Rename URL filtering policy **news** to **hello**, and enter the view of URL filtering policy **hello**.

```
<Sysname> system-view
[Sysname] url-filter policy news
[Sysname-url-filter-policy-news] rename hello
[Sysname-url-filter-policy-hello]
```

reset url-filter statistics

Use **reset url-filter statistics** to clear URL filtering statistics.

Syntax

reset url-filter statistics

Views

User view

Predefined user roles

network-admin

context-admin

Examples

Clear URL filtering statistics.

```
<Sysname> reset url-filter statistics
```

Related commands

display url-filter statistics

rule

Use **rule** to create a URL filtering rule for a user-defined URL category.

Use **undo rule** to delete a URL filtering rule from a user-defined URL category.

Syntax

rule *rule-id* **host** { **regex** *regex* | **text** *string* } [**uri** { **regex** *regex* | **text** *string* }]

undo rule *rule-id*

Default

A user-defined URL category does not have any URL filtering rules.

Views

URL category view

Predefined user roles

network-admin

context-admin

Parameters

rule-id: Assigns an ID to the URL filtering rule, in the range of 1 to 65535.

host: Matches URLs by the hostname field.

uri: Matches URLs by the URI field.

regex *regular-expression*: Specifies a case-sensitive regular expression string pattern. The string can start with only letters, digits, or underscores (_), and it must contain a minimum of three consecutive non-wildcard characters.

- If the **host** keyword is specified, the string can contain 3 to 224 characters.
- If the **uri** keyword is specified, the string can contain 3 to 253 characters.

text *string*: Specifies a case-insensitive text string pattern, which must contain a minimum of three consecutive non-wildcard characters.

- If the **host** keyword is specified, the string can contain 3 to 224 characters. Valid characters are letters, digits, underscores (_), hyphens (-), colons (:), left square brackets ([), right square brackets (]), dots (.), and asterisk (*).
- If the **uri** keyword is specified, the string can contain 3 to 255 characters.

Usage guidelines

A URL filtering rule supports the following URL matching methods:

- **Text-based matching**—Matches the hostname and URI fields of a URL against text string patterns.

  When performing text-based matching for the hostname field of a URL, the device first determines if the text string pattern contains the asterisk (*) wildcard character at the beginning or end.

- If the text string pattern does not contain the asterisk (*) wildcard character at the beginning or end, the hostname matching succeeds if the hostname of the URL matches the text string pattern.
- If the text string pattern contains the asterisk (*) wildcard character at the beginning, the hostname matching succeeds if the hostname of the URL matches or ends with the text string pattern without the wildcard character.
- If the text string pattern contains the asterisk (*) wildcard character at the end, the hostname matching succeeds if the hostname of the URL matches or starts with the text string pattern without the wildcard character.
- If the text string pattern contains the asterisk (*) wildcard character at both the beginning and the end, the hostname matching succeeds if the hostname of the URL matches or includes the text string pattern without the wildcard characters.

Text-based matching for the URI field works in the same way that text-based matching for the hostname field works.

- **Regular expression-based matching**—Matches the hostname and URI fields of a URL against regular expressions. For example, if you set the regular expression for hostname matching to **sina.*cn**, URLs that carry the **news.sina.com.cn** hostname will be matched.

Follow these guidelines when you use the asterisk character (*) in the text string for hostname or URI matching:

- For hostname matching, the asterisk (*) can appear only at the beginning or end of the text string as a wildcard character to match zero or more characters.
- For URI matching, the asterisk (*) can appear at the beginning or end of the text string pattern as a wildcard character to match zero or more characters, or appear in the middle as a non-wildcard character.

When you configure a regular expression in a URL filtering rule, follow these restrictions and guidelines:

- The regular expression pattern can contain a maximum of four branches. For example, **'abc(c|d|e|\x3D)'** is valid, and **'abc(c|onreset|onselect|onchange|style\x3D)'** is invalid.
- Nested braces are not allowed. For example, **'ab((abcs*?))'** is invalid.
- A branch cannot be specified after another branch. For example, **'ab(a|b)(c|d)^\\r\\n]+?'** is invalid.
- A minimum of four non-wildcard characters must exist before an asterisk (*) or question mark (?). For example, **'abc*'** is invalid and **'abcd*DoS\x2d\d{5}\x20\x2bxi\\r\\nJOIN'** is valid.

Examples

In URL category **news**, create a URL filtering rule to match URLs with the host field starting with **sina.com**.

```
<Sysname> system-view
[Sysname] url-filter category news
[Sysname-url-filter-category-news] rule 10 host text sina.com*
```

Related commands

url-filter category

update schedule (automatic URL signature library update configuration view)

Use **update schedule** to configure a schedule for automatic URL signature library update.

Use **undo update schedule** to restore the default.

Syntax

update schedule { **daily** | **weekly** { **fri** | **mon** | **sat** | **sun** | **thu** | **tue** | **wed** } } **start-time** *time* **tingle** *minutes*

undo update schedule

Default

The device starts the URL signature library update at a random time between 01:00:00 and 03:00:00 every day.

Views

Automatic URL signature library update configuration view

Predefined user roles

network-admin

context-admin

Parameters

daily: Updates the URL signature library every day.

weekly: Updates the URL signature library every week.

fri: Updates the URL signature library every Friday.

mon: Updates the URL signature library every Monday.

sat: Updates the URL signature library every Saturday.

sun: Updates the URL signature library every Sunday.

thu: Updates the URL signature library every Thursday.

tue: Updates the URL signature library every Tuesday.

wed: Updates the URL signature library every Wednesday.

start-time *time*: Specifies the start time in hh:mm:ss format. The value range is 00:00:00 to 23:59:59.

tingle *minutes*: Specifies the tolerance time in minutes. The value range is 0 to 120. An automatic library update will occur at a random time between the following time points:

- Start time minus half the tolerance time.
- Start time plus half the tolerance time.

Examples

Configure the device to automatically update the URL signature library every Sunday at a random time between 20:25:00 and 20:35:00.

```
<Sysname> system-view
[Sysname] url-filter signature auto-update
[Sysname-url-filter-autoupdate] update schedule weekly sun start-time 20:30:00 tingle 10
```

Related commands

url-filter signatures auto-update

url-filter apply policy

Use **url-filter apply policy** to apply a URL filtering policy to a DPI application profile.

Use **undo url-filter apply policy** to remove the URL filtering policy from a DPI application profile.

Syntax

url-filter apply policy *policy-name*

undo url-filter apply policy

Default

No URL filtering policy is applied to a DPI application profile.

Views

DPI application profile view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies a URL filtering policy by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A URL filtering policy takes effect only after it is applied to a DPI application profile.

You can apply only one URL filtering policy to a DPI application profile. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Apply URL filtering policy **news** to DPI application profile **abc**.

```
<Sysname> system-view
[Sysname] app-profile abc
[Sysname-app-profile-abc] url-filter apply policy news
```

Related commands

app-profile

display app-profile

display url-filter policy

url-filter cache size

Use **url-filter cache size** to set the URL filtering cache size.

Use **undo url-filter cache size** to restore the default.

Syntax

url-filter cache size *cache-size*

undo url-filter cache size

Default

The URL filtering cache can cache a maximum of 16384 URL entries.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

cache-size: Specifies the cache size in the range of 8192 to 65535.

Usage guidelines

The device caches the URL filtering rules and categories returned from the cloud server. The cached rules can be used directly for subsequent URL filtering.

This command is supported only on the default context. For more information about contexts, see context configuration in *Virtual Technologies Configuration Guide*.

Examples

Set the URL filtering cache size to 20000.

```
<Sysname> system-view
[Sysname] url-filter cache size 20000
```

url-filter cache-time

Use **url-filter cache-time** to set the minimum cache time for a URL filtering rule.

Use **undo url-filter cache-time** to restore the default.

Syntax

url-filter cache-time *value*

undo url-filter cache-time

Default

The minimum cache time of a URL filtering rule is 10 minutes.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies the minimum cache time in minutes. The value range is 10 to 720.

Usage guidelines

Setting the minimum cache time for URL filtering rules ensures that the cached rules will not be deleted during the specified period of time.

When the URL filtering cache is full, the system identifies the cache time of the oldest URL filtering rule to determine whether to overwrite it:

- If the cache time of the rule is equal to or less than the minimum cache time, the system does not delete the rule. The new rule is not cached.
- If the cache time of the rule is greater than the minimum cache time, the system overwrites the rule with the new rule.

This command is supported only on the default context. For more information about contexts, see context configuration in *Virtual Technologies Configuration Guide*.

Examples

Set the minimum cache time to 36 minutes for URL filtering rules.

```
<Sysname> system-view
[Sysname] url-filter cache-time 36
```

url-filter category

Use **url-filter category** to create a user-defined URL category and enter its view, or enter the view of an existing URL category.

Use **undo url-filter category** to delete a URL category.

Syntax

url-filter category *category-name* [**severity** *severity-level*]

undo url-filter category *category-name*

Default

The device has only predefined URL categories with the name prefix **Pre-**.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

category-name: Specify the URL category name, a case-insensitive string of 1 to 63 characters. Valid characters are letters, digits, underscores (_), hyphens (-), and dots (.). The category name cannot start with **Pre-**.

severity *severity-value*: Specifies a severity level for the URL category. The value range is 1000 to 65535, and the default is 65535. The larger the value, the higher the severity level. The severity level of each user-defined URL category must be unique. This option is required when you create a URL category.

Usage guidelines

URL filtering provides the URL categorization feature to facilitate filtering rule management.

You can classify multiple URL filtering rules into a URL category and specify an action for the category. If a matching rule is in multiple URL categories, the system takes the action for the category with the highest severity level.

URL filtering supports the following types of URL categories:

- Predefined URL categories.

  The predefined URL categories contain the predefined URL filtering rules. Each predefined URL category has a unique severity level in the range of 1 to 999, and a category name that begins with **Pre**-. Predefined URL categories cannot be modified.

- User-defined URL categories.

  You can create user-defined URL categories and configure filtering rules for them. The severity level of a user-defined URL category is in the range of 1000 to 65535. You can edit the filtering rules and change the severity level for a user-defined URL category.

Examples

Create a URL category named **news** and set its severity level to 2000.

```
<Sysname> system-view
[Sysname] url-filter category news severity 2000
```

```
[Sysname-url-filter-category-news]
```

Related commands

display url-filter category

url-filter copy category

Use **url-filter copy policy** to copy a URL category.

Syntax

url-filter copy category *old-name new-name* **severity** *severity-level*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

old-name: Specifies the name of the URL category to be copied. The specified URL category must already exist.

new-name: Specifies a name for the new URL category. The name is a case-insensitive string of 1 to 63 characters and cannot begin with **Pre**.

severity *severity-level*: Assigns a unique severity level to the new URL category. The value range is 1000 to 65535. The larger the value, the higher the severity level.

Usage guidelines

This command allows you to create a new URL category by copying an existing one.

The device supports copying only user-defined URL categories.

Examples

Create URL category **test** by copying URL category **news**.

```
<Sysname> system-view
[Sysname] url-filter copy category news test severity 1001
[Sysname-url-filter-category-test]
```

Related commands

url-filter category

url-filter copy policy

Use **url-filter copy policy** to copy a URL filtering policy.

Syntax

url-filter copy policy *old-name new-name*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

old-name: Specifies the name of the URL filtering policy to be copied, a case-insensitive string of 1 to 31 characters.

new-name: Specifies a name for the new URL filtering policy, a case-insensitive string of 1 to 31 characters.

Usage guidelines

This command allows you to create a new URL filtering policy by copying an existing one.

Examples

Create two URL filtering policies by copying URL filtering policy **news**.

```
<Sysname> system-view
[Sysname] url-filter copy policy news news1
[Sysname-url-filter-policy-news_1] quit
[Sysname] url-filter copy policy news new2
[Sysname-url-filter-policy-news_2] quit
```

Related commands

url-filter policy

url-filter log directory root

Use **url-filter log directory root** to configure URL filtering to log only access to resources in the root directories of websites.

Use **undo url-filter log directory root** to restore the default.

Syntax

url-filter log directory root

undo url-filter log directory root

Default

URL filtering logs access to Web resources in all directories.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

After this command is configured, the **url-filter log except pre-defined** and **url-filter log except user-defined** commands become invalid.

Examples

Configure URL filtering to log only access to resources in the root directories of websites.

```
<Sysname> system-view
[Sysname] url-filter log directory root
```

Related commands

category action logging

default-action logging

url-filter log except pre-defined

url-filter log except user-defined

url-filter log enable

Use **url-filter log enable** to enable DPI engine logging.

Use **undo url-filter log enable** to disable DPI engine logging.

Syntax

url-filter log enable

undo url-filter log enable

Default

DPI engine logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

You can enable DPI engine logging for audit. Log messages generated by DPI engine are output to the device information center. The information center then sends the messages to designated destinations based on log output rules. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

DPI engine logging is memory intensive. To guarantee system performance, enable DPI engine logging only when necessary.

Examples

Enable DPI engine logging.

```
<Sysname> system-view
[Sysname] url-filter log enable
```

url-filter log except pre-defined

Use **url-filter log except pre-defined** to disable URL filtering logging for access to resources of a predefined resource type.

Use **undo url-filter log except pre-defined** to enable URL filtering logging for access to resources of a predefined resource type.

Syntax

url-filter log except pre-defined { **css** | **gif** | **ico** | **jpg** | **js** | **png** | **swf** | **xml** }

undo url-filter log except pre-defined { **css** | **gif** | **ico** | **jpg** | **js** | **png** | **swf** | **xml** }

Default

URL filtering does not log access to resources of the predefined resource types (CSS, GIF, ICO, JPG, JS, PNG, SWF, and XML resources).

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

`css`: Specifies the CSS resource type.

`gif`: Specifies the GIF resource type.

`ico`: Specifies the ICO resource type.

`jpg`: Specifies the JPG resource type.

`js`: Specifies the JS resource type.

`png`: Specifies the PNG resource type.

`swf`: Specifies the SWF resource type.

`xml`: Specifies the XML resource type.

Usage guidelines

Repeat this command to disable URL filtering logging for access to multiple types of predefined resources.

This command does not take effect if the **`url-filter log directory root`** command is configured. To validate this command, you must execute **`undo url-filter log directory root`** command.

Examples

Disable URL filtering logging for access to CSS resources.

```
<Sysname> system-view
[Sysname] url-filter log except pre-defined css
```

Related commands

`category action logging`

`default-action logging`

`url-filter log directory root`

`url-filter log except user-defined`

url-filter log except user-defined

Use **`url-filter log except user-defined`** to disable URL filtering logging for access to resources of a user-defined resource type.

Use **`undo url-filter log except user-defined`** to enable URL filtering logging for access to resources of a user-defined resource type.

Syntax

`url-filter log except user-defined` *`text`*

undo url-filter log except user-defined [*text*]

Default

URL filtering logs access to all resources except for resources of the predefined types.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a Web resource type. The value is a case-insensitive string of 1 to 63 characters.

Usage guidelines

Repeat this command to disable URL logging for access to multiple types of user-defined resources.

This command does not take effect if the **url-filter log directory root** command is configured. To validate this command, you must execute **undo url-filter log directory root** command.

Executing the **undo url-filter log except user-defined** command without the *text* parameter enables URL logging for access to all resources except resources of the predefined resource types.

Examples

Disable URL filtering logging for access to HTML resources.

```
<Sysname> system-view
[Sysname] url-filter log except user-defined html
```

Related commands

url-filter policy

Use **url-filter policy** to create a URL filtering policy and enter its view, or enter the view of an existing URL filtering policy.

Use **undo url-filter policy** to delete a URL filtering policy.

Syntax

url-filter policy *policy-name*

undo url-filter policy *policy-name*

Default

No URL filtering policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Assigns a name to the URL filtering policy, a case-insensitive string of 1 to 31 characters.

Usage guidelines

In a URL filtering policy, you can specify an action for each URL category. You can also use the **default action** command to specify the default action for packets that do not match any URL filtering rules in the policy.

A URL filtering policy takes effect only after it is applied to a DPI application profile. For information about DPI application profiles, see *DPI Configuration Guide*.

Examples

Create a URL filtering policy named **news** and enter its view.

```
<Sysname> system-view
[Sysname] url-filter policy news
[Sysname-url-filter-policy-news]
```

url-filter signature auto-update

Use **url-filter signature auto-update** to enable automatic URL signature library update and enter automatic URL signature library update configuration view.

Use **undo url-filter signature auto-update** to disable automatic URL signature library update.

Syntax

url-filter signature auto-update

undo url-filter signature auto-update

Default

Automatic URL signature library update is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The automatic update enables the device to periodically access the company's website to download the latest URL filtering signatures and update the local signature library.

You can schedule the time for automatic signature update by using the **update schedule** command.

Examples

Enable automatic URL signature library update and enter automatic URL signature library update configuration view.

```
<Sysname> system-view
[Sysname] url-filter signature auto-update
[Sysname-url-filter-autoupdate]
```

Related commands

update schedule

url-filter signature auto-update-now

Use **url-filter signature auto-update-now** to trigger an automatic URL signature library update manually.

Syntax

url-filter signature auto-update-now

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command immediately starts the automatic signature library update process. The device accesses the company's website to update the local URL signature library.

You can execute this command anytime you find a new version of signature library on the company's website.

Examples

Trigger an automatic URL signature library update manually.

```
<Sysname> system-view
[Sysname] url-filter signature auto-update-now
```

url-filter signature rollback

Use **url-filter signature rollback** to roll back the URL signature library.

Syntax

url-filter signature rollback { **factory** | **last** }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

factory: Rolls back the URL signature library to the factory default version.

last: Rolls back the URL signature library to the previous version.

Usage guidelines

If a URL signature library update causes exceptions or a high false alarm rate, you can roll back the URL signature library.

Before rolling back the URL signature library, the device backs up the current signature library as the "previous version." For example, the previous library version is V1 and the current library version is V2. If you perform a rollback to the previous version, library version V1 becomes the current version and library version V2 becomes the previous version. If you perform a rollback to the previous version again, the library rolls back to library version V2.

Examples

Roll back the URL signature library to the previous version.

```
<Sysname> system-view
[Sysname] url-filter signature rollback last
```

url-filter signature update

Use **`url-filter signature update`** to manually update the URL signature library.

Syntax

`url-filter signature update` *`file-path`*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

`file-path`: Specifies the URL filtering signature file path, a string of 1 to 255 characters.

Usage guidelines

△ **CAUTION:**

Select a signature file according to the memory size and software version of the device. NSFOCUS provides signature files separately for high-memory (equal to or higher than 8 GB) and low-memory (lower than 8 GB) devices and for different software versions. If you use a signature file applicable to high-memory devices to update the URL filtering signature library on a low-memory device, exceptions might occur on the low-memory device. As a best practice, use a signature file that is compatible with the software version and memory size of the device to update the URL filtering signature library on the device.

If the device cannot access the company's website, use one of the following methods to manually update the URL signature library:

- **Local update**—Updates the URL signature library on the device by using the locally stored update URL filtering signature file.

  Store the update file on the master device for successful signature library update.

  The following describes the format of the *`file-path`* parameter for different update scenarios.

Update scenario	Format of *file-path*	Remarks
The update file is stored in the current working directory.	*filename*	To display the current working directory, use the **pwd** command (see file system management in *Fundamentals Command Reference)*.
The update file is stored in a different directory on the same storage medium.	*filename*	Before updating the signature library, you must first use the **cd** command to open the directory where the file is stored. For information about the **cd** command, see file system management in *Fundamentals Command Reference.*
The update file is stored on a different storage medium.	*path/filename*	Before updating the signature library, you must first use the **cd** command to open the root directory of the storage medium where the file is stored. For information about the **cd** command, see file system management in *Fundamentals Command Reference.*

- **FTP/TFTP update**—Updates the URL signature library on the device by using the file stored on the FTP or TFTP server.

  The following describes the format of the *file-path* parameter for different update scenarios.

Update scenario	Format of *file-path*	Remarks
The update file is stored on an FTP server.	*ftp://username:password@ server address/filename*	The *username* parameter represents the FTP login username. The *password* parameter represents the FTP login password. The *server address* parameter represents the IP address or host name of the FTP server. Replace the following special characters in the FTP login username and password with their respective escape characters: • **Colon (:)**—%3A or %3a. • **At sign (@)**—%40. • **Forward slash (/)**—%2F or %2f.
The update file is stored on a TFTP server.	*tftp://server address/filename*	The *server address* parameter represents the IP address or host name of the TFTP server.

NOTE:

To update the signature library successfully, make sure the device and the FTP or TFTP server can reach each other. If you specify the FTP or TFTP server by its host name, you must also make sure the device can resolve the host name into an IP address through static or dynamic DNS. For more information about DNS, see *Layer 3—IP Services Configuration Guide*.

Examples

Manually update the local URL signature library by using a signature file stored on a TFTP server.

```
<Sysname> system-view
[Sysname] url-filter signature update tftp://192.168.0.10/url-filter-1.0.2-en.dat
```

Manually update the local URL signature library by using a signature file stored on an FTP server. The FTP login username and password are **user:123** and **user@abc/123**, respectively.

```
<Sysname> system-view
[Sysname] url-filter signature update
ftp://user%3A123:user%40abc%2F123@192.168.0.10/url-filter-1.0.2-en.dat
```

Manually update the local URL signature library by using a signature file stored on the device. The file is stored in directory **cfa0:/url-filter-1.0.23-en.dat**, and the current working directory is **cfa0:**.

```
<Sysname> system-view
[Sysname] url-filter signature update url-filter-1.0.23-en.dat
```

Manually update the local URL signature library by using a signature file stored on the device. The file is stored in directory **cfa0:/dpi/url-filter-1.0.23-en.dat**, and the current working directory is **cfa0:**.

```
<Sysname> cd dpi
<Sysname> system-view
[Sysname] url-filter signature update url-filter-1.0.23-en.dat
```

Manually update the local URL signature library by using a signature file stored on the device. The file is stored in directory **cfb0:/dpi/url-filter-1.0.23-en.dat**, and the current working directory is **cfa0:**.

```
<Sysname> cd cfb0:/
<Sysname> system-view
[Sysname] url-filter signature update dpi/url-filter-1.0.23-en.dat
```

whitelist-only enable

Use **whitelist-only enable** to enable URL whitelist-only filtering.

Use **undo whitelist-only enable** to disable URL whitelist-only filtering.

Syntax

whitelist-only enable

undo whitelist-only enable

Default

URL whitelist-only filtering is disabled.

Views

URL filtering policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature allows only the HTTP or HTTPS requests that match the whitelist rules to pass through, and the other settings in the URL filtering policy will not take effect.

Examples

Enable URL whitelist-only filtering in URL filtering policy **news**.

```
<Sysname> system-view
[Sysname] url-filter policy news
[Sysname-url-filter-policy-news] whitelist-only enable
```

Related commands

add

Contents

Data filtering commands

action

Use **action** to specify actions for a data filtering rule.

Use **undo action** to remove the action setting from a data filtering rule.

Syntax

action { **drop** | **permit** } [**logging**]

undo action

Default

The default action of a data filtering rule is **drop**.

Views

Data filtering rule view

Predefined user roles

network-admin

context-admin

Parameters

drop: Drops the matching packets.

permit: Permits the matching packets to pass.

logging: Logs the matching packets.

Usage guidelines

If a packet matches multiple data filtering rules, the device determines the actions as follows:

- If the matching rules have both the **permit** and **drop** actions, the device takes the **drop** action.
- If the **logging** action is specified for any of the matching rules, the device logs the packet.

Examples

Create data filtering policy **def**.

```
<Sysname> system-view
[Sysname] data-filter policy def
```

Specify action **permit** for data filtering rule **r1** in the policy.

```
[Sysname-data-filter-policy-def] rule r1
[Sysname-data-filter-policy-def-rule-r1] action permit
```

application

Use **application** to specify application layer protocols for a data filtering rule.

Use **undo application** to remove application layer protocols from a data filtering rule.

Syntax

application { **all** | **type** { **ftp** | **http** | **imap** | **nfs** | **pop3** | **rtmp** | **smb** | **smtp** } * }

undo application { **all** | **type** { **ftp** | **http** | **imap** | **nfs** | **pop3** | **rtmp** | **smb** | **smtp** } * }

Default

No application layer protocols are specified for a data filtering rule.

Views

Data filtering rule view

Predefined user roles

network-admin

context-admin

Parameters

all: Specifies all application layer protocols.

type: Specifies specific types of application layer protocols.

ftp: Specifies the FTP protocol.

http: Specifies the HTTP protocol.

imap Specifies the IMAP protocol.

nfs Specifies the NFS protocol. Only NFSv3 is supported.

pop3 Specifies the POP3 protocol.

rtmp Specifies the RTMP protocol.

smb Specifies the SMB protocol. Only SMBv1 and SMBv2 are supported.

smtp: Specifies the SMTP protocol.

Usage guidelines

Use this command to specify the application layer protocols to which a data filtering rule applies.

Examples

Create data filtering policy **def**.

```
<Sysname> system-view
[Sysname] data-filter policy def
```

Specify the HTTP protocol for data filtering rule **r1** in the policy.

```
[Sysname-data-filter-policy-def] rule r1
[Sysname-data-filter-policy-def-rule-r1] application type http
```

data-filter apply policy

Use **data-filter apply policy** to apply a data filtering policy to a DPI application profile.

Use **undo data-filter apply policy** to remove the data filtering policy from a DPI application profile.

Syntax

data-filter apply policy *policy-name*

undo data-filter apply policy

Default

No data filtering policy is applied to a DPI application profile.

Views

DPI application profile view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies a data filtering policy by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A data filtering policy takes effect only after it is applied to a DPI application profile.

You can apply only one data filtering policy to a DPI application profile. If you execute this command for a DPI application profile multiple times, the most recent configuration takes effect.

Examples

Apply data filtering policy **def** to DPI application profile **abc**.

```
<Sysname> system-view
[Sysname] app-profile abc
[Sysname-app-profile-abc] data-filter apply policy def
```

Related commands

data-filter policy

data-filter keyword-group

Use **data-filter keyword-group** to create a keyword group and enter its view, or enter the view of an existing keyword group.

Use **undo data-filter keyword-group** to delete a keyword group.

Syntax

data-filter keyword-group *keywordgroup-name*

undo data-filter keyword-group *keywordgroup-name*

Default

No keyword groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

keywordgroup-name: Assigns a name to the keyword group, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A keyword group is a group of keyword match patterns. A packet matches a keyword group if it matches a pattern in the group.

Examples

Create a keyword group named **kg1** and enter its view.

```
<Sysname> system-view
[Sysname] data-filter keyword-group kg1
[Sysname-data-filter-keygroup-kg1]
```

data-filter policy

Use **data-filter policy** to create a data filtering policy and enter its view, or enter the view of an existing data filtering policy.

Use **undo data-filter policy** to delete a data filtering policy.

Syntax

data-filter policy *policy-name*

undo data-filter policy *policy-name*

Default

No data filtering policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Assigns a name to the data filtering policy, a case-insensitive string of 1 to 31 characters. Hyphens (-) are not allowed.

Usage guidelines

A data filtering policy can contain a maximum of 32 data filtering rules.

Examples

Create data filtering policy **def** and enter its view.

```
<Sysname> system-view
[Sysname] data-filter policy def
[Sysname-data-filter-policy-def]
```

Related commands

data-filter apply policy

description (data filtering policy view)

Use **description** to configure a description for a data filtering policy.

Use **undo description** to restore the default.

Syntax

description *string*

undo description

Default

A data filtering policy does not have a description.

Views

Data filtering policy view

Predefined user roles

network-admin

context-admin

Parameters

string: Specifies a description, a case-sensitive string of 1 to 255 characters.

Usage guidelines

Use this command to configure descriptions for data filtering policies for easy maintenance.

Examples

Configure the description as **The data filter** for data filtering policy **def**.

```
<Sysname> system-view
[Sysname] data-filter policy def
[Sysname-data-filter-policy-def] description The data filter
```

description (keyword group view)

Use **description** to configure a description for a keyword group.

Use **undo description** to restore the default.

Syntax

description *string*

undo description

Default

A keyword group does not have a description.

Views

Keyword group view

Predefined user roles

network-admin

context-admin

Parameters

string: Specifies a description, a case-sensitive string of 1 to 255 characters.

Usage guidelines

Use this command to configure descriptions for keyword groups for easy maintenance.

Examples

Configure the description as **The data filter keyword group** for keyword group **kg1**.

```
<Sysname> system-view
[Sysname] data-filter keyword-group kg1
[Sysname-data-filter-kgroup-kg1] description The data filter keyword group
```

direction

Use **direction** to specify the traffic direction for a data filtering rule.

Use **undo direction** to restore the default.

Syntax

direction { **both** | **download** | **upload** }

undo direction

Default

A data filtering rule applies to upload traffic.

Views

Data filtering rule view

Predefined user roles

network-admin

context-admin

Parameters

both: Specifies both the upload and download traffic directions.

download: Specifies the download traffic direction.

upload: Specifies the upload traffic direction.

Usage guidelines

Use this command to specify the traffic direction to which a data filtering rule applies.

Examples

Create data filtering policy **def**.

```
<Sysname> system-view
[Sysname] data-filter policy def
```

Specify the **download** traffic direction for data filtering rule **r1** in the policy.

```
[Sysname-data-filter-policy-def] rule r1
[Sysname-data-filter-policy-def-rule-r1] direction download
```

keyword-group

Use **keyword-group** to specify a keyword group for a data filtering rule.

Use **undo keyword-group** to restore the default.

Syntax

keyword-group *keygroup-name*

undo keyword-group

Default

A data filtering rule does not have a keyword group.

Views

Data filtering rule view

Predefined user roles

network-admin

context-admin

Parameters

keygroup-name: Specifies a keyword group by its name, a case-insensitive string of 1 to 31 characters. The specified keyword group must exist on the device.

Usage guidelines

A data filtering rule uses the keyword group to filter packets based on the application layer data.

You can specify only one keyword group for a data filtering rule. If you execute this command for a data filtering rule multiple times, the most recent configuration takes effect.

Examples

Create data filtering policy **def**.

```
<Sysname> system-view
[Sysname] data-filter policy def
```

Specify keyword group **kg1** for data filtering rule **r1** in the policy.

```
[Sysname-data-filter-policy-def] rule r1
[Sysname-data-filter-policy-def-rule-r1] keyword-group kg1
```

Related commands

data-filter keyword-group

pattern

Use **pattern** to configure a pattern for keyword matching.

Use **undo pattern** to delete a pattern.

Syntax

pattern *pattern-name* { **regex** | **text** } *pattern-string*

undo pattern *pattern-name*

Default

A keyword group does not contain any keyword match patterns.

Views

Keyword group view

Predefined user roles

network-admin

context-admin

Parameters

pattern-name: Assigns a name to the match pattern, a case-insensitive string of 1 to 31 characters.

regex *pattern-string*: Specifies a regular expression, a case-sensitive string of 3 to 245 characters. All printable characters are supported. The regular expression must include a minimum of three consecutive non-wildcard characters.

text *pattern-string*: Specifies a case-sensitive string of 3 to 245 characters for exact match. All printable characters are supported.

Usage guidelines

A pattern for keyword matching can be a regular expression or a text string.

A keyword group can contain a maximum of 32 keyword match patterns. A packet matches a keyword group if it matches a pattern in the group.

When you configure a regular expression pattern for keyword matching, follow these restrictions and guidelines:

- The regular expression pattern can contain a maximum of four branches. For example, **'abc(c|d|e|\x3D)'** is valid, and **'abc(c|onreset|onselect|onchange|style\x3D)'** is invalid.
- Nested braces are not allowed. For example, **'ab((abcs*?))'** is invalid.
- A branch cannot be specified after another branch. For example, **'ab(a|b)(c|d)^\\r\\n]+?'** is invalid.
- A minimum of four non-wildcard characters must exist before an asterisk (*) or question mark (?). For example, **'abc*'** is invalid and **'abcd*DoS\x2d\d{5}\x20\x2bxi\\r\\nJOIN'** is valid.

Examples

In keyword group **kg1**, configure a keyword match pattern with regular expression **(?i)^.***__abc.*__.

```
<Sysname> system-view
[Sysname] data-filter keyword-group kg1
[Sysname-data-filter-kgroup-kg1] pattern 1 regex (?i)^.*abc.*
```

pre-defined-pattern

Use **pre-defined-pattern** to enable a predefined pattern in a keyword group.

Use **undo pre-defined-pattern** to disable a predefined pattern in a keyword group.

Syntax

pre-defined-pattern name { **bank-card-number** | **credit-card-number** | **id-card-number** | **phone-number** }

undo pre-defined-pattern name { **bank-card-number** | **credit-card-number** | **id-card-number** | **phone-number** }

Default

No predefined patterns are enabled in a keyword group.

Views

Keyword group view

Predefined user roles

network-admin

context-admin

Parameters

name: Specifies a predefined pattern by its name.

bank-card-number: Specifies the bank card number pattern.

credit-card-number: Specifies the credit card number pattern.

id-card-number: Specifies the ID card number pattern.

phone-number: Specifies the phone number pattern.

Usage guidelines

To match packets that contain phone numbers, bank card numbers, credit card numbers, or ID card numbers in a keyword group, enable the corresponding predefined pattern in the keyword group.

You can execute this command multiple times in a keyword group to enable multiple predefined patterns.

Examples

Enable the phone number predefined pattern in keyword group **kg1** to match packets that contain phone numbers.

```
<Sysname> system-view
[Sysname] data-filter keyword-group kg1
[Sysname-data-filter-kgroup-kg1] pre-defined-pattern name phone-number
```

rule

Use **rule** to create a data filtering rule and enter its view, or enter the view of an existing data filtering rule.

Use **undo rule** to delete a data filtering rule.

Syntax

rule *rule-name*

undo rule *rule-name*

Default

No data filtering rules exist.

Views

Data filtering policy view

Predefined user roles

network-admin

context-admin

Parameters

rule-name: Assigns a name to the data filtering rule, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A data filtering rule contains a set of filtering criteria and the actions for matching packets. The filtering criteria include keyword group, traffic direction, and application layer protocol. The actions include drop, permit, and logging. A packet must match all the filtering criteria for the actions specified for the rule to apply.

Examples

In data filtering policy **def**, create a data filtering rule named **r1** and enter its view.

```
<Sysname> system-view
[Sysname] data-filter policy def
[Sysname-data-filter-policy-def] rule r1
[Sysname-data-filter-policy-def-rule-r1]
```

Contents

File filtering commands

action

Use **action** to specify actions for a file filtering rule.

Use **undo action** to remove the action setting from a file filtering rule.

Syntax

action { **drop** | **permit** } [**logging**]

undo action

Default

The default action of a file filtering rule is **drop**.

Views

File filtering rule view

Predefined user roles

network-admin

context-admin

Parameters

drop: Drops the matching packets.

permit: Permits the matching packets to pass.

logging: Logs the matching packets.

Usage guidelines

If a packet matches only one file filtering rule, the device takes the actions specified for the rule.

If a packet matches multiple file filtering rules, the device determines the actions as follows:

- If the matching rules have both the **permit** and **drop** actions, the device takes the **drop** action.
- If the **logging** action is specified for any of the matching rules, the device logs the packet.

Examples

Create file filtering policy **def**.

```
<Sysname> system-view
[Sysname] file-filter policy def
```

Specify action **permit** for file filtering rule **ch1** in the policy.

```
[Sysname-file-filter-policy-def] rule ch1
[Sysname-file-filter-policy-def-rule-ch1] action permit
```

application

Use **application** to specify application layer protocols for a file filtering rule.

Use **undo application** to remove application layer protocols from a file filtering rule.

Syntax

application { **all** | **type** { **ftp** | **http** | **imap** | **nfs** | **pop3** | **rtmp** | **smb** | **smtp** } * }

undo application { **all** | **type** { **ftp** | **http** | **imap** | **nfs** | **pop3** | **rtmp** | **smb** | **smtp** } * }

Default

No application layer protocols are specified for a file filtering rule.

Views

File filtering rule view

Predefined user roles

network-admin

context-admin

Parameters

all: Specifies all application layer protocols.

type: Specifies specific types of application layer protocols.

ftp: Specifies the FTP protocol.

http: Specifies the HTTP protocol.

imap Specifies the IMAP protocol.

nfs Specifies the NFS protocol. Only NFSv3 is supported.

pop3 Specifies the POP3 protocol.

rtmp Specifies the RTMP protocol.

smb Specifies the SMB protocol. Only SMBv1 and SMBv2 are supported.

smtp: Specifies the SMTP protocol.

Usage guidelines

Use this command to specify the application layer protocols to which a file filtering rule applies.

Examples

Create file filtering policy **def**.

```
<Sysname> system-view
[Sysname] file-filter policy def
```

Specify the HTTP protocol for file filtering rule **ch1** in the policy.

```
[Sysname-file-filter-policy-def] rule ch1
[Sysname-file-filter-policy-def-rule-ch1] application type http
```

description (file filtering policy view)

Use **description** to configure a description for a file filtering policy.

Use **undo description** to restore the default.

Syntax

description *string*

undo description

Default

A file filtering policy does not have a description.

Views

File filtering policy view

Predefined user roles

network-admin

context-admin

Parameters

string: Specifies a description, a case-sensitive string of 1 to 255 characters.

Usage guidelines

Use this command to configure descriptions for file filtering policies for easy maintenance.

Examples

Configure the description as **The file filter** for file filtering policy **def**.

```
<Sysname> system-view
[Sysname] file-filter policy def
[Sysname-file-filter-policy-def] description The file filter
```

Related commands

file-filter policy

description (file type group view)

Use **description** to configure a description for a file type group.

Use **undo description** to restore the default.

Syntax

description *string*

undo description

Default

A file type group does not have a description.

Views

File type group view

Predefined user roles

network-admin

context-admin

Parameters

string: Specifies a description, a case-sensitive string of 1 to 255 characters.

Usage guidelines

Use this command to configure descriptions for file type groups for easy maintenance.

Examples

Configure the description as **def** for file type group **abc**.

```
<Sysname> system-view
```

```
[Sysname] file-filter filetype-group abc
[Sysname-file-filter-fgroup-abc] description def
```

Related commands

file-filter filetype-group

direction

Use **direction** to specify the traffic direction for a file filtering rule.

Use **undo direction** to restore the default.

Syntax

direction { **both** | **download** | **upload** }

undo direction

Default

A file filtering rule applies to upload traffic.

Views

File filtering rule view

Predefined user roles

network-admin

context-admin

Parameters

both: Specifies both the upload and download traffic directions.

download: Specifies the download traffic direction.

upload: Specifies the upload traffic direction.

Usage guidelines

Use this command to specify the traffic direction to which a file filtering rule applies.

For FTP and SMTP, the upload and download directions refer to the upload and download directions of the FTP or SMTP session.

For HTTP, the upload direction refers to HTTP POST requests, and the download direction refers to HTTP GET requests.

Examples

Create file filtering policy **def**.

```
<Sysname> system-view
[Sysname] file-filter policy def
```

Specify the **download** traffic direction for file filtering rule **ch1** in the policy.

```
[Sysname-file-filter-policy-def] rule ch1
[Sysname-file-filter-policy-def-rule-ch1] direction download
```

file-filter apply policy

Use **data-filter apply policy** to apply a file filtering policy to a DPI application profile.

Use **undo data-filter apply policy** to remove the file filtering policy from a DPI application profile.

Syntax

file-filter apply policy *policy-name*

undo file-filter apply policy

Default

No file filtering policy is applied to a DPI application profile.

Views

DPI application profile view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies a file filtering policy by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A file filtering policy takes effect only after it is applied to a DPI application profile.

You can apply only one file filtering policy to a DPI application profile. If you execute this command for a DPI application profile multiple times, the most recent configuration takes effect.

Examples

Apply file filtering policy **def** to DPI application profile **abc**.

```
<Sysname> system-view
[Sysname] app-profile abc
[Sysname-app-profile-abc] file-filter apply policy def
```

Related commands

app-profile

data**-filter policy**

file-filter false-extension action

Use **file-filter false-extension action** to set the action for packets with files carrying false extensions.

Use **undo file-filter false-extension action** to restore the default.

Syntax

file-filter false-extension action { **drop** | **permit** }

undo file-filter false-extension action

Default

The default action is **permit**, which enables the device to determine the packet processing action based on the real file extension.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

drop: Drops the packet.

permit: Permits the packet to pass so the action for the packet can be determined based on the real file extension.

Usage guidelines

A packet might contain files that carry false extensions. For example, a file that carries the .exe file extension might actually be a .txt file.

Use this command to specify the action for packets with files carrying false extensions. To perform file filtering inspection based on the real file extension, set the action to **permit**. To discard such packets directly, set the action to **drop**.

Examples

Set the action to drop for packets with files carrying false extensions.

```
<Sysname> system-view
[Sysname] file-filter false-extension action drop
```

file-filter filetype-group

Use **file-filter filetype-group** to create a file type group and enter its view, or enter the view of an existing file type group.

Use **undo file-filter filetype-group** to delete a file type group.

Syntax

file-filter filetype-group *group-name*

undo file-filter filetype-group *group-name*

Default

No file type groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Assigns a name to the file type group, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A file type group is a group of file type match patterns. A file matches a file type group if it matches a pattern in the group.

Examples

Create a file type group named **fg1** and enter its view.

```
<Sysname> system-view
[Sysname] file-filter filetype-group fg1
[Sysname-file-filter-fgroup-fg1]
```

file-filter policy

Use **file-filter policy** to create a file filtering policy and enter its view, or enter the view of an existing file filtering policy.

Use **undo file-filter policy** to delete a file filtering policy.

Syntax

file-filter policy *policy-name*

undo file-filter policy *policy-name*

Default

No file filtering policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Assigns a name to the file filtering policy, a case-sensitive string of 1 to 31 characters. Hyphens (-) are not allowed.

Usage guidelines

A file filtering policy can contain a maximum of 32 file filtering rules.

Examples

Create file filtering policy **def** and enter its view.

```
<Sysname> system-view
[Sysname] file-filter policy def
[Sysname-file-filter-policy-def]
```

Related commands

file-filter apply policy

filetype-group

Use **filetype-group** to apply a file type group to a file filtering rule.

Use **undo filetype-group** to restore the default.

Syntax

filetype-group *group-name*

undo filetype-group

Default

A file filtering rule does not have a file type group.

Views

File filtering rule view

Predefined user roles

network-admin

context-admin

Parameters

keygroup-name: Specifies a file type group by its name, a case-sensitive string of 1 to 31 characters. The specified file type group must exist on the device.

Usage guidelines

A file filtering rule uses the file type group to filter files based on the file extension.

You can specify only one file type group for a file filtering rule. If you execute this command for a file filtering rule multiple times, the most recent configuration takes effect.

Examples

Create file filtering policy **def**.

```
<Sysname> system-view
[Sysname] file-filter policy def
```

Specify file type group **fg1** for file filtering rule **ch1** in the policy.

```
[Sysname-file-filter-policy-def] rule ch1
[Sysname-file-filter-policy-def-rule-ch1] filetype-group fg1
```

Related commands

file-filter filetype-group

pattern

Use **pattern** to configure a pattern for file type matching.

Use **undo pattern** to delete a pattern.

Syntax

pattern *pattern-name* **text** *pattern-string*

undo pattern *pattern-name*

Default

A file type group does not contain any file type match patterns.

Views

File type group view

Predefined user roles

network-admin

context-admin

Parameters

pattern-name: Assigns a name to the match pattern, a case-insensitive string of 1 to 31 characters.

text *pattern-string*: Specifies a file extension, a case-insensitive string of 1 to 8 characters.

Usage guidelines

File filtering uses file type match patterns to identify files based on the file extension.

A file type group can contain a maximum of 32 file type match patterns. A file matches a file type group if it matches a pattern in the group.

Examples

In file type group **fg1**, configure a file type match pattern to match files that use the **doc** extension.

```
<Sysname> system-view
[Sysname] file-filter filetype-group fg1
[Sysname-file-filter-fgroup-fg1] pattern 1 text doc
```

rule

Use **rule** to create a file filtering rule and enter its view, or enter the view of an existing file filtering rule.

Use **undo rule** to delete a file filtering rule.

Syntax

rule *rule-name*

undo rule *rule-name*

Default

No file filtering rules exist.

Views

File filtering policy view

Predefined user roles

network-admin

context-admin

Parameters

rule-name: Assigns a name to the file filtering rule, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A file filtering rule contains a set of filtering criteria and the actions for matching files. The filtering criteria include file type group, traffic direction, and application layer protocol. The actions include drop, permit, and logging.

A file must match all the filtering criteria for the actions specified for the rule to apply.

A file filtering policy can contain a maximum of 32 filtering rules.

Examples

In file filtering policy **def**, create a file filtering rule named **ch1** and enter its view.

```
<Sysname> system-view
[Sysname] file-filter policy def
[Sysname-file-filter-policy-def]rule ch1
[Sysname-file-filter-policy-def-rule-ch1]
```

Contents

Anti-virus commands

anti-virus apply policy

Use **anti-virus apply policy** to apply an anti-virus policy to a DPI application profile.

Use **undo anti-virus apply policy** to remove the application.

Syntax

anti-virus apply policy *policy-name* **mode** { **alert** | **protect** }

undo anti-virus apply policy

Default

No anti-virus policy is applied to a DPI application profile.

Views

DPI application profile view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies an anti-virus policy by its name, a case-insensitive string of 1 to 63 characters.

mode: Specifies an anti-virus policy mode.

alert: Only logs matching packets.

protect: Takes the action specified in the anti-virus policy on matching packets.

Usage guidelines

An anti-virus policy takes effect only after it is applied to a DPI application profile. You can apply only one anti-virus policy to a DPI application profile. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Apply anti-virus policy **abc** to DPI application profile **sec**. Set the anti-virus policy mode to **protect**.

```
<Sysname> system-view
[Sysname] app-profile sec
[Sysname-app-profile-sec] anti-virus apply policy abc mode protect
```

anti-virus cache min-time

Use **anti-virus cache min-time** to set the minimum cache period for an anti-virus MD5 entry.

Use **undo anti-virus cache min-time** to restore the default.

Syntax

anti-virus cache min-time *value*

undo anti-virus cache min-time

Default

The minimum cache period of an anti-virus MD5 entry is 10 minutes.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies the minimum cache period in minutes. The value range is 10 to 720.

Usage guidelines

When anti-virus cloud query is required, the device performs the following tasks:

1. Creates an MD5 entry in the cache.
2. Submits the MD5 value to the cloud server.
3. Updates the cached MD5 entry with the returned cloud query result.

Setting the minimum cache period for anti-virus MD5 entries ensures that the cached entries will not be overwritten by new entries during the specified period of time.

When the anti-virus cache is full, the system identifies the cache period of the oldest MD5 entry to determine whether to overwrite it with a new entry that requires cloud query:

- If the cache period of the entry is equal to or shorter than the minimum cache period, the system does not delete the entry. The new entry is not cached and cloud query will not be performed.
- If the cache period of the entry is longer than the minimum cache period, the system overwrites it with the new entry and submits the new entry to the cloud server.

After the **anti-virus cache size** command sets a smaller cache size, the system will delete the exceeding oldest entries immediately without checking their minimum cache periods.

Examples

Set the minimum cache period for an anti-virus MD5 entry to 36 minutes.

```
<Sysname> system-view
[Sysname] anti-virus cache min-time 36
```

Related commands

anti-virus cache size

anti-virus cache size

Use **anti-virus cache size** to set the anti-virus cache size.

Use **undo anti-virus cache size** to restore the default.

Syntax

anti-virus cache size *cache-size*

undo anti-virus cache size

Default

The anti-virus cache can cache a maximum of 100000 entries.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

cache-size: Specifies the cache size in the range of 100000 to 200000.

Usage guidelines

The device caches the anti-virus query result returned from the cloud server for subsequent virus detection. The query result identifies whether or not the MD5 value submitted for cloud query is a virus.

If you set a smaller anti-virus cache size, the system will delete the existing oldest entries without checking their minimum cache periods.

Examples

Set the anti-virus cache size to 20000.

```
<Sysname> system-view
[Sysname] anti-virus cache size 200000
```

Related commands

anti-virus cache min-time

anti-virus policy

Use **anti-virus policy** to create an anti-virus policy and enter its view, or enter the view of an existing anti-virus policy.

Use **undo anti-virus policy** to delete an anti-virus policy.

Syntax

anti-virus policy *policy-name*

undo anti-virus policy *policy-name*

Default

An anti-virus policy named **default** exists.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies the anti-virus policy name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

All virus signatures in the virus signature library are available for an anti-virus policy, whether the policy is the default policy or a user-defined policy.

The default anti-virus policy cannot be modified or deleted.

Examples

Create anti-virus policy **abc** and enter its view.

```
<Sysname> system-view
[Sysname] anti-virus policy abc
[Sysname-anti-virus-policy-abc]
```

anti-virus parameter-profile

Use **anti-virus parameter-profile** to specify a parameter profile for an anti-virus action.

Use **undo anti-virus parameter-profile** to remove the parameter profile specified for an anti-virus action.

Syntax

anti-virus { **email** | **logging** | **redirect** } **parameter-profile** *profile-name*

undo anti-virus { **email** | **logging** | **redirect** } **parameter-profile**

Default

No parameter profile is specified for an anti-virus action.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

email: Specifies the email action.

logging: Specifies the logging action.

redirect: Specifies the redirect action.

parameter-profile *parameter-name*: Specifies a parameter profile by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

Before you can specify a parameter profile for an anti-virus action, configure the parameter profile in the DPI engine. For more information, see DPI engine configuration in *DPI Configuration Guide*.

A parameter profile defines the parameters for executing an action. For example, you can configure parameters such as the email server address and email recipients in the email parameter profile, and then apply the profile to the email action.

If no parameter profile is specified for an anti-virus action, or if the specified parameter profile does not exist, the default parameter settings of the action are used.

Examples

Create an email parameter profile named **av1** and specify a plaintext login password (**abc123**) in the parameter profile.

```
<Sysname> system-view
[Sysname] inspect email parameter-profile av1
[Sysname-inspect-email-av1] password simple abc123
[Sysname-inspect-logging-av1] quit
```

Specify parameter profile **av1** for the email action.

```
[Sysname] anti-virus email parameter-profile av1
```

Related commands

inspect email parameter-profile

inspect logging parameter-profile

inspect redirect parameter-profile

anti-virus signature auto-update

Use **anti-virus signature auto-update** to enable automatic virus signature library update and enter automatic virus signature library update configuration view.

Use **undo anti-virus signature auto-update** to disable automatic virus signature library update.

Syntax

anti-virus signature auto-update

undo anti-virus signature auto-update

Default

Automatic virus signature library update is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

To automatically update the virus signature library, make sure the device can access the NSFOCUS website.

Examples

Enable automatic virus signature library update and enter automatic virus signature library update configuration view.

```
<Sysname> system-view
[Sysname] anti-virus signature auto-update
[Sysname-anti-virus-autoupdate]
```

Related commands

update schedule

anti-virus signature auto-update-now

Use **anti-virus signature auto-update-now** to manually trigger an automatic signature library update.

Syntax

anti-virus signature auto-update-now

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

After you execute this command, the device immediately starts the automatic signature library update process whether automatic signature library update is enabled or not. The device automatically backs up the current signature library before overwriting it.

You can execute this command anytime you find a new version of signature library on the NSFOCUS website.

Examples

Manually trigger an automatic signature library update.

```
<Sysname> system-view
[Sysname] anti-virus signature auto-update-now
```

anti-virus signature rollback

Use **anti-virus signature rollback** to roll back the virus signature library.

Syntax

anti-virus signature rollback { **factory** | **last** }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

factory: Rolls back the virus signature library to the factory default version.

last: Rolls back the virus signature library to the previous version.

Usage guidelines

If a virus signature library update causes abnormal situations or a high false alarm rate, you can roll back the virus signature library.

Before performing a virus signature library rollback, the device backs up the current virus signature library as the previous version. For example, the previous version is V1 and the current version is V2. If you perform a rollback to the previous version, version V1 becomes the current version and version V2 becomes the previous version. If you perform a rollback to the previous version again, version V2 becomes the current version and version V1 becomes the previous version.

Examples

Roll back the virus signature library to the previous version.

```
<Sysname> system-view
[Sysname] anti-virus signature rollback last
```

anti-virus signature update

Use **anti-virus signature update** to manually update the virus signature library.

Syntax

anti-virus signature update *file-path*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

file-path: Specifies the virus signature file path, a string of 1 to 255 characters.

Usage guidelines

CAUTION:

The NSFOCUS website provides different signature libraries for devices with different memory sizes and software versions. You must obtain the signature library that is suitable for your device. If your device has a small memory (8 GB or less) but you choose a signature library that is for a large memory (more than 8 GB), the signature update might result in device anomaly.

If the device cannot access the NSFOCUS website, use one of the following methods to manually update the virus signature library:

- **Local update**—Updates the virus signature library by using the locally stored virus signature file.

  Store the update file on the master device for successful signature library update.

  The following table describes the format of the *file-path* argument for different update scenarios.

Update scenario	Format of *file-path*	Remarks
The signature file is stored in the current working directory.	*filename*	To display the current working directory, use the **pwd** command. For information about the **pwd** command, see file system management in *Fundamentals Command Reference*.
The signature file is stored in a different directory on the same storage medium.	*filename*	Before updating the signature library, you must first use the **cd** command to open the directory where the file is stored. For information about the **cd** command, see file system management in *Fundamentals Command Reference*.
The signature file is stored on a different storage medium.	*path/filename*	Before updating the signature library, you must first use the **cd** command to open the root directory of the storage medium where the file is stored. For information about the **cd** command, see file system management in *Fundamentals Command Reference.*

- **FTP/TFTP update**—Updates the virus signature library by using the virus signature file stored on an FTP or TFTP server.

  The following table describes the format of the *file-path* argument for different update scenarios.

Update scenario	Format of *file-path*	Remarks
The signature file is stored on an FTP server.	*ftp://username:password@server/filename*	The *username* argument represents the FTP login username. The *password* argument represents the FTP login password. The *server* argument represents the IP address or host name of the FTP server. If a colon (:), at sign (@), or forward slash (/) exists in the username or password, you must convert it into its escape characters. The escape characters are %3A or %3a for a colon, %40 for an at sign, and %2F or %2f for a forward slash.
The signature file is stored on a TFTP server.	*tftp://server/filename*	The *server* argument represents the IP address or host name of the TFTP server.

NOTE:

To update the signature library successfully, make sure the device and the FTP or TFTP server can reach each other. If you specify the FTP or TFTP server by its host name, you must also make sure the device can resolve the host name into an IP address through static or dynamic DNS. For more information about DNS, see *Layer 3—IP Services Configuration Guide*.

Examples

Manually update the virus signature library by using a virus signature file stored on a TFTP server.

```
<Sysname> system-view
[Sysname] anti-virus signature update tftp://192.168.0.10/av-1.0.2-en.dat
```

Manually update the virus signature library by using a virus signature file stored on an FTP server. The FTP login username and password are **user:123** and **user@abc/123**, respectively.

```
<Sysname> system-view
[Sysname] anti-virus signature update
ftp://user%3A123:user%40abc%2F123@192.168.0.10/av-1.0.2-en.dat
```

Manually update the virus signature library by using a virus signature file stored on the device. The file is stored in directory **cfa0:/av-1.0.23-en.dat**. The current working directory is **cfa0:**.

```
<Sysname> system-view
[Sysname] anti-virus signature update av-1.0.23-en.dat
```

Manually update the virus signature library by using a virus signature file stored on the device. The file is stored in directory **cfa0:/dpi/av-1.0.23-en.dat**. The current working directory is **cfa0:**.

```
<Sysname> cd dpi
<Sysname> system-view
[Sysname] anti-virus signature update av-1.0.23-en.dat
```

Manually update the virus signature library by using a virus signature file stored on the device. The file is stored in directory **cfb0:/dpi/av-1.0.23-en.dat**. The current working directory is the **cfa0:**.

```
<Sysname> cd cfb0:/
<Sysname> system-view
```

```
[Sysname] anti-virus signature update dpi/av-1.0.23-en.dat
```

cloud-query enable

Use **cloud-query enable** to enable MD5 value-based anti-virus cloud query.

Use **undo cloud-query enable** to disable MD5 value-based anti-virus cloud query.

Syntax

cloud-query enable

undo cloud-query enable

Default

MD5 value-based anti-virus cloud query is disabled.

Views

Anti-virus policy view

Predefined user roles

network-admin

context-admin

Usage guidelines

You can enable cloud query in an anti-virus policy. If no virus is found in the file, the device will send the MD5 value of the file to the cloud server for cloud query. The cloud server determines whether the MD5 value is a virus and returns the result to the device so appropriate action can be taken. The anti-virus module will save the result returned from the cloud server to the anti-virus buffer so the virus detection for subsequent packets can be performed locally.

Examples

Enable MD5 value-based anti-virus cloud query in anti-virus policy **news**.

```
<Sysname> system-view
[Sysname] anti-virus policy news
[Sysname-anti-virus-policy-news] cloud-query enable
```

description

Use **description** to configure a description for an anti-virus policy.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

An anti-virus policy does not have a description.

Views

Anti-virus policy view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 255 characters. The description can contain spaces.

Usage guidelines

A description can identify an anti-virus policy or provide details about an anti-virus policy. Policies with descriptions can be easily maintained.

Examples

Configure **"RD Department anti-virus policy"** as the description of anti-virus policy **abc**.

```
<Sysname> system-view
[Sysname] anti-virus policy abc
[Sysname-anti-virus-policy-abc] description "RD Department anti-virus policy"
```

display anti-virus cache

Use **display anti-virus cache** to display anti-virus cache information.

Syntax

display anti-virus cache [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information for all member devices.

Usage guidelines

The anti-virus cache contains the anti-virus query results returned from the cloud server. For anti-virus to cache the cloud query results, cloud query must be enabled in a minimum of one anti-virus policy.

If the file in a flow does not match any rule in the local virus signature library, the device will send the MD5 value of the file to the cloud server for cloud query.

- If the MD5 value matches a virus rule, the result will be cached as an entry on the hit entry list.
- If the MD5 value does not match any virus rule or if it matches a non-virus rule, the result will be cached as an entry on the non-hit entry list.

Examples

Display anti-virus cache information.

```
<Sysname> display anti-virus cache
Slot 1:
Anti-virus cache information:
 Cloud-query state: Disabled
 Total cached non-hit entries: 0
 Total cached hit entries: 0
```

```
Non-hit list min update interval: 0 seconds
Non-hit list max update interval: 0 seconds
Hit list min update interval: 0 seconds
Hit list max update interval: 0 seconds
Last query message sent: 0 seconds ago
Last query result received: 0 seconds ago
```

Table 1 Command output

Field	Description
Cloud-query state	Enabling state of the cloud query.
Total cached non-hit entries	Number of entries on the non-hit entry list.
Total cached hit entries	Number of entries on the hit entry list.
Non-hit list min update interval	Time elapsed since the last update on the non-hit entry list, in seconds.
Non-hit list max update interval	Time elapsed since the first entry was created on the non-hit entry list, in seconds.
Hit list min update interval	Time elapsed since the last update on the hit entry list, in seconds.
Hit list max update interval	Time elapsed since the first entry was created on the hit entry list, in seconds.
Last query message sent	Time elapsed since the last query request was sent, in seconds.
Last query result received	Time elapsed since the last query result was received, in seconds.

Related commands

`cloud-query enable`

display anti-virus signature

Use **`display anti-virus signature`** to display virus signature information.

Syntax

`display anti-virus signature` [[*`signature-id`*] | [**`severity`** { **`critical`** | **`high`** | **`low`** | **`medium`** }]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`signature-id`: Specifies a signature by its ID in the range of 1 to 4294967294. If you do not specify a signature ID, this command displays the total number of virus signatures in the virus signature library.

`severity`: Specifies a severity level of virus signatures.

`critical`: Specifies the critical severity level.

high: Specifies the high severity level.

low: Specifies the low severity level.

medium: Specifies the medium severity level.

Usage guidelines

You can use this command to display the severity level of virus signatures for a better use of the **signature severity enable** command.

Examples

Display information about virus signature 10000001.

```
<Sysname> display anti-virus signature 10000001
Signature ID: 10000001
Name        : Trojan [Downloader].VBS.Agent
Severity    : Medium
```

Table 2 Command output

Field	Description
Signature ID	ID of the virus signature.
Name	Name of the virus signature.
Severity	Severity level of the virus signature: **Low**, **Medium**, **High**, or **Critical**.

Display the total number of virus signatures and the number of virus signatures failed to be deployed from the virus signature library to the DPI engine.

```
<Sysname> display anti-virus signature
 Total count:9206
 failed:0
```

display anti-virus signature family-info

Use **display anti-virus signature family-info** to display virus signature family information.

context-operator

Examples

Display virus signature library information.

```
<Sysname> display anti-virus signature library
Anti-Virus signature library information:
Type      SigVersion         ReleaseTime               Size
Current   1.0.9              Wed Apr 22 09:51:13 2015  976432
Last      -                  -                         -
Factory   1.0.0              Fri Dec 31 16:00:00 1999  20016
```

Table 4 Command output

Field	Description
Type	Version type of the virus signature library: • **Current**—Current version. • **Last**—Previous version. • **Factory**—Factory default version.
SigVersion	Version number of the virus signature library.
ReleaseTime	Release time of the virus signature library.
Size	Size of the virus signature library in bytes.

display anti-virus statistics

Use **display anti-virus statistics** to display anti-virus statistics.

Syntax

display anti-virus statistics [**policy** *policy-name*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

policy *policy-name*: Specifies an anti-virus policy by its name, a case-insensitive string of 1 to 63 characters. If you do not specify an anti-virus policy, this command displays anti-virus statistics for all anti-virus policies.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays anti-virus statistics for all member devices.

Examples

Display anti-virus statistics for slot 4.

```
<Sysname> display anti-virus statistics slot 4 cpu 1
CPU 1 on slot 4:
Total Block:    0
Total Redirect: 0
Total Alert:    0
Type           http      ftp       smtp      pop3      imap
Block           0         0         0         0         0
Redirect        0         0         0         0         0
Alert+Permit    0         0         0         0         0
```

Table 5 Command output

Field	Description
Total Block	Total number of times that the block action is taken.
Total Redirect	Total number of times that the redirect action is taken.
Total Alert	Total number of times that the alert action is taken.
Type	Action type: • **Block**—Blocks and logs matching packets. • **Redirect**—Redirects matching HTTP connections to a URL and generates logs. • **Alert+Permit**—Permits and logs matching packets.
http	Number of times that the action is taken on HTTP packets.
ftp	Number of times that the action is taken on FTP packets.
smtp	Number of times that the action is taken on SMTP packets.

Field	Description
pop3	Number of times that the action is taken on POP3 packets.
imap	Number of times that the action is taken on IMAP packets.

exception application

Use **exception application** to set an application as an application exception and specify an anti-virus action for the application exception.

Use **undo exception application** to remove an application exception or all application exceptions.

Syntax

exception application *application-name* **action** { **alert** | **block** | **permit** }

undo exception application { *application-name* | **all** }

Default

No application exceptions exist.

Views

Anti-virus policy view

Predefined user roles

network-admin

context-admin

Parameters

application-name: Specifies the application name.

action: Specifies an action for the application exception.

all: Specifies all application exceptions.

alert: Permits and logs matching packets.

block: Blocks and logs matching packets.

permit: Permits matching packets.

Usage guidelines

By default, an anti-virus action is protocol specific and applies to all applications carried by the protocol. To take a different action on an application, you can set the application as an exception and specify a different anti-virus action for the application. Application exceptions use application-specific actions and the other applications use protocol-specific actions. For example, the anti-virus action for HTTP is alert. To block the games carried by HTTP, you can set the games as application exceptions and specify the block action for them.

Examples

Set the **163Email** application as an application exception. Specify alert as the anti-virus action for the application exception.

```
<Sysname> system-view
[Sysname] anti-virus policy abc
[Sysname-anti-virus-policy-abc] exception application 163Email action alert
```

exception md5

Use **exception md5** to set an MD5 value as an MD5 exception.

Use **undo exception md5** to remove an MD5 exception or all MD5 exceptions.

Syntax

exception md5 *md5-value*

undo exception md5 { *md5-value* | **all** }

Default

No MD5 exceptions exist.

Views

Anti-virus policy view

Predefined user roles

network-admin

context-admin

Parameters

md5-value: Specifies an MD5 value.

all: Specifies all MD5 exceptions.

Usage guidelines

If false positives occur for a virus, you can set the MD5 value of the virus as an MD5 exception. The device will permit subsequent packets matching the MD5 exception to pass.

You can get the MD5 value of the virus through the threat log.

Examples

In anti-virus policy abc, set MD5 value **2b9c5137769b613f0ea11bd51c324afc** as an MD5 exception.

```
<Sysname> system-view
[Sysname] anti-virus policy abc
[Sysname-anti-virus-policy-abc] exception md5 2b9c5137769b613f0ea11bd51c324afe
```

exception signature

Use **exception signature** to set a signature as a signature exception.

Use **undo exception signature** to remove a signature exception or all signature exceptions.

Syntax

exception signature *signature-id*

undo exception signature { *signature-id* | **all** }

Default

No signature exceptions exist.

Views

Anti-virus policy view

Predefined user roles

network-admin

context-admin

Parameters

signature-id: Specifies the signature ID in the range of 1 to 4294967292.

all: Specifies all signature exceptions.

Usage guidelines

If a virus proves to be a false alarm, you can set the virus signature as a signature exception. Packets matching the signature exception are permitted to pass.

Examples

Set virus signature 101000 as a signature exception.

```
<Sysname> system-view
[Sysname] anti-virus policy abc
[Sysname-anti-virus-policy-abc] exception signature 101000
```

Related commands

display anti-virus signature

inspect

Use **inspect** to configure anti-virus for an application layer protocol.

Use **undo inspect** to cancel anti-virus for an application layer protocol.

Syntax

inspect { **ftp** | **http** | **imap** | **nfs** | **pop3** | **smb** | **smtp** } **direction** { **both** | **download** | **upload** } [**cache-file-size** *file-size*] **action** { **alert** | **block** | **redirect** }

undo inspect { **ftp** | **http** | **imap** | **nfs** | **pop3** | **smb** | **smtp** }

Default

The device performs virus detection on the following packets:

- Upload and download packets for FTP, HTTP, SMB, NFS, and IMAP.
- Download packets for POP3.
- Upload packets for SMTP.

The anti-virus action for FTP, HTTP, NFS, and SMB is block and for IMAP, SMTP, and POP3 is alert.

The maximum size for the file that can be cached for virus detection is 1 MB.

Views

Anti-virus policy view

Predefined user roles

network-admin

context-admin

Parameters

ftp: Specifies the FTP protocol.

http: Specifies the HTTP protocol.

imap: Specifies the IMAP protocol.

nfs: Specifies the NFS protocol. Only NFSv3 is supported.

pop3: Specifies the POP3 protocol.

smb: Specifies the SMB protocol. Only SMBv1 and SMBv2 are supported.

smtp: Specifies the SMTP protocol.

direction: Specifies the anti-virus detection direction. You cannot specify this keyword for POP3 and SMTP because POP3 supports only **download** and SMTP supports only **upload**.

both: Specifies the upload and download directions.

download: Specifies the download direction.

upload: Specifies the upload direction.

cache-file-size *file-size*: Specifies the size of a file that can be cached for virus detection. The file size is in the range of 1 to 24 MB. Only the HTTP protocol supports this option.

action: Specifies an anti-virus action. The anti-virus action for IMAP can only be **alert**.

alert: Permits and logs matching packets.

block: Blocks and logs matching packets.

redirect: Redirects matching HTTP connections to a URL and generates logs. This keyword is applicable to only uploading connections.

Usage guidelines

After you configure this command, the device performs virus detection on packets from the specified direction for the specified protocol. If viruses are detected, the device takes the specified action on the virus packets.

The **direction** keyword is not available for the POP3 and SMTP protocols because the POP3 protocol supports only the download direction and the SMTP protocol supports only the upload direction.

With the HTTP protocol and the **block** action configured, in addition to blocking and logging matching packets, the device also supports displaying an alarm message on the client browser. A default message is predefined. To configure a user-defined alarm message, you can execute the **import block warning-file** command to import the message from a file. For more information about the warning file, see DPI engine configuration in *DPI Configuration Guide*.

Connections of the protocols that anti-virus supports are all initiated by clients. For connections to be established successfully and anti-virus to function correctly, make sure the security zone or the zone pair is correctly configured. The security zone that the clients reside in must be the source security zone and the security zone that the servers reside in must be the destination security zone.

Examples

Configure anti-virus for HTTP. Specify the direction as download and the anti-virus action as alert.

```
<Sysname> system-view
[Sysname] anti-virus policy abc
[Sysname-anti-virus-policy-abc] inspect http direction download action alert
```

Cancel anti-virus for HTTP.

```
<Sysname> system-view
[Sysname] anti-virus policy abc
[Sysname-anti-virus-policy-abc] undo inspect ftp
```

signature severity enable

Use **signature severity enable** to enable the virus signatures at and above a severity level.

Use **undo signature severity enable** to restore the default.

Syntax

signature severity { **critical** | **high** | **medium** } **enable**

undo signature severity enable

Default

Virus signatures of all severity levels are enabled.

Views

Anti-virus policy view

Predefined user roles

network-admin

context-admin

Parameters

critical: Specifies the critical severity level.

high: Specifies the high severity level.

medium: Specifies the medium severity level.

Usage guidelines

After you configure this command, only the virus signatures at and above the specified severity level take effect.

Examples

Enable the virus signatures at and above the high level.

```
<Sysname> system-view
[Sysname] anti-virus policy abc
[Sysname-anti-virus-policy-abc] signature severity high enable
```

update schedule

Use **update schedule** to schedule the automatic virus signature library update.

Use **undo update schedule** to restore the default.

Syntax

update schedule { **daily** | **weekly** { **mon** | **tue** | **wed** | **thu** | **fri** | **sat** | **sun** } } **start-time** *time* **tingle** *minutes*

undo update schedule

Default

The device starts updating the virus signature library at a random time between 02:01:00 and 04:01:00 every day.

Views

Automatic virus signature library update configuration view

Predefined user roles

network-admin

context-admin

Parameters

daily: Updates the virus signature library every day.

weekly: Updates the virus signature library every week.

mon: Updates the virus signature library every Monday.

tue: Updates the virus signature library every Tuesday.

wed: Updates the virus signature library every Wednesday.

thu: Updates the virus signature library every Thursday.

fri: Updates the virus signature library every Friday.

sat: Updates the virus signature library every Saturday.

sun: Updates the virus signature library every Sunday.

start-time *time*: Specifies the start time in the hh:mm:ss format. The value range is 00:00:00 to 23:59:59.

tingle *minutes*: Specifies the tolerance time in minutes. The value range is 0 to 120. An automatic library update will occur at a random time between the following time points:

- Start time minus half the tolerance time.
- Start time plus half the tolerance time.

Examples

Configure the device to automatically update the virus signature library every Monday at a random time between 20:25:00 and 20:35:00.

```
<Sysname> system-view
[Sysname] anti-virus signature auto-update
[Sysname-anti-virus-autoupdate] update schedule weekly mon start-time 20:30:00 tingle 10
```

Related commands

anti-virus signature auto-update

warning parameter-profile

Use **warning parameter-profile** to apply a warning parameter profile to an anti-virus policy, and enable sending the alarm message defined in the profile.

Use **undo warning parameter-profile** to restore the default.

Syntax

warning parameter-profile *profile-name*

undo warning parameter-profile

Default

No warning parameter profile is applied and the device does not support sending alarm messages.

Views

Anti-virus policy view

Predefined user roles

network-admin

context-admin

Parameters

profile-name: Specifies a warning parameter profile by its name, a case-insensitive string of 1 to 63 characters. Valid characters are letters, digits, underscores (_).

Usage guidelines

If an endpoint user visits a virus-infected website, the device will display an alarm message on the user's browser. The alarm message is stored in the warning parameter profile applied to the policy. For more information about configuring a warning parameter profile, see DPI engine configuration in *DPI Configuration Guide*.

Examples

Apply warning parameter profile **av1** to anti-virus policy **abc** and enable the sending of alarm message defined in the profile.

```
<Sysname> system-view
[Sysname] anti-virus policy abc
[Sysname-anti-virus-policy-abc] warning parameter-profile av1
```

Related commands

inspect warning parameter-profile

Data analysis center commands

dac email-server client-authentication enable

Use **dac email-server client-authentication enable** to enable email client authentication.

Use **undo dac email-server client-authentication enable** to disable email client authentication.

Syntax

dac email-server client-authentication enable

undo dac email-server client-authentication enable

Default

Email client authentication is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Enable email client authentication on the device if the email server (specified by the **dac email-server server-address** command) requires client identity authentication.

For successful email client authentication, you must configure the correct username and password for connecting to the email server.

Examples

Enable email client authentication.

```
<Sysname> system-view
[Sysname] dac email-server client-authentication enable
```

Related commands

dac email-server server-address

dac email-server username

dac email-server password

dac email-server password

Use **dac email-server password** to set the password for connecting to the email server.

Use **unto dac email-server password** to restore the default.

Syntax

dac email-server password { **cipher** | **simple** } *string*

undo dac email-server password

Default

The password for connecting to the email server is not specified.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 63 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

Both the username and password for connecting to the email server are required if email client authentication is enabled.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify **abc123** as the password for connecting to the email server.

```
<Sysname> system-view
[Sysname] dac email-server password simple abc123
```

Related commands

dac email-server client-authentication enable

dac email-server username

Use **dac email-server secure-authentication enable** to enable secure transmission of authentication credentials.

Use **undo dac email-server secure-authentication enable** to disable secure transmission of authentication credentials.

Syntax

dac email-server secure-authentication enable

undo dac email-server secure-authentication enable

Default

Secure transmission of authentication credentials is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command enables the device to transmit email client authentication credentials to the email server over a secure channel.

This command takes effect only after email client authentication is enabled.

Examples

Enable secure transmission of authentication credentials.

```
<Sysname> system-view
[Sysname] dac email-server secure-authentication enable
```

Related commands

dac email-server client-authentication enable

dac email-server sender

Use **dac email-server sender** to specify the email sender address.

Use **undo dac email-server sender** to restore the default.

Syntax

dac email-server sender *address-string*

undo dac email-server sender

Default

The email sender address is not specified.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

address-string: Specifies the email sender address, as case-sensitive string of 3 to 63 characters.

Usage guidelines

The data analysis center (DAC) uses the specified email sender address send emails.

Examples

Specify **mailto:abc@123.com** as the email sender address.

```
<Sysname> system-view
[Sysname] dac email-server sender abc@123.com
```

Related commands

dac email-server server-address

dac email-server server-address

Use **dac email-server server-address** to specify the email server address for the DAC.

Use undo **dac email-server server-address** to restore the default.

Syntax

dac email-server server-address *address-string*

undo dac email-server server-address

Default

No email server is specified for the DAC.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

address-string: Specifies the IP address or host name of the email server. The host name is a case-sensitive string of 3 to 63 characters.

Usage guidelines

The DAC can send emails only after the both email server address and email sender address are configured.

If you specify the host name of the email server, make sure the device can obtain the IP address of the email server through a static or dynamic domain name resolution method. The device must reach the IP address of the email server. For more information about domain name resolution, see DNS configuration in *Layer 3—IP Services*.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify 101.1.1.255 as email server address for the DAC.

```
<Sysname> system-view
[Sysname] dac email-server server-address 101.1.1.225
```

Related commands

Syntax

dac email-server username *username*

undo dac email-server username

Default

The username for connecting to the email server is not specified.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

username: Specifies the username, a case-sensitive string of 1 to 63 characters.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify **admin** as the username for connecting to the email server.

```
<Sysname> system-view
[Sysname] dac email-server username admin
```

Related commands

dac email-server client-authentication enable

dac email-server password

dac log-collect enable

Use **dac log-collect enable** to enable the log collection for a service that is registered to the DAC.

Use **undo dac log-collect enable** to disable the log collection for a service.

Syntax

dac log-collect service *service-type service-name* **enable**

undo dac log-collect service *service-type service-name* **enable**

Default

The log collection status for each service varies by service setting when the service module is registered to the DAC.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

service-type: Specifies the type of a service that is registered to the DAC. The service type name is a case-insensitive string. To view the supported service type, enter a question mark (?) for this argument.

service-name: Specifies the name of a service that is registered to the DAC. The service name is a case-insensitive string. To view the supported service name, enter a question mark (?) for this argument.

Usage guidelines

This command enables the log collection for a specific service. To collect the log messages for the traffic service, first enable the session statistics collection and then enable the log collection.

Repeat this command to enable log collection for multiple services.

Examples

Enable the log collection for the DPI traffic service.

```
<Sysname> system-view
[Sysname] dac log-collet service dpi traffic enable
```

Related commands

display dac log-collect

dac log-display enable

Use **dac log-display enable** to enable the real-time log display.

Use **undo dac log-collect enable** to disable the real-time log display.

Syntax

dac log-display service *service-type service-name* **enable**

undo dac log-display service *service-type service-name* **enable**

Default

The real-time log display for all services is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

service-type: Specifies the type of a service that is registered with the DAC. The service type name is a case-insensitive string. To view the supported service type, enter a question mark (?) for this argument.

service-name: Specifies the name of a service that is registered with the DAC. The service name is a case-insensitive string. To view the supported service name, enter a question mark (?) for this argument.

Usage guidelines

This command for a service takes effect only after the log collection for the service is enabled by the **dac log-collect enable** command.

With this feature enabled, you can see the real-time log messages displayed on the Web interface.

Repeat this command to enable real-time log display for multiple services.

DPI do not support this feature in the current software version.

Examples

Enable the real-time display for system logs.

```
<Sysname> system-view
[Sysname] dac log-display service syslog syslog enable
```

dac report

Use **dac report** to configure the subscription parameters for a report type.

Use **undo dac report** to remove the subscription parameters for a report type.

Syntax

dac report type { **comparison** | **integrated** | **intelligent** | **summary** } **subscriber** *mail-address* [**language** { **chinese** | **english** }]

undo dac report type { **comparison** | **integrated** | **intelligent** | **summary** } [**subscriber** *mail-address*]

Default

No report subscription parameters are configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

comparison: Specifies the comparison report.

integrated: Specifies the integrated report.

intelligent: Specifies the intelligent report.

summary: Specifies the summary report.

subscriber *mail-address*: Specifies the email address of the report subscriber, a case-sensitive string of 3 to 63 characters. If you do not specify a subscriber, the **undo** command removes all subscribers for the specified report type.

language: Specifies a language for the reports. If you do not specify this keyword, Chinese is used in the reports.

chinese: Uses Chinese in the reports.

english: Uses English in the reports.

Usage guidelines

You can configure a maximum of 50 subscribers for each report type.

Examples

Specify **admin@qq.com** and English as the subscriber address and language for the summary report, respectively.

```
<Sysname> system-view
[Sysname] dac report type summary subscriber admin@qq.com language english
```

Remove subscriber address **admin@qq.com** for the summary report.

```
<Sysname> system-view
[Sysname] undo dac report type summary subscriber admin@qq.com
```

Related commands

display dac report

dac report export

Use **dac report export** to configure report export parameters.

Use **undo dac report export** to delete report export parameters.

Syntax

dac report export period { **day** | **hour** | **month** | **quarter** | **week** | **year** } **template** *template-name* [**mail-address** *mail-address*]

undo dac report export period { **day** | **hour** | **month** | **quarter** | **week** | **year** } **template** *template-name* [**mail-address** *mail-address*]

Default

No report export parameters are configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

period: Specifies the type of the periodic report.

day: Specifies the daily report.

hour: Specifies the hourly report.

month: Specifies the monthly report.

quarter: Specifies the quarterly report.

week: Specifies the weekly report.

year: Specifies the annual report.

template *template-name*: Specifies the template name, a case insensitive string of 1 to 63 characters.

mail-address *mail-address*: Specifies the mail address to which the reports are exported. The mail address is a case sensitive string of 3 to 63 characters. If you do not specify this option, the reports are exported to the local device.

Usage guidelines

This command enables the device to periodically export the reports of the specified types.

To export reports of multiple types to multiple mail addresses, repeat this command.

If you do not specify the mail address for the **undo** command, all mail addresses are deleted.

Examples

Configure the device to use template **template1** to export reports to the address www@126.com every week.

```
<Sysname> system-view
[Sysname] dac report export period week template template1 mail-address www@126.com
```

Related commands

display dac report export

dac report export template

dac report export template

Use **dac report export template** to create a report export template and enter its view, or enter the view of an existing report export template.

Use **undo dac report export template** to delete a report export template.

Syntax

dac report export template *template-name*

undo dac report export template *template-name*

Default

No report export template exists.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

template-name: Specifies the name of a report export template. The name is a case insensitive string of 1 to 63 characters.

Usage guidelines

In a report export template, you can define the following items:

- Report language.
- Statistics contents in the report.

Examples

Create a report export template named **template1**, and enter its view.

```
<Sysname> system-view
[Sysname] dac report export template template1
[Sysname-dac-report-export-template-template1]
```

Related commands

display dac report export template

dac storage

Use **dac storage** to configure the data storage limits for a service.

Use **undo dac storage** to restore the default.

Syntax

dac storage service *service-type service-name* **limit** { **hold-time** *time-value* | **usage** *usage-value* | **action** { **delete** | **log-only** } }

undo dac storage service *service-type service-name* **limit** { **hold-time** | **usage** | **action** }

Default

The service data can be saved for a maximum of 365 days.

The data of each service can occupy up to 20% of the total storage space.

If the storage time or storage space usage limit is exceeded, the system deletes the expired or the oldest data.

Views

System view

Predefined user roles

network-admin

Parameters

service-type: Specifies the type of a service that is registered with the DAC. The service type name is a case-insensitive string. To view the supported service type, enter a question mark (?) for this argument.

service-name: Specifies the name of a service that is registered with the DAC. The service name is a case-insensitive string. To view the supported service name, enter a question mark (?) for this argument.

limit: Configures the data storage limits for a service.

hold-time *time-value*: Specifies the storage time limit in days. The value range is 1 to 65535. The storage time limit should be longer than the number of days that the oldest service data has been stored for.

usage *usage-value*: Specifies the percentage of the total storage space the service data can occupy. The value range is 1 to 100. The storage usage limit should be higher than the current storage usage of the service.

action: Specifies the action to take when a data storage limit is exceeded.

delete: Deletes data collected on the oldest dates and generates a log message. The data of the current date cannot be deleted.

log-only: Generates a log message only. When a storage limit is exceeded, old data are not deleted and new data cannot be saved.

Usage guidelines

The DAC periodically checks the data of each service to determine if the storage time or storage space usage limit is exceeded.

- If a storage limit is exceeded and the action is **delete**, the system deletes the expired or the oldest service data. A log will be generated to report the event.
- If a storage limit is exceeded and the action is **log-only**, the system generates a log message. New data will not be saved.

If you execute this command to set the storage time limit for a service multiple times, the most recent configuration takes effect. The same is true for setting the storage space limit or storage limit-violated action for a service. You can view the storage space usage of each service on the Web interface.

This command is supported only on the default context. For more information about contexts, see context configuration in *Virtual Technologies Configuration Guide.*

Examples

Set the storage time limit, storage space limit, and the action to take when the limits are exceeded for the traffic service.

```
<Sysname> system-view
```

```
[Sysname] dac storage service dpi traffic limit hold-time 60
[Sysname] dac storage service dpi traffic limit usage 30
[Sysname] dac storage service dpi traffic limit action delete
```

dac traffic-statistic enable

Use **dac traffic-statistic enable** to enable real-time traffic statistics collection.

Use **undo dac traffic-statistic enable** to disable real-time traffic statistics collection.

Syntax

dac traffic-statistic { **application** | **user** } **enable** [**verbose**]

undo dac traffic-statistic { **application** | **user** } **enable**

Default

The real-time traffic statistics collection is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

application: Collects application traffic statistics in real time.

user: Collects user traffic statistics in real time.

verbose: Collects detailed traffic information in real time. If you do not specify this keyword, this command collects brief traffic information in real time.

Usage guidelines

Enable real-time traffic statistics collection with caution when large-volume service traffic exists. This feature is CPU intensive.

To collect the traffic statistics in real time, you must first enable the session statistics collection. For more information about the collected session statistics, see session management in *Security Configuration Guide*.

The detailed information about user traffic that is collected in real time provides used applications on a per-user basis.

The detailed information about application traffic that is collected in real time provides user information on a per-application basis.

Repeat this command to enable multiple collections of real-time traffic statistics.

Examples

Enable the collection of detailed user traffic statistics in real time.

```
<Sysname> system-view
[Sysname] dac traffic-statistic user enable verbose
```

display dac report

Use **display dac report** to display report subscriber information.

Syntax

display dac report [**comparison** | **integrated** | **intelligent** | **summary**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

comparison: Specifies the comparison report.

integrated: Specifies the integrated report.

intelligent: Specifies the intelligent report.

summary: Specifies the summary report.

Usage guidelines

If you do not specify a report type, this command displays subscriber information for all report types.

Examples

Display subscriber information for all report types.

```
<Sysname> display dac report
Total subscribers:4
Summary subscribers:1
Comparison subscribers:1
Intelligent subscribers:1
Integrated subscribers:1
Report type       Language    Subscriber email
Summary           CH          124@123.com
Comparison        CH          111@123.com
Intelligent       EN          123@123.com
Integrated        EN          112@123.com
```

Table 4 Command output

Field	Description
Total subscribers	Total number of subscribers.
Summary subscribers	Number of subscribers for the summary report.
Comparison subscribers	Number of subscribers for the comparison report.
Intelligent subscribers	Number of subscribers for the intelligent report.
Integrated subscribers	Number of subscribers for the integrated report.
Language	Language used in the reports:

Field	Description
	• **CH**—Chinese. • **EN**—English.
Subscriber email	Email address of a report subscriber.

display dac report export

Use **display dac report export** to display report export configuration.

Syntax

display dac report export

Views

Use **display dac report export template** command to display report export templates.

Syntax

display dac report export template [*template-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

template-name: Specifies the name the report export template. The name is a case insensitive string of 1 to 63 characters. If you do not specify a template name, this command exports all report export templates.

Examples

Display all report export templates.

```
<Sysname> display dac report export template
Template name: template1
  Language:             English
  Export service:       lb-link
    Statistics content: app
    Link name:          lk
  Export service:       lb-vs
    Statistics content: class
    Virtual server:     lkvs
```

Table 6 Command output

Field	Description
Template name	Name of the report export template.
Language	Language used by the report: • Chinese. • English.
Export service	Service that the report is about: • lb-link—Load balancing link. • lb-vs—Load balancing virtual server.
Statistic content	Statistics content.
Link-name	Load balancing link name.
Virtual Server	Load balancing virtual server name.

display dac storage

Use **display dac storage** to display the data storage limit configuration for services.

Syntax

display dac storage [*service-type service-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

service-type: Specifies the type of a service that is registered with the DAC. The service type name is a case-insensitive string. To view the supported service type, enter a question mark (?) for this argument.

service-name: Specifies the name of a service that is registered with the DAC. The service name is a case-insensitive string. To view the supported service name, enter a question mark (?) for this argument.

Usage guidelines

If you do not specify a service, this command displays the data storage limit configuration for all services.

This command is supported only on the default context. For more information about contexts, see context configuration in *Virtual Technologies Configuration Guide*.

Examples

Displays the data storage limit configuration for all services.

```
<Sysname> display dac storage
Total services           :25

Service type     Service name            Time limit (days)       Usage limit
         Action
syslog           cfglog                  365                     20%
         delete
lb               virtualserver           365                     20%
         delete
lb               overviewvs              365                     20%
         delete
sandbox          log                     365                     20%
---- More ----
```

Table 7 Command output

Field	Description
Total services	Total number of services.
Time limit	Storage time limit in days.
Usage limit	Storage space usage limit in percentage.
Action	Action to take when the storage time limit or space limit is exceed.

Field	Description
	• **delete**—Delete the oldest data, and generates a log message. • **log-only**—Generate a log message only.

display dac traffic-statistic

Use **display dac traffic-statistic** to display the configuration of the real-time traffic statistics collection.

Syntax

display dac traffic-statistic [**application** | **user**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

application: Specifies the collection of the real-time application traffic statistics.

user: Specifies the collection of the real-time user traffic statistics.

Usage guidelines

If you do not specify any keyword, this command displays the configuration of the collection for all real-time traffic statistics.

Examples

Displays the configuration of the real-time user traffic statistics collection.

```
<Sysname> system-view
[Sysname] display dac traffic-statistic user
Slot 1:
Type               Status
User               Enabled (verbose)
```

Table 8 Command output

Field	Description
Type	Type of traffic collected in real time: • **Application**. • **User**.
Status	Status of the real-time traffic statistics collection: • **Disabled**—This feature is disabled. • **Enabled (brief)**—This feature is enabled, and the DAC collects brief traffic information. • **Enabled (verbose)**—This feature is enabled, and the DAC collects detailed traffic information.

Related commands

dac traffic-statistic enable

export-service

Use **export-service** to create the statistics report view of a service and enter the view.

Use **undo export-service** to delete the configuration in the specified statistics report view.

Syntax

export-service { **lb-link** | **lb-virtual-server** }

undo export-service { **lb-link** | **lb-virtual-server** }

Views

Report export template view

Predefined user roles

network-admin

context-admin

Parameters

lb-link: Specifies the LB link statistics.

lb-virtual-server: Specifies the LB virtual server statistics.

Usage guidelines

In the report view of a service, you can specify the statistics contents to be included in the report.

Examples

In report export template **template1**, enter the LB link statistics report view.

```
<Sysname> system-view
[Sysname] dac report export template template1
[Sysname-dac-template-template1] export-service lb-link
[Sysname-dac-template-template1-service-lblink]
```

Related commands

statistics virtual-server

language

Use **language** to specify the language used in exported reports.

Use **undo language** to restore the default.

Syntax

language { **chinese** | **english** }

undo language

Default

Chinese is used.

Views

Report export template view

Predefined user roles

network-admin

context-admin

Parameters

chinese: Specifies Chinese.

english: Specifies English.

Examples

In report export template **template1**, specify English as the language used in exported reports.

```
<Sysname> system-view
[Sysname] dac report export template template1
[Sysname-dac-template-template1] language english
```

statistics content (LB link statistics report view)

Use **statistics content** to specify the contents for the LB link statistics report.

Use **undo statistics content** to delete contents from the LB link statistics report.

Syntax

statistics content { abnormal-flow | app | connection-count | connection-rate | delay | packetloss | stability } *

undo statistics content { abnormal-flow | app | connection-count | connection-rate | delay | packetloss | stability } *

Default

No content is specified for the LB link statistics report.

Views

LB link statistics report view

Predefined user roles

network-admin

context-admin

Parameters

abnormal: Specifies abnormal traffic statistics.

app: Specifies application statistics.

connection-count: Specifies the connection count statistics.

connection-rate: Specifies the connection rate statistics.

delay: Specifies the delay statistics.

packetloss: Specifies the packet loss statistics.

stability: Specifies link state statistics.

Usage guidelines

This command is required for LB link statistics reports. If no contents are specified, no LB link statistics reports will be exported.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

In LB link statistics report view, specify the application statistics as the report content.

```
<Sysname> system-view
[Sysname] dac report export template template1
[Sysname-dac-template-template1] export-service lb-link
[Sysname-dac-template-template1-service-lblink] statistics content app
```

statistics content (LB virtual server statistics report view)

Use **statistics content** to specify the content for the LB virtual link statistics report.

Use **undo statistics content** to delete content from the LB virtual server statistics report.

Syntax

statistics content class

undo statistics content class

Default

No content is specified for the LB virtual server statistics report.

Views

LB virtual server statistics report view

Predefined user roles

network-admin

context-admin

Parameters

class: Specify the LB class. The report contains the packet matching statistics for LB classes.

Usage guidelines

This command is required for LB virtual server statistics reports. If no content is specified, no LB virtual server statistics reports will be exported.

Examples

In LB virtual server statistics report view, specify the LB classes as the content in LB virtual server statistics report.

```
<Sysname> system-view
[Sysname] dac report export template template1
[Sysname-dac-template-template1] export-service lb-virtual-server
[Sysname-dac-template-template1-service-lbvs] statistics content class
```

statistics link

Use **statistics link** to specify an LB link for the LB link statistics report.

Use **undo statistics link** to delete an LB link from the LB link statistics report.

Syntax

statistics link *name*

undo statistics link *name*

Default

No LB link is specified for the LB link statistics report.

Views

LB link statistics report view

Predefined user roles

network-admin

context-admin

Parameters

Name: Specifies the name of an LB link, a case insensitive string of 1 to 63 characters.

Usage guidelines

This command allows the DAC to export statistics report for the specified LB links.

Repeat this command to specify multiple object links.

Examples

In LB link statistics report view, specify **link1** and **link2** as the statistics objects.

```
<Sysname> system-view
[Sysname] dac report export template template1
[Sysname-dac-template-template1] export-service lb-link
[Sysname-dac-template-template1-service-lblink] statistics link link1
[Sysname-dac-template-template1-service-lblink] statistics link link2
```

Related commands

statistics content (LB link statistics report view)

statistics virtual-server

Contents

Proxy policy commands

action

Use **action** to set the action for traffic matching a proxy policy rule.

Use **undo action** to restore the default.

Syntax

action { **no-proxy** | **ssl-decrypt** | **tcp-proxy** }

undo action

Default

The no-proxy action is used.

Views

Proxy policy rule view

Predefined user roles

network-admin

context-admin

Parameters

no-proxy: Specifies the no-proxy action.

ssl-decrypt: Specifies the SSL decryption action.

tcp-proxy: Specifies the TCP proxy action.

Usage guidelines

The device supports the following actions for traffic matching a proxy policy rule:

- **No-proxy**—The device directly transmits the traffic without TCP or SSL proxy.
- **SSL-decryption**—The device acts as an SSL proxy to decrypt the SSL traffic and performs deep packet inspection and Layer 7 load balancing on the decrypted traffic. SSL decryption is implemented based on TCP proxy.
- **TCP-proxy**—The device acts as a TCP proxy and provides TCP-layer isolation between the TCP client and TCP server to effectively intercept malicious connections and attacks.

If you execute this command for a proxy policy rule multiple times, the most recent configuration takes effect.

Examples

Specify the **ssl-decrypt** action for proxy policy rule **rule1**.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule 1 name rule1
[Sysname-app-proxy-policy-0-rule1] action ssl-decrypt
```

Related commands

display app-proxy-policy

rule

app-proxy internal-server-certificate delete

Use **app-proxy internal-server-certificate delete** to delete an internal server certificate.

Syntax

app-proxy internal-server-certificate delete md5 *md5-value*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

md5 *md5-value*: Specifies the MD5 value of an internal server certificate.

Usage guidelines

When an internal server certificate expires or an internal server does not need to be protected, you can execute this command to delete the imported internal server certificate.

You can execute the **display app-proxy imported internal-server-certificate** command to view the MD5 values of the internal server certificates.

Examples

Delete the internal server certificate with the MD5 value **c4f5f2c41ca1de4258d893c9887bf287**.

```
<Sysname> system-view
[Sysname] app-proxy internal-server-certificate delete md5
c4f5f2c41ca1de4258d893c9887bf287
```

Related commands

display app-proxy imported internal-server-certificate

app-proxy internal-server-certificate import

Use **app-proxy internal-server-certificate import** to import an internal server certificate.

Syntax

app-proxy internal-server-certificate import { **p12** | **pem** } **filename** *filename*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

p12: Specifies the PKCS#12 certificate file format.

pem: Specifies the PEM certificate file format.

filename *filename*: Specifies the certificate file name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

The internal server certificates are required in the scenario of protecting internal servers. With an internal server certificate imported, the device will decrypt the certificate and generate a CER file and a key file. The CER file is used to identify the server and the key file is used to encrypt and decrypt the packets in the subsequent SSL proxy process. The device will calculate the MD5 value of the CER file and use the MD5 value as the unique identifier of the file.

The SSL proxy process is as follows:

1. The device receives an internal server certificate and calculates the MD5 value of the certificate.
2. The device compares the calculated MD5 value with the MD5 value of the imported internal server certificate:
   - If they are the same, the certificate is trusted and the device will use the certificate to establish an SSL connection with the client.
   - If they are different, the certificate is untrusted.

You can import multiple internal server certificates. If two certificates have the same MD5 value, the new certificate will overwrite the old certificate.

Examples

Import a PKCS#12 certificate file as an internal server certificate.

```
<Sysname> system-view
[Sysname] app-proxy internal-server-certificate import p12 filename server.p12
Password:
```

Related commands

display app-proxy imported internal-server-certificate

app-proxy ssl whitelist activate

Use **app-proxy ssl whitelist activate** to activate SSL proxy whitelist settings.

Syntax

app-proxy ssl whitelist activate

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The following SSL proxy whitelist settings must be manually activated by using this command:

- Adding or removing hostnames to or from the user-defined SSL hostname whitelist.
- Enabling or disabling hostnames on the predefined SSL hostname whitelist.

This command is supported only on the default context. For more information about contexts, see context configuration in *Virtual Technologies Configuration Guide.*

Examples

Add **example.com** to the user-defined SSL hostname whitelist and activate the setting.

```
<Sysname> system-view
[Sysname] app-proxy ssl whitelist user-defined-hostname example.com
To activate the setting, execute app-proxy ssl whitelist activate.
[Sysname] app-proxy ssl whitelist activate
```

Related commands

app-proxy ssl whitelist predefined-hostname enable

app-proxy ssl whitelist user-defined-hostname

app-proxy ssl whitelist predefined-hostname enable

Use **app-proxy ssl whitelist predefined-hostname enable** to enable hostnames on the predefined SSL hostname whitelist.

Use **undo app-proxy ssl whitelist predefined-hostname enable** to disable hostnames on the predefined SSL hostname whitelist.

Syntax

app-proxy ssl whitelist predefined-hostname { **chrome-hsts** [*hostname*] | *hostname* } **enable**

undo app-proxy ssl whitelist predefined-hostname { **chrome-hsts** [*hostname*] | *hostname* } **enable**

Default

The entire predefined SSL hostname whitelist is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

chrome-hsts [*hostname*]: Specifies a hostname on the Chrome HSTS list. The *hostname* argument represents the hostname, a case-insensitive string of 1 to 63 characters. If the hostname contains spaces, enclose it in double quotation marks. For example, **"user for test"**. If you do not specify a hostname, this command applies to all hostnames on the Chrome HSTS list.

host-name: Specifies a hostname that is not on the Chrome HSTS list. The hostname is a case-insensitive string of 1 to 63 characters. If the hostname contains spaces, enclose it in double quotation marks. For example, **"user for test"**.

Usage guidelines

The Chrome HSTS list is a predefined list of server hostnames that are accessible to Web browsers only through HTTPS.

Follow these guidelines to enable or disable hostnames on the Chrome HSTS list:

- When the entire Chrome HSTS list is enabled, you can disable individual hostnames on the list.
- When the entire Chrome HSTS list is disabled, all hostnames on the list are disabled and cannot be enabled individually.

This command is supported only on the default context. For more information about contexts, see context configuration in *Virtual Technologies Configuration Guide.*

Examples

Disable the entire Chrome HSTS list.

```
<Sysname> system-view
[Sysname] undo app-proxy ssl whitelist predefined-hostname chrome-hsts enable
To activate the setting, execute app-proxy ssl whitelist activate.
```

Disable hostname **12306.cn** on the predefined SSL hostname whitelist.

```
<Sysname> system-view
[Sysname] undo app-proxy ssl whitelist predefined-hostname 12306.cn enable
To activate the setting, execute app-proxy ssl whitelist activate.
```

Related commands

app-proxy ssl whitelist activate

display app-proxy ssl whitelist

app-proxy ssl whitelist user-defined-hostname

Use **app-proxy ssl whitelist user-defined-hostname host-name** to add a hostname to the user-defined SSL hostname whitelist.

Use **undo app-proxy ssl whitelist user-defined-hostname** to remove hostnames from the user-defined SSL hostname whitelist.

Syntax

app-proxy ssl whitelist user-defined-hostname *host-name*

undo app-proxy ssl whitelist user-defined-hostname { *host-name* | **all** }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

host-name: Specifies a hostname, a case-insensitive string of 1 to 63 characters. If the hostname contains spaces, enclose it in double quotation marks. For example, **"user for test"**.

all: Specifies all hostnames on the user-defined SSL hostname whitelist.

Usage guidelines

If the **DNS Name** or **Common Name** value in a server certificate contains a hostname on the SSL hostname whitelist, the device does not proxy the SSL connections destined for the server.

This command must be manually activated by using the **app-proxy ssl whitelist activate** command.

This command is supported only on the default context. For more information about contexts, see context configuration in *Virtual Technologies Configuration Guide.*

Examples

Add **example.com** to the user-defined SSL hostname whitelist and active the configuration.

```
<Sysname> system-view
[Sysname] app-proxy ssl whitelist user-defined-hostname example.com
To activate the setting, execute app-proxy ssl whitelist activate.
```

```
[Sysname] app-proxy ssl whitelist activate
```

Related commands

app-proxy ssl whitelist activate

display app-proxy ssl whitelist

app-proxy ssl-decrypt-certificate delete

Use **app-proxy ssl-decrypt-certificate delete** to delete an SSL decryption certificate.

Syntax

app-proxy ssl-decrypt-certificate delete filename *filename*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

filename: Specifies an SSL decryption certificate by its file name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

The device, acting as an SSL proxy, requires the correct SSL decryption certificate to issue proxy server certificates to send to clients for server authentication. If the required SSL decryption certificate is not available, the device cannot set up a connection with the client and the SSL traffic will be transmitted directly without SSL decryption.

After an SSL decryption certificate is imported, its file extension will be changed to .cer, which must be appended to the file name when you delete the certificate.

Examples

Delete SSL decryption certificate **aaa.cer**.

```
<Sysname> system-view
[Sysname] app-proxy ssl-decrypt-certificate delete filename aaa.cer
```

Related commands

display app-proxy ssl-decrypt-certificate

app-proxy ssl-decrypt-certificate import

Use **app-proxy ssl-decrypt-certificate import** to import a CA certificate as a trusted or untrusted SSL decryption certificate.

Syntax

app-proxy ssl-decrypt-certificate import { **trusted** | **untrusted** } { **pem** | **p12** } **filename** *filename*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

trusted: Imports the CA certificate as a trusted SSL decryption certificate.

untrusted: Imports the CA certificate as an untrusted SSL decryption certificate.

pem: Specifies the PEM certificate file format.

p12: Specifies the PKCS#12 certificate file format.

filename *filename*: Specifies the certificate file name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

The device supports a maximum of one trusted SSL decryption certificate and one untrusted SSL decryption certificate. When importing an SSL decryption certificate, you must mark the certificate as **Trusted** or **Untrusted**. If you import multiple trusted or multiple untrusted SSL decryption certificates to the device, the most recent configuration takes effect.

To use the same CA certificate as both the trusted and untrusted SSL decryption certificate, first import the certificate with the **Trusted** or **Untrusted** tag, and then add the other tag to the certificate by using the **app-proxy ssl-decrypt-certificate modify** command.

After an SSL decryption certificate is imported, its file extension will be changed to .cer.

After receiving the certificate of the real server, the device verifies the legitimacy of the server certificate on behalf of the SSL client.

- If the server certificate is legitimate, the device uses the trusted SSL decryption certificate to issue a new certificate to the client. A server certificate issued by the trusted SSL decryption certificate is trusted by the client.
- If the server certificate is illegitimate, the device uses the untrusted SSL decryption certificate to issue a new certificate to the client. A security alarm will be generated on the client and users must clear the alarm to continue the access.

The trusted SSL decryption certificate must be installed on the client browser. Otherwise, the client cannot trust the proxy server certificate signed by the trusted SSL decryption certificate and might display a warning or directly terminate proxied SSL connections without a warning.

A Firefox browser does not use the SSL decryption certificate in the Windows certificate store by default. To use the SSL decryption certificate on the Firefox browser, you can take the following methods:

- Import the SSL decryption certificate into the Firefox browser.
- Configure the Firefox browser to use the SSL decryption certificate in the Windows certificate store through the following steps:
  a. Enter **about:config** in the address bar.
  b. In the **Search** box, enter **security.enterprise_roots.enabled**.
  c. Locate this entry, and double-click or right-click its value to change **false** to **true**.

Examples

Import a PKCS#12 certificate file as a trusted SSL decryption certificate.

```
<Sysname> system-view
[Sysname] app-proxy ssl-decrypt-certificate import trusted p12 filename aaa.p12
Password:
```

Related commands

Use **undo app-proxy ssl-decrypt-certificate modify** to remove the **Trusted** or **Untrusted** tag from an SSL decryption certificate.

Syntax

app-proxy ssl-decrypt-certificate modify { **trusted** | **untrusted** } **filename** *filename*

undo app-proxy ssl-decrypt-certificate modify { **trusted** | **untrusted** }

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

trusted: Specifies the **Trusted** tag.

untrusted: Specifies the **Untrusted** tag.

filename: Specifies the SSL decryption certificate by its file name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

To use the same CA certificate as both the trusted and untrusted SSL decryption certificate, first import the certificate with the **Trusted** or **Untrusted** tag, and then use this command add the other tag to the certificate.

When you add the **Trusted** or **Untrusted** tag to an SSL decryption certificate, the system asks whether you want to overwrite the SSL decryption certificate with the same tag if such a certificate already exists.

Removing the **Trusted** or **Untrusted** tag from an SSL decryption certificate does not remove the certificate file from the system. You can use the **app-proxy ssl-decrypt-certificate modify** command to add the **Trusted** or **Untrusted** tag to the certificate again.

After an SSL decryption certificate is imported, its file extension will be changed to .cer. Append the .cer file extension when you specify the file containing the certificate whose credibility you want to change.

Examples

Add the **Trusted** tag to the CA certificate in certificate file **aaa**.

```
<Sysname> system-view
[Sysname] app-proxy ssl-decrypt-certificate modify trusted filename aaa.cer
[Sysname] A trusted CA certificate already exists. Overwrite the existing trusted CA
certificate with the specified certificate? [Y/N]:
```

Related commands

display app-proxy ssl-decrypt-certificate

app-proxy-policy

Use **app-proxy-policy** to enter proxy policy view.

Use **undo app-proxy-policy** to remove all proxy policy configurations.

Syntax

app-proxy-policy

undo app-proxy-policy

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The device supports only one IPv4 proxy policy.

Examples

Enter proxy policy view.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy]
```

Related commands

display app-proxy-policy

default action

Use **default-action** to specify the default action for the proxy policy.

Use **undo default-action** to restore the default.

Syntax

default action { **no-proxy** | **ssl-decrypt** | **tcp-proxy** }

undo default action

Default

The proxy policy uses the no-proxy action.

Views

Proxy policy view

Predefined user roles

network-admin

context-admin

Parameters

no-proxy: Specifies the no-proxy action.

ssl-decrypt: Specifies the SSL decryption action.

tcp-proxy: Specifies the TCP proxy action.

Usage guidelines

The default action applies to packets that do not match any rules in the proxy policy.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Set the default action to **ssl-decrypt** for the proxy policy.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] default action ssl-decrypt
```

default ssl-decrypt protect-mode

Use **default ssl-decrypt protect-mode** to specify an SSL decryption protection mode for the proxy policy.

Use **undo default ssl-decrypt protect-mode** to restore the default.

Syntax

default ssl-decrypt protect-mode { **client** | **server** }

undo default ssl-decrypt protect-mode

Default

The SSL decryption protection mode of the proxy policy is **client**.

Views

Proxy policy view

Predefined user roles

network-admin

context-admin

Parameters

client: Specifies client protection.

server: Specifies server protection.

Usage guidelines

The SSL decryption supports the following protection services:

- **Internal client protection**—The device is deployed at the exit of the network where the internal clients are. When the internal clients access an external server, the device acts as a proxy server to decrypt the packets and perform deep packet inspection on the decrypted packets. It protects the internal clients from being attacked by external malicious websites. In this scenario, the device requires imported SSL decryption certificates to establish SSL connections with the clients.
- **Internal server protection**—The device is deployed at the entrance of the network where the internal servers are. When the external clients access an internal server, the device acts as a proxy server to decrypt the packets and perform deep packet inspection on the decrypted packets. It protects the internal servers from being attacked by external malicious traffic. In this scenario, the device requires imported internal server certificates to establish SSL connections with the clients.

For more information about DPI, see "DPI overview."

By default, the SSL proxy protects the internal clients. You can select a protection service of the SSL decryption as required and import the corresponding certificates to the device for SSL connection establishment with the clients.

This command takes effect only when the SSL decryption action is used as the default action for the proxy policy.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify **server** as the SSL decryption protection mode for the proxy policy.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] default ssl-decrypt protect-mode server
```

Related commands

display app-proxy-policy

destination-ip object-group

Use **destination-ip object-group** to configure an object group as a destination address filtering criterion in a proxy policy rule.

Use **undo destination-ip object-group** to remove destination address filtering criteria from a proxy policy rule.

Syntax

destination-ip object-group *object-group-name*

undo destination-ip object-group [*object-group-name*]

Default

A proxy policy rule does not contain any destination address filtering criterion.

Views

Proxy policy rule view

Predefined user roles

network-admin

context-admin

Parameters

object-group-name: Specifies an IP address object group by its name, a case-insensitive string of 1 to 63 characters. The object group must already exist and its name cannot be **any**.

Usage guidelines

You can repeat this command to set multiple destination address filtering criteria in a proxy policy rule. A packet passes the destination address filtering if it matches any of the configured destination address filtering criteria.

If you execute the **undo destination-ip object-group** command without specifying an object group, all destination address filtering criteria in the proxy policy rule will be deleted.

For more information about object groups, see object group configuration in *Security Configuration Guide*.

Examples

In proxy policy rule **rule1**, set IP address object groups **client1** and **client2** as destination address filtering criteria.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule 1 name rule1
[Sysname-app-proxy-policy-0-rule1] destination-ip object-group client1
[Sysname-app-proxy-policy-0-rule1] destination-ip object-group client2
```

Related commands

display app-proxy-policy

object-group (*Security Command Reference*)

destination-zone

Use **destination-zone** to configure a destination security zone filtering criterion in a proxy policy rule.

Use **undo destination-zone** to remove destination security zone filtering criteria from a proxy policy rule.

Syntax

destination-zone *destination-zone-name*

undo destination-zone [*destination-zone-name*]

Default

A proxy policy rule does not contain any destination security zone filtering criterion.

Views

Proxy policy rule view

Predefined user roles

network-admin

context-admin

Parameters

destination-zone-name: Specifies a destination security zone by its name, a case-insensitive string of 1 to 31 characters. The destination security zone name cannot be **any**.

Usage guidelines

You can repeat this command to set multiple destination security zone filtering criteria in a proxy policy rule. A packet passes the destination security zone filtering if it matches any of the configured destination security zone filtering criteria.

You can specify a nonexistent security zone for a destination security zone filtering criterion. However, the destination security zone filtering criterion does not take effect until the security zone is configured.

If you execute the **undo destination-zone** command without specifying a security zone, all destination security zone filtering criteria in the proxy policy rule will be deleted.

For more information about security zones, see security zone configuration in *Security Configuration Guide*.

Examples

In proxy policy rule **rule1**, set security zones **trust** and **server** as destination security zone filtering criteria.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule 1 name rule1
[Sysname-app-proxy-policy-0-rule1] destination-zone trust
[Sysname-app-proxy-policy-0-rule1] destination-zone server
```

Related commands

display app-proxy-policy

security-zone (*Security Configuration Guide*)

disable

Use **disable** to disable a proxy policy rule.

Use **undo disable** to enable a proxy policy rule.

Syntax

disable

undo disable

Default

A proxy policy rule is enabled.

Views

Proxy policy rule view

Predefined user roles

network-admin

context-admin

Usage guidelines

The device compares a packet against only the enabled proxy policy rules. The match process stops once a matching rule is found.

Examples

Disable proxy policy rule **rule1**.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule 1 name rule1
[Sysname-app-proxy-policy-0-rule1] disable
```

Figure 1 Command output

Field	Description
Certificate Md5	MD5 value of the certificate.
Certificate	Information about the certificate.
Version	Version number of the certificate.
Serial Number	Serial number of the certificate.
Signature Algorithm	Signature algorithm used in the certificate.
Issuer	Issuer of the certificate.
Validity	Validity of the certificate.

Field	Description
Subject	Identity of the entity to which the certificate belongs.
Subject Public Key Info	Public key information of the certificate subject.
Modulus	Modulus length of the key.
Exponent	Key exponent.
X509v3 extensions	X.509v3 extensions in the certificate.
X509v3 Subject Alternative Name	Alternative name of the certificate subject.
IP Address	IP address of the certificate subject.
DNS	DNS name of the certificate subject.
email	Email address of the certificate subject.
X509v3 Basic Constraints	Indicates whether the certificate belongs to a CA.
X509v3 Key Usage	Identifies the cryptographic operations which may be performed using the public key contained in the certificate.
X509v3 Subject Key Identifier	Key identifier of the certificate subject.
Netscape Cert Type	Netscape certificate type, an extension defined by Netscape to limit what the certificate can be used for.
Netscape Comment	Netscape comment that can be displayed in certain browsers.

Related commands

app-proxy server-certificate import

app-proxy server-certificate delete

display app-proxy server-certificate

Use **display app-proxy server-certificate** to display the SSL server certificates received by the device as the SSL proxy client.

Syntax

display app-proxy server-certificate [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays certificate information on all member devices.

Usage guidelines

When implementing the SSL proxy function, the device acts as the SSL proxy client to complete the SSL handshake and establish an SSL connection with the SSL server. This command displays information about the SSL server certificates received by the device as the SSL proxy client.

Examples

Display the SSL server certificates received by the device as the SSL proxy client on slot 1.

```
<Sysname> display app-proxy server-certificate slot 1
Slot1:
Total server certificates: --
Certificate info: /cn=nsfocus-https-self-signed-certificate-13a73249669cc70a
     Proxy count: 198
     Most recent proxy time: 2017/10/25 10:7:7
     First proxy at: 2017/10/23 15:52:59
```

Figure 2 Command output

Field	Description
Total server certificates	Total number of server certificates received by the device as the SSL proxy client.
Certificate info	Information about the certificate. This field displays the value in the **DNS Name** field (in the format of **example.com**) of the certificate. If the server certificate does not contain the **DNS Name** field, the value in the **Common Name** field (in the format of **/cn=example.com**) is displayed.
Proxy count	Number of times connections to the server had been proxied.
Most recent proxy time	Most recent time the device proxied a connection to the server.
First proxy at	First time the device proxied a connection to the server.

Figure 5 Command output

Field	Description
Trusted	Credibility of the SSL decryption certificate, **Trusted** or **Untrusted**.
Version	Version number of the certificate.
Serial Number	Serial number of the certificate.
Signature Algorithm	Signature algorithm used in the certificate.
Issuer	Issuer of the certificate.
Validity	Validity of the certificate.
Subject	Identity of the entity to which the certificate belongs.

Field	Description
Subject Public Key Info	Public key information of the certificate subject.
Modulus	Modulus length of the key.
Exponent	Key exponent.
X509v3 extensions	X.509v3 extensions in the certificate.
X509v3 Subject Alternative Name	Alternative name of the certificate subject.
IP Address	IP address of the certificate subject.
DNS	DNS name of the certificate subject.
email	Email address of the certificate subject.
X509v3 Basic Constraints	Indicates whether the certificate belongs to a CA.
X509v3 Key Usage	Identifies the cryptographic operations which may be performed using the public key contained in the certificate.
X509v3 Subject Key Identifier	Key identifier of the certificate subject.
Netscape Cert Type	Netscape certificate type, an extension defined by Netscape to limit what the certificate can be used for.
Netscape Comment	Netscape comment that can be displayed in certain browsers.

display app-proxy-policy

Use **display app-proxy-policy** to display proxy policy information.

Syntax

display app-proxy-policy [**rule** *rule-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

rule *rule-name*: Specifies a proxy policy rule by its name, a case-insensitive string of 1 to 63 characters. If you do not specify a proxy policy rule, this command displays information about all proxy policy rules.

Examples

Display proxy policy information and all rules in the policy.

```
<Sysname> display app-proxy-policy
Default action: ssl-decrypt (Protect mode: server)
```

```
Rule with ID 0 and name rule0:
  Action: ssl-decrypt
  Status: Enabled
  Protect mode: server
  Match criteria:
   Source security zones: trust
   Destination security zones: trust
   Source IP address object groups: srcobj
   Destination IP address object groups: destobj
   Service object groups: serviceobj
   Users: user1
   User groups: usergroup1

  Rule with ID 2 and name rule2:
  Action: ssl-decrypt
  Status: Enabled
  Match criteria:
  source-zone: trust
  destination-zone: Untrust
  Protection mode: Client
```

Figure 6 Command output

Field	Description
Default action	Default action of the policy: • **no-proxy**. • **ssl-decrypt**. • **tcp-proxy**.
(Protect mode: XXX)	SSL decryption protection mode of the proxy policy: • **client**—Protects internal clients from attacks. • **server**—Protects internal servers from attacks. This field is available only when the SSL decryption action is used as the default action for the proxy policy.
Rule with ID *rule-id* and name *rule-name*	ID and name of a proxy policy rule.
Action	Action for traffic matching the proxy policy rule: • **no-proxy**. • **ssl-decrypt**. • **tcp-proxy**.
Protect mode	SSL decryption protection mode of the proxy policy rule: • **client**—Protects internal clients from attacks. • **server**—Protects internal clients from attacks.
Source security zones	Source security zones to which the proxy policy rule applies.
Destination security zones	Destination security zones to which the proxy policy rule applies.
Source IP address object groups	Source IP address object groups to which the proxy policy rule applies.
Destination IP address object groups	Destination IP address object groups to which the proxy policy rule applies.

Field	Description
Service object groups	Service object groups to which the proxy policy rule applies.
Users	Users to whom the proxy policy rule applies.
User groups	User groups to which the proxy policy rule applies.

reset app-proxy server-certificate

Use **reset app-proxy server-certificate** to clear information about the SSL server certificates received by the device as the SSL proxy client.

Syntax

reset app-proxy server-certificate

Views

User view

Predefined user roles

network-admin

context-admin

Examples

Clear information about the SSL server certificates received by the device as the SSL proxy client.

```
<Sysname> reset app-proxy server-certificate
```

Related commands

display app-proxy server-certificate

reset app-proxy ssl whitelist ip

Use **reset app-proxy ssl whitelist ip** to clear the SSL IP address whitelist.

Syntax

reset app-proxy ssl whitelist

Views

User view

Predefined user roles

network-admin

context-admin

Examples

Clear the SSL IP address whitelist.

```
<Sysname> reset app-proxy ssl whitelist ip
```

Related commands

display app-proxy ssl whitelist ip

rule

Use **rule** to create a proxy policy rule and enter its view, or enter the view of an existing proxy policy rule.

Use **undo rule** to remove a proxy policy rule.

Syntax

rule { *rule-id* | [*rule-id*] **name** *rule-name* }

undo rule { *rule-id* | **name** *rule-name* }

Views

Proxy policy view

Predefined user roles

network-admin

context-admin

Parameters

rule-id: Specifies a rule ID, which must be an integer in the range of 1 to 65535. If you do not specify a rule ID when creating a rule, the system automatically assigns a rule ID that is larger than that the largest rule ID already used. If rule ID 65535 is already used, the system assigns the smallest unused ID to the rule.

name *rule-name*: Specifies a rule name, a case-insensitive string of 1 to 63 characters. The rule name is required when you create a rule and it cannot be set to **default**.

Examples

Create rule 1 named **rule1**.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule 1 name rule1
[Sysname-app-proxy-policy-1-rule1]
```

Related commands

display app-proxy-policy

rule move id

Use **rule move id** to move a proxy policy rule to a new position through rule IDs.

Syntax

rule move id *rule-id* **before** *insert-rule-id*

Views

Proxy policy view

Predefined user roles

network-admin

context-admin

Parameters

rule-id: Specifies the target rule to be moved by its ID in the range of 1 to 65535. The specified rule must already exist.

before *insert-rule-id*: Specifies the reference rule ID in the range of 1 to 65535. The target rule is moved to the position before the reference rule. To move the rule to the end of all rules, set the reference rule ID to 65535. The specified reference rule must already exist.

Examples

Move rule 5 to the position before rule 2.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule move id 5 before 2
```

Related commands

rule

rule move name

Use **rule move name** to move a proxy policy rule to a new position through rule names.

Syntax

rule move name *rule-name1* { **before** [*rule-name2*] | **after** *rule-name2* }

Views

Proxy policy view

Predefined user roles

network-admin

context-admin

Parameters

rule-name1: Specifies the target rule to be moved by its name.

before [*rule-name2*]: Moves the target rule before another rule. If you do not specify a rule, the target rule is moved before all rules.

after [*rule-name2*]: Moves the target rule after another rule.

Usage guidelines

If the two rules are the same or one of the two rules does not exist, no move operation is performed.

Examples

Move rule **a** to the position before rule **b**.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule move name a before b
```

service

Use **destination-zone** to configure a service filtering criterion in a proxy policy rule.

Use **undo destination-zone** to remove service filtering criteria from a proxy policy rule.

Syntax

service object-group { *object-group-name* }

undo service object-group [*object-group-name*]

Default

A proxy policy rule does not contain any service filtering criterion.

Views

Proxy policy rule view

Predefined user roles

network-admin

context-admin

Parameters

object-group-name: Specifies a service object group by its name, a case-insensitive string of 1 to 63 characters. The object group must already exist and its name cannot be **any**.

Usage guidelines

You can repeat this command to set multiple service filtering criteria in a proxy policy rule. A packet passes the service filtering if it matches any of the service filtering criteria.

If you execute the **undo service object-group** command without specifying an object group zone, all service filtering criteria in the proxy policy rule will be deleted.

Examples

In proxy rule **rule1**, specify object group **ftp** as a service filtering criterion.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule 1 name rule1
[Sysname-app-proxy-policy-0-rule1] service object-group ftp
```

Related commands

display app-proxy-policy

object-group (*Security Command Reference*)

source-ip object-group

Use **source-ip object-group** to configure an object group as a source address filtering criterion in a proxy policy rule.

Use **undo source-ip object-group** to remove source address filtering criteria from a proxy policy rule.

Syntax

source-ip object-group *object-group-name*

undo source-ip object-group [*object-group-name*]

Default

A proxy policy rule does not contain any source address filtering criterion.

Views

Proxy policy rule view

Predefined user roles

network-admin

context-admin

Parameters

object-group-name: Specifies an IP address object group by its name, a case-insensitive string of 1 to 63 characters. The object group must already exist and its name cannot be **any**.

Usage guidelines

You can repeat this command to set multiple source address filtering criteria in a proxy policy rule. A packet passes the source address filtering if it matches any of the configured destination address filtering criteria.

If you execute the **undo source-ip object-group** command without specifying an object group, all source address filtering criteria in the proxy policy rule will be deleted.

For more information about object groups, see object group configuration in *Security Configuration Guide*.

Examples

In proxy policy rule **rule1**, specify IP address object groups **server1** and **server2** as source address filtering criteria.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule 1 name rule1
[Sysname-app-proxy-policy-0-rule1] source-ip object-group server1
[Sysname-app-proxy-policy-0-rule1] source-ip object-group server2
```

Related commands

display app-proxy-policy

object-group (*Security Command Reference*)

source-zone

Use **source-zone** to configure a source security zone filtering criterion in a proxy policy rule.

Use **undo source-zone** to remove source security zone filtering criteria from a proxy policy rule.

Syntax

source-zone *source-zone-name*

undo source-zone [*source-zone-name*]

Default

A proxy policy rule does not contain any source security zone filtering criterion.

Views

Proxy policy rule view

Predefined user roles

network-admin

context-admin

Parameters

source-zone-name: Specifies a source security zone by its name, a case-insensitive string of 1 to 31 characters. The source security zone name cannot be **any**.

Usage guidelines

You can repeat this command to set multiple source security zone filtering criteria in a proxy policy rule. A packet passes the source security zone filtering if it matches any of the configured source security zone filtering criteria.

You can specify a nonexistent security zone for a source security zone filtering criterion. However, the source security zone filtering criterion does not take effect until the security zone is configured.

If you execute the **undo source-zone** command without specifying a security zone, all source security zone filtering criteria in the proxy policy rule will be deleted.

For more information about security zones, see security zone configuration in *Security Configuration Guide*.

Examples

In proxy policy rule **rule1**, specify security zones **trust** and **server** as source security zone filtering criteria.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule 1 name rule1
[Sysname-app-proxy-policy-0-rule1] source-zone trust
[Sysname-app-proxy-policy-0-rule1] source-zone server
```

Related commands

display app-proxy-policy

security-zone (*Security Command Reference*)

ssl-decrypt protect-mode

Use **ssl-decrypt protect-mode** to specify an SSL decryption protection mode for a proxy policy rule.

Use **ssl-decrypt protect-mode** to restore the default.

Syntax

ssl-decrypt protect-mode { **client** | **server** }

undo ssl-decrypt protect-mode

Default

The SSL decryption protection mode of a proxy policy rule is **client**.

Views

Proxy policy rule view

Predefined user roles

network-admin

context-admin

Parameters

client: Specifies client protection.

server: Specifies server protection.

Usage guidelines

The SSL decryption supports the following protection services:

- **Internal client protection**—The device is deployed at the exit of the network where the internal clients are. When the internal clients access an external server, the device acts as a proxy server to decrypt the packets and perform deep packet inspection on the decrypted packets. It protects the internal clients from being attacked by external malicious websites. In this scenario, the device requires imported SSL decryption certificates to establish SSL connections with the clients.
- **Internal server protection**—The device is deployed at the entrance of the network where the internal servers are. When the external clients access an internal server, the device acts as a proxy server to decrypt the packets and perform deep packet inspection on the decrypted packets. It protects the internal servers from being attacked by external malicious traffic. In this scenario, the device requires imported internal server certificates to establish SSL connections with the clients.

For more information about DPI, see "DPI overview."

By default, the SSL proxy protects the internal clients. You can select a protection service of the SSL decryption as required and import the corresponding certificates to the device for SSL connection establishment with the clients.

This command takes effect only when the SSL decryption action is used as the default action for the proxy policy.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify **server** as the SSL decryption protection mode for proxy policy rule **rule1**.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule 1 name rule1
[Sysname-app-proxy-policy-0-rule1] ssl-decrypt protect-mode server
```

Related commands

display app-proxy-policy

user

Use **user** to configure a user filtering criterion in a proxy policy rule.

Use **undo user** to remove user filtering criteria from a proxy policy rule.

Syntax

user *user-name* [**domain** *domain-name*]

undo user [*username* [**domain** *domain-name*]]

Default

A proxy policy rule does not contain any user filtering criterion.

Views

Proxy policy rule view

Predefined user roles

network-admin

context-admin

Parameters

username: Specify a username, a case-sensitive string of 1 to 55 characters. The username cannot be **a**, **al**, or **all**, and cannot contain special characters listed in Table 1.

Table 1 Special characters

Character name	Symbol
Backslash	\
Vertical bar	|
Forward slash	/
Colon	:
Asterisk	*
Question mark	?
Left angle bracket	<
Right angle bracket	>
At sign	@

domain *domain-name*: Specifies the name of the identity domain to which the user belongs. The identity domain name is a case-insensitive string of 1 to 255 characters which cannot contain special characters listed in Table 1.

Usage guidelines

You can repeat this command to set multiple user filtering criteria in a proxy policy rule. A packet passes the user filtering if it matches any of the user filtering criteria.

If the specified user does not exist for the following reasons, the configuration succeeds but does not take effect:

- The user does not exist.
- The domain does not exist.
- The user does not exist in the domain.

For successful user filtering criterion configuration, the user must exist and belong to the domain, if specified.

Follow these guidelines when you execute the **undo user** command:

- To remove all user filtering criteria in a proxy policy rule, do not specify any parameters.
- To remove a user in a domain as a user filtering criterion, specify the *username* parameter with the **domain** *domain-name* option.
- To remove a user that does not belong to any identity domains, specify the *username* parameter without the **domain** *domain-name* option.

Examples

In proxy rule **rule1**, specify users **usera** and **userb** in domain **test** as user filtering criteria.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule 1 name rule1
[Sysname-app-proxy-policy-0-rule1] user usera domain test
[Sysname-app-proxy-policy-0-rule1] user userb domain test
```

Related commands

display app-proxy-policy

user-identity enable (*Security Command Reference*)

user-identity static-user (*Security Command Reference*)

user-group

Use **user-group** to configure a user group filtering criterion in a proxy policy rule.

Use **undo user-group** to remove user group filtering criteria from a proxy policy rule.

Syntax

user-group *user-group-name* [**domain** *domain-name*]

undo user-group [*user-group-name* [**domain** *domain-name*]]

Default

A proxy policy rule does not contain any user group filtering criterion.

Views

Proxy policy rule view

Predefined user roles

network-admin

context-admin

Parameters

user-group-name: Specify a user group by its name, a case-insensitive string of 1 to 200 characters.

domain *domain-name*: Specifies the name of the identity domain to which the user group belongs. The identity domain name is a case-insensitive string of 1 to 255 characters which cannot contain special characters listed in Table 2.

Table 2 Special characters

Character name	Symbol
Backslash	\
Vertical bar	|
Forward slash	/
Colon	:
Asterisk	*
Question mark	?
Left angle bracket	<
Right angle bracket	>
At sign	@

Usage guidelines

You can repeat this command to set multiple user group filtering criteria in a proxy policy rule. A packet passes the user group filtering if it matches any of the user group filtering criteria.

The command succeeds but does not take effect if the specified user group does not exist for the following reasons:

- The user does not exist.
- The domain does not exist.
- The user does not exist in the domain.

Follow these guidelines when you execute the **undo user-group** command:

- To remove all user group filtering criteria in a proxy policy rule, do not specify any parameters.
- To remove a user group in a domain as a user group filtering criterion, specify the *user-group-name* parameter with the **domain** *domain-name* option.
- To remove a user group that does not belong to any identity domains, specify the *user-group-name* parameter without the **domain** *domain-name* option.

For more information about user groups, see user identification configuration in *Security Configuration Guide*.

Examples

In proxy rule **rule1**, specify user groups **groupa** and **groupb** in domain **test** as user group filtering criteria.

```
<Sysname> system-view
[Sysname] app-proxy-policy
[Sysname-app-proxy-policy] rule 1 name rule1
[Sysname-app-proxy-policy-0-rule1] user-group groupa domain test
[Sysname-app-proxy-policy-0-rule1] user-group groupb domain test
```

NSFOCUS Firewall Series

NF NAT Command Reference

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

This command reference describes the commands for configuring NAT, NAT66, and AFT

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

NAT commands

Interface-based NAT is not supported on the NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280

action

Use **action** to specify an address translation method for a NAT rule.

Use **undo action** to delete the address translation method configuration for a NAT rule.

Syntax

Easy IP method:

action easy-ip

NO-NAT method:

action no-nat

NO-PAT method:

action address-group { *group-id* | **name** *group-name* } **no-pat** [**reversible**]

PAT method:

action address-group { *group-id* | **name** *group-name* } [**port-preserved**]

Default

No address translation method is specified in a NAT rule.

Views

NAT rule view

context-admin

Parameters

address-group: Uses the NAT address group for address translation.

group-id: Specifies the ID of the address group. The value range for this argument is 0 to 65535.

name *group-name*: Specifies the name of the address group. The name is a case-sensitive string of 1 to 63 characters.

easy-ip: Uses the Easy IP method on the interface where the NAT rule is configured. The IP address of the interface is used as the NAT IP address.

no-nat: Disables the rule and its subsequent rules from translating matching packets.

no-pat: Uses the NO-PAT mode in which port numbers are not translated.

reversible: Allows reverse address translation. Reverse address translation uses existing NO-PAT entries to translate destination addresses for packets of connections actively initiated by external hosts to internal hosts.

port-preserved: Tries to preserve port number for PAT.

Usage guidelines

PAT supports TCP, UDP, and UDPLITE packets, and ICMP request packets.

A NAT address group cannot be used by both the PAT and NO-PAT methods.

If excessive NAT rules exist and you want to disable address translation for specific traffic temporarily, locate the NAT rule matching the traffic and specify the **no-nat** keyword in the rule.

Examples

Configure NAT rule **aaa** to use the PAT mode and NAT address group 0 for address translation.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy] rule name aaa
[Sysname-nat-policy-rule-aaa] action address-group 0
```

Configure NAT rule **aaa** to use the NO-PAT mode and address group 0 for address translation.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy] rule name aaa
[Sysname-nat-policy-rule-aaa] action address-group 0 no-pat
```

Configure NAT rule **aaa** to use Easy IP for address translation.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy] rule name aaa
[Sysname-nat-policy-rule-aaa] action easy-ip
```

Disable NAT rule **aaa** and its subsequent rules from translating matching packets.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy] rule name aaa
[Sysname-nat-policy-rule-aaa] action no-nat
```

nat address-group

action dnat (NAT64-type rule view)

Use **action dnat** to specify a destination address translation method for a NAT rule.

Use **undo action dnat** to delete the destination address translation method configuration for a NAT rule.

Syntax

Static NAT method:

action dnat static ip-address *local-ipv4-address* [*ipv6-***vrrp** *virtual-router-id*] [**vrf** *vrf-name*]

action dnat static ip-address *local-ipv6-address* [**ipv4-vrrp** *virtual-router-id*] [**vrf** *vrf-name*]

undo action dnat

Server mapping method:

action dnat server ip-address *local-ipv4-address* [**local-port** *local-port*] [**vrf** *vrf-name*]

action dnat server ip-address *local-ipv6-address* [**local-port** *local-port*] [**ipv4-vrrp** *virtual-router-id*] [**vrf** *vrf-name*]

undo action dnat

Prefix method:

action dnat prefix { **general v6tov4** | **nat64 v6tov4** } [**vrf** *vrf-name*]

action dnat prefix { **general v4tov6** *prefix-general prefix-length* | **ivi v4tov6** *prefix-ivi* } [**ipv4-vrrp** *virtual-router-id*] [**vrf** *vrf-name*]

undo action dnat

Default

No destination address translation method is specified in a NAT rule.

Parameters

static: Uses the static NAT method. Mappings between IPv6 and IPv4 addresses are manually configured.

server: Uses the internal server method for address translation.

ip-address: Specifies the IP address after translation.

local-ipv4-address: Specifies the internal destination IPv4 address after translation.

local-ipv6-address: Specifies the internal destination IPv6 address after translation.

local-port *port-number*: Specifies the internal destination port number after translation, in the range of 1 to 65535. If you do not specify this keyword, the destination port number is not translated. This feature is supported only for TCP, UDP, and ICMP query packets. Because ICMP IPv4/IPv6 packets do not have port numbers, the ICMP IDs in these packets are used as their destination port numbers.

prefix: Uses the prefix method for address translation.

general: Uses the general prefix method for destination address translation.

v4tov6: Translates IPv4 addresses to IPv6 addresses.

v6tov4: Translates IPv6 addresses to IPv4 addresses.

ivi: Uses the IVI prefix method for IPv6-to-IPv4 destination address translation.

prefix-ivi: Specifies an IVI prefix, which is fixed at 32.

nat64: Uses the NAT64 prefix method for destination address translation.

prefix-general: Specifies a general prefix.

general-prefix-length: Specifies the general prefix length. Available values include 32, 40, 48, 56, 64, and 96. When 96 is specified as the general prefix length, make sure the 64th bit through the 71st bit of the general prefix are 0.

ipv4-vrrp *virtual-router-id*: Specifies an IPv4 VRRP group by its virtual router ID in the range of 1 to 255.

ipv6-vrrp *virtual-router-id*: Specifies an IPv6 VRRP group by its virtual router ID in the range of 1 to 255.

vrf *vrf-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, this command applies to IPv4 or IPv6 addresses after destination address translation on the public network.

Usage guidelines

When an IPv6 user accesses an IPv4 network, the following methods are available:

- **Static method**—In this method, you must manually configure the one-to-one IPv4-to-IPv6 address mappings. An IPv6 user uses the IPv6 address in the matching address mapping as the destination address, and the NAT64 device translates the destination IPv6 address to an IPv4 address according to the address mapping.
- **Internal server method**—In this method, an IPv4 server address and its port number are mapped to the IPv6 network. An IPv6 user can access the server in the IPv4 network through accessing the translated IPv6 address and port number.
- **Prefix method**—In this method, a NAT64 prefix or general prefix is used to translate a destination IPv6 address to an IPv4 address.

When an IPv4 user accesses an IPv6 network, the address translation procedure is similar to that when an IPv6 user accesses an IPv4 network.

In a hot backup system collaborating with VRRP, bind the translation actions in the following address translation methods to VRRP groups:

- **Static NAT**—Bind the IPv6-to-IPv4 destination address translation action to the VRRP group on the IPv6 side.
- **Static NAT**—Bind the IPv4-to-IPv6 destination address translation action to the VRRP group on the IPv4 side.
- **Server mapping**—Bind the IPv4-to-IPv6 destination address translation action to the VRRP group on the IPv4 side.
- **Prefix**—Bind the IPv4-to-IPv6 destination address translation action to the VRRP group on the IPv4 side.

If you do not bind the translation actions to VRRP groups, the uplink Layer 3 device directly connected to the hot backup system might send downlink packets to the backup device, causing service anomalies.

When you use this command together with the packet match criteria, if you first execute the **destination-ip** command and then the **action dnat static ip-address** command, you cannot repeatedly execute the **destination-ip** command to modify the packet match criteria.

To perform source and destination address translations simultaneously in a VPN environment, make sure the translated addresses belong to the same VPN instance. To perform address translation, execute the **action snat** and **action dnat** commands.

This command is available only in NAT rule view of the global NAT policy.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure NAT rule **rule1** to use the server mapping method to translate the destination IP address to 1.1.1.5.

```
<Sysname> system-view
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name rule1 type nat64
[Sysname-nat-global-policy-rule-nat64-rule1] action dnat ip-address 1.1.1.5
```

Parameters

static: Uses the static method for address translation. The mappings between destination IPv6 addresses before and after translation are manually configured.

ip-address *local-ipv6-address*: Specifies the internal destination IPv6 address after translation.

local-port *port-number*: Specifies the internal destination port number after translation, in the range of 1 to 65535. If you do not specify this keyword, the destination port number is not translated. This feature is supported only for TCP, UDP, and ICMPv6 query packets. Because ICMPv6 packets do not have port numbers, the ICMP IDs in these packets are used as their destination port numbers.

nptv6: Uses the NPTv6 method for IPv6 address prefix translation.

translated-ipv6-prefix prefix-length: Specifies the IPv6 address prefix after translation. The *translated-ipv6-prefix* argument indicates the address prefix. The *prefix-length* argument specifies the IPv6 address prefix length in the range of 1 to 112.

no-nat: Disables the rule and its subsequent rules from translating the destination IP address of the matching packets.

vrf *vrf-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, this command applies to IPv6 addresses after destination address translation on the public network.

Usage guidelines

This command is applicable to scenarios where a server in an internal network provides services (for example, Web or FTP service) for external networks. Through configuring mappings between internal servers and external servers in a NAT66-type rule, users in external networks can access servers in internal networks through the specified external network address.

If excessive NAT rules exist and you want to disable address translation for specific traffic temporarily, locate the NAT rule that matches the traffic and specify the **no-nat** keyword in the rule.

When you use this command together with packet match criteria, follow these restrictions and guidelines:

- When you use the **action dnat nptv6** command together with the **destination-ip** command, if you first execute the **destination-ip** command and then the **action dnat nptv6** command, you cannot repeatedly execute the **destination-ip** command to modify the packet match criteria.
- You cannot use this command together with the security zone match criteria. To use destination security zones as the packet match criteria for a NAT rule, first execute the **undo action dnat** command and then the **destination-zone** command.

To perform source and destination address translations simultaneously in a VPN environment, make sure the translated addresses belong to the same VPN instance. To perform address translation, execute the **action snat** and **action dnat** commands.

This command is available only in NAT rule view of the global NAT policy.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure NAT rule **rule1** to use the server mapping method to translate the destination IPv6 address to 3001::5.

```
<Sysname> system-view
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name rule1 type nat66
[Sysname-nat-global-policy-rule-nat66-rule1] action dnat ip-address 3001::5
```

Views

NAT rule view

Predefined user roles

network-admin

context-admin

Parameters

ip-address *local-address*: Specifies a private destination IP address after translation.

object-group *ipv4-object-group-name*: Specifies an object group by its name. The name is a case-insensitive string of 1 to 63 characters, and it cannot be **any**. If spaces are included in the name, enclose the name in quotation marks ("), for example, "XXX XXX".

local-port *local-port*: Specifies a private destination port number after translation, in the range of 1 to 65535. If you do not specify this option, the device does not translate destination ports of the packets. Only TCP, UDP, and ICMP query packets are supported. For an ICMP packet, the ICMP ID is used as its destination port number.

no-nat: Disables the rule and its subsequent rules from translating the destination IP address of the matching packets.

vrrp *virtual-router-id*: Binds the destination translation method to a VRRP group. The *virtual-router-id* parameter represents the virtual router ID in the range of 1 to 255.

vrf *vrf-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, this command applies to IPv4 addresses after destination address translation on the public network.

Usage guidelines

When external users access an internal server, the NAT device translates the destination IP addresses and ports of the matching packets to the IP address and port of the internal server.

If excessive NAT rules exist and you want to disable address translation for specific traffic temporarily, locate the NAT rule that matches the traffic and specify the **no-nat** keyword in the rule.

In a hot backup system collaborating with VRRP, bind the destination address translation method on the primary device in the hot backup system to the VRRP group facing the external network. If you do not perform the binding, the uplink Layer 3 device directly connected to the hot backup system might send downlink packets to the backup device, causing service anomalies.

A NAT rule that uses the destination address translation method does support using a destination security zone as the packet match criterion. To use the destination security zone as the packet match criterion for the rule, execute the **undo action dnat** command first and then execute the **destination-zone** command.

To perform source and destination address translations simultaneously in a VPN environment, make sure the translated addresses belong to the same VPN instance. To perform address translation, execute the **action snat** and **action dnat** commands.

This command is available only in NAT rule view of the global NAT policy.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

For NAT rule **rule1**, specify the server mapping method and specify 1.1.1.5 as the destination address after translation.

```
<Sysname> system-view
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name rule1
[Sysname-nat-global-policy-rule-rule1] action dnat ip-address 1.1.1.5
```

Parameters

object-group: Specifies the address object group used for address translation.

ipv4-object-group-name: Specifies an IPv4 address object group by its name. The name is a case-insensitive string of 1 to 63 characters, and it cannot be **any**. If spaces are included in the name, enclose the name in quotation marks ("), for example, "XXX XXX".

ipv6-object-group-name: Specifies an IPv6 address object group by its name. The name is a case-insensitive string of 1 to 63 characters, and it cannot be **any**. If spaces are included in the name, enclose the name in quotation marks ("), for example, "XXX XXX".

prefix: Uses the prefix method for source address translation.

general: Uses the general prefix method for source address translation.

ivi: Uses the IVI prefix method for source address translation.

nat64: Uses the NAT64 prefix method for source address translation.

v4tov6: Translates IPv4 addresses to IPv6 addresses.

v6tov4: Translates IPv6 addresses to IPv4 addresses.

prefix-general: Specifies a general prefix.

general-prefix-length: Specifies the general prefix length. Available values include 32, 40, 48, 56, 64, and 96.

prefix-nat64: Specifies a NAT64 prefix.

nat64-prefix-length: Specifies the NAT64 prefix length. Available values include 32, 40, 48, 56, 64, and 96. When 96 is specified as the NAT64 prefix length, make sure the 64th bit through the 71st bit of the NAT64 prefix are 0.

static: Uses the static method for source address translation.

ip-address: Specifies the IP address after translation.

global-ipv4-address: Specifies the source IPv4 address after translation.

global-ipv6-address: Specifies source IPv6 address after translation.

ipv4-vrrp *virtual-router-id*: Specifies an IPv4 VRRP group by its virtual router ID in the range of 1 to 255.

ipv6-vrrp *virtual-router-id*: Specifies an IPv6 VRRP group by its virtual router ID in the range of 1 to 255.

vrf *vrf-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, this command applies to IPv4 or IPv6 addresses after source address translation on the public network.

Usage guidelines

You can use different source IP address match criteria together with different source address translation methods to perform address translation. For example, when the **source-ip host** { *ipv4-address* | *ipv6-address* } command is used to configure packet match criteria for a NAT rule, the command can be used together with the **action snat static ip-address** { *global-ipv4-address* | *global-ipv6-address* } command to implement one-to-one static address translation.

When you use this command together with packet match criteria, follow these restrictions and guidelines:

- When you use the **action snat static ip-address** command together with the **source-ip** command, if you first execute the **source-ip** command and then the **action snat static ip-address** command, you cannot repeatedly execute the **source-ip** command to modify packet match criteria.
- When you use the static method for address translation, make sure the number of IP addresses in the packet match criteria for matching the source addresses of packets is the same as that in the static address translation method.

When a source address translation method references an address object group, follow these restrictions and guidelines:

- For an address object group to be successfully referenced by the source address translation method, make sure the objects in the referenced address object group are created through the following methods:
  - [*object-id*] **network host address** *ip-address*
  - [*object-id*] **network subnet** *ip-address* { *mask-length* | *mask* }
  - [*object-id*] **network range** *ip-address1 ip-address2*

  For more information about these commands, see object group commands in *Security Command Reference*.
- The number of IP addresses in the address object groups referenced by the source address translation method cannot exceed 65535.
- The address object group referenced by the static address translation method cannot contain excluded addresses.

In a hot backup system collaborating with VRRP, bind the translation actions in the following address translation methods to VRRP groups:

- **NO-PAT method**—Bind the IPv6-to-IPv4 source address translation action to the VRRP group on the IPv4 side.
- **PAT method**—Bind the IPv6-to-IPv4 source address translation action to the VRRP group on the IPv4 side.
- **Static NAT method**—Bind the IPv6-to-IPv4 source address translation action to the VRRP group on the IPv4 side.
- **Static NAT method**—Bind the IPv4-to-IPv6 source address translation action to the VRRP group on the IPv6 side.

If you do not bind the translation actions to VRRP groups, the uplink Layer 3 device directly connected to the hot backup system might send downlink packets to the backup device, causing service anomalies.

To perform source and destination address translations simultaneously in a VPN environment, make sure the translated addresses belong to the same VPN instance. To perform address translation, execute the **action snat** and **action dnat** commands.

This command is available only in NAT rule view of the global NAT policy.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure NAT rule **aaa** to use the PAT method and reference source IPv4 address object group **srcIP1**.

```
<Sysname> system
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name aaa type nat64
[Sysname-nat-global-policy-rule-nat64-aaa] action snat object-group srcIP1
```

Parameters

object-group *ipv6-object-group-name*: Specifies an IPv6 address object group by its name for address translation. The name is a case-insensitive string of 1 to 63 characters, and it cannot be **any**. If spaces are included in the name, enclose the name in quotation marks ("), for example, "XXX XXX".

no-pat: Uses the NO-PAT mode in which port numbers are not translated.

static: Uses the static method for address translation. The mappings between source IPv6 addresses before and after translation are manually configured.

ipv6-address *global-ipv6-address*: Specifies the source IPv6 address after translation.

nptv6: Uses the NPTv6 method for IPv6 address prefix translation.

translated-ipv6-prefix nptv6-prefix-length: Specifies the IPv6 address prefix after translation. The *translated-ipv6-prefix* argument indicates the address prefix. The *nptv6-prefix-length* argument specifies the IPv6 address prefix length in the range of 1 to 112.

no-nat: Disables the rule and its subsequent rules from translating the source IP address of the matching packets.

ipv6-vrrp *virtual-router-id*: Specifies an IPv6 VRRP group by its virtual router ID in the range of 1 to 255.

vrf *vrf-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, this command applies to IPv6 addresses after source address translation on the public network.

Usage guidelines

You can use different source IP address match criteria together with different source address translation methods to perform address translation. For example, when the **source-ip host** { *ipv4-address* | *ipv6-address* } command is used to configure packet match criteria for a NAT rule, the command can be used together with the **action snat static ip-address** { *global-ipv4-address* | *global-ipv6-address* } command to implement one-to-one static address translation.

If you have configured a large number of NAT rules, to exclude some packets with addresses in a small range from source address translation, use the NO-PAT method.

When you use this command together with packet match criteria, follow these restrictions and guidelines:

- When you use the **action snat static ip-address** command together with the **source-ip** command, if you first execute the **source-ip** command and then the **action snat static ip-address** command, you cannot repeatedly execute the **source-ip** command to modify packet match criteria.
- The **action snat nptv6** command can be used together with only the **source-ip subnet** command. If you first execute the **source-ip subnet** command and then the **action snat nptv6** command, you cannot repeatedly execute the **source-ip** command to modify the packet match criteria.
- When you use the static method for address translation, make sure the number of IP addresses in the packet match criteria for matching the source addresses of packets is the same as that in the static address translation method.

When a source address translation method references an address object group, follow these restrictions and guidelines:

- For an address object group to be successfully referenced by the source address translation method, make sure the objects in the referenced address object group are created through the following methods:
  - [*object-id*] **network host address** *ip-address*
  - [*object-id*] **network subnet** *ip-address* { *mask-length* | *mask* }
  - [*object-id*] **network range** *ip-address1 ip-address2*

  For more information about these commands, see object group commands in *Security Command Reference*.

- The number of IP addresses in the address object group referenced by the source address translation method cannot exceed 65535.
- An address object group referenced by the static address translation method cannot contain excluded addresses.

In a hot backup system collaborating with VRRP, bind the static address translation action to the VRRP group on the IPv6 side. If you do not perform the binding, the uplink Layer 3 device directly connected to the hot backup system might send downlink packets to the backup device, causing service anomalies.

To perform source and destination address translations simultaneously in a VPN environment, make sure the translated addresses belong to the same VPN instance. To perform address translation, execute the **action snat** and **action dnat** commands.

This command is available only in NAT rule view of the global NAT policy.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure NAT rule **aaa** to use the NAT66 prefix method to translate the source IPv6 address prefix to 2101::/64 for packets whose source IP addresses match subnet fd9C:58ed:7d73:2::/64.

```
<Sysname> system
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name aaa type nat66
[Sysname-nat-global-policy-rule-nat66-aaa] source-ip subnet fd9C:58ed:7d73:2:: 64
[Sysname-nat-global-policy-rule-nat66-aaa] action snat prefix 2101:: 64
```

Parameters

address-group: Uses the NAT address group for address translation.

group-id: Specifies the ID of the NAT address group. The value range is 0 to 65535.

name *group-name*: Specifies the name of an address group, a case-sensitive string of 1 to 63 characters.

easy-ip: Uses the Easy IP method. The IP address of the packet output interface is used as the NAT IP address.

ip-address *global-address*: Specifies a public IP address as the NAT IP address for source address translation.

no-nat: Disables the rule and its subsequent rules from translating the source IP address of the matching packets.

no-pat: Uses the NO-PAT mode in which port numbers are not translated.

reversible: Enables reverse address translation. Reverse address translation uses existing NO-PAT entries to translate the destination address for connections actively initiated from the internal network to the external network.

port-preserved: Tries to preserve port number for PAT.

static: Uses the static NAT method. Mappings between private and public addresses are manually configured.

object-group *object-group-name*: Specifies the name of an address object group. The name is a case-insensitive string of 1 to 63 characters, and it cannot be **any**. If spaces are included in the name, enclose the name in quotation marks ("), for example, "XXX XXX".

subnet *subnet-ip-address mask-length*: Specifies a subnet as NAT IP address resources for address translation. The *subnet-ip-address* argument specifies the subnet address. The *mask-length* argument specifies the mask length, which can be 8, 16, or an integer in the range of 24 to 31.

vrrp *virtual-router-id*: Binds the source translation method to a VRRP group. The *virtual-router-id* parameter represents the virtual router ID in the range of 1 to 255.

vrf *vrf-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, this command applies to IPv4 addresses after source address translation on the public network.

Usage guidelines

A NAT address group cannot be used by both the PAT and NO-PAT methods.

You can configure combinations between source IP address match criteria and source IP address translation methods. In each static combination, the number of IP addresses in the match criteria must equal the number of NAT IP addresses in the translation method. For example, the **action snat static ip-address** *global-address* command and the **source-ip host** *ip-address* command can define a one-to-one static source address translation.

If excessive NAT rules exist and you want to disable address translation for specific traffic temporarily, locate the NAT rule that matches the traffic and specify the **no-nat** keyword in the rule.

When the source address translation method references an address object group, follow these restrictions and guidelines:

- For an address object group to be successfully referenced by the source address translation method, make sure the objects in the referenced address object group are created through the following methods:
  - [*object-id*] **network host address** *ip-address*
  - [*object-id*] **network subnet** *ip-address* { *mask-length* | *mask* }
  - [*object-id*] **network range** *ip-address1 ip-address2*

  For more information about these commands, see object group commands in *Security Command Reference*.
- The number of IP addresses in the address object groups referenced by the source address translation method cannot exceed 65535.
- An address object group referenced by the static address translation method cannot contain excluded addresses.

In a hot backup system collaborating with VRRP, bind the source address translation method on the primary device in the hot backup system to the VRRP group facing the external network. If you do not perform the binding, the uplink Layer 3 device directly connected to the hot backup system might send downlink packets to the backup device, causing service anomalies.

For dual-active hot backup, select one of the following configuration methods:

- The two devices can share the same NAT address group. To prevent different master devices from using the same IP-port mapping for different hosts, specify the PAT translation mode and execute the **nat remote-backup port-alloc** command on the primary device.
- As a best practice to prevent different master devices from using the same IP-port mapping for different hosts, configure the two devices to use different public IP addresses for address translation. For example, if the two devices use different NAT addresses, user traffic with different source IP addresses is identified by source IP address match criteria in NAT rules. To enable different master devices to translate the forward user traffic, specify different gateway addresses for different internal users. To direct the reverse traffic to different master devices, configure VRRP group binding on the primary device for load sharing.

To perform source and destination address translations simultaneously in a VPN environment, make sure the translated addresses belong to the same VPN instance. To perform address translation, execute the **action snat** and **action dnat** commands.

This command is available only in NAT rule view of the global NAT policy.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure NAT rule **aaa** to use the PAT mode and NAT address group **0** for address translation.

```
<Sysname> system
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name aaa
[Sysname-nat-global-policy-rule-aaa] action address-group 0
```

Configure NAT rule **aaa** to use the NO-PAT mode and address group **0** for address translation.

```
<Sysname> system
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name aaa
[Sysname-nat-global-policy-rule-aaa] action address-group 0 no-pat
```

Configure NAT rule **aaa** to use the static NAT method to translate source IP address 1.1.1.1 to 100.10.0.1.

```
<Sysname> system
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name aaa
[Sysname-nat-global-policy-rule-aaa] source-ip host 1.1.1.1
[Sysname-nat-global-policy-rule-aaa] action snat static ip-address 100.10.0.1
```

Disable address translation for NAT rule **aaa**.

```
<Sysname> system
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name aaa
[Sysname-nat-global-policy-rule-aaa] action snat no-nat
```

Related commands

nat address-group

address

Use **address** to add an address range to a NAT address group.

Use **undo address** to remove an address range from a NAT address group.

Syntax

address *start-address end-address*

undo address *start-address end-address*

Default

No address ranges exist.

Views

NAT address group view

Predefined user roles

network-admin

context-admin

Parameters

start-address end-address: Specifies the start and end IP addresses of the address range. The end address must not be lower than the start address. If they are the same, the address range has only one IP address.

Usage guidelines

A NAT address group is a set of address ranges. The source address in a packet destined for an external network is translated into an address in one of the address ranges.

You can specify a maximum of 65535 addresses in one command execution. Make sure the address ranges do not overlap.

The **address** command and the **address interface** command are mutually exclusive for one NAT address group.

Examples

Add address ranges to an address group.

```
<Sysname> system-view
[Sysname] nat address-group 2
[Sysname-address-group-2] address 10.1.1.1 10.1.1.15
[Sysname-address-group-2] address 10.1.1.20 10.1.1.30
```

Related commands

nat address-group

block-size

Use **block-size** to set the port block size.

Use **undo block-size** to restore the default.

Syntax

block-size *block-size*

undo block-size

Default

The port block size is 256.

Views

NAT port block group view

Predefined user roles

network-admin

context-admin

Parameters

block-size: Specifies the number of ports for a port block. The value range for this argument is 1 to 65535.

Usage guidelines

Set an appropriate port block size based on the number of private IP addresses, the number of public IP addresses, and the port range in the port block group.

The port block size cannot be larger than the number of ports in the port range.

Examples

Set the port block size to 1024 for port block group **1**.

```
<Sysname> system-view
[Sysname] nat port-block-group 1
[Sysname-port-block-group-1] block-size 1024
```

Related commands

nat port-block-group

counting enable

Use **counting enable** to enable hit counting for a NAT rule.

Use **undo counting enable** to disable hit counting for a NAT rule.

Syntax

counting enable

undo counting enable

Default

NAT rule hit counting is disabled.

Views

NAT rule view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command enables the devices to count the number of times the rule is matched (or hit). To view hit statistics for the rule, execute the **display nat policy** command.

Examples

Enable hit counting for NAT rule **aaa** in the interface-based NAT policy.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy] rule name aaa
[Sysname-nat-policy-rule-aaa] counting enable
```

Enable hit counting for NAT rule **aaa** in the global NAT policy.

```
<Sysname> system
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name aaa
[Sysname-nat-global-policy-rule-aaa] counting enable
```

Related commands

display nat all

display nat global-policy

display nat policy

description

Use **description** to configure a description for the NAT rule.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

A NAT rule does not have any description.

Views

NAT rule view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies the description, a case-sensitive string of 1 to 63 characters.

Examples

Configure a description for NAT rule **aaa** in the interface-based NAT policy.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy] rule name aaa
[Sysname-nat-policy-rule-aaa] description This is a nat rule of abc policy
```

Configure a description for NAT rule **aaa** in the global NAT policy.

```
<Sysname> system
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name aaa
[Sysname-nat-global-policy-rule-aaa] description This is a nat rule of abc policy
```

destination-ip

Use **destination-ip** to specify a destination IP address match criterion in a NAT rule.

Use **undo destination-ip** to delete a destination IP address match criterion from a NAT rule.

Syntax

NAT-type rule view in the interface-based NAT policy:

destination-ip *ipv4-object-group-name*

undo destination-ip [*ipv4-object-group-name*]

NAT-type rule view in the global NAT policy:

destination-ip { **host** *ip-address* | **subnet** *subnet-ip-address mask-length* }

undo destination-ip { **host** [*ip-address*] | **subnet** [*subnet-ip-address mask-length*] }

NAT64-type rule view in the global NAT policy:

destination-ip { *ipv4-object-group-name* | *ipv6-object-group-name* }

undo destination-ip [*ipv4-object-group-name* | *ipv6-object-group-name*]

destination-ip { **host** { *ipv4-address* | *ipv6-address* } | **subnet** { *subnet-ipv4-address mask-length* | *ipv6-prefix prefix-length* } }

undo destination-ip { **host** [*ipv4-address* | *ipv6-address*] | **subnet** [*subnet-ipv4-address mask-length* | *ipv6-prefix prefix-length*] }

NAT66-type rule view in the global NAT policy:

destination-ip *ipv6-object-group-name*

undo destination-ip [*ipv6-object-group-name*]

destination-ip { **host** *ipv6-address* | **subnet** *ipv6-prefix prefix-length* }

undo destination-ip { **host** [*ipv6-address*] | **subnet** [*ipv6-prefix prefix-length*] }

Default

A NAT rule does not have any destination IP address match criteria.

Views

NAT rule view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-object-group-name: Specifies the name of an IPv4 address object group. The name is a case-insensitive string of 1 to 63 characters, and it cannot be **any**. If spaces are included in the name, enclose the name in quotation marks ("), for example, "XXX XXX".

ipv6-object-group-name: Specifies the name of an IPv6 address object group. The name is a case-insensitive string of 1 to 63 characters, and it cannot be **any**. If spaces are included in the name, enclose the name in quotation marks ("), for example, "XXX XXX".

host *ipv4-address*: Specifies an IPv4 address to match destination IP address. The IPv4 address cannot be an all-zero address, all-one address, Class D address, Class E address, or loopback address.

host *ipv6-address*: Specifies an IPv6 address to match destination IP address.

subnet *subnet-ipv4-address mask-length*: Specifies a subnet to match destination IPv4 addresses. The *subnet-ip-address* argument specifies the subnet address. The *mask-length* argument specifies the mask length, which can be 8, 16, or an integer in the range of 24 to 31.

subnet *ipv6-prefix prefix-length*: Specifies an IPv6 prefix for a NAT rule. The *ipv6-prefix* argument indicates an IPv6 prefix. The *prefix-length* argument indicates the prefix length in the range of 1 to 128.

Usage guidelines

The NAT device uses the destination IP addresses specified in this command to identify matching packets. Only packets with the matching destination IP addresses are translated.

To translate destination IP addresses of packets from the internal network to the external network, use this command with the **action dnat** command.

When referencing an address object group, follow these restrictions and guidelines:

- The address object group must already exist.
- For an address object group to be successfully referenced by the destination address translation method, make sure the objects in the referenced address object group are created through the following methods:
  - [*object-id*] **network host address** *ip-address*
  - [*object-id*] **network subnet** *ip-address* { *mask-length* | *mask* }
  - [*object-id*] **network range** *ip-address1 ip-address2*

  For more information about these commands, see object group commands in *Security Command Reference*.

If you do not specify any parameters in the **undo destination-ip** command, the command deletes all destination address match criteria in the NAT rule.

When you configure match criteria for a NAT rule, follow these restrictions and guidelines:

- A NAT rule can have a maximum of 256 destination address object groups.
- A NAT rule can have a maximum of 256 destination IP addresses.
- If you configure multiple packet match criteria in a NAT64-type rule, the IP address type in the later configured packet match criteria must be the same as that in the earlier configured packet match criteria. For example, if you first execute the **destination-ip host 192.168.1.1** command, the **destination-ip host 100::1** command executed later does not take effect. Select an IP type as needed.
- If you execute the following commands in the same NAT rule, the most recent configuration takes effect:
  - **destination-ip subnet**
  - **destination-ip**
  - **destination-ip host**

Examples

In the interface-based NAT policy, configure NAT rule **aaa** to use destination address object groups **desIP1**, **desIP2**, and **desIP3** as the packet match criteria.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy] rule name aaa
[Sysname-nat-policy-rule-aaa] destination-ip desIP1
[Sysname-nat-policy-rule-aaa] destination-ip desIP2
[Sysname-nat-policy-rule-aaa] destination-ip desIP3
```

In the global NAT policy, configure NAT rule **aaa** to use destination address object groups **desIP1**, **desIP2**, and **desIP3** as the packet match criteria.

```
<Sysname> system-view
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name aaa
[Sysname-nat-global-policy-rule-aaa] destination-ip desIP1
[Sysname-nat-global-policy-rule-aaa] destination-ip desIP2
[Sysname-nat-global-policy-rule-aaa] destination-ip desIP3
```

display nat policy

object-group (*Security Command Reference*)

destination-zone

Use **destination-zone** to specify a destination security zone in a NAT rule.

Use **undo destination-zone** to delete a destination security zone from a NAT rule.

Syntax

destination-zone *destination-zone-name*

undo destination-zone [*destination-zone-name*]

Default

No destination security zones are specified in a NAT rule.

Views

NAT rule view

Predefined user roles

network-admin

context-admin

Parameters

destination-zone-name: Specifies the name of a destination security zone. The name is a case-insensitive string of 1 to 31 characters, and it cannot be **any**. You can specify a nonexistent security zone. This command takes effect after you use the **security-zone name** command to create the security zone. For more information about security zones, see *Security Configuration Guide*.

Usage guidelines

The NAT device uses the destination security zones specified in this command to identify matching packets. Only packets with the matching destination security zones are translated.

To translate source IP addresses of outgoing packets, use this command with the **action snat** command. This command cannot be used with the **action dnat** command.

This command does not support modifying destination security zones. To modify the destination security zone for a NAT rule, first execute the **undo destination-zone** command to delete the zone, and then execute the **destination-zone** command to specify a new one.

If you do not specify a destination security zone in the **undo destination-zone** command, the command deletes all destination security zones in the rule.

This command is available only in NAT-type rule view and NAT66-type rule view of the global NAT policy.

A NAT rule can have a maximum of 16 destination security zones.

Examples

Specify destination security zone **trust** for NAT rule **rule1**.

```
<Sysname> system-view
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name rule1
[Sysname-nat-global-policy-rule-rule1] destination-zone trust
```

Related commands

Parameters

group-id: Specifies the ID of a NAT address group. The value range for this argument is 0 to 65535. If you do not specify the *group-id* argument, this command displays information about all NAT address groups.

Examples

Display information about all NAT address groups.

```
<Sysname> display nat address-group
NAT address group information:
  Totally 5 NAT address groups.
  Address group ID: 1    Address group name: a
    Port range: 1-65535
    Address information:
      Start address         End address
      202.110.10.10         202.110.10.15

  Address group ID: 2
    Port range: 1-65535
    VRID      : 1
    Address information:
      Start address         End address
      202.110.10.20         202.110.10.25
      202.110.10.30         202.110.10.35

  Address group ID: 3
    Port range: 1024-65535
    Address information:
      Start address         End address
      202.110.10.40         202.110.10.50

  Address group ID: 4
    Port range: 10001-65535
    Port block size: 500
    Extended block number: 1
    Address information:
      Start address         End address
      202.110.10.60         202.110.10.65

  Address group ID: 5
    Port range: 1-1024
    Port block size: 500
    Address information:
      20.1.1.1 (GigabitEthernet1/0/1)
```

```
  Address group ID: 6
    Port range: 1-65535
    Address information:
      Start address         End address
      ---                   ---
```

Display information about NAT address group **1**.

```
<Sysname> display nat address-group 1
  Address group ID: 1    Address group name: a
    VRID      : 1
    Port range: 1-65535
    Address information:
      Start address         End address
      202.110.10.10         202.110.10.15
```

Table 1 Command output

Field	Description
NAT address group information	Information about the NAT address group
Address group ID	ID of the NAT address group.
Totally *n* NAT address groups	Total number of NAT address groups.
Address group name	Name of the NAT address group. If no address group name is configured, this field is not displayed.
VRID	Virtual router ID (VRRP group number). If no VRRP group is specified, this field is not displayed.
Port range	Port range for public IP addresses.
Port block size	Number of ports in a port block. This field is not displayed if the port block size is not set.
Extended block number	Number of extended port blocks. This field is not displayed if the number of extended port blocks is not set.

Address information	Information about the IP addresses in the address group.
	• For addresses added by using the **address** command:
	  ○ **Start address**—Start IP address of an address range. If you do not specify a start address for the range, this field displays hyphens (**---**).
	  ○ **End address**—End IP address of an address range. If you do not specify an end address for the range, this field displays hyphens (**---**).
	• For addresses added by using the **address interface** command:
	  ○ **20.1.1.1 (GigabitEthernet1/0/1)**—IP address 20.1.1.1 of GigabitEthernet 1/0/1 has been added to the NAT address group.
	  ○ **--- (GigabitEthernet1/0/2)**—Failed to add the IP address of GigabitEthernet 1/0/2 to the NAT address group because this interface does not have an IP address.

```

```
  Port block group 2:
    Port range: 10001-30000
    Block size: 500
    Local IP address information:
      Start address        End address          VPN instance
      10.1.1.1             10.1.10.255          ---
    Global IP pool information:
      Start address        End address
      202.10.10.101        202.10.10.120

  Port block group 3:
    Port range: 1-65535
    Block size: 256
    Local IP address information:
      Start address        End address          VPN instance
      ---                  ---                  ---
    Global IP pool information:
      Start address        End address
      ---                  ---

NAT outbound port block group information:
  Totally 2 outbound port block group items.
  Interface: GigabitEthernet1/0/2
    port-block-group: 2
    Rule name: stone
    Config status   : Active

  Interface: GigabitEthernet1/0/2
    port-block-group: 10
    Config status   : Inactive
    Reasons for inactive status:
      The following items don't exist or aren't effective: port block group.

Static NAT load balancing:     Disabled

NAT link-switch recreate-session: Disabled

NAT configuration-for-new-connection: Disabled
```

The output shows all NAT configuration information. Table 2 describes only the fields for the output of the **nat hairpin enable**, **nat mapping-behavior**, and **nat alg** commands.

Table 2 Command output

Field	Description
NAT address group information	Information about the NAT address group. See Table 1 for output description.
NAT server group information	Information about the internal server group. See Table 19 for output description.
NAT inbound information:	Inbound dynamic NAT configuration. See Table 6 for output

Field	Description
	description.
NAT outbound information	Outbound dynamic NAT configuration. See Table 10 for output description.
NAT internal server information	NAT server mapping configuration. See Table 18 for output description.
NAT global-policy information	Configuration of the global NAT policy. See Table 5 for output description.
NAT policy information	Configuration of the NAT policy. See Table 13 for output description.
Static NAT mappings	Static NAT mappings. See Table 21 for output description.
NAT DNS mappings	NAT DNS mappings. See Table 3 for output description.
NAT logging	NAT logging configuration. See Table 7 for output description.
NAT hairpinning	NAT hairpin configuration.
Totally *n* interfaces enabled NAT hairpinning	Number of interfaces with NAT hairpin enabled.
Interface	NAT hairpin-enabled interface.
Rule name	Name of the NAT rule.
Priority	Priority of the NAT rule.
Config status	Status of the NAT hairpin configuration: **Active** or **Inactive**.
NAT mapping behavior	Mapping behavior mode of PAT: **Endpoint-Independent** or **Address and Port-Dependent**.
ACL	ACL number or name. If no ACL is specified for NAT, this field displays hyphens (---).
Config status	Status of the NAT mapping behavior configuration: **Active** or **Inactive**.
Reasons for inactive status	Reasons why the NAT mapping behavior configuration does not take effect. This field is available when the **Config status** is **Inactive**.
NAT ALG	NAT ALG configuration for different protocols.
NAT port block group information	Configuration information about NAT port block groups. See Table 15 for output description.
NAT outbound port block group information	Configuration information about static outbound port block mapping rules. See Table 11 for output description.
Static NAT load balancing	Whether load balancing is enabled for static NAT on service engines: • Enabled. • Disabled.
NAT link-switch recreate-session	Whether NAT session recreation after link switchover is enabled: • Enabled. • Disabled.
NAT configuration-for-new-connection	Whether NAT configuration changes taking effect only on new connections is enabled: • Enabled. • Disabled.

display nat dns-map

Use **display nat dns-map** to display NAT DNS mappings.

Syntax

display nat dns-map

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display NAT DNS mappings.

```
<Sysname> display nat dns-map
NAT DNS mapping information:
  Totally 2 NAT DNS mappings.
  Domain name  : www.server.com
  Global IP    : 6.6.6.6
  Global port  : 23
  Protocol     : TCP(6)
  Config status: Active

  Domain name  : www.service.com
  Global IP    : ---
  Global port  : 12
  Protocol     : TCP(6)
  Config status: Inactive
  Reasons for inactive status:
    The following items don't exist or aren't effective: interface IP address.
```

Table 3 Command output

Field	Description
NAT DNS mapping information	Information about NAT DNS mappings.
Totally *n* NAT DNS mappings	Total number of NAT DNS mappings.
Domain name	Domain name of the internal server.
Global IP	Public IP address of the internal server. • If Easy IP is configured, this field displays the IP address of the specified interface. • If you do not specify a public IP address, this field displays hyphens (**---**).
Global port	Public port number of the internal server.
Protocol	Protocol name and number of the internal server.

Field	Description
Config status	Status of the DNS mapping: **Active** or **Inactive**.
Reasons for inactive status	Reasons why the DNS mapping does not take effect. This field is available when the **Config status** is **Inactive**.

Related commands

nat dns-map

display nat eim

Use **display nat eim** to display information about NAT Endpoint-Independent Mapping (EIM) entries.

Syntax

display nat eim [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays EIM entry information for all member devices.

Usage guidelines

EIM entries are created when PAT operates in EIM mode. An EIM entry is a 3-tuple entry, and it records the mapping between a private address/port and a public address/port.

The EIM entry provides the following functions:

- The same EIM entry applies to subsequent connections initiated from the same source IP and port.
- The EIM entries allow reverse translation for connections initiated from external hosts to internal hosts.

Examples

Display information about EIM entries for the specified slot.

```
<Sysname> display nat eim slot 1
Slot 1:
Local  IP/port: 192.168.100.100/1024
Global IP/port: 200.100.1.100/2048
Local  VPN: vpn1
Global VPN: vpn2
Protocol: TCP(6)

Local  IP/port: 192.168.100.200/2048
```

```
Global IP/port: 200.100.1.200/4096
Protocol: UDP(17)

Total entries found: 2
```

Table 4 Command output

Field	Description
Local VPN	MPLS L3VPN instance to which the private IP address belongs. If the private IP address does not belong to any VPN instance, this field is not displayed.
Global VPN	MPLS L3VPN instance to which the public IP address belongs. If the public IP address does not belong to any VPN instance, this field is not displayed.
Protocol	Protocol name and number.
Total entries found	Total number of EIM entries.

Related commands

nat mapping-behavior

nat outbound

display nat global-policy

Use **display nat global-policy** to display configuration of the global NAT policy.

Syntax

display nat global-policy [**rule-type** { **nat** | **nat64** | **nat66** }]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

rule-type: Specifies a NAT rule type. If you do not specify this keyword, this command displays information about all types of NAT rules.

nat: Specifies NAT-type rules.

nat64: Specifies NAT64-type rules.

nat66: Specifies NAT66-type rules.

Examples

Display configuration of all types of NAT rules in the global NAT policy.

```
<Sysname> display nat global-policy
NAT global-policy information:
  Totally 8 NAT global-policy rules.
```

```

Table 5 Command output

Field	Description
NAT global-policy information	Configuration of the global NAT policy.
Totally *n* NAT global-policy rules	Total number of NAT rules in the policy.
Rule name	Name of the NAT rule.
Type	NAT rule type: • **nat**—NAT rule, which is used for translation between IPv4 addresses. • **nat64**—NAT64-type rule, which is used for translation between IPv4 addresses and IPv6 addresses. • **nat66**—NAT66-type rule, which is used for translation between IPv6 addresses or IPv6 address prefixes.
Description	Description of the NAT rule.
SrcIP object group	Source IP address object group in the NAT rule.
SrcIP address	IP address that the NAT rule uses to match packet source IP addresses.
SrcIP subnet	Subnet address that the NAT rule uses to match packet source IP addresses.
DestIP object group	Destination IP address object group in the NAT rule.
DestIP address	IP address that the NAT rule uses to match packet destination IP addresses.

Field	Description
DestIP subnet	Subnet address that the NAT rule uses to match packet destination IP addresses.
Service object group	Service object group in the NAT rule.
Source-zone name	Source security zone in the NAT rule.
Destination-zone name	Destination security zone in the NAT rule.
Vrf	VPN instance in the NAT rule.
IPv4 VRRP VRID	Virtual router ID (IPv4 VRRP group number) bound to the NAT rule.
IPv6 VRRP VRID	Virtual router ID (IPv6 VRRP group number) bound to the NAT rule.
SNAT action	Source address translation method in the NAT rule.
NO-NAT	No address translation.
Address group ID	ID of the NAT address group used in the NAT rule. If no NAT address group is specified, this field is not displayed.
Address group name	Name of the NAT address group used in the NAT rule. If no NAT address group is specified, this field is not displayed.
Easy-IP	Easy IP method used in the NAT rule. This field is not displayed if the Easy IP method is not specified.
IPv4 address	NAT IP address for source address translation. This field is not displayed if no translated source IP address is configured.
IPv6 address	NAT IPv6 address for source address translation. This field is not displayed if no translated source IPv6 address is configured.
Subnet	A range of NAT IP addresses for source address translation. This field is not displayed if no translated source subnet is configured.
NO-PAT	Whether NO-PAT or PAT is used: • **Y**—NO-PAT is used. • **N**—PAT is used.
Reversible	Whether reverse address translation is allowed: • **Y**—Reverse address translation is allowed. • **N**—Reverse address translation is not allowed.
Prefix	Prefix translation method used for source address translation in a NAT64-type rule: • **nat64 v4tov6**—Uses the NAT64 prefix to translate source IPv4 addresses to IPv6 addresses. • **General v4tov6**—Uses the general prefix to translate source IPv4 addresses to IPv6 addresses. • **General v6tov4**—Uses the general prefix to translate source IPv6 addresses to IPv4 addresses. This field is not displayed if the prefix method is not configured for source address translation.
Port-preserved	Whether to try to preserve the port numbers for PAT. • **Y**—Tries to preserve the port numbers. • **N**—Allows translating port numbers.
NPTv6	IPv6 address prefix used for source IPv6 address translation in NPTv6 method. The format is *translated-ipv6-prefix nptv6-prefix-length*, where the

Field	Description
	translated-ipv6-prefix argument indicates the address prefix and the *nptv6-prefix-length* argument specifies the IPv6 address prefix length. This field is not displayed if the NPTv6 method is not configured for source IPv6 address translation.
Vrf	VPN instance to which the source IP address after translation belongs.
DNAT action	Destination IP address translation method of the NAT rule.
IPv4 address	NAT IPv4 address for destination IP address translation.
IPv6 address	NAT IPv6 address for destination IP address translation.
Port	Translated port number for destination IP address translation.
Prefix	Prefix translation method used for destination address translation in a NAT64-type rule: • **nat64 v6tov4**—Uses the NAT64 prefix to translate destination IPv6 addresses to IPv4 addresses. • **General v4tov6**—Uses the general prefix to translate destination IPv4 addresses to IPv6 addresses. • **General v6tov4**—Uses the general prefix to translate destination IPv6 addresses to IPv4 addresses. • **IVI v4tov6**—Uses the IVI prefix to translate IPv4 addresses to IPv6 addresses. This field is not displayed if the prefix method is not configured for destination address translation.
NPTv6	IPv6 address prefix used for destination IPv6 address translation in NPTv6 method. The format is *translated-ipv6-prefix nptv6-prefix-length*, where the *translated-ipv6-prefix* argument indicates the address prefix and the *nptv6-prefix-length* argument specifies the IPv6 address prefix length. This field is not displayed if the NPTv6 method is not configured for source IPv6 address translation.
Vrf	VPN instance to which the destination IP address after translation belongs.
NAT counting	Number of times the NAT rule is matched.
Config status	Status of the global NAT policy: **Active** or **Inactive**.
Reasons for inactive status	Reasons why the NAT rule does not take effect. This field is available when the **Config status** is **Inactive**.

display nat inbound

Use **display nat inbound** to display inbound dynamic NAT configuration.

Examples

Display inbound dynamic NAT configuration.

```
<Sysname> display nat inbound
NAT inbound information:
  Totally 2 NAT inbound rules.
  Interface: GigabitEthernet1/0/2
    ACL: 2038
    Address group ID: 2
    Add route: Y            NO-PAT: Y  Reversible: N
    VPN instance: vpn1
    Rule name: abcd
    Priority: 1000
    Description: NatInbound1
    NAT counting: 0
    Config status: Active

Interface: GigabitEthernet1/0/3
    Address group ID: 1
    Add route: Y             NO-PAT: Y  Reversible: N
    Rule name: eif
    Priority: 1001
    NAT counting: 0
    Config status: Inactive
    Reasons for inactive status:
      The following items don't exist or aren't effective: ACL.
```

Table 6 Command output

Field	Description
NAT inbound information	Information about inbound dynamic NAT configuration.
Totally *n* NAT inbound rules	Total number of inbound dynamic NAT rules.
Interface	Interface where the inbound dynamic NAT rule is configured.
ACL	ACL number or name.
Address group ID	ID of the NAT address group used by the inbound dynamic NAT rule.
Address group name	Name of the NAT address group. If no address group name is configured, this field is not displayed.
Add route	Whether to add a route when a packet matches the inbound dynamic NAT rule: • **Y**—Adds a route. • **N**—Does not add a route.
NO-PAT	Whether NO-PAT or PAT is used:

Field	Description
	• **Y**—NO-PAT is used. • **N**—PAT is used.
Reversible	Whether reverse address translation is allowed: • **Y**—Reverse address translation is allowed. • **N**—Reverse address translation is not allowed.
VPN instance	MPLS L3VPN instance to which the NAT address group belongs. If the NAT address group does not belong to any VPN instance, the field is not displayed.
Rule name	Name of the NAT rule.
Priority	Priority of the NAT rule.
Description	Description of the NAT rule. This field is not displayed if no description is configured for the rule.
NAT counting	Number of times the NAT rule is matched.
Config status	Status of the inbound dynamic NAT rule: **Active** or **Inactive**.
Reasons for inactive status	Reasons why the inbound dynamic NAT rule does not take effect: This field is available when the **Config status** is **Inactive**.

context-operator

Examples

Display NAT logging configuration.

```
<Sysname> display nat log
NAT logging:
  Log enable          : Enabled(ACL 2000)
  Flow-begin          : Disabled
  Flow-end            : Disabled
  Flow-active         : Enabled(10 minutes)
  Port-block-assign   : Disabled
  Port-block-withdraw : Disabled
```

```
Alarm               : Disabled
NO-PAT IP usage     : Disabled
```

Table 7 Command output

Field	Description
NAT logging	NAT logging configuration.
Log enable	Enabling status of NAT logging. If an ACL is specified for NAT logging, this field also displays the ACL number or name.
Flow-begin	Enabling status of logging for NAT session establishment events.
Flow-end	Enabling status of logging for NAT session removal events.
Flow-active	Enabling status of logging for active NAT flows. If it is enabled, this field also displays the interval in minutes at which active flow logs are generated.
Port-block-assign	Enabling status of NAT444 user logging for port block assignment.
Port-block-withdraw	Enabling status of NAT444 user logging for port block withdrawal.
Alarm	Enabling status of logging for NAT444 alarms.
NO-PAT IP usage	Enabling status of logging for IP usage of NAT address groups when NO-PAT mode is used. If it is enabled, this field also displays IP usage for each configured NAT address group, in percentage.

`nat log flow-active`

`nat log flow-begin`

`nat log no-pat ip-usage`

display nat no-pat

Use **`display nat no-pat`** command to display information about NAT NO-PAT entries.

Syntax

`display nat no-pat` { **`ipv4`** | **`ipv6`** } [**`slot`** *`slot-number`*]

Views

Any view

Default user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`ipv4`: Displays NO-PAT entry information for IPv4 NAT sessions.

`ipv6`: Displays NO-PAT entry information for IPv6 NAT sessions.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays NO-PAT entry information for all member devices.

Usage guidelines

A NO-PAT entry records the mapping between a private address and a public address.

The NO-PAT entry provides the following functions:

- The same entry applies to subsequent connections initiated from the same source IP address.
- The NO-PAT entries allow reverse translation for connections initiated from external hosts to internal hosts.

Outbound and inbound NO-PAT address translations create their own NO-PAT tables. These two types of tables are displayed separately.

Examples

Display information about NO-PAT entries for IPv4 NAT sessions on the specified slot.

```
<Sysname> display nat no-pat ipv4 slot 1
Slot 1:
Global  IPv4: 200.100.1.100
Local   IPv4: 192.168.100.100
Global VPN: vpn2
Local  VPN: vpn1
Reversible: N
Type      : Inbound

Local   IPv4: 192.168.100.200
Global  IPv4: 200.100.1.200
Reversible: Y
Type      : Outbound

Total Ipv4 entries found: 2
```

Display information about NO-PAT entries for IPv6 NAT sessions on all cards.

```
<Sysname> display nat no-pat ipv6
Slot 0:
Global  IPv6: FD01:203:405::1
Local   IPv6: 2001:DB8:1::100
Global VPN: vpn2
Local  VPN: vpn1
Reversible: N
Type      : Inbound

Total Ipv6 entries found: 1
```

Display information about NO-PAT entries for IPv6 NAT sessions on the specified slot.

```
<Sysname> display nat no-pat slot 1 ipv6
Slot 1:
Global  IPv6: FD01:203:405::1
Local   IPv6: 2001:DB8:1::100
Global VPN: vpn2
Local  VPN: vpn1
Reversible: N
Type      : Inbound
```

```
Total Ipv6 entries found: 1
```

Table 8 Command output

Field	Description
Global IPv4	Public IPv4 address.
Local IPv4	Private IPv4 address.
Global IPv6	Public IPv6 address.
Local IPv6	Private IPv6 address.
Local VPN	MPLS L3VPN instance to which the private IP address belongs. If the private IP address does not belong to any VPN instance, this field is not displayed.
Global VPN	MPLS L3VPN instance to which the public IP address belongs. If the public IP address does not belong to any VPN instance, this field is not displayed.
Reversible	Whether reverse address translation is allowed: • **Y**—Reverse address translation is allowed. • **N**—Reverse address translation is not allowed.
Type	Type of the NO-PAT entry: • **Inbound**—A NO-PAT entry created during inbound dynamic NAT. • **Outbound**—A NO-PAT entry created during outbound dynamic NAT.
Total Ipv4 entries found	Total number of IPv4 NO-PAT entries.
Total Ipv6 entries found	Total number of IPv6 NO-PAT entries.

Predefines user roles

network-admin

network-operator

context-admin

context-operator

Parameters

address-group: Displays the IP usage of the specified NAT address group. If you do not specify this keyword, the command displays the IP usage of each NAT address group.

group-id: Specifies the ID of a NAT address group. The value range is 0 to 65535.

name *group-name*: Specifies the name of a NAT address group, a case-insensitive string of 1 to 63 characters.

object-group *object-group-name*: Specifies the IP usage of the specified object group. The name is a case-insensitive string of 1 to 63 characters.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays the IP usage of NAT address groups or object groups in NO-PAT mode for all member devices.

Examples

Display IP usage of address resources for all types in NO-PAT mode for the specified slot.

```
<Sysname> display nat no-pat ip-usage slot 1
```

CPU 0 on slot 1:

```
Totally 2 pieces of information about address usage.
  Address group 0:
    Total IP addresses   :10
    Used IP addresses    :9
    Unused IP addresses  :1
    NO-PAT IP usage      :90% (channel 0)

  Object group name: obj1
    Total IP addresses    :10
    Used IP addresses     :0
    Unused IP addresses   :10
    NO-PAT IP usage       :0%
```

Table 9 Command output

Field	Description
Address group	NAT address group ID.
NO-PAT IP usage	IP usage of the NAT address group or object group in NO-PAT mode.
channel	Field-programmable gate array (FPGA) ID.

    NAT counting: 0
    Config status: Active
```

Table 10 Command output

Field	Description
NAT outbound information	Information about outbound dynamic NAT configuration.
Totally *n* NAT outbound rules	Total number of outbound dynamic NAT rules.
Interface	Interface where the outbound dynamic NAT rule is configured.

Field	Description
ACL	IPv4 ACL number or name. If no IPv4 ACL is specified for outbound dynamic NAT rule, this field displays hyphens (**---**).
DS-Lite B4 ACL	Number or name of the IPv6 ACL used by DS-Lite B4 address translation.
Address group ID	ID of the address group used by the outbound dynamic NAT rule. If no address group is specified, the field displays hyphens (---).
Address group name	Name of the NAT address group. If no address group name is configured, this field is not displayed.
Port-preserved	Whether to try to preserve the port numbers for PAT. • **Y**—Tries to preserve the port numbers. • **N**—Allows translating port numbers.
NO-PAT	Whether NO-PAT is used: • **Y**—NO-PAT is used. • **N**—PAT is used.
Reversible	Whether reverse address translation is allowed: • **Y—**Reverse address translation is allowed. • **N—**Reverse address translation is not allowed.
VPN instance	MPLS L3VPN instance to which the NAT address group belongs. If the NAT address group does not belong to any VPN instance, the field is not displayed.
Rule name	Name of the NAT rule.
Priority	Priority of the NAT rule.
Description	Description of the NAT rule. This field is not displayed if no description is configured for the rule.
Configuration mode	Configuration method of the device. • This field displays **NETCONF (action)** if the device is configured by using a NETCONF action operation. • This field is not displayed if the device is configured by using other methods.
NAT counting	Number of times the NAT rule is matched.
Config status	Status of the outbound dynamic NAT rule: **Active** or **Inactive**.
Reasons for inactive status	Reasons why the outbound dynamic NAT rule does not take effect. This field is available when the **Config status** is **Inactive**.

Parameters

address-group: Displays periodic NAT statistics for the specified NAT address group.

group-id: Specifies the ID of a NAT address group. The value range for this argument is 0 to 65535.

name *group-name*: Specifies the name of a NAT address group. The name is a case-insensitive string of 1 to 63 characters.

ip *global-ip*: Displays periodic NAT statistics for the specified IP address. The *global-ip* argument specifies an IP address.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays periodic NAT statistics for all member devices.

Usage guidelines

If you do not specify the *group-id* argument or the **name** keyword, this command displays periodic NAT statistics for all NAT address groups.

Examples

Display periodic NAT statistics for address groups for slot 1.

```
<Sysname> display nat periodic-statistics address-group slot 1
Slot 1:
Totally 1 NAT address groups.
  Address group ID: 1     Address group name: abc
    NAT sessions                      : 10
    NAT port-block assign failures    : 0
```

Display periodic NAT statistics for IP address 202.38.6.12 for slot 1.

```
<Sysname> display nat periodic-statistics ip 202.38.6.12 slot 1
Slot 1:
  Global IP: 202.38.6.12
    NAT sessions                      : 10
```

```
    NAT port-block assign failures   : 0
```

Table 12 Command output

Field	Description

Parameters

dynamic: Displays dynamic port block mappings.

address-group: Displays port block mappings for the specified address group. If you do not specify a NAT address group, this command displays port block mappings for all address groups.

group-id: Specifies the ID of the address group. The value range for this argument is 0 to 65535.

name *group-name*: Specifies the name of the address group. The name is a case-insensitive string of 1 to 63 characters.

ds-lite-b4: Displays port block mappings for DS-Lite B4 address translation.

static: Displays static port block mappings.

port-block-group *group-id*: Displays port block mappings for the specified port block group. The *group-id* argument specifies the ID of the port block group. The value range for the *group-id* argument is 0 to 65535. If you do not specify a port block group, this command displays port block mappings for all port block groups.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays port block mappings for all member devices.

Examples

Display static port block mappings for the specified slot.

```
<Sysname> display nat port-block static slot 1
Slot 1:
Local VPN     Local IP         Global IP        Port block   Connections
---           100.100.100.111  202.202.100.101  10001-10256  0
---           100.100.100.112  202.202.100.101  10257-10512  0
---           100.100.100.113  202.202.100.101  10513-10768  0
```

```
---           100.100.100.113  202.202.100.101  10769-11024  0
Total entries found: 4
```

Display dynamic port block mappings.

```
<Sysname> display nat port-block dynamic slot 1
Slot 1:
Local VPN     Local IP         Global IP        Port block   Connections
---           101.1.1.12       192.168.135.201  10001-11024  1
Total entries found: 1
```

Display port block mappings for DS-Lite B4 address translation.

```
<Sysname> display nat port-block dynamic ds-lite-b4 slot 1
Slot 1:
Local VPN     DS-Lite B4 addr  Global IP        Port block   Connections
---           2000::2          192.168.135.201  10001-11024  1
Total entries found: 1
```

Table 14 Command output

Field	Description
Local VPN	MPLS L3VPN instance to which the private IP address belongs. If the private IP address does not belong to any VPN instance, this field displays hyphens (**---**).
Local IP	Private IP address.
DS-Lite B4 addr	IPv6 address of the DS-Lite B4 element.
Global IP	Public IP address.
Port block	Port block defined by a start port number and an end port number.
Connections	Number of connections established by using the ports in the port block.

display nat port-block-group

```

Table 15 Command output

Field	Description
NAT port block group information	Information about the port block group configuration.
Totally *n* NAT port block groups	Total number of port block groups.
Port block group	ID of the port block group.
VRID	Virtual router ID (VRRP group number). If no VRRP group is specified, this field is not displayed.
Port range	Port range for the public IP addresses.
Block size	Number of ports in a port block.
Local IP address information	Information about the private IP addresses.
Global IP pool information	Information about the public IP addresses.
Start address	Start IP address of a private or public IP address range. If no start IP address is specified for the address range, this field displays hyphens (**---**).
End address	End IP address of a private or public IP address range. If no end IP address is specified for the address range, this field displays hyphens (**---**).
VPN instance	MPLS L3VPN instance to which the private IP address range belongs. If no VPN instance is specified for the private address range, this field displays hyphens (**---**).

Related commands

nat port-block-group

display nat port-block-usage

Use **display nat port-block-usage** to display the port block usage for address groups.

Syntax

display nat port-block-usage [**address-group** *group-id*] [**slot** *slot-number*]

Views

System view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

address-group *group-id*: Specifies the ID of an address group. The value range for the *group-id* argument is 0 to 65535. If you do not specify an address group, this command displays the port block usage for all address groups.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays the port block usage for all member devices.

Examples

Display the port block usage for address groups for slot 1.

```
<Sysname> display nat port-block-usage slot 1
Slot 1:
Address group 0 on channel 0:
  Total port block entries :10
  Active port block entries:9
  Current port block usage :90%
Total NAT address groups found: 1
```

Table 16 Command output

Field	Description
Address group	ID of the address group.
channel	Field-programmable gate array (FPGA) ID.
Total port block entries	Total number of port blocks in the address group.
Active port block entries	Total number of assigned port blocks in the address group.
Current port block usage	Port block usage in the address group.
Total NAT address groups found	Total number of address groups.

display nat probe address-group

Use **display nat probe address-group** to display NAT address group probe information.

Syntax

display nat probe address-group [*group-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

group-id: Specifies the address group ID. The value range for this argument is 0 to 65535. If you do not specify this argument, the command displays probe information for all address groups.

Usage guidelines

The excluded IP addresses displayed by this command only refers to those detected by the address group probe. The excluded IP addresses configured by the **exclude-ip** command are not included.

Examples

Display NAT address group probe information

```
<Sysname> display nat probe address-group
Address group ID: 1
Address-group name: dududu1
Address-group probe status: Partial available
Detected IP count: 5
Excluded IP count: 4
  IP address      Excluded  Excluded time
  1.1.1.1         YES       2017/12/26 09:30:39

  1.1.1.5         NO        ----
```

Table 17 Command output

Field	Description
Address group ID	ID of the NAT address group.
Address group name	Name of the address group. If the address group does not have a name, this field is not displayed.
Address-group probe status	Status of the address group status: • **Inactive**—The probe is not enabled. • **In progress**—The probe is in progress. • **All available**—All IP addresses in the group are available. • **Partial available**—Partial IP addresses are available. • **None available**—None of the IP addresses are available.
Detected IP count	Number of IP addresses that have been detected.
Excluded IP count	Number of IP addresses that are excluded from address translation.
IP address	IP addresses in the NAT address group.
Excluded	Whether the IP address is excluded from address translation: • **YES**—The IP address is excluded from address translation. • **NO**—The IP address is not excluded and can be used for address translation.
Excluded time	Time when the IP address is excluded from address translation.

Table 18 Command output

Field	Description
NAT internal server information (object-group)	Information about the object group-based NAT server mappings.
Totally *n* object-group-based NAT server rules	Total number of object group-based NAT server mappings.
Rule name	Name of the NAT server mapping.
Priority	Priority of the NAT server mapping.
Configuration mode	Configuration method of the device. • This field displays **NETCONF (action)** if the device is configured by using a NETCONF action operation. • This field is not displayed if the device is configured by using other methods.
NAT internal server information	Information about NAT server mapping.
Interface	Interface where the NAT server mapping is configured.
Protocol	Protocol number and name of the internal server.
VRID	Virtual router ID (VRRP group number). If no VRRP group is specified, this field is not displayed.
Global IP/port	Public IP address and port number of the internal server. • **Global IP**—A single IP address or an IP address range. If you use Easy IP, this field displays the IP address of the specified interface. If you do not specify an address for the interface, the **Global IP** field displays hyphens (**---**). • **port**—A single port number or a port number range. If no port number is in the specified protocol, the **port** field displays hyphens (**---**).
Local IP/port	For common NAT server mappings and object group-based NAT server mappings, this field displays the private IP address and port number of the internal server. • **Local IP**—A single IP address or an IP address range. • **port**—A single port number or a port number range. If no port number is in the specified protocol, the **port** field displays hyphens (---). For a load sharing NAT server mapping, this field displays the internal server group ID, IP address, port number, and number of connections of each member.
DestIP Object group	Destination IP object group used by the NAT server mapping.
Service Object group	Service object group used by the NAT server mapping.

Field	Description
Global VPN	MPLS L3VPN instance to which the public IP addresses belong. If the public IP addresses do not belong to any VPN instance, this field is not displayed.
Local VPN	MPLS L3VPN instance to which the private IP addresses belong. If the private IP addresses do not belong to any VPN instance, this field is not displayed.
ACL	ACL number or name. If no ACL is specified, this field is not displayed.
Rule name	Name of the NAT server mapping.
NAT counting	Number of times the NAT server mapping is matched.
Description	Description of the NAT server mapping. This field is not displayed if no description is configured for the mapping.
Config status	Status of the NAT server mapping: **Active** or **Inactive**.
Reasons for inactive status	Reasons why the NAT server mapping does not take effect. This field is available when the **Config status** is **Inactive**.

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

group-id: Specifies the ID of the internal server group. The value range for this argument is 0 to 65535. If you do not specify this argument, the command displays the configuration of all internal server groups.

Examples

Display the configuration of all internal server groups.

```
<Sysname> display nat server-group
NAT server group information:
  Totally 3 NAT server groups.
  Group Number        Inside IP             Port        Weight
  1                   192.168.0.26          23          100
                      192.168.0.27          23          500
  2                   ---                   ---         ---
```

```
  3                   192.168.0.26          69          100
```

Display the configuration of internal server group **1**.

```
<Sysname> display nat server-group 1
  Group Number        Inside IP             Port        Weight
  1                   192.168.0.26          23          100
                      192.168.0.27          23          500
```

Table 19 Command output

Field	Description
NAT server group information	Information about the NAT server group configuration.
Totally *n* NAT server groups	Total number of NAT server groups.
Group Number	ID of the internal server group.
Inside IP	Private IP address of a server in the internal server group. If no address is specified, this field displays hyphens (---).
Port	Private port number of a server in the internal server group. If no port number is specified, this field displays hyphens (**---**).
Weight	Weight of a server in the internal server group. If no weight value is specified, this field displays hyphens (**---**).

network-admin

network-operator

context-admin

context-operator

Parameters

`responder`: Displays NAT sessions by responder. If you do not specify this keyword, this command displays NAT sessions by initiator.

`source-ip` *`source-ip`*: Displays NAT sessions for the source IP address specified by the *`source-ip`* argument. The IP address must be the source IP address of the packet that triggers the session establishment.

destination-ip *destination-ip*: Displays NAT sessions for the destination IP address specified by the *destination-ip* argument. The IP address must be the destination IP address of the packet that triggers the session establishment.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. The VPN must be the VPN inside the packet. If you do not specify a VPN instance, this command displays NAT sessions that do not belong to any VPN instance.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays NAT sessions for all member devices.

brief: Displays brief information about NAT sessions.

verbose: Displays detailed information about NAT sessions.

Usage guidelines

If you do not specify any parameters, this command displays detailed information about session initiators of all NAT sessions.

Examples

Display detailed information about NAT sessions for the specified slot.

```
<Sysname> display nat session slot 1 verbose
Slot 1:
Initiator:
  Source      IP/port: 192.168.1.18/1877
  Destination IP/port: 192.168.1.55/22
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/1
  Source security zone: SrcZone
Responder:
  Source      IP/port: 192.168.1.55/22
  Destination IP/port: 192.168.1.10/1877
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/2
  Source security zone: DestZone
State: TCP_SYN_SENT
Application: SSH
Rule ID: -/-/-
Rule name:
Start time: 2011-07-29 19:12:36  TTL: 28s
Initiator->Responder:         1 packets         48 bytes
Responder->Initiator:         0 packets          0 bytes

Total sessions found: 1
```

Display brief information about NAT sessions for the specified slot.

```
<Sysname> display nat session brief
Slot 1:
Protocol   Source IP/port         Destination IP/port    Global IP/port
```

```
TCP        2.1.1.20/1351          10.1.1.110/21          2.1.1.50/1025

Total sessions found: 1
```

Table 20 Command output

Field	Description
Initiator	Session information about the initiator.
Responder	Session information about the responder.
Source IP/port	Source IP address and port number.
Destination IP/port	Destination IP address and port number.
Global IP/port	Public IP address and port number.
DS-Lite tunnel peer	Destination address of the DS-Lite tunnel interface. If the session does not belong to any DS-Lite tunnel, this field displays a hyphen (**-**).
VPN instance/VLAN ID/Inline ID	The fields identify the following information: • **VPN instance**—MPLS L3VPN instance to which the session belongs. • **VLAN ID**—VLAN ID to which the session belongs for Layer 2 forwarding. • **Inline ID**——INLINE to which the session belongs for Layer 2 forwarding. If no VPN instance, VLAN ID, or inline ID is specified, a hyphen (-) is displayed for the related field.
Protocol	Transport layer protocol type: **DCCP**, **ICMP**, **Raw IP**, **SCTP**, **TCP**, **UDP**, or **UDP-Lite**.
Inbound interface	Input interface.
Source security zone	Security zone to which the input interface belongs. If the input interface does not belong to any security zone, this field displays a hyphen (**-**).
State	NAT session status.
Application	Application layer protocol type, such as **FTP** and **DNS**. This field displays **OTHER** for the protocol types identified by non-well-known ports.
Rule ID	ID of the security policy rule.
Rule name	Name of the security policy rule.
Start time	Time when the session starts.
TTL	Remaining NAT session lifetime in seconds.
Initiator->Responder	Number of packets and packet bytes from the initiator to the responder.
Responder->Initiator	Number of packets and packet bytes from the responder to the initiator.
Total sessions found	Total number of sessions.

context-operator

Parameters

summary: Displays NAT statistics summary. If you do not specify this keyword, this command displays detailed NAT statistics.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays NAT statistics for all member devices.

Examples

Display detailed information about NAT statistics.

```
<Sysname> display nat statistics
Slot 1:
  Total session entries: 100
  Session creation rate: 0
  Total EIM entries: 1
  Total inbound NO-PAT entries: 0
  Total outbound NO-PAT entries: 0
  Total static port block entries: 10
  Total dynamic port block entries: 15
  Active static port block entries: 0
  Active dynamic port block entries: 0
```

Table 22 Command output

Field	Description
Total session entries	Number of NAT session entries.
Session creation rate	Number of NAT sessions created per second.
Total EIM entries	Total number of EIM entries.
Total inbound NO-PAT entries	Total number of inbound NO-PAT entries.
Total outbound NO-PAT entries	Total number of outbound NO-PAT entries.
Total static port block entries	Total number of static NAT444 mappings.
Total dynamic port block entries	Total number of dynamic port block mappings that can be created. It equals the number of port blocks for dynamic assignment, including the assigned and unassigned port blocks.
Active static port block entries	Number of static port block mappings that are in use.
Active dynamic port block entries	Number of dynamic port block mappings that have been created. It equals the number of dynamically assigned port blocks.

Display NAT statistics summary.

```
<Sysname> display nat statistics summary
EIM: Total EIM entries.
SPB: Total static port block entries.
DPB: Total dynamic port block entries.
ASPB: Active static port block entries.
ADPB: Active dynamic port block entries.
Slot Sessions  EIM       SPB       DPB       ASPB      ADPB
2    0         0         0         1572720   0         0
```

Table 23 Command output

Field	Description
Sessions	Number of NAT session entries.
EIM	Number of EIM entries.

Field	Description
SPB	Number of static NAT444 mappings.
DPB	Number of dynamic port block mappings that can be created. It equals the number of port blocks for dynamic assignment, including the assigned and unassigned port blocks.
ASPB	Number of static port block mappings in use.
ADPB	Number of dynamic port block mappings that have been created. It equals the number of dynamically assigned port blocks.

exclude-ip

Use **exclude-ip** to exclude IP addresses from being used in address translation.

Use **undo exclude-ip** to allow the IP addresses to be used in address translation.

Syntax

exclude-ip *start-address end-address*

undo exclude-ip *start-address end-address*

Default

All IP addresses in the NAT address group can be used as the NAT addresses.

Views

NAT address group view

Predefined user roles

network-admin

context-admin

Parameters

start-address end-address: Specifies the start and end IP addresses of the address range. The end address must not be lower than the start address. If they are the same, you specify only one IP address.

Usage guidelines

If some IP addresses in a NAT address group cannot be used for address translation, you can use this command to exclude them.

You can configure this command multiple times to specify a maximum of 100 IP address ranges excluded from address translation. No address ranges can overlap. The start IP address and the end IP address in an excluded range must be in the range configured in the **address** *start-address end-address* command. Each excluded IP address range can contain a maximum of 4096 IP addresses.

Examples

Exclude IP addresses 10.1.1.2, 10.1.1.3 to 10.1.1.5 in NAT address group from being used in address translation.

```
<Sysname> system-view
[Sysname] nat address-group 2
[Sysname-address-group-2] address 10.1.1.1 10.1.1.15
[Sysname-address-group-2] exclude-ip 10.1.1.2 10.1.1.2
[Sysname-address-group-2] exclude-ip 10.1.1.3 10.1.1.5
```

Related commands

address

global-ip-pool

Use **global-ip-pool** to add a public IP address range to a NAT port block group.

Use **undo global-ip-pool** to remove a public IP address range from a NAT port block group.

Syntax

global-ip-pool *start-address end-address*

undo global-ip-pool *start-address*

Default

No public IP address ranges exist.

Views

NAT port block group view

Predefined user roles

network-admin

context-admin

Parameters

start-address end-address: Specifies the start IP address and end IP address of a public IP address range. The end IP address cannot be lower than the start IP address. If the start and end IP addresses are the same, only one public IP address is specified.

Usage guidelines

A static port block mapping maps a public IP address to multiple private IP addresses and assigns a unique port block to each private IP address. The number of port blocks that a public IP address can assign is determined by dividing the number of ports in the port range by the port block size.

Every time you execute this command, an address range can contain a maximum of 256 public IP addresses. All public IP address ranges in one port block group cannot overlap.

Public IP address ranges in different port block groups can overlap. The port ranges for overlapped public IP address ranges cannot overlap.

Examples

Add a public IP address range to the port block group **1**. The public IP address range consists of IP addresses from 202.10.1.1 to 202.10.1.10.

```
<Sysname> system-view
[Sysname] nat port-block-group 1
[Sysname-port-block-group-1] global-ip-pool 202.10.1.1 202.10.1.10
```

Related commands

nat port-block-group

inside ip

Use **inside ip** to add a server to an internal server group.

Use **undo inside ip** to remove a server from an internal server group.

Syntax

inside ip *inside-ip* **port** *port-number* [**weight** *weight-value*]

undo inside ip *inside-ip* **port** *port-number*

Default

An internal server group has no server members.

Views

Internal server group view

Predefined user roles

network-admin

context-admin

Parameters

inside-ip: Specifies the IP address of an internal server.

port *port-number*: Specifies the port number of an internal server, in the range of 1 to 65535, excluding FTP port 20.

weight *weight-value*: Specifies the weight of the internal server. The value range is 1 to 1000, and the default value is 100.

Usage guidelines

An internal server with a larger weight receives a larger percentage of connections in the internal server group.

Examples

Add a server with IP address 10.1.1.2 and port number 30 to internal server group 1.

```
<Sysname> system-view
[Sysname] nat server-group 1
[Sysname-nat-server-group-1] inside ip 10.1.1.2 port 30
```

Related commands

nat server-group

local-ip-address

Use **local-ip-address** to add a private IP address range to a NAT port block group.

Use **undo local-ip-address** to remove a private IP address range from a NAT port block group.

Syntax

local-ip-address *start-address end-address* [**vpn-instance** *vpn-instance-name*]

undo local-ip-address *start-address end-address* [**vpn-instance** *vpn-instance-name*]

Default

No private IP address ranges exist in a NAT port block group.

Views

NAT port block group view

Predefined user roles

network-admin

context-admin

Parameters

start-address end-address: Specifies the start IP address and end IP address of a private IP address range. The end IP address cannot be lower than the start IP address. If the start and end IP addresses are the same, only one private IP address is specified.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the private IP address range belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the private IP address range does not belong to any VPN instance, do not specify this option.

Usage guidelines

A static port block mapping maps one public IP address to multiple private IP addresses and assigns a unique port block to each private IP address.

When you add multiple private IP address ranges to the same port block group, follow these restrictions:

- The private IP address ranges in the same VPN instance cannot overlap.
- The private IP address ranges that do not belong to any VPN instances cannot overlap.

In a NAT port block group, the number of private IP addresses cannot be larger than the number of assignable port blocks. Otherwise, some private IP addresses cannot obtain port blocks. The number of port blocks that a public IP address can assign is determined by dividing the number of ports in the port range by the port block size.

Examples

Add a private IP address range to port block group 1. The private IP address range consists of IP addresses from 172.16.1.1 to 172.16.1.255.

```
<Sysname> system-view
[Sysname] nat port-block-group 1
[Sysname-port-block-group-1] local-ip-address 172.16.1.1 172.16.1.255
```

Related commands

nat port-block-group

nat address-group

Use **nat address-group** to create a NAT address group and enter its view, or enter the view of an existing NAT address group.

Use **undo nat address-group** to delete a NAT address group.

Syntax

nat address-group *group-id* [**name** *group-name*]

undo nat address-group *group-id*

Default

No NAT address groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

group-id: Specifies the ID of a NAT address group. The value range for this argument is 0 to 65535.

name *group-name*: Assigns a name to the NAT address group. The *group-name* argument is a case-sensitive string of 1 to 63 characters.

Usage guidelines

A NAT address group is a set of address ranges. Use the **address** command to add an address range to a NAT address group. Dynamic NAT translates the source IP address of a packet into an IP address in the address group.

Examples

Create a NAT address group numbered 1 and named **abc**.

```
<Sysname> system-view
[Sysname] nat address-group 1 name abc
```

Related commands

address

display nat address-group

display nat all

nat inbound

nat outbound

nat alg

Use **nat alg** to enable NAT ALG for the specified or all supported protocols.

Use **undo nat alg** to disable NAT ALG for the specified or all supported protocols.

Syntax

nat alg { **all** | **dns** | **ftp** | **h323** | **icmp-error** | **ils** | **mgcp** | **nbt** | **pptp** | **rsh** | **rtsp** | **sccp** | **sctp** | | **sip** | **sqlnet** | **tftp** | **xdmcp** }

undo nat alg { **all** | **dns** | **ftp** | **h323** | **icmp-error** | **ils** | **mgcp** | **nbt** | **pptp** | **rsh** | **rtsp** | **sccp** | **sctp** | | **sip** | **sqlnet** | **tftp** | **xdmcp** }

Default

NAT ALG is enabled for DNS, FTP, ICMP error messages, PPTP, and RTSP, and is disabled for the other supported protocols.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

all: Enables NAT ALG for all supported protocols.

dns: Enables NAT ALG for DNS.

ftp: Enables NAT ALG for FTP.

h323: Enables NAT ALG for H.323.

icmp-error: Enables NAT ALG for ICMP error packets.

ils: Enables NAT ALG for ILS.

mgcp: Enables NAT ALG for MGCP.

nbt: Enables NAT ALG for NBT.

pptp: Enables NAT ALG for PPTP.

rsh: Enables NAT ALG for RSH.

rtsp: Enables NAT ALG for RTSP.

sccp: Enables NAT ALG for SCCP.

sctp: Enables NAT ALG for SCTP.

sip: Enables NAT ALG for SIP.

sqlnet: Enables NAT ALG for SQLNET.

tftp: Enables NAT ALG for TFTP.

xdmcp: Enables NAT ALG for XDMCP.

Usage guidelines

NAT ALG translates address or port information in the application layer payload to ensure connection establishment.

For example, an FTP application includes a data connection and a control connection. The IP address and port number for the data connection depend on the payload information of the control connection. This requires NAT ALG to translate the address and port information to establish the data connection.

Examples

Enable NAT ALG for FTP.

```
<Sysname> system-view
[Sysname] nat alg ftp
```

Related commands

display nat all

nat configuration-for-new-connection

Use **nat configuration-for-new-connection enable** to enable NAT configuration changes to take effect only on new connections.

Use **undo configuration-for-new-connection enable** to disable NAT configuration changes from taking effect only on new connections.

Syntax

nat configuration-for-new-connection enable

undo nat configuration-for-new-connection enable

Default

NAT configuration change taking effect only on new connections is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Non-default vSystems do not support this command.

By default, NAT configuration changes (such as adding, deleting, editing, or moving NAT rules) might cause traffic on an established connection to match a new NAT rule. As a result, you must create a new connection.

Execute this command if you do not want the NAT configuration change to affect existing connections. After you execute this command on the device, it still performs address translation according to the NAT rules before the configuration change for traffic on existing connections. For traffic on new connections, the device matches the traffic according to the priority of NAT rules after the configuration change and performs address translation based on the matching NAT rules.

Examples

Enable NAT configuration change to take effect only on new connections.

```
<Sysname> system-view
[Sysname] nat configuration-for-new-connection enable
```

Related commands

display nat all

nat dns-map

Use **nat dns-map** to configure a NAT DNS mapping.

Use **undo nat dns-map** to remove a NAT DNS mapping.

Syntax

nat dns-map domain *domain-name* **protocol** *pro-type* { **interface** *interface-type interface-number* | **ip** *global-ip* } **port** *global-port*

undo nat dns-map domain *domain-name*

Default

No NAT DNS mappings exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

domain *domain-name*: Specifies the domain name of an internal server. A domain name is a dot-separated case-insensitive string that can include letters, digits, hyphens (-), underscores (_), and dots (.) (for example, aabbcc.com). The domain name can contain a maximum of 253 characters, and each separated string contains no more than 63 characters.

protocol *pro*-type: Specifies the type of the protocol used by the internal server, **tcp** or **udp**.

ip *global-ip*: Specifies the public IP address used by the internal server to provide services for the external network.

port *global-port*: Specifies the public port number used by the internal server to provide services for the external network. The port number format can be one of the following:

- A number in the range of 1 to 65535.
- A protocol name, a string of 1 to 15 characters. For example, **ftp** and **telnet**.

Usage guidelines

NAT DNS mapping must cooperate with the NAT Server feature.

- A NAT DNS mapping maps the domain name of an internal server to the public IP address, public port number, and protocol type of the internal server.
- A NAT server mapping maps the public IP and port to the private IP and port of the internal server.

The cooperation allows an internal host to access an internal server on the same private network by using the domain name of the internal server when the DNS server is on the public network. The DNS reply from the external DNS server contains only the domain name and public IP address of the internal server in the payload. The NAT interface might have multiple internal servers configured with the same public IP address but different private IP addresses. DNS ALG might find an incorrect internal server by using only the public IP address. If a DNS mapping is configured, DNS ALG can obtain the public IP address, public port number, and protocol type of the internal server by using the domain name. Then it can find the correct internal server by using the public IP address, public port number, and protocol type of the internal server.

You can configure multiple NAT DNS mappings.

Examples

Configure a NAT DNS mapping to map the domain name **www.server.com** to the public IP address **202.112.0.1**, public port number **12345**, and protocol type TCP.

```
<Sysname> system-view
[Sysname] nat dns-map domain www.server.com protocol tcp ip 202.112.0.1 port 12345
```

nat server

nat global-policy

Use **nat global-policy** to create the global NAT policy and enter its view, or enter the view of the existing global NAT policy.

Use **undo nat global-policy** to delete the global NAT policy and all the configuration in the global NAT policy.

Syntax

nat global-policy

undo nat global-policy

Default

No global NAT policy exists.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The global NAT policy contains a set of NAT rules to identify and translate matching packets. The packet match criteria includes source IP address, destination IP address, service type, source security zone, and destination security zone. The global NAT policy supports translating the source IP address and destination IP address of the matching packets.

You do not need to apply the global NAT policy to any interface.

The global NAT policy has priority over interface-based NAT. If both are configured, the matching packets are translated as follows:

- If the global NAT policy contains only source address translation rules, the source address translation follows the NAT policy, and the destination address translation follows the interface-based rules.
- If the global NAT policy contains only destination address translation rules, the destination address translation follows the NAT policy, and the source address translation follows the interface-based rules.
- If the global NAT policy contains both source and destination address translation rules, both the source and destination address translations follow the NAT policy. The interface-based source and destination address translation rules do not take effect.

Examples

Create the global NAT policy and enter its view.

```
<Sysname> system-view
[Sysname] nat global-policy
[Sysname-nat-global-policy]
```

Related commands

display nat all

display nat global-policy

nat hairpin enable

Use **nat hairpin enable** to enable NAT hairpin.

Use **undo nat hairpin enable** to disable NAT hairpin.

Syntax

nat hairpin enable

undo nat hairpin enable

Default

NAT hairpin is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

NAT hairpin allows internal hosts to access each other or allows internal hosts to access internal servers. It must cooperate with NAT Server, outbound dynamic NAT, or outbound static NAT. The source and destination IP addresses of the packets are translated on the interface connected to the internal network.

When NAT hairpin works in conjunction with NAT Server, you must configure NAT server mappings in one of the following methods with a protocol type specified:

- Configuring common NAT server mappings
- Configuring load sharing NAT server mappings

Examples

Enable NAT hairpin on interface GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat hairpin enable
```

Related commands

display nat all

nat outbound

nat server

nat static outbound

nat icmp-error reply

Use **nat icmp-error reply** to enable sending ICMP error messages upon NAT failures.

Use **undo nat icmp-error reply** to restore the default.

Syntax

nat icmp-error reply

undo nat icmp-error reply

Default

No ICMP error messages are sent upon NAT failures.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

By default, sending ICMP error messages upon NAT failures is disabled on the NAT device. Applications using the ICMP protocol cannot be notified when an event occurs. With this feature enabled, the NAT device sends ICMP error messages upon NAT failures for the applications to locate and troubleshoot the failures.

Examples

Enable sending ICMP error messages upon NAT failures.

```
<Sysname> system-view
[Sysname] nat icmp-error reply
```

nat inbound

Use **nat inbound** to configure an inbound dynamic NAT rule.

Use **undo nat inbound** to delete an inbound dynamic NAT rule.

Syntax

nat inbound { *ipv4-acl-number* | **name** *ipv4-acl-name* } **address-group** { *group-id* | **name** *group-name* } [**vpn-instance** *vpn-instance-name*] [**no-pat** [**reversible**] [**add-route**]] [**rule** *rule-name*] [**priority** *priority*] [**disable**] [**counting**] [**description** *text*]

undo nat inbound { *ipv4-acl-number* | **name** *ipv4-acl-name* }

Default

No inbound dynamic NAT rules exist.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-acl-number: Specifies an ACL by its number in the range of 2000 to 3999.

name *ipv4-acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters. The ACL name must start with an English letter and to avoid confusion, it cannot be **all**.

address-group *group-id*: Specifies an address group for address translation.

group-id: Specifies the address group ID. The value range for this argument is 0 to 65535.

name *group-name*: Specifies the address group name, a case-insensitive string of 1 to 63 characters.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the addresses in the address group belong. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the addresses in the address group do not belong to any VPN instance, do not specify this option.

no-pat: Uses the NO-PAT mode. If you do not specify this keyword, PAT is used. PAT supports only TCP, UDP, and ICMP query packets. For an ICMP packet, the ICMP ID is used as its source port number.

reversible: Enables reverse address translation. Reverse address translation uses existing NO-PAT entries to translate the destination address for connections actively initiated from the internal network to the external network.

add-route: Automatically adds a route to the source address after translation. The output interface is the NAT interface and the next hop is the source address before translation.

rule *rule-name*: Specifies a name for the rule, a case-sensitive string of 1 to 63 characters. It cannot contain backward slashes (\), forward slashes (/), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), vertical bars (|), quotation marks ("), or at signs (@). If you do not specify this option, the rule does not have a name.

priority *priority*: Specifies a priority for the rule, in the range of 0 to 2147483647. The default value is 4294967295. A smaller value represents a higher priority. If you do not specify this option, the rule has the lowest priority among the same type of NAT rules.

disable: Disables the inbound dynamic NAT rule. If you do not specify this keyword, the rule is enabled.

counting: Enables NAT counting. The number of flows that use the address mapping is counted.

description *text*: Specifies a description for the inbound dynamic NAT rule. The *text* argument is a case-insensitive string of 1 to 63 characters.

Usage guidelines

Inbound dynamic NAT translates the source IP addresses of incoming packets permitted by the ACL into IP addresses in the address group.

Inbound dynamic NAT supports the following modes:

- **PAT**—Performs both IP address translation and port translation.
- **NO-PAT**—Performs only IP address translation.

The NO-PAT mode supports reverse address translation. Reverse address translation uses ACL reverse matching to identify packets to be translated. ACL reverse matching works as follows:

- Compares the source IP address/port of a packet with the destination IP addresses/ports in the ACL.
- Translates the destination IP address of the packet according to the matching NO-PAT entry, and then compares the translated destination IP address/port with the source IP addresses/ports in the ACL.

Inbound dynamic NAT typically cooperates with one of the following to implement bidirectional NAT:

- Outbound dynamic NAT (the **nat outbound** command).
- NAT Server (the **nat server** command).
- Outbound static NAT (the **nat static** command).

An address group cannot be used by both the **nat inbound** and **nat outbound** commands. It cannot be used by the **nat inbound** command in both PAT and NO-PAT modes.

Do not specify the **add-route** keyword if the subnets where the internal and external networks reside overlap. For other network scenarios:

- If you specify the **add-route** keyword, the device automatically adds a route to the source address after translation for a packet. The destination address is the NAT address in the NAT address group, the output interface is the interface where the command is executed, and the next hop is the source address before translation.
- If you do not specify the **add-route** keyword, you must manually add the route. As a best practice, add routes manually because automatic route adding is slow.

An ACL can be used by only one inbound dynamic NAT rule on an interface.

You can configure multiple inbound dynamic NAT rules on an interface.

The **vpn-instance** parameter is required if you deploy inbound dynamic NAT for VPNs. The specified VPN instance must be the VPN instance to which the NAT interface belongs.

Inbound dynamic NAT rules configured with the same priority value are matched by using their ACLs.

- NAT rules with named ACLs have higher priorities than NAT rules with unnamed ACLs.
- NAT rules with named ACLs are matched in alphabetical order of their ACL names.
- NAT rules with unnamed ACLs are matched in descending order of their ACL numbers.

Examples

Configure ACL 2001 to permit packets only from subnet 10.110.10.0/24 in VPN **vpn10** to pass through.

```
<Sysname> system-view
[Sysname] acl basic 2001
```

```
[Sysname-acl-ipv4-basic-2001] rule permit vpn-instance vpn10 source 10.110.10.0 0.0.0.255
[Sysname-acl-ipv4-basic-2001] rule deny
[Sysname-acl-ipv4-basic-2001] quit
```

Configure the MPLS L3VPN instance named **vpn10**.

```
[Sysname] ip vpn-instance vpn10
[Sysname-vpn-instance-vpn10] route-distinguisher 100:001
[Sysname-vpn-instance-vpn10] vpn-target 100:1 export-extcommunity
[Sysname-vpn-instance-vpn10] vpn-target 100:1 import-extcommunity
[Sysname-vpn-instance-vpn10] quit
```

Create address group 1 and add the address range of 202.110.10.10 to 202.110.10.12 to the group.

```
[Sysname] nat address-group 1
[Sysname-address-group-1] address 202.110.10.10 202.110.10.12
[Sysname-address-group-1] quit
```

Configure an inbound NO-PAT rule on interface GigabitEthernet 1/0/1. NAT translates the source addresses of incoming packets into the addresses in address group 1, and automatically adds routes for translated packets. Set the rule name to **abc**, and the priority to 0.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat inbound 2001 address-group 1 vpn-instance vpn10 no-pat
add-route rule abc priority 0
```

display nat no-pat

nat inbound rule move

Use **nat inbound rule move** to change the priority of an inbound dynamic NAT rule.

Syntax

nat inbound rule move *nat-rule-name1* { **after** | **before** } *nat-rule-name2*

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

nat-rule-name1: Specifies the name of the rule be moved.

after: Moves the rule *nat-rule-name1* to the line after the rule *nat-rule-name2* (called the reference rule). The priority value of the reference rule is not changed. The priority value of the moved rule equals the priority value of the reference rule plus one.

before: Moves the rule *nat-rule-name1* to the line before the rule *nat-rule-name2*. The priority value of the reference rule is not changed. The priority value of the moved rule equals the priority value of the reference rule minus one.

nat-rule-name2: Specifies the name of the NAT rule as a reference rule for the NAT rule to be moved.

Usage guidelines

This command is applicable only to named inbound dynamic NAT rules.

A NAT rule appearing earlier on the rule list has a higher priority for packet matching.

Examples

Move the inbound dynamic NAT rule **abc** to the line before the rule **def**.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat inbound rule move abc before def
```

Related commands

nat inbound

nat link-switch recreate-session

Use **nat link-switch recreate-session** to enable NAT session recreation after link switchover.

Use **undo nat link-switch recreate-session** to disable NAT session recreation after link switchover.

Syntax

nat link-switch recreate-session

undo nat link-switch recreate-session

Default

NAT session recreation is disabled after link switchover.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command is applicable to a WAN network where two interfaces of the NAT device are configured with outbound dynamic NAT rules using different address groups. When the link of one interface fails, traffic on this link is switched to the link of another interface and the NAT device operates as follows:

- If the two interfaces are in different security zones, the NAT device deletes old session entries after link switchover. When user traffic later arrives, it triggers the NAT session recreation. This mechanism ensures that internal users can access the external network.
- If the two interfaces are in the same security zone, the NAT device retains old session entries after link switchover. Internal users cannot access the external network because the device uses old session entries to match the user traffic. To avoid this issue, enable this feature to ensure availability of NAT services.

Examples

Enable NAT session recreation after link switchover.

```
<Sysname> system-view
[Sysname] nat link-switch recreate-session
```

network-admin

context-admin

Usage guidelines

Packets that need to be translated are dropped if the NAT resources are not enough. In NO-PAT, the NAT resources refer to the public IP addresses. In EIM PAT, the NAT resources refer to public IP addresses and ports. In NAT444, the NAT resources refer to public IP addresses, port blocks, or ports in port blocks. NAT alarm logging monitors the usage of NAT resources and outputs logs if the NAT resources are not enough.

For NAT444 dynamic port block mappings, an alarm log is generated upon the port block assignment failure or the failure that port resources cannot meet the user address translation requirement.

Before configuring alarm logging for NAT, you must configure the custom NAT log generation and outputting features. For more information about information center, see *Network Management and Monitoring Configuration Guide*.

This command take effect only after you use the **nat log enable** command to enable NAT logging.

Examples

Enable NAT alarm logging.

```
<Sysname> system-view
[Sysname] nat log alarm
```

Related commands

undo nat log enable

Default

NAT logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

acl: Specifies an ACL.

ipv4-acl-number: Specifies an ACL by its number in the range of 2000 to 3999.

name *ipv4-acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters. The ACL name must start with an English letter and to avoid confusion, it cannot be **all**.

Usage guidelines

You must enable NAT logging before you enable NAT session logging, NAT444 user logging (including port block assignment and withdrawal logging), NAT alarm logging, or NAT NO-PAT logging.

The **acl** keyword takes effect only for NAT session logging. If an ACL is specified, flows matching the permit rule might trigger NAT session logs. If you do not specify an ACL, all flows processed by NAT might trigger NAT session logs.

Examples

Enable NAT logging.

```
<Sysname> system-view
[Sysname] nat log enable
```

Parameters

time-value: Specifies the interval for logging active NAT flows, in the range of 10 to 120 minutes.

Usage guidelines

Active NAT flows are NAT sessions that last for a long time. The logging feature helps track active NAT flows by periodically logging the active NAT flows.

Logging for active NAT flows takes effect only after you enable NAT logging.

Examples

Enable logging for active NAT flows and set the logging interval to 10 minutes.

```
<Sysname> system-view
[Sysname] nat log flow-active 10
```

undo nat log port-block-withdraw

Default

NAT444 user logging is disabled for port block withdrawal.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

For static port block mappings, the NAT444 gateway generates a user log when all connections from a private IP address are disconnected.

For dynamic port block mappings, the NAT444 gateway generates a user log when all the following conditions are met:

- The port blocks (including the extended ones) assigned to the private IP address are withdrawn.
- The corresponding mapping entry is deleted.

This command takes effect only after you use the **nat log enable** command to enable NAT logging.

Examples

Enable NAT444 user logging for port block withdrawal.

```
<Sysname> system-view
[Sysname] nat log port-block-withdraw
```

nat log enable

nat mapping-behavior endpoint-independent

Use **nat mapping-behavior endpoint-independent** to specify the Endpoint-Independent Mapping (EIM) mode for PAT.

Use **undo nat mapping-behavior** to restore the default.

Syntax

nat mapping-behavior endpoint-independent [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* }]

undo nat mapping-behavior endpoint-independent

Default

Address and Port-Dependent Mapping applies.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

acl: Specifies an ACL to define the applicable scope of Endpoint-Independent Mapping.

ipv4-acl-number: Specifies an ACL by its number in the range of 2000 to 3999.

name *ipv4-acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters. The ACL name must start with an English letter and to avoid confusion, it cannot be **all**.

Usage guidelines

PAT supports the following NAT mapping modes:

- **Endpoint-Independent Mapping**—Uses the same IP and port mapping (EIM entry) for packets from the same source and port to any destination. EIM allows external hosts to access the internal hosts by using the NAT IP address and port. It allows internal hosts behind different NAT gateways to access each other.
- **Address and Port-Dependent Mapping**—Uses different IP and port mappings for packets with the same source IP and port to different destination IP addresses and ports. APDM allows an external host to access an internal host only under the condition that the internal host has previously accessed the external host. It is secure, but it does not allow internal hosts behind different NAT gateways to access each other.

This command takes effect only on outbound PAT. Address and Port-Dependent Mapping always applies to inbound PAT.

If you specify an ACL, Endpoint-Independent Mapping applies to packets that are permitted by the ACL. If you do not specify an ACL, Endpoint-Independent Mapping applies to all packets.

Examples

Apply the Endpoint-Independent Mapping mode to all packets for address translation.

```
<Sysname> system-view
[Sysname] nat mapping-behavior endpoint-independent
```

Apply the Endpoint-Independent Mapping mode to FTP and HTTP packets, and the Address and Port-Dependent Mapping mode to other packets for address translation.

```
<Sysname> system-view
[Sysname] acl advanced 3000
```

```
[Sysname-acl-ipv4-adv-3000] rule permit tcp destination-port eq 80
[Sysname-acl-ipv4-adv-3000] rule permit tcp destination-port eq 21
[Sysname-acl-ipv4-adv-3000] quit
[Sysname] nat mapping-behavior endpoint-independent acl 3000
```

Related commands

nat outbound

nat outbound

Use **nat outbound** to configure an outbound dynamic NAT rule.

Use **undo nat outbound** to delete an outbound dynamic NAT rule.

Syntax

NO-PAT:

nat outbound [*ipv4-acl-number* | **name** *ipv4-acl-name*] **address-group** { *group-id* | **name** *group-name* } [**vpn-instance** *vpn-instance-name*] **no-pat** [**reversible**] [**rule** *rule-name*] [**priority** *priority*] [**disable**] [**counting**] [**description** *text*]

undo nat outbound [*ipv4-acl-number* | **name** *ipv4-acl-name*]

PAT:

nat outbound [*ipv4-acl-number* | **name** *ipv4-acl-name*] [**address-group** { *group-id* | **name** *group-name* }] [**vpn-instance** *vpn-instance-name*] [**port-preserved**] [**rule** *rule-name*] [**priority** *priority*] [**disable**] [**counting**] [**description** *text*]

undo nat outbound [*ipv4-acl-number* | **name** *ipv4-acl-name*]

Default

No outbound dynamic NAT rules exist.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-acl-number: Specifies an ACL by its number in the range of 2000 to 3999.

name *ipv4-acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters. The ACL name must start with an English letter and to avoid confusion, it cannot be **all**.

address-group: Specifies an address group for NAT. If you do not specify an address group, the IP address of the interface is used as the NAT address. Easy IP is used.

group-id: Specifies the address group ID. The value range for this argument is 0 to 65535.

name *group-name*: Specifies the address group name, a case-insensitive string of 1 to 63 characters.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the addresses in the address group belong. The *vpn-instance-name* argument is a case-sensitive

string of 1 to 31 characters. If the addresses in the address group do not belong to any VPN instance, do not specify this option.

no-pat: Uses the NO-PAT mode. If you do not specify this keyword, PAT is used. PAT only supports TCP, UDP, and ICMP query packets. For an ICMP packet, the ICMP ID is used as its source port number.

reversible: Enables reverse address translation. Reverse address translation uses existing NO-PAT entries to translate the destination address for connections actively initiated from the external network to the internal network.

port-preserved: Tries to preserve port number for PAT. This keyword does not take effect on dynamic NAT port block mapping.

rule *rule-name*: Specifies a name for the rule, a case-sensitive string of 1 to 63 characters. It cannot contain backward slashes (\), forward slashes (/), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), vertical bars (|), quotation marks ("), or at signs (@). If you do not specify this option, the rule does not have a name.

priority *priority*: Specifies a priority for the rule, in the range of 0 to 2147483647. The default value is 4294967295. A smaller value represents a higher priority. If you do not specify this option, the rule has the lowest priority among the same type of NAT rules.

disable: Disables the outbound dynamic NAT rule. If you do not specify this keyword, the rule is enabled.

counting: Enables NAT counting. The number of flows that use the address mapping is counted.

description *text*: Specifies a description for the outbound dynamic NAT rule. The *text* argument is a case-insensitive string of 1 to 63 characters.

Usage guidelines

Outbound dynamic NAT is typically configured on the interface connected to the external network. You can configure multiple outbound dynamic NAT rules on an interface.

Outbound dynamic NAT supports the following modes:

- **PAT**—Performs both IP address translation and port translation. The PAT mode allows external hosts to actively access the internal hosts if the Endpoint-Independent Mapping behavior is used.
- **NO-PAT**—Performs only IP address translation. The NO-PAT mode allows external hosts to actively access the internal hosts if you specify the **reversible** keyword. If an ACL is specified, reverse address translation only applies to packets permitted by ACL reverse matching. ACL reverse matching works as follows:
  - Compares the source IP address/port of a packet with the destination IP addresses/ports in the ACL.
  - Translates the destination IP address of the packet according to the matching NO-PAT entry, and then compares the translated destination IP address/port with the source IP addresses/ports in the ACL.

  Dynamic NAT444 does not support the NO-PAT mode.

When you specify a NAT address group, follow these restrictions and guidelines:

- An address group cannot be used by both the **nat inbound** and **nat outbound** commands.
- An address group cannot be used by the **nat outbound** command in both PAT and NO-PAT modes.
- When port block parameters are specified in the NAT address group, this command configures a dynamic NAT port block mapping. Packets matching the ACL permit rule are processed by dynamic NAT444.

When you specify an ACL, follow these restrictions and guidelines:

- An ACL can be used by only one outbound dynamic NAT rule on an interface.

- If you configure multiple outbound dynamic NAT rules, only one outbound dynamic NAT rule can contain no ACL.
- If you specify an ACL, NAT translates the source IP addresses of outgoing packets permitted by the ACL into IP addresses in the address group. If you do not specify an ACL, NAT translates all packets.
- Outbound dynamic NAT rules with ACLs configured on an interface takes precedence over those without ACLs. If two ACL-based dynamic NAT rules are configured, the rule with the higher ACL number has higher priority.

The **vpn-instance** parameter is required if you deploy outbound dynamic NAT for VPNs. The specified VPN instance must be the VPN instance to which the NAT interface belongs.

Outbound dynamic NAT rules configured with the same priority value and an ACL are matched by using the ACLs in the rule.

- NAT rules with named ACLs have higher priorities than NAT rules with unnamed ACLs.
- NAT rules with named ACLs are matched in alphabetical order of their ACL names.
- NAT rules with unnamed ACLs are matched in descending order of their ACL numbers.

Examples

Configure ACL 2001 to permit packets only from subnet 10.110.10.0/24 to pass through.

```
<Sysname> system-view
[Sysname] acl basic 2001
[Sysname-acl-ipv4-basic-2001] rule permit source 10.110.10.0 0.0.0.255
[Sysname-acl-ipv4-basic-2001] rule deny
[Sysname-acl-ipv4-basic-2001] quit
```

Create address group 1 and add the address range of 202.110.10.10 to 202.110.10.12 to the group.

```
[Sysname] nat address-group 1
[Sysname-address-group-1] address 202.110.10.10 202.110.10.12
[Sysname-address-group-1] quit
```

Configure an outbound dynamic PAT rule on interface GigabitEthernet 1/0/1 to translate the source addresses of outgoing packets permitted by ACL 2001 into the addresses in address group 1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat outbound 2001 address-group 1
[Sysname-GigabitEthernet1/0/1] quit
```

Or

Configure an outbound NO-PAT rule on interface GigabitEthernet 1/0/1 to translate the source addresses of outgoing packets permitted by ACL 2001 into the addresses in address group 1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat outbound 2001 address-group 1 no-pat
[Sysname-GigabitEthernet1/0/1] quit
```

Or

Enable Easy IP to use the IP address of GigabitEthernet 1/0/1 as the NAT address.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet 1/0/1] nat outbound 2001
[Sysname-GigabitEthernet 1/0/1] quit
```

Or

Configure an outbound NO-PAT rule on GigabitEthernet 1/0/1 to translate the source addresses of outgoing packets permitted by ACL 2001 into the addresses in address group 1. Enable reverse address translation.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat outbound 2001 address-group 1 no-pat reversible
```

Syntax

nat outbound ds-lite-b4 { *ipv6-acl-number* | **name** *ipv6-acl-name* } **address-group** *group-id*

undo nat outbound ds-lite-b4 { *ipv6-acl-number* | **name** *ipv6-acl-name* }

Default

No DS-Lite B4 address translation configuration exists.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-acl-number: Specifies the number of an IPv6 ACL to match the IPv6 addresses of B4 elements. The value range for the argument is 2000 to 2999.

name *ipv6-acl-name*: Specifies the name of an IPv6 ACL to match the IPv6 addresses of B4 elements. The ACL name is a case-insensitive string of 1 to 63 characters. It must start with an English letter and to avoid confusion, it cannot be **all**.

address-group *group-id*: Specifies an address group by its ID. The value range for the *group-id* argument is 0 to 65535. Port block parameters are required in the address group for DS-Lite B4 address translation.

Usage guidelines

DS-Lite B4 address translation applies to the scenario where a DS-Lite tunnel connects an IPv6 network to an IPv4 network. DS-Lite port block mapping is configured on the AFTR's interface connected to the external IPv4 network and performs dynamic port block mapping based on the B4 element. The B4 element refers to a B4 router or a DS-Lite host.

DS-Lite B4 address translation dynamically maps a public IPv4 address and a port block to the IPv6 address of the B4 element. The DS-Lite host or hosts behind the B4 router use the mapped public IPv4 address and port block to access the public IPv4 network.

Examples

Configure IPv6 ACL 2100 to identify packets from subnet 2000::/64.

```
<Sysname> system-view
[Sysname] acl ipv6 basic 2100
```

```
[Sysname-acl-ipv6-basic-2100] rule permit source 2000::/64
[Sysname-acl-ipv6-basic-2100] quit
```

Create address group 1 and add public addresses 202.110.10.10 through 202.110.10.12 to the group.

```
[Sysname] nat address-group 1
[Sysname-nat-address-group-1] address 202.110.10.10 202.110.10.12
```

Set the port block size to 256.

```
[Sysname-nat-address-group-1] port-block block-size 256
[Sysname-nat-address-group-1] quit
```

Configure DS-Lite port block mapping on GigabitEthernet 1/0/1 to use address group 1 to translate packets permitted by ACL 2100.

```
 [Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat outbound ds-lite-b4 2100 address-group 1
```

Related commands

display nat outbound

nat outbound port-block-group

Use **nat outbound port-block-group** to configure a static outbound port block mapping rule on an interface.

Use **undo nat outbound port-block-group** to delete a static port block mapping rule on an interface.

Syntax

nat outbound port-block-group *group-id* [**rule** *rule-name*] [**counting**]

undo nat outbound port-block-group *group-id*

Default

No static outbound port block mapping rule is configured on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

group-id: Specifies a NAT port block group by its ID. The value range for this argument is 0 to 65535.

rule *rule-name*: Specifies a name for the rule, a case-sensitive string of 1 to 63 characters. It cannot contain backward slashes (\), forward slashes (/), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), vertical bars (|), quotation marks ("), or at signs (@). If you do not specify this option, the rule does not have a name.

counting: Enables NAT counting. The number of flows that use the address mapping is counted.

Usage guidelines

After you configure this command on an interface, the system automatically computes the mappings and creates entries for them. When a private IP address accesses the public network, the private IP

address is translated to the mapped public IP address, and the ports are translated to ports in the selected port block.

You can configure multiple port block mapping rules on an interface.

In an IRF fabric, you must execute the **ip fast-forwarding load-sharing** command. Otherwise, the port assignment conflict will occur.

Examples

Configure a static outbound port block mapping rule on GigabitEthernet 1/0/1, and specify the rule name as **abc**.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat outbound port-block-group 1 rule abc
```

Related commands

display nat all

display nat outbound port-block-group

display nat port-block

nat port-block-group

nat outbound rule move

Use **nat outbound rule move** to change the priority of an outbound dynamic NAT rule.

Syntax

nat outbound rule move *nat-rule-name1* { **after** | **before** } *nat-rule-name2*

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

nat-rule-name1: Specifies the name of the NAT rule to be moved.

after: Moves the rule *nat-rule-name1* to the line after the rule *nat-rule-name2* (called the reference rule). The priority value of the reference rule is not changed. The priority value of the moved rule equals the priority value of the reference rule plus one.

before: Moves the rule *nat-rule-name1* to the line before the rule *nat-rule-name2*. The priority value of the reference rule is not changed. The priority value of the moved rule equals the priority value of the reference rule minus one.

nat-rule-name2: Specifies the name of the NAT rule as a reference rule for the NAT rule to be moved.

Usage guidelines

This command is applicable only to named outbound dynamic NAT rules.

A NAT rule appearing earlier on the rule list has a higher priority for packet matching.

Examples

Move the outbound dynamic NAT rule **abc** to the line before the rule **def**.

```
<Sysname> system-view
```

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat outbound rule move abc before def
```

Usage guidelines

The NAT policy performs address translation for outgoing packets on the interfaces that the rules are applied. The NAT policy contains a set of NAT rules. The device identifies the packets based on the object groups in the NAT rules, and translates addresses according to the method in the matching rule.

The NAT policy supports only dynamic address translation, and the NAT policy has a higher priority than the dynamic address translation configuration on the interface.

Examples

Create a NAT policy and enter its view.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy]
```

nat port-block global-share enable

Use **`nat port-block global-share enable`** to enable port block global sharing.

Use **`undo nat port-block global-share enable`** to disable port block global sharing.

Syntax

`nat port-block global-share enable`

`undo nat port-block global-share enable`

Default

Port block global sharing is disabled.

Usage guidelines

When multiple interfaces have dynamic NAT port block mapping configured, the interfaces might create different port block mappings for packets from the same IP address. You can use this command to configure the interfaces to use the same port block mapping for translating packets from the same IP address.

Examples

Enable port block global sharing.

```
<Sysname> system-view
[Sysname] nat port-block global-share enable
```

Related commands

port-block

nat port-block synchronization enable

Use **nat port-block synchronization enable** to enable dynamic NAT port block mapping synchronization.

Use **undo nat port-block synchronization enable** to disable dynamic NAT port block mapping synchronization.

Syntax

nat port-block synchronization enable

undo nat port-block synchronization enable

Default

Dynamic NAT port block mapping synchronization is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Dynamic NAT port block mapping synchronization enables the master and the backup to synchronize dynamic port block mappings, which ensures smooth switchover without service interruption.

Examples

Enable dynamic NAT port block mapping synchronization.

```
<Sysname> system-view
[Sysname] nat port-block synchronization enable
```

nat port-block-group

Use **nat port-block-group** to create a NAT port block group and enter its view, or enter the view of an existing NAT port block group.

Use **undo nat port-block-group** to delete a NAT port block group.

Syntax

nat port-block-group *group-id*

undo nat port-block-group *group-id*

Default

No NAT port block groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

group-id: Assigns an ID to the NAT port block group. The value range for this argument is 0 to 65535.

Usage guidelines

A NAT port block group is configured to implement static port block mapping for NAT444.

You must configure the following items for a NAT port block group:

- A minimum of one private IP address range (see the **local-ip-address** command).
- A minimum of one public IP address range (see the **global-ip-address** command).
- A port range (see the **port-range** command).
- A port block size (see the **block-size** command).

The system computes static port block mappings according to the port block group configuration, and creates entries for the mappings.

Examples

Create NAT port block group **1**.

```
<Sysname>system-view
[Sysname]nat port-block-group 1
[Sysname-port-block-group-1]
```

Related commands

nat port-load-balance enable

Use **nat port-load-balance enable** to enable NAT port halving.

Use **undo nat port-load-balance enable** to disable NAT port halving.

Syntax

nat port-load-balance enable slot *slot-number*

undo nat port-load-balance enable slot *slot-number*

Default

NAT port halving is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. This device will use the lower half portion of the port block.

Usage guidelines

After you enable NAT port halving in VRRP load balancing on an IRF fabric, each port block will be equally divided between the two devices. The two devices will use different ports to translate packets from the same IP address, avoiding port assignment conflicts.

Before enabling this feature, for successfully port allocation, make sure the address group meets the following requirements:

- For dynamic outbound NAT, the number of ports for the public IP addresses in the address group must not less than 2.
- For dynamic NAT444, the number of port blocks and ports for public IP addresses in the address group must not less than 2.

Do not use this feature in VRRP standard mode.

Examples

Enable NAT port halving.

```
<Sysname> system
[Sysname] nat port-load-balance enable slot 1
```

Related commands

nat port-block synchronization enable

nat redirect reply-route

Use **nat redirect reply-route enable** to enable NAT reply redirection.

Use **undo nat redirect reply-route enable** to disable NAT reply redirection.

Syntax

nat redirect reply-route enable

undo nat redirect reply-route enable

Default

NAT reply redirection is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

NAT reply redirection allows an interface to use the NAT session entry information to translate the destination IP addresses for NAT reply packets and find the output interfaces for the NATed reply packets.

Examples

Enable NAT reply redirection on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat redirect reply-route enable
```

nat remote-backup port-alloc

Use **nat remote-backup port-alloc** to specify NAT port ranges for the two devices in the hot backup system.

Use **undo nat remote-backup port-alloc** to restore the default.

Syntax

nat remote-backup port-alloc { **primary** | **secondary** }

undo nat remote-backup port-alloc

Default

The two devices in the hot backup system share NAT port resources.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

primary: Specifies the first half of the port range.

secondary: Specifies the second half of the port range.

Usage guidelines

For dual-active hot backup, different IP+port combinations on the two devices might be translated to the same NAT IP+port resources due to the following reasons:

- The two devices in the hot backup system share NAT addresses.
- The same NAT port range is assigned to each device.

To avoid this situation, execute this command on the primary device to equally divide the port resources for the two devices. Executing the command on the primary device also makes the remaining half of the port range be automatically assigned to the secondary device. For example, if you execute the **nat remote-backup port-alloc secondary** command on the primary device, the **nat remote-backup port-alloc primary** command is automatically executed on the secondary device. For more information about the hot backup system, see *High Availability Configuration Guide*.

You do not need to execute this command for active/standby hot backup. No port conflict exists in this mode because only one device processes NAT services.

Examples

Specify one device in the hot backup system to use the first half of the port range.

```
<Sysname> system-view
[Sysname] nat remote-backup port-alloc primary
```

nat server

Use **nat server** to create a NAT server mapping (also called NAT server rule). The mapping maps the private IP address and port of an internal server to a public address and port.

Use **undo nat server** to delete a NAT server mapping.

Syntax

Common NAT server mapping:

- A single public address with no or a single public port:

  nat server [**protocol** *pro-type*] **global** { *global-address* | **current-interface** | **interface** *interface-type interface-number* } [*global-port*] [**vpn-instance** *global-vpn-instance-name*] **inside** *local-address* [*local-port*] [**vpn-instance** *local-vpn-instance-name*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* }] [**reversible**] [**vrrp** *virtual-router-id*] [**rule** *rule-name*] [**disable**] [**counting**] [**description** *text*]

  undo nat server [**protocol** *pro-type*] **global** { *global-address* | **current-interface** | **interface** *interface-type interface-number* } [*global-port*] [**vpn-instance** *global-vpn-instance-name*]

- A single public address with consecutive public ports:

  nat server protocol *pro-type* **global** { *global-address* | **current-interface** | **interface** *interface-type interface-number* } *global-port1 global-port2* [**vpn-instance** *global-vpn-instance-name*] **inside** { { *local-address* | *local-address1 local-address2* } *local-port* | *local-address local-port*1 *local-port*2 } [**vpn-instance** *local-vpn-instance-name*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* }] [**vrrp** *virtual-router-id*] [**rule** *rule-name*] [**disable**] [**counting**] [**description** *text*]

  undo nat server protocol *pro-type* **global** { *global-address* | **current-interface** | **interface** *interface-type interface-number* } *global-port1 global-port2* [**vpn-instance** *global-vpn-instance-name*]

- Consecutive public addresses with no public port:

  nat server protocol *pro-type* **global** *global-address1 global-address2* [**vpn-instance** *global-vpn-instance-name*] **inside** { *local-address* |

local-address1 local-address2 } [*local-port*] [**vpn-instance** *local-vpn-instance-name*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* }] [**vrrp** *virtual-router-id*] [**rule** *rule-name*] [**disable**] [**counting**] [**description** *text*]

undo nat server protocol *pro-type* **global** *global-address1 global-address2* [*global-port*] [**vpn-instance** *global-vpn-instance-name*]

- Consecutive public addresses with one single public port:

  nat server protocol *pro-type* **global** *global-address1 global-address2 global-port* [**vpn-instance** *global-vpn-instance-name*] **inside** { *local-address* [*local-port1 local-port2*] | [*local-address* | *local-address1 local-address2*] [*local-port*] } [**vpn-instance** *local-vpn-instance-name*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* }] [**vrrp** *virtual-router-id*] [**rule** *rule-name*] [**disable**] [**counting**] [**description** *text*]

  undo nat server protocol *pro-type* **global** *global-address1 global-address2 global-port* [**vpn-instance** *global-vpn-instance-name*]

Load sharing NAT server mapping:

nat server protocol *pro-type* **global** { { *global-address* | **current-interface** | **interface** *interface-type interface-number* } { *global-port* | *global-port1 global-port2* } | *global-address1 global-address2 global-port* } [**vpn-instance** *global-vpn-instance-name*] **inside server-group** *group-id* [**vpn-instance** *local-vpn-instance-name*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* }] [**vrrp** *virtual-router-id*] [**rule** *rule-name*] [**disable**] [**counting**] [**description** *text*]

undo nat server protocol *pro-type* **global** { { *global-address* | **current-interface** | **interface** *interface-type interface-number* } { *global-port* | *global-port1 global-port2* } | *global-address1 global-address2 global-port* } [**vpn-instance** *global-vpn-instance-name*]

ACL-based NAT server mapping:

nat server global { *ipv4-acl-number* | **name** *ipv4-acl-name* } **inside** *local-address* [*local-port*] [**vpn-instance** *local-vpn-instance-name*] [**vrrp** *virtual-router-id*] [**rule** *rule-name*] [**priority** *priority*] [**disable**] [**counting**] [**description** *text*]

undo nat server global { *ipv4-acl-number* | **name** *ipv4-acl-name* }

Default

No NAT server mappings exist.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

protocol *pro-type*: Specifies a protocol type. When the protocol is TCP or UDP, NAT Server can be configured with port information. If you do not specify a protocol type, the command applies to packets of all protocols. The protocol type format can be one of the following:

- A number in the range of 1 to 255.

- A protocol name of **icmp**, **tcp**, or **udp**.

global: Specifies the public network information about the internal server.

global-address: Specifies the public address of an internal server.

global-address1 global address2: Specifies a public IP address range, which can include a maximum of 10000 addresses. The *global-address1* argument specifies the start address, and the *global address2* argument specifies the end address that must be greater than the start address.

ipv4-acl-number: Specifies an ACL by its number in the range of 2000 to 3999.

name *ipv4-acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters. The ACL name must start with an English letter and to avoid confusion, it cannot be **all**.

current-interface: Enables Easy IP on the current interface. The primary IP address of the interface is used as the public address for the internal server.

interface *interface-type interface-number*: Enables Easy IP on the interface specified by its type and number. The primary IP address of the interface is used as the public address for the internal server. Only loopback interfaces are supported.

global-port1 global-port2: Specifies a public port number range, which can include a maximum of 10000 ports. The *global-port1* argument specifies the start port, and the *global-port2* argument specifies the end port that must be greater than the start port. The public port number format can be one of the following:

- A number in the range of 1 to 65535. Both the start port and the end port support this format.
- A protocol name, a string of 1 to 15 characters. For example, **http** and **telnet**. Only the start port supports this format.

inside: Specifies the private network information about the internal server.

local-address1 local-address2: Specifies a private IP address range. The *local-address1* argument specifies the start address, and the *local-address2* argument specifies the end address that must be greater than the start address. The number of addresses in the range must equal the number of ports in the public port number range.

local-port: Specifies the private port number. The private port number format can be one of the following:

- A number in the range of 1 to 65535, excluding FTP port 20.
- A protocol name, a string of 1 to 15 characters. For example, **http** and **telnet**.

global-port: Specifies the public port number. The default value and value range are the same as those for the *local-port* argument.

local-address: Specifies the private IP address.

vpn-instance *global-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the advertised public IP addresses belong. The *global-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the public IP addresses do not belong to any VPN instance, do not specify this option.

vpn-instance *local-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the internal server belongs. The *local-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the internal server does not belong to any VPN instance, do not specify this option.

server-group *group-id*: Specifies the internal server group to which the internal server belongs. With this parameter, the load sharing NAT Server feature is configured. The *group-id* argument specifies the internal server group ID. The value range for the *group-id* argument is 0 to 65535.

acl: Specifies an ACL. If you specify an ACL, only packets permitted by the ACL can be translated by using the mapping.

ipv4-acl-number: Specifies an ACL by its number in the range of 2000 to 3999.

name *ipv4-acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters. The ACL name must start with an English letter and to avoid confusion, it cannot be **all**.

reversible: Allows reverse address translation. Reverse address translation applies to connections actively initiated by internal servers to the external network. It translates the private IP addresses of the internal servers to their public IP addresses.

vrrp *virtual-router-id*: Specifies a VRRP group by its virtual router ID in the range of 1 to 255.

rule *rule-name*: Specifies a name for the mapping, a case-sensitive string of 1 to 63 characters. It cannot contain backward slashes (\), forward slashes (/), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), vertical bars (|), quotation marks ("), or at signs (@). If you do not specify this option, the mapping does not have a name.

priority *priority*: Specifies a priority for the mapping, in the range of 0 to 2147483647. The default value is 4294967295. A smaller value represents a higher priority. If you do not specify this option, the mapping has the lowest priority among the same type of NAT rules.

disable: Disables the NAT server mapping. If you do not specify this keyword, the mapping is enabled.

counting: Enables NAT counting. The number of flows that use the address mapping is counted.

description *text*: Specifies a description for the NAT server mapping. The *text* argument is a case-insensitive string of 1 to 63 characters.

Usage guidelines

You can configure the NAT server mapping to allow servers (such as Web, FTP, Telnet, POP3, and DNS servers) in the internal network or an MPLS VPN instance to provide services for external users.

NAT server mappings are usually configured on the interface connected to the external network on a NAT device. By using the *global-address* and *global-port* arguments, external users can access the internal server at *local-address* and *local-port*. When the protocol type is not **udp** (protocol number 17) or **tcp** (protocol number 6), you can configure only one-to-one IP address mappings. The following table describes the address-port mappings between an external network and an internal network for NAT Server.

Table 24 Address-port mappings for NAT Server

External network	Internal network
One public address	One private address
One public address and one public port number	One private address and one private port number
One public address and *N* consecutive public port numbers	• One private address and one private port number • *N* consecutive private addresses and one private port number • One private address and *N* consecutive private port numbers
N consecutive public addresses	• One private address • *N* consecutive private addresses

External network	Internal network
N consecutive public addresses and one public port number	• One private address and one private port number • *N* consecutive private addresses and one private port number • One private address and *N* consecutive private port numbers
One public address and one public port number	One internal server group
One public address and *N* consecutive public port numbers	
N consecutive public addresses and one public port number	
Public addresses matching an ACL	One private address
	One private address and one private port

The mapping of the protocol type, public address, and public port number must be unique for an internal server on an interface. This restriction also applies when Easy IP is used. The maximum number of NAT server mappings equals the number of public ports in the specified public port range.

The **vpn-instance** parameter is required if you configure NAT server mappings in VPN networks. The specified VPN instance must be the VPN instance to which the NAT interface belongs.

As a best practice, do not configure Easy IP for multiple NAT server mappings by using the same interface.

If the IP address of an interface used by Easy IP changes and conflicts with the IP address of a NAT server mapping not using Easy IP, the Easy IP configuration becomes invalid. If the conflicting IP address is modified to another IP address or the NAT server mapping without Easy IP is removed, the Easy IP configuration takes effect.

When you configure a load sharing NAT server mapping, you must make sure a user uses the same public address and public port to access the same service on an internal server. For this purpose, make sure value *N* in the following mappings is equal to or less than the number of servers in the internal server group:

- One public address and *N* consecutive public port numbers are mapped to one internal server group.
- *N* consecutive public addresses and a public port number are mapped to one internal server group.

ACL-based NAT server mappings that are configured with the same priority value are matched by using the ACLs in their rules:

- Mappings with named ACLs have higher priorities than mappings with unnamed ACLs.
- Mappings with named ACLs are matched in alphabetical order of their ACL names.
- Mappings with unnamed ACLs are matched in descending order of their ACL numbers.

In a hot backup system collaborating with VRRP, when you configure a NAT server mapping on the primary device in the hot backup system, specify a VRRP group facing the external network. If you do not perform the binding, the uplink Layer 3 device directly connected to the hot backup system might send downlink packets to the backup device, causing service anomalies.

An error message for a rollback failure when you perform a configuration rollback for an internal server in the following situation:

- In the running configuration, the name of a NAT server mapping is assigned automatically by the system.
- In the replacement configuration file, the name does not exist.

The system will compare the running configuration file and the replacement file, and display an error message about the mismatch. You can ignore the error message because the NAT server mapping configuration in the configuration file is installed successfully. For example, the NAT server mapping configuration is **nat server global 112.1.1.1 inside 192.168.20.1** in the running configuration, and the is **nat server global 112.1.1.1 inside 192.168.20.1 rule *ServerRule_num*** in the replacement configuration file. After the rollback operation, the new NAT server configuration is successfully installed.

Examples

Allow external users to access the internal Web server at 10.110.10.10 through http://202.110.10.10:8080.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat server protocol tcp global 202.110.10.10 8080 inside 10.110.10.10 http
[Sysname-GigabitEthernet1/0/1] quit
```

Allow external users to access the internal FTP server at 10.110.10.11 in the VPN instance **vrf10** through ftp://202.110.10.10.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat server protocol tcp global 202.110.10.10 21 inside 10.110.10.11 vpn-instance vrf10
[Sysname-GigabitEthernet1/0/1] quit
```

Allow external hosts to ping the host at 10.110.10.12 in the VPN instance **vrf10** by using the **ping 202.110.10.11** command.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat server protocol icmp global 202.110.10.11 inside 10.110.10.12 vpn-instance vrf10
[Sysname-GigabitEthernet1/0/1] quit
```

Allow external hosts to access the Telnet services of internal servers at 10.110.10.1 to 10.110.10.100 in the VPN instance **vrf10** through the public address 202.110.10.10 and port numbers from 1001 to 1100. As a result, a user can Telnet to 202.110.10.10:1001 to access 10.110.10.1, Telnet to 202.110.10.10:1002 to access 10.110.10.2, and so on.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat server protocol tcp global 202.110.10.10 1001 1100 inside 10.110.10.1 10.110.10.100 telnet vpn-instance vrf10
```

Configure an ACL-based NAT server mapping to allow users to use IP addresses in subnet 192.168.0.0/24 to access the internal server at 10.0.0.172.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule 5 permit ip destination 192.168.0.0 0.0.0.255
[Sysname-acl-ipv4-adv-3000] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat server global 3000 inside 10.0.0.172
```

display nat server

nat server-group

nat server rule

Use **nat server rule global destination-ip inside** to create an object group-based NAT server rule.

Use **undo nat server rule** to delete an object group-based NAT server mapping.

Syntax

nat server rule *rule-name* **global destination-ip** *object-group-name*&<1-5> [**service** *object-group-name*] **inside** *local-address* [*local-port*] [**vrrp** *virtual-router-id*] [**disable**] [**counting**] [**description** *text*]

undo nat server rule *rule-name*

nat server rule *rule-name* **global** { **destination-ip** *object-group-name*&<1-5> | **service** *object-group-name* }

undo nat server rule *rule-name* **global** { **destination-ip** *object-group-name*&<1-5> | **service** *object-group-name* }

Default

No object group-based NAT server mapping exists.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

rule-name: Specifies a rule name. The name is a case-insensitive string of 1 to 63 characters, excluding hyphens (-) and percent signs (%). You must use the escape character (\) if you use a backslash (\) or quotation marks (") in the name.

global: Specifies the external network information that the internal server uses to provide services to the external network.

destination-ip *object-group-name*&<1-5>: Specifies a space-separated list of up to five address object group items. The *object-group-name* argument specifies the name of an address object group, a case-insensitive string of 1 to 5 characters. If spaces are included in the object group name, enclose the name in quotation marks, for example, "a 1".

service *object-group-name*: Specifies a service object group by its name, a case-insensitive string of 1 to 31 characters.

inside: Specifies the internal information of the server.

local-address: Specifies the private IP address of the internal server.

local-port: Specifies the private port number of the server. The private port number format can be one of the following:

- A number in the range of 1 to 65535, excluding FTP port 20.
- A protocol name, a string of 1 to 15 characters. For example, **http** and **telnet**.

vrrp *virtual-router-id*: Specifies a VRRP group by its virtual router ID in the range of 1 to 255.

disable: Disables the object group-based NAT Server rule.

counting: Enables NAT counting. The number of flows that use the address mapping is counted.

description *text*: Specifies a description for the object group-based NAT Server rule. The *text* argument is a case-insensitive string of 1 to 63 characters.

Usage guidelines

When multiple object group-based NAT server rules are configured, the rule configured earlier has a higher priority. The match process of a packet stops when the packet matches a rule. Different object group-based NAT server rules can use the same address object group or service object group.

Before you use the **nat server rule** *rule-name* **global destination-ip** *object-group-name* or **nat server rule** *rule-name* **global service** *object-group-name* command, follow these restrictions and guidelines:

- Make sure the rule has been created.
- You cannot add duplicate address object groups to the same rule by using the **nat server rule** *rule-name* **global destination-ip** *object-group-name* command. If only one address object group is used by the rule, you cannot use the **undo nat server rule** *rule-name* **global destination-ip** *object-group-name* command to delete this address object group.
- Only one service object group can be used by one rule. If no service object group is specified when you create a rule, you can use the **nat server rule** *rule-name* **global service** *object-group-name* command to specify it. If a service object group has been specified when you create the rule, you cannot use this command to modify the service object group.

In a hot backup system collaborating with VRRP, when you configure an object group-based NAT server on the primary device in the hot backup system, specify a VRRP group facing the external network. If you do not perform the binding, the uplink Layer 3 device directly connected to the hot backup system might send downlink packets to the backup device, causing service anomalies.

Before you configure an object group-based NAT server rule, make sure the object groups to be used by the NAT server rule have been created.

Only IPv4 address object groups are supported, and the IPv4 address object groups cannot have excluded IPv4 addresses.

The private port number in the NAT server rule takes effect only when the protocol type is TCP or UDP for the service object group.

You can create a maximum of 4096 object group-based NAT server rules.

Examples

Configure the NAT Server on GigabitEthernet 1/0/1 and use address object groups **a1**, **a2**, and **a3** to match public IP addresses and use service object group **b1** to match public ports.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat server rule aaa global destination-ip a1 a2 a3 service b1 inside 1.1.1.1 80
```

Configure the NAT Server on GigabitEthernet 1/0/1 and use address object group **a1** to match public IP addresses, and then add address object groups **a2** and **a3** and service object group **b1** to the rule.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat server rule aaa global destination-ip a1 inside 1.1.1.1 80
[Sysname-GigabitEthernet1/0/1] nat server rule aaa global destination-ip a1 a2 service b1
```

nat server rule move

Use **nat server rule move** to change the priority of an ACL-based NAT server rule.

Syntax

nat server rule move *nat-rule-name1* { **after** | **before** } *nat-rule-name2*

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

nat-rule-name1: Specifies the name of the NAT rule to be moved.

after: Moves the rule *nat-rule-name1* to the line after the rule *nat-rule-name2* (called the reference rule). The priority value of the reference rule is not changed. The priority value of the moved rule equals the priority value of the reference rule plus one.

before: Moves the rule *nat-rule-name1* to the line before the rule *nat-rule-name2*. The priority value of the reference rule is not changed. The priority value of the moved rule equals the priority value of the reference rule minus one.

nat-rule-name2: Specifies the name of the NAT rule as a reference rule for the NAT rule to be moved.

Usage guidelines

This command is applicable only to named ACL-based NAT server rules.

A NAT rule appearing earlier on the rule list has a higher priority for packet matching.

Examples

Move the ACL-based NAT server rule **abc** to the line before the ACL-based NAT server rule **def**.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat server rule move abc before def
```

Related commands

nat server

nat server-group

Use **nat server-group** to create an internal server group and enter its view, or enter the view of an existing internal server group.

Use **undo nat server-group** to delete an internal server group.

Syntax

nat server-group *group-id*

undo nat server-group *group-id*

Default

No internal server groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

group-id: Assigns an ID to the internal server group. The value range for this argument is 0 to 65535.

Usage guidelines

An internal server group can contain multiple members configured by the **inside ip** command.

Examples

Create internal server group 1.

```
<Sysname> system-view
[Sysname] nat server-group 1
```

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

global-ip: Specifies a public IP address.

vpn-instance *global-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the public IP address belongs. The *global-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the public IP address does not belong to any VPN instance, do not specify this option.

local-ip: Specifies a private IP address.

vpn-instance *local-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the private IP address belongs. The *local-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the private IP address does not belong to any VPN instance, do not specify this option.

acl: Specifies an ACL to identify the internal hosts that can access the external network.

ipv4-acl-number: Specifies an ACL by its number in the range of 2000 to 3999.

name *ipv4-acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters. The ACL name must start with an English letter and to avoid confusion, it cannot be **all**.

reversible: Enables reverse address translation for connections actively initiated from the internal network to the private IP address.

rule *rule-name*: Specifies a name for the mapping, a case-sensitive string of 1 to 63 characters. It cannot contain backward slashes (\), forward slashes (/), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), vertical bars (|), quotation marks ("), or at signs (@). If you do not specify this option, the mapping does not have a name.

priority *priority*: Specifies a priority for the mapping, in the range of 0 to 2147483647. The default value is 4294967295. A smaller value represents a higher priority. If you do not specify this option, the mapping has the lowest priority among the same type of NAT rules.

disable: Disables the one-to-one inbound static mapping. If you do not specify this keyword, the mapping is enabled.

counting: Enables NAT counting. The number of flows that use the address mapping is counted.

description *text*: Specifies a description for the one-to-one inbound static mapping. The *text* argument is a case-insensitive string of 1 to 63 characters.

Usage guidelines

When the source IP address of a packet from the external network to the internal network matches the *global-ip*, the source IP address is translated into the *local-ip*. When the destination IP address of a packet from the internal network to the external network matches the *local-ip*, the destination IP address is translated into the *global-ip*.

When you specify an ACL, follow these restrictions and guidelines:

- If you do not specify an ACL, the source address of all incoming packets and the destination address of all outgoing packets are translated.
- If you specify an ACL and do not specify the **reversible** keyword, the source address of incoming packets permitted by the ACL is translated. The destination address is not translated for connections actively initiated from the internal network to the private IP address.
- If you specify both an ACL and the **reversible** keyword, the source address of incoming packets permitted by the ACL is translated. If packets of connections actively initiated from the internal network to the private IP address are permitted by ACL reverse matching, the destination address is translated. ACL reverse matching works as follows:
  - Compares the source IP address/port of a packet with the destination IP addresses/ports in the ACL.
  - Translates the destination IP address of the packet according to the mapping, and then compares the translated destination IP address/port with the source IP addresses/ports in the ACL.

Static NAT takes precedence over dynamic NAT when both are configured on an interface.

You can configure multiple inbound static NAT mappings by using the **nat static inbound** command and the **nat static inbound net-to-net** command.

The **vpn-instance** parameter is required if you deploy inbound static NAT in VPN networks. The specified VPN instance must be the VPN instance to which the NAT interface belongs.

One-to-one mappings for inbound static NAT that are configured with the same priority value and an ACL are matched by using the ACLs in the mappings.

- Mappings with named ACLs have higher priorities than mappings with unnamed ACLs.
- Mappings with named ACLs are matched in alphabetical order of their ACL names.
- Mappings with unnamed ACLs are matched in descending order of their ACL numbers.

Examples

Configure an inbound static NAT mapping between public IP address 2.2.2.2 and private IP address 192.168.1.1.

```
<Sysname> system-view
[Sysname] nat static inbound 2.2.2.2 192.168.1.1
```

Default

No NAT mappings exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

global-start-address global-end-address: Specifies a public address range which can contain a maximum of 256 addresses. The *global-end-address* must not be lower than *global-start-address*. If they are the same, only one public address is specified.

vpn-instance *global-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the public IP addresses belong. The *global-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the public IP addresses do not belong to any VPN instance, do not specify this option.

local-network: Specifies a private network address.

mask-length: Specifies the mask length of the private network address, in the range of 8 to 31.

mask: Specifies the mask of the private network address.

vpn-instance *local-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the private network address belongs. The *local-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the private network address does not belong to any VPN instance, do not specify this option.

acl: Specifies an ACL to identify the internal hosts that can access the external network.

ipv4-acl-number: Specifies an ACL by its number in the range of 2000 to 3999.

name *ipv4-acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters. The ACL name must start with an English letter and to avoid confusion, it cannot be **all**.

reversible: Enables reverse address translation for connections actively initiated from the internal network to the private IP addresses.

rule *rule-name*: Specifies a name for the mapping, a case-sensitive string of 1 to 63 characters. It cannot contain backward slashes (\), forward slashes (/), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), vertical bars (|), quotation marks ("), or at signs (@). If you do not specify this option, the mapping does not have a name.

priority *priority*: Specifies a priority for the mapping, in the range of 0 to 2147483647. The default value is 4294967295. A smaller value represents a higher priority. If you do not specify this option, the mapping has the lowest priority among the same type of NAT rules.

disable: Disables the net-to-net inbound static mapping. If you do not specify this keyword, the mapping is enabled.

counting: Enables NAT counting. The number of flows that use the address mapping is counted.

Usage guidelines

Specify a public network through a start address and an end address, and a private network through a private address and a mask.

When the source address of a packet from the external network matches the public address range, the source address is translated into a private address in the private address range. When the destination address of a packet from the internal network matches the private address range, the destination address is translated into a public address in the public address range.

The public end address cannot be greater than the greatest IP address in the subnet determined by the public start address and the private network mask. For example, if the private address is 2.2.2.0 with a mask 255.255.255.0 and the public start address is 1.1.1.100, the public end address cannot be greater than 1.1.1.255, the greatest IP address in the subnet 1.1.1.0/24.

When you specify an ACL, follow these restrictions and guidelines:

- If you do not specify an ACL, the source address of all incoming packets and the destination address of all outgoing packets are translated.
- If you specify an ACL and do not specify the **reversible** keyword, the source address of incoming packets permitted by the ACL is translated. The destination address is not translated for connections actively initiated from the internal network to the private IP addresses.
- If you specify both an ACL and the **reversible** keyword, the source address of incoming packets permitted by the ACL is translated. If packets of connections actively initiated from the internal network to the private IP addresses are permitted by ACL reverse matching, the destination address is translated. ACL reverse matching works as follows:
  - Compares the source IP address/port of a packet with the destination IP addresses/ports in the ACL.
  - Translates the destination IP address of the packet according to the mapping, and then compares the translated destination IP address/port with the source IP addresses/ports in the ACL.

Static NAT takes precedence over dynamic NAT when both are configured on an interface.

You can configure multiple inbound static NAT mappings by using the **nat static inbound** command and the **nat static inbound net-to-net** command.

The **vpn-instance** parameter is required if you deploy inbound static NAT in VPN networks. The specified VPN instance must be the VPN instance to which the NAT interface belongs.

Net-to-net mappings for inbound static NAT that are configured with the same priority value and an ACL are matched by using the ACLs in the mappings.

- Mappings with named ACLs have higher priorities than mappings with unnamed ACLs.
- Mappings with named ACLs are matched in alphabetical order of their ACL names.
- Mappings with unnamed ACLs are matched in descending order of their ACL numbers.

Examples

Configure an inbound static NAT between public network address 202.100.1.0/24 and private network address 192.168.1.0/24.

```
<Sysname> system-view
[Sysname] nat static inbound net-to-net 202.100.1.1 202.100.1.255 local 192.168.1.0 24
```

Related commands

display nat all

display nat static

nat static enable

nat static inbound net-to-net rule move

Use **nat static inbound net-to-net rule move** to change the priority of an inbound net-to-net static NAT rule.

Syntax

nat static inbound net-to-net rule move *nat-rule-name1* { **after** | **before** } *nat-rule-name2*

Default

An inbound net-to-net static NAT rule appearing earlier on the rule list has a higher priority for packet matching.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

nat-rule-name1: Specifies the name of the NAT rule to be moved.

after: Moves the rule *nat-rule-name1* to the line after the rule *nat-rule-name2* (called the reference rule). The priority value of the reference rule is not changed. The priority value of the moved rule equals the priority value of the reference rule plus one.

before: Moves the rule *nat-rule-name1* to the line before the rule *nat-rule-name2*. The priority value of the reference rule is not changed. The priority value of the moved rule equals the priority value of the reference rule minus one.

nat-rule-name2: Specifies the name of the NAT rule as a reference rule for the NAT rule to be moved.

Examples

Move the inbound net-to-net static NAT rule **abc** to the line before the inbound net-to-net static NAT rule **def**.

```
<Sysname> system-view
[Sysname] nat static inbound net-to-net rule move abc before def
```

Related commands

nat static inbound net-to-net

Use **undo nat static inbound object-group** to remove an object group-based inbound static NAT mapping.

Syntax

nat static inbound object-group *global-object-group-name* [**vpn-instance** *global-vpn-instance-name*] **object-group** *local-object-group-name*

[**vpn-instance** *local-vpn-instance-name*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } [**reversible**]] [**disable**] [**counting**]

undo nat static inbound object-group *global-object-group-name* [**vpn-instance** *global-vpn-instance-name*]

Default

No NAT mappings exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

object-group *global-object-group-name*: Specifies an object group of public IPv4 addresses. The *global-object-group-name* argument is a case-insensitive string of 1 to 31 characters.

vpn-instance *global-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the public IP addresses belong. The *global-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the public IP addresses do not belong to any VPN instance, do not specify this option.

object-group *local-object-group-name*: Specifies an object group of private IPv4 addresses. The *local-object-group-name* argument is a case-insensitive string of 1 to 31 characters.

vpn-instance *local-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the private IP addresses belong. The *local-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the private IP addresses do not belong to any VPN instance, do not specify this option.

acl: Specifies an ACL to identify the packets that can use the mapping.

ipv4-acl-number: Specifies an ACL by its number in the range of 2000 to 3999.

name *ipv4-acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters. The ACL name must start with an English letter and to avoid confusion, it cannot be **all**.

reversible: Enables reverse address translation. Reverse address translation applies to connections actively initiated by internal hosts to the external hosts. It uses the mapping to translate destination addresses for packets of these connections if the packets are permitted by ACL reverse matching.

disable: Disables the object group based inbound static mapping. If you do not specify this keyword, the mapping is enabled.

counting: Enables NAT counting. The number of flows that use the address mapping is counted.

Usage guidelines

This command specifies public and private IP addresses through IPv4 address object groups.

When the source address of an income packet matches the public address object group, the source address is translated into a private address in the private address object group. When the destination address of an outgoing packet matches the private address object group, the destination address is translated into a public address in the public address object group.

When you specify object groups for an inbound static mapping, follow these restrictions and guidelines:

- The public or private IPv4 address object group can contain only one IPv4 address object.
- The quantity of IPv4 addresses in the private IPv4 address object group cannot be smaller than that in the public IPv4 address object group.
- The object in the private IPv4 address object group cannot be an address range.
- If the private IPv4 object group contains a host address, the host address cannot be on the same subnet as the interface configured with this mapping.
- One IPv4 address object group can only contain one host object or subnet object. Otherwise, the mapping does not take effect.
- A subnet object cannot have excluded addresses. Otherwise, the mapping does not take effect.

When you specify an ACL, follow these restrictions and guidelines:

- If you do not specify an ACL, the source addresses of all incoming packets and the destination addresses of all outgoing packets are translated.
- If you specify an ACL and do not specify the **reversible** keyword, the source addresses of incoming packets permitted by the ACL are translated. The destination addresses of packets are not translated for connections actively initiated by internal hosts to the external hosts.
- If you specify both an ACL and the **reversible** keyword, the source addresses of incoming packets permitted by the ACL are translated. If packets of connections actively initiated by internal hosts to the external hosts are permitted by ACL reverse matching, the destination addresses are translated. ACL reverse matching works as follows:
  - Compares the source IP address/port of a packet with the destination IP addresses/ports in the ACL.
  - Translates the destination IP address of the packet according to the mapping, and then compares the translated destination IP address/port with the source IP addresses/ports in the ACL.

Static NAT takes precedence over dynamic NAT when they are both configured on an interface.

You can configure multiple inbound static NAT mappings by using the **nat static inbound** , **nat static inbound net-to-net** , and **nat static inbound object-group** commands.

The **vpn-instance** parameter is required if you deploy inbound static NAT in VPN networks. The specified VPN instance must be the VPN instance to which the NAT interface belongs.

Examples

Configure an object group-based inbound static NAT mapping between public IP address 2.2.2.2 and private IP address 192.168.1.1.

```
<Sysname> system-view
[Sysname] object-group ip address global
[Sysname-obj-grp-ip-global] network host address 2.2.2.2
[Sysname-obj-grp-ip-global] quit
[Sysname] object-group ip address local
[Sysname-obj-grp-ip-local] network host address 192.168.1.1
[Sysname-obj-grp-ip-local] quit
[Sysname] nat static inbound object-group global object-group local
```

Default

No NAT mappings exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

local-ip: Specifies a private IP address.

vpn-instance *local-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the private IP address belongs. The *local-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the private IP address does not belong to any VPN instance, do not specify this option.

global-ip: Specifies a public IP address.

vpn-instance *global-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the public IP address belongs. The *global-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the public IP address does not belong to any VPN instance, do not specify this option.

acl: Specifies an ACL to define the destination IP addresses that internal hosts can access.

ipv4-acl-number: Specifies an ACL by its number in the range of 3000 to 3999.

name *ipv4-acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters. The ACL name must start with an English letter and to avoid confusion, it cannot be **all**.

reversible: Enables reverse address translation for connections actively initiated from the external network to the public IP address.

vrrp *virtual-router-id*: Specifies a VRRP group by its virtual router ID in the range of 1 to 255.

rule *rule-name*: Specifies a name for the mapping, a case-sensitive string of 1 to 63 characters. It cannot contain backward slashes (\), forward slashes (/), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), vertical bars (|), quotation marks ("), or at signs (@). If you do not specify this option, the mapping does not have a name.

priority *priority*: Specifies a priority for the mapping, in the range of 0 to 2147483647. The default value is 4294967295. A smaller value represents a higher priority. If you do not specify this option, the mapping has the lowest priority among the same type of NAT rules.

disable: Disables the one-to-one outbound static mapping. If you do not specify this keyword, the mapping is enabled.

counting: Enables NAT counting. The number of flows that use the address mapping is counted.

description *text*: Specifies a description for the one-to-one outbound static mapping. The *text* argument is a case-insensitive string of 1 to 63 characters.

Usage guidelines

When the source IP address of an outgoing packet matches the *local-ip*, the IP address is translated into the *global-ip*. When the destination IP address of an incoming packet matches the *global-ip*, the destination IP address is translated into the *local-ip*.

When you specify an ACL, follow these restrictions and guidelines:

- If you do not specify an ACL, the source address of all outgoing packets and the destination address of all incoming packets are translated.
- If you specify an ACL and do not specify the **reversible** keyword, the source address of outgoing packets permitted by the ACL is translated. The destination address is not translated for connections actively initiated from the external network to the public IP address.
- If you specify both an ACL and the **reversible** keyword, the source address of outgoing packets permitted by the ACL is translated. If packets of connections actively initiated from the external network to the public IP address are permitted by ACL reverse matching, the destination address is translated. ACL reverse matching works as follows:
  - Compares the source IP address/port of a packet with the destination IP addresses/ports in the ACL.
  - Translates the destination IP address of the packet according to the mapping, and then compares the translated destination IP address/port with the source IP addresses/ports in the ACL.

Static NAT takes precedence over dynamic NAT when they are both configured on an interface.

You can configure multiple outbound static NAT mappings by using the **nat static outbound** command and the **nat static outbound net-to-net** command.

The **vpn-instance** parameter is required if you deploy outbound static NAT in VPN networks. The specified VPN instance must be the VPN instance to which the NAT interface belongs.

In a hot backup system collaborating with VRRP, when you configure a one-to-one mapping for outbound static NAT on the primary device in the hot backup system, specify a VRRP group facing the external network. If you do not perform the binding, the uplink Layer 3 device directly connected to the hot backup system might send downlink packets to the backup device, causing service anomalies.

One-to-one mappings for outbound static NAT that are configured with the same priority value and an ACL are matched by using the ACLs in the mappings.

- Mappings with named ACLs have higher priorities than mappings with unnamed ACLs.
- Mappings with named ACLs are matched in alphabetical order of their ACL names.
- Mappings with unnamed ACLs are matched in descending order of their ACL numbers.

Examples

Configure an outbound static NAT mapping between public IP address 2.2.2.2 and private IP address 192.168.1.1.

```
<Sysname> system-view
[Sysname] nat static outbound 192.168.1.1 2.2.2.2
```

Configure outbound static NAT, and allow the internal user 192.168.1.1 to access the external network 3.3.3.0/24 by using the public IP address 2.2.2.2.

```
<Sysname> system-view
[Sysname] acl advanced 3001

nat static outbound net-to-net

Use **nat static outbound net-to-net** to configure a net-to-net outbound static NAT mapping.

Use **undo nat static outbound net-to-net** to remove the specified net-to-net outbound static NAT mapping.

Syntax

nat static outbound net-to-net *local-start-address local-end-address* [**vpn-instance** *local-vpn-instance-name*] **global** *global-network* { *mask-length* | *mask* } [**vpn-instance** *global-vpn-instance-name*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } [**reversible**]] [**vrrp** *virtual-router-id*] [**rule** *rule-name*] [**priority** *priority*] [**disable**] [**counting**]

undo nat static outbound net-to-net *local-start-address local-end-address* [**vpn-instance** *local-vpn-instance-name*] **global** *global-network* { *mask-length* | *mask* } [**vpn-instance** *global-vpn-instance-name*]

Default

No NAT mappings exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

local-start-address local-end-address: Specifies a private address range which can contain a maximum of 256 addresses. The *local-end-address* must not be lower than *local-start-address*. If they are the same, only one private address is specified.

vpn-instance *local-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the private IP addresses belong. The *local-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the private IP addresses do not belong to any VPN instance, do not specify this option.

global-network: Specifies a public network address.

mask-length: Specifies the mask length of the public network address, in the range of 8 to 31.

mask: Specifies the mask of the public network address.

vpn-instance *global-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the public network address belongs. The *global-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the public network address does not belong to any VPN instance, do not specify this option.

acl: Specifies an ACL to define the destination IP addresses that internal hosts can access.

ipv4-acl-number: Specifies an ACL number in the range of 2000 to 3999.

name *ipv4-acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters. The ACL name must start with an English letter and to avoid confusion, it cannot be **all**.

reversible: Enables reverse address translation for connections actively initiated from the external network to the public IP addresses.

vrrp *virtual-router-id*: Specifies a VRRP group by its virtual router ID in the range of 1 to 255.

rule *rule-name*: Specifies a name for the mapping, a case-sensitive string of 1 to 63 characters. It cannot contain backward slashes (\), forward slashes (/), colons (:), asterisks (*), question marks (?), left angle brackets (<), right angle brackets (>), vertical bars (|), quotation marks ("), or at signs (@). If you do not specify this option, the mapping does not have a name.

priority *priority*: Specifies a priority for the mapping, in the range of 0 to 2147483647. The default value is 4294967295. A smaller value represents a higher priority. If you do not specify this option, the mapping has the lowest priority among the same type of NAT rules.

disable: Disables the net-to-net outbound static mapping. If you do not specify this keyword, the mapping is enabled.

counting: Enables NAT counting. The number of flows that use the address mapping is counted.

Usage guidelines

Specify a private network through a start address and an end address, and a public network through a public address and a mask.

When the source address of a packet from the internal network matches the private address range, the source address is translated into a public address in the public address range. When the destination address of a packet from the external network matches the public address range, the destination address is translated into a private address in the private address range.

The private end address cannot be greater than the greatest IP address in the subnet determined by the private start address and the public network mask. For example, the public address is 2.2.2.0 with a mask 255.255.255.0, and the private start address is 1.1.1.100. The private end address cannot be greater than 1.1.1.255, the greatest IP address in the subnet 1.1.1.0/24.

When you specify an ACL, follow these restrictions and guidelines:

- If you do not specify an ACL, the source address of all outgoing packets and the destination address of all incoming packets are translated.
- If you specify an ACL and do not specify the **reversible** keyword, the source address of outgoing packets permitted by the ACL is translated. The destination address is not translated for connections actively initiated from the external network to the public IP addresses.
- If you specify both an ACL and the **reversible** keyword, the source address of outgoing packets permitted by the ACL is translated. If packets of connections actively initiated from the external network to the public IP addresses are permitted by ACL reverse matching, the destination address is translated. ACL reverse matching works as follows:
  - Compares the source IP address/port of a packet with the destination IP addresses/ports in the ACL.
  - Translates the destination IP address of the packet according to the mapping, and then compares the translated destination IP address/port with the source IP addresses/ports in the ACL.

Static NAT takes precedence over dynamic NAT when they are both configured on an interface.

You can configure multiple outbound static NAT mappings by using the **nat static outbound** command and the **nat static outbound net-to-net** command.

The **vpn-instance** parameter is required if you deploy outbound static NAT in VPN networks. The specified VPN instance must be the VPN instance to which the NAT interface belongs.

In a hot backup system collaborating with VRRP, when you configure a net-to-net outbound static NAT mapping on the primary device in the hot backup system, specify a VRRP group facing the external network. If you do not perform the binding, the uplink Layer 3 device directly connected to the hot backup system might send downlink packets to the backup device, causing service anomalies.

Net-to-net mappings for outbound static NAT that are configured with the same priority value and an ACL are matched by using the ACLs in the mappings.

- Mappings with named ACLs have higher priorities than mappings with unnamed ACLs.
- Mappings with named ACLs are matched in alphabetical order of their ACL names.
- Mappings with unnamed ACLs are matched in descending order of their ACL numbers.

Examples

Configure an outbound static NAT mapping between private network address 192.168.1.0/24 and public network address 2.2.2.0/24.

```
<Sysname> system-view
[Sysname] nat static outbound net-to-net 192.168.1.1 192.168.1.255 global 2.2.2.0 24
```

Configure outbound static NAT. Allow internal users on subnet 192.168.1.0/24 to access the external subnet 3.3.3.0/24 by using public IP addresses on subnet 2.2.2.0/24.

```
<Sysname> system-view
[Sysname] acl advanced 3001
[Sysname-acl-ipv4-adv-3001] rule permit ip destination 3.3.3.0 0.0.0.255
[Sysname-acl-ipv4-adv-3001] quit
[Sysname] nat static outbound net-to-net 192.168.1.1 192.168.1.255 global 2.2.2.0 24 acl
3001
```

Related commands

display nat all

display nat static

nat static enable

nat static outbound net-to-net rule move

Use **nat static outbound net-to-net rule move** to change the priority of an outbound net-to-net static NAT rule.

Syntax

nat static outbound net-to-net rule move *nat-rule-name1* { **after** | **before** } *nat-rule-name2*

Default

An outbound net-to-net static NAT rule appearing earlier on the rule list has a higher priority for packet matching.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

nat-rule-name1: Specifies the name of the NAT rule to be moved.

after: Moves the rule *nat-rule-name1* to the line after the rule *nat-rule-name2* (called the reference rule). The priority value of the reference rule is not changed. The priority value of the moved rule equals the priority value of the reference rule plus one.

before: Moves the rule *nat-rule-name1* to the line before the rule *nat-rule-name2*. The priority value of the reference rule is not changed. The priority value of the moved rule equals the priority value of the reference rule minus one.

nat-rule-name2: Specifies the name of the NAT rule as a reference rule for the NAT rule to be moved.

Examples

Move the outbound net-to-net static NAT rule **abc** to the line before the outbound net-to-net static NAT rule **def**.

```
<Sysname> system-view
[Sysname] nat static outbound net-to-net rule move abc before def
```

Related commands

nat static outbound net-to-net

nat static outbound object-group

Use **nat static outbound object-group** to configure an object group-based outbound static NAT mapping.

Use **undo nat static outbound object-group** to remove an object group-based outbound static NAT mapping.

Syntax

nat static outbound object-group *local-object-group-name* [**vpn-instance** *local-vpn-instance-name*] **object-group** *global-object-group-name* [**vpn-instance** *global-vpn-instance-name*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } [**reversible**]] [**vrrp** *virtual-router-id*] [**disable**] [**counting**]

undo nat static outbound object-group *local-object-group-name* [**vpn-instance** *local-vpn-instance-name*]

Default

No NAT mappings exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

object-group *local-object-group-name*: Specifies an object group of private IPv4 addresses. The *local-object-group-name* argument is a case-insensitive string of 1 to 31 characters.

vpn-instance *local-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the private IP addresses belong. The *local-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the private IP addresses do not belong to any VPN instance, do not specify this option.

object-group *global-object-group-name*: Specifies an object group of public IPv4 addresses. The *global-object-group-name* argument is a case-insensitive string of 1 to 31 characters.

vpn-instance *global-vpn-instance-name*: Specifies the MPLS L3VPN instance to which the public IP addresses belong. The *global-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the public IP addresses do not belong to any VPN instance, do not specify this option.

acl: Specifies an ACL to identify the packets that can use the mapping.

ipv4-acl-number: Specifies an ACL number in the range of 2000 to 3999.

name *ipv4-acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters. The ACL name must start with an English letter and to avoid confusion, it cannot be **all**.

reversible: Allows reverse address translation. Reverse address translation applies to connections actively initiated by external hosts to the internal hosts. It uses the mapping to translate destination addresses for packets of these connections if the packets are permitted by ACL reverse matching.

vrrp *virtual-router-id*: Specifies a VRRP group by its virtual router ID in the range of 1 to 255.

disable: Disables the object group based outbound static mapping. If you do not specify this keyword, the mapping is enabled.

counting: Enables NAT counting. The number of flows that use the address mapping is counted.

Usage guidelines

This command specifies public and private IP addresses through IPv4 address object groups.

When the source address of a packet from the private network matches the private address object group, the source address is translated into a public address in the public address object group. When the destination address of a packet from the public network matches the public address object group, the destination address is translated into a private address in the private address object group.

When you specify object groups for an outbound static mapping, follow these restrictions and guidelines:

- The public or private IPv4 address object group can contain only one IPv4 address object.
- The quantity of IPv4 addresses in the private IPv4 address object group cannot be larger than that in the public IPv4 address object group.
- The object in the public IPv4 address object group cannot be an address range.
- An IPv4 address object group can only contain a host object or a subnet object. Otherwise, the mapping does not take effect.
- A subnet object cannot have excluded IPv4 addresses. Otherwise, the mapping does not take effect.

When you specify an ACL, follow these restrictions and guidelines:

- If you do not specify an ACL, the source addresses of all outgoing packets and the destination addresses of all incoming packets are translated.
- If you specify an ACL and do not specify the **reversible** keyword, the source addresses of outgoing packets permitted by the ACL are translated. The destination addresses of packets are not translated for connections actively initiated by external hosts to the internal hosts.
- If you specify both an ACL and the **reversible** keyword, the source addresses of outgoing packets permitted by the ACL are translated. If packets of connections actively initiated by external hosts to the internal hosts are permitted by ACL reverse matching, the destination addresses are translated. ACL reverse matching works as follows:
    - Compares the source IP address/port of a packet with the destination IP addresses/ports in the ACL.

- Translates the destination IP address of the packet according to the mapping, and then compares the translated destination IP address/port with the source IP addresses/ports in the ACL.

Static NAT takes precedence over dynamic NAT when they are both configured on an interface.

You can configure multiple outbound static NAT mappings by using the **nat static outbound**, **nat static outbound net-to-net**, and **nat static outbound object-group** commands.

The **vpn-instance** parameter is required if you deploy outbound static NAT in VPN networks. The specified VPN instance must be the VPN instance to which the NAT interface belongs.

In a hot backup system collaborating with VRRP, when you configure an object group-based outbound static NAT mapping on the primary device in the hot backup system, specify a VRRP group facing the external network. If you do not perform the binding, the uplink Layer 3 device directly connected to the hot backup system might send downlink packets to the backup device, causing service anomalies.

Examples

Configure an object group-based outbound static NAT mapping between private IP address 192.168.1.1 and public IP address 2.2.2.2.

```
<Sysname> system-view
[Sysname] object-group ip address global
[Sysname-obj-grp-ip-global] network host address 2.2.2.2
[Sysname-obj-grp-ip-global] quit
[Sysname] object-group ip address local
[Sysname-obj-grp-ip-local] network host address 192.168.1.1
[Sysname-obj-grp-ip-local] quit
[Sysname] nat static outbound object-group local object-group global
```

nat static outbound rule move

Use **nat static outbound rule move** to change the priority of an outbound one-to-one static NAT rule.

Syntax

nat static outbound rule move *nat-rule-name1* { **after** | **before** } *nat-rule-name2*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

nat-rule-name1: Specifies the name of the NAT rule to be moved.

after: Moves the rule *nat-rule-name1* to the line after the rule *nat-rule-name2* (called the reference rule). The priority value of the reference rule is not changed. The priority value of the moved rule equals the priority value of the reference rule plus one.

before: Moves the rule *nat-rule-name1* to the line before the rule *nat-rule-name2*. The priority value of the reference rule is not changed. The priority value of the moved rule equals the priority value of the reference rule minus one.

nat-rule-name2: Specifies the name of the NAT rule as a reference rule for the NAT rule to be moved.

Usage guidelines

This command is applicable only to named outbound one-to-one static NAT rules..

A NAT rule appearing earlier on the rule list has a higher priority for packet matching.

Examples

Move the outbound one-to-one static NAT rule **abc** to the line before the outbound one-to-one static NAT rule **def**.

```
<Sysname> system-view
[Sysname] nat static outbound rule move abc before def
```

Related commands

nat static outbound

nat timestamp delete

Use **nat timestamp delete** to enable the deletion of timestamps in TCP SYN and SYN ACK packets.

Use **undo nat timestamp delete** to restore the default.

Syntax

nat timestamp delete [**vpn-instance** *vpn-instance-name*]

undo nat timestamp delete [**vpn-instance** *vpn-instance-name*]

Default

The TCP SYN and SYN ACK packets carry the timestamp.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN to which the TCP SYN and SYN ACK packets belong. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If you do not specify this option, this command applies to TCP SYN and SYN ACK packets on the public network.

Usage guidelines

With this feature configured, the system deletes the timestamps from the TCP SYN and SYN ACK packets after dynamic address translation.

If PAT mode is configured on an interface by using **nat inbound** or **nat outbound**, and the tcp_timestamp and tcp_tw_recycle function is configured on the TCP server, TCP connections might not be established. To solve the problem, you can shut down the tcp_tw_recycle function or configure the **nat timestamp delete** command.

You can enable this feature for multiple VPN instances by repeating the command with different VPN parameters.

Examples

Enable the deletion of the timestamp for TCP SYN and SYN ACK packets on the public network.

```
<Sysname> system-view
[Sysname] nat timestamp delete
```

Enable the deletion of the timestamp for TCP SYN and SYN ACK packets on the VPN instance **aa**.

```
<Sysname> system-view
[Sysname] nat timestamp delete vpn-instance aa
```

Related commands

nat outbound

nat inbound

outbound-interface

Use **outbound-interface** to apply the NAT rule to the outgoing traffic on an interface.

Use **undo outbound-interface** to restore the default.

Syntax

outbound-interface *interface-type interface-number*

undo outbound-interface

Default

A NAT rule is not applied to the outgoing traffic on an interface.

Views

NAT rule view

Predefined user roles

network-admin

context-admin

Parameters

interface-type interface-number: Specifies an interface by its type and number.

Usage guidelines

After you execute the command, the NAT rule applies to the outgoing traffic passing through the specified interface.

Examples

Apply the NAT rule **aaa** to the outgoing traffic on GigabitEthernet 1/0/2.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy] rule name aaa
[Sysname-nat-policy-rule-aaa] outbound-interface gigabitethernet 1/0/2
```

port-block

Use **port block** to configure port block parameters for a NAT address group.

Use **undo port block** to restore the default.

Syntax

port block block-size *block-size* [**extended-block-number** *extended-block-number*]

undo port block

Default

No port block parameters are configured for a NAT address group.

Views

NAT address group view

Predefined user roles

network-admin

context-admin

Parameters

block-size *block-size*: Specifies the port block size. The value range for the *block-size* argument is 1 to 65535. In a NAT address group, the port block size cannot be larger than the number of ports in the port range.

extended-block-number *extended-block-number*: Specifies the number of extended port blocks, in the range of 1 to 5. When a private IP address accesses the public network, but the ports in the selected port block are all occupied, the NAT444 gateway extends port blocks one by one for the private IP address.

Usage guidelines

To configure dynamic port block mappings, port block parameters are required in the NAT address group. When a private IP address initiates a connection to the public network, the NAT444 gateway assigns it a public IP address and a port block, and creates an entry for the mapping. For subsequent connections from the private IP address, the NAT444 gateway translates the private IP address to the mapped public IP address and the ports to ports in the selected port block.

Examples

Set the port block size to 256 and the number of extended port blocks to 1 in NAT address group 2.

```
<Sysname> system-view
[Sysname] nat address-group 2
[Sysname-address-group-2] port-block block-size 256 extended-block-number 1
```

Related commands

nat address-group

port-range

Use **port-range** to specify a port range for public IP addresses.

Use **undo port-range** to restore the default.

Syntax

port-range *start-port-number end-port-number*

undo port-range

Default

The port range for public IP addresses is 1 to 65535.

Views

NAT address group view

NAT port block group view

Predefined user roles

network-admin

context-admin

Parameters

start-port-number end-port-number: Specifies the start port number and end port number for the port range. The end port number cannot be smaller than the start port number. As a best practice, set the start port number to be equal to or larger than 1024 to avoid an application protocol identification error.

Usage guidelines

The port range must include all ports that public IP addresses use for address translation.

The number of ports in a port range cannot be smaller than the port block size.

Examples

Specify the port range as 1024 to 65535 for NAT address group 1.

```
<Sysname> system-view
[Sysname] nat address-group 1
[Sysname-address-group-1] port-range 1024 65535
```

Specify the port range as 30001 to 65535 for NAT port block group 1.

```
<Sysname> system-view
[Sysname] nat port-block-group 1
[Sysname-port-block-group-1] port-range 30001 65535
```

Related commands

probe

Use **probe** to specify a probe method for a NAT address group.

Use **undo probe** to cancel the probe method for a NAT address group.

Syntax

probe *template-name*

undo probe *template-name*

Default

No probe method is specified for a NAT address group.

Views

NAT address group view

Predefined user roles

network-admin

context-admin

Parameters

template-name: Specifies the name of an NQA template used for address probe. The name is a case-insensitive string of 1 to 32 characters.

Usage guidelines

The NAT address group probing uses an NQA template to detect the reachability of the addresses in the group.

The device periodically sends probe packets to the specified destination address in the NQA template. The source IP addresses in the probe packets are the IP addresses in the NAT address group.

- If the device receives a response packet for a probe, the probed source IP address can be used for address translation.
- If the device does not receive a response packet for a probe, the probed source IP address will be excluded from address translation temporarily. However, in the next NQA operation period, this excluded IP address is also probed. If a response is received in this round, the IP address can be used for address translation.

You can specify multiple NQA templates for one NAT address group. An IP address in the address group is identified as reachable as long as one probe for this IP address succeeds.

This command is applicable to NAT address groups used for outbound address translation. The manually configured excluded IP addresses are not probed.

When you configure NQA template for probing IP addresses in NAT address group, do not configure the source IP address in the template.

Examples

Create NQA ICMP template **4**, and specify it as the probe method for NAT address group **1**.

```
<Sysname> system-view
[Sysname] nqa template icmp t4
[Sysname-nqatplt-icmp-t4] quit
[Sysname] nat address-group 1
[Sysname-lb-lgroup-lg] probe t4
```

rule move (interface-based NAT policy view)

Use **rule move** to rearrange NAT rules to change their priority.

Syntax

rule move *rule-name1* { **after** | **before** } [*rule-name2*]

Views

Interface-based NAT policy view

Predefined user roles

network-admin

context-admin

Parameters

rule-name1: Specifies the name of the NAT rule to be moved. The rule name is a case-insensitive string of 1 to 63 characters.

after: Places the rule *rule-name1* after the rule *rule-name2* (called the reference rule).

before: Places the rule *rule-name1* before the reference rule.

rule-name2: Specifies the NAT rule as a reference rule. The rule name is a case-insensitive string of 1 to 63 characters. If you do not specify this argument, the priority of *rule-name1* changes as follows:

- If **after** is specified, the rule *rule-name1* will have the lowest priority.
- If **before** is specified, the rule *rule-name1* will have the highest priority.

Usage guidelines

You can execute this command to rearrange only existing NAT rules to change their priority.

Examples

Place the NAT rule **aaa** before the NAT rule **bbb** in the interface-based NAT policy.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy] rule move aaa before bbb
```

rule move (global NAT policy view)

Use **rule move** to rearrange NAT rules to change their priority.

Syntax

rule move *rule-name1* [**type** { **nat** | **nat64** | **nat66** }] { **after** | **before** } [*rule-name2* [**type** { **nat** | **nat64** | **nat66** }]]

Views

Global NAT policy view

Predefined user roles

network-admin

context-admin

Parameters

rule-name1: Specifies the name of the NAT rule to be moved. The rule name is a case-insensitive string of 1 to 63 characters.

type: Specifies a NAT rule type.

nat: Specifies the IPv4-to-IPv4 address translation rule.

nat64: Specifies the rule for translation between IPv4 and IPv6 addresses.

nat66: Specifies the IPv6-to-IPv6 address translation rule.

after: Places the rule *rule-name1* after the rule *rule-name2* (called the reference rule).

before: Places the rule *rule-name1* before the reference rule.

rule-name2: Specifies the NAT rule as a reference rule. The rule name is a case-insensitive string of 1 to 63 characters. If you do not specify this argument, the priority of *rule-name1* changes as follows:

- If **after** is specified, the rule *rule-name1* will have the lowest priority.
- If **before** is specified, *rule-name1* will have the highest priority.

Usage guidelines

You can execute this command to rearrange only existing NAT rules to change their priority.

The rule type is optional in this command. Specify an exact rule type if you specify the **type** keyword.

When you rearrange global NAT rules to change their priority, make sure all NAT rules containing destination address translation methods are before the NAT rules containing only source address translation methods.

- Do not place a NAT rule containing a destination address translation method after a NAT rule containing only a source address translation method.
- Do not place a NAT rule containing only a source address translation method before a NAT rule containing a destination address translation method.

Examples

Place the NAT rule **aaa** before the NAT rule **bbb** in the global NAT policy.

```
<Sysname> system
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule move aaa before bbb
```

Related commands

Global NAT policy view

Predefined user roles

network-admin

context-admin

Parameters

rule-name: Specifies the name of the NAT rule. The rule name is a case-insensitive string of 1 to 63 characters. Valid characters cannot include hyphens (-) and percent signs (%). If you want to use a backslash (\) or a quotation mark ("), you must enter the escape character (\) before the backslash or the quotation mark. If you want to include spaces in the string, you must enclose the name string in quotation marks ("), for example, "XXX XXX".

type: Specifies the type of NAT rules in the global NAT policy. If you do not specify this keyword, the NAT rule type is NAT.

nat: Specifies the NAT-type rules in the global NAT policy, which are used for translation between IPv4 addresses.

nat64: Specifies the NAT64-type rules in the global NAT policy, which are used for translation between IPv4 addresses and IPv6 addresses.

nat66: Specifies the NAT66-type rules in the global NAT policy, which are used for translation between IPv6 addresses or translation between IPv6 prefixes.

Usage guidelines

When you create, move, or modify the type of a NAT rule, follow these restrictions and guidelines:

- In a NAT policy, the priority of NAT rules are determined by the configuration order. A rule configured earlier has a higher priority. You can use the **rule move** command to rearrange the NAT rules. To view the priority order of the NAT rules in a policy, use the **display nat policy** command.
- You cannot repeatedly execute the **rule name** *rule-name* **type** command to modify the type of a NAT rule. To modify the type of a NAT rule, first use the **undo rule name** command to delete the NAT rule, and then execute the **rule name** *rule-name* **type** command to create a NAT rule.
- The interface-based NAT policy supports a maximum of 4096 NAT rules. The global NAT policy supports a maximum of 10000 NAT rules.

Examples

In the interface-based NAT policy, create a NAT rule named **aaa** and enter its view.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy] rule name aaa
[Sysname-nat-policy-rule-aaa]
```

In the global NAT policy, create a NAT rule named **aaa** and enter its view.

```
<Sysname> system
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name aaa
[Sysname-nat-global-policy-rule-aaa]
```

Related commands

display nat all

display nat global-policy

display nat policy

rule move

service

Use **service** to specify a service object group for the NAT rule.

Use **undo service** to delete a service object group from a NAT rule.

Syntax

service *object-group-name*

undo service [*object-group-name*]

Default

No service object group is specified for a NAT rule.

Views

NAT rule view

Predefined user roles

network-admin

context-admin

Parameters

object-group-name: Specifies the name of a service object group. The name is a case-insensitive string of 1 to 31 characters, and it cannot be **any**. If spaces are included in the name, enclose the name in quotation marks ("), for example, "XXX XXX".

Usage guidelines

The NAT device uses the services specified in this command to identify matching packets. Only packets with the matching services are translated.

To translate source IP addresses of outgoing packets, use this command with the **action snat** command. To translate both the source IP address and destination IP address of incoming packets, use this command together with the **action snat** and **action dnat** commands.

The service object group must already exist.

If you do not specify a service object group in the **undo service** command, the command deletes all service object groups in the NAT rule.

A NAT rule can have a maximum of 256 service object groups.

Examples

In the interface-based policy, specify NAT rule **aaa** to use **service1**, **service2**, and **service3** as the service object groups.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy] rule name aaa
[Sysname-nat-policy-rule-aaa] service service1
[Sysname-nat-policy-rule-aaa] service service2
[Sysname-nat-policy-rule-aaa] service service3
```

In the global NAT policy, specify NAT rule **aaa** to use **service1**, **service2**, and **service3** as the service object groups.

```
<Sysname> system
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name aaa
[Sysname-nat-global-policy-rule-aaa] service service1
[Sysname-nat-global-policy-rule-aaa] service service2
[Sysname-nat-global-policy-rule-aaa] service service3
```

display nat policy

object-group (*Security Command Reference*)

source-ip

Use **source-ip** to specify a source IP address match criterion for a NAT rule.

Use **undo source-ip** to delete a source IP address match criterion from a NAT rule.

Syntax

NAT-type rule view in the interface-based NAT policy:

source-ip *ipv4-object-group-name*

undo source-ip [*ipv4-object-group-name*]

NAT-type rule view in the global NAT policy:

source-ip { **host** *ip-address* | **subnet** *subnet-ip-address mask-length* }

undo source-ip { **host** [*ip-address*] | **subnet** [*subnet-ip-address mask-length*] }

NAT64-type rule view in the global NAT policy:

source-ip { *ipv4-object-group-name* | *ipv6-object-group-name* }

undo source-ip [*ipv4-object-group-name* | *ipv6-object-group-name*]

source-ip { **host** { *ipv4-address* | *ipv6-address* } | **subnet** { *subnet-ipv4-address mask-length* | *ipv6-prefix prefix-length* } }

undo source-ip { **host** [*ipv4-address* | *ipv6-address*] | **subnet** [*ipv4-address mask-length* | *ipv6-prefix prefix-length*] }

NAT66-type rule view in the global NAT policy:

source-ip *ipv6-object-group-name*

undo source-ip [*ipv6-object-group-name*]

source-ip { **host** *ipv6-address* | **subnet** *ipv6-prefix prefix-length* }

undo source-ip { **host** *ipv6-address* | **subnet** *ipv6-prefix prefix-length* }

Default

A NAT rule does not have any source IP address match criteria.

Views

NAT rule view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-object-group-name: Specifies the name of a source IPv4 address object group. The name is a case-insensitive string of 1 to 63 characters, and it cannot be **any**. If spaces are included in the name, enclose the name in quotation marks ("), for example, "XXX XXX".

ipv6-object-group-name: Specifies the name of a source IPv6 address object group. The name is a case-insensitive string of 1 to 63 characters, and it cannot be **any**. If spaces are included in the name, enclose the name in quotation marks ("), for example, "XXX XXX".

host *ipv4-address*: Specifies an IPv4 address to match source IPv4 address. The IPv4 address cannot be an all-zero address, all-one address, Class D address, Class E address, or loopback address.

host *ipv6-address*: Specifies an IPv6 address to match source IPv6 address.

subnet *subnet-ipv4-address mask-length*: Specifies a subnet to match source IPv4 addresses. The *subnet-ipv4-address* argument specifies the subnet address. The *mask-length* argument specifies the mask length, which can be 8, 16, or an integer in the range of 24 to 31.

subnet *ipv6-prefix prefix-length*: Specifies an IPv6 prefix for a NAT rule. The *ipv6-prefix* argument indicates an IPv6 prefix. The *prefix-length* argument indicates the prefix length in the range of 1 to 128.

Usage guidelines

The NAT device uses the source IP addresses specified in this command to identify matching packets. Only packets with the matching source IP addresses are translated.

When you reference an address object group, follow these restrictions and guidelines:

- The address object group must already exist.
- For an address object group to be successfully referenced by the source address translation method, make sure the objects in the referenced address object group are created through the following methods:
  - [*object-id*] **network host address** *ip-address*
  - [*object-id*] **network subnet** *ip-address* { *mask-length* | *mask* }
  - [*object-id*] **network range** *ip-address1 ip-address2*

  For more information about these commands, see object group commands in *Security Command Reference*.

If you do not specify any parameters in the **undo source-ip** command, the command deletes all source address match criteria in the NAT rule.

When you configure match criteria for a NAT rule, follow these restrictions and guidelines:

- A NAT rule can have a maximum of 256 source address object groups.
- If you configure multiple packet match criteria in a NAT64-type rule, the IP address type in the later configured packet match criteria must be the same as that in the earlier configured packet match criteria. For example, if you first execute the **source-ip host 192.168.1.1** command, the **source-ip host 100::1** command executed later does not take effect. Select an IP type as needed.
- If you execute the following commands in the same NAT rule, the most recent configuration takes effect:
  - **source-ip**
  - **source-ip host**
  - **source-ip subnet**

Examples

In the interface-based NAT policy, configure NAT rule **aaa** to use source address object groups **desIP1**, **desIP2**, and **desIP3** as the packet match criteria.

```
<Sysname> system
[Sysname] nat policy
[Sysname-nat-policy] rule name aaa
[Sysname-nat-policy-rule-aaa] source-ip srcip1
[Sysname-nat-policy-rule-aaa] source-ip srcip2
[Sysname-nat-policy-rule-aaa] source-ip srcip3
```

In the global NAT policy, configure NAT rule **aaa** to use source address object groups **desIP1**, **desIP2**, and **desIP3** as the packet match criteria.

```
<Sysname> system
```

```
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name aaa
[Sysname-nat-global-policy-rule-aaa] source-ip srcip1
[Sysname-nat-global-policy -rule-aaa] source-ip srcip2
[Sysname-nat-global-policy -rule-aaa] source-ip srcip3
```

object-group *(Security Command Reference)*

source-zone

Use **source-zone** to specify a source security zone in a NAT rule.

Use **undo source-zone** to delete a source security zone from a NAT rule.

Syntax

source-zone *source-zone-name*

undo source-zone [*source-zone-name*]

Default

No source security zones are specified in a NAT rule.

Views

NAT rule view

Predefined user roles

network-admin

context-admin

Parameters

source-zone-name: Specifies the name of a source security zone. The name is a case-insensitive string of 1 to 31 characters, and it cannot be **any**. You can specify a nonexistent security zone. This command takes effect after you use the **security-zone name** command to create the security zone. For more information about security zones, see *Security Configuration Guide*.

Usage guidelines

The NAT device uses the source security zones specified in this command to identify matching packets. Only packets with the matching source security zones are translated.

To translate source IP addresses of outgoing packets, use this command with the **action snat** command. To translate both the source IP address and destination IP address of incoming packets, use this command together with the **action snat** and **action dnat** commands.

This command does not support modifying source security zones. To modify the source security zone for a NAT rule, first execute the **undo destination-zone** command to delete the zone, and then execute the **destination-zone** command to specify a new one.

If you do not specify a source security zone in the **undo source-zone** command, the command deletes all source security zones in the NAT rule.

This command is available only in NAT rule view of the global NAT policy.

A NAT rule can have a maximum of 16 source security zones.

Examples

Specify source security zone **trust** for NAT rule **rule1**.

```
<Sysname> system-view
[Sysname] nat global-policy
[Sysname-nat-global-policy] rule name rule1
[Sysname-nat-global-policy-rule-rule1] source-zone trust
```

Related commands

security-zone name (*Security Command Reference*)

vrf

Use **vrf** to specify a VPN instance in a NAT rule.

Use **undo vrf** to delete a VPN instance from a NAT rule.

Syntax

vrf *vrf-name*

undo vrf *vrf-name*

Default

No VPN instances are specified in a NAT rule.

Views

NAT rule view

Predefined user roles

network-admin

context-admin

Parameters

vrf-name: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

If you use this command together with the **action snat** command, it works as follows:

1. The NAT device uses the VPN instance to which the packet belongs to identify matching packets. Only packets with the matching VPN instances are translated. The NAT device records the VPN information in the mapping entry.
2. When the server in the external network replies to the internal host, the NAT device translates addresses according to the mapping entry and forwards the packets after source address translation to the internal host.

If you use this command together with the **action dnat** command, it works as follows:

1. The NAT device uses the VPN instance to which the packet belongs to identify matching packets. Only packets with the matching VPN instances are translated. The NAT device records the VPN information in the mapping entry.
2. When the internal server replies to the host in the external network, the NAT device translates addresses according to the mapping entry and forwards the packets after destination address translation to the host.

This command is available only in NAT rule view of the global NAT policy.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify VPN instance **vpn1** for NAT rule **rule1**.

```
<sysname> system-view
[sysname] nat global-policy
[sysname-nat-global-policy] rule name rule1
[sysname-nat-global-policy-rule-rule1] vrf vpn1
```

vrrp vrid (interface-based NAT)

Use **vrrp vrid** to bind a VRRP group to a NAT address group or a NAT port block group.

Use **undo vrrp vrid** to restore the default.

Syntax

vrrp vrid *virtual-router-id*

undo vrrp vrid

Default

A NAT address group or a NAT port block group is not bound to any VRRP group.

Views

NAT address group view

NAT port block group view

Predefined user roles

network-admin

context-admin

Parameters

virtual-router-id: Specifies a VRRP group by its virtual router ID in the range of 1 to 255.

Usage guidelines

In a hot backup system collaborating with VRRP, source address translation that uses a NAT address group or port block group assigns the public IP address after translation to the address management module. Both the active and standby devices advertise the mappings between the public IP address and MAC addresses of their own physical interfaces to all nodes in the same LAN. As a result, the uplink Layer 3 device directly connected to the hot backup system might send downlink packets to the backup device, causing service anomalies.

To avoid such an issue, bind the NAT address group or port block group to a VRRP group. Then, only the master device responds to ARP requests with the virtual MAC address of the VRRP group. The uplink Layer 3 device directly connected to the hot backup system sends downlink packets only to the master device.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Bind VRRP group **1** to NAT address group **2**.

```
<Sysname> system-view
```

```
[Sysname] nat address-group 2
[Sysname-address-group-2] vrrp vrid 1
```

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays NAT66 sessions for all member devices.

verbose: Displays detailed information about NAT66 sessions. If you do not specify this keyword, the command displays brief information about NAT66 sessions.

Usage guidelines

If you do not specify any parameters, this command displays brief information about all NAT66 sessions.

Examples

Display brief information about NAT66 sessions for the specified slot.

```
<Sysname> display nat66 session slot 1
Slot 1:
Initiator:
  Source      IP/port: FD01:203:405::1/4048
  Destination IP/port: 2001:DB8:1::100/21
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/2

Total sessions found: 1
```

Display detailed information about NAT66 sessions for the specified slot.

```
<Sysname> display nat session slot 1 verbose
Slot 1:
Initiator:
  Source      IP/port: FD01:203:405::1/4048
  Destination IP/port: 2001:DB8:1::100/21
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
```

```
  Inbound interface: GigabitEthernet1/0/2
  Source security zone: Trust
Responder:
  Source      IP/port: 2001:DB8:1::100/21
  Destination IP/port: 1:0:0:309::1/4048
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/1
  Source security zone: Trust
State: TCP_ESTABLISHED
Application: FTP
Rule ID: -/-/-
Rule name:
Start time: 2018-12-10 09:19:28  TTL: 3585s
Initiator->Responder:            0 packets          0 bytes
Responder->Initiator:            0 packets          0 bytes

Total sessions found: 1
```

Table 2 Command output

Field	Description
Initiator	Session information about the initiator.
Responder	Session information about the responder.
Source IP/port	Source IPv6 address and port number.
Destination IP/port	Destination IPv6 address and port number.
VPN instance/VLAN ID/Inline ID	This field is not supported in the current software version. • **VPN instance**—MPLS L3VPN instance to which the session belongs. • **VLAN ID**—ID of the VLAN to which the session belongs for Layer 2 forwarding. • **Inline ID**—ID of the INLINE to which the session belongs for Layer 2 forwarding. If no settings are specified, this field displays slash-separated hyphens (***-/-/-***).
Protocol	Transport layer protocol type: **DCCP**, **ICMPv6**, **Raw IP**, **SCTP**, **TCP**, **UDP**, or **UDP-Lite**. The number after the protocol is the protocol number.
Inbound interface	Input interface.
Source security zone	Security zone to which the input interface belongs. If the input interface does not belong to any security zone, this field displays a hyphen (**-**).
State	NAT66 session state.
Application	Application layer protocol type, such as **FTP** and **DNS**. This field displays **OTHER** for the protocol types identified by non-well-known ports.
Rule ID	ID of the security policy rule.
Rule name	Name of the security policy rule.
Start time	Time when the session starts.
TTL	Remaining lifetime of the NAT66 session, in seconds.

Initiator->Responder	Number of packets and packet bytes from the initiator to the responder.
Responder->Initiator	Number of packets and packet bytes from the responder to the initiator.
Total sessions found	Total number of sessions.

Parameters

summary: Displays NAT66 statistics summary. If you do not specify this keyword, the command displays detailed NAT66 statistics.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays NAT66 statistics for all member devices.

Examples

Display detailed NAT66 statistics.

```
<Sysname> display nat66 statistics
Slot 1:
  Total session entries: 0
  Total outbound NO-PAT entries: 0
```

Table 3 Command output

Field	Description
Total session entries	Number of NAT66 session entries.
Total outbound NO-PAT entries	Number of NAT66 NO-PAT entries.

Display NAT66 statistics summary.

```
<Sysname> display nat66 statistics summary
Slot Sessions
1    100
```

Table 4 Command output

Field	Description
Sessions	Number of NAT66 session entries.

nat66 prefix destination

Use **nat66 prefix destination** to configure an IPv6 prefix mapping for IPv6 destination address translation.

Use **undo nat66 prefix destination** to remove an IPv6 prefix mapping for IPv6 destination address translation.

Syntax

nat66 prefix destination *original-ipv6-prefix prefix-length* [**protocol** *pro-type* [*global-port*]] *translated-ipv6-prefix prefix-length* [*local-port*]

undo nat66 prefix destination *original-ipv6-prefix prefix-length* [**protocol** *pro-type* [*global-port*]] *translated-ipv6-prefix prefix-length* [*local-port*]

Default

No IPv6 prefix mappings are configured for IPv6 destination address translation.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

original-ipv6-prefix: Specifies the original IPv6 prefix. For IPv6 destination address translation, specify the external prefix.

protocol *pro-type*: Specifies a protocol type. If you do not specify a protocol type, the command applies to packets of all protocols. The protocol type format can be one of the following:

- A number in the range of 1 to 255. The values 50 (ESP) and 51 (AH) are not supported.
- A protocol name of **ipv6-icmp**, **tcp**, or **udp**.

global-port: Specifies a public port number for the internal server, in the range of 1 to 65535. If you do not specify this argument, the translation will be performed no matter what the destination port number is. You can specify this argument only when the protocol type is TCP or UDP.

translated-ipv6-prefix: Specifies the translated IPv6 prefix. For IPv6 destination address translation, specify the internal prefix.

prefix-length: Specifies a prefix length, in the range of 1 to 128.

local-port: Specifies a private port number for the internal server, in the range of 1 to 65535. If you do not specify this argument, the value for this argument is the same as the value of the *global-port* argument. If you do not specify the *global-port* and *local-port* arguments, the port number is not translated. You can specify this argument only when the protocol type is TCP or UDP.

Usage guidelines

To allow external users to access internal servers (such as Web or FTP server), configure IPv6 destination prefix mappings on the interface connected to the external network.

When you configure IPv6 destination prefix mappings, follow these restrictions and guidelines:

- The prefix length before and after NAT66 must be the same.
- On one interface, the mapping between an external prefix and an internal prefix must be unique.
- On different interfaces, one external prefix cannot be mapped to different internal prefixes.
- The translated IPv6 prefix cannot be the same as the prefix of the public IPv6 address of the NAT66 device or the prefix of the IPv6 address of an external host.
- The command does not support modifying an existing IPv6 prefix mapping. To modify it, first execute the **undo nat66 prefix destination** command to remove the mapping, and then configure the new one.

This feature cannot perform translation on IPsec protected packets with encapsulated by ESP or AH.

Examples

On GigabitEthernet 1/0/1, configure an IPv6 destination prefix mapping to translate IPv6 prefix 2001::/64 to IPv6 prefix 2101::/64.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat66 prefix destination 2001:: 64 2101:: 64
```

On GigabitEthernet 1/0/1, configure an IPv6 destination prefix mapping to translate IPv6 prefix 2001::/64 and port 64 to IPv6 prefix 2101::/64 and port 200 for packets destined for the internal FTP server.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat66 prefix destination 2001:: 64 protocol tcp 100 2101:: 64 200
```

Related commands

display nat66 all

nat66 prefix source

Use **nat66 prefix source** to configure an IPv6 prefix mapping for IPv6 source address translation.

Use **undo nat66 prefix source** to remove an IPv6 prefix mapping for IPv6 source address translation.

Syntax

nat66 prefix source *original-ipv6-prefix prefix-length translated-ipv6-prefix prefix-length* [**pat**]

undo nat66 prefix source *original-ipv6-prefix prefix-length translated-ipv6-prefix prefix-length* [**pat**]

Default

No IPv6 prefix mappings are configured for IPv6 source address translation.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

original-ipv6-prefix: Specifies the original IPv6 prefix. For IPv6 source address translation, specify the internal prefix.

translated-ipv6-prefix: Specifies the translated IPv6 prefix. For IPv6 source address translation, specify the external prefix.

prefix-length: Specifies a prefix length, in the range of 1 to 128.

pat: Uses the PAT mode for address translation. In this mode, port information is translated. If you do not specify this keyword, the device does not translate port information.

Usage guidelines

NAT66 source address translation is applicable to the following scenarios:

- **Single internal and external network**—The NAT66 device is connected to an internal network and an external network. Hosts in the internal network uses locally routed IPv6 prefixes. When an internal host sends packets to access the external network, the NAT66 device translates the source IPv6 address prefix in the packets to a global unicast address prefix.
- **Redundancy and load sharing**—Multiple NAT66 devices are deployed between two IPv6 networks and they use ECMPs for load sharing. To allow any NAT66 device to process IPv6 traffic among different sites, configure the same source prefix mappings on these NAT66 devices.
- **Multihoming**—In a multihomed network, NAT66 devices are connected to an internal network and multiple external networks. One internal prefix is mapped to different external prefixes on the NAT66 devices, so that one internal address can be translated to multiple external addresses.

When you configure source prefix mappings, follow these restrictions and guidelines:

- Source prefix mappings are typically configured on the interface connected to the external network.
- The prefix length before and after NAT66 in a mapping must be the same if this mapping does not support port translation.
- On one interface, the mapping between an internal prefix and an external prefix must be unique.
- On different interfaces, different internal prefixes cannot be mapped to the same external prefix.
- The translated IPv6 prefix cannot be the same as the prefix of the public IPv6 address of the NAT66 device or the prefix of the destination public IPv6 address.
- The command does not support modifying an existing prefix mapping. To modify it, first execute the **undo nat66 prefix source** command to remove the mapping, and then configure the new one.

This feature cannot perform translation on IPsec protected packets with encapsulated by ESP or AH.

Examples

On GigabitEthernet 1/0/1, configure an IPv6 source prefix mapping to translate IPv6 prefix FD9C:58ED:7D73:2::/64 to 2101::/64.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat66 prefix source fd9C:58ed:7d73:2:: 64 2101:: 64
```

On GigabitEthernet 1/0/1, configure an IPv6 source prefix mapping in PAT mode to translate IPv6 prefix FD9C:58ED:7D73:2::/64 to 2101::/64.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] nat66 prefix source fd9C:58ed:7d73:2:: 64 2101:: 64 pat

AFT commands

address

Use **address** to add an address range to an AFT address group.

Use **address** to remove an address range from an AFT address group.

Syntax

address *start-address end-address*

undo address *start-address end-address*

Default

No address ranges exist.

Views

AFT address group view

Predefined user roles

network-admin

context-admin

Parameters

start-address end-address: Specifies the start and end IP addresses for an address range. The end address cannot be lower than the start address. If they are the same, the address range has only one IP address.

Usage guidelines

An AFT address group is a set of address ranges. Dynamic AFT translates an IPv6 address to an IPv4 address in one of the address ranges.

Each address range can contain a maximum of 256 addresses.

Make sure the address ranges do not overlap.

Examples

Add two address ranges to AFT address group 2.

```
<Sysname> system-view
[Sysname] aft address-group 2
[Sysname-aft-address-group-2] address 10.1.1.1 10.1.1.15
[Sysname-aft-address-group-2] address 10.1.1.20 10.1.1.30
```

Related commands

aft address-group

aft address-group

Use **aft address-group** to create an AFT address group and enter its view, or enter the view of an existing AFT address group.

Use **undo aft address-group** to delete an AFT address group.

Syntax

aft address-group *group-id*

undo aft address-group *group-id*

Default

No AFT address groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

group-id: Assigns an ID to the address group. The value range for this argument is 0 to 65535.

Usage guidelines

An AFT address group is a set of address ranges. Use the **address** command to add an address range.

The AFT address group is used in dynamic AFT. Dynamic AFT translates the source address of an IPv6 packet to an IPv4 address in the address group.

Examples

Create AFT address group 1 and enter its view.

```
<Sysname> system-view
[Sysname] aft address-group 1
[Sysname-aft-address-group-1]
```

aft alg

Use **aft alg** to enable AFT ALG for the specified or all supported protocols.

Use **undo aft alg** to disable AFT ALG for the specified or all supported protocols.

Syntax

aft alg { **all** | **dns** | **ftp** | **http** | **icmp-error** }

undo aft alg { **all** | **dns** | **ftp** | **http** | **icmp-error** }

Default

AFT ALG is enabled for DNS, FTP, ICMP error messages, and HTTP.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

all: Enables AFT ALG for all supported protocols.

dns: Enables AFT ALG for DNS.

ftp: Enables AFT ALG for FTP.

http: Enables AFT ALG for HTTP.

icmp-error: Enables AFT ALG for ICMP error packets.

Usage guidelines

AFT ALG translates address or port information in the application layer payloads.

For example, an FTP application includes a data connection and a control connection. The IP address and port number for the data connection depend on the payload information of the control connection. This requires AFT ALG to translate the address and port information.

You can execute this command multiple times to enable AFT ALG for different protocols.

Examples

Enable AFT ALG for FTP.

```
<Sysname> system-view
[Sysname] aft alg ftp
```

Related commands

Default

AFT logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

For security auditing, you can enable AFT logging to record AFT session information. An AFT session is a session whose source and destination IP addresses are translated by AFT.

AFT can log the following events:

- An AFT port block is created.
- An AFT port block is deleted.
- An AFT session is established.

  To log AFT session establishment events, you must also execute the **aft log flow-begin** command.
- An AFT session is removed.

  To log AFT session removal events, you must also execute the **aft log flow-end** command.

The logs are sent to the information center of the device. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Examples

Enable AFT logging.

```
<Sysname> system-view
[Sysname] aft log enable
```

aft port-load-balance enable

Use **aft port-load-balance enable** to enable AFT port halving.

Use **undo aft port-load-balance enable** to disable AFT port halving.

Syntax

aft port-load-balance enable slot *slot-number*

undo aft port-load-balance enable

Default

AFT port halving is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. This device will use the lower half of the port block.

Usage guidelines

AFT supports IRF hot backup in active/standby and dual-active mode. The AFT configuration for IRF hot backup depends on the deployment mode.

- In dual-active mode, if the two IRF member devices in an IRF fabric use the same AFT address group, the devices might map different IPv6 addresses and ports to the same IPv4 address and

port. To avoid this situation, enable AFT port halving on the devices. After you enable AFT port halving, each port block will be equally divided between the two devices. The two devices will use different ports to translate packets from different IP addresses, avoiding port assignment conflicts.

- You do not need to enable AFT port halving on the IRF member devices in active/standby mode.

This command is exclusive with the **aft remote-backup port-alloc** command.

Examples

Enable AFT port halving.

```
<Sysname> system-view
[Sysname] aft port-load-balance enable slot 1
```

Related commands

aft remote-backup port-alloc

aft prefix-general

Use **aft prefix-general** to configure a general prefix.

Use **undo aft prefix-general** to delete a general prefix.

Syntax

aft prefix-general *prefix-general prefix-length*

undo aft prefix-general *prefix-general prefix-length*

Default

No general prefixes exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

prefix-general: Specifies the general prefix.

prefix-length: Specifies the prefix length. The value for this argument can be 32, 40, 48, 56, 64, or 96.

Usage guidelines

A general prefix is an IPv6 address prefix of 32, 40, 48, 56, 64, or 96 bits. A general prefix can be used for source and destination address translation between IPv4 and IPv6.

When a general prefix is used alone, it provides IPv6-to-IPv4 source and destination address translation. If a source or destination IPv6 address matches the general prefix, AFT translates it to the embedded IPv4 address.

When a general prefix is used in the **aft v4tov6 source** or **aft v4tov6 destination** command, it provides IPv4-to-IPv6 source or destination address translation. If a source or destination IPv4 address matches the ACL, AFT constructs the IPv6 address by using the general prefix and the IPv4 address.

A general prefix cannot be on the same subnet as any interface on the device.

A general prefix must be different from a NAT64 prefix or an IVI prefix.

Examples

Specify **2000:db8e::** as a general prefix and set its prefix length to 32.

```
<Sysname> system-view
[Sysname] aft prefix-general 2000:db8e:: 32
```

Use **undo aft prefix-ivi** to delete an IVI prefix.

Syntax

aft prefix-ivi *prefix-ivi*

undo aft prefix-ivi *prefix-ivi*

Default

No IVI prefixes exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

prefix-ivi: Specifies an IVI prefix.

Usage guidelines

An IVI prefix is an IPv6 address prefix whose length is fixed at 32 bits. An IVI prefix can be used for IPv6-to-IPv4 source address translation and IPv4-to-IPv6 destination address translation.

When an IVI prefix is used alone, it provides IPv6-to-IPv4 source address translation. If a source IPv6 address matches the IVI prefix, AFT translates it to the embedded IPv4 address.

When an IVI prefix is used in the **aft v4tov6 destination** command, it provides IPv4-to-IPv6 destination address translation. If a destination IPv4 address matches the ACL, AFT constructs the IPv6 address by using the IVI prefix and the IPv4 address.

An IVI prefix must be different from a NAT64 prefix or a general prefix.

Examples

Specify **3000:db8e::** as an IVI prefix.

```
<Sysname> system-view
[Sysname] aft prefix-ivi 3000:db8e::
```

Related commands

aft v4tov6 destination

display aft configuration

aft prefix-nat64

Use **aft prefix-nat64** to configure a NAT64 prefix.

Use **undo aft prefix-nat64** to delete a NAT64 prefix.

Syntax

aft prefix-nat64 *prefix-nat64 prefix-length*

undo aft prefix-nat64 *prefix-nat64 prefix-length*

Default

No NAT64 prefixes exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

prefix-nat64: Specifies a NAT64 prefix.

prefix-length: Specifies the NAT64 prefix length. The value for this argument can be 32, 40, 48, 56, 64, or 96.

Usage guidelines

A NAT64 prefix is an IPv6 address prefix of 32, 40, 48, 56, 64, or 96 bits. A NAT64 prefix can be used for IPv4-to-IPv6 source address translation and IPv6-to-IPv4 destination address translation.

When a NAT64 prefix is used alone, it provides IPv6-to-IPv4 destination address translation. If a destination IPv6 address matches the NAT64 prefix, AFT translates it to the embedded IPv4 address.

When a NAT64 prefix is used alone or in the **aft v4tov6 source** command, it also provides IPv4-to-IPv6 source address translation. AFT constructs the IPv6 address by using the NAT64 prefix and the source IPv4 address. If the NAT64 prefix is used in the **aft v4tov6 source** command, AFT only translates packets permitted by the ACL.

To configure a 96-bit NAT64 prefix, make sure bits 64 through 71 are all 0. Otherwise, the configuration cannot be deployed.

A NAT64 prefix cannot be on the same subnet as any of the interfaces on the device.

A NAT64 prefix must be different from an IVI prefix or a general prefix.

Examples

Specify **2000:db8e::** as a NAT64 prefix and set its prefix length to 32.

```
<Sysname> system-view
[Sysname] aft prefix-nat64 2000:db8e:: 32
```

Related commands

aft v4tov6 source

display aft configuration

aft remote-backup port-alloc

Use **aft remote-backup port-alloc** to specify AFT port ranges for the two devices in the HA group.

Use **undo remote-backup port-alloc** to restore the default.

Syntax

aft remote-backup port-alloc { **primary** | **secondary** }

undo aft remote-backup port-alloc

Default

The two devices in the HA group share AFT port resources.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

primary: Specifies the lower half of the port block.

secondary: Specifies the higher half of the port block.

Usage guidelines

In the HA group in dual-active mode, different IP+port combinations on the two devices might be translated to the same AFT IP+port resources due to the following reasons:

- The two devices in the HA group share AFT addresses.
- The same AFT port range is assigned to each device.

To avoid this situation, execute this command on the primary device to equally divide the port resources for the two devices. Executing the command on the primary device also makes the remaining half of the port block be automatically assigned to the secondary device. For example, if you execute the **ft remote-backup port-alloc secondary** command on the primary device, the **aft remote-backup port-alloc primary** command is automatically executed on the secondary device. For more information about configuring the HA group, see *High Availability Configuration Guide*.

You do not need to execute this command for the HA group in active/standby mode. No port conflict exists in active/standby mode because only one device processes AFT services.

This command is exclusive with the **aft port-load-balance enable** command.

Examples

Specify the primary device in the HA group to use the lower half of the port block.

```
<Sysname> system-view
[Sysname] aft remote-backup port-alloc primary
```

Related commands

[Sysname] aft turn-off traffic-class
```

aft v4server

Use **aft v4server** to configure an AFT mapping for an IPv4 internal server.

Use **undo aft v4server** to delete an AFT mapping for an IPv4 internal server.

Syntax

aft v4server protocol *protocol-type ipv6-destination-address ipv6-port-number* [**vpn-instance** *ipv6-vpn-instance-name*] *ipv4-destination-address ipv4-port-number* [**vpn-instance** *ipv4-vpn-instance-name*] [**vrrp** *virtual-router-id*]

undo aft v4server protocol { **tcp** | **udp** } *ipv6-destination-address ipv6-port-number* [**vpn-instance** *ipv6-vpn-instance-name*]

Default

No AFT mapping for an IPv4 internal server is configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

protocol *protocol-type*: Specifies a transport layer protocol by its type. The *protocol-type* argument can be **tcp** or **udp**.

ipv6-destination-address: Specifies an IPv6 address.

ipv6-port-number: Specifies an IPv6 port number in the range of 1 to 65535.

vpn-instance *ipv6-vpn-instance-name*: Specifies an IPv6 MPLS L3VPN instance to which the IPv6 address belongs. The *ipv6-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the IPv6 address belongs to the public network, do not specify this option.

ipv4-destination-address: Specifies an IPv4 address.

ipv4-port-number: Specifies an IPv4 port number in the range of 1 to 65535.

vpn-instance *ipv4-vpn-instance-name*: Specifies an IPv4 MPLS L3VPN instance to which the IPv4 address belongs. The *ipv4-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the IPv4 address belongs to the public network, do not specify this option.

vrrp *virtual-router-id*: Binds the IPv4 server to a VRRP group on the IPv6 network. The *virtual-router-id* parameter represents the virtual router ID of the VRRP group, in the range of 1 to 255.

Usage guidelines

This command maps the IPv4 address and port number of an IPv4 server to an IPv6 address and port number. IPv6 hosts can use the IPv6 address and port number to access the services provided by the IPv4 server.

In an HA hot backup network, execute this command on the primary device to bind an AFT IPv4 server to an HA-associated VRRP group on the IPv6 network. If you fail to do so, ARP might fail to resolve an IPv4-mapped IPv6 address into a correct MAC address.

An IPv4 server can be bound to only one VRRP group. You can execute this command multiple times to change the bound VRRP group for the IPv4 server.

The AFT mappings for different IPv4 internal servers cannot be the same.

Examples

Map IPv4 address **2.2.2.123** and port number **1720** of an IPv4 internal server to IPv6 address **3001::5** and port number **1720** for TCP packets.

```
<Sysname> system-view
[Sysname] aft v4server protocol tcp 3001::5 1720 2.2.2.123 1720
```

aft v4tov6 destination

Use **aft v4tov6 destination** to configure an IPv4-to-IPv6 destination address translation policy.

Use **undo aft v4tov6 destination** to delete an IPv4-to-IPv6 destination address translation policy.

Syntax

aft v4tov6 destination acl { **name** *ipv4-acl-name* **prefix-ivi** *prefix-ivi* [**vpn-instance** *ipv6-vpn-instance-name*] | **number** *ipv4-acl-number* { **prefix-general** *prefix-general prefix-length* | **prefix-ivi** *prefix-ivi* [**vpn-instance** *ipv6-vpn-instance-name*] } }

undo aft v4tov6 destination acl { **name** *ipv4-acl-name* | **number** *ipv4-acl-number* }

Default

No IPv4-to-IPv6 destination address translation policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

acl: Identifies IPv4 packets for address translation. AFT translates destination addresses for IPv4 packets permitted by the ACL.

name *ipv4-acl-name*: Specifies an IPv4 ACL by its name. The *ipv4-acl-name* argument is a case-insensitive string of 1 to 63 characters. It must start with an English letter and to avoid confusion, it cannot be **all**.

number *ipv4-acl-number*: Specifies an IPv4 ACL by its number in the range of 2000 to 3999.

prefix-general *prefix-general prefix-length*: Specifies a general prefix and its prefix length. The value for the *prefix-length* argument can be 32, 40, 48, 56, 64, or 96. AFT uses the general prefix to translate destination addresses for packets permitted by the ACL.

prefix-ivi *prefix-ivi*: Specifies an IVI prefix. AFT uses the IVI prefix to translate destination addresses for packets permitted by the ACL.

vpn-instance *ipv6-vpn-instance-name*: Specifies an IPv6 MPLS L3VPN instance to which translated IPv6 addresses belong. The *ipv6-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the IPv6 addresses belong to the public network, do not specify this option.

Usage guidelines

You must specify different ACLs for different IPv4-to-IPv6 destination address translation policies.

You can specify a nonexistent IVI prefix or general prefix in a policy, but the policy takes effect only after you configure the prefix.

Examples

Configure the device to use IVI prefix **3000:db8e::** to translate IPv4 destination addresses to IPv6 addresses for IPv4 packets permitted by ACL 2000.

```
<Sysname> system-view
[Sysname] aft prefix-ivi 3000:db8e::
[Sysname] aft v4tov6 destination acl number 2000 prefix-ivi 3000:db8e::
```

Configure the device to use general prefix **2000:db8e::/32** to translate IPv4 destination addresses to IPv6 addresses for IPv4 packets permitted by ACL 2000.

```
<Sysname> system-view
[Sysname] aft v4tov6 destination acl number 2000 prefix-general 2000:db8e:: 32
```

IPv4-to-IPv6 source address translation policy using a NAT64 prefix or general prefix:

aft v4tov6 source acl { **name** *ipv4-acl-name* **prefix-nat64** *prefix-nat64 prefix-length* [**vpn-instance** *ipv6-vpn-instance-name*] | **number** *ipv4-acl-number* { **prefix-general** *prefix-general prefix-length* | **prefix-nat64** *prefix-nat64 prefix-length* [**vpn-instance** *ipv6-vpn-instance-name*] } }

undo aft v4tov6 source acl { **name** *ipv4-acl-name* | **number** *ipv4-acl-number* }

Default

No IPv4-to-IPv6 source address translation policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies an IPv4 address.

vpn-instance *ipv4-vpn-instance-name*: Specifies an IPv4 MPLS L3VPN instance to which the IPv4 address belongs. The *ipv4-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the IPv4 address belongs to the public network, do not specify this option.

ipv6-address: Specifies an IPv6 address. The IPv6 address in a static mapping cannot be on the same subnet as any interface on the device.

vpn-instance *ipv6-vpn-instance-name*: Specifies an IPv6 MPLS L3VPN instance to which the IPv6 address belongs. The *ipv6-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the IPv6 address belongs to the public network, do not specify this option.

acl: Identifies IPv4 packets for address translation. AFT translates source addresses for packets permitted by the ACL.

name *ipv4-acl-name*: Specifies an IPv4 ACL by its name. The *ipv4-acl-name* argument is a case-insensitive string of 1 to 63 characters. It must start with an English letter and to avoid confusion, it cannot be **all**.

number *ipv4-acl-number*: Specifies an IPv4 ACL by its number in the range of 2000 to 3999.

prefix-general*prefix-general prefix-length*: Specifies a general prefix and its prefix length. The value for the *prefix-length* argument can be 32, 40, 48, 56, 64, or 96. AFT uses the general prefix to translate source IPv4 address for packets permitted by the ACL.

prefix-nat64 *prefix-nat64 prefix-length*: Specifies a NAT64 prefix and its prefix length. The value for the *prefix-length* argument can be 32, 40, 48, 56, 64, or 96. AFT uses the NAT64 prefix to translate source IPv4 address for packets permitted by the ACL.

vrrp *virtual-router-id*: Binds the IPv4-to-IPv6 source address translation policy to a VRRP group on the IPv6 network. The *virtual-router-id* parameter represents the virtual router ID of the VRRP group, in the range of 1 to 255.

Usage guidelines

In an HA hot backup network, execute this command on the primary device to bind an IPv4-to-IPv6 source address translation policy to an HA-associated VRRP group on the IPv6 network. If you do not do so, ARP might fail to resolve an IPv4-mapped IPv6 address into a correct MAC address.

An IPv4-to-IPv6 source address translation policy can be bound to only one VRRP group. You can execute this command multiple times to change the bound VRRP group for the policy.

The IPv4 or IPv6 addresses in different static mappings cannot be the same.

You must specify different ACLs for IPv4-to-IPv6 source address translation policies that use NAT64 prefixes or general prefixes.

You can specify a nonexistent NAT64 prefix or general prefix in a policy, but the policy takes effect only after you configure the prefix.

Examples

Map IPv4 source address **2.2.2.123** to IPv6 source address **3001::5**.

```
<Sysname> system-view
[Sysname] aft v4tov6 source 2.2.2.123 3001::5
```

Configure the device to use NAT64 prefix **2000::/32** to translate IPv4 source addresses to IPv6 addresses for IPv4 packets permitted by ACL 2000.

```
<Sysname> system-view
[Sysname] aft prefix-nat64 2000:: 32
```

```
[Sysname] aft v4tov6 source acl number 2000 prefix-nat64 2000:: 32
```

Configure the device to use general prefix **3000::/32** to translate IPv4 source addresses to IPv6 addresses for IPv4 packets permitted by ACL 2000.

context-admin

Parameters

protocol *protocol-type*: Specifies a transport layer protocol by its type. The *protocol-type* argument can be **tcp** or **udp**.

ipv4-destination-address: Specifies an IPv4 address.

ipv4-port-number: Specifies an IPv4 port number in the range of 1 to 65535.

vpn-instance *ipv4-vpn-instance-name*: Specifies an IPv4 MPLS L3VPN instance to which the IPv4 address belongs. The *ipv4-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the IPv4 address belongs to the public network, do not specify this option.

ipv6-destination-address: Specifies an IPv6 address.

ipv6-port-number: Specifies an IPv6 port number in the range of 1 to 65535.

vpn-instance *ipv6-vpn-instance-name*: Specifies an IPv6 MPLS L3VPN instance to which the IPv6 address belongs. The *ipv6-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the IPv6 address belongs to the public network, do not specify this option.

vrrp *virtual-router-id*: Binds the IPv6 server to a VRRP group on the IPv4 network. The *virtual-router-id* parameter represents the virtual router ID of the VRRP group, in the range of 1 to 255.

Usage guidelines

This command maps the IPv6 address and port number of an IPv6 server to an IPv4 address and port number.

In an HA hot backup network, execute this command on the primary device to bind an AFT IPv6 server to an HA-associated VRRP group on the IPv4 network. If you do not do so, ARP might fail to resolve an IPv6-mapped IPv4 address into a correct MAC address.

The AFT mappings for different IPv6 internal servers cannot be the same.

Examples

Map IPv6 address **3001::5** and port number **1720** of an IPv6 internal server to IPv4 address **2.2.2.123** and port number **1720** for TCP packets.

```
<Sysname> system-view
[Sysname] aft v6server protocol tcp 2.2.2.123 1720 3001::5 1720
```

Related commands

display aft configuration

aft v6tov4 source

Use **aft v6tov4 source** to configure an IPv6-to-IPv4 source address translation policy.

Use **undo aft v6tov4 source** to delete an IPv6-to-IPv4 source address translation policy.

Syntax

IPv6-to-IPv4 source address static mapping:

aft v6tov4 source *ipv6-address* [**vpn-instance** *ipv6-vpn-instance-name*] *ipv4-address* [**vpn-instance** *ipv4-vpn-instance-name*] [**vrrp** *virtual-router-id*]

undo aft v6tov4 source *ipv6-address* [**vpn-instance** *ipv6-vpn-instance-name*]

IPv6-to-IPv4 source address translation policy:

aft v6tov4 source { **acl ipv6** { **name** *ipv6-acl-name* | **number** *ipv6-acl-number* } | **prefix-nat64** *prefix-nat64 prefix-length* [**vpn-instance** *ipv6-vpn-instance-name*] } { **address-group** *group-id* [**no-pat** | **port-block-size** *blocksize*] | **interface** *interface-type interface-number* } [**vpn-instance** *ipv4-vpn-instance-name*]

undo aft v6tov4 source { **acl ipv6** { **name** *ipv6-acl-name* | **number** *ipv6-acl-number* } | **prefix-nat64** *prefix-nat64 prefix-length* [**vpn-instance** *ipv6-vpn-instance-name*] }

Default

No IPv6-to-IPv4 source address translation policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies an IPv6 address.

vpn-instance *ipv6-vpn-instance-name*: Specifies an IPv6 MPLS L3VPN instance to which the IPv6 address belongs. The *ipv6-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the IPv6 address belongs to the public network, do not specify this option.

ipv4-address: Specifies an IPv4 address.

vpn-instance *ipv4-vpn-instance-name*: Specifies an IPv4 MPLS L3VPN instance to which the IPv4 address belongs. The *ipv4-vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If the IPv4 address belongs to the public network, do not specify this option.

vrrp *virtual-router-id*: Binds the IPv6-to-IPv4 source address translation policy to a VRRP group on the IPv4 network. The *virtual-router-id* parameter represents the virtual router ID of the VRRP group, in the range of 1 to 255.

acl ipv6: Identifies IPv6 packets for address translation. AFT translates source addresses for IPv6 packets permitted by the ACL.

name *ipv6-acl-name*: Specifies an IPv6 ACL by its name. The *ipv6-acl-name* argument is a case-insensitive string of 1 to 63 characters. It must start with an English letter and to avoid confusion, it cannot be **all**.

number *ipv6-acl-number*: Specifies an IPv6 ACL by its number in the range of 2000 to 3999.

prefix-nat64 *prefix-nat64 prefix-length*: Specifies a NAT64 prefix and its prefix length. The *prefix-length* argument represents a prefix length, which can be 32, 40, 48, 56, 64, or 96. AFT translates source IPv6 addresses for packets whose destination IPv6 addresses match the NAT64 prefix.

address-group *group-id*: Specifies an AFT address group by its ID in the range of 0 to 65535.

no-pat: Specifies the NO-PAT mode. If you do not specify the keyword, AFT uses the PAT mode.

port-block-size *blocksize*: Specifies the port block size in the range of 100 to 64512. If you do not specify the option, the port range will not be divided.

interface *interface-type interface-number*: Specifies an interface by its type and number. AFT translates source IPv6 addresses to the primary IPv4 address of the specified interface.

Usage guidelines

If you set a port block size, the port range (1024 to 65535) will be divided into port blocks by the port block size. For example, if you set the port block size to 1000, the port range is divided into port blocks 1024 to 2023, 2024 to 3023, and so on. The port blocks are used for PAT.

The IPv4 or IPv6 addresses in different static mappings cannot be the same.

You must specify different ACLs, NAT64 prefixes, and AFT address groups for different IPv6-to-IPv4 source address translation policies.

You can specify a nonexistent NAT64 prefix in a policy, but the policy takes effect only after you configure the prefix.

In an HA hot backup network, execute this command on the primary device to bind an IPv6-to-IPv4 source address translation policy to an HA-associated VRRP group on the IPv4 network. If you do not do so, ARP might fail to resolve an IPv6-mapped IPv4 address into a correct MAC address.

An IPv6-to-IPv4 source address translation policy can be bound to only one VRRP group. You can execute this command multiple times to change the bound VRRP group for the policy.

Examples

Map source IPv6 address **3001::5** to source IPv4 address **2.2.2.123**.

```
<Sysname> system-view
[Sysname] aft v6tov4 source 3001::5 2.2.2.123
```

Configure the device to use AFT address group 0 to translate source addresses for IPv6 packets permitted by ACL 2000.

```
<Sysname> system-view
[Sysname] aft v6tov4 source acl ipv6 number 2000 address-group 0 port-block-size 100
```

context-operator

Parameters

group-id: Specifies an AFT address group ID in the range of 0 to 65535. If you do not specify this argument, the command displays information about all AFT address groups.

Examples

Display information about all AFT address groups.

```
<Sysname> display aft address-group
There are 3 AFT address groups.
Group ID   VRID   Start address         End address
1          ---    202.110.10.10         202.110.10.15
2          ---    202.110.10.20         202.110.10.25
                  202.110.10.30         202.110.10.35
6          ---    ---                   ---
```

Display information about AFT address group 1.

```
<Sysname> display aft address-group 1
Group ID   VRID   Start address         End address
1          ---    202.110.10.10         202.110.10.15
```

Table 1 Command output

Field	Description
There are *n* AFT address groups	Total number of existing AFT address groups.
Group ID	Address group ID.
VRID	Virtual router ID of a VRRP group. If no VRRP group is specified, this field displays three hyphens (---).
Start address	Start IP address of an address range. If you do not specify the start address, this field displays three hyphens (---).
End address	End IP address of an address range. If you do not specify the end address, this field displays three hyphens (---).

display aft address-mapping

Use **aft address-mapping** to display AFT mappings.

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays AFT mappings for all member devices.

Examples

Display AFT mappings.

```
<Sysname> display aft address-mapping
Slot 1:
IPv6: Source IP/port: 2000:0:FF01:101:100::8/1024
      Destination IP/port: 5000::1717:1714/1025
      VPN instance/VLAN ID/Inline ID: -/-/-
      Protocol: TCP(6)
IPv4: Source IP/port: 1.1.1.1/1031
      Destination IP/port: 23.23.23.20/1025
      VPN instance/VLAN ID/Inline ID: -/-/-
      Protocol: TCP(6)

Total address mappings found: 1
```

Table 2 Command output

Field	Description
IPv4	IPv4 address information.
IPv6	IPv6 address information.
Source IP/port	Source IP address and port number.
Destination IP/port	Destination IP address and port number.
VPN instance/VLAN ID/Inline ID	The fields identify the following information: • **VPN instance**—MPLS L3VPN instance to which the session belongs. • **VLAN ID**—VLAN to which the session belongs for Layer 2 forwarding. • **Inline ID**—Inline to which the session belongs for Layer 2 forwarding. If no VPN instance, VLAN ID, or Inline ID is specified, a hyphen (-) is displayed for the related field.
Protocol	Transport layer protocol type: **DCCP**, **ICMP**, **ICMPv6**, **Raw IP**, **SCTP**, **TCP**, **UDP**, or **UDP-Lite**.

display aft configuration

Usage guidelines

To view AFT configurations by using the **`display aft configuration`** command, you must execute commands to configure the configurations first except the AFT ALG configuration.

Examples

Display AFT configuration.

```
<Sysname> display aft configuration
<Sysname> display aft configuration
aft address-group 1
  address 202.110.10.10 202.110.10.15
  address 101.1.1.100 101.1.1.200

aft prefix-ivi 3000:DB8E::
```

```
aft prefix-general 2000:DB8E:: 32

aft v6tov4 source acl ipv6 number 2000 address-group 0 port-block-size 100

aft v4tov6 source acl number 2000 prefix-nat64 2000:: 32

aft v4tov6 destination acl number 2000 prefix-ivi 3000:DB8E::

aft v6server protocol tcp 2.2.2.123 1720 3001::5 1720

aft turn-off tos

aft turn-off traffic-class

aft log enable

aft log flow-begin

aft log flow-end

interface GigabitEthernet1/0/1
  aft enable

AFT ALG:
  DNS        : Enabled
  FTP        : Enabled
  HTTP       : Enabled
  ICMP-ERROR : Enabled
```

Table 3 Command output

Field	Description
aft address-group XX	AFT address group ID.
VRID	Virtual router ID (VRRP group number).
address	Address ranges in the AFT address group.
aft port-load-balance enable XX	AFT port halving is enabled. The XX is in **slot** *number* format, which represents the member ID of an IRF member device.
aft remote-backup port-alloc XX	The XX indicates the AFT port ranges used by the primary and secondary devices in the HA group. **primary**—The primary device uses the lower half of the port block, and the secondary device uses the higher half of the port block. **secondary**—The primary device uses the higher half of the port block, and the secondary device uses the lower half of the port block.
aft prefix-nat64 X:X::X:X	NAT64 prefix address.
aft prefix-ivi X:X::X:X	IVI prefix.
aft prefix-general X:X::X:X	General prefix.
aft v6tov4 source XX	IPv6-to-IPv4 source address translation policy. For more information,

	see the **aft v6tov4 source** command.
aft v4tov6 source XX	IPv4-to-IPv6 source address translation policy. For more information, see the **aft v4tov6 source** command.
aft v4tov6 destination XX	IPv4-to-IPv6 destination address translation policy. For more information, see the **aft v4tov6 destination** command.
aft v6server protocol	AFT mapping for the IPv6 internal server.
aft v4server	AFT mapping for an IPv4 internal server.
aft turn-off tos	Value of the ToS field in IPv4 packets translated from IPv6 packets.
aft turn-off traffic-class	Value of the Traffic Class field in IPv6 packets translated from IPv4 packets.
aft log enable	AFT logging is enabled.
aft log flow-begin	AFT session establishment logging is enabled.
aft log flow-end	AFT session removal logging is enabled.
interface XXX	AFT-enabled interface.
aft enable	AFT is enabled.
AFT ALG	AFT ALG status: • Enabled. • Disabled.

display aft no-pat

Use **display aft no-pat** to display AFT NO-PAT entries.

Syntax

display aft no-pat [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays AFT NO-PAT entries for all member devices.

Usage guidelines

An AFT NO-PAT entry records a mapping between an IPv4 address and an IPv6 address without ports.

Examples

Display AFT NO-PAT entries.

```
<Sysname> display aft no-pat
Slot 1:
```

```
IPv6 address: 3006::0002
IPv4 address: 200.100.1.100
IPv4 VPN    : vpn2
IPv6 VPN    : vpn1

IPv6 address: 4016::1102
IPv4 address: 202.120.12.110
IPv4 VPN    : vpn2
IPv6 VPN    : vpn1

Total entries found: 2
```

Table 4 Command output

Field	Description
IPv6 address	Original IPv6 address.
IPv4 address	Translated IPv4 address.
IPv4 VPN	VPN instance to which the translated IPv4 address belongs. If the IPv4 address does not belong to a VPN instance, this field is not displayed.
IPv6 VPN	VPN instance to which the original IPv6 address belongs. If the IPv6 address does not belong to a VPN instance, this field is not displayed.
Total entries found	Total number of AFT NO-PAT entries.

display aft port-block

Use **display aft port-block** to display AFT port block mappings.

Syntax

display aft port-block [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays AFT port block mappings for all member devices.

Examples

Display AFT port block mappings.

```
<Sysname> display aft port-block
Slot 1:
IPv6 address: 3006::0002
IPv4 address: 200.100.1.100
```

```
Port block  : [1024 – 1123]
IPv4 VPN    : vpn2
IPv6 VPN    : vpn1

IPv6 address: 4016::1102
IPv4 address: 202.120.12.110
Port block  : [1024 – 1200]
IPv4 VPN    : vpn2
IPv6 VPN    : vpn1

Total entries found: 2
```

Table 5 Command output

Field	Description
IPv6 address	Original IPv6 address.
IPv4 address	Translated IPv4 address.
Port block	Port range for the translated IPv4 address.
IPv4 VPN	VPN instance to which the translated IPv4 address belongs. If the IPv4 address does not belong to a VPN instance, this field is not displayed.
IPv6 VPN	VPN instance to which the original IPv6 address belongs. If the IPv6 address does not belong to a VPN instance, this field is not displayed.
Total entries found	Total number of AFT port block mapping entries.

display aft session

Use **display aft session** to display AFT sessions.

Syntax

display aft session ipv4 [{ **source-ip** *source-ip-address* | **destination-ip** *destination-ip-address* } * [**vpn-instance** *ipv4-vpn-instance-name*]] [**slot** *slot-number*] [**verbose**]

display aft session ipv6 [{ **source-ip** *source-ipv6-address* | **destination-ip** *destination-ipv6-address* } * [**vpn-instance** *ipv6-vpn-instance-name*]] [**slot** *slot-number*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ipv4: Displays IPv4 AFT sessions.

source-ip *source-ip-address*: Specifies the source IPv4 address of the packets that initiate AFT sessions.

destination-ip *destination-ip-address*: Specifies the destination IPv4 address of the packets that initiate AFT sessions.

vpn-instance *ipv4-vpn-instance-name*: Specifies an IPv4 MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays AFT sessions for the public network.

ipv6: Displays IPv6 AFT sessions.

source-ip *source-ipv6-address*: Specifies the source IPv6 address of the packets that initiate AFT sessions.

destination-ip *destination-ipv6-address*: Specifies the destination IPv6 address of the packets that initiate AFT sessions.

vpn-instance *ipv6-vpn-instance-name*: Specifies an IPv6 MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays AFT sessions for the public network.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays AFT sessions for all member devices.

verbose: Display detailed information about AFT sessions. If you do not specify this keyword, this command displays brief information about AFT sessions.

Usage guidelines

If you do not specify any parameters, this command displays all AFT sessions.

Examples

Display detailed information about AFT sessions for the specified slot.

```
<Sysname> display aft session ipv4 slot 1 verbose
Slot 1:
Initiator:
  Source      IP/port: 10.1.1.1/217
  Destination IP/port: 20.1.1.1/2048
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: ICMP(1)
  Inbound interface: GigabitEthernet1/0/1
  Source security zone: Trust
Responder:
  Source      IP/port: 20.1.1.1/217
  Destination IP/port: 10.1.1.1/0
  DS-Lite tunnel peer: -
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: ICMP(1)
  Inbound interface: GigabitEthernet1/0/2
  Source security zone: Local
State: ICMP_REPLY
Application: ICMP
Rule ID: -/-/-
Rule name:
Start time: 2022-07-18 09:42:38  TTL: 28s
Initiator->Responder:            0 packets          0 bytes
```

```
Responder->Initiator:            0 packets          0 bytes
Total sessions found: 1
```

Table 6 Command output

Field	Description
Initiator	Session information about the initiator.
Source IP/port	Source IP address and port number.
Destination IP/port	Destination IP address and port number.
VPN instance/VLAN ID/Inline ID	The fields identify the following information: • **VPN instance**—MPLS L3VPN instance to which the session belongs. • **VLAN ID**—VLAN to which the session belongs for Layer 2 forwarding. • **Inline ID**—Inline to which the session belongs for Layer 2 forwarding. If no VPN instance, VLAN ID, or Inline ID is specified, a hyphen (-) is displayed for the related field.
Protocol	Transport layer protocol type: **DCCP**, **ICMP**, **ICMPv6**, **Raw IP**, **SCTP**, **TCP**, **UDP**, or **UDP-Lite**.
Inbound interface	Input interface.
Responder	Session information about the responder.
Source security zone	Security zone of the incoming interface.
State	AFT session state.
Application	Application layer protocol, such as **FTP** and **DNS**. This field displays **unknown** for the protocol types that are identified by non-well-known ports and are not user-defined.
Rule ID	ID of the security policy rule.
Rule name	Name of the security policy rule.
Start time	Time when the session starts.
TTL	Remaining lifetime of the session, in seconds.
Initiator->Responder	Number of packets and bytes from the initiator to the responder.
Responder->Initiator	Number of packets and bytes from the responder to the initiator.
Total sessions found	Total number of AFT sessions.

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays AFT statistics for all member devices.

Usage guidelines

If you do not specify any parameters, this command displays all AFT statistics.

Examples

Display all AFT statistics.

```
<Sysname> display aft statistics
Total NO-PAT entries found: 0
Total port-block entries found: 0
Total IPv4 sessions: 0
Total IPv6 sessions: 0
Dropped packets: 3006
  Configuration sequence changed: 0
  Failed to transfer payload: 0
  Failed to transfer packet header: 0
  Packet examination failed before packet sending: 0
  Failed to translate destination address: 0
  The translated destination address is invalid: 0
  Failed to translate source address: 0
  Failed to transfer FSBUF to MBUF: 0
  Session ext-info is null: 0
  Peer session is null: 0
  Failed to get translation information from session: 0
  Failed to create session: 0
  Failed to fragment the MBUF: 0
  Failed to create fast forwarding table: 0
  Failed to formalize session: 0
  Other reasons: 0
```

Table 7 Command output

Field	Description
Total NO-PAT entries found	Total number of AFT NO-PAT entries.
Total port-block entries found	Total number of AFT port block mappings.
Total IPv4 sessions	Total number of AFT IPv4 sessions.
Total IPv6 sessions	Total number of AFT IPv6 sessions.
Dropped packets	Number of packets dropped by AFT.
Configuration sequence changed	Number of packets dropped due to configuration sequence changes.

Field	Description
Failed to transfer payload	Number of packets dropped due to ALG failures.
Failed to transfer packet header	Number of packets dropped due to packet header transformation failures.
Packet examination failed before packet sending	Number of packets dropped due to packet examination failures before packet sending.
Failed to translate destination address	Number of packets dropped due to destination address translation failures.
The translated destination address is invalid	Number of packets dropped due to the invalidity of the translated destination address.
Failed to translate source address	Number of packets dropped due to source address translation failures.
Failed to transfer FSBUF to MBUF	Number of packets dropped due to FSBUF-to-MBUF transformation failures.
Session ext-info is null	Number of packets dropped due to session extended information acquisition failures.
Peer session is null	Number of packets dropped due to peer session lookup failures.
Failed to get translation information from session	Number of packets dropped due to translation information acquisition failures from sessions.
Failed to create session	Number of packets dropped due to session creation failures.
Failed to fragment the MBUF	Number of packets dropped due to fragmentation failures.
Failed to create fast forwarding table	Number of packets dropped due to fast forwarding table creation failures.
Failed to formalize session	Number of packets dropped due to session formalization failures.
Other reasons	Number of packets dropped due to other reasons.

Related commands

`reset aft statistics`

reset aft session

Use **`reset aft session`** to clear AFT sessions.

Syntax

`reset aft session` [**`slot`** *`slot-number`*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

`slot` *`slot-number`*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command clears AFT sessions for all member devices.

Usage guidelines

After you clear AFT sessions, the corresponding AFT NO-PAT entries and port block mappings are also cleared.

Examples

Clear all AFT sessions.

```
<Sysname> reset aft session
```

Related commands

display aft session

reset aft statistics

Use **reset aft** statistics to clear AFT statistics.

Syntax

reset aft statistics [**slot** *slot-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command clears AFT statistics for all member devices.

Usage guidelines

The AFT statistics include the number of dropped packets, the number of NO-PAT entries, and the number of port block entries. This command only resets the counter for dropped packets.

Examples

Clear all AFT statistics.

```
<Sysname> reset aft statistics
```

Related commands

display aft statistics

vrrp vrid

Use **vrrp vrid** to bind a VRRP group to an AFT address group.

Use **undo vrrp vrid** to restore the default.

Syntax

vrrp vrid *virtual-router-id*

undo vrrp vrid

Default

An AFT address group is not bound to any VRRP group.

Views

AFT address group view

Predefined user roles

network-admin

context-admin

Parameters

virtual-router-id: Specifies a VRRP group by its virtual router ID in the range of 1 to 255.

Usage guidelines

On an HA network, the virtual IP address of the VRRP group might be on the same subnet as the public IP addresses in the AFT address group. In this case, both of the HA group members might reply to ARP requests for MAC addresses corresponding to these public IP addresses. As a result, MAC addresses in ARP replies and ARP entries on the Layer 3 devices connected to the HA group might be incorrect. To avoid this situation, execute this command to force the master device to use the virtual MAC address of VRRP group in ARP replies. For more information about configuring the HA group, see *High Availability Configuration Guide*.

For active/standby HA, execute this command on the primary device in the HA group.

For dual-active HA, select one of the following methods for VRRP group binding according to the AFT resource allocation between the two devices in the HA group:

- If the two devices share the same AFT address group, execute the **vrrp vrid** command on the primary device. To prevent different master devices from using the same IP-port mapping for different hosts, specify the PAT translation mode and execute the **aft remote-backup port-alloc** command on the primary device.
- If the two devices use different AFT address groups, user traffic with different source IPv6 addresses is identified by ACLs in AFT rules. To enable different master devices to translate the forward user traffic, specify different gateway addresses for different internal users. To direct the reverse traffic to different master devices, bind AFT address groups to different VRRP groups on the primary device.

If you execute the **vrrp vrid** command multiple times, the most recent configuration takes effect.

Examples

Bind VRRP group **1** to AFT address group **2**.

```
<Sysname> system-view
[Sysname] aft address-group 2
[Sysname-aft-address-group-2] vrrp vrid 1
```

Related commands

display aft address-group

NSFOCUS Firewall Series

NF VPN Command Reference

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

This command reference describes the commands for configuring VPN features, including:SSL VPN, IPsec, tunneling, GRE, L2TP, and ADVPN.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

SSL VPN commands

aaa domain

Use **aaa domain** to specify an ISP domain for authentication, authorization, and accounting of SSL VPN users in an SSL VPN context.

Use **undo aaa domain** to restore the default.

Syntax

aaa domain *domain-name*

undo aaa domain

Default

The default ISP domain is used for authentication, authorization, and accounting of SSL VPN users in an SSL VPN context.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies the ISP domain name, a case-insensitive string of 1 to 255 characters. The name must meet the following requirements:

- The name cannot contain a forward slash (/), backslash (\), vertical bar (|), quotation marks ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).
- The name cannot be **d**, **de**, **def**, **defa**, **defau**, **defaul**, **default**, **i**, **if**, **if-**, **if-u**, **if-un**, **if-unk**, **if-unkn**, **if-unkno, if-unknow**, or **if-unknown**.

Usage guidelines

An SSL VPN username cannot carry ISP domain information. After this command is executed, an SSL VPN gateway uses the specified ISP domain for authentication, authorization, and accounting of SSL VPN users in the context.

Examples

Specify ISP domain **myserver** for authentication, authorization, and accounting of SSL VPN users in SSL VPN context **ctx1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] aaa domain myserver
```

authentication server-type

Use **authentication server-type** to specify the authentication server type.

Use **undo authentication server-type** to restore the default.

Syntax

authentication server-type { **aaa** | **custom** }

undo authentication server-type

Default

The SSL VPN authentication server is an AAA authentication server.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

aaa: Specifies the AAA authentication server.

custom: Specifies the custom authentication server.

Usage guidelines

If you use a custom authentication server, you must also configure custom authentication settings, such as the URL of the custom authentication server and custom authentication HTTP request and response settings.

If you use an AAA authentication server, you must configure the AAA server. For more information about AAA server configuration, see *Security Configuration Guide*.

Examples

Specify the authentication server type as custom authentication server in SSL VPN context **ctx1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] authentication server-type custom
```

Related commands

custom-authentication request-method

custom-authentication request-template

custom-authentication response-custom-template

custom-authentication response-field

custom-authentication response-format

custom-authentication response-success-value

custom-authentication timeout

custom-authentication url

authentication use

Use **authentication use** to specify the authentication methods required for user login.

Use **undo authentication use** to restore the default.

Syntax

authentication use { **all** | **any-one** }

undo authentication use

Default

To log in to an SSL VPN context, a user must pass all the authentication methods enabled for the context.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

all: Uses all enabled authentication methods.

any-one: Uses any enabled authentication method.

Usage guidelines

You can enable username/password authentication, certificate authentication, or both for an SSL VPN context. The authentication methods required for logging in to the SSL VPN context depend on the configuration of this command:

- If the **authentication use all** command is configured, a user must pass all the enabled authentication methods for login.
- If the **authentication use any-one** command is configured, a user can log in after passing any enabled authentication method.

Examples

Configure SSL VPN context **ctx** to allow users to log in after passing any enabled authentication method.

```
<Sysname> system-view
[Sysname] sslvpn context ctx
[Sysname-sslvpn-context-ctx] authentication use any-one
```

Related commands

certificate-authentication enable

display sslvpn context

password-authentication enable

bandwidth

Use **bandwidth** to set the expected bandwidth for an interface.

Use **undo bandwidth** to restore the default.

Syntax

bandwidth *bandwidth-value*

undo bandwidth

Default

The expected bandwidth is 64 kbps for an interface.

Views

SSL VPN AC interface view

Predefined user roles

network-admin

context-admin

Parameters

bandwidth-value: Specifies the expected bandwidth in the range of 1 to 400000000 kbps.

Usage guidelines

The expected bandwidth for an interface affects CBQ bandwidth and link costs in OSPF, OSPFv3, and IS-IS. For more information about CBQ bandwidth, see QoS configuration in *ACL and QoS Configuration Guide*. For more information about link costs, see *Layer 3—IP Routing Configuration Guide*.

Examples

Set the expected bandwidth to 10000 kbps for SSL VPN AC 1000.

```
<Sysname> system-view
[Sysname] interface sslvpn-ac 1000
[Sysname-SSLVPN-AC1000] bandwidth 10000
```

certificate username-attribute

Use **certificate username-attribute** to specify the certificate attribute as the SSL VPN username.

Use **undo certificate username-attribute** to restore the default.

Syntax

certificate username-attribute { **cn** | **email-prefix** | **oid** *extern-id* }

undo certificate username-attribute

Default

The device uses the value of the CN attribute in the subject of the user certificate as the SSL VPN username.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

cn: Specifies the CN attribute value in the subject of the user certificate as the SSL VPN username.

email-prefix: Specifies the string before the at sign (@) of the email address in the subject of the user certificate as the SSL VPN username.

oid *extern-id*: Specifies a user certificate attribute by its OID. The value of the attribute will be used as the SSL VPN username. The *extern-id* argument represents the OID, which is an object identifier in dotted decimal notation.

Usage guidelines

The SSL VPN username specified by this command takes effect only after you execute the **certificate-authentication enable** command.

Examples

Use the value of the attribute whose OID is 1.1.1.1 in the user certificate as the SSL VPN username.

```
<Sysname> system-view
[Sysname] sslvpn context ctx
[Sysname-sslvpn-context-ctx] certificate username-attribute oid 1.1.1.1
```

Related commands

certificate-authentication enable

certificate-authentication enable

Use **certificate-authentication enable** to enable certificate authentication.

Use **undo certificate-authentication enable** to disable certificate authentication.

Syntax

certificate-authentication enable

undo certificate-authentication enable

Default

Certificate authentication is disabled.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Usage guidelines

After you enable certificate authentication, you must also execute the **client-verify** command in SSL server policy view. The SSL VPN gateway uses the digital certificate sent by an SSL VPN client to authenticate the client's identity. If the client's username and the username in the digital certificate are not the same, the client cannot log in to the SSL VPN gateway.

Examples

Enable certificate authentication.

```
<Sysname> system-view
[Sysname] sslvpn context ctx
[Sysname-sslvpn-context-ctx] certificate-authentication enable
```

Related commands

client-verify enable

client-verify optional

content-type

Use **content-type** to configure a file policy to rewrite a file in an HTTP response to a specific type of file.

Use **undo content-type** to restore the default.

Syntax

content-type { **css** | **html** | **javascript** | **other** }

undo content-type

Default

A file policy rewrites a file carried in an HTTP response to a file of the type indicated by the content-type field in the HTTP response.

Views

File policy view

Predefined user roles

network-admin

context-admin

Parameters

css: Changes the file type to CSS.

html: Changes the file type to HTML.

javascript: Changes the file type to JavaScript.

other: Does not change the file type.

Usage guidelines

A file policy rewrites a file carried in an HTTP response to a file of the type specified by this command. If the specified file type is different from that indicated by the content-type field in the HTTP response, users might not be able to read the file correctly.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure file policy **fp** to rewrite files to HTML files.

```
<Sysname> system-view
[Sysname] sslvpn context ctx
[Sysname-sslvpn-context-ctx] file-policy fp
[Sysname-sslvpn-context-ctx-file-policy-fp] content-type html
```

country code

Use **country-code** to specify the mobile country code.

Use **undo country-code** to restore the default.

Syntax

country-code *country-code*

undo country-code

Default

The country code is 86.

Views

SMS gateway authentication view

Predefined user roles

network-admin

context-admin

Parameters

country-code: Specifies the country code, a string of 1 to 7 characters. Only digits are supported.

Examples

Set the country code to 86 in SMS gateway authentication view.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] sms-auth sms-gw
[Sysname-sslvpn-context-ctx1-sms-auth-sms-gw] country-code 86
```

custom-authentication request-header-field

Use **custom-authentication request-header-field** to configure an HTTP request header field for custom authentication.

Use **undo custom-authentication request-header-field** to remove the configuration of an HTTP request header field for custom authentication.

Syntax

custom-authentication request-header-field *field-name* **value** *value*

undo custom-authentication request-header-field *field-name*

Default

A custom authentication request header includes the following fields:

- **Content-type:application/x-www-form-urlencoded**.
- **User-Agent:nodejs 4.1**.
- **Accept:text/html,application/xhtml+xml,application/xml;q=0.9,image/webp,*/*;q**.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

field-name: Specifies a request header field name, a case-insensitive string of 1 to 63 characters. The name cannot include the following characters:

- ()<>@,;:\"/[]?={}
- Spaces.
- Horizontal tabs.

- ASCII characters with codes ≤ 31 or ≥ 127.

value *value*: Specifies the value of the request header field, a string of 1 to 255 characters, which cannot contain question mark (?) metacharacters.

Usage guidelines

Use this command to configure HTTP request header fields sent to the custom authentication server. Perform this configuration after the custom authentication server is specified by using the **authentication server-type custom** command. To have the configuration take effect, you must also configure other custom authentication request settings, such as the HTTP request method and the request template.

Execute this command multiple times to configure multiple HTTP request header fields. For the same field, the most recent configuration takes effect.

Examples

Specify the **host** field as 192.168.56.2:8080 in the HTTP request header for custom authentication in SSL VPN context **ctx1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] custom-authentication request-header-field host value
192.168.56.2:8080
```

Related commands

authentication server-type

custom-authentication request-method

custom-authentication request-template

custom-authentication url

custom-authentication request-method

Use **custom-authentication request-method** to configure the HTTP request method for custom authentication.

Use **undo custom-authentication request-method** to restore the default.

Syntax

custom-authentication request-method { **get** | **post** }

undo custom-authentication request-method

Default

The HTTP request method is GET.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

get: Specifies the GET method.

post: Specifies the POST method.

Usage guidelines

Use this command to configure the HTTP request method for authentication requests sent to the custom authentication server. Perform this configuration after the custom authentication server is specified by using the **authentication server-type custom** command. To have the configuration take effect, you must also configure other custom authentication request settings, such as the HTTP request header fields and the request template.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the POST request method for custom authentication in SSL VPN context **ctx1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] custom-authentication request-method post
```

Related commands

authentication server-type

custom-authentication request-template

custom-authentication url

custom-authentication request-template

Use **custom-authentication request-template** to configure the request template for custom authentication.

Use **undo custom-authentication request-template** to restore the default.

Syntax

custom-authentication request-template *template*

undo custom-authentication request-template

Default

No request template is configured for custom authentication.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

template: Specifies the request template through which the SSL VPN gateway sends username and password information to the custom authentication server. The template is a case-insensitive string of 1 to 255 characters.

Usage guidelines

Use this command to configure the HTTP request template through which the SSL VPN gateway sends the username and password to the custom authentication server. Perform this configuration after the custom authentication server is specified by the **authentication server-type custom** command. To have the configuration take effect, you must also configure other custom authentication request settings, such as the HTTP request header fields and the request method.

If you execute this command multiple times, the most recent configuration takes effect.

This command supports the following request template formats:

- Form format for the POST and GET methods: username=$$USERNAME$$&password=$$PASSWORD_MD5$$&resid=1234.
- JSON type for the POST method: {“name”:”$$USERNAME$$”,“password”:”,$$PASSWORD$$”,“resid”:”1234”}.
- XML type for the GET method: <uname>$$USERNAME$$</uname><psw>$$PASSWORD$$</psw>.

The **USERNAME**, **PASSWORD**, and **PASSWORD_MD5** between $$ pairs in the request templates are variables. The **PASSWORD_MD5** represents a password encrypted by MD5. When a user logs in to the SSL VPN gateway, the gateway replaces these variables with the login username and password. Then, the SSL VPN gateway sends the authentication request to the custom authentication server.

Examples

Configure the custom authentication HTTP request template as **username=$$USERNAME$$&password=$$PASSWORD_MD5$$&resid=1952252223973828** in SSL VPN context **ctx1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] custom-authentication request-template
username=$$USERNAME$$&password=$$PASSWORD_MD5$$&resid=1952252223973828
```

Related commands

authentication server-type

custom-authentication request-template

custom-authentication url

custom-authentication response-custom-template

Use **custom-authentication response-custom-template** to configure response templates for the fields in the HTTP response for custom authentication.

Use **undo custom-authentication response-custom-template** to restore the default.

Syntax

custom-authentication response-custom-template { **group** | **message** | **result** } *template*

undo custom-authentication response-custom-template { **group** | **message** | **result** }

Default

No response templates are configured for custom authentication.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

group: Specifies the group field in the authentication response.

message: Specifies the message field in the authentication response.

result: Specifies the result field in the authentication response.

template: Specifies the content of the response template for the specified field. The template is a case-insensitive string of 1 to 63 characters.

Usage guidelines

Use this command to configure the response templates for the device to identify the fields in a custom-format authentication response. Perform this configuration after the custom authentication server is specified by using the **authentication server-type custom** command. This configuration is applicable when the HTTP response format is **custom**. When you configure response templates, the response template for the result field is required.

When you configure a response template for a field, follow these restrictions and guidelines:

- A response template for a field must contain **$$value$$**.
  - The **value** keyword represents the field value in the response.
  - The pairs of dollar signs ($$) are used to identify the start and end of the field in a response. The device considers the content before the first $$ the start identifier and that after the second $$ the end identifier for parsing the field of the response.
- Make sure the contents before and after **$$value$$** in the response template are consistent with those before and after the field value in the response from the authentication server.

Here is an example. Assume that the result field information in the response from the authentication server is **auth-result=true,**. You must configure the response template for the result field as **auth-result=$$value$$,**. The contents before and after **$$value$$** are **auth-result=** and a comma (,), which are the same as those before and after **true**, respectively. Then, the device can use the **auth-result=$$value$$,** template to correctly identify and parse the result field in the authentication response.

Examples

Configure the response templates in SSL VPN context **ctx1** as **result=$$value$$,company=$$value$$,message=$$value$$**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] custom-authentication response-custom-template result
result=$$value$$,
[Sysname-sslvpn-context-ctx1] custom-authentication response-custom-template group
company=$$value$$,
[Sysname-sslvpn-context-ctx1] custom-authentication response-custom-template message
message=$$value$$
```

Related commands

authentication server-type

custom-authentication response-format

custom-authentication response-success-value

custom-authentication response-field

Use **custom-authentication response-field** to configure a field name in the HTTP response for custom authentication.

Use **undo custom-authentication response-field** to restore the default.

Syntax

custom-authentication response-field { **group** *group* | **message** *message* | **result** *result* }

undo custom-authentication response-field { **group** | **message** | **result** }

Default

No HTTP response field names are configured.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

group *group*: Specifies the name of the policy group field in the HTTP response, a case-insensitive string of 1 to 31 characters. In the authentication response, the value following the *group* argument represents the policy groups authorized to the user.

message *message*: Specifies the name of the message field in the HTTP response, a case-insensitive string of 1 to 31 characters. In the authentication response, the value following the *message* argument represents the authentication prompt.

result *result*: Specifies the name of the result field in the HTTP response, a case-insensitive string of 1 to 31 characters. In the authentication response, the value following the *message* argument represents the authentication result.

Usage guidelines

Use this command to configure the names of the fields in the HTTP response. Perform this configuration after the custom authentication server is specified by using the **authentication server-type custom** command. This configuration is applicable when the HTTP response format is JSON or XML. When you configure HTTP response field names, the result field name is required.

The device uses the configured field names to parse the HTTP response returned from the custom authentication server, as follows:

- If you specify the policy field name, the SSL VPN gateway uses the specified name to identify the policy group field in the response. For example, if the policy group field name is specified as **company**, the device uses the value following **company** in the response as the server-authorized policy group.

  The policy group finally assigned to the user is determined as follows:

  - If the SSL VPN context has the server-authorized policy group configured, the gateway assigns the authorized policy group to the user.
  - If the SSL VPN context has no policy groups, or the server does not authorize a policy group, the gateway assigned the default policy to the user.
- If you specify the message field name, the SSL VPN gateway uses the specified name to identify the authentication result message in the response. The message indicates the authentication result, such as authentication success or failure.
- If you specify the result field name, the SSL VPN gateway uses the specified name to identify the authentication result value in the response. The gateway then determines the authentication result based on the configured authentication success value (see the **custom-authentication response-success-value** command).

If you execute this command multiple times for a field, the most recent configuration takes effect.

Examples

Specify the group field name as **company** and the message field name as **resultDescription** in the custom authentication response for SSL VPN context **ctx1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] custom-authentication response-field group company
[Sysname-sslvpn-context-ctx1] custom-authentication response-field message
resultDescription
```

Related commands

authentication server-type

custom-authentication response-format

Use **custom-authentication response-format** to specify the HTTP response format for custom authentication.

Use **undo custom-authentication response-format** to restore the default.

Syntax

custom-authentication response-format { **custom** | **json** | **xml** }

undo custom-authentication response-format

Default

The HTTP response format for custom authentication is JSON.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

custom: Specifies the XML format.

json: Specifies the JSON format.

xml: Specifies the custom response format.

Usage guidelines

Use this command to configure the HTTP response format for custom authentication after the custom authentication server is specified by using the **authentication server-type custom** command. After you specify the HTTP response format, you must also configure corresponding HTTP response settings (such as the HTTP response templates and field names) for the specified format.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the HTTP response format as **JSON** in SSL VPN context **ctx1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] custom-authentication response-format json
```

Related commands

authentication server-type

custom-authentication response-custom-template

custom-authentication response-success-value

Use **custom-authentication response-success-value** to configure the authentication success value in the HTTP response for custom authentication.

Use **undo custom-authentication response-success-value** to restore the default.

Syntax

custom-authentication response-success-value *success-value*

undo custom-authentication response-success-value

Default

No authentication success value is configured for custom authentication.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

success-value: Specifies the value that represents the authentication success result, a case-insensitive string of 1 to 31 characters.

Usage guidelines

Use this command to configure the authentication success value in the HTTP response. Perform this configuration after the custom authentication server is specified by using the **authentication server-type custom** command. To have the configuration take effect, you must also configure other custom authentication settings, such as specifying the result field name in the HTTP response.

The SSL VPN gateway considers the user authentication successful only when the value of the result field in the custom authentication response is the value specified by this command.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the authentication success value as **true** in the custom authentication response for SSL VPN context **ctx1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] custom-authentication response-success-value true
```

Related commands

authentication server-type

custom-authentication response-field

custom-authentication timeout

Use **custom-authentication timeout** to specify the custom authentication timeout.

Use **undo custom-authentication timeout** to restore the default.

Syntax

custom-authentication timeout *seconds*

undo custom-authentication timeout

Default

The custom authentication timeout is 15 seconds.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the custom authentication timeout, in the range of 5 to 50 seconds.

Usage guidelines

After sending an HTTP request to the custom authentication server, the SSL VPN gateway waits for responses from the server. If the gateway receives no response within the authentication timeout, it returns an authentication failure message to the SSL VPN client.

Examples

Specify the custom authentication timeout as 20 seconds in SSL VPN context **ctx1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] custom-authentication timeout 20
```

Related commands

authentication server-type

custom-authentication url

Use **custom-authentication url** to configure the URL of the custom authentication server.

Use **undo custom-authentication url** to restore the default.

Syntax

custom-authentication url *url*

undo custom-authentication url

Default

No URL is configured for the custom authentication server.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

url: Specifies the URL of the authentication server in an HTTP request sent by the SSL VPN gateway to the custom authentication server. The URL is a case-insensitive string of 1 to 255 characters, and it cannot contain question mark (?) metacharacters.

Usage guidelines

Use this command to configure the URL of the custom authentication server after the custom authentication server is specified by the **authentication server-type custom** command. To have the configuration take effect, you must also configure other custom authentication settings, such as the HTTP request header fields, request method, and request template.

A URL consists of the protocol type, host name or address, port number, and resource path. The complete URL format is *protocol type*://*host name or address*:*port number/resource path*. The protocol type currently supports only HTTP and HTTPS. If not specified, the protocol type is HTTP by default. If the URL contains an IPv6 address, enclose the IPv6 address in brackets, for example, http://[1234::5678]:8080.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure the URL of the custom authentication server in SSL VPN context **ctx1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] custom-authentication url
http://192.168.56.2:8080/register/user/checkUserAndPwd
```

context-admin

Usage guidelines

CAUTION:

The **default** command might interrupt ongoing network services. Make sure you are fully aware of the impact of this command when you use it on a live network.

This command might fail to restore the default settings for some commands for reasons such as command dependencies or system restrictions. Use the **display this** command in interface view to identify these commands. Use their **undo** forms or follow the command reference to restore their

default settings. If your restoration attempt still fails, follow the error message instructions to resolve the problem.

Examples

Restore the default settings of **sslvpn-ac 1000**.

```
<Sysname> system-view
[Sysname] interface sslvpn-ac 1000
[Sysname-SSLVPN-AC1000] default
This command will restore the default settings. Continue? [Y/N]:y
```

default-policy-group

Use **default-policy-group** to specify a policy group as the default policy group.

Use **undo default-policy-group** to restore the default.

Syntax

default-policy-group *group-name*

undo default-policy-group

Default

No policy group is specified as the default policy group.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a policy group by its name, a case-insensitive string of 1 to 31 characters. The specified policy group must have been created.

Usage guidelines

You can configure multiple policy groups for an SSL VPN context. When a remote user accesses the SSL VPN context, the AAA server issues the authorized policy group to the associated SSL VPN gateway. The user can access only the resources allowed by the authorized policy group. If the AAA server does not issue an authorized policy group to the user, the user can access only the resources allowed by the default policy group.

Examples

Specify policy group **pg1** as the default policy group.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] policy-group pg1
[Sysname-sslvpn-context-ctx1-policy-group-pg1] quit
[Sysname-sslvpn-context-ctx1] default-policy-group pg1
```

Related commands

display sslvpn context

policy-group

description (shortcut view)

Use **description** to configure a description for a shortcut.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

No description is configured for a shortcut.

Views

Shortcut view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 63 characters.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure a description for shortcut **shortcut1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] shortcut shortcut1
[Sysname-sslvpn-context-ctx1-shortcut-shortcut1] description shortcut1
```

description (SSL VPN AC interface view)

Use **description** to configure the description of an interface.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

The description of an interface is *interface name* **Interface**, for example, **SSLVPN-AC1000 Interface**.

Views

SSL VPN AC interface view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 255 characters.

Usage guidelines

Configure descriptions for interfaces for identification and management purposes.

You can use the **display interface** command to display the configured interface descriptions.

Examples

Configure a description of **SSL VPN A** for SSL VPN AC 1000.

```
<Sysname> system-view
[Sysname] interface sslvpn-ac 1000
[Sysname-SSLVPN-AC1000] description SSL VPN A
```

display interface sslvpn-ac

Use **display interface sslvpn-ac** to display SSL VPN AC interface information.

Syntax

display interface [**sslvpn-ac** [*interface-number*]] [**brief** [**description** | **down**]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

sslvpn-ac [*interface-number*]: Specifies an SSL VPN AC interface by its number in the range of 0 to 4095. If you do not specify the **sslvpn-ac** keyword, this command displays information about all interfaces except virtual access (VA) interfaces. If you specify the **sslvpn-ac** keyword without the *interface-number* argument, this command displays information about all SSL VPN AC interfaces. For more information about VA interfaces, see PPP configuration in *Layer 2—WAN Access Configuration Guide*.

brief: Displays brief interface information. If you do not specify this keyword, the command displays detailed interface information.

description: Displays complete interface descriptions. If you do not specify this keyword, the command displays only the first 27 characters of interface descriptions.

down: Displays information about interfaces in the physical state of DOWN and the causes. If you do not specify this keyword, the command displays information about interfaces in all states.

Examples

Display detailed information about SSL VPN AC 1000.

```
<Sysname> display interface sslvpn-ac 1000
SSLVPN-AC1000
Current state: UP
Line protocol state: DOWN
```

```
Description: SSLVPN-AC1000 Interface
Bandwidth: 64kbps
Maximum transmission unit: 1500
Internet protocol processing: Disabled
Link layer protocol is SSLVPN
Last clearing of counters: Never
Last 300 seconds input rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Last 300 seconds output rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Input: 0 packets, 0 bytes, 0 drops
Output: 0 packets, 0 bytes, 0 drops
```

Table 1 Command output

Field	Description
SSLVPN-AC1000	Information about interface SSL VPN AC 1000.
Current state	Physical link state of the interface: • **Administratively DOWN**—The interface has been shut down by using the **shutdown** command. • **DOWN**—The interface is administratively up, but its physical state is down (possibly because no physical link exists or the link has failed). • **UP**—The interface is both administratively and physically up.
Line protocol state	Data link layer state of the interface. The state is determined through automatic parameter negotiation at the data link layer. • **UP**—The data link layer protocol is up. • **UP (spoofing)**—The data link layer protocol is up, but the link is an on-demand link or does not exist. This attribute is typical of null interfaces and loopback interfaces. • **DOWN**—The data link layer protocol is down.
Description	Description of the interface.
Bandwidth	Expected bandwidth of the interface.
Maximum transmission unit	MTU of the interface.
Internet protocol processing: Disabled	The interface is not assigned an IP address and cannot process IP packets.
Internet address: *ip-address*/*mask-length* (*Type*)	IP address of the interface and type of the address in parentheses. Possible IP address types include: **Primary**—Manually configured primary IP address.
Last clearing of counters	Most recent time the counters were cleared by using the **reset counters interface** command. If the **reset counters interface** command has never been executed since the device starts up, this field displays **Never**.
Last 300 seconds input rate	Average input rate in the last 300 seconds.
Last 300 seconds output rate	Average output rate in the last 300 seconds.

Display brief information about all SSL VPN AC interfaces.

```
<Sysname> display interface sslvpn-ac brief
Brief information of interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Protocol: (s) - spoofing
```

```
Interface            Link Protocol Primary IP         Description
SSLVPN-AC1000        UP   DOWN     --
```

Display brief information about SSL VPN AC 1000, including the complete interface description.

```
<Sysname> display interface sslvpn-ac 1000 brief description
Brief information of interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Protocol: (s) - spoofing
Interface            Link Protocol Primary IP         Description
SSLVPN-AC1000        UP    UP      1.1.1.1            SSLVPN-AC1000 Interface
```

Display information about interfaces in DOWN state and the causes.

```
<Sysname> display interface sslvpn-ac brief down
Brief information of interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Interface            Link Cause
SSLVPN-AC1000        ADM
SSLVPN-AC1001        ADM
```

Table 2 Command output

Field	Description
Brief information of interfaces in route mode:	Brief information about Layer 3 interfaces.
Interface	Abbreviated interface name.
Link	Physical link state of the interface: • **UP**—The interface is physically up. • **DOWN**—The interface is physically down. • **ADM**—The interface has been shut down by using the **shutdown** command. To restore the physical state of the interface, use the **undo shutdown** command. • **Stby**—The interface is a backup interface in standby state.
Protocol	Data link layer protocol state of the interface: • **UP**—The data link layer protocol of the interface is up. • **UP(s)**—The data link layer protocol of the interface is up, but the link is an on-demand link or does not exist. The **(s)** attribute represents the spoofing flag. This value is typical of null interfaces and loopback interfaces. • **DOWN**—The data link layer protocol of the interface is down.
Primary IP	Primary IP address of the interface.
Description	Description of the interface.
Cause	Cause for the physical link state of an interface to be **DOWN**: • **Administratively**—The interface has been manually shut down by using the **shutdown** command. To restore the physical state of the interface, use the **undo shutdown** command. • **Not connected**—No physical connection exists (possibly because the network cable is disconnected or faulty).

display sslvpn context

Use **display sslvpn context** to display SSL VPN context information.

Syntax

display sslvpn context [**brief** | **name** *context-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

brief: Displays brief SSL VPN context information. If you do not specify this keyword, the command displays detailed SSL VPN context information.

name *context-name*: Specifies an SSL VPN context by its name. An SSL VPN context name is a case-insensitive string of 1 to 31 characters, and can contain only letters, digits, and underscores (_). If you do not specify an SSL VPN context, this command displays information about all SSL VPN contexts.

Examples

Display detailed information about all SSL VPN contexts.

```
<Sysname> display sslvpn context
Context name: ctx1
  Operation state: Up
  AAA domain: domain1
  Certificate authentication: Enabled
  Certificate username-attribute: CN
  Password authentication: Enabled
  Authentication use: All
  SMS auth type: iMC
  Code verification: Disabled
  Default policy group: Not configured
  Associated SSL VPN gateway: gw1
    Domain name: 1
  Associated SSL VPN gateway: gw2
    Virtual host: abc.com
  Associated SSL VPN gateway: gw3
  SSL client policy configured: ssl1
  SSL client policy in use: ssl
  Maximum users allowed: 200
  VPN instance:vpn1
  Idle timeout: 30 min
  Idle-cut traffic threshold: 100 Kilobytes
  Authentication server-type: aaa
  Password changing: Disabled
```

```
Context name: ctx2
  Operation state: Down
  Down reason: Administratively down
  AAA domain not specified
  Certificate authentication: Enabled
  Certificate username-attribute: OID(2.5.4.10)
  Password authentication: Disabled
  Authentication use: Any-one
  SMS auth type: sms-gw
  Code verification: Disabled
  Default group policy: gp
  Associated SSL VPN gateway: -
  SSL client policy configured: ssl1
  SSL client policy in use: ssl
  Maximum users allowed: 200
  VPN instance not configured
  Idle timeout: 50 min
  Idle-cut traffic threshold: 100 Kilobytes
  Address pool: Conflicted with an IP address on the device
  Authentication server-type: custom
  Password changing: Disabled
```

Table 3 Command output

Field	Description
Context name	Name of the SSL VPN context.
Operation state	Operation state of the SSL VPN context: • **Up**—The context is running. • **Down**—The context is not running.
Down reason	Causes for the **Down** operations status: • **Administratively down**—The context is disabled. To enable the context, use the **`service enable`** command. • **No gateway associated**—The context is not associated with an SSL VPN gateway.
AAA domain	ISP domain for the SSL VPN context.
Certificate authentication	Whether certificate authentication is enabled for the SSL VPN context.
Password authentication	Whether username/password authentication is enabled for the SSL VPN context.
Authentication use	Authentication methods required for user login: • **All**—A user must pass all the enabled authentication methods to log in to the SSL VPN context. • **Any-one**—A user can log in to the SSL VPN context after passing any enabled authentication method.

Field	Description
Certificate username-attribute	Certificate attribute whose value is used as the SSL VPN username: • **CN**—CN attribute in the subject of the user certificate. • **Email-prefix**—String before the at sign (@) of the email address in the subject of the user certificate. • **OID(x.x.x.x)**—Object identifier of a user certificate attribute in dotted decimal notation. This field is displayed only when certificate authentication is enabled.
SMS auth type	SMS authentication types: • **iMC**—SMS authentication by an IMC server. • **sms-gw**—SMS authentication by an SMS gateway.
Code verification	Whether code verification is enabled for the SSL VPN context.
Default policy group	Default policy group used by the SSL VPN context.
Associated SSL VPN gateway	SSL VPN gateway associated with the SSL VPN context.
Domain name	Domain name specified for the SSL VPN context.
Virtual host	Virtual host name specified for the SSL VPN context.
SSL client policy configured	SSL client policy configured for the SSL VPN context. A newly configured SSL client policy takes effect only after the SSL VPN context is restarted.
SSL client policy in use	SSL client policy being used by the SSL VPN context.
Maximum users allowed	Maximum number of sessions allowed in the SSL VPN context.
VPN instance	VPN instance associated with the SSL VPN context.
Idle timeout	Maximum idle time of an SSL VPN session, in minutes.
Idle-cut traffic threshold	SSL VPN idle session disconnection traffic threshold.
Address pool: Conflicted with an IP address on the device	An IP address conflict was detected in the SSL VPN context.
Authentication server-type	Authentication server types: • **aaa**—AAA server. • **custom**—Custom authentication server.
Password changing	Status of the SSL VPN login password modification feature: • **Enabled**. • **Disabled**.

Display brief information about all SSL VPN contexts.

```
<Sysname> display sslvpn context brief
Context name   Admin   Operation   VPN instance   Gateway   Domain/VHost
ctx1           Up      Up          -              gw1       -/1
                                                  gw2       abc.com/-
                                                  gw3       -/-
ctx2           Down    Down        -              -         -/-
```

Table 4 Command output

Field	Description
Context name	Name of the SSL VPN context.

Field	Description
Admin	Administrative status of the SSL VPN context: • **Up**—The context has been enabled by using the **service enable** command. • **Down**—The context is disabled.
Operation	Operation state of the SSL VPN context: • **Up**—The context is running. • **Down**—The context is not running.
VPN instance	VPN instance associated with the SSL VPN context.
Gateway	SSL VPN gateway associated with the SSL VPN context.
Domain/VHost	Domain name or virtual host name specified for the SSL VPN context.

display sslvpn gateway

Use **display sslvpn gateway** to display SSL VPN gateway information.

Syntax

display sslvpn gateway [**brief** | **name** *gateway-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

brief: Displays brief SSL VPN gateway information. If you do not specify this keyword, the command displays detailed SSL VPN gateway information.

name *gateway-name*: Specifies an SSL VPN context by its name. An SSL VPN context name is a case-insensitive string of 1 to 31 characters, and can contain only letters, digits, and underscores (_). If you do not specify an SSL VPN context, this command displays information about all SSL VPN gateways.

Examples

Display detailed information about all SSL VPN gateways.

```
<Sysname> display sslvpn gateway
Gateway name: gw1
  Operation state: Up
  IP: 192.168.10.75  Port: 443
  HTTP redirect port: 80
  SSL server policy configured: ssl1
  SSL server policy in use: ssl
  Front VPN instance: vpn1
Gateway name: gw2
  Operation state: Down
```

```
  Down reason: Administratively down
  IP: 0.0.0.0  Port: 443
  SSL server policy configured: ssl1
  SSL server policy in use: ssl
  Front VPN instance: Not configured
Gateway name: gw3
  Operation state: Up
  IPv6: 3000::2  Port: 443
  SSL server policy configured: ssl1
  SSL server policy in use: ssl
  Front VPN instance: Not configured
```

Table 5 Command output

Field	Description
Gateway name	Name of the SSL VPN gateway.
Operation state	Operation state of the SSL VPN gateway: • **Up**—The gateway is running. • **Down**—The gateway is not running.
Down reason	Causes for the **Down** operation status: • **Administratively down**—The SSL VPN gateway is disabled. To enable the gateway, use the **service enable** command. • **VPN instance not exist**—The VPN instance to which the SSL VPN gateway belongs does not exist. • **Applying SSL server-policy failed**—Failed to apply the SSL server policy to the SSL VPN gateway.
IP	IPv4 address of the SSL VPN gateway.
IPv6	IPv6 address of the SSL VPN gateway.
Port	Port number of the SSL VPN gateway.
HTTP redirect port	HTTP redirection port number of the SSL VPN gateway.
SSL server policy configured	SSL server policy configured for the SSL VPN gateway. A newly configured SSL server policy takes effect only after the SSL VPN gateway is restarted.
SSL server policy in use	SSL server policy being used by the SSL VPN gateway.
Front VPN instance	Front VPN instance to which the SSL VPN gateway belongs.

Display brief information about all SSL VPN gateways.

```
<Sysname> display sslvpn gateway brief
Gateway name                    Admin  Operation
gw1                             Up     Up
gw2                             Down   Down (Administratively down)
gw3                             Up     Up
```

Table 6 Command output

Field	Description
Gateway name	Name of the SSL VPN gateway.

Field	Description
Admin	Administrative status of the SSL VPN gateway: • **Up**—The gateway has been enabled by using the **service enable** command. • **Down**—The gateway is disabled.
Operation	Operation state of the SSL VPN gateway: • **Up**—The gateway is running. • **Down (Administratively down)**—The gateway is disabled. To enable the gateway, use the **service enable** command. • **Down (VPN instance not exist)**—The gateway is down because the VPN instance to which the gateway belongs does not exist. • **Down (Applying SSL server-policy failed)**—The gateway is down because the SSL server policy failed to be applied to the gateway.

display sslvpn ip-tunnel statistics

Use **display sslvpn ip-tunnel statistics** to display packet statistics for IP access users.

Syntax

display sslvpn ip-tunnel statistics [**context** *context-name*] [**user** *user-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

context *context-name*: Specifies an SSL VPN context by its name. An SSL VPN context name is a case-insensitive string of 1 to 31 characters, and can contain only letters, digits, and underscores (_).

user *user-name*: Specifies an IP access user by username, a case-insensitive string of 1 to 63 characters.

Usage guidelines

If you do not specify any parameters, this command displays IP access packets statistics for all SSL VPN contexts.

If you only specify an SSL VPN context, this command displays IP access packet statistics for the specified context and for each SSL VPN user in the context.

If you only specify an SSL VPN user, this command displays IP access packet statistics for the specified user in all SSL VPN contexts.

If you specify both an SSL VPN context and user, this command displays IP access packet statistics for the specified user in the specified context.

Examples

Display IP access packet statistics for all SSL VPN contexts.

```
<Sysname> display sslvpn ip-tunnel statistics
IP-tunnel statistics in SSL VPN context ctx1:
  Client:
    In bytes  : 125574              Out bytes  : 1717349
  Server:
    In bytes  : 1717349             Out bytes  : 116186

IP-tunnel statistics in SSL VPN context ctx2:
  Client:
    In bytes  : 521                 Out bytes  : 1011
  Server:
    In bytes  : 1011                Out bytes  : 498
```

Display IP access packet statistics for SSL VPN context **ctx1** and for each user in the context.

```
<Sysname> display sslvpn ip-tunnel statistics context ctx1
IP-tunnel statistics in SSL VPN context ctx1:
  Client:
    In bytes  : 125574              Out bytes  : 1717349
  Server:
    In bytes  : 1717349             Out bytes  : 116186

SSL VPN session IP-tunnel statistics:

Table 7 Command output

Field	Description
Context	SSL VPN context to which the SSL VPN user belongs.
User	Login username used by the SSL VPN user.
User IPv4 address	IPv4 address of the SSL VPN user.
User IPv6 address	IPv6 address of the SSL VPN user.
Received requests	Number of IP access requests received by the SSL VPN gateway from the user.
Sent requests	Number of IP access requests forwarded by the SSL VPN gateway to internal servers.
Dropped requests	Number of IP access requests dropped by the SSL VPN gateway.
Received replies	Number of IP access replies received by the SSL VPN gateway from internal servers.
Sent replies	Number of IP access replies forwarded by the SSL VPN gateway to the user.
Dropped replies	Number of IP access replies dropped by the SSL VPN gateway.
Received keepalives	Number of keepalive messages received by the SSL VPN gateway from the user.
Sent keepalives replies	Number of keepalive replies sent by the SSL VPN gateway to the user.
Received configuration updates	Number of configuration update messages received by the SSL VPN gateway from the user.
Sent configuration updates	Number of configuration update messages sent by the SSL VPN gateway to the user.

Field	Description
Client	Statistics of the traffic transmitted between the SSL VPN gateway and the IP access client: • **In bytes**—Number of bytes received by the SSL VPN gateway from the client. • **Out bytes**—Number of bytes sent by the SSL VPN gateway to the client.
Server	Statistics of the traffic transmitted between the SSL VPN gateway and the server: • **In bytes**—Number of bytes received by the SSL VPN gateway from the server. • **Out bytes**—Number of bytes sent by the SSL VPN gateway to the client.

display sslvpn policy-group

Use **display sslvpn policy-group** to display SSL VPN policy group information.

Syntax

display sslvpn policy-group *group-name* [**context** *context-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

group-name: Specifies a policy group by its name, a case-insensitive string of 1 to 31 characters.

context *context-name*: Specifies an SSL VPN context by its name. An SSL VPN context name is a case-insensitive string of 1 to 31 characters, and can contain only letters, digits, and underscores (_). If you do not specify an SSL VPN context, this command displays information about policy groups with the specified group name in all SSL VPN contexts.

Examples

Display information about policy groups named **pg1** in all SSL VPN contexts.

```
<Sysname> display sslvpn policy-group pg1
Group policy: pg1
  Context: context1
   Idle timeout: 35 min
   Redirect resource type: url-item
   Redirect resource name: url1

  Context: context2
   Idle timeout: 40 min
   Redirect resource: Not configured
```

Table 8 Command output

Field	Description
Idle timeout	Maximum idle time of an SSL VPN session, in minutes.
Redirect resource	Redirect resource in the policy group assigned to the SSL VPN context.

display sslvpn port-forward connection

Use **display sslvpn port-forward connection** to display TCP port forwarding connection information.

Syntax

display sslvpn port-forward connection [**context** *context-name*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

context *context-name*: Specifies an SSL VPN context by its name. An SSL VPN context name is a case-insensitive string of 1 to 31 characters, and can contain only letters, digits, and underscores (_). If you do not specify an SSL VPN context, this command displays TCP port forwarding connection information for all SSL VPN contexts.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays TCP port forwarding connection information for all member devices.

Examples

Display TCP port forwarding connection information for all SSL VPN contexts.

```
<Sysname> display sslvpn port-forward connection
SSL VPN context  : ctx1
  Client address : 192.0.2.1
  Client port    : 1025
  Server address : 192.168.0.39
  Server port    : 80
  Slot           : 1
  Status         : Connected
SSL VPN context  : ctx2
  Client address : 3000::983F:7A36:BD06:342D
  Client port    : 56190
  Server address : 300::1
  Server port    : 23
  Slot           : 1
  Status         : Connecting
```

Table 9 Command output

Field	Description
Client address	IP address of the SSL VPN client.
Client port	Port number of the SSL VPN client.
Server address	IP address of the internal server.
Server port	Port number of the internal server.
Slot	IRF member ID of the device.
Status	Connection status, **Connected** or **Connecting**.

display sslvpn prevent-cracking frozen-ip

Use **display sslvpn prevent-cracking frozen-ip** to display information about IP addresses frozen for cracking prevention.

Syntax

display sslvpn prevent-cracking frozen-ip { **statistics** | **table** } [**context** *context-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

statistics: Displays frozen IP address statistics.

table: Displays information about frozen IP address entries.

context *context-name*: Specifies an SSL VPN context by its name. An SSL VPN context name is a case-insensitive string of 1 to 31 characters, and can contain only letters, digits, and underscores (_). If you do not specify an SSL VPN context, this command displays frozen IP address information for all SSL VPN contexts.

Examples

Display frozen IP address statistics in all SSL VPN contexts.

```
<Sysname> display sslvpn prevent-cracking frozen-ip statistics
SSL VPN context: ctx1
Total number of frozen IP addresses: 1
Total number of username/password authentication failures: 1
Total number of code verification failures: 1
Total number of SMS authentication failures: 1
Total number of custom authentication failures: 1
SSL VPN context: ctx2
Total number of frozen IP addresses: 1
```

```
Total number of username/password authentication failures: 1
Total number of code verification failures: 1
Total number of SMS authentication failures: 1
Total number of custom authentication failures: 1
```

Display frozen IP address entries in all SSL VPN contexts.

```
<Sysname> display sslvpn prevent-cracking frozen-ip table
SSL VPN context: ctx1
IP address   Authentication method             Frozen at            Unfrozen at
8.1.1.80     code verification                2019-10-08 08:30:01  2019-10-08 08:35:04
3.3.3.30     Username/password authentication 2019-10-08 08:35:01  2019-10-08 08:39:04
SSL VPN context: ctx2
IP address   Authentication method             Frozen at            Unfrozen at
121.5.5.32   Username/password authentication  2019-10-08 08:31:01  2019-10-08 08:45:04
123.3.3.3    code verification                2019-10-08 08:35:01  2019-10-08 08:55:04
```

Table 10 Command output

Field	Description
SSL VPN context	Name of the SSL VPN context.
IP address	Frozen IP address.
Authentication method	Authentication methods required for logging in to the SSL VPN context. Options include: • **Username/password authentication**. • **Code verification**. • **SMS authentication**. • **Custom authentication**. The use of authentication methods must meet the following requirements: • You can enable one or multiple authentication methods. • Username/password authentication must be enabled in an SSL VPN context. • Custom authentication and SMS authentication cannot both be enabled at the same time. All authentication methods can be used independently except for code verification.
Frozen at	Time when the IP address was frozen.
Unfrozen at	Time when the frozen IP address is to be unfrozen. **N/A** means that the IP address will never be unfrozen.

display sslvpn session

Use **display sslvpn session** to display SSL VPN session information.

Syntax

display sslvpn session [**context** *context-name*] [**user** *user-name* | **verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

context *context-name*: Specifies an SSL VPN context by its name. An SSL VPN context name is a case-insensitive string of 1 to 31 characters, and can contain only letters, digits, and underscores (_). If you do not specify an SSL VPN context, this command displays SSL VPN session information for all SSL VPN contexts.

user *user-name*: Specifies an SSL VPN user by the username, a case-insensitive string of 1 to 63 characters. If you specify a user, this command displays detailed SSL VPN session information for the user. If you do not specify a user, this command displays brief SSL VPN session information for all users.

verbose: Displays detailed SSL VPN session information for all SSL VPN users. If you do not specify this keyword, the command displays brief SSL VPN session information for the specified or all SSL VPN users.

Examples

Display brief SSL VPN session information for all users in all SSL VPN contexts.

```
<Sysname> display sslvpn session
Total users: 4

SSL VPN context: ctx1
Users: 2
Username        Connections  Idle time   Created       User IP
user1           5            0/00:00:23  0/04:47:16    192.0.2.1
user2           5            0/00:00:46  0/04:48:36    192.0.2.2

SSL VPN context: ctx2
Users: 2
Username        Connections  Idle time   Created       User IP
user3           5            0/00:00:30  0/04:50:06    192.168.2.1
user4           5            0/00:00:50  0/04:51:16    192.168.2.2
```

Table 11 Command output

Field	Description
Total users	Total number of users in all SSL VPN contexts.
SSL VPN context	Name of the SSL VPN context.
Users	Number of users in the SSL VPN context.
Username	Login name for the SSL VPN session.
Connections	Number of connections in the SSL VPN session.
Idle time	Duration that the SSL VPN session has been idle, in the format of days/hh:mm:ss.
Created	Time elapsed since the SSL VPN session was created, in the format of days/hh:mm:ss.
User IP	IP address used by the SSL VPN session.

Display SSL VPN session information for SSL VPN user **user1**.

```
<Sysname> display sslvpn session user user1
User                    : user1
Authentication method   : Username/password authentication
Context                 : context1

```

Table 12 Command output

Field	Description
User	SSL VPN username.
Authentication method	Authentication methods required for logging in to the SSL VPN context. Options include: • **Username/password authentication**. • **Certificate authentication**. • **Code verification**. • **SMS authentication**. • **Custom authentication**. The use of authentication methods must meet the following requirements: • You can enable one or multiple authentication methods. • Username/password authentication, certificate authentication, or both must be enabled in an SSL VPN context. • Custom authentication and SMS authentication cannot both be enabled at the same time. • All authentication methods can be used independently except for code verification.
Context	Context to which the user belongs.
Policy group	Policy group used by the user.
Idle timeout	Idle timeout time of the SSL VPN session, in seconds.
Created at	Time at which the SSL VPN session was created.
Lastest	Most recent time when the SSL VPN user accessed resources through the SSL VPN session.
Allocated IP	IP address allocated to the iNode client of the SSL VPN user. This field is displayed only for iNode users.
User IPv4 address	IPv4 address used by the SSL VPN session.
User IPv6 address	IPv6 address used by the SSL VPN session.
Web browser/OS	Web browser or operating system used by the SSL VPN user.
Send rate	Sending rate of the SSL VPN session in one of the following units: • **B/s**—Bytes per second.

Field	Description
	• **KB/s**—Kilobytes per second. • **MB/s**—Megabytes per second. • **GB/s**—Gigabytes per second. • **TB/s**—Terabytes per second. • **PB/s**—Petabytes per second.
Receive rate	Receiving rate of the SSL VPN session in one of the following units: • **B/s**—Bytes per second. • **KB/s**—Kilobytes per second. • **MB/s**—Megabytes per second. • **GB/s**—Gigabytes per second. • **TB/s**—Terabytes per second. • **PB/s**—Petabytes per second.
Sent bytes	Traffic sent by the SSL VPN session in one of the following units: • **B**—Bytes. • **KB**—Kilobytes. • **MB**—Megabytes. • **GB**—Gigabytes. • **TB**—Terabytes. • **PB**—Petabytes.
Received bytes	Traffic received by the SSL VPN session in one of the following units: • **B**—Bytes. • **KB**—Kilobytes. • **MB**—Megabytes. • **GB**—Gigabytes. • **TB**—Terabytes. • **PB**—Petabytes.

display sslvpn webpage-customize template

Use **display sslvpn webpage-customize template** to display SSL VPN webpage template information.

Syntax

display sslvpn webpage-customize template

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display information about all webpage templates.

```
<Sysname> display sslvpn webpage-customize template
Template name            Type             Status
```

```
default                 Pre-defined       Normal
system                  Predefined        Normal
User1                   User-defined      File login.html missing
User2                   User-defined      File home.html missing
```

Table 13 Command output

Field	Description
Template name	Name of the SSL VPN webpage template.
Type	Type of the SSL VPN webpage template: • **Pre-defined**. • **User-defined**.
Status	State of the SSL VPN webpage template: • **Normal**—The template is complete and can be used. • **File login.html missing**—The login.html file is missing in the template. • **File home.html missing**—The home.html file is missing in the template. • **Version incompatible**—The version of the template is inconsistent with the version of the predefined template.

Related commands

sslvpn webpage-customize

webpage-customize

emo-server

Use **emo-server** to specify an Endpoint Mobile Office (EMO) server for mobile clients.

Use **undo emo-server** to restore the default.

Syntax

emo-server address { *host-name* | *ipv4-address* } **port** *port-number*

undo emo-server

Default

No EMO server is specified for mobile clients.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

address: Specifies the host name or IPv4 address of the EMO server.

host-name: Specifies the host name of the EMO server, a case-insensitive string of 1 to 127 characters. Valid characters are letters, digits, underscores (_), hyphens (-), and dots (.).

ipv4-address: Specifies the IPv4 address of the EMO server, in dotted decimal notation. The IP address cannot be a multicast, broadcast, or loopback address.

port *port-number*: Specifies the port number of the EMO server, in the range of 1025 to 65535.

Usage guidelines

An EMO server provides services for mobile clients. The SSL VPN gateway issues the EMO server information to the clients, and the clients can access available service resources through the EMO server.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the IP address of the EMO server as 10.10.1.1 and the port number as 9058 for context **ctx1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] emo-server address 10.10.1.1 port 9058
```

exclude

Use **exclude** to add an excluded route to a route list.

Use **undo exclude** to delete an excluded route from a route list.

Syntax

exclude *ip-address* { *mask* | *mask-length* }

undo exclude *ip-address* { *mask* | *mask-length* }

Default

No excluded routes exist in a route list.

Views

Route list view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the destination IP address of the route. It cannot be a multicast, broadcast, or loopback address.

mask: Specifies the subnet mask of the destination IP address.

mask-length: Specifies the mask length of the destination IP address, an integer in the range of 0 to 32.

Usage guidelines

To deny user access to specific network nodes or segments behind an SSL VPN gateway, configure excluded routes for those nodes or segments.

When a client accesses the SSL VPN gateway in IP access mode, the SSL VPN gateway issues excluded routes to the client. The client adds the excluded routes to the local routing table. Traffic that matches the excluded routes are not sent to the SSL VPN gateway.

You can add multiple excluded routes to a route list.

If you execute the **include** and **exclude** commands to add the same route to a route list, the most recent configuration takes effect.

Examples

Add excluded route 192.168.0.0/16 to route list **rtlist**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] ip-route-list rtlist
[Sysname-sslvpn-context-ctx1-route-list-rtlist] exclude 192.168.0.0 16
```

Related commands

include

execution (port forwarding item view)

Use **execution** to configure a resource link for a port forwarding item.

Use **undo execution** to restore the default.

Syntax

execution *script*

undo execution

Default

No resource link is configured for a port forwarding item.

Views

Port forwarding item view

Predefined user roles

network-admin

context-admin

Parameters

script: Specifies the script for the resource link, a case-insensitive string of 1 to 255 characters.

Usage guidelines

You can configure a resource link in one of the following methods:

- Enter a URL resource in the format of **url(**'*url-value*'**)**. The *url-value* argument specifies the URL link. The complete format for *url-value* is *protocol*://*hostname or address*:*port number*/*resource path*.
- Enter an executable JavaScript for a resource to provide access to the resource.

After you configure a resource link for a port forwarding item, you can click the port forwarding name on the SSL VPN Web page to access the resource.

If you execute this command for a port forwarding item multiple times, the most recent configuration takes effect.

Examples

Configure the **url('http://127.0.0.1')** resource for port forwarding item **pfitem1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] port-forward-item pfitem1
[Sysname-sslvpn-context-ctx1-forward-item-pfitem1] execution url('http://127.0.0.1')
```

execution (shortcut view)

Use **execution** to configure a resource link for a shortcut.

Use **undo execution** to restore the default.

Syntax

execution *script*

undo execution

Default

No resource link is configured for a shortcut.

Views

Shortcut view

Predefined user roles

network-admin

context-admin

Parameters

script: Specifies the script for the resource, a case-insensitive string of 1 to 255 characters.

Usage guidelines

You can configure a resource link in either of the following methods:

- Enter the resource link in the format of **url(**'*url-value*'**)**. The *url-value* argument specifies the corresponding resource. The complete format for *url-value* is *protocol*://*hostname or address*:*port number*/*resource path*.
- Enter an application resource in the format of **app**('*app-value*'). The *app-value* argument specifies the application path. For example, the *app-value* argument can be **c:\windows\system32\notepad++.exe,** which is used for opening the notepad++.exe application.
- Enter an executable JavaScript for a resource to provide access to the resource.

After you configure a resource link for a shortcut, you can click the shortcut name on the SSL VPN Web page to access the resource.

If you execute this command for a shortcut multiple times, the most recent configuration takes effect.

Examples

Configure the **url('http://10.0.0.1')** resource for shortcut **shortcut1**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] shortcut shortcut1
[Sysname-sslvpn-context-ctx1-shortcut-shortcut1] execution url('http://10.0.0.1')
```

Configure the **app('c:\windows\system32\notepad++.exe')** resource for shortcut **shortcut2**.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] shortcut shortcut2
[Sysname-sslvpn-context-ctx1-shortcut-shortcut2] execution
app('c:\windows\system32\notepad++.exe')
```

file-policy

Use **file-policy** to create a file policy and enter its view, or enter the view of an existing file policy.

Use **undo file-policy** to delete a file policy.

Syntax

file-policy *policy-name*

undo file-policy *policy-name*

Default

No file policies exist.

Views

SSL VPN context view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies a file policy name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

The SSL VPN gateway uses a file policy to rewrite the content of Web page files before forwarding them to requesting Web access users.

You can configure multiple file policies in an SSL VPN context.

Examples

Create a file policy named **fp** and enter its view.

```
<Sysname> system-view
[Sysname] sslvpn context ctx
[Sysname-sslvpn-context-ctx] file-policy fp
[Sysname-sslvpn-context-ctx-file-policy-fp]
```

Related commands

sslvpn context

filter ip-tunnel acl

Use **filter ip-tunnel acl** to specify an advanced ACL for IP access filtering.

Use **undo filter ip-tunnel acl** to remove the advanced ACL configuration for IP access filtering.

Syntax

filter ip-tunnel [**ipv6**] **acl** *advanced-acl-number*

undo filter ip-tunnel [**ipv6**] **acl**

Default

All IP accesses are permitted.

Views

SSL VPN policy group view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies an IPv6 ACL. Do not configure this keyword if you want to specify an IPv4 ACL.

acl *advanced-acl-number*: Specifies an advanced ACL by its number in the range of 3000 to 3999. If a rule in the specified ACL contains VPN settings, the rule does not take effect.

Usage guidelines

You can specify both an advanced ACL and a URI ACL for IP access filtering.

The SSL VPN gateway uses the following procedure to determine whether to forward an IP access request:

1. Matches the request against rules in the URI ACL:
   - If the request matches a permit rule, the gateway forwards the request.
   - If the request matches a deny rule, the gateway drops the request.
   - If the request does not match any rules in the URI ACL or if no URI ACL is available, the gateway proceeds to step 2.
2. Matches the request against rules in the advanced ACL:
   - If the request matches a permit rule, the gateway forwards the request.
   - If the request matches a deny rule, the gateway drops the request.
   - If the request does not match any rules in the advanced ACL or if no advanced ACL is available, the gateway drops the request.

If no URI ACL or advanced ACL is specified for IP access filtering, the SSL VPN gateway permits all IP accesses by default.

You can specify an IPv4 ACL, IPv6 ACL, or both by using this command, but you cannot specify multiple IPv4 ACLs or IPv6 ACLs. If you specify IPv4 or IPv6 ACLs multiple times, the most recent IPv4 or IPv6 ACL configuration takes effect.

Examples

Configure policy group **pg1** to use IPv4 ACL 3000 and IPv6 ACL 3500 for IP access filtering.

```
<Sysname> system-view
[Sysname] sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] policy-group pg1
[Sysname-sslvpn-context-ctx1-policy-group-pg1] filter ip-tunnel acl 3000
[Sysname-sslvpn-context-ctx1-policy-group-pg1] filter ip-tunnel ipv6 acl 3500
```

Related commands

filter ip-tunnel uri-acl

filter ip-tunnel uri-acl

Use **filter ip-tunnel uri-acl** to specify a URI ACL for IP access filtering.

Use **undo filter ip-tunnel uri-acl** to remove the URI ACL configuration for IP access filtering.

Syntax

filter ip-tunnel uri-acl *uri-acl-name*

undo filter ip-tunnel uri-acl

Default

All IP accesses are permitted.

Views

SSL VPN policy group view

Predefined user roles

network-admin

context-admin

Parameters

uri-acl-name: Specifies a URI ACL by its name, a case-insensitive string of 1 to 31 characters. The specified URI ACL must already exist.

Usage guidelines

You can specify both an advanced ACL and a URI ACL for IP access filtering.

The SSL VPN gateway uses the following procedure to determine whether to forward an IP access request:

1. Matches the request against rules in the URI ACL:
   - If the request matches a permit rule, the gateway forwards the request.
   - If the request matches a deny rule, the gateway drops the request.
   - If the request does not match any rules in the URI ACL or if no URI ACL is available, the gateway proceeds to step 2.
2. Matches the request against rules in the advanced ACL:
   - If the request matches a permit rule, the gateway forwards the request.
   - If the request matches a deny rule, the gateway drops the request.
   - If the request does not match any rules in the advanced ACL or if no advanced ACL is available, the gateway drops the request.

If no URI ACL or advanced ACL is specified for IP access filtering, the SSL VPN gateway permits all IP accesses by default.

If a rule in the URI ACL specified for IP access filtering contains HTTP or HTTPS settings, the rule does not take effect.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure policy group **abcpg** to use URI ACL **abcuriacl** for IP access filtering.

```
<Sysname> system-view
[Sysname] sslvpn context abc
[Sysname-sslvpn-context-abc] policy-group abcpg
[Sysname-sslvpn-context-abc-policy-group-abcpg] filter ip-tunnel uri-acl abcuriacl
```

filter tcp-access acl

Use **filter tcp-access acl** to specify an advanced ACL for TCP access filtering.

Use **undo filter tcp-access acl** to remove the advanced ACL configuration for TCP access filtering.

Syntax

filter tcp-access [**ipv6**] **acl** *advanced-acl-number*

undo filter tcp-access [**ipv6**] **acl**

Default

A user can access only the TCP resources in the TCP port forwarding list authorized to the user.

Views

SSL VPN policy group view

Predefined user roles

network-admin

context-admin

Parameters

ipv6: Specifies an IPv6 ACL. Do not configure this keyword if you want to specify an IPv4 ACL.

acl *advanced-acl-number*: Specifies an advanced ACL by its number in the range of 3000 to 3999. If a rule in the specified ACL contains VPN settings, the rule does not take effect.

Usage guidelines

You can specify both an advanced ACL and a URI ACL for TCP access filtering.

For mobile client users, the SSL VPN gateway uses the following procedure to determine whether to forward a TCP access request:

1. Matches the request against the authorized port forwarding list.
   - If the request matches a port forwarding item in the list, the gateway forwards the request.
   - If the request does not match any port forwarding items in the list, the gateway proceeds to step 2.
2. Matches the request against the rules in the URI ACL:
   - If the request matches a permit rule, the gateway forwards the request.
   - If the request matches a deny rule, the gateway drops the request.
   - If the request does not match any rules in the URI ACL or if no URI ACL is available, the gateway proceeds to step 3.
3. Matches the request against the rules in the advanced ACL:
   - If the request matches a permit rule, the gateway forwards the request.
   - If the request matches a deny rule, the gateway drops the request.
   - If the request does not match any rules in the advanced ACL or if no advanced ACL is available, the gateway drops the request.

For PC users, the ACLs configured for TCP access filtering do not take effect. They can access only the TCP resources authorized to them through the TCP port forwarding list.

You can specify an IPv4 ACL, IPv6 ACL, or both by using this command, but you cannot specify multiple IPv4 ACLs or IPv6 ACLs. If you specify IPv4 or IPv6 ACLs multiple times, the most recent IPv4 or IPv6 ACL configuration takes effect.

Examples

Configure policy group **pg1** to use IPv4 ACL 3000 and IPv6 ACL 3500 for TCP access filtering.

```
<Sysname> system-view
[Sysname]sslvpn context ctx1
[Sysname-sslvpn-context-ctx1] policy-group pg1
[Sysname-sslvpn-context-ctx1-policy-group pg1] filter tcp-access acl 3000
[Sysname-sslvpn-context-ctx1-policy-group pg1] filter tcp-access ipv6 acl 3500
```
