lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **notification remote-change enable**

undo lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **notification remote-change enable**

In Layer 2/Layer 3 aggregate interface view:

lldp agent { **nearest-customer** | **nearest-nontpmr** } **notification remote-change enable**

undo lldp agent { **nearest-customer** | **nearest-nontpmr** } **notification remote-change enable**

Default

LLDP trapping is disabled.

Views

Layer 2 Ethernet interface view

Layer 3 Ethernet interface view

Layer 2 aggregate interface view

Layer 3 aggregate interface view

Predefined user roles

network-admin

context-admin

Parameters

agent: Specifies an LLDP agent type. If you do not specify an agent type in Ethernet interface view, the command enables LLDP trapping for nearest bridge agents.

nearest-customer: Specifies nearest customer bridge agents.

nearest-nontpmr: Specifies nearest non-TPMR bridge agents.

Examples

Enable LLDP trapping for the nearest customer bridge agent on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface GigabitEthernet 1/0/1
[Sysname-GigabitEthernet1/0/1] lldp agent nearest-customer notification remote-change enable
```

lldp source-mac vlan

Use **lldp source-mac vlan** to set the source MAC address of LLDP frames to the MAC address of a Layer 3 Ethernet subinterface.

Use **undo lldp source-mac vlan** to restore the default.

Syntax

lldp source-mac vlan *vlan-id*

undo lldp source-mac vlan

Default

The source MAC address of LLDP frames is the MAC address of the egress interface.

Views

Layer 3 Ethernet interface view

Predefined user roles

network-admin

context-admin

Parameters

vlan *vlan-id*: Specifies the Layer 3 Ethernet subinterface that terminates the specified VLAN to provide the source MAC address for LLDP frames. The VLAN ID is in the range of 1 to 4094.

Usage guidelines

This command must be used together with the **lldp management-address** command for the device to use the MAC address of a Layer 3 Ethernet subinterface as the source MAC address of LLDP frames. This ensures that the LLDP neighbor can learn correct ARP or ND entries.

This command enables the device to use the MAC address of the Layer 3 Ethernet subinterface that terminates the specified VLAN as the source MAC address of outgoing LLDP frames. If the VLAN is not terminated by any Layer 3 Ethernet subinterface, the MAC address of the Layer 3 Ethernet interface is used as the source MAC address of outgoing LLDP frames. For more information about VLAN termination, see VLAN termination configuration in *Layer 2—LAN Switching Configuration Guide*.

Examples

Set the source MAC address of LLDP frames to the MAC address of the Layer 3 Ethernet subinterface that terminates VLAN 4094.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] lldp source-mac vlan 4094
```

Related commands

lldp timer fast-interval

Use **lldp timer fast-interval** to set an interval for fast LLDP frame transmission.

Use **undo lldp timer fast-interval** to restore the default.

Syntax

lldp timer fast-interval *interval*

undo lldp timer fast-interval

Default

The interval for fast LLDP frame transmission is 1 second.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Sets an interval for fast LLDP frame transmission, in the range of 1 to 3600 seconds.

Examples

Set the interval for fast LLDP frame transmission to 2 seconds.

```
<Sysname> system-view
[Sysname] lldp timer fast-interval 2
```

lldp timer notification-interval

Use **lldp timer notification-interval** to set the LLDP trap and LLDP-MED trap transmission interval.

Use **undo lldp timer notification-interval** to restore the default.

Syntax

lldp timer notification-interval *interval*

undo lldp timer notification-interval

Default

The LLDP trap and LLDP-MED trap transmission interval is 30 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Sets the LLDP trap and LLDP-MED trap transmission interval in the range of 5 to 3600 seconds.

Examples

Set both the LLDP trap and LLDP-MED trap transmission interval to 8 seconds.

```
<Sysname> system-view
[Sysname] lldp timer notification-interval 8
```

lldp timer reinit-delay

Use **lldp timer reinit-delay** to set the LLDP reinitialization delay.

Use **undo lldp timer reinit-delay** to restore the default.

Syntax

lldp timer reinit-delay *delay*

undo lldp timer reinit-delay

Default

The LLDP reinitialization delay is 2 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

delay: Sets the LLDP reinitialization delay in the range of 1 to 10 seconds.

Examples

Set the LLDP reinitialization delay to 4 seconds.

```
<Sysname> system-view
[Sysname] lldp timer reinit-delay 4
```

lldp timer rx-timeout

Use **lldp timer rx-timeout** to set the timeout for receiving LLDP frames and enable the device to report no LLDP neighbor events.

Use **undo lldp timer rx-timeout** to restore the default.

Syntax

lldp timer rx-timeout *timeout*

undo lldp timer rx-timeout

Default

No timeout is set for receiving LLDP frames, and the device does not report no LLDP neighbor events.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

timeout: Sets the timeout for receiving LLDP frames, in the range of 30 to 32768 seconds.

Usage guidelines

This command can detect only directly connected LLDP neighbors.

When you use this command, make sure the following requirements are met:

- LLDP is enabled.
- Interfaces are physically up.
- Nearest bridge agents operate in **Rx** or **TxRx** mode.

After this command is executed, the device restarts the timeout timer for receiving LLDP frames on an interface in one of the following situations:

- When LLDP is enabled, the interface state changes from down to up.
- When the interface is physically up, LLDP is enabled.
- When LLDP is enabled and the interface is physically up, the mode of nearest bridge agents is changed from disabled to **Rx** or **TxRx**.

If an interface has not received any LLDP frames when the timeout timer expires, the device reports a no LLDP neighbor event to the NETCONF module.

To avoid misdetection, make sure the timeout for receiving LLDP frames is greater than the LLDP frame transmission interval.

Examples

Set the timeout for receiving LLDP frames to 30 seconds.

```
<Sysname> system-view
[Sysname] lldp timer rx-timeout 30
```

Related commands

lldp timer tx-interval

lldp timer tx-interval

Use **lldp timer tx-interval** to set the LLDP frame transmission interval.

Use **undo lldp timer tx-interval** to restore the default.

Syntax

lldp timer tx-interval *interval*

undo lldp timer tx-interval

Default

The LLDP frame transmission interval is 30 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Sets the LLDP frame transmission interval in the range of 5 to 32768 seconds.

Examples

Set the LLDP frame transmission interval to 20 seconds.

```
<Sysname> system-view
[Sysname] lldp timer tx-interval 20
```

lldp tlv-enable

Use **lldp tlv-enable** to configure the types of advertisable TLVs on a port.

Use **undo lldp tlv-enable** to disable the advertising of the specified types of TLVs on a port.

Syntax

In Layer 2 Ethernet interface view:

- For nearest bridge agents:

lldp tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **port-vlan-id** | **link-aggregation** | **protocol-vlan-id** [*vlan-id*] | **vlan-name** [*vlan-id*] | **management-vid** [*mvlan-id*] } | **dot3-tlv** { **all** | **mac-physic** | **max-frame-size** | **power** } | **med-tlv** { **all** | **capability** | **inventory** | **network-policy** [*vlan-id*] | **power-over-ethernet** | **location-id** { **civic-address** *device-type country-code* { *ca-type ca-value* }&<1-10> | **elin-address** *tel-number* } } }

undo lldp tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **port-vlan-id** | **link-aggregation** | **protocol-vlan-id** | **vlan-name** | **management-vid** } | **dot3-tlv** { **all** | **mac-physic** | **max-frame-size** | **power** } |

med-tlv { **all** | **capability** | **inventory** | **network-policy** [*vlan-id*] | **power-over-ethernet** | **location-id** } }

- For nearest non-TPMR bridge agents:

lldp agent nearest-nontpmr tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **port-vlan-id** | **link-aggregation** } }

lldp tlv-enable dot1-tlv { **protocol-vlan-id** [*vlan-id*] | **vlan-name** [*vlan-id*] | **management-vid** [*mvlan-id*] }

undo lldp agent nearest-nontpmr tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **port-vlan-id** | **link-aggregation** } }

undo lldp tlv-enable dot1-tlv { **protocol-vlan-id** | **vlan-name** | **management-vid** }

- For nearest customer bridge agents:

lldp agent nearest-customer tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **port-vlan-id** | **link-aggregation** } }

lldp tlv-enable dot1-tlv { **protocol-vlan-id** [*vlan-id*] | **vlan-name** [*vlan-id*] | **management-vid** [*mvlan-id*] }

undo lldp agent nearest-customer tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **port-vlan-id** | **link-aggregation** } }

undo lldp tlv-enable dot1-tlv { **protocol-vlan-id** | **vlan-name** | **management-vid** }

In Layer 3 Ethernet interface view:

lldp tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address* | **interface loopback** *interface-number*] } | **dot1-tlv** { **all** | **link-aggregation** } | **dot3-tlv** { **all** | **mac-physic** | **max-frame-size** | **power** } | **med-tlv** { **all** | **capability** | **inventory** | **power-over-ethernet** | **location-id** { **civic-address** *device-type country-code* { *ca-type ca-value* }&<1-10> | **elin-address** *tel-number* } } }

lldp agent { **nearest-nontpmr** | **nearest-customer** } **tlv-enable** { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **link-aggregation** } }

undo lldp tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address* | **interface loopback** *interface-number*] } | **dot1-tlv** { **all** | **link-aggregation** } | **dot3-tlv** { **all** | **mac-physic** | **max-frame-size** | **power** } | **med-tlv** { **all** | **capability** | **inventory** | **power-over-ethernet** | **location-id** } }

undo lldp agent { **nearest-nontpmr** | **nearest-customer** } **tlv-enable** { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **link-aggregation** } }

In Layer 2 aggregate interface view:

lldp agent nearest-nontpmr tlv-enable { **basic-tlv** { **all** | **management-address-tlv** [**ipv6**] [*ip-address*] | **port-description** | **system-capability** | **system-description** | **system-name** } | **dot1-tlv** { **all** | **port-vlan-id** } }

lldp agent nearest-customer tlv-enable { **basic-tlv** { **all** | **management-address-tlv** [**ipv6**] [*ip-address*] | **port-description** | **system-capability** | **system-description** | **system-name** } | **dot1-tlv** { **all** | **port-vlan-id** } }

lldp tlv-enable dot1-tlv { **protocol-vlan-id** [*vlan-id*] | **vlan-name** [*vlan-id*] | **management-vid** [*mvlan-id*] }

undo lldp agent nearest-nontpmr tlv-enable { **basic-tlv** { **all** | **management-address-tlv** [**ipv6**] [*ip-address*] | **port-description** | **system-capability** | **system-description** | **system-name** } | **dot1-tlv** { **all** | **port-vlan-id** } }

undo lldp agent nearest-customer tlv-enable { **basic-tlv** { **all** | **management-address-tlv** [**ipv6**] [*ip-address*] | **port-description** | **system-capability** | **system-description** | **system-name** } | **dot1-tlv** { **all** | **port-vlan-id** } }

undo lldp tlv-enable dot1-tlv { **protocol-vlan-id** | **vlan-name** | **management-vid** }

In Layer 3 aggregate interface view:

lldp agent { **nearest-customer** | **nearest-nontpmr** } **tlv-enable basic-tlv** { **all** | **management-address-tlv** [**ipv6**] [*ip-address*] | **port-description** | **system-capability** | **system-description** | **system-name** }

undo lldp agent { **nearest-customer** | **nearest-nontpmr** } **tlv-enable basic-tlv** { **all** | **management-address-tlv** [**ipv6**] [*ip-address*] | **port-description** | **system-capability** | **system-description** | **system-name** }

Default

On Layer 2 Ethernet interfaces:

- Nearest bridge agents can advertise all types of LLDP TLVs except the following types:
  - Location identification TLVs.
  - Port and protocol VLAN ID TLVs.
  - VLAN name TLVs.
  - Management VLAN ID TLVs.
- Nearest customer bridge agents can advertise basic TLVs and IEEE 802.1 organizationally specific TLVs.

On Layer 3 Ethernet interfaces:

- Nearest bridge agents can advertise all types of LLDP TLVs except network policy TLVs. Among all the 802.1 organizationally specific TLVs, only the link aggregation TLV is supported.
- Nearest non-TPMR bridge agents do not advertise TLVs.
- Nearest customer bridge agents can advertise basic TLVs and IEEE 802.1 organizationally specific TLVs (only link aggregation TLV is supported).

On Layer 2 aggregate interfaces:

- Nearest non-TPMR bridge agents do not advertise any TLVs.

- Nearest customer bridge agents can advertise basic TLVs and IEEE 802.1 organizationally specific TLVs. Among the IEEE 802.1 organizationally specific TLVs, only port and protocol VLAN ID TLVs, VLAN name TLVs, and management VLAN ID TLVs are supported.

On Layer 3 aggregate interfaces:

- Nearest non-TPMR bridge agents do not advertise TLVs.
- Nearest customer bridge agents can advertise only basic TLVs.

context-admin

Parameters

agent: Specifies an LLDP agent type. If you do not specify an agent type in Ethernet interface view, the command configures the types of advertisable TLVs for nearest bridge agents.

nearest-customer: Specifies nearest customer bridge agents.

nearest-nontpmr: Specifies nearest non-TPMR bridge agents.

all: Advertises all TLVs of the specified type. This keyword enables the interface to advertise following TLVs:

- All basic LLDP TLVs if the **all** keyword is specified for **basic-tlv**.
- All IEEE 802.1 organizationally specific LLDP TLVs if the **all** keyword is specified for **dot1-tlv**.
- All IEEE 802.3 organizationally specific LLDP TLVs if the **all** keyword is specified for **dot3-tlv**.
- All LLDP-MED TLVs except location identification TLVs if the **all** keyword is specified for **med-tlv**.

basic-tlv: Advertises basic LLDP TLVs.

management-address-tlv [**ipv6**] [*ip-address* | **interface loopback** *interface-number*]: Advertises management address TLVs. The **ipv6** keyword indicates that the management address to be advertised is in IPv6 format. The *ip-address* argument specifies the management address to be advertised. The **interface loopback** *interface-number* option specifies the management address as the IP address of a loopback interface specified by its number. By default, the following rules apply:

- When you execute the **lldp tlv-enable** command:
  - For a Layer 2 Ethernet or aggregate interface, the IPv4 or IPv6 address of the VLAN interface that meets the following requirements will be advertised as the management address:
    - In up state.
    - The corresponding VLAN ID is the lowest among the VLANs permitted on the interface.

    If you specify the **ipv6** keyword, the IPv6 address of the VLAN interface will be advertised. If you do not specify the **ipv6** keyword, the IPv4 address of the VLAN interface will be advertised.

If none of the VLAN interfaces of the permitted VLANs is assigned an IPv4 or IPv6 address or all VLAN interfaces are down, the MAC address of the interface will be advertised.

- For a Layer 3 Ethernet interface, the IPv4 or IPv6 address of the interface will be advertised when the following conditions exist:
  - The *ip-address* argument is not configured.
  - The specified loopback interface does not have an IPv4 or IPv6 address, or the specified loopback interface does not exist.

  If you specify the **ipv6** keyword, the IPv6 address of the interface will be advertised. If you do not specify the **ipv6** keyword, the IPv4 address of the interface will be advertised.

  If the interface does not have an IPv4 or IPv6 address, the MAC address of the interface will be advertised.
- For a Layer 3 aggregate interface, the IPv4 or IPv6 address of the interface will be advertised when the *ip-address* argument is not configured.

  If you specify the **ipv6** keyword, the IPv6 address of the interface will be advertised. If you do not specify the **ipv6** keyword, the IPv4 address of the interface will be advertised.

  If the interface does not have an IPv4 or IPv6 address, the MAC address of the interface will be advertised.

- For a Layer 2/Layer 3 Ethernet interface or Layer 2/Layer 3 aggregate interface, when you execute the **undo lldp tlv-enable** command:
  - If you do not specify *ip-address*, **ipv6**, or **interface loopback** *interface-number*, the interface does not advertise any management address TLVs.
  - If you specify *ip-address*, **ipv6**, or **interface loopback** *interface-number*, the interface advertises the default management address TLVs.

port-description: Advertises port description TLVs.

system-capability: Advertises system capabilities TLVs.

system-description: Advertises system description TLVs.

system-name: Advertises system name TLVs.

dot1-tlv: Advertises IEEE 802.1 organizationally specific LLDP TLVs.

port-vlan-id: Advertises port VLAN ID TLVs.

protocol-vlan-id [*vlan-id*]: Advertises port and protocol VLAN ID TLVs. The *vlan-id* argument specifies a VLAN ID in the TLVs to be advertised. The VLAN ID is in the range of 1 to 4094, and the default is the lowest VLAN ID on the port.

vlan-name [*vlan-id*]: Advertises VLAN name TLVs. The *vlan-id* argument specifies a VLAN ID in the TLVs to be advertised. The VLAN ID is in the range of 1 to 4094, and the default is the lowest VLAN ID on the port. If you do not specify a VLAN ID and the port is not assigned to any VLAN, the PVID of the port is advertised.

management-vid [*mvlan-id*]: Advertises management VLAN ID TLVs. The m*vlan-id* argument specifies a management VLAN ID in the TLVs to be advertised. The management VLAN ID is in the range of 1 to 4094. If you do not specify this option, the value 0 is advertised, which means that the LLDP agent is not configured with a management VLAN ID.

link-aggregation: Advertises link aggregation TLVs.

dot3-tlv: Advertises IEEE 802.3 organizationally specific LLDP TLVs.

mac-physic: Advertises MAC/PHY configuration/status TLVs.

max-frame-size: Advertises maximum frame size TLVs.

power: Advertises power in MDI TLVs and power stateful control TLVs.

med-tlv: Advertises LLDP-MED TLVs.

capability: Advertises LLDP-MED capabilities TLVs.

inventory: Advertises the following TLVs: hardware revision, firmware revision, software revision, serial number, manufacturer name, model name, and asset ID.

location-id: Advertises location identification TLVs.

civic-address: Inserts the typical address information about the network device in location identification TLVs .

device-type: Sets a device type value in the range of 0 to 2:

- Value 0 specifies a DHCP server.
- Value 1 specifies a network device.
- Value 2 specifies an LLDP-MED endpoint.

country-code: Sets a country code defined in ISO 3166.

{ *ca-type ca-value* }&<1-10>: Configures address information. *ca-type* represents the address information type in the range of 0 to 255. *ca-value* represents address information, a string of 1 to 250 characters. &<1-10> indicates that you can specify up to 10 *ca-type ca-value* pairs.

elin-address: Inserts telephone numbers for emergencies in location identification TLVs.

tel-number: Sets the telephone number for emergencies, a string of 10 to 25 characters.

network-policy [*vlan-id*]: Advertises network policy TLVs. The *vlan-id* argument specifies the VLAN ID to be advertised, in the range of 1 to 4094.

power-over-ethernet: Advertises extended power-via-MDI TLVs.

Usage guidelines

Nearest bridge agents are not supported on aggregate interfaces.

You can enable the device to advertise multiple types of TLVs by using this command without the **all** keyword specified.

If the MAC/PHY configuration/status TLV is not advertisable, none of the LLDP-MED TLVs will be advertised whether or not they are advertisable. If the LLDP-MED capabilities TLV is not advertisable, the other LLDP-MED TLVs will not be advertised regardless of whether or not they are advertisable.

The port and protocol VLAN ID, VLAN name, and management VLAN ID TLVs in IEEE 802.1 organizationally specific LLDP TLVs can be configured only for nearest bridge agents. The configuration can be inherited by nearest customer bridge agents and nearest non-TPMR bridge agents.

Examples

Enable the nearest customer bridge agents on GigabitEthernet 1/0/1 to advertise link aggregation TLVs of the IEEE 802.1 organizationally specific TLVs.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] lldp agent nearest-customer tlv-enable dot1-tlv
link-aggregation
```

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify this option, the command displays Layer 2 forwarding statistics on all interfaces.

Examples

Display Layer 2 forwarding statistics on all interfaces.

```
<Sysname> display mac-forwarding statistics
Input:
   Sum:               888        Unknown Unicast:   0
   Broadcast:         0          Multicast:         0
   Filtered:          0          STP discarded:     0
   Service dropped:   0          Source dropped:    0
   Unknown dropped: 0          Learning dropped:  0
   Blackhole dropped: 0          Suppress dropped:  0
   Source MAC dropped:0
Deliver:
   Sum:               111        L2 protocol:       11
   Local MAC address: 100
Output:
   Sum:               666        Filtered:          0
   Blackhole dropped: 0          STP discarded:     0
   Service dropped:   0          Dest MAC dropped:  0
```

Display Layer 2 forwarding statistics on GigabitEthernet 1/0/1.

```
<Sysname> display mac-forwarding statistics interface gigabitethernet 1/0/1
GigabitEthernet1/0/1:
Input frames: 100    Output frames:100
```

```
Filtered:     0
```

Table 1 Command output

Field	Description
Input	Inbound Ethernet frame statistics. • **Sum**—Total number of received Ethernet frames. • **Filtered**—Number of Ethernet frames filtered out by 802.1Q VLAN inbound filtering rules. • **STP discarded**—Number of inbound Ethernet frames dropped on the ports blocked by STP. • **Service dropped**—Number of Ethernet frames dropped by inbound service features. • **Source dropped**—Number of Ethernet frames dropped because their source MAC addresses are all-zeros, multicast, or broadcast MAC addresses. • **Unknown dropped**—Number of Ethernet frames dropped because the device is disabled from forwarding frames with unknown source MAC addresses. • **Learning dropped**—Number of Ethernet frames dropped because the device is disabled from forwarding unknown frames after the number of learned MAC addresses reaches the upper limit. • **Suppress dropped**—Number of Ethernet frames dropped by storm suppression. • **Broadcast**—Number of received broadcast Ethernet frames. • **Multicast**—Number of received multicast Ethernet frames. • **Unknown unicast**—Number of received unknown unicast Ethernet frames. • **Blackhole dropped**—Number of Ethernet frames dropped because they are sourced from blackhole MAC addresses. • **Source MAC dropped**—Number of Ethernet frames dropped by features based on the source MAC addresses.
Deliver	Statistics of Ethernet frames delivered to the CPU. • **Sum**—Total number of Ethernet frames delivered to the CPU. • **L2 protocol**—Number of Layer 2 protocol Ethernet frames delivered to the CPU. • **Local MAC address**—Number of Ethernet frames that use the MAC addresses of local Layer 3 VLAN interfaces as the destination MAC addresses.
Output	Outbound Ethernet frame statistics. • **Sum**—Total number of sent Ethernet frames. • **Filtered**—Number of Ethernet frames filtered out by 802.1Q VLAN outbound filtering rules. • **Blackhole dropped**—Number of Ethernet frames dropped because they are destined for blackhole MAC addresses. • **STP discarded**—Number of outbound Ethernet frames dropped on the ports blocked by STP. • **Service dropped**—Number of Ethernet frames dropped by outbound service features. • **Dest MAC dropped**—Number of Ethernet frames dropped by features based on the destination MAC addresses.
GigabitEthernet1/0/1	Layer 2 forwarding statistics on GigabitEthernet 1/0/1: • **Input frames**—Number of Ethernet frames received on the interface. • **Output frames**—Number of Ethernet frames sent out of the interface. • **Filtered**—Number of Ethernet frames filtered out because they are from other VLANs.

context-operator

Parameters

ip-address: Specifies an IPv4 address. If you do not specify an IPv4 address, this command displays all IPv4 fast forwarding entries.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv4 fast forwarding entries for all member devices.

Examples

Display all IPv4 fast forwarding entries.

```
<Sysname> display mac-forwarding cache ip
Total number of mac-forwarding entries: 2
SIP            SPort DIP             DPort Pro Input_If    Output_If   VLAN
```

```
1.1.1.2         99    1.1.1.1         2048  1   GE1/0/1     GE1/0/2     2
1.1.1.1         98    1.1.1.2         2012  1   GE1/0/2     GE1/0/1     2
```

Table 2 Command output

Field	Description
Total number of mac-forwarding entries	Total number of IPv4 fast forwarding entries.
SIP	Source IPv4 address.
SPort	Source port number.
DIP	Destination IPv4 address.
DPort	Destination port number.
Pro	Protocol number.
Input_If	Input interface type and number. If no input interface is involved in fast forwarding, this field displays **N/A**. If no input interface is available, this field displays a hyphen (-).
Output_If	Output interface type and number. If no output interface is involved in fast forwarding, this field displays **N/A**. If no output interface is available, this field displays a hyphen (-).
VLAN	VLAN ID.

display mac-forwarding cache ip fragment

Use **display mac-forwarding cache ip fragment** to display IPv4 fast forwarding entries for fragments.

Syntax

display mac-forwarding cache ip fragment [*ip-address*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ip-address: Specifies an IPv4 address. If you do not specify an IPv4 address, this command displays IPv4 fast forwarding entries for all fragments.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv4 fast forwarding entries for fragments on all member devices.

Examples

Display IPv4 fast forwarding entries for all fragments.

```
<Sysname> display mac-forwarding cache ip fragment
Total number of fragment mac-forwarding entries: 2
SIP             SPort DIP             DPort Pro Input_If    ID     VLAN
1.1.1.1         117   1.1.1.2         0     1   GE1/0/1     2828   1
1.1.1.2         110   1.1.1.1         67    17  GE1/0/2     2322   1
```

Table 3 Command output

Field	Description
Total number of fragment mac-forwarding entries	Total number of IPv4 fast forwarding entries for fragments.
SIP	Source IPv4 address.
SPort	Source port number.
DIP	Destination IPv4 address.
DPort	Destination port number.
Pro	Protocol number.
Input_If	Input interface type and number. If no input interface is involved in fast forwarding, this field displays **N/A**. If no input interface is available, this field displays a hyphen (-).
ID	Fragment ID.
VLAN	VLAN ID.

display mac-forwarding cache ipv6

Use **display mac-forwarding cache ipv6** to display IPv6 fast forwarding entries.

Syntax

display mac-forwarding cache ipv6 [*ipv6-address*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ipv6-address: Specifies an IPv6 address. If you do not specify an IPv6 address, this command displays all IPv6 fast forwarding entries.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv6 fast forwarding entries for all member devices.

Examples

Display all IPv6 fast forwarding entries.

```
<Sysname> display mac-forwarding cache ipv6
Total number of IPv6 mac-forwarding items: 1
Src IP: 2002::1                                         Src port: 129
Dst IP: 2001::1                                         Dst port: 65535
VLAN ID: 2
Protocol: 2
Input interface: GE1/0/2
Output interface: GE1/0/1
```

Table 4 Command output

Field	Description
Total number of IPv6 mac-forwarding items	Total number of IPv6 fast forwarding entries.
Src IP	Source IPv6 address.
Src port	Source port number.
Dst IP	Destination IPv6 address.
Dst Port	Destination port number.
Protocol	Protocol number.
Input interface	Input interface type and number. If no input interface is involved in fast forwarding, this field displays **N/A**. If no input interface is available, this field displays a hyphen (-).
Output interface	Output interface type and number. If no output interface is involved in fast forwarding, this field displays **N/A**. If no output interface is available, this field displays a hyphen (-).

mac fast-forwarding check-vlan-id

Use **mac fast-forwarding check-vlan-id** to enable VLAN ID check for fast Layer 2 forwarding.

Use **undo mac fast-forwarding check-vlan-id** to disable VLAN ID check for fast Layer 2 forwarding.

Syntax

mac fast-forwarding check-vlan-id

undo mac fast-forwarding check-vlan-id

Default

VLAN ID check is enabled for fast Layer 2 forwarding.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature allows the device to check whether the VLAN ID of a flow matches that of any fast forwarding entry. If no match is found, the flow does not match any fast forwarding entry.

The VLAN ID of a packet helps the device to determine the TCP session to which the packet belongs. On a hot backup system formed by two firewalls, you must disable VLAN ID check if the traffic incoming interfaces on the primary and secondary devices belong to different VLANs. If you enable VLAN ID check, traffic cannot match session entries correctly when asymmetric-path traffic exists.

Examples

Enable VLAN ID check for fast Layer 2 forwarding.

```
<Sysname> system-view
[Sysname] mac fast-forwarding check-vlan-id
```

Bridge forwarding commands

add interface

Use **add interface** to add an interface to a reflect-type, forward-type, or blackhole-type bridge instance.

Use **undo add interface** to remove an interface from a reflect-type, forward-type, or blackhole-type bridge instance.

Syntax

add interface *interface-type interface-number*

undo add interface *interface-type interface-number*

Default

No interfaces exist in a reflect-type, forward-type, or blackhole-type bridge instance.

Views

Reflect-type bridge view

Forward-type bridge view

Blackhole-type bridge view

Predefined user roles

network-admin

context-admin

Parameters

interface-type interface-number: Specifies an interface by its type and number.

Usage guidelines

You can add only Layer 2 physical interfaces, Layer 3 physical interfaces, or Layer 2 aggregate interfaces to reflect-type, forward-type, or blackhole-type bridge instances.

Only one interface can be added to a reflect-type or blackhole-type bridge instance.

Only two interfaces can be added to a manually created forward-type bridge instance. The two interfaces must be the same type.

Each interface can be added to only one bridge instance.

This command is not available for a forward-type bridge instance that is automatically created upon insertion of a hardware bypass subcard. An automatically created forward-type bridge instance uses the pair of interfaces on the bypass subcard by default and you cannot edit the interfaces in the instance.

If you execute this command multiple times in reflect-type or blackhole-type bridge view, the most recent configuration takes effect.

If you execute this command multiple times in forward-type bridge view, the most recent two configurations take effect.

Examples

Add GigabitEthernet 1/0/1 to reflect-type bridge instance 1.

```
<Sysname> system-view
[Sysname] bridge 1 reflect
[Sysname-bridge1-reflect] add interface gigabitethernet 1/0/1
```

add vlan

Use **add vlan** to add a list of VLANs to an inter-VLAN bridge instance.

Use **undo add vlan** to remove VLANs from an inter-VLAN bridge instance.

Syntax

add vlan *vlan-id-list*

undo add vlan [*vlan-id-list*]

Default

No VLANs exist in an inter-VLAN bridge instance.

Views

Inter-VLAN bridge view

Predefined user roles

network-admin

context-admin

Parameters

vlan-id-list: Specifies a space-separated list of up to 10 VLAN items. Each VLAN item specifies a VLAN ID or a range of VLAN IDs in the form of *start-vlan-id* **to** *end-vlan-id*. The end VLAN ID must be greater than the start VLAN ID. Valid VLAN IDs are from 1 to 4094.

Usage guidelines

You can add VLANs to a bridge instance before or after you create the VLANs.

You can add a VLAN to only one bridge instance.

If you execute the command multiple times, all configurations take effect.

If you do not specify the *vlan-id-list* argument, the **undo add vlan** command removes all VLANs from the inter-VLAN bridge instance.

Examples

Add VLANs 2, 3, 5, and VLANs 50 through 70 to bridge instance 2.

```
<Sysname> system-view
[Sysname] bridge 2 inter-vlan
[Sysname-bridge2-inter-vlan] add vlan 2 3 5 50 to 70
```

bridge

Use **bridge** to create a specific type of bridge instance and enter its view, or enter the view of an existing bridge instance.

Use **undo bridge** to delete bridge instances.

Syntax

bridge *bridge-index* [**blackhole** | **forward** | **inter-vlan** | **reflect**]

undo bridge { *bridge-index* | **all** }

Default

No bridge instances exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

bridge-index: Specifies a bridge instance index. For an automatically created forward-type bridge instance, the system will assign an index in the range of 32768 to 1082400.

The following compatibility matrixes show the value ranges for the *bridge-index* argument for a manually created bridge instance:

Models	Value range
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	1 to 128

blackhole: Specifies a blackhole-type bridge instance.

forward: Specifies a forward-type bridge instance.

inter-vlan: Specifies an inter-VLAN bridge instance.

reflect: Specifies a reflect-type bridge instance.

all: Deletes all bridge instances.

Usage guidelines

Use this command to create a bridge instance. You can create reflect-type, forward-type, and blackhole-type bridge instances for inline forwarding.

When you create a bridge instance, you must specify its type. You can specify only one type for a bridge instance.

The device will automatically create a forward-type bridge instance upon insertion of a hardware bypass subcard. The automatically created forward-type bridge instance uses the pair of interfaces on the bypass subcard by default. You cannot edit the interfaces in the bridge instance or delete the bridge instance.

Examples

Create blackhole-type bridge instance 1 and enter its view.

```
<Sysname> system-view
[Sysname] bridge 1 blackhole
[Sysname-bridge1-blackhole]
```

Create forward-type bridge instance 2 and enter its view.

```
<Sysname> system-view
[Sysname] bridge 2 forward
[Sysname-bridge2-forward]
```

Create inter-VLAN bridge instance 3 and enter its view.

```
<Sysname> system-view
[Sysname] bridge 3 inter-vlan
[Sysname-bridge3-inter-vlan]
```

Create reflect-type bridge instance 4 and enter its view.

```
<Sysname> system-view
[Sysname] bridge 4 reflect
[Sysname-bridge4-reflect]
```

bridge mac-address timer aging

Use **bridge mac-address timer aging** to set the aging timer for dynamic MAC address entries in bridge instances.

Use **undo bridge** to restore the default.

Syntax

bridge mac-address timer aging *seconds*

undo bridge mac-address timer aging

Default

The aging timer for dynamic MAC address entries is 300 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies a MAC address aging timer, in seconds. The value range is 60 to 1440.

Usage guidelines

Follow these guidelines to set the aging timer appropriately:

- A long aging interval causes the MAC address table to retain outdated entries and fail to accommodate the most recent network changes.

- A short aging interval results in removal of valid entries. Then, unnecessary broadcast packets appear and affect device performance.

After you set an aging time for dynamic MAC address entries, the device automatically deletes the expired dynamic MAC address entries. Then, the device learns new MAC addresses to build new MAC address entries.

Examples

Set the aging timer to 500 seconds for dynamic MAC address entries.

```
<Sysname> system-view
[Sysname] bridge mac-address timer aging 500
```

bridge tunnel-encapsulation skip

Use **bridge tunnel-encapsulation skip** to configure the device to ignore the tunnel encapsulation when forwarding tunneled packets in inline mode.

Use **undo bridge tunnel-encapsulation skip** to restore the default.

Syntax

bridge tunnel-encapsulation skip

undo bridge tunnel-encapsulation skip

Default

In inline forwarding mode, tunneled packets are forwarded based on information in the tunnel encapsulation.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command takes effect only for inline forwarding.

In inline forwarding mode, tunneled packets are forwarded based on information in the tunnel encapsulation by default.

Use this command to enable the device to ignore the tunnel encapsulation and forward tunneled packets based on the original packet header information.

Examples

Configure the device to ignore the tunnel encapsulation when forwarding tunneled packets in inline mode.

```
<Sysname> system-view
[Sysname] bridge tunnel-encapsulation skip
```

bypass enable

Use **bypass enable** to enable internal security service bypass.

Use **undo bypass enable** to disable security service bypass.

Syntax

bypass enable

undo bypass enable

Default

Security service bypass is disabled.

Views

Reflect-type bridge view

Forward-type bridge view

Blockhole-type bridge view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the device to bypass the security service and to directly process received packets according to the configured bridge forwarding mode.

If you configure the **bypass enable** command multiple times, the most recent configuration takes effect.

Examples

Enable internal security service bypass.

```
<Sysname> system-view
[Sysname] bridge 1 forward
[Sysname-bridge-1-forward] bypass enable
```

display bridge mac-address

Use **display bridge mac-address** to display MAC address entries in bridge instances.

Syntax

display bridge mac-address [*bridge-index* [**vlan** *vlan-id*]] [**count**] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

bridge-index: Specifies a bridge instance by its index.

vlan *vlan-id*: Specifies a VLAN by its ID.

count: Displays only the total number of MAC address entries that match all entry attributes you specify in this command. In this case, the detailed information about MAC address entries is not

displayed. For example, you can use the **display bridge mac-address 2 vlan 20 count** command to display the total number of entries for VLAN 20 in bridge instance 2. If you do not specify this keyword, this command displays detailed information about specified MAC address entries.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays MAC address entries for the master device.

Usage guidelines

If you do not specify any parameters, this command displays MAC address entries for all bridge instances.

This command displays dynamic MAC address entries because the MAC address entries in a bridge instance are all learned MAC addresses.

Examples

Display MAC address entries for bridge instance 100.

```
<Sysname> display bridge mac-address 100
MAC Address      BRIDGE ID  State        VLAN ID  Port            Aging
0033-0033-0033   100        Learned      44       GE1/0/1         Y
0000-0000-0002   100        Learned      66       GE1/0/2         Y
```

Display the number of MAC address entries in bridge instance 100.

```
<Sysname> display bridge mac-address 100 count
1 mac address(es) found.
```

Table 5 Command output

Field	Description
BRIDGE ID	Index of the bridge instance to which the MAC address entry belongs.
State	MAC address entry state: **Learned**.
VLAN ID	VLAN of the outgoing interface.
Port	Outgoing interface.
Aging	Whether the entry can age out: • **Y**—The entry can age out. • **N**—The entry never ages out.
1 mac address(es) found	Number of matching MAC address entries.

mac-address max-mac-count

Use **mac-address max-mac-count** to set the MAC learning limit on an inter-VLAN bridge instance.

Use **undo mac-address max-mac-count** to restore the default.

Syntax

mac-address max-mac-count *count*

undo mac-address max-mac-count

Default

The MAC learning limit is 4096 on an inter-VLAN bridge instance.

Views

Inter-VLAN bridge view

Predefined user roles

network-admin

context-admin

Parameters

count: Sets the maximum number of MAC addresses that can be learned on an inter-VLAN bridge instance. The value range for this argument is 0 to 4096. To prevent an inter-VLAN bridge instance from learning any MAC addresses, set the limit to 0 for the bridge instance.

Usage guidelines

The command sets the size of the inter-VLAN bridge forwarding MAC address table. When the number of MAC address entries learned by an inter-VLAN bridge instance reaches the limit, the bridge instance stops learning MAC address entries.

Examples

Configure inter-VLAN bridge instance 2 to learn a maximum of 10 MAC address entries.

```
<Sysname> system-view
[Sysname] bridge 2 inter-vlan
[Sysname-bridge2-inter-vlan] mac-address max-mac-count 10
```

Fast bridge forwarding commands

bridge fast-forwarding check-vlan-id

Use **bridge fast-forwarding check-vlan-id** to enable VLAN ID check for fast bridge forwarding.

Use **undo bridge fast-forwarding check-vlan-id** to disable VLAN ID check for fast bridge forwarding.

Syntax

bridge fast-forwarding check-vlan-id

undo bridge fast-forwarding check-vlan-id

Default

VLAN ID check is enabled for fast bridge forwarding.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature allows the device to check whether the VLAN ID of a flow matches that of any fast forwarding entry. If no match is found, the flow does not match any fast forwarding entry.

The VLAN ID of a packet helps the device to determine the TCP session to which the packet belongs. On a hot backup system formed by two firewalls, you must disable VLAN ID check if the traffic

incoming interfaces on the primary and secondary devices belong to different VLANs. If you enable VLAN ID check, traffic cannot match session entries correctly when asymmetric-path traffic exists.

On a hot backup system formed by two firewalls, inter-VLAN fast bridge forwarding enables a packet to match the same session after being transmitted between the primary and secondary devices. Because the device does not check VLAN IDs for inter-VLAN fast bridge forwarding. That is, this command does not take effect on inter-VLAN fast bridge forwarding.

Examples

Enable VLAN ID check for fast bridge forwarding.

```
<Sysname> system-view
[Sysname] bridge fast-forwarding check-vlan-id
```

display bridge cache ip

Use **display bridge cache ip** to display IPv4 fast bridge forwarding entries.

Syntax

display bridge cache ip { **inline** | **inter-vlan** } [*ip-address*] [**slot** *slot-number*]

Views

Any view

network-operator

context-admin

context-operator

Parameters

inline: Displays IPv6 inline forwarding entries.

inter-vlan: Displays IPv6 inter-VLAN forwarding entries.

ipv6-address: Specifies an IPv6 address. If you do not specify an IPv6 address, this command displays all IPv6 fast bridge forwarding entries.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv6 fast bridge forwarding entries for all member devices.

Examples

Display IPv6 inline fast bridge forwarding entries.

```
<Sysname> display bridge cache ipv6 inline
Total number of IPv6 bridge-forwarding items: 1
Src IP: 10::12                                  Src Port: 427
Dst IP: 10::11                                  Dst Port: 32768
```

```
InVLAN: 2                                        OutVLAN: 3
Protocol: 58
Context ID: 257
Bridge ID: 10
Output interface: GE1/0/1
```

Table 8 Command output

Field	Description
Total number of IPv6 bridge-forwarding items	Total number of IPv6 fast bridge forwarding entries.
Src IP	Source IPv6 address.
Src port	Source port number.
Dst IP	Destination IPv6 address.
Dst Port	Destination port number.
InVLAN	Input VLAN.
OutVLAN	Output VLAN.
Protocol	Protocol number.
Context ID	Context ID.
Output interface	Output interface type and number. If no output interface is involved in fast forwarding, this field displays **N/A**. If no output interface is available, this field displays a hyphen (-).

NSFOCUS Firewall Series

NF Layer 2—WAN Access Command Reference

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

This command reference describes the commands for configuring Layer 2 WAN access features, including PPP and Mobile communication modem.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

PPP commands

PPP commands

bandwidth

Use **bandwidth** to set the expected bandwidth of an interface.

Use **undo bandwidth** to restore the default.

Syntax

bandwidth *bandwidth-value*

undo bandwidth

Default

The expected bandwidth (in kbps) is the interface baud rate divided by 1000.

Views

VT interface view

Predefined user roles

network-admin

context-admin

Parameters

bandwidth-value: Specifies the expected bandwidth in the range of 1 to 400000000 kbps.

Usage guidelines

The expected bandwidth of an interface affects the link costs in OSPF, OSPFv3, and IS-IS. For more information, see *Layer 3—IP Routing Configuration Guide*.

Examples

Set the expected bandwidth of Virtual-Template 10 to 1000 kbps.

```
<Sysname> system-view
[Sysname] interface virtual-template 10
[Sysname-Virtual-Template10] bandwidth 1000
```

default

Use **default** to restore the default settings for an interface.

Syntax

default

Views

VT interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

CAUTION:

The **default** command might interrupt ongoing network services. Make sure you are fully aware of the impact of this command before using it on a live network.

This command might fail to restore the default settings for some commands for reasons such as command dependencies or system restrictions. Use the **display this** command in interface view to identify these commands. Use the **undo** forms of these commands or follow the command reference to individually restore their default settings. If your restoration attempt still fails, follow the error message instructions to resolve the problem.

Examples

Restore the default settings of Virtual-Template 10.

```
<Sysname> system-view
[Sysname] interface virtual-template 10
[Sysname-Virtual-Template10] default
```

description

Use **description** to set the description for an interface.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

The description for an interface is *interface name* **Interface** (for example, **Virtual-Template1 Interface**).

Views

VT interface view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies the interface description, a case-sensitive string of 1 to 255 characters.

Examples

Set the description for Virtual-Template 10 to **virtual-interface**.

```
<Sysname> system-view
[Sysname] interface virtual-template 10
[Sysname-Virtual-Template10] description virtual-interface
```

display interface virtual-access

Use **display interface virtual-access** to display information about VA interfaces.

Syntax

display interface [**virtual-access** [*interface-number*]] [**brief** [**description** | **down**]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

virtual-access [*interface-number*]: Specifies an existing VA interface by its number. If you do not specify the **virtual-access** keyword, the command displays information about all interfaces except VA interfaces on the device. If you specify the **virtual-access** keyword without the *interface-number* argument, the command displays information about all VA interfaces.

brief: Displays brief interface information. If you do not specify this keyword, the command displays detailed interface information.

description: Displays interface description information. This keyword does not apply to VA interfaces because VA interfaces do not support description configuration.

down: Displays information about interfaces in physically down state and the causes. If you do not specify this keyword, the command displays information about all interfaces.

Examples

Display information about Virtual-Access 1.

```
<Sysname> display interface virtual-access 1
Virtual-Access1
Current state: UP
Line protocol state: UP
Description: Virtual-Access1 Interface
Bandwidth: 1920kbps
Maximum transmission unit: 1500
Hold timer: 10 seconds, retry times: 5
Internet address: 122.1.1.1/24 (primary)
Link layer protocol: PPP
LCP: opened, IPCP: opened
Main interface: Virtual-Template1
Output queue - Urgent queuing: Size/Length/Discards 0/100/0
Output queue - Protocol queuing: Size/Length/Discards 0/500/0
Output queue - FIFO queuing: Size/Length/Discards 0/75/0
Last link flapping: Never
Last clearing of counters: Never
Last 300 seconds input rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Last 300 seconds output rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Input: 2 packets, 24 bytes, 0 drops
Output: 2 packets, 24 bytes, 0 drops
```

Display brief information about Virtual-Access 1.

```
<Sysname> display interface virtual-access 1 brief
Brief information on interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Protocol: (s) - spoofing
Interface            Link Protocol Primary IP         Description
VA1                  DOWN DOWN     --
```

Display brief information about VA interfaces in physically down state and the causes.

```
<Sysname> display interface virtual-access brief down
Brief information on interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Interface            Link Cause
VA1                  DOWN Not connected
```

Table 1 Command output

Field	Description
Current state	Physical and administrative states of the interface: • **DOWN**—The interface is administratively up but physically down. • **UP**—The interface is both administratively and physically up.
Line protocol state	Data link layer state: UP or DOWN.
Description	Interface description.
Bandwidth	Expected bandwidth of the interface.
Hold timer	Interval at which the interface sends keepalive packets.
retry times	Keepalive retry limit. The interface determines that its peer has been down if it does not receive a keepalive response when the keepalive retry limit is reached.
Internet protocol processing: Disabled	The interface cannot process IP packets currently.
Internet address: *ip-address*/*mask-length* (*Type*)	IP address of the interface and type of the address in parentheses. Possible IP address types include: • **Primary**—Manually configured primary IP address. • **Sub**—Manually configured secondary IP address. If the interface has both primary and secondary IP addresses, the primary IP address is displayed. If the interface has only secondary IP addresses, the lowest secondary IP address is displayed. • **DHCP-allocated**—DHCP allocated IP address. For more information, see DHCP client configuration in *Layer 3—IP Services Configuration Guide*. • **BOOTP-allocated**—BOOTP allocated IP address. For more information, see BOOTP client configuration in *Layer 3—IP Services Configuration Guide*. • **PPP-negotiated**—IP address assigned by a PPP server during PPP negotiation. For more information, see PPP configuration in *Layer 2—WAN Access Configuration Guide*. • **Unnumbered**—IP address borrowed from another interface. • **Cellular-allocated**—IP address allocated through the modem-manufacturer's proprietary protocol. For more information, see mobile communication modem management in *Layer 2—WAN Access Configuration Guide*.

Field	Description
	• **MAD**—IP address assigned to an IRF member device for MAD on the interface. For more information, see IRF configuration in *Virtual Technologies Configuration Guide*.
LCP: opened, IPCP: opened	The PPP connection has been successfully established.
Main interface	VT interface associated with the VA interface.
Output queue - Urgent queuing: Size/Length/Discards 0/100/0 Output queue - Protocol queuing: Size/Length/Discards 0/500/0 Output queue - FIFO queuing: Size/Length/Discards 0/75/0	Traffic statistics of the interface output queues.
Last link flapping	The amount of time that has elapsed since the most recent physical state change of the interface. This field displays **Never** if the interface has been physically down since device startup.
Last clearing of counters: Never	Last time when statistics on the interface were cleared. **Never** indicates that statistics on the interface were never cleared.
Last 300 seconds input rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec Last 300 seconds output rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec	Average rate of input packets and output packets in the last 300 seconds.
Input: 2 packets, 24 bytes, 0 drops	Total number of inbound packets of the interface (in the number of packets and in bytes), and the number of packets dropped among the inbound packets.
Output: 2 packets, 24 bytes, 0 drops	Total number of outbound packets of the interface (in the number of packets and in bytes), and the number of packets dropped among the outbound packets.
Brief information on interfaces in route mode	Brief information about Layer 3 interfaces.
Link: ADM - administratively down; Stby - standby	Link status: • **ADM**—The interface has been administratively shut down. To recover its physical state, execute the **undo shutdown** command. • **Stby**—The interface is a backup interface. To see the primary interface, use the **display interface-backup state** command in *High Availability Command Reference*.
Protocol: (s) - spoofing	Indicates the line protocol is UP, but the physical link is an on-demand link or is not present.
Interface	Abbreviated interface name.
Link	Physical link state of the interface: • **UP**—The interface is physically up. • **DOWN**—The interface is physically down.
Protocol	Line protocol state: • **UP**—The line protocol is up. • **DOWN**—The line protocol is down. • **UP(s)**—The line protocol is up, but the physical link is an on-demand link or is not present.
Primary IP	Primary IP address of the interface.
Description	Interface description configured by using the **description** command. This field does not apply to VA interfaces because VA

Field	Description
	interfaces do not support description configuration.
Cause	Cause for the physical state of the interface to be Down. **Not connected** indicates no physical link exists (possibly because the network cable is disconnected or faulty).

Related commands

display interface virtual-template

Use **display interface virtual-template** to display information about VT interfaces.

Syntax

display interface [**virtual-template** [*interface-number*]] [**brief** [**description** | **down**]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

virtual-template [*interface-number*]: Specifies an existing VT interface by its number. If you do not specify the **virtual-template** keyword, the command displays information about all interfaces except VA interfaces on the device. If you specify the **virtual-template** keyword without the *interface-number* argument, the command displays information about all existing VT interfaces.

brief: Displays brief interface information. If you do not specify this keyword, the command displays detailed interface information.

description: Displays complete interface description. If you do not specify this keyword, the command displays only the first 27 characters of the interface description if the description contains more than 27 characters.

down: Displays information about interfaces in physically down state and the causes. If you do not specify this keyword, the command displays information about all interfaces.

Examples

Display detailed information about Virtual-Template 1.

```
<Sysname> display interface virtual-template 1
Virtual-Template1
Current state: DOWN
Line protocol state: DOWN
Description: Virtual-Template1 Interface
Bandwidth: 100000kbps
Maximum transmission unit: 1500
Hold timer: 10 seconds, retry times: 5
```

```
Internet address: 192.168.1.200/24 (primary)
Link layer protocol: PPP
LCP: initial
Physical: None, baudrate: 100000000 bps
Output queue - Urgent queuing: Size/Length/Discards 0/100/0
Output queue - Protocol queuing: Size/Length/Discards 0/500/0
Output queue - FIFO queuing: Size/Length/Discards 0/75/0
```

Display brief information about Virtual-Template 1.

```
<Sysname> display interface virtual-template 1 brief
Brief information on interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Protocol: (s) - spoofing
Interface            Link Protocol Primary IP       Description
VT1                  DOWN DOWN     --
```

Display brief information about the VT interfaces in physically down state and the causes.

```
<Sysname> display interface Virtual-Template brief down
Brief information on interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Interface            Link Cause
VT0                  DOWN Not connected
VT12                 DOWN Not connected
VT1023               DOWN Not connected
```

Table 2 Command output

Field	Description
Current state	Physical state of the interface. This field for a VT interface can only be **DOWN**.
Line protocol state	Data link layer state. This field for a VT interface can only be **DOWN**.
Description	Interface description.
Bandwidth	Expected bandwidth of the interface.
Hold timer	Interval at which the interface sends keepalive packets.
retry times	Keepalive retry limit. The interface determines that its peer has been down if it does not receive a keepalive response when the keepalive retry limit is reached.
Internet protocol processing: Disabled	The interface cannot process IP packets currently.
Internet address: *ip-address*/*mask-length* (*Type*)	IP address of the interface and type of the address in parentheses. Possible IP address types include: • **Primary**—Manually configured primary IP address. • **Sub**—Manually configured secondary IP address. If the interface has both primary and secondary IP addresses, the primary IP address is displayed. If the interface has only secondary IP addresses, the lowest secondary IP address is displayed. • **DHCP-allocated**—DHCP allocated IP address. For more information, see DHCP client configuration in *Layer 3—IP Services Configuration Guide*. • **BOOTP-allocated**—BOOTP allocated IP address. For more

Field	Description
	information, see BOOTP client configuration in *Layer 3—IP Services Configuration Guide*. • **PPP-negotiated**—IP address assigned by a PPP server during PPP negotiation. For more information, see PPP configuration in *Layer 2—WAN Access Configuration Guide*. • **Unnumbered**—IP address borrowed from another interface. • **Cellular-allocated**—IP address allocated through the modem-manufacturer's proprietary protocol. For more information, see mobile communication modem management in *Layer 2—WAN Access Configuration Guide*. • **MAD**—IP address assigned to an IRF member device for MAD on the interface. For more information, see IRF configuration in *Virtual Technologies Configuration Guide*.
LCP initial	LCP initialization is complete.
Physical	Physical type of the interface.
Output queue - Urgent queuing: Size/Length/Discards 0/100/0) Output queue - Protocol queuing: Size/Length/Discards 0/500/0) Output queue - FIFO queuing: Size/Length/Discards 0/75/0)	Traffic statistics of the interface output queues.
Brief information on interfaces in route mode	Brief information about Layer 3 interfaces.
Link: ADM - administratively down; Stby - standby	Link status: • **ADM**—The interface has been administratively shut down. To recover its physical state, use the **undo shutdown** command. • **Stby**—The interface is operating as a backup interface. To see the primary interface, use the **display interface-backup state** command in *High Availability Command Reference*.
Protocol: (s) - spoofing	Indicates the line protocol is UP, but the physical link is an on-demand link or is not present.
Interface	Abbreviated interface name.
Link	Physical link state of the interface. This field for a VT interface can only be **DOWN**.
Protocol	Line protocol state of the interface. This field for a VT interface can only be **DOWN**.
Primary IP	Primary IP address of the interface.
Description	Interface description configured by using the **description** command. If you do not specify the **description** keyword, the **display interface brief** command displays a maximum of 27 characters of the description. If you specify the **description** keyword, the command displays the complete description.
Cause	Causes for the physical state of the interface to be Down. **Not connected** indicates no physical link exists (possibly because the network cable is disconnected or faulty).

display ip pool

Use **`display ip pool`** to display PPP address pools.

Syntax

display ip pool [*pool-name* | **group** *group-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

pool-name: Specifies a PPP address pool by its name, a case-sensitive string of 1 to 31 characters.

group *group-name*: Displays PPP address pools in a group specified by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

If you do not specify any parameters, the command displays brief information about all PPP address pools.

If you specify an address pool, the command displays detailed information about the specified PPP address pool.

Examples

Display brief information about all PPP address pools.

```
<Sysname> display ip pool
Group name: a
  Pool name           Start IP address    End IP address      Free   In use
  aaa1                1.1.1.1             1.1.1.5             5      0
  aaa2                1.1.1.6             1.1.1.10            5      0
Group name: b
  Pool name           Start IP address    End IP address      Free   In use
  bbb                 1.1.2.1             1.1.2.5             4      1
                      2.2.2.1             2.2.2.5             5      0
```

Display brief information about the PPP address pools in group **a**.

```
<Sysname> display ip pool group a
Group name: a
  Pool name           Start IP address    End IP address      Free   In use
  aaa1                1.1.1.1             1.1.1.5             5      0
  aaa2                1.1.1.6             1.1.1.10            5      0
```

Display detailed information about PPP address pool **bbb**.

```
<Sysname> display ip pool bbb
Group name: b
  Pool name           Start IP address    End IP address      Free   In use
  bbb                 1.1.2.1             1.1.2.5             4      1
                      2.2.2.1             2.2.2.5             5      0
In use IP addresses:
  IP address      Interface
```

```
1.1.2.1         Virtual-Template1
```

Table 3 Command output

Field	Description
Free	Number of free IP addresses.
In use	Number of IP addresses that have been assigned.
In use IP addresses	Information about the IP addresses that have been assigned.
Interface	Local interface that requests the IP address for the peer interface.

Related commands

ip pool

display ppp access-user

Use **display ppp access-user** to display PPP user information.

Syntax

display ppp access-user { **domain** *domain-name* | **interface** *interface-type interface-number* [**count**] | **ip-address** *ipv4-address* | **ipv6-address** *ipv6-address* | **username** *user-name* | **user-type** { **lac** | **lns** | **pppoe** } [**count**] }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

domain *domain-name*: Displays information about PPP access users coming online through an ISP domain specified by its name, a case-sensitive string of 1 to 255 characters.

interface *interface-type interface-number*: Displays brief information about PPP users on the specified interface.

ip-address *ipv4-address*: Displays detailed information about the PPP user specified by its IPv4 address.

ipv6-address *ipv6-address*: Displays detailed information about the PPP user specified by its IPv6 address.

username *user-name*: Displays detailed information about the PPP user specified by its username, a case-sensitive string of 1 to 80 characters.

user-type: Displays brief information about online users of the specified type.

lac: Displays brief information about L2TP users for an LAC.

lns: Displays brief information about L2TP users for an LNS.

pppoe: Displays brief information about PPPoE users.

count: Displays the total number of PPP users matching the specified criterion.

Usage guidelines

Brief information about a PPP user includes the following:

- Brief name of the VA interface.
- Username.
- MAC address.
- IPv4 address, IPv6 address, or IPv6 prefix of the PPP user.

Detailed information about a PPP user includes the following:

- Brief name of the VA interface.
- User ID.
- Username.
- Authentication information.
- Uplink and downlink traffic.
- Access start time of the PPP user.

In an L2TP network, this command is supported on an LAC only if a remote system dials in to the LAC through a PPPoE network. For more information about L2TP, see L2TP configuration in *VPN Configuration Guide*.

Examples

Display brief information about PPP users on GigabitEthernet 1/0/1.

```
<Sysname> display ppp access-user interface gigabitethernet 1/0/1
Interface     Username    MAC address     IP address       IPv6 address    IPv6 PDPrefix
VA0           user1@dm1   0001-0101-9101  192.168.100.173  -                 -
VA1           user2@dm2   0001-0101-9101  192.168.80.173   2000::1           -
```

Display the total number of PPP users on GigabitEthernet 1/0/1.

```
<Sysname> display ppp access-user interface gigabitethernet 1/0/1 count
Total users: 2
```

Table 4 Command output

Field	Description
Interface	Name of the VA interface corresponding to the user.
Username	Username of the user. A hyphen (-) means that the user does not need authentication.
MAC address	MAC address of the user. A hyphen (-) means that the user is not a PPPoE user.
IP address	IP address of the user. A hyphen (-) means that no IP address is assigned to the user.
IPv6 address	IPv6 address of the user. A hyphen (-) means that no IPv6 address is assigned to the user.
IPv6 PD prefix	IPv6 prefix of the user. A hyphen (-) means that no IPv6 prefix is assigned to the user.
Total users	Total number of PPP users.

Display detailed information about the PPP user whose IP address is 50.50.50.3.

```
<Sysname> display ppp access-user ip-address 50.50.50.3
Basic:
  Interface: VA0
```

```
  User ID: 0x28000002
  Username: user1@hrss

```

Table 5 Command output

Field	Description
Basic	Basic information.
Interface	Brief name of the VA interface that corresponds to the user.
Username	Username of the user. A hyphen (-) means that the user does not need authentication.
Domain	ISP domain name for authentication. A hyphen (-) means that no ISP domain is specified for authentication.
Access interface	Name of the access interface of the user.
Service-VLAN/Customer-VLAN	Service provider VLAN and customer VLAN information of the user. A hyphen (-) means that no VLAN information is available.
IP address	IP address of the user. A hyphen (-) means that no IP address is assigned to the user.
IPv6 address	IPv6 address of the user. A hyphen (-) means that no IPv6 address is assigned to the user.
IPv6 PD prefix	Delegated IPv6 prefix of the user. A hyphen (-) means that no delegated IPv6 prefix is assigned to the user.
VPN instance	VPN instance to which the user belongs. A hyphen (-) means that the user is not bound to any VPN instance.
Access type	Access type of the user: • PPPoE. • L2TP.
Authentication type	Authentication type of the user: • PAP. • CHAP. • MS-CHAP. • MS-CHAP-V2.
Authentication state	Authentication state of the user: • **Idle**—The user has not been authenticated. • **Authenticating**—The user is being authenticated. • **Authenticated**—The user has been authenticated.
Authorization state	Authorization state of the user: • **Idle**—The user has not been authorized. • **Authorizing**—The user is being authorized. • **Authorized**—The user has been authorized.
Realtime accounting switch	• **Open**—The switch is on. • **Closed**—The switch is off.
Realtime accounting interval	Realtime accounting interval in seconds. A hyphen (-) means that no real-time accounting interval is authorized.
Login time	Time when the user accessed the device through PPP.
Accounting start time	Time when accounting started. A hyphen (-) means that no accounting is performed on the user.

Field	Description
Online time(hh:mm:ss)	Online duration of the current login.
Accounting state	Accounting state of the user: • **Accounting**—Accounting is on. • **Stop**—Accounting stops.
Idle cut	Traffic threshold for logging off the user in idle state. If the traffic is less than the threshold within the specified period, the user is forcibly logged off.
Session timeout	Authorization time for the user, in seconds. A hyphen (-) means that no authorization time is specified for the user.
Time remained	Remaining time for the user to stay online, in seconds. A hyphen (-) means that no authorization time is specified for the user.
Traffic quota	Authorized traffic quota for the user, in bytes. A hyphen (-) means that no traffic quota is authorized to the user.
Traffic remained	Remaining traffic for the user, in bytes. A hyphen (-) means that no traffic quota is authorized to the user.
Redirect WebURL	Redirect Web URL address for the user. A hyphen (-) means that no redirect Web URL address is specified for the user.
Inbound CAR	Authorized inbound CAR parameters, which contain the CIR (in bps), the PIR (in bps), and the CBS (in bits).
Outbound CAR	Authorized outbound CAR parameters, which contain the CIR (in bps), the PIR (in bps), and the CBS (in bits).
Global IP address	Global IP address of the user. This field is displayed if NAT444 is used. For information about NAT444, see *Layer 3—IP Services Configuration Guide*.
Port block	Port block of the user, from the start port to the end port. This field is displayed if NAT444 is used.
IPv4 uplink packets/bytes	Number of packets and bytes for IPv4 uplink traffic.
IPv4 downlink packets/bytes	Number of packets and bytes for IPv4 downlink traffic.
IPv6 uplink packets/bytes	Number of packets and bytes for IPv6 uplink traffic.
IPv6 downlink packets/bytes	Number of packets and bytes for IPv6 downlink traffic.
ITA	ITA statistics. ITA statistics are displayed after ITA is enabled. If the **`traffic-separate enable`** command is configured, ITA statistics are not included in flow statistics. For information about ITA and the **`traffic-separate enable`** command, see *Security Configuration Guide*.
Level-n uplink packets/bytes downlink packets/bytes	Number of packets and bytes for uplink traffic at accounting level *n*. The value for *n* depends on the **traffic level** command, and its value range is 1 to 8.

Related commands

`reset ppp access-user`

display ppp compression iphc

Use **display ppp compression iphc** to display IP header compression (IPHC) statistics.

Syntax

display ppp compression iphc { **rtp** | **tcp** } [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

rtp: Displays IPHC RTP header compression statistics.

tcp: Displays IPHC TCP header compression statistics.

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify this option, the command displays IPHC statistics on all interfaces.

Usage guidelines

When IPHC applies to a normal PPP link, the physical interface performs IPHC. You can view the compression information on the physical interface.

Examples

Display IPHC RTP header compression statistics.

```
<Sysname> display ppp compression iphc rtp
----------------------Slot1----------------------
Interface: Virtual-Access0
  Received:
    Compressed/Error/Total: 0/0/0 packets
  Sent:
    Compressed/Total: 0/0 packets
    Sent/Saved/Total: 0/0/0 bytes
    Packet-based compression ratio: 0%
    Byte-based compression ratio: 0%
  Connections:
    Rx/Tx: 16/16
    Five-Minute-Miss: 0 (Misses/5Mins)
    Max-Miss: 0

----------------------Slot2----------------------
Interface: Virtual-Access0
  Received:
    Compressed/Error/Total: 20/5/40 packets
  Sent:
    Compressed/Total: 34/40 packets
```

```
    Sent/Saved/Total: 1131/1210/2341 bytes
    Packet-based compression ratio: 85%
    Byte-based compression ratio: 51%
  Connections:
    Rx/Tx: 16/16
    Five-Minute-Miss: 0 (Misses/5Mins)
    Max-Miss: 0
```

Display IPHC TCP header compression statistics.

```
<Sysname>display ppp compression iphc tcp
----------------------Slot1----------------------
Interface: Virtual-Access0
  Received:
    Compressed/Error/Total: 0/0/0 packets
  Sent:
    Compressed/Total: 0/0 packets
    Sent/Saved/Total: 0/0/0 bytes
    Packet-based compression ratio: 0%
    Byte-based compression ratio: 0%
  Connections:
    Rx/Tx: 16/16
    Five-Minute-Miss: 0 (Misses/5Mins)
    Max-Miss: 0

----------------------Slot2----------------------
Interface: Virtual-Access0
  Received:
    Compressed/Error/Total: 20/5/40 packets
  Sent:
    Compressed/Total: 34/40 packets
    Sent/Saved/Total: 1131/1210/2341 bytes
    Packet-based compression ratio: 85%
    Byte-based compression ratio: 51%
  Connections:
    Rx/Tx: 16/16
    Five-Minute-Miss: 0 (Misses/5Mins)
    Max-Miss: 0
```

Table 6 Command output

Field	Description
Received: Compressed/Error/Total	Statistics for received packets: • **Compressed**—Number of compressed packets. • **Error**—Number of error packets. • **Total**—Total number of received packets.
Sent: Compressed/Total Sent/Saved/Total Packet-based compression ratio Byte-based compression ratio	Statistics for sent packets: • **Compressed**—Number of compressed packets. • **Total**—Total number of sent packets. • **Sent**—Bytes of sent packets. • **Saved**—Bytes of saved packets.

Field	Description
	• **Total**—Total bytes to be sent if packets are not compressed. • **Packet-based compression ratio**—Ratio of compressed packets to the total sent packets. • **Byte-based compression ratio**—Ratio of saved bytes to the total sent bytes.
Connections: Rx/Tx Five-Minute-Miss Max-Miss	Number of connections. • **Rx**—Number of connections that the receiver can decompress. • **Tx**—Number of connections that the sender can compress. • **Five-Minute-Miss**—Number of search failures within the last 5 minutes. • **Max-Miss**—Maximum number of search failures within 5 minutes.

Related commands

ppp compression iphc enable

reset ppp compression iphc

display ppp packet statistics

Use **display ppp packet statistics** to display PPP negotiation packet statistics.

Syntax

display ppp packet statistics [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays PPP negotiation packet statistics for all IRF member devices.

Examples

Display PPP negotiation packet statistics for slot 1.

```
<Sysname> display ppp packet statistics slot 1
PPP packet statistics in slot 1:
------------------------------LCP-----------------------------------
SEND_LCP_CON_REQ      : 0           RECV_LCP_CON_REQ      : 0
SEND_LCP_CON_NAK      : 0           RECV_LCP_CON_NAK      : 0
SEND_LCP_CON_REJ      : 0           RECV_LCP_CON_REJ      : 0
SEND_LCP_CON_ACK      : 0           RECV_LCP_CON_ACK      : 0
SEND_LCP_CODE_REJ     : 0           RECV_LCP_CODE_REJ     : 0
SEND_LCP_PROT_REJ     : 0           RECV_LCP_PROT_REJ     : 0
```

```
SEND_LCP_TERM_REQ     : 0           RECV_LCP_TERM_REQ     : 0
SEND_LCP_TERM_ACK     : 0           RECV_LCP_TERM_ACK     : 0

Table 7 Command output

Field	Description
LCP	LCP packet statistics. • **SEND_LCP_CON_REQ**—Number of sent link configuration request packets. • **RECV_LCP_CON_REQ**—Number of received link configuration request packets. • **SEND_LCP_CON_NAK**—Number of sent link configuration NAK packets. • **RECV_LCP_CON_NAK**—Number of received link configuration NAK packets. • **SEND_LCP_CON_REJ**—Number of sent link configuration reject packets. • **RECV_LCP_CON_REJ**—Number of received link configuration reject packets. • **SEND_LCP_CON_ACK**—Number of sent link configuration ACK packets. • **RECV_LCP_CON_ACK**—Number of received link configuration ACK packets. • **SEND_LCP_CODE_REJ**—Number of sent link configuration code reject packets. • **RECV_LCP_CODE_REJ**—Number of received link configuration code reject packets. • **SEND_LCP_PROT_REJ**—Number of sent link configuration protocol reject packets. • **RECV_LCP_PROT_REJ**—Number of received link configuration protocol reject packets. • **SEND_LCP_TERM_REQ**—Number of sent link termination request packets. • **RECV_LCP_TERM_REQ**—Number of received link termination request packets. • **SEND_LCP_TERM_ACK**—Number of sent link termination ACK packets. • **RECV_LCP_TERM_ACK**—Number of received link termination ACK packets. • **SEND_LCP_ECHO_REQ**—Number of sent LCP echo request packets. • **RECV_LCP_ECHO_REQ**—Number of received LCP echo request packets. • **SEND_LCP_ECHO_REP**—Number of sent LCP echo reply packets. • **RECV_LCP_ECHO_REP**—Number of received LCP echo reply packets. • **SEND_LCP_FAIL**—Number of sent link failure packets.
IPCP	IPCP packet statistics. • **SEND_IPCP_CON_REQ**—Number of sent IP address negotiation request packets. • **RECV_IPCP_CON_REQ**—Number of received IP address negotiation request packets. • **SEND_IPCP_CON_NAK**—Number of sent IP address negotiation NAK packets. • **RECV_IPCP_CON_NAK**—Number of received IP address negotiation NAK packets. • **SEND_IPCP_CON_REJ**—Number of sent IP address negotiation reject packets. • **RECV_IPCP_CON_REJ**—Number of received IP address negotiation reject packets. • **SEND_IPCP_CON_ACK**—Number of sent IP address negotiation ACK packets. • **RECV_IPCP_CON_ACK**—Number of received IP address negotiation ACK packets. • **SEND_IPCP_CODE_REJ**—Number of sent IP address negotiation code reject packets. • **RECV_IPCP_CODE_REJ**—Number of received IP address negotiation code reject packets. • **SEND_IPCP_PROT_REJ**—Number of sent IP address negotiation protocol reject packets. • **RECV_IPCP_PROT_REJ**—Number of received IP address negotiation protocol reject packets. • **SEND_IPCP_TERM_REQ**—Number of sent IP address negotiation termination request packets. • **RECV_IPCP_TERM_REQ**—Number of received IP address negotiation termination

Field	Description
	request packets. • **SEND_IPCP_TERM_ACK**—Number of sent IP address negotiation termination ACK packets. • **RECV_IPCP_TERM_ACK**—Number of received IP address negotiation termination ACK packets. • **SEND_IPCP_FAIL**—Number of sent IP address negotiation failure packets.
IPV6CP	IPv6CP packet statistics. • **SEND_IPV6CP_CON_REQ**—Number of sent IPv6 address negotiation request packets. • **RECV_IPV6CP_CON_REQ**—Number of received IPv6 address negotiation request packets. • **SEND_IPV6CP_CON_NAK**—Number of sent IPv6 address negotiation NAK packets. • **RECV_IPV6CP_CON_NAK**—Number of received IPv6 address negotiation NAK packets. • **SEND_IPV6CP_CON_REJ**—Number of sent IPv6 address negotiation reject packets. • **RECV_IPV6CP_CON_REJ**—Number of received IPv6 address negotiation reject packets. • **SEND_IPV6CP_CON_ACK**—Number of sent IPv6 address negotiation ACK packets. • **RECV_IPV6CP_CON_ACK**—Number of received IPv6 address negotiation ACK packets. • **SEND_IPV6CP_CODE_REJ**—Number of sent IPv6 address negotiation code reject packets. • **RECV_IPV6CP_CODE_REJ**—Number of received IPv6 address negotiation code reject packets. • **SEND_IPV6CP_PROT_REJ**—Number of sent IPv6 address negotiation protocol reject packets. • **RECV_IPV6CP_PROT_REJ**—Number of received IPv6 address negotiation protocol reject packets. • **SEND_IPV6CP_TERM_REQ**—Number of sent IPv6 address negotiation termination request packets. • **RECV_IPV6CP_TERM_REQ**—Number of received IPv6 address negotiation termination request packets. • **SEND_IPV6CP_TERM_ACK**—Number of sent IPv6 address negotiation termination ACK packets. • **RECV_IPV6CP_TERM_ACK**—Number of received IPv6 address negotiation termination ACK packets. • **SEND_IPV6CP_FAIL**—Number of sent IPv6 address negotiation failure packets.
OSICP	OSICP packet statistics. • **SEND_OSICP_CON_REQ**—Number of sent OSI address negotiation request packets. • **RECV_OSICP_CON_REQ**—Number of received OSI address negotiation request packets. • **SEND_OSICP_CON_NAK**—Number of sent OSI address negotiation NAK packets. • **RECV_OSICP_CON_NAK**—Number of received OSI address negotiation NAK packets. • **SEND_OSICP_CON_REJ**—Number of sent OSI address negotiation reject packets. • **RECV_OSICP_CON_REJ**—Number of received OSI address negotiation reject packets. • **SEND_OSICP_CON_ACK**—Number of sent OSI address negotiation ACK packets. • **RECV_OSICP_CON_ACK**—Number of received OSI address negotiation ACK packets. • **SEND_OSICP_CODE_REJ**—Number of sent OSI address negotiation code reject packets. • **RECV_OSICP_CODE_REJ**—Number of received OSI address negotiation code reject packets.

Field	Description
	• **SEND_OSICP_PROT_REJ**—Number of sent OSI address negotiation protocol packets. • **RECV_OSICP_PROT_REJ**—Number of received OSI address negotiation protocol reject packets. • **SEND_OSICP_TERM_REQ**—Number of sent OSI address negotiation termination request packets. • **RECV_OSICP_TERM_REQ**—Number of received OSI address negotiation termination request packets. • **SEND_OSICP_TERM_ACK**—Number of sent OSI address negotiation termination ACK packets. • **RECV_OSICP_TERM_ACK**—Number of received OSI address negotiation termination ACK packets. • **SEND_OSICP_FAIL**—Number of sent OSI address negotiation failure packets.
MPLSCP	MPLSCP packet statistics. • **SEND_MPLSCP_CON_REQ**—Number of sent MPLS address negotiation request packets. • **RECV_MPLSCP_CON_REQ**—Number of received MPLS address negotiation request packets. • **SEND_MPLSCP_CON_NAK**—Number of sent MPLS address negotiation NAK packets. • **RECV_MPLSCP_CON_NAK**—Number of received MPLS address negotiation NAK packets. • **SEND_MPLSCP_CON_REJ**—Number of sent MPLS address negotiation reject packets. • **RECV_MPLSCP_CON_REJ**—Number of received MPLS address negotiation reject packets. • **SEND_MPLSCP_CON_ACK**—Number of sent MPLS address negotiation ACK packets. • **RECV_MPLSCP_CON_ACK**—Number of received MPLS address negotiation ACK packets. • **SEND_MPLSCP_CODE_REJ**—Number of sent MPLS address negotiation code reject packets. • **RECV_MPLSCP_CODE_REJ**—Number of received MPLS address negotiation code reject packets. • **SEND_MPLSCP_PROT_REJ**—Number of sent MPLS address negotiation protocol packets. • **RECV_MPLSCP_PROT_REJ**—Number of received MPLS address negotiation protocol reject packets. • **SEND_MPLSCP_TERM_REQ**—Number of sent MPLS address negotiation termination request packets. • **RECV_MPLSCP_TERM_REQ**—Number of received MPLS address negotiation termination request packets. • **SEND_MPLSCP_TERM_ACK**—Number of sent MPLS address negotiation termination ACK packets. • **RECV_MPLSCP_TERM_ACK**—Number of received MPLS address negotiation termination ACK packets. • **SEND_MPLSCP_FAIL**—Number of sent MPLS address negotiation failure packets.
AUTH	Authentication packet statistics. • **SEND_PAP_AUTH_REQ**—Number of sent PAP authentication request packets. • **RECV_PAP_AUTH_REQ**—Number of received PAP authentication request packets. • **SEND_PAP_AUTH_ACK**—Number of sent PAP authentication ACK packets. • **RECV_PAP_AUTH_ACK**—Number of received PAP authentication ACK packets. • **SEND_PAP_AUTH_NAK**—Number of sent PAP authentication NAK packets. • **RECV_PAP_AUTH_NAK**—Number of received PAP authentication NAK packets.

Field	Description
	• **SEND_CHAP_AUTH_CHALLENGE**—Number of sent CHAP authentication request packets. • **RECV_CHAP_AUTH_CHALLENGE**—Number of received CHAP authentication request packets. • **SEND_CHAP_AUTH_RESPONSE**—Number of sent CHAP authentication response packets. • **RECV_CHAP_AUTH_RESPONSE**—Number of received CHAP authentication response packets. • **SEND_CHAP_AUTH_ACK**—Number of sent CHAP authentication ACK packets. • **RECV_CHAP_AUTH_ACK**—Number of received CHAP authentication ACK packets. • **SEND_CHAP_AUTH_NAK**—Number of sent CHAP authentication NAK packets. • **RECV_CHAP_AUTH_NAK**—Number of received CHAP authentication NAK packets. • **SEND_PAP_AUTH_FAIL**—Number of sent PAP authentication failure packets. • **SEND_CHAP_AUTH_FAIL**—Number of sent CHAP authentication failure packets.

Related commands

reset ppp packet statistics

interface virtual-template

Use **interface virtual-template** to create a VT interface and enter its view, or enter the view of an existing VT interface.

Use **undo interface virtual-template** to remove a VT interface.

Syntax

interface virtual-template *number*

undo interface virtual-template *number*

Default

No VT interfaces exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies a VT interface by its number. The value range for this argument is 1 to 1024.

Usage guidelines

To remove a VT interface, make sure all the corresponding VA interfaces are removed and the VT interface is not in use.

Examples

Create interface Virtual-Template 10.

```
<Sysname> system-view
[Sysname] interface virtual-template 10
[Sysname-Virtual-Template10]
```

ip address ppp-negotiate

Use **ip address ppp-negotiate** to enable IP address negotiation on an interface, so that the interface can accept the IP address allocated by the server.

Use **undo ip address ppp-negotiate** to restore the default.

Syntax

ip address ppp-negotiate

undo ip address ppp-negotiate

Default

IP address negotiation is disabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

If you execute the **ip address ppp-negotiate** and **ip address** commands multiple times, the most recent configuration takes effect.

Examples

Enable IP address negotiation on Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ip address ppp-negotiate
```

Related commands

ip address (*Layer 3—IP Services Command Reference*)

ip pool

Use **ip pool** to configure a PPP address pool.

Use **undo ip pool** to remove a PPP address pool or an IP address range of the PPP address pool.

Syntax

ip pool *pool-name start-ip-address* [*end-ip-address*] [**group** *group-name*]

undo ip pool *pool-name* [*start-ip-address* [*end-ip-address*]]

Default

No PPP address pool is configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

pool-name: Specifies a name for the PPP address pool to be created, a case-sensitive string of 1 to 31 characters.

start-ip-address [*end-ip-address*]: Specifies an IP address range. If you do not specify the *end-ip-address* argument, the PPP address pool has only the start IP address.

group *group-name*: Specifies a group by its name to which the PPP address pool belongs. The group name is a case-sensitive string of 1 to 31 characters. If you do not specify this option, the group name is **default** (the default group).

Usage guidelines

The system supports multiple address spaces that each correspond to a VPN instance. The same IP addresses can exist in different address spaces.

Each address space is represented by a group. One group can contain multiple PPP address pools, but one PPP address pool can belong to only one group.

One PPP address pool can contain multiple IP address ranges. You can execute this command multiple times to specify multiple IP address ranges for a PPP address pool. A PPP address pool can contain a maximum of 65535 IP addresses, and so can an IP address range.

IP address ranges in different groups can be overlapping, but those in the same group cannot.

Changes to a PPP address pool do not affect assigned IP addresses. For example, if you delete a PPP address pool from which an IP address has been assigned, the IP address can still be used.

When assigning IP address to users through a PPP address pool, make sure the PPP address pool excludes the gateway IP address of the PPP address pool.

Examples

Configure PPP address pool **aaa** that contains IP addresses 129.102.0.1 through 129.102.0.10 for group **a**.

```
<Sysname> system-view
[Sysname] ip pool aaa 129.102.0.1 129.102.0.10 group a
```

Related commands

display ip pool

ip pool gateway

Use **ip pool gateway** to configure a gateway address for a PPP address pool.

Use **undo ip pool gateway** to remove the gateway address for the specified PPP address pool.

Syntax

ip pool *pool-name* **gateway** *ip-address* [**vpn-instance** *vpn-instance-name*]

undo ip pool *pool-name* **gateway**

Default

A PPP address pool is not configured with a gateway address.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

pool-name: Specifies an existing PPP address pool by its name, a case-sensitive string of 1 to 31 characters.

ip-address: Specifies a gateway address for the PPP address pool.

vpn-instance *vpn-instance-name*: Specifies an existing MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the specified gateway belongs to the public network.

Usage guidelines

An interface on a BRAS must have an IP address before it can assign an IP address from a PPP or DHCP address pool to a client. This command enables interfaces that have no IP address to use a gateway address for IPCP negotiation and address allocation.

When you configure a gateway address for a PPP address pool, follow these restrictions and guidelines:

- If you also specify an IP address for an interface, the interface uses its own IP address to perform IPCP negotiation.
- You can specify only one gateway address for a PPP address pool. Different PPP address pools must have different gateway addresses (different combinations of *ip-address* and *vpn-instance-name*).
- You can specify any gateway address for a PPP address pool.

Examples

Specify gateway address **1.1.1.1** for PPP address pool **aaa**.

```
<Sysname> system-view
[Sysname] ip pool aaa gateway 1.1.1.1
```

Related commands

ip pool

mtu

Use **mtu** to set the MTU size of an interface.

Use **undo mtu** to restore the default.

Syntax

mtu *size*

undo mtu

Default

The MTU size of a VT interface is 1500 bytes.

Views

VT interface view

Predefined user roles

network-admin

context-admin

Parameters

size: Specifies the MTU size. The value range for this argument is 128 to 1500.

Usage guidelines

The MTU size setting of an interface affects the fragmentation and reassembly of IP packets on that interface.

For the configured MTU size to take effect, you must execute the **shutdown** command and then the **undo shutdown** command on the interface.

Examples

Set the MTU size of Virtual-Template 10 to 1400 bytes.

```
<Sysname> system-view
[Sysname] interface virtual-template 10
[Sysname-Virtual-Template10] mtu 1400
```

nas-port-type

Use **nas-port-type** to configure the NAS-Port-Type attribute on a VT interface.

Use **undo nas-port-type** to restore the default.

Syntax

nas-port-type { **ethernet** | **virtual** }

undo nas-port-type

Default

The NAS-Port-Type attribute is determined by the service type and link type of the PPP user, as shown in Table 8.

Table 8 Default NAS-Port-Type attribute

Service type	Link type	NAS-Port-Type attribute
PPPoE	Any	**ethernet**
L2TP	Any	**virtual**

Views

VT interface view

Predefined user roles

network-admin

context-admin

Parameters

ethernet: Specifies Ethernet. The code value is 15.

virtual: Specifies virtual. The code value is 5.

Usage guidelines

The NAS-Port-Type attribute is used for RADIUS authentication and accounting. For more information about the NAS-Port-Type attribute, see RFC 2865.

This command does not affect existing users.

Examples

Set the NAS-Port-Type attribute to **virtual** for Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
```

```
[Sysname-Virtual-Template1] nas-port-type virtual
```

ppp access-user log enable

Use **ppp access-user log enable** to enable PPP user logging.

Use **undo ppp access-user log enable** to disable PPP user logging.

Syntax

ppp access-user log enable [**abnormal-logout** | **failed-login** | **normal-logout** | **successful-login**] *

undo ppp access-user log enable [**abnormal-logout** | **failed-login** | **normal-logout** | **successful-login**] *

Default

Logging is disabled for PPP users.

context-admin

Parameters

successful-login: Specifies login success logs.

failed-login: Specifies login failure logs.

normal-logout: Specifies normal logout logs.

abnormal-logout: Specifies abnormal logout logs.

Usage guidelines

IMPORTANT:

Typically, disable this feature to prevent excessive PPP log output.

The PPP user logging feature enables the device to generate PPP logs and send them to the information center. Logs are generated after a user comes online, goes offline, or fails to come online. A log entry contains information such as the username, IP address, interface name, inner VLAN, outer VLAN, MAC address, and failure causes. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

When you execute this command without specifying any keyword, this command enables or disables logging for login successes, login failures, normal logouts, and abnormal logouts.

Examples

Enable PPP user logging.

```
<Sysname> system-view
[Sysname] ppp access-user log enable
```

ppp account-statistics enable

Use **ppp account-statistics enable** to enable PPP accounting on an interface.

Use **undo ppp account-statistics enable** to disable PPP accounting on an interface.

Syntax

ppp account-statistics enable [**acl** { *acl-number* | **name** *acl-name* }]

undo ppp account-statistics enable

Default

PPP accounting is disabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

acl: Specifies an ACL to match traffic. If no ACL is specified, the device generates statistics for all PPP traffic.

acl-number: Specifies an ACL by its number in the range of 2000 to 3999, where:

- 2000 to 2999 are numbers for basic IPv4 and IPv6 ACLs.
- 3000 to 3999 are numbers for advanced IPv4 and IPv6 ACLs.

If the specified ACL number corresponds to an IPv4 ACL and an IPv6 ACL, both ACLs take effect.

name *acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters that start with an alphabetical character. To avoid confusion, do not use **all** as an ACL name.

Examples

Enable PPP accounting on Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp account-statistics enable
```

ppp acfc local-request

Use **ppp acfc local-request** to configure an interface to send ACFC requests by including the ACFC option in outbound LCP negotiation requests.

Use **undo ppp acfc local-request** to restore the default.

Syntax

ppp acfc local-request

undo ppp acfc local-request

Default

An interface does not include the ACFC option in outbound LCP negotiation requests.

Views

Interface view

Predefined user roles

network-admin

context-admin

Examples

Configure Virtual-Template 1 to send ACFC requests to the peer in PPP negotiation.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp acfc local-request
```

ppp acfc remote-reject

Use **ppp acfc remote-reject** to configure an interface to reject ACFC requests received from the remote peer.

Use **undo ppp acfc remote-reject** to restore the default.

Syntax

ppp acfc remote-reject

undo ppp acfc remote-reject

Default

An interface accepts ACFC requests received from the remote peer, and it performs ACFC on frames sent to the peer.

Views

Interface view

Predefined user roles

network-admin

context-admin

Examples

Configure Virtual-Template 1 to reject ACFC requests received from the remote peer.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp acfc remote-reject
```

ppp authentication-mode

Use **ppp authentication-mode** to configure PPP authentication on an interface.

Use **undo ppp authentication-mode** to restore the default.

Syntax

ppp authentication-mode { **chap** | **ms-chap** | **ms-chap-v2** | **pap** } * [[**call-in**] **domain** { *isp-name* | **default enable** *isp-name* }]

undo ppp authentication-mode

Default

PPP authentication is disabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

chap: Uses CHAP authentication.

ms-chap: Uses MS-CHAP authentication.

ms-chap-v2: Uses MS-CHAP-V2 authentication.

pap: Uses PAP authentication.

call-in: Authenticates the call-in users only.

domain *isp-name*: Specifies the ISP domain name for authentication, a case-insensitive string of 1 to 255 characters.

default enable *isp-name*: Specifies the default ISP domain name for authentication, a case-insensitive string of 1 to 255 characters.

Usage guidelines

PPP authentication includes the following categories:

- **PAP**—Two-way handshake authentication. The password is in plain text or cipher text.
- **CHAP**—Three-way handshake authentication. The password is in plain text or cipher text.
- **MS-CHAP**—Three-way handshake authentication. The password is in cipher text.
- **MS-CHAP-V2**—Three-way handshake authentication. The password is in cipher text.

You can configure multiple authentication modes.

In any PPP authentication mode, AAA determines whether a user can pass the authentication through a local authentication database or an AAA server. For more information about AAA authentication, see *Security Configuration Guide*.

If multiple ISP domains are available, the ISP domains are used in the following order:

1. ISP domain specified by the **domain** *isp-name* option in this command.
2. ISP domain contained in the username.
3. ISP domain specified by the **domain default enable** *isp-name* option in this command.
4. ISP domain selected by using the AAA module. For more information about AAA, see *Security Configuration Guide*.

For authentication on a dialup interface, configure authentication on both the physical interface and the dialer interface. When a physical interface receives a DDR call request, it first initiates PPP negotiation and authenticates the dial-in user. Then it passes the call to the upper layer protocol.

Examples

Configure Virtual-Template 1 to authenticate the peer by using PAP.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp authentication-mode pap
```

Configure Virtual-Template 1 to authenticate the peer by using PAP and CHAP.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp authentication-mode pap chap
```

Related commands

local-user (*Security Command Reference*)

ppp chap password

ppp chap user

ppp pap local-user

ppp chap password

Use **ppp chap password** to set the password for CHAP authentication on an interface.

Use **undo ppp chap password** to restore the default.

Syntax

ppp chap password { **cipher** | **simple** } *string*

undo ppp chap password

Default

No password is set for CHAP authentication on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 255 characters. Its encrypted form is a case-sensitive string of 1 to 373 characters.

Examples

Set the password for CHAP authentication to plaintext password **sysname** on Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp chap password simple sysname
```

Related commands

ppp authentication-mode

ppp chap user

Use **ppp chap user** to set the username for CHAP authentication on an interface.

Use **undo ppp chap user** to restore the default.

Syntax

ppp chap user *username*

undo ppp chap user

Default

The username for CHAP authentication is null on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

username: Specifies the username for CHAP authentication, a case-sensitive string of 1 to 80 characters. The username is sent to the peer for the local device to be authenticated.

Usage guidelines

To pass CHAP authentication, the username/password of one side must be the local username/password on the peer.

Examples

Set the username for CHAP authentication to **Root** on Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp chap user Root
```

Related commands

ppp authentication-mode

ppp compression iphc enable

Use **ppp compression iphc enable** to enable IPHC on an interface.

Use **undo ppp compression iphc enable** to disable IPHC on an interface.

Syntax

ppp compression iphc enable [**nonstandard**]

undo ppp compression iphc enable

Default

IPHC is disabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

nonstandard: Specifies the nonstandard encapsulation format. If you do not specify this keyword, packets are encapsulated in standard format. You must specify this keyword when the device communicates with a non-NSFOCUS device. If you specify this keyword, this command enables RTP header compression.

Usage guidelines

IPHC includes RTP header compression and TCP header compression.

Enabling or disabling IPHC enables or disables both RTP header compression and TCP header compression.

To use IPHC, you must enable it on both sides of a PPP link.

When you enable IPHC on a VT or dialer interface, the setting does not immediately take effect. For the setting to take effect, execute the **shutdown** and then **undo shutdown** commands on the interface or its bound physical interface.

Examples

Enable IPHC on Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp compression iphc enable
```

ppp compression iphc rtp-connections

Use **ppp compression iphc rtp-connections** to set the maximum number of connections for which an interface can perform RTP header compression.

Use **undo ppp compression iphc rtp-connections** to restore the default.

Syntax

ppp compression iphc rtp-connections *number*

undo ppp compression iphc rtp-connections

Default

An interface can perform RTP header compression for a maximum of 16 connections.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the maximum number of connections for which an interface can perform RTP header compression. The value range for this argument is 3 to 1000:

- When the *number* argument is set to a value less than or equal to 256, packets are compressed in the format of COMPRESSED RTP 8.
- When the *number* argument is set to a value greater than 256, packets are compressed in the format of COMPRESSED RTP 16.

Usage guidelines

RTP is a connection-oriented protocol. An interface can accommodate multiple RTP connections.

RTP header compression occupies memory resources for maintaining connection information. This command can limit memory resources used by compression. For example, if you set the limit to 3, RTP header compression only applies to a maximum of three RTP connections.

After you execute this command, you must shut down and then bring up the interface to make the command take effect.

You can configure this command only when IPHC is enabled. The configuration is removed after IPHC is disabled.

Examples

Set the maximum number of connections for which Virtual-Template 1 can perform RTP header compression to 10.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp compression iphc enable
[Sysname-Virtual-Template1] ppp compression iphc rtp-connections 10
```

Related commands

ppp compression iphc enable

ppp compression iphc tcp-connections

Use **ppp compression iphc tcp-connections** to set the maximum number of connections for which an interface can perform TCP header compression.

Use **undo ppp compression iphc tcp-connections** to restore the default.

Syntax

ppp compression iphc tcp-connections *number*

undo ppp compression iphc tcp-connections

Default

An interface can perform TCP header compression for a maximum of 16 connections.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the maximum number of connections for which an interface can perform TCP header compression. The value range for this argument is 3 to 256.

Usage guidelines

TCP is a connection-oriented protocol. A link can accommodate multiple TCP connections.

TCP header compression occupies memory resources for maintaining connection information. This command can limit memory resources used by compression. For example, if you set the limit to 3, TCP header compression only applies to a maximum of three TCP connections.

After you execute this command, you must shut down and then bring up the interface to make the command take effect.

You can configure this command only when IPHC is enabled and packets are encapsulated in standard format. The configuration is removed after IPHC is disabled or packets are encapsulated in nonstandard format.

Examples

Set the maximum number of connections for which Virtual-Template 1 can perform TCP header compression to 10.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp compression iphc enable
[Sysname-Virtual-Template1] ppp compression iphc tcp-connections 10
```

Related commands

ppp compression iphc enable

ppp ipcp dns

Use **ppp ipcp dns** to configure the primary and secondary DNS server IP addresses to be allocated in PPP negotiation on an interface.

Use **undo ppp ipcp dns** to delete the primary and secondary DNS server IP addresses to be allocated in PPP negotiation on an interface.

Syntax

ppp ipcp dns *primary-dns-address* [*secondary-dns-address*]

undo ppp ipcp dns *primary-dns-address* [*secondary-dns-address*]

Default

The DNS server IP addresses to be allocated in PPP negotiation are not configured on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

primary-dns-address: Specifies a primary DNS server IP address.

secondary-dns-address: Specifies a secondary DNS server IP address.

Usage guidelines

A device can assign DNS server IP addresses to its peer during PPP negotiation when the peer initiates requests.

To check the allocated DNS server IP addresses, execute the **winipcfg** or **ipconfig /all** command on the host.

Examples

Set the primary and secondary DNS server IP addresses to 100.1.1.1 and 100.1.1.2 for the peer on Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp ipcp dns 100.1.1.1 100.1.1.2
```

ppp ipcp dns admit-any

Use **ppp ipcp dns admit-any** to configure an interface to accept the DNS server IP addresses assigned by the peer even though it does not request DNS server IP addresses from the peer.

Use **undo ppp ipcp dns admit-any** to restore the default.

Syntax

ppp ipcp dns admit-any

undo ppp ipcp dns admit-any

Default

An interface does not accept the DNS server IP addresses assigned by the peer if it does not request DNS server IP addresses from the peer.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

You can configure an interface to accept the DNS server IP addresses assigned by the peer, through which domain names can be resolved for the device.

Typically, the server assigns a DNS server address to a client in PPP negotiation only when the client is configured with the **ppp ipcp dns request** command. Some servers, however, forcibly assign DNS server addresses to clients. You must configure the **ppp ipcp dns admit-any** command on the client devices to accept the DNS server addresses.

Examples

Configure Virtual-Template 1 to accept DNS server IP addresses allocated by the peer.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp ipcp dns admit-any
```

Related commands

ppp ipcp dns request

ppp ipcp dns request

Use **ppp ipcp dns request** to enable an interface to actively request the DNS server IP address from its peer.

Use **undo ppp ipcp dns request** to restore the default.

Syntax

ppp ipcp dns request

undo ppp ipcp dns request

Default

An interface does not actively request the DNS server IP address from its peer.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

If a device is connected to a provider's access server through a PPP link, you can use this command. Then, the device can obtain the specified DNS server IP address from the access server during IPCP negotiation.

You can check the DNS server IP addresses by displaying information about the interface.

Examples

Enable Virtual-Template 1 to actively request the DNS server IP address from its peer.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp ipcp dns request
```

ppp ipcp remote-address match

Use **ppp ipcp remote-address match** to enable the IP segment match feature for PPP IPCP negotiation on an interface.

Use **undo ppp ipcp remote-address match** to restore the default.

Syntax

ppp ipcp remote-address match

undo ppp ipcp remote-address match

Default

The IP segment match feature is disabled for PPP IPCP negotiation on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command enables the local interface to check whether its IP address and the IP address of the remote interface are in the same network segment. If they are not, IPCP negotiation fails.

Examples

Enable the IP segment match feature on Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp ipcp remote-address match
```

ppp ip-pool route

Use **ppp ip-pool route** to configure a PPP address pool route.

Use **undo ppp ip-pool route** to remove a PPP address pool route.

Syntax

ppp ip-pool route *ip-address* { *mask-length* | *mask* } [**vpn-instance** *vpn-instance-name*]

undo ppp ip-pool route *ip-address* { *mask-length* | *mask* } [**vpn-instance** *vpn-instance-name*]

Default

No PPP address pool route is configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the destination IP address of the PPP address pool route, in dotted decimal notation.

mask-length: Specifies a mask length for the IP address, in the range of 0 to 32.

mask: Specifies a mask for the IP address, in dotted decimal notation.

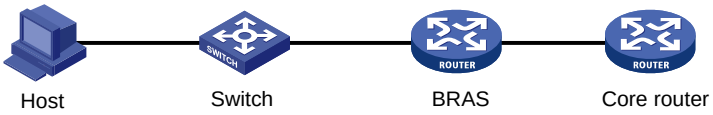
vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the PPP address pool route applies to the public network.

Usage guidelines

The BRAS uses PPP address pool routes to control downlink traffic forwarding.

After you configure a PPP address pool route, the BRAS generates a static blackhole route destined for the specified network. All traffic matching the blackhole route is discarded. When a legal user logs in, the BRAS adds a host route destined for the specified network. In addition, the BRAS uses a dynamic routing protocol to redistribute the PPP address pool route to the upstream device.

Figure 1 Network diagram for the PPP address pool route



Make sure the destination network of the PPP address pool route includes the PPP address pool. You can execute this command multiple times to configure multiple PPP address pool routes.

Examples

Configure the PPP address pool route as 2.2.2.2/24.

```
<Sysname> system-view
[Sysname] ppp ip-pool route 2.2.2.2 24
```

ppp lcp delay

Use **ppp lcp delay** to set the LCP negotiation delay timer.

Use **undo ppp lcp delay** to restore the default.

Syntax

ppp lcp delay *milliseconds*

undo ppp lcp delay

Default

PPP starts LCP negotiation immediately after the physical layer comes up.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

milliseconds: Specifies the LCP negotiation delay timer in the range of 1 to 10000 milliseconds.

Usage guidelines

If two ends of a PPP link vary greatly in the LCP negotiation packet processing rate, configure this command on the end with a higher processing rate. The LCP negotiation delay timer prevents frequent LCP negotiation packet retransmission. After the physical layer comes up, PPP starts LCP negotiation when the delay timer expires. If PPP receives LCP negotiation packets before the delay timer expires, it starts LCP negotiation immediately.

Examples

Set the LCP negotiation delay timer to 130 milliseconds.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp lcp delay 130
```

ppp pap local-user

Use **ppp pap local-user** to set the local username and password for PAP authentication on an interface.

Use **undo ppp pap local-user** to restore the default.

Syntax

ppp pap local-user *username* **password** { **cipher** | **simple** } *string*

undo ppp pap local-user

Default

The local username and password for PAP authentication are blank on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

username: Specifies the username of the local device for PAP authentication, a case-sensitive string of 1 to 80 characters.

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 255 characters. Its encrypted form is a case-sensitive string of 1 to 373 characters.

Usage guidelines

For the local device to pass PAP authentication on the peer, make sure the username and password configured for the local device are also configured on the peer. You can configure the peer's

username and password by using the **local-user** *username* and **password** { **cipher** | **simple** } *string* commands, respectively.

Examples

Set the local username and password for PAP authentication to **user1** and plaintext **pass1** on Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp pap local-user user1 password simple pass1
```

Related commands

[Sysname-Virtual-Template1] ppp pfc local-request
```

ppp pfc remote-reject

Use **ppp pfc remote-reject** to configure an interface to reject PFC requests received from the remote peer.

Use **undo ppp pfc remote** to restore the default.

Syntax

ppp pfc remote-reject

undo ppp pfc remote-reject

Default

An interface accepts PFC requests received from the remote peer, and it performs PFC on frames sent to the peer.

Views

Interface view

Predefined user roles

network-admin

context-admin

Examples

Configure Virtual-Template 1 to reject PFC requests received from the remote peer.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp pfc remote-reject
```

ppp timer negotiate

Use **ppp timer negotiate** to set the PPP negotiation timeout time on an interface.

Use **undo ppp timer negotiate** to restore the default.

Syntax

ppp timer negotiate *seconds*

undo ppp timer negotiate

Default

The PPP negotiation timeout time is 3 seconds on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the negotiation timeout time in the range of 1 to 10 seconds.

Usage guidelines

In PPP negotiation, if the local device receives no response from the peer during the timeout time after it sends a packet, the local device sends the last packet again.

Examples

Set the PPP negotiation timeout time to 5 seconds on Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] ppp timer negotiate 5
```

remote address

Use **remote address** to configure an interface to assign an IP address to the client.

Use **undo remote address** to restore the default.

Syntax

remote address { *ip-address* | **pool** *pool-name* }

undo remote address

Default

An interface does not assign an IP address to the client.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IP address to be assigned to the client.

pool *pool-name*: Specifies a PPP or DHCP address pool by its name from which an IP address is assigned to the client. The pool name is a case-sensitive string of 1 to 31 characters.

Usage guidelines

This command can be used when the local interface is configured with an IP address, but the peer has no IP address. To enable the peer to accept the IP address assigned by the local interface (server), you must configure the **ip address ppp-negotiate** command on the peer to make the peer act as a client.

This command enables the local interface to forcibly assign an IP address to the peer. If the peer is not configured with the **ip address ppp-negotiate** command but configured with an IP address, the peer will not accept the assigned IP address. This results in an IPCP negotiation failure.

PPP supports IP address assignment from a PPP or DHCP address pool, but the PPP address pool takes precedence over the DHCP address pool. For example, if you use a pool name that identifies both a PPP address pool and a DHCP address pool, the system uses only the PPP address pool for address assignment.

To make the configuration of the **remote address** command take effect, configure this command before the **ip address** command, which triggers IPCP negotiation. If you configure the **remote address** command after the **ip address** command, the server assigns an IP address to the client during the next IPCP negotiation.

After you use the **remote address** command to assign an IP address to the client, you can configure the **remote address** command again or the **undo remote address** command for the peer. However, the new configuration does not take effect until the next IPCP negotiation.

Examples

Specify the IP address to be assigned to the client as 10.0.0.1 on Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] remote address 10.0.0.1
```

Configure Virtual-Template 1 to assign an IP address from address pool **aaa** to the client.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] remote address pool aaa
```

Related commands

ip address ppp-negotiate

ip pool

remote address dhcp client-identifier

Use **remote address dhcp client-identifier username** to configure the DHCP client IDs for PPP users acting as DHCP clients.

Use **undo remote address dhcp client-identifier** to restore the default.

Syntax

remote address dhcp client-identifier { **callingnum** | **username** }

undo remote address dhcp client-identifier

Default

No DHCP client IDs are configured for PPP users acting as DHCP clients.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

callingnum: Uses the calling numbers as the DHCP client IDs. The calling numbers are carried in the calling number AVPs in L2TP negotiation packets. A calling number is formed by the user MAC address and the VLAN to which the user belongs. For example, if the MAC address of a user is 000f-e235-dc71, and the inner VLAN and outer VLAN of the user are VLAN 1 and VLAN 2, respectively, the calling number of the user is 000f-e235-dc71-00010002.

username: Uses the PPP usernames as the DHCP client IDs.

Usage guidelines

By default, a PPP client randomly selects a DHCP client ID when the PPP client requests an IP address through DHCP. In this case, the DHCP server cannot assign specific IP addresses to specific clients based on client IDs. For the DHCP server to assign specific IP addresses to specific clients based on client IDs, use this command to configure the calling numbers or usernames as the DHCP client IDs.

When PPP usernames are used as the DHCP client IDs, make sure different users use different PPP usernames to come online.

Examples

Use the PPP usernames as the DHCP client IDs for PPP users acting as DHCP clients on Virtual-template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] remote address dhcp client-identifier username
```

reset counters interface virtual-access

Use **reset counters interface virtual-access** to clear statistics on VA interfaces.

Syntax

reset counters interface [**virtual-access** [*interface-number*]]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

virtual-access: Clears statistics on VA interfaces.

interface-number: Specifies an existing VA interface by its number.

Usage guidelines

Before collecting traffic statistics regularly on a VA interface, clear the existing statistics.

If you do not specify the **virtual-access** keyword, the command clears statistics on all interfaces.

If you specify the **virtual-access** keyword without the *interface-number* argument, the command clears statistics on all VA interfaces.

If you specify both **virtual-access** and *interface-number*, the command clears statistics on the specified VA interface.

Examples

Clear statistics on Virtual-Access 10.

```
<Sysname> reset counters interface virtual-access 10
```

Related commands

display interface virtual-access

reset ppp access-user

Use **reset ppp access-user** to log off a PPP user.

Syntax

reset ppp access-user { **ip-address** *ipv4-address* [**vpn-instance** *ipv4-vpn-instance-name*] | **ipv6-address** *ipv6-address* [**vpn-instance** *ipv6-vpn-instance-name*] | **username** *user-name* }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

ip-address *ipv4-address*: Specifies a PPP user by its IPv4 address.

ipv6-address *ipv6-address*: Specifies a PPP user by its IPv6 address.

vpn-instance *ipv4-vpn-instance-name*: Specifies a PPP user by the VPN to which the user belongs. The *ipv4-vpn-instance-name* argument specifies the name of the IPv4 MPLS

L3VPN instance, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the specified user belongs to the public network.

vpn-instance *ipv6-vpn-instance-name*: Specifies a PPP user by the VPN to which the user belongs. The *ipv6-vpn-instance-name* argument specifies the name of the IPv6 MPLS L3VPN instance, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the specified user belongs to the public network.

username *user-name*: Specifies a PPP user by username, a case-sensitive string of 1 to 80 characters.

Usage guidelines

This command takes effect only on the current login for a PPP user. The user can come online after it is logged off.

Examples

Log off the PPP user at 192.168.100.2.

```
<Sysname> reset ppp access-user ip-address 192.168.100.2
```

Related commands

display ppp access-user

reset ppp compression iphc

Use **reset ppp compression iphc** to clear IPHC statistics.

Syntax

reset ppp compression iphc [**rtp** | **tcp**] [**interface** *interface-type interface-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

rtp: Clears IPHC RTP header compression statistics.

tcp: Clears IPHC TCP header compression statistics.

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify this option, the command clears IPHC statistics on all interfaces.

Usage guidelines

If neither **rtp** nor **tcp** is specified, this command clears both RTP header compression and TCP header compression statistics.

Examples

Clear IPHC statistics on all interfaces.

```
<Sysname> reset ppp compression iphc
```

Related commands

display ppp compression iphc

reset ppp packet statistics

Use **reset ppp packet statistics** to clear PPP negotiation packet statistics.

Syntax

reset ppp packet statistics [**slot** *slot-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command clears PPP negotiation packet statistics for all IRF member devices.

Examples

Clear PPP negotiation packet statistics for slot 2.

```
<Sysname> reset ppp packet statistics slot 2
```

Related commands

display ppp packet statistics

timer-hold

Use **timer-hold** to set the keepalive interval on an interface.

Use **undo timer-hold** to restore the default.

Syntax

timer-hold *seconds*

undo timer-hold

Default

The keepalive interval is 10 seconds on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the interval for sending keepalive packets, in the range of 0 to 32767 seconds. The value 0 disables an interface from sending keepalive packets. In this case, the interface can respond to keepalive packets from the peer.

Usage guidelines

An interface sends keepalive packets at keepalive intervals to detect the availability of the peer. If the interface receives no response to keepalive packets when the keepalive retry limit is reached, it determines that the link fails and reports a link layer down event.

To set the keepalive retry limit, use the **timer-hold retry** command.

On a slow link, increase the keepalive interval to prevent false shutdown of the interface. This situation might occur when keepalive packets are delayed because a large packet is being transmitted on the link.

Examples

Set the keepalive interval to 20 seconds on Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] timer-hold 20
```

Related commands

timer-hold retry

timer-hold retry

Use **timer-hold retry** to set the keepalive retry limit on an interface.

Use **undo timer-hold retry** to restore the default.

Syntax

timer-hold retry *retries*

undo timer-hold retry

Default

The keepalive retry limit is 5 on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

retries: Specifies the maximum number of keepalive attempts in the range of 1 to 255.

Usage guidelines

An interface sends keepalive packets at keepalive intervals to detect the availability of the peer. If the interface receives no response to keepalive packets when the keepalive retry limit is reached, it determines that the link fails and reports a link layer down event.

To set the keepalive interval, use the **timer-hold** command.

On a slow link, increase the keepalive retry limit to prevent false shutdown of the interface. This situation might occur when keepalive packets are delayed because a large packet is being transmitted on the link.

Examples

Set the keepalive retry limit to 10 for Virtual-Template 1.

```
<Sysname> system-view
[Sysname] interface virtual-template 1
[Sysname-Virtual-Template1] timer-hold retry 10
```

Related commands

`timer-hold`

PPPoE commands

PPPoE client commands

dialer bundle enable

Use **dialer bundle enable** to enable bundle DDR on a dialer interface.

Use **undo dialer bundle enable** to disable bundle DDR on a dialer interface.

Syntax

dialer bundle enable

undo dialer bundle enable

Default

Bundle DDR is disabled on a dialer interface.

Views

Dialer interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

DDR includes traditional DDR and bundle DDR.

Before using bundle DDR, use this command to enable bundle DDR on a dialer interface. Then assign physical interfaces to the corresponding dialer bundle by using the **dialer bundle-member** command. To enable bundle DDR to receive calls, configure the **dialer peer-name** command on the dialer interface.

After you configure this command on a dialer interface already enabled with traditional DDR, the system clears the original traditional DDR settings.

The **undo dialer bundle enable** command clears all bundle DDR settings on the dialer interface.

Examples

Enable bundle DDR on Dialer 1.

```
<Sysname> system-view
[Sysname] interface dialer 1
[Sysname-Dialer1] dialer bundle enable
```

dialer diagnose

Use **dialer diagnose** to configure DDR to operate in diagnostic mode.

Use **undo dialer diagnose** to restore the default.

Syntax

dialer diagnose [**interval** *interval*]

undo dialer diagnose

Default

DDR operates in non-diagnostic mode.

Views

Dialer interface view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the diagnostic interval in the range of 5 to 65535 seconds. The default is 120 seconds.

Usage guidelines

This command takes effect only when a dialer interface is used with PPPoE client applications.

In diagnostic mode, the device performs the following operations:

- Dials a PPPoE connection immediately after the device configurations are complete.
- Automatically terminates the connection.
- Starts the auto-dial timer after a configurable diagnostic interval.
- Redials a connection when the auto-dial timer expires.

By establishing and terminating PPPoE sessions periodically, you can monitor the operating status of the PPPoE link.

In diagnostic mode, the link idle-timeout timer is ignored.

Examples

Configure Dialer 1 to operate in diagnostic mode, with a diagnostic interval of 300 seconds.

```
<Sysname> system-view
[Sysname] interface dialer 1
[Sysname-Dialer1] dialer diagnose interval 300
```

Related commands

dialer timer autodial

dialer timer idle

dialer timer autodial

Use **dialer timer autodial** to set the auto-dial timer.

Use **undo dialer timer autodial** to restore the default.

Syntax

dialer timer autodial *autodial-interval*

undo dialer timer autodial

Default

The auto-dial timer is 300 seconds.

Views

Dialer interface view

Predefined user roles

network-admin

context-admin

Parameters

autodial-interval: Specifies the interval between auto-dial attempts, in the range of 1 to 604800 seconds.

Usage guidelines

This command takes effect only when the **autodial** keyword is specified in the **dialer number** or **dialer route** command. DDR automatically dials the dial string at the specified interval until a connection is established. In the auto-dial method, dial attempts are not traffic triggered. Once a connection is established, it will not disconnect based on the idle timer mechanism.

Examples

Set the auto-dial timer to 60 seconds on Dialer 1.

```
<Sysname> system-view
[Sysname] interface dialer 1
[Sysname-Dialer1] dialer timer autodial 60
```

dialer timer idle

Use **dialer timer idle** to set the link idle-timeout timer.

Use **undo dialer timer idle** to restore the default.

Syntax

dialer timer idle *idle* [**in** | **in-out**]

undo dialer timer idle

Default

The link idle-timeout timer is 120 seconds, and only outgoing interesting packets reset this timer.

Views

Dialer interface view

Predefined user roles

network-admin

context-admin

Parameters

idle: Specifies the link idle-timeout timer value in the range of 0 to 65535 seconds.

in: Allows only incoming interesting packets to reset the timer.

in-out: Allows both incoming and outgoing interesting packets to reset the timer.

Usage guidelines

The link idle-timeout timer starts when a link is established. If no interesting packets arrive before the timer expires, DDR disconnects the link.

If you do not specify the **in** or **in-out** keyword, only outgoing interesting packets reset the timer.

If the timer is set to 0, DDR will never disconnect the link. For a PPPoE client application, if the timer is set to 0, a dialup connection is created automatically and remains active permanently.

Examples

Set the link idle-timeout timer to 50 seconds on Dialer 1.

```
<Sysname> system-view
[Sysname] interface dialer 1
[Sysname-Dialer1] dialer timer idle 50
```

dialer-group

Use **dialer-group** to assign a dialer interface to a dialer group.

Use **undo dialer-group** to restore the default.

Syntax

dialer-group *group-number*

undo dialer-group

Default

A dialer interface does not belong to any dialer group.

Views

Dialer interface view

Predefined user roles

network-admin

context-admin

Parameters

group-number: Specifies a dialer group by its number in the range of 1 to 255. Before the assignment, you must create the dialer group by using the **dialer-group rule** command.

Usage guidelines

A dialup interface can belong to only one dialer group. If you configure this command multiple times, the most recent configuration takes effect.

You must configure this command for DDR to send packets.

Examples

Assign Dialer 1 to dialer group 1.

```
<Sysname> system-view
[Sysname] dialer-group 1 rule acl 3101
[Sysname] interface dialer 1
[Sysname-Dialer1] dialer-group 1
```

Related commands

dialer-group rule

dialer-group rule

Use **dialer-group rule** to create a dialer group and configure a dial rule for it.

Use **undo dialer-group rule** to delete a dialer group.

Syntax

dialer-group *group-number* **rule** { **ip** | **ipv6** } { **deny** | **permit** | **acl** { *acl-number* | **name** *acl-name* } }

undo dialer-group *group-number* **rule** [**ip** | **ipv6**]

Default

No dialer group exists.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

group-number: Specifies the number of the dialer group to be created, in the range of 1 to 255.

ip: Specifies the IPv4 protocol.

ipv6: Specifies the IPv6 protocol.

deny: Denies packets of the specified protocol.

permit: Permits packets of the specified protocol.

acl *acl-number*: Specifies an ACL by its number in the range of 2000 to 3999.

name *acl-name*: Specifies an ACL by its name.

Usage guidelines

A dial rule determines when an interface initiates DDR calls. You need to configure dial rules only on the initiator of DDR calls.

You can configure a dial rule to match only IP packets or use an ACL to match packets.

Permitted protocol packets or packets that match a permit statement of an ACL are interesting packets. When receiving an interesting packet, DDR performs one of the following operations:

- Sends it out and resets the idle-timeout timer if a link is present.
- Originates a new call to establish a link if no link is present.

Denied protocol packets or packets that match a deny statement of an ACL are uninteresting packets. When receiving an uninteresting packet, DDR performs one of the following operations:

- Sends it out without resetting the idle-timeout timer if a link is present.
- Drops it if no link is present.

For DDR to forward packets correctly, you must configure a dial rule and associate it with the dialup interface by using the **dialer-group** command.

Examples

Create dialer group 1 and configure DDR to place calls for IPv4 packets. Associate Dialer 1 with dialer group 1.

```
<Sysname> system-view
[Sysname] dialer-group 1 rule ip permit
[Sysname] interface dialer 1
[Sysname-Dialer] dialer-group 1
```

Create dialer group 1 and configure DDR to place calls for IPv6 packets. Associate Dialer 1 with dialer group 1.

```
<Sysname> system-view
[Sysname] dialer-group 1 rule ipv6 permit
[Sysname] interface dialer 1
[Sysname-Dialer1] dialer-group 1
```

Related commands

dialer-group

display pppoe-client session packet

Use **display pppoe-client session packet** to display the protocol packet statistics for a PPPoE session.

Syntax

display pppoe-client session packet [**dial-bundle-number** *number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

dial-bundle-number *number*: Specifies the dialer bundle number corresponding to a PPPoE session. The value range for the number argument is 0 to 1023. If you do not specify this option, the command displays the protocol packet statistics for all PPPoE sessions.

Usage guidelines

To display the data packet statistics for a PPPoE session, use the **display interface virtual-access** command to display information about the specified VA interface.

Examples

Display the protocol packet statistics for all PPPoE sessions.

```
<Sysname> display pppoe-client session packet
Bundle:    1                    Interface:  GE1/0/1
InPackets: 19                   OutPackets: 19
InBytes:   816                  OutBytes:   816
InDrops:   0                    OutDrops:   0

Bundle:    2                    Interface:  GE1/0/1
InPackets: 18                   OutPackets: 18
InBytes:   730                  OutBytes:   730
InDrops:   0                    OutDrops:   0
```

Table 9 Command output

Field	Description
Bundle	Dialer bundle to which a PPPoE session belongs.
Interface	Ethernet interface where the PPPoE session is present.

Field	Description
InPackets	Number of packets received.
OutPackets	Number of packets transmitted.
InBytes	Number of bytes received.
OutBytes	Number of bytes transmitted.
InDrops	Number of discarded incoming packets.
OutDrops	Number of discarded outgoing packets.

Related commands

reset pppoe-client session packet

display pppoe-client session summary

Use **display pppoe-client session summary** to display summary PPPoE session information.

Syntax

display pppoe-client session summary [**dial-bundle-number** *number*]

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

dial-bundle-number *number*: Specifies the dialer bundle number corresponding to a PPPoE session. The value range for the number argument is 0 to 1023. If you do not specify this option, the command displays summary information for all PPPoE sessions.

Examples

Display summary information for all PPPoE sessions.

```
<Sysname> display pppoe-client session summary
Bundle ID    Interface    VA          RemoteMAC      LocalMAC       State
1      1     GE1/0/1      VA0         00e0-1400-4300 00e0-1500-4100 SESSION
2      1     GE1/0/2      VA1         00e0-1500-4300 00e0-1600-4100 SESSION
```

Table 10 Command output

Field	Description
Bundle	Dialer bundle to which the PPPoE session belongs.
Interface	Ethernet interface where the PPPoE session is present.
VA	Virtual access interface created for the PPPoE session.
RemoteMAC	MAC address of the remote end.
LocalMAC	MAC address of the local end.

Field	Description
State	PPPoE session state: • **IDLE**—Initialization state. • **PADI SENT**—A PPPoE Active Discovery Initiation (PADI) packet has been sent, and a PPPoE Active Discovery Offer (PADO) packet is being expected. • **PADR SENT**—A PPPoE Active Discovery Request (PADR) packet has been sent, and a PPPoE Active Discovery Session-confirmation (PADS) packet is being expected. • **SESSION**—The PPPoE session has been successfully established.

mtu

Use **mtu** to set the maximum transmission unit (MTU) of a dialer interface.

Use **undo mtu** to restore the default.

Syntax

mtu *size*

undo mtu

Default

The MTU of dialer interfaces is 1500 bytes.

Views

Dialer interface view

Predefined user roles

network-admin

context-admin

Parameters

size: Specifies the MTU in bytes. The value range for this argument is 128 to 1500.

Usage guidelines

The MTU setting of a dialer interface affects the fragmentation and reassembly of IP packets.

Examples

Set the MTU of Dialer 1 to 1200 bytes.

```
<Sysname> system-view
[Sysname] interface dialer 1
[Sysname-Dialer1] mtu 1200
```

pppoe-client

Use **pppoe-client** to establish a PPPoE session and specify the dialer bundle corresponding to the session.

Use **undo pppoe-client** to remove a PPPoE session.

Syntax

pppoe-client dial-bundle-number *number* [**no-hostuniq**]

undo pppoe-client dial-bundle-number *number*

Default

No PPPoE session is established.

Views

Layer 3 Ethernet interface/subinterface view

VLAN interface view

Layer 3 aggregate interface/subinterface view

Predefined user roles

network-admin

context-admin

Parameters

dial-bundle-number *number*: Specifies the dialer bundle number corresponding to a PPPoE session. A dialer bundle number uniquely identifies a PPPoE session. It can also be used as a PPPoE session ID. The value range for the number argument is 0 to 1023.

no-hostuniq: Configures the client not to carry the Host-Uniq field in discovery packets. If you do not specify this keyword, the client carries the Host-Unique field. The Host-Unique field uniquely identifies a PPPoE client when an interface is configured with multiple PPPoE sessions. When the PPPoE server receives a packet with this field, it must include this field unmodified in the response packet. The device identifies the PPPoE client where the response packet belongs based on the Host-Unique field in the response packet.

Examples

Establish a PPPoE session on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] pppoe-client dial-bundle-number 1
```

Establish a PPPoE session on VLAN-Interface 1.

```
<Sysname> system-view
[Sysname] interface vlan-interface 1
[Sysname-Vlan-interface1] pppoe-client dial-bundle-number 1
```

reset pppoe-client

Use **reset pppoe-client** to reset a PPPoE session corresponding to a dialer bundle.

Syntax

reset pppoe-client { **all** | **dial-bundle-number** *number* }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

all: Resets all the PPPoE sessions.

dial-bundle-number *number*: Specifies a dialer bundle by its number. The value range for the number argument is 0 to 1023.

Usage guidelines

A PPPoE session in permanent mode and terminated by this command will be established again when the auto dial timer expires.

A PPPoE session in on-demand mode and terminated by this command will be established again only when there is a need for data transmission.

Examples

Reset all PPPoE sessions.

```
<Sysname> reset pppoe-client all
```

Related commands

dialer timer autodial

reset pppoe-client session packet

Use **reset pppoe-client session packet** to reset the protocol packet statistics for a PPPoE session.

Common management commands

controller cellular

Use **controller cellular** to enter cellular interface view.

Syntax

controller cellular *cellular-number*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

cellular-number: Specifies a cellular interface by its number.

Examples

Enter Cellular 1/0/1 interface view.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1]
```

description

Use **description** to configure the description of an interface.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

The description for a cellular interface is in the *interface name* **Interface** format, for example, Cellular 1/0/1 Interface.

Views

Cellular interface view

Predefined user roles

network-admin

Table 1 Command output

Field	Description
Model	Modem name.
International Mobile Equipment Identity (IMEI)	IMEI serial number of the modem.
Modem Status	Status of the modem: • **Online**—The modem is powered on. • **Offline**—The modem is powered off or in lower power mode. The cellular interface is unavailable.
Profile Information	Profile settings for the modem.
Profile index	Index of the profile for modem.

Field	Description
PDP Type	PDP type, displayed only when Profile 1 is **Active**: • IPv4. • IPv6. • PPP (transparent transmission).
Header Compression	PDP header compression status • On. • Off.
Data Compression	PDP data compression status: • On. • Off.
Current Service Status	Service status of the modem: • **Limited**—The modem is not in the coverage of the selected network. The cellular interface is not available. • **Service available**—The modem is providing services correctly. • **Emergency**—The modem is providing limited services. The cellular interface is not available. • **No service**—The modem cannot provide services. The cellular interface is not available. • **Low power**—The modem is in low power mode. The cellular interface is not available.
Current Roaming Status	Roaming status: • Roaming. • Home.
Current Data Bearer Technology	Current data carrier technology: • CDMA2000 1X. • CDMA2000 HRPD (1xEV-DO). • GSM. • UMTS. • CDMA2000 HRPD (1xEV-DO RevA). • EDGE. • HSDPA and WCDMA. • WCDMA and HSUPA. • HSDPA and HSUPA. • LTE. • CDMA2000 EHRPD. • HSDPA+ and WCDMA. • HSDPA+ and HSUPA. • DC_HSDPA+ and WCDMA. • DC_HSDPA+ and HSUPA. • HSDPA+ and 64QAM. • HSDPA+, 64QAM and HSUPA. • TDSCDMA. • TDSCDMA and HSDPA. • Unknown.
Network Selection Mode	Network selection mode • Manual. • Automatic.

Field	Description
Mobile Country Code (MCC)	The MCC is displayed if the modem has found the network.
Mobile Network Code (MNC)	The MNC is displayed if the modem is successfully registered with a mobile network.
Location Area Code (LAC)	The LAC is displayed if the modem is successfully registered with a mobile network.
Cell ID	The Cell ID is displayed if the modem is successfully registered with a mobile network.
Radio Information	Radio communication information.
Technology Preference	Network connecting preference: • **AUTO**—Connects to a network automatically. • **GSM only**—Connects to a GSM network only. • **GSM precedence**—Connects to a GSM network with preference. • **WCDMA only**—Connects to a WCDMA network only. • **WCDMA precedence**—Connects to a WCDMA network with preference. • **TD-SCDMA only**—Connects to a TD-SCDMA network only. • **TD-SCDMA precedence**—Connects to a TD-SCDMA network with preference. • **EVDO**—Connects to a CDMA-EVDO network only. • **1x RTT**—Connects to a CDMA-1x RTT network only. • **1xRTT/EVDO HYBRID**—Connects to the CDMA-EVDO and CDMA-1x RTT hybrid networks only. • **LTE only**—Connects to an LTE network only.
Technology Selected	Current network: • **GSM**—Has connected to a GSM network. • **WCDMA**—Has connected to a WCDMA network. • **TD-SCDMA**—Has connected to a TD-SCDMA network. • **EVDO**—Has connected to a CDMA-EVDO network. • **1Xrtt**—Has connected to a CDMA-1x RTT network. • **1xRTT/EVDO HYBRID**—Has connected to the CDMA-EVDO and CDMA-1x RTT networks. • **LTE**—Has connected to an LTE network.
LTE related info	Information about the LTE network.
Current RSSI	Current RSSI: • An RSSI value in the range of –110 dBm and –51 dBm. • **Unknown**—No signal. The cellular interface is unavailable.
Current RSRQ	Reference Signal Received Quality.
Current RSRP	Reference Signal Receiving Power.
Current SNR	Signal to noise ratio.
Tx Power	Transmitting power.
Modem Security Information	Information about modem security.

Field	Description
PIN Verification	PIN authentication status: • Disabled. • Enabled. • Unknown.
PIN Status	PIN status: • **Ready**—The SIM card is ready. • **PIN Requirement**—Requires you to execute the **`pin verify`** command to enter the PIN for PIN verification. • **PUK Requirement**—Requires you to execute the **`pin unlock`** command to unlock the SIM or UIM card.
SIM Status	SIM card status: • **OK**—The SIM card is normal. • **Network Reject**—The SIM card is denied access to the network. The cellular interface is not available. • **Not Insert**—The SIM card is absent. The cellular interface is not available. • **Not Initialized**—The SIM card status cannot be identified.
ICCID	ID of the SIM card, displayed only when the SIM card status is **OK**.

display controller cellular

Use **`display controller cellular`** to display information about cellular interfaces.

Syntax

`display controller` [**`cellular`** [*`interface-number`*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

cellular [*interface-number*]: Specifies cellular interfaces or a cellular interface by its number. If you do not specify the **cellular** keyword, this command displays information about all interfaces. If you specify the **cellular** keyword but not the *interface-number* argument, this command displays information about all cellular interfaces.

Usage guidelines

Hot swapping a USB mobile communication modem clears the cellular interface statistics.

Examples

Display information about Cellular 1/0/1.

```
<Sysname> display controller cellular 1/0/1
Cellular1/0/1
Current state: UP
Description: Cellular1/0/1 Interface
Modem status: Present
DM port status: Disabled
Capability:
  1 Control channel, 1 PPP channel
Control channel 0 traffic statistics:
  TX: 0 packets, 0 errors
  RX: 0 packets, 0 errors
PPP channel 0 traffic statistics:
  TX: 0 packets, 0 errors
  RX: 0 packets, 0 errors
```

Table 2 Command output

Field	Description
Cellular1/0/1 Current state	Status of the interface: • **DOWN(Administratively)**—The interface has been administratively shut down by using the **shutdown** command. • **DOWN**—The interface is administratively up but its physical state is down, possibly because of a connection or link failure. • **UP**—The administrative and physical states of the interface are both up.
Description	Description of the interface.
Modem status	Status of the USB mobile communication modem: • **Present**—The modem is present. • **Absent**—The modem is absent.
DM port status	DM status: • Enabled. • Disabled.
Capability: 1 Control channel, 1 PPP channel	Type and number of channels the cellular interface supports: • **1 Control channel**—Supports one control channel. • **1 PPP channel**—Supports one asynchronous serial subchannel. • **1 ETH channel**—Supports one Ethernet subchannel.

Field	Description
Control channel 0 traffic statistics: TX: 0 packets, 0 errors RX: 0 packets, 0 errors	Control channel statistics: • **TX: 0 packets, 0 errors**—Number of packets and number of error packets sent through the control channel. • **RX: 0 packets, 0 errors**—Number of packets and number of error packets received through the control channel.
PPP channel 0 traffic statistics TX: 0 packets, 0 errors RX: 0 packets, 0 errors	PPP channel statistics: • **TX: 0 packets, 0 errors**—Number of packets and number of error packets sent through the PPP channel. • **RX: 0 packets, 0 errors**—Number of packets and number of error packets received through the PPP channel.
ETH channel 0 traffic statistics TX: 0 packets, 0 errors RX: 0 packets, 0 errors	Ethernet channel statistics: • **TX: 0 packets, 0 errors**—Number of packets and number of error packets sent through the Ethernet channel. • **RX: 0 packets, 0 errors**—Number of packets and number of error packets received through the Ethernet channel.

Related commands

reset counters controller cellular

dm-port open

Use **dm-port open** to enable diagnostic and monitoring (DM) on a mobile communication modem.

Use **undo dm-port open** to disable DM on a mobile communication modem.

Syntax

dm-port open

undo dm-port open

Default

The default setting for this command depends on the modem model.

Views

Cellular interface view

Predefined user roles

network-admin

network-admin

context-admin

Usage guidelines

Enabling DM on a mobile communication modem allows third-party debugging tools to diagnose and monitor the mobile communication modem through cellular interface debugging output.

Examples

Enable DM on a mobile communication modem.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] dm-port open
```

mode

Use **mode** to specify network services for a mobile communication modem.

Syntax

mode { **1xrtt** | **auto** | **evdo** | **gsm** | **gsm-precedence** | **hybrid** | **lte** | **td** | **td-precedence** | **wcdma** | **wcdma-precedence** }

Default

The default setting for this command depends on the modem model.

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

1xrtt: Connects to a CDMA-1x RTT network only.

auto: Connects to a network automatically.

evdo: Connects to a CDMA-EVDO network only.

gsm: Connects to a GSM network only.

gsm-preference: Connects to a GSM network with preference.

hybrid: Connects to the CDMA-EVDO and CDMA-1xRTT networks only.

lte: Connects to an LTE network only.

td: Connects to a TD-SCDMA network only.

td-preference: Connects to a TD-SCDMA network with preference.

wcdma: Connects to a WCDMA network only.

wcdma-preference: Connects to a WCDMA network with preference.

Usage guidelines

The available parameters depend on the modem model.

Examples

Specify the LTE service for the 4G modem.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] mode lte
```

modem reboot

Use **modem reboot** to reboot a mobile communication modem.

Syntax

modem reboot

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

CAUTION:

Execute this command with caution. This command will disconnect the established 3G/4G modem connections.

A mobile communication modem module can automatically detect running errors and reboot. If the mobile communication modem fails to reboot by itself, you can use this command to reboot it.

Examples

Manually reboot the mobile communication modem.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] modem reboot
```

modem response

Use **modem response** to set a mobile communication modem response timer and a consecutive response failure threshold for auto recovery.

Use **undo modem response** to restore the default.

Syntax

modem response timer *time* **auto-recovery** *threshold*

undo modem response

Default

The response timer is 10 seconds and the consecutive response failure threshold is 3.

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

timer *time*: Sets the response timer, in the range of 1 to 300, in seconds.

auto-recovery *threshold*: Specifies the consecutive response failure threshold for auto recovery. The value range for the *threshold* argument is 0 to 10. To disable auto recovery, set the value to 0.

Usage guidelines

A mobile communication modem might malfunction in an unstable mobile communication network or when the application environment changes. During a malfunction, the modem cannot respond to the device's requests or configuration commands. If the device does not receive any responses from the mobile communication modem before the timer times out, a response failure occurs. When the number of consecutive response failures reaches the threshold, the device restarts the mobile communication modem automatically. This releases the user from manually rebooting the modem.

The device does not restart the mobile communication modem when the mobile communication modem has not made a successful dialup since the last restart. This restriction avoids repeated restarts of the mobile communication modem when there are configuration errors.

Examples

Set the response timer to 20 seconds and the consecutive response failure threshold for auto recovery to 4.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] modem response timer 20 auto-recovery 4
```

pin modify

Use **pin modify** to modify the PIN of a SIM/UIM card.

Syntax

pin modify *current-pin new-pin*

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

current-pin: Specifies the current PIN of the SIM/UIM card, a string of 4 to 8 digits.

new-pin: Specifies the new PIN, a string of 4 to 8 digits.

Usage guidelines

The new PIN is saved on the SIM/UIM card.

If PIN verification is enabled, execute the **pin verify** command to save the new PIN on the device after the PIN is modified.

Failure to modify the PIN in a maximum number of attempts locks the SIM/UIM card. The maximum number of attempts depend on the mobile communication modem model. To unlock the card, execute the **pin unlock** command.

For some mobile communication modems, you can modify their PINs only when the mobile communication modems pass the PIN authentication.

Examples

Modify the PIN of a SIM/UIM card.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] pin modify 1234 4321
PIN will be changed to “4321”. Continue? [Y/N]:y
PIN has been changed successfully.
```

Related commands

pin unlock

pin verification enable

pin verify

pin unlock

Use **pin unlock** to specify the Personal Unlock Code (PUK) to unlock a SIM/UIM card.

Syntax

pin unlock *puk new-pin*

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

puk: Specifies the PUK of the SIM/UIM card, a string of 4 to 8 digits. The PUK code of a SIM/UIM card is provided by the network service provider.

new-pin: Specifies the new PIN, a string of 4 to 8 digits.

Usage guidelines

A SIM/UIM card will be locked in the following circumstances:

- Consecutive PIN modification failures.
- Consecutive failures for enabling or disabling PIN authentication.
- Consecutive PIN authentication failures.

If the SIM/UIM card is locked, the modem cannot be used. To unlock the card, you can use the **pin unlock** command. The new PIN is saved on the SIM/UIM card.

If PIN verification is enabled, use the **pin verify** command to save the new PIN on the device after the SIM/UIM card is unlocked.

If you consecutively fail to unlock a card by using the PUK, the card will be locked permanently. To unlock a permanently locked card, contact the service provider of the card.

Examples

Use the PUK to unlock a SIM/UIM card.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] pin unlock 87654321 1234
PIN will be unlocked and changed to “1234”. Continue? [Y/N]:y
PIN has been unlocked and changed successfully.
```

Related commands

pin modify

pin verification enable

pin verification enable

Use **pin verification enable** to enable PIN verification for a mobile communication modem.

Use **undo pin verification enable** to disable PIN verification for a mobile communication modem.

Syntax

pin verification enable [*pin*]

undo pin verification enable [*pin*]

Default

The default setting for this command depends on the modem model.

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

pin: Specifies the PIN of the SIM/UIM card, a string of 4 to 8 digits.

Usage guidelines

If PIN verification is enabled, PIN verification is performed after you perform any of the following tasks:

- Install a mobile communication modem.
- Reboot the device.
- Execute the **modem reboot** command to reboot a mobile communication modem.
- Hot swap a USB mobile communication modem.

To perform PIN verification, you also need to execute the **pin verify** command to save the PIN of the SIM/UIM card on the device. After the PIN is saved on the device, the PIN is used for verification automatically when required.

You might be required to provide the current PIN when you enable or disable PIN verification. Consecutive failures for enabling or disabling PIN verification lock a SIM/UIM card. To unlock the card, execute the **pin unlock** command.

For some mobile communication modems, you can disable PIN verification only when the mobile communication modems pass PIN authentication.

Examples

Enable PIN authentication.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] pin verification enable 1234
```

Related commands

pin unlock

pin verify

pin verify

Use **pin verify** to specify the PIN of a SIM/UIM card on a mobile communication modem.

Use **undo pin verify** to restore the default.

Syntax

pin verify { **cipher** | **simple** } *string*

undo pin verify

Default

No PIN is specified for a SIM/UIM card.

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

cipher *ciphered-pin*: Specifies a PIN in encrypted form.

simple *pin*: Specifies a PIN in plaintext form. For security purposes, the PIN specified in plaintext form will be stored in encrypted form.

string: Specifies the PIN. Its plaintext form is 4 to 8 digits long. Its encrypted form is a string of 37 to 41 characters.

Usage guidelines

This command saves the PIN of the SIM/UIM card on the device. The PIN is used for verifying the mobile communication modem when PIN verification is performed. You can execute this command before or after you enable PIN verification.

Consecutive PIN verification failures might lock a SIM/UIM card. To unlock the card, execute the **pin unlock** command.

Examples

Specify the plaintext form PIN **1234** for the SIM/UIM card.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] pin verify simple 1234
```

Related commands

pin unlock

pin verification enable

plmn search

Use **plmn search** to search for available mobile networks.

Syntax

plmn search

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

Before you use a mobile communication modem to access a mobile network, use the **plmn search** command to search a PLMN for available mobile networks. The search takes a few minutes. After

the search is complete, the CLI displays the available mobile networks. Some mobile communication modems automatically access an available network. You can also specify a mobile network for the mobile communication modem from the available mobile networks.

Examples

Search for mobile networks on Cellular 1/0/1.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] plmn search
PLMN search done.
Available PLMNs:
PLMN No.     MCC    MNC    Status     Type
01           460    00     Current    GSM
02           460    00     Available  UTRAN
03           460    01     Forbidden  GSM
```

Table 3 Command output

Field	Description
PLMN No	PLMN number.
MCC	Mobile Country Code.
MNC	Mobile Network Code: • **00, 02, and 07**—China Mobile. • **01**—China Unicom. • **03**—China Telecom.
Status	Status of the mobile network: • Current. • Available. • Forbidden.
Type	Type of the mobile network.

Related commands

display cellular

plmn select

plmn select

Use **plmn select** to configure the mobile network selection mode.

Syntax

plmn select { **auto** | **manual** *mcc mnc* }

Default

The default setting for this command depends on the modem model.

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

auto: Specifies the auto selection mode. The modem automatically selects a mobile network.

manual: Specifies the manual selection mode.

mcc: Specifies the mobile country code (MCC) in the range of 0 to 65535.

mnc: Specifies the mobile network code (MNC) in the range of 0 to 65535.

Usage guidelines

For manual selection, you can first use the **plmn search** command to obtain the MCC and MNC of a mobile network.

Examples

Manually specify a mobile network.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] plmn select manual 65524 65524
```

Related commands

display cellular

plmn search

reset counters controller cellular

Use **reset counters controller cellular** to clear statistics on cellular interfaces.

Syntax

reset counters controller cellular [*interface-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

cellular [*interface-number*]: Specifies cellular interfaces or a cellular interface by its number. If you do not specify the *interface-number* argument, this command clears statistics on all cellular interfaces. If you specify the *interface-number* argument, this command clears statistics on the specified cellular interface.

Usage guidelines

To collect traffic statistics on an interface during a period of time, first use the **reset counters controller cellular** command to clear the existing statistics on the interface.

Examples

Clear statistics on Cellular 1/0/1.

```
<Sysname> reset counters controller cellular 1/0/1
```

Related commands

display controller cellular

rssi

Use **rssi** to set the RSSI thresholds for a mobile communication modem.

Use **undo rssi** to restore the default.

Syntax

rssi { **1xrtt** | **evdo** | **gsm** | **lte** } { **low** *lowthreshold* | **medium** *mediumthreshold* } *

undo rssi { **1xrtt** | **evdo** | **gsm** | **lte** } [**low** | **medium**]

Default

The lower and upper RSSI thresholds for a mobile communication modem are –150 dBm and 0 dBm, respectively.

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

1xrtt: Specifies the 1xRTT mode.

evdo: Specifies the EVDO mode.

gsm: Specifies the GSM mode.

lte: Specifies the LTE mode.

low *lowthreshold*: Specifies the lower RSSI threshold value in the range of 0 to 150, which represents a lower RSSI threshold in the range of –150 dBm to 0 dBm. The value of *lowthreshold* cannot be smaller than the value of mediumthreshold because the system automatically adds a negative sign to the RSSI thresholds.

medium *mediumthreshold*: Specifies the upper RSSI threshold value in the range of 0 to 150, which represents an upper RSSI threshold in the range of –150 dBm to 0 dBm.

Usage guidelines

The device performs the following operations based on the actual RSSI of the mobile communication modem:

- Sends a trap that indicates high RSSI when the RSSI exceeds the upper threshold.
- Sends a trap that indicates normal RSSI when the RSSI is between the lower threshold and upper threshold (included).
- Sends a trap that indicates low RSSI when the RSSI drops to or below the lower threshold.
- Sends a trap that indicates low RSSI every 10 minutes when the RSSI remains equal to or smaller than the lower threshold.

To view the RSSI change information for a mobile communication modem, use the **display cellular** command.

Examples

Set the lower threshold for a mobile communication modem in GSM mode to –110 dBm.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
```

```
[Sysname-Cellular1/0/1] rssi gsm low 110
```

sendat

Use **sendat** to issue a configuration directive to a mobile communication modem.

Syntax

sendat *at-string*

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

at-string: Specifies a configuration directive string, a string of 1 to 300 characters. This argument can be an AT directive (containing **+++**, **A/**, or be any string beginning with **AT**) or a CNS directive. For more information about AT directives, see the **sendat** command in *Layer 2—WAN Access Command Reference*. Table 4 describes the CNS directive samples.

Table 4 CNS directive description

Directive	Description
CNS*n*	Controls the CNS heartbeat debugging switch. • **n = 00000500000000000000**—Enables CNS heartbeat debugging. • **n = 00000800000000000000**—Disables CNS heartbeat debugging.

Usage guidelines

The **sendat** command does not verify the configuration directive. Each time it issues one configuration directive to the mobile communication modem, lowercase characters are automatically converted to uppercase characters.

One **sendat** command issues one configuration directive. To issue multiple configuration directives to a modem, you must repeat the **sendat** command.

Configuration directives might cause malfunction of a mobile communication modem. When you issue a configuration directive to the modem, make sure you understand the impact on the mobile communication modem.

Examples

Issue the **ATD169** directive to the mobile communication modem to call number 169.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] sendat ATD169
```

Issue the **cns00000500000000000000** directive to the mobile communication modem to enable CNS heartbeat debugging.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] sendat cns00000500000000000000
```

shutdown

Use **shutdown** to shut down a cellular interface.

Use **undo shutdown** to bring up a cellular interface.

Syntax

shutdown

undo shutdown

Default

The cellular interface is up.

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Examples

Shut down Cellular 1/0/1.

```
<Sysname> system-view
[Sysname] interface cellular 1/0/1
[Sysname-Cellular1/0/1] shutdown
```

3G modem-specific management commands

gsm band

Use **gsm band** to specify a GSM frequency band.

Use **undo gsm band** to restore the default.

Syntax

gsm band { **egsm900** | **gsm450** | **gsm480** | **gsm750** | **gsm850** | **gsm1800** | **gsm1900** | **pgsm900** | **rsgm900** }

undo gsm band

Default

No GSM band is specified.

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

egsm900: Specifies the E-GSM 900 MHz band.

gsm450: Specifies the GSM 450 MHz band.

gsm480: Specifies the GSM 480 MHz band

gsm750: Specifies the GSM 750 MHz band.

gsm850: Specifies the GSM 850 MHz band.

gsm1800: Specifies the GSM 1800 MHz band.

gsm1900: Specifies the GSM 1900 MHz band.

pgsm900: Specifies the P-GSM 900 MHz band.

rgsm900: Specifies the GSM-R 900 MHz band.

Usage guidelines

This command is supported only by Sierra MC7354 (ATT version) and MC7304 4G modules.

Multiple frequency bands are available for accessing the GSM network. When the network environment changes, the 3G/4G modem might change the working band automatically to adapt to the change. To avoid link instability caused by frequency changes, you can specify a GSM band for the 3G/4G modem.

Examples

Specify the GSM 1800 MHz band for the 3G/4G modem.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] gsm band gsm1800
```

profile create

Use **profile create** to create a profile for the 3G modem.

Syntax

profile create *profile-number* { **dynamic** | **static** *apn* } **authentication-mode** { **none** | { **chap** | **pap** } **user** *username* [**password** *password*] }

Default

The default setting for this command depends on the modem model.

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

profile-number: Specifies a profile number. The value range varies by the modem model.

dynamic: Uses an access point automatically assigned by the service provider.

static *apn*: Specifies the access point provided by the service provider. It is a string of 1 to 100 characters. Whether the string is case-sensitive varies by service providers.

authentication-mode: Specifies the authentication mode, which can be **none**, **pap**, or **chap**.

none: Performs no authentication.

chap: Specifies CHAP authentication.

pap: Specifies PAP authentication.

user *username*: Specifies the username provided by the service provider. It is a case-sensitive string of 1 to 32 characters.

password *password*: Specifies the authentication password provided by the service provider. It is a case-sensitive string of 1 to 32 characters.

Usage guidelines

If you specify **chap** or **pap,** make sure the authentication settings are identical to those assigned by the service provider.

Examples

Create a profile for Cellular 1/0/1. Specify the profile number as 1 and the access point name as **cmnet**, and specify the PAP authentication mode.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] profile create 1 static cmnet authentication-mode pap user abc password abc
```

display cellular

profile create

profile main

Use **profile main** to specify the primary and backup profiles for 3G modem dialup.

Use **undo profile main** to restore the default.

Syntax

profile main *profile-M-number* **backup** *profile-B-number*

undo profile main

Default

Profile 1 is used for 3G modem dialup.

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

main *profile-M-number*: Specifies the primary profile by its number. The value range varies by the modem model.

backup *profile-B-number*: Specifies the backup profile by its number. The value range varies by the modem model.

Usage guidelines

The primary profile always has priority over the backup profile. For each dialup connection establishment, the 3G modem uses the backup profile only when it has failed to dial up using the primary profile.

You must configure the same user name and password for the primary and backup profiles.

This command takes effect only on dialup connections initiated after the command is configured. It does not take effect on a dialup connection that has been established.

Examples

Specify the profiles numbered **1** and **2** as the primary and backup profiles, respectively.

```
<sysname>system-view
[sysname]interface cellular 1/0/1
[sysname-Cellular1/0/1]profile main 1 backup 2
```

wcdma band

Use **wcdma band** to specify a WCDMA band.

Use **undo wcdma band** to restore the default.

Syntax

wcdma band { **wcdma800** | **wcdma850** | **wcdma900** | **wcdma1700ip** | **wcdma1700us** | **wcdma1800** | **wcdma1900** | **wcdma2100** | **wcdma2600** }

undo wcdma band

Default

No WCDMA band is specified.

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

wcdma800: Specifies the WCDMA 800 MHz band.

wcdma850: Specifies the WCDMA 850 MHz band.

wcdma900: Specifies the WCDMA 900 MHz band.

wcdma1700jp: Specifies the Japan WCDMA 1700 MHz band.

wcdma1700us: Specifies the US WCDMA 1700 MHz band.

wcdma1800: Specifies the WCDMA 1800 MHz band.

wcdma1900: Specifies the WCDMA 1900 MHz band.

wcdma2100: Specifies the WCDMA 2100 MHz band.

wcdma2600: Specifies the WCDMA 2600 MHz band.

Usage guidelines

This command is supported only by Sierra MC7354 (ATT version) and MC7304 4G modules.

Multiple frequency bands are available for accessing the WCDMA network. When the network environment changes, the 3G/4G modem might change the working band automatically to adapt to the change. To avoid link instability caused by frequency changes, you can specify a WCDMA band for the 3G/4G modem.

Examples

Specify the WCDMA 1700 MHz band for the 3G/4G modem.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] wcdma band wcdma1700

profile-name: Specifies a 4G modem profile name.

Usage guidelines

A 4G modem profile takes effect only after you apply the profile to a 4G interface. To remove a 4G modem profile, you must first remove the association between the profile and the 4G interface.

Examples

Create 4G modem profile **test**.

```
<Sysname> system-view
[Sysname] apn-profile test
```

Related commands

apn-profile apply

apn-profile apply

Use **apn-profile apply** to specify 4G modem profiles for an interface.

Use **undo apn-profile apply** to restore the default.

Syntax

apn-profile apply *profile-name* [**backup** *profile-name*]

undo apn-profile apply

Default

No 4G modem profiles are specified for an interface.

Views

Eth-channel interface view

Predefined user roles

network-admin

context-admin

Parameters

profile-name: Specifies a primary 4G modem profile name.

backup *profile-name*: Specifies a backup 4G modem profile name.

Usage guidelines

After you specify a 4G modem profile, the 4G modem uses the settings in the profile to negotiate with the service provider's device.

A primary profile always takes precedence over a backup profile. For each dialup connection establishment, the 4G modem uses the backup profile only when it has failed to dial up using the primary profile.

This command takes effect only on dialup connections initiated after the command is configured. It does not take effect on a dialup connection that has been established.

Examples

Specify primary 4G modem profile **test** and backup 4G modem profile **bktest** for Eth-channel 1/0/1:0.

```
<Sysname> system-view
[Sysname] interface eth-channel 1/0/1:0
[Sysname-Eth-channel1/0/1:0] apn-profile apply test backup bktest
```

Related commands

apn-profile

attach-format imsi-sn split

Use **attach-format imsi-sn split** to specify a delimiter for the IMSI/SN binding authentication information.

Use **undo attach-format imsi-sn split** to restore the default.

Syntax

attach-format imsi-sn split *splitchart*

undo attach-format imsi-sn split

Default

No delimiter is specified for the IMSI/SN binding authentication information.

Views

4G modem profile view

Predefined user roles

network-admin

context-admin

Parameters

split *splitchart*: Specifies a delimiter. It can be a letter, a digit, or a sign such as a percent sign (%) or a pound sign (#).

Usage guidelines

If IMSI/SN binding authentication is enabled, the IMSI/SN information is included in the authentication information in addition to the username. You need to configure a delimiter to separate different types of information. For example, if you specify the delimiter as #, the authentication information will be sent in the imsiinfo#sninfo#username format.

Examples

Configure the pound sign (#) as the delimiter for the IMSI/SN binding authentication information.

```
<Sysname> system-view
[Sysname] apn-profile test
[Sysname-apn-profile-test] attach-format imsi-sn split #
```

Related commands

apn-profile

authentication-mode

Use **authentication-mode** to specify an authentication mode for accessing a 4G network.

Use **undo authentication-mode** to restore the default.

Syntax

authentication-mode { **pap** | **chap**| **pap-chap** } **user** *user-name* **password** { **cipher** | **simple** } *string*

undo authentication-mode

Default

No authentication mode is specified for accessing a 4G network.

Views

4G modem profile view

Predefined user roles

network-admin

context-admin

Parameters

chap: Specifies CHAP authentication.

pap: Specifies PAP authentication.

pap-chap: Specifies CHAP or PAP authentication.

user *username*: Specifies the username for authentication, a case-sensitive string of 1 to 32 characters.

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 32 characters. Its encrypted form is a case-sensitive string of 1 to 73 characters.

Examples

Specify the CHAP authentication mode for 4G modem profile **test**. Specify the username as **user1** and the password as **123456**.

```
<Sysname> system-view
[Sysname] apn-profile test
[Sysname-apn-profile-test] authentication-mode chap user user1 password simple 123456
```

Related commands

apn-profile

bandwidth

Use **bandwidth** to configure the expected bandwidth for an Eth-channel interface.

Use **undo bandwidth** to restore the default.

Syntax

bandwidth *bandwidth-value*

undo bandwidth

Default

The expected bandwidth (in kbps) is the interface baud rate divided by 1000.

Views

Eth-channel interface view

Predefined user roles

network-admin

context-admin

Parameters

bandwidth-value: Specifies the expected bandwidth in the range of 1 to 400000000 kbps.

Usage guidelines

The expected bandwidth for an interface affects the link costs in OSPF, OSPFv3, and IS-IS. For more information, see *Layer 3—IP Routing Configuration Guide*.

Examples

Set the expected bandwidth for Eth-channel 1/0/1:0 to 1000 kbps.

```
<Sysname> system-view
[Sysname] interface eth-channel 1/0/1:0
[Sysname-Eth-channel1/0/1:0] bandwidth 1000
```

default

Use **default** to restore the default settings for an interface.

Syntax

default

Views

Eth-channel interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

CAUTION:

The **default** command might interrupt ongoing network services. Make sure you are fully aware of the impact of this command before using it on a live network.

This command might fail to restore the default settings for some commands for reasons such as command dependencies and system restrictions. Use the **display this** command in interface view to identify these commands. Then, use their **undo** forms or follow the command reference to individually restore their default settings. If your restoration attempt fails, follow the error message instructions to resolve the problem.

Examples

Restore the default settings for Eth-channel 1/0/1:0.

```
<Sysname> system-view
[Sysname] interface eth-channel 1/0/1:0
[Sysname-Eth-channel1/0/1:0] default
```

description

Use **description** to configure the description of an interface.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

The description for an interface is in the *interface name* Interface format, for example, Echannel1/0/1:0 Interface.

Views

Eth-channel interface view

Predefined user roles

network-admin

context-admin

Parameters

text: Sets an interface description, a case-sensitive string of 1 to 255 characters.

Usage guidelines

Configure the description of an interface for easy identification and management purposes.

You can use the **display interface** command to view the description for an interface.

Examples

Configure the description for Eth-channel 1/0/1:0 as **Echannel-interface**.

```
<Sysname> system-view
[Sysname] interface eth-channel 1/0/1:0
[Sysname-Eth-channel1/0/1:0] description Echannel-interface
```

display interface eth-channel

Use **display interface eth-channel** to display information about the specified or all Eth-channel interfaces.

Syntax

display interface [**eth-channel** [*channel-id*]] [**brief** [**description** | **down**]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

eth-channel [*channel-id*]: Specifies Eth-channel interfaces or an Eth-channel interface by its number. If you do not specify the **eth-channel** keyword, the command displays information about all interfaces. If you specify the **eth-channel** keyword but not the *channel-id* argument, this command displays information about all Eth-channel interfaces.

brief: Displays brief interface information. If you do not specify this keyword, the command displays detailed interface information.

description: Displays complete interface descriptions. If you do not specify this keyword, the command displays only the first 27 characters of interface descriptions.

down: Displays information about interfaces in down state and the causes. If you do not specify this keyword, the command displays information about interfaces in all states.

Examples

Display detailed information about Eth-channel 1/0/1:0, including its operating status.

```
<Sysname> display interface eth-channel 1/0/1:0
Echannel1/0/1:0
Current state: DOWN
Line protocol state: DOWN
Description: Echannel1/0/1:0 Interface
Bandwidth: 100000kbps
Maximum Transmit Unit: 1500
Internet protocol processing: disabled
IP Packet Frame Type:PKTFMT_ETHNT_2, Hardware Address: 000c-2963-b75d
IPv6 Packet Frame Type:PKTFMT_ETHNT_2, Hardware Address: 000c-2963-b75d
Output queue - Urgent queuing: Size/Length/Discards 0/100/0
Output queue - Protocol queuing: Size/Length/Discards 0/500/0
Output queue - FIFO queuing: Size/Length/Discards 0/75/0
Last link flapping: Never
Last clearing of counters: Never
Last 300 seconds input rate 0.00 bytes/sec, 0.00 packets/sec
Last 300 seconds output rate 0.00 bytes/sec, 0.00 packets/sec
Input: 0 packets, 0 bytes, 0 buffers
Output:0 packets, 0 bytes
```

Display brief information about Eth-channel 1/0/1:0.

```
<Sysname> display interface eth-channel 1/0/1:0 brief
Brief information on interface(s) under route mode:
Link: ADM - administratively down; Stby - standby
Protocol: (s) - spoofing
Interface            Link Protocol Main IP         Description
Echannel1/0/1:0      UP   UP(s)    192.168.80.239
```

Display information about all Eth-channel interfaces in down state and the causes.

```
<Sysname> display interface eth-channel brief down
Brief information on interface(s) under route mode:
Link: ADM - administratively down; Stby - standby
Interface            Link Cause
Echannel1/0/1:0      ADM  Administratively
```

Table 5 Command output

Field	Description
Current state	Physical link state of the interface: • **Administratively DOWN**—The interface has been shut down by using the **shutdown** command. • **DOWN**—The interface is administratively up, but its physical state is down (possibly because no physical link exists or the link has failed). • **UP**—The interface is both administratively and physically up.

Field	Description
Line protocol state	Data link layer state of the interface. The state is determined through automatic parameter negotiation at the data link layer. • **UP**—The data link layer protocol is up. • **UP (spoofing)**—The data link layer protocol is up, but the link is an on-demand link or does not exist. This attribute is typical of null interfaces and loopback interfaces. • **DOWN**—The data link layer protocol is down.
Description	Description for the interface.
Bandwidth	Expected bandwidth of the interface.
Maximum Transmit Unit	MTU of the interface.
Internet address: *ip-address*/*mask-length* (*Type*)	IP address of the interface and type of the address in parentheses. Possible IP address types include: • **Primary**—Manually configured primary IP address. • **Sub**—Manually configured secondary IP address. If the interface has both primary and secondary IP addresses, the primary IP address is displayed. If the interface has only secondary IP addresses, the lowest secondary IP address is displayed. • **DHCP-allocated**—DHCP allocated IP address. For more information, see DHCP client configuration in *Layer 3—IP Services Configuration Guide*. • **BOOTP-allocated**—BOOTP allocated IP address. For more information, see BOOTP client configuration in *Layer 3—IP Services Configuration Guide*. • **PPP-negotiated**—IP address assigned by a PPP server during PPP negotiation. For more information, see PPP configuration in *Layer 2—WAN Access Configuration Guide*. • **Unnumbered**—IP address borrowed from another interface. • **Cellular-allocated**—IP address allocated through the modem-manufacturer's proprietary protocol. For more information, see mobile communication modem management in *Layer 2—WAN Access Configuration Guide*. • **MAD**—IP address assigned to an IRF member device for MAD on the interface. For more information, see IRF configuration in *Virtual Technologies Configuration Guide*.
Internet protocol processing: disabled	The interface is not assigned an IP address and cannot process IP packets.
Internet Address is 192.168.1.200/24 Primary	IP address of the interface. The **primary** attribute indicates that the address is the primary IP address..
IP Packet Frame Type	IPv4 packet framing format.
Hardware Address	MAC address of the interface.
IPv6 Packet Frame Type	IPv6 packet framing format.
Output queue - Urgent queuing: Size/Length/Discards	Packet statistics for urgent queuing in the output queue of the interface: • **Size**—Current number of packets in the queue. • **Length**—Maximum number of packets that can stay in the queue. • **Discards**—Number of dropped packets.

Field	Description
Output queue - Protocol queuing: Size/Length/Discards	Packet statistics for protocol queuing in the output queue of the interface: • **Size**—Current number of packets in the queue. • **Length**—Maximum number of packets that can stay in the queue. • **Discards**—Number of dropped packets.
Output queue - FIFO queuing: Size/Length/Discards	Packet statistics for FIFO queuing in the output queue of the interface: • **Size**—Current number of packets in the queue. • **Length**—Maximum number of packets that can stay in the queue. • **Discards**—Number of dropped packets.
Last link flapping	The amount of time that has elapsed since the most recent physical state change of the interface. This field displays **Never** if the interface has been physically down since device startup.
Last clearing of counters	Time when statistics on the logical interface were last cleared by using the **reset counters interface** command. If the statistics of the interface have never been cleared by using the **reset counters interface** command since the device started, this field displays **Never**.
Last 300 seconds input rate	Average input rate during the last 300 seconds: • **bytes/sec**—Average number of received bytes per second. • **bits/sec**—Average number of received bits per second. • **packets/sec**—Average number of received packets per second.
Last 300 seconds output rate	Average output rate over the last 300 seconds: • **bytes/sec**—Average number of sent bytes per second. • **bits/sec**—Average number of sent bits per second. • **packets/sec**—Average number of sent packets per second.
Input: 0 packets, 0 bytes, 0 buffers	Incoming packet statistics: • **0 packets**—Packet number. • **0 bytes**—Packet size in bytes. • **0 buffers**—Number of buffered units.
Output: 0 packets, 0 bytes	Outgoing packet statistics: • **0 packets**—Packet number. • **0 bytes**—Packet size in bytes.
Link	Physical link state of the interface: • **UP**—The interface is physically up. • **DOWN**—The interface is physically down. • **ADM**—The interface has been shut down by using the **shutdown** command. To restore the physical state of the interface, use the **undo shutdown** command. • **Stby**—The interface is a backup interface in standby state. To see the primary interface, use the **display interface-backup state** command.

Field	Description
Protocol	Data link layer protocol state of the interface: • **UP**—The data link layer protocol of the interface is up. • **DOWN**—The data link layer protocol of the interface is down. • **UP(s)**—The data link layer protocol of the interface is up, but the link is an on-demand link or does not exist. The **(s)** attribute represents the spoofing flag. This value is typical of null interfaces and loopback interfaces.
Main IP	Main IP address of the interface.
Description	Description of the interface.
Cause	Cause for the physical link state of the interface to be **DOWN**. The value of the field varies by device model. **Administratively** represents that the interface has been manually shut down by using the **shutdown** command. To restore the physical state of the interface, use the **undo shutdown** command.

eth-channel

Use **eth-channel** to channelize a cellular interface into an Eth-channel interface.

Use **undo eth-channel** to remove the Eth-channel interface channelized from a cellular interface.

Syntax

eth-channel *channel-number*

undo eth-channel *channel-number*

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

channel-number: Specifies an Eth-channel interface by its number. The value range for this argument varies by device model.

Usage guidelines

This command names the Eth-channel interface channelized from a cellular interface as **eth-channel** *cellular-number*:*channel-number*.

Examples

Channelize Cellular 1/0/1 into an Eth-channel interface.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] eth-channel 0
```

interface eth-channel

Use **interface eth-channel** to enter Eth-channel interface view.

Syntax

interface eth-channel *interface-number*

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface-number: Specifies an Eth-channel interface by its number.

Examples

Enter Eth-channel 1/0/1:0 interface view.

```
<Sysname> system-view
[Sysname] interface eth-channel 1/0/1:0
[Sysname-Eth-channel1/0/1:0]
```

ip address cellular-alloc

Use **ip address cellular-alloc** to enable an Eth-channel interface to obtain an IP address by using the modem-manufacturer's proprietary protocol.

Use **undo ip address cellular-alloc** to restore the default.

Syntax

ip address cellular-alloc

undo ip address cellular-alloc

Default

An Eth-channel interface does not obtain an IP address by using the modem-manufacturer's proprietary protocol.

Views

Eth-channel interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

To enable an interface to obtain an IP address from the modem by using the modem-manufacturer's proprietary protocol, use the **ip address cellular-alloc** command.

To enable an interface to obtain an IP address from the modem by using DHCP, use the **ip address dhcp-alloc** command.

The IP address of the modem is automatically allocated by the service provider.

Examples

Channelize Cellular 1/0/1 into an Eth-channel interface. Enable the Eth-channel interface to obtain an IP address by using the modem-manufacturer's proprietary protocol.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] eth-channel 0
[Sysname-Cellular1/0/1] quit
[Sysname] interface eth-channel 1/0/1:0
[Sysname-Eth-channel1/0/1:0] ip address cellular-alloc
```

ipv6 address cellular-alloc

Use **ipv6 address cellular-alloc** to enable an interface to obtain an IPv6 address by using the modem-manufacturer's proprietary protocol.

Use **undo ipv6 address cellular-alloc** to restore the default.

Syntax

ipv6 address cellular-alloc

undo ipv6 address cellular-alloc

Default

An interface does not obtain an IPv6 address by using the modem-manufacturer's proprietary protocol.

Views

Eth-channel interface view

Predefined user roles

network-admin

Usage guidelines

To enable an interface to obtain an IPv6 address by using the modem-manufacturer's proprietary protocol, use the **ipv6 address cellular-alloc** command.

To enable an interface to obtain an IP address by using DHCP, use the **ipv6 address dhcp-alloc** command.

The IPv6 address of the modem is automatically allocated by the service provider.

Examples

Channelize Cellular 1/0/1 into an Eth-channel interface. Enable the Eth-channel interface to obtain an IPv6 address by using the modem-manufacturer's proprietary protocol.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Cellular1/0/1] eth-channel 0
[Sysname-Cellular1/0/1] quit
[Sysname] interface eth-channel 1/0/1:0
[Sysname-Eth-channel1/0/1:0] ipv6 address cellular-alloc
```

Related commands

ip address cellular-alloc

lte band

Use **lte band** to specify a band for a 4G module.

Use **undo lte band** to restore the default.

Syntax

lte band *band-number*

undo lte band

Default

The default setting for this command varies by 4G modem model.

Views

Cellular interface view

Predefined user roles

network-admin

context-admin

Parameters

band-number: Specifies an LTE band for a 4G module. The available bands vary by module model.

Usage guidelines

This command is supported by the following 4G modules:

- Sierra MC7354 and MC7304.
- Long Sung U8300C, U8300W, and U8300.
- WNC DM11-2.

Examples

Specify band 3 for Cellular 1/0/1.

```
<Sysname> system-view
[Sysname] controller cellular 1/0/1
[Sysname-Controller-Cellular1/0/1] lte band 3
```

mtu

Use **mtu** to set the maximum transmission unit (MTU) for an interface.

Use **undo mtu** to restore the default.

Syntax

mtu *size*

undo mtu

Default

The MTU of an interface is 1500 bytes.

Views

Eth-channel interface view

Predefined user roles

network-admin

context-admin

Parameters

size: Sets the MTU in bytes. The value range for this argument varies by device model.

Examples

Set the MTU for Eth-channel 1/0/1:0 to 1430 bytes.

```
<Sysname> system-view
[Sysname] interface eth-channel 1/0/1:0
[Sysname-Eth-channel1/0/1:0] mtu 1430
```

pdp-type

Use **pdp-type** to specify the PDP data carrying protocol.

Use **undo pdp-type** to restore the default.

Syntax

pdp-type { **ipv4** | **ipv6** | **ipv4v6** }

undo pdp-type

Default

The PDP data carrying protocol is IPv4 and IPv6.

Views

Apn-profile view

Predefined user roles

network-admin

Parameters

ipv4: Specifies the IPv4 protocol.

ipv6: Specifies the IPv6 protocol.

ipv4v6: Specifies the IPv4 and IPv6 protocols.

Examples

Specify the PDP data carrying protocol as IPv4.

```
<Sysname> system-view
[Sysname] apn-profile 1
[Sysname-apn-profile-1] pdp-type ipv4
```

reset counters interface

Use **reset counters interface** to clear the statistics on the specified or all Eth-channel interfaces.

Syntax

reset counters interface [**eth-channel** [*channel-id*]]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

eth-channel [*channel-id*]: Specifies Eth-channel interfaces or an Eth-channel interface by its number. If you do not the **eth-channel** keyword, the command clears statistics on all interfaces. If you specify the **eth-channel** keyword but not the *channel-id* argument, this command clears statistics on all Eth-channel interfaces. If you specify both the **eth-channel** keyword and the *channel-id* argument, this command clears statistics on the specified Eth-channel interface.

Usage guidelines

Use this command to clear history statistics if you want to collect traffic statistics for a specific period.

Examples

Clear the statistics on Eth-channel 1/0/1:0.

```
<Sysname> reset counters interface eth-channel 1/0/1:0
```

shutdown

Use **shutdown** to shut down an Eth-channel interface.

Use **undo shutdown** to bring up an Eth-channel interface.

Syntax

shutdown

undo shutdown

Default

The default setting for this command depends on the device model.

Views

Eth-channel interface view

Predefined user roles

network-admin

context-admin

Examples

Shut down Eth-channel 1/0/1:0.

```
<Sysname> system-view
[Sysname] interface eth-channel 1/0/1:0
[Sysname-Eth-channel1/0/1:0] shutdown
```

NSFOCUS Firewall Series

NF Layer 3—IP Services Command Reference

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

This command reference describes the commands for configuring IP services features, including ARP, IP addressing, DHCP, DNS, IP forwarding basics, fast forwarding, adjacency table, IP performance optimization, IPv6 basics, DHCPv6, IPv6 fast forwarding, and multi-CPU packet distribution.

This preface includes the following topics about the documentation:

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

IP addressing commands

display ip interface

Use **display ip interface** to display IP configuration and statistics for Layer 3 interfaces.

Syntax

display ip interface [*interface-type* [*interface-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface-type: Specifies an interface by its type.

interface-number: Specifies an interface by its number.

Usage guidelines

Use the **display ip interface** command to display IP configuration and statistics for the specified Layer 3 interface. The statistics include the following information:

- The number of unicast packets, bytes, and multicast packets the interface has sent and received.
- The number of TTL-invalid packets and ICMP packets the interface has received.

The packet statistics helps you locate a possible attack on the network.

If you specify only the interface type, this command displays IP configuration and statistics for all interfaces of this interface type. If you do not specify any optional parameters, this command displays IP configuration and statistics for all Layer 3 interfaces except VA interfaces. For more information about VA interfaces, see PPP configuration in *PPP and PPPoE Configuration Guide*.

Examples

Display IP configuration and statistics for GigabitEthernet 1/0/1.

```
<Sysname> display ip interface gigabitethernet 1/0/1
GigabitEthernet1/0/1 current state : DOWN
Line protocol current state : DOWN
Internet address is 1.1.1.1/8 Primary
Broadcast address : 1.255.255.255
The Maximum Transmit Unit : 1500 bytes
input packets : 0, bytes : 0, multicasts : 0
output packets : 0, bytes : 0, multicasts : 0
TTL invalid packet number:         0
ICMP packet input number:          0
  Echo reply:                      0
  Unreachable:                     0
```

```
Source quench:                  0
Routing redirect:               0
Echo request:                   0
Router advert:                  0
Router solicit:                 0
Time exceed:                    0
IP header bad:                  0
Timestamp request:              0
Timestamp reply:                0
Information request:            0
Information reply:              0
Netmask request:                0
Netmask reply:                  0
Unknown type:                   0
```

Table 1 Command output

Field	Description
current state	Physical link state of the interface: • **Administrative DOWN**—The interface has been shut down by using the **shutdown** command. • **DOWN**—The interface is administratively up, but its physical state is down (possibly because no physical link exists or the link has failed). • **UP**—The interface is both administratively and physically up.
Line protocol current state	Data link layer state of the interface. • **DOWN**—The data link layer protocol is down. • **UP**—The data link layer protocol is up. • **UP (spoofing)**—The data link layer protocol is up, but the link is an on-demand link or does not exist.
Internet address is *ip-address*/*mask-length* (*Type*)	IP address of the interface and type of the address in parentheses. Possible IP address types include: • **Primary**—Manually configured primary IP address. • **Sub**—Manually configured secondary IP address. • **SSLVPN**—An SSL VPN AC interface IP address. For more information, see SSL VPN configuration in V*PN Configuration Guide.* • **PPP-negotiated**—IP address assigned by a PPP server during PPP negotiation. For more information, see PPP configuration in *Layer 2—WAN Access Configuration Guide*. • **Unnumbered**—IP address borrowed from another interface. • **DHCP-allocated**—DHCP allocated IP address. For more information, see DHCP client configuration in *Layer 3—IP Services Configuration Guide*. • **BOOTP-allocated**—BOOTP allocated IP address. For more information, see BOOTP client configuration in *Layer 3—IP Services Configuration Guide*. • **Cellular-allocated**—IP address allocated through the modem-manufacturer's proprietary protocol. For more information, see mobile communication modem management in *Layer 2—WAN Access Configuration Guide*.
Broadcast address	Broadcast address of the subnet attached to an interface.
The Maximum Transmit Unit	MTU of the interface, in bytes.

Field	Description
input packets, bytes, multicasts output packets, bytes, multicasts	All received and sent packets and bytes, and received and sent multicast packets on an interface (statistics start at the device startup).
TTL invalid packet number	Number of TTL-invalid packets received on the interface (statistics start at the device startup).
ICMP packet input number: Echo reply: Unreachable: Source quench: Routing redirect: Echo request: Router advert: Router solicit: Time exceed: IP header bad: Timestamp request: Timestamp reply: Information request: Information reply: Netmask request: Netmask reply: Unknown type:	Total number of ICMP packets received on the interface (statistics start at the device startup): • Echo reply packets. • Unreachable packets. • Source quench packets. • Routing redirect packets. • Echo request packets. • Router advertisement packets. • Router solicitation packets. • Time exceeded packets. • IP header bad packets. • Timestamp request packets. • Timestamp reply packets. • Information request packets. • Information reply packets. • Netmask request packets. • Netmask reply packets. • Unknown type packets.

display ip interface brief

Use **`display ip interface brief`** to display brief IP configuration for Layer 3 interfaces.

Syntax

`display ip interface` [*`interface-type`* [*`interface-number`*]] **`brief`** [**`description`**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface-type: Specifies an interface type. If you do not specify an interface type, this command displays brief IP configuration for all Layer 3 interfaces.

interface-number: Specifies an interface number. If you do not specify an interface number, this command displays brief IP configuration for all Layer 3 interfaces of the specified type.

description: Displays complete interface descriptions. If you do not specify this keyword, the command displays a maximum of 16 characters for each interface description. If the description is longer than 16 characters, the first 14 characters are displayed, followed by an ellipsis (...).

Usage guidelines

Information displayed by the command includes the state of the physical and link layer protocols, IP address, and interface descriptions.

Examples

Display brief IP configuration for GigabitEthernet interfaces.

```
<Sysname> display ip interface gigabitethernet brief
*down: administratively down
(s): spoofing  (l): loopback
Interface           Physical Protocol IP address/Mask    VPN instance Description
GE1/0/1             up       up       5.5.5.1/24         --           Link to Co...
<Sysname> display ip interface gigabitethernet brief description
*down: administratively down
(s): spoofing  (l): loopback
Interface           Physical Protocol IP address/Mask    VPN instance Description
GE1/0/1             up       up       5.5.5.1/24         --           Link to CoreR
                                                                      outer
```

Table 2 Command output

Field	Description
*down: administratively down	The interface is administratively shut down by using the **shutdown** command.
(s) : spoofing	Spoofing attribute of the interface. The link protocol state of the interface is up, but the link is temporarily established on demand or does not exist.
Interface	Interface name.
Physical	Physical state of the interface: • ***down**—The interface is administratively shut down by using the **shutdown** command. • **down**—The interface is administratively up but its physical state is down, possibly because of a connection or link failure. • **up**—Both the administrative and physical states of the interface are up.
Protocol	Link layer protocol state of the interface: • **down**—The protocol state of the interface is down. • **down(l)**—The protocol state of the interface is down (loopback). • **up**—The protocol state of the interface is up. • **up(l)**—The protocol state of the interface is up (loopback). • **up(s)**—The protocol state of the interface is up (spoofing).
IP address/Mask	IP address and mask length of the interface. If no IP address is configured, this field displays hyphens (**--**).

Field	Description
VPN instance	Name of the VPN instance to which the interface belongs. This field displays a maximum of 12 characters. If the VPN instance name is longer than 12 characters, the first 9 characters are displayed, followed by an ellipsis (...). If the interface does not belong to any VPN instance, this field displays hyphens (**--**).
Description	Description of the interface. This field displays a maximum of 13 characters. If the description is longer than 13 characters, the first 10 characters are displayed, followed by an ellipsis (...). If no description is configured, this field displays hyphens (**--**).

Related commands

`display ip interface`

`ip address`

ip address

Use **`ip address`** to assign an IP address to the interface.

Use **`undo ip address`** to remove the IP address from the interface.

Syntax

Default

No IP address is assigned to an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

`ip-address`: Specifies the IP address of the interface, in dotted decimal notation.

`mask-length`: Specifies the subnet mask length in the range of 1 to 31. For a loopback interface, the value range is 1 to 32.

`mask`: Specifies the subnet mask in dotted decimal notation.

`sub`: Assigns a secondary IP address to the interface.

Usage guidelines

Use the command to assign a primary or secondary IP address to an interface.

An interface can have only one primary IP address. If you execute this command multiple times to specify different primary IP addresses, the most recent configuration takes effect. If the interface connects to multiple subnets, configure primary and secondary IP addresses on the interface so the subnets can communicate with each other through the interface.

You cannot assign secondary IP addresses to an interface that obtains an IP address through BOOTP, DHCP, PPP address negotiation, or IP unnumbered.

If you do not specify any parameters, the **undo ip address** command removes all IP addresses from the interface. The **undo ip address** *ip-address* { *mask* | *mask-length* } command removes the primary IP address. The **undo ip address** *ip-address* { *mask* | *mask-length* } **sub** command removes a secondary IP address.

The primary and secondary IP addresses assigned to the interface can be located on the same network segment. Different interfaces on your device must reside on different network segments.

Examples

Assign GigabitEthernet 1/0/1 a primary IP address 129.102.0.1 and a secondary IP address 202.38.160.1, with the subnet masks both 255.255.255.0.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip address 129.102.0.1 255.255.255.0
[Sysname-GigabitEthernet1/0/1] ip address 202.38.160.1 255.255.255.0 sub
```

Related commands

display ip interface

display ip interface brief

ip address unnumbered

Use **ip address unnumbered** to configure the current interface as IP unnumbered to borrow an IP address from the specified interface.

Use **undo ip address unnumbered** to restore the default.

Syntax

ip address unnumbered interface *interface-type interface-number*

undo ip address unnumbered

Default

The interface does not borrow IP addresses from other interfaces.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies an interface from which the current interface can borrow an IP address.

Usage guidelines

Typically, you assign an IP address to an interface either manually or through DHCP. If the IP addresses are not enough, or the interface is used only occasionally, you can configure an interface to borrow an IP address from other interfaces. This is called IP unnumbered, and the interface borrowing the IP address is called IP unnumbered interface.

Loopback interfaces cannot borrow IP addresses of other interfaces, but other interfaces can borrow IP addresses of loopback interfaces.

Multiple interfaces can use the same unnumbered IP address. If an interface has multiple manually configured IP addresses, only the primary IP address manually configured can be borrowed.

You cannot enable a dynamic routing protocol on the interface that has no IP address configured. To enable the interface to communicate with other devices, you must configure a static route to the peer device on the interface.

Examples

Configure GigabitEthernet 1/0/2 to borrow the IP address of GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface GigabitEthernet1/0/2
[Sysname-GigabitEthernet1/0/2] ip address unnumbered interface gigabitethernet 1/0/1
```

Contents

Basic IP forwarding commands

display fib

Use **display fib** to display FIB entries.

Syntax

display fib [**vpn-instance** *vpn-instance-name*] [*ip-address* [*mask* | *mask-length*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. To display the FIB entries for the public network, do not specify any VPN instance.

ip-address: Displays the FIB entry that matches the specified destination IP address.

mask: Specifies the mask for the IP address.

mask-length: Specifies the mask length for the IP address. The value range is 0 to 32.

Usage guidelines

If you specify an IP address without a mask or mask length, this command displays the longest matching FIB entry.

If you specify an IP address and a mask or mask length, this command displays the exactly matching FIB entry.

Examples

Display all FIB entries of the public network.

```
<Sysname> display fib

Destination count: 5 FIB entry count: 5

Flag:
  U:Useable   G:Gateway   H:Host   B:Blackhole   D:Dynamic   S:Static
  R:Relay     F:FRR

```

Table 1 Command output

Field	Description
Destination count	Total number of destination addresses.
FIB entry count	Total number of FIB entries.
Destination/Mask	Destination address and the mask length.
Nexthop	Next hop address.
Flag	Flags of routes: • **U**—Usable route. • **G**—Gateway route. • **H**—Host route. • **B**—Blackhole route. • **D**—Dynamic route. • **S**—Static route. • **R**—Relay route. • **F**—Fast reroute.
OutInterface/Token	Output interface/LSP index number.
Label	Inner label.

inner-interface learn arp-nd

Use **inner-interface learn arp-nd** to enable ARP and ND entry learning on inner interfaces

Use **undo inner-interface learn arp-nd** to disable ARP and ND entry learning on inner interfaces.

Syntax

inner-interface learn arp-nd vlan *vlan-id*

undo inner-interface learn arp-nd

Default

ARP and ND entry learning is disabled on inner interfaces.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

vlan *vlan-id*: Specifies a VLAN by its ID in the range of 2 to 4094. The specified VLAN must be a VLAN terminated on an inner subinterface and cannot be the default VLAN ID of the peer inner interface.

Usage guidelines

You must enable this feature if NetStream statistics are sent out by inner interfaces. Otherwise, inner interfaces cannot learn ARP or ND entries and fail to transmit NetStream statistics.

This command is supported only on the default context.

Examples

Enable inner interfaces to learn ARP and ND entries in VLAN 200.

```
<Sysname> system-view
[Sysname] inner-interface learn arp-nd vlan 200
```

last-hop backup enable

Use **last-hop backup enable** to enable last hop backup.

Use **undo last-hop backup enable** to disable last hop backup.

Syntax

last-hop backup enable

undo last-hop backup enable

Default

Last hop backup is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the system to transmit the forward flow and reverse flow between the local node and a peer node over the same path.

In an IRF fabric enabled with this feature, the IRF master device performs the following operations when receiving the first IP packet of a forward flow on an interface enabled with last hop holding:

1. Saves the last hop information of the packet.
2. Synchronizes the last hop information to subordinate devices in the IRF fabric.

The last hop information can be used for guiding the backward flow when the flow arrives at the master device or is forwarded through a subordinate device.

For this feature to take effect in an IRF fabric, you must also enable session synchronization by using the **session synchronization enable** command. For more information about the **session synchronization enable** command, see *Security Command Reference*.

This feature is also applicable to multi-module devices enabled with service backup. If this feature is enabled on such a device, a device module performs the following operations when receiving the first IP packet of a forward flow on an interface enabled with last hop holding:

1. Saves the last hop information of the packet.
2. Synchronizes the last hop information to other modules in the device.

The last hop information can be used for guiding the backward flow when the flow arrives at one of these modules.

For this feature to take effect on a multi-module device, you must also enable session flow redirection by using the **session flow-redirect enable** command. For more information about the **session flow-redirect enable** command, see *Security Command Reference*.

Examples

Disable last hop backup.

```
<Sysname> system-view
[Sysname] undo last-hop backup enable
```

Related commands

ip last-hop hold

session flow-redirect enable (*Security Command Reference*)

session synchronization enable (*Security Command Reference*)

ip last-hop hold

Use **ip last-hop hold** to enable last hop holding.

Use **undo ip last-hop hold** to disable last hop holding.

Syntax

ip last-hop hold

undo ip last-hop hold

Default

Last hop holding is disabled.

Views

Layer 3 Ethernet interface view

Layer 3 Ethernet subinterface view

Predefined user roles

network-admin

context-admin

Usage guidelines

Last hop holding implements symmetric routing.

When the interface enabled with this feature receives the first IP packet of a forward flow, this feature implements the following operations:

- Obtains the forward flow information and last hop information of the packet.
- Based on the obtained information, creates a fast forwarding entry for the return flow.

When packets of the return flow arrive at the device, the device forwards those packets according to the fast forwarding entry.

Last hop holding relies on fast forwarding entries. If the MAC address of a last hop changes on an Ethernet link, this feature can function correctly only after the fast forwarding entry is updated for the MAC address.

Examples

Enable the last hop holding feature.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip last-hop hold
```

Load sharing commands

ip load-sharing local-first enable

Use **ip load-sharing local-first enable** to enable local-first load sharing.

Use **undo ip load-sharing local-first enable** to disable local-first load sharing.

Syntax

ip load-sharing local-first enable

undo ip load-sharing local-first enable

Default

Local-first load sharing is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Local-first load sharing takes effect only on an IRF fabric.

Examples

Enable local-first load sharing.

```
<Sysname> system-view
[Sysname] ip load-sharing local-first enable
```

ip load-sharing mode

Use **ip load-sharing mode** to configure the load sharing mode.

Use **undo ip load-sharing mode** to restore the default.

Syntax

ip load-sharing mode { **per-flow** [**dest-ip** | **dest-port** | **ip-pro** | **src-ip** | **src-port**] * | **per-packet** } { **global** | **slot** *slot-number* }

undo ip load-sharing mode { **global** | **slot** *slot-number* }

The following compatibility matrixes show the support of hardware platforms for this command:

Models	Command compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB1180, NFNX3-HDB1480	No

Default

The device performs per-flow load sharing.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

`per-flow`: Implements per-flow load sharing.

`dest-ip`: Identifies flows by destination IP address.

`dest-port`: Identifies flows by destination port.

`ip-pro`: Identifies flows by protocol number.

`src-ip`: Identifies flows by source IP address.

`src-port`: Identifies flows by source port.

`global`: Configures the load sharing mode globally.

`per-packet`: Implements per-packet load sharing.

`slot` *`slot-number`*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command configures the load sharing mode for all member devices.

Usage guidelines

The per-packet load sharing mode does not take effect in fast forwarding.

Examples

Configure per-flow load sharing for slot 1.

```
<Sysname> system-view
[Sysname] ip load-sharing mode per-flow slot 1
```

ip fast-forwarding aging-time

Use **ip fast-forwarding aging-time** to configure the aging time for fast forwarding entries.

Use **undo ip fast-forwarding aging-time** to restore the default.

Syntax

ip fast-forwarding aging-time *aging-time*

undo ip fast-forwarding aging-time

Default

The aging time is 30 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

aging-time: Specifies the aging time in the range of 10 to 300 seconds.

Examples

Set the aging time to 20 seconds for fast forwarding entries.

```
<Sysname> system-view
[Sysname] ip fast-forwarding aging-time 20
```

Related commands

display ip fast-forwarding aging-time

ip fast-forwarding dscp

Use **ip fast-forwarding dscp** to enable DSCP-based fast forwarding for GRE packets.

Use **undo ip fast-forwarding dscp** to restore the default.

Syntax

ip fast-forwarding dscp

undo ip fast-forwarding dscp

Default

DSCP-based fast forwarding for GRE packets is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command is applicable to GRE packets (with IP as the passenger protocol) that are processed by software.

This feature uses the DSCP value in the outer header instead of the source port number among the identification criteria to identify GRE traffic flows.

This command is mutually exclusive with NAT and load balancing.

Examples

Enable DSCP-based GRE packet fast forwarding.

```
<Sysname> system-view
[Sysname] ip fast-forwarding dscp
```

ip fast-forwarding load-sharing

Use **ip fast-forwarding load-sharing** to enable fast forwarding load sharing.

Use **undo ip fast-forwarding load-sharing** to disable fast forwarding load sharing.

Syntax

ip fast-forwarding load-sharing

undo ip fast-forwarding load-sharing

Default

Fast forwarding load sharing is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Fast forwarding load sharing enables the device to load share packets of the same flow. This feature identifies a data flow by using the packet information.

If fast forwarding load sharing is disabled, the device identifies a data flow by the packet information and the input interface. No load sharing is implemented.

Examples

Enable fast forwarding load sharing.

```
<Sysname> system-Views
[Sysname] ip fast-forwarding load-sharing
```

ip fast-forwarding vxlan-port

Use **ip fast-forwarding vxlan-port** to specify the destination UDP port number for identifying VXLAN packets.

Use **undo ip fast-forwarding vxlan-port** to restore the default.

Syntax

ip fast-forwarding vxlan-port *port-number*

undo ip fast-forwarding vxlan-port

Default

The destination UDP port number is 4789.

Views

System view

Predefined use roles

network-admin

context-admin

Parameters

port-number: Specifies a UDP port number in the range of 1 to 65535.

Usage guidelines

This feature is applicable to only the UDP packets that are processed by software.

In a VXLAN network, configure this command on intermediate devices to identify VXLAN packets.

Examples

Specify the destination UDP port number to 4900 for identifying VXLAN packets.

```
<Sysname> system-view
```

```
[Sysname] ip fast-forwarding vxlan-port 4900
```

reset ip fast-forwarding cache

Use **reset ip fast-forwarding cache** to clear the fast forwarding table.

Syntax

reset ip fast-forwarding cache [**slot** *slot-number*]

Views

User view

Predefined use roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command clears the fast forwarding table for all member devices.

Examples

Clear the fast forwarding table.

```
<Sysname> reset ip fast-forwarding cache
```

Related commands

display ip fast-forwarding cache

display ip fast-forwarding fragcache

Contents

ARP commands

arp check enable

Use **arp check enable** to enable dynamic ARP entry check.

Use **undo arp check enable** to disable dynamic ARP entry check.

Syntax

arp check enable

undo arp check enable

Default

Dynamic ARP entry check is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Dynamic ARP entry check disables a device from supporting dynamic ARP entries with multicast MAC addresses. The device cannot learn dynamic ARP entries containing multicast MAC addresses. You cannot manually add static ARP entries that contain multicast MAC addresses.

When dynamic ARP entry check is disabled, ARP entries containing multicast MAC addresses are supported. The device can learn dynamic ARP entries containing multicast MAC addresses obtained from the ARP packets sourced from a unicast MAC address. You can also manually add static ARP entries containing multicast MAC addresses.

Examples

Enable dynamic ARP entry check.

```
<Sysname> system-view
[Sysname] arp check enable
```

arp check log enable

Use **arp check log enable** to enable the ARP logging feature.

Use **undo arp check log enable** to disable the ARP logging feature.

Syntax

arp check log enable

undo arp check log enable

Default

ARP logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables a device to log ARP events when ARP cannot resolve IP addresses correctly. The log information helps administrators locate and solve problems. The device can log the following ARP events:

- On a proxy ARP-disabled interface, the target IP address of a received ARP packet is not one of the following IP addresses:
  - The IP address of the receiving interface.
  - The virtual IP address of the VRRP group.
  - The public IP address after NAT.
- The sender IP address of a received ARP reply conflicts with one of the following IP addresses:
  - The IP address of the receiving interface.
  - The virtual IP address of the VRRP group.
  - The public IP address after NAT.

The device sends ARP log messages to the information center. You can use the **info-center source** command to specify the log output rules for the information center. For more information about information center, see *Network Management and Monitoring Configuration Guide*.

The device can generate a large number of ARP logs. To conserve system resources, enable ARP logging only when you are auditing or troubleshooting ARP events.

Examples

Enable ARP logging.

```
<Sysname> system-view
[Sysname] arp check log enable
```

arp ip-unnumbered learning enable

Use **arp ip-unnumbered learning enable** to enable an IP unnumbered interface to learn ARP entries for different subnets.

Use **undo arp ip-unnumbered learning enable** to disable an IP unnumbered interface from learning ARP entries for different subnets.

Syntax

arp ip-unnumbered learning enable

undo arp ip-unnumbered learning enable

Default

An IP unnumbered interface cannot learn ARP entries for different subnets.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

An IP unnumbered interface cannot learn the ARP entry of the peer device if the unnumbered interface and the peer device are on different subnets. To ensure communication between them, you can enable this feature on the IP unnumbered interface.

This feature takes effect only on an interface configured with the **ip address unnumbered** command. This interface is an unnumbered interface and borrows the IP address from another interface.

If an IP unnumbered interface is disabled from learning ARP entries for different subnets, existing ARP entries learned for different subnets are deleted after they age out.

Examples

Configure GigabitEthernet 1/0/1 to borrow the IP address of GigabitEthernet 1/0/2, and enable GigabitEthernet 1/0/1 to learn ARP entries for different subnets.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip address unnumbered interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/1] arp ip-unnumbered learning enable
```

Related commands

ip address unnumbered

arp max-learning-num

Use **arp max-learning-num** to set the dynamic ARP learning limit for an interface.

Use **undo arp max-learning-num** to restore the default.

Syntax

arp max-learning-num *max-number*

undo arp max-learning-num

Default

An interface can learn a maximum of 16384 dynamic ARP entries.

Views

Reth subinterface view

VLAN interface view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of dynamic ARP entries for an interface. The value range for this argument is 0 to 16384.

Usage guidelines

An interface can dynamically learn ARP entries. To prevent an interface from holding too many ARP entries, you can set the maximum number of dynamic ARP entries that the interface can learn. When the maximum number is reached, the interface stops learning ARP entries.

When the *number* argument is set to 0, the interface is disabled from learning dynamic ARP entries.

Examples

Specify VLAN-interface 40 to learn a maximum of 10 dynamic ARP entries.

```
<Sysname> system-view
[Sysname] interface vlan-interface 40
[Sysname-Vlan-interface40] arp max-learning-num 10
```

Specify GigabitEthernet 1/0/1 to learn a maximum of 10 dynamic ARP entries.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] arp max-learning-num 10
```

Specify Layer 2 aggregate interface Bridge-Aggregation 1 to learn a maximum of 10 dynamic ARP entries.

```
<Sysname> system-view
[Sysname] interface bridge-aggregation 1
[Sysname-Bridge-Aggregation1] arp max-learning-num 10
```

Specify Layer 3 aggregate interface Route-Aggregation 1 to learn a maximum of 10 dynamic ARP entries.

```
<Sysname> system-view
[Sysname] interface route-aggregation 1
[Sysname-Route-Aggregation1] arp max-learning-num 10
```

arp max-learning-number

Use **arp max-learning-number** to set the dynamic ARP learning limit for a device.

Use **undo arp max-learning-number** to restore the default.

Syntax

arp max-learning-number *max-number* **slot** *slot-number*

undo arp max-learning-number slot *slot-number*

Default

The device can learn a maximum of 16384 dynamic ARP entries.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of dynamic ARP entries for a device. The value range for this argument is 0 to 16384.

slot *slot-number*: Specifies an IRF member device by its member ID.

Usage guidelines

A device can dynamically learn ARP entries. To prevent a device from holding too many ARP entries, you can set the maximum number of dynamic ARP entries that the device can learn. When the maximum number is reached, the device stops learning ARP entries.

When the *number* argument is set to 0, the device is disabled from learning dynamic ARP entries.

Examples

Set the ARP learning limit to 64 for slot 1.

```
<Sysname> system-view
[Sysname] arp max-learning-number 64 slot 1
```

arp static

Use **arp static** to configure a static ARP entry.

Use **undo arp** to delete an ARP entry.

Syntax

arp static *ip-address mac-address* [*vlan-id interface-type interface-number*] [**vpn-instance** *vpn-instance-name*] [**description** *text*]

undo arp *ip-address* [*vpn-instance-name*]

Default

No static ARP entries exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies an IP address for the static ARP entry.

mac-address: Specifies a MAC address for the static ARP entry, in the format of H-H-H.

vlan-id: Specifies the ID of a VLAN to which the static ARP entry belongs. The value range is 1 to 4094.

interface-type interface-number: Specifies an interface by its type and number.

tunnel *number*: Specifies a tunnel interface by its number. The value range for the *number* argument is 0 to 1023.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the static ARP entry belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. The VPN instance must already exist. To specify a static ARP entry on the public network, do not specify this option.

description *text*: Specifies the description for the static ARP entry, a case-sensitive string of 1 to 255 characters.

Usage guidelines

A static ARP entry is manually configured and maintained. It does not age out and cannot be overwritten by any dynamic ARP entry.

Static ARP entries can be short or long.

A resolved short static ARP entry becomes unresolved upon certain events, for example, when the resolved output interface goes down, or the corresponding VLAN or VLAN interface is deleted.

Long static ARP entries are effective or ineffective. Ineffective long static ARP entries cannot be used for packet forwarding. A long static ARP entry is ineffective when any of the following conditions exists:

- The IP address in the entry conflicts with a local IP address.
- No local interface has an IP address in the same subnet as the IP address in the ARP entry.

If you specify the *vlan-id interface-type interface-number* argument, follow these restrictions and guidelines:

- The interface can be an Ethernet interface or an aggregate interface.
- The VLAN and VLAN interface must already exist. The specified Ethernet interface must belong to the specified VLAN.
- The IP address of the VLAN interface and the IP address specified by the *ip-address* argument must be on the same network.
- If a VLAN or VLAN interface is deleted, a long static ARP entry for the VLAN is deleted and a resolved short static ARP entry for the VLAN becomes unresolved.

You can configure a description for each static ARP entry for easy identification.

Examples

Configure a long static ARP entry that contains IP address 202.38.10.2, MAC address 00e0-fc01-0000, and output interface GigabitEthernet 1/0/1 in VLAN 10.

```
<Sysname> system-view
[Sysname] arp static 202.38.10.2 00e0-fc01-0000 10 gigabitethernet 1/0/1
```

Configure a long static ARP entry that contains IP address 1.1.1.1, MAC address 00e0-fc01-0000, input interface VSI-interface 1, output interface Tunnel 1, and the VSI **a**.

```
<Sysname> system-view
[Sysname] arp static 1.1.1.1 00e0-fc01-0000 vsi-interface 1 tunnel 1 vsi a
```

Related commands

display arp

reset arp

arp timer aging

Use **arp timer aging** to set the aging timer for dynamic ARP entries.

Use **undo arp timer aging** to restore the default.

Syntax

arp timer aging *aging-time*

undo arp timer aging

Default

The aging timer for dynamic ARP entries is 20 minutes.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

aging-time: Specifies the aging timer in minutes. The value range for this argument is 1 to 1440.

Usage guidelines

Each dynamic ARP entry in the ARP table has a limited lifetime, called an aging timer. The aging timer of a dynamic ARP entry is reset each time the dynamic ARP entry is updated. Dynamic ARP entries that are not updated before their aging timers expire are deleted from the ARP table.

Set the aging timer for dynamic ARP entries as needed. For example, when you configure proxy ARP, set a short aging time so that invalid dynamic ARP entries can be deleted in a timely manner.

Examples

Set the aging timer for dynamic ARP entries to 10 minutes.

```
<Sysname> system-view
[Sysname] arp timer aging 10
```

Related commands

display arp timer aging

display arp

Use **display arp** to display ARP entries.

Syntax

display arp [[**all** | **dynamic** | **static**] [**slot** *slot-number*] | **vlan** *vlan-id* | **interface** *interface-type interface-number*] [**count** | **verbose**]

Views

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

all: Displays all ARP entries.

dynamic: Displays dynamic ARP entries.

static: Displays static ARP entries.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays ARP entries for the master device.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID. The VLAN ID is in the range of 1 to 4094.

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays ARP entries for all interfaces.

count: Displays the number of ARP entries.

verbose: Displays detailed information about ARP entries.

Usage guidelines

This command displays information about static and dynamic ARP entries, including the IP address, MAC address, VLAN ID, output interface, entry type, and aging timer.

Examples

Display all ARP entries.

```
<Sysname> display arp all
  Type: S-Static   D-Dynamic   O-Openflow   R-Rule  I-Invalid
IP address      MAC address    VLAN/VSI name Interface/Link ID        Aging Type

```

Table 1 Command output

Field	Description
IP address	IP address in an ARP entry.
MAC address	MAC address in an ARP entry.
VLAN/VSI name	ID of the VLAN to which the ARP entry belongs. This field displays hyphens (**--**) in either of the following situations: • The ARP entry is an unresolved short static ARP entry. • The output interface of the ARP entry does not belong to the VLAN.
Interface	Output interface in the ARP entry. This field displays hyphens (**--**) in either of the following situations: The ARP entry is an unresolved short static ARP entry.
Link ID	Link ID in the ARP entry. This field displays hyphens (**--**) if the ARP entry does not belong to any VSI.
Aging	Aging time for an ARP entry in minutes. For a static ARP entry, this field always displays hyphens (**--**). The static ARP entry never ages out unless you delete it manually. For a dynamic ARP entry, this field displays hyphens (**--**) if the aging time is unknown.
Type	ARP entry type: • **D**—Dynamic. • **S**—Static. • **R**—Rule. • **I**—Invalid.
SVLAN/CVLAN	Outer VLAN ID and inner VLAN ID in the ARP entry. This field displays hyphens (**--**) in either of the following situations: • The ARP entry is an unresolved short static ARP entry. • The interface in the ARP entry does not belong to the VLAN.
VPN instance	Name of VPN instance. If no VPN instance is configured for the ARP entry, this field displays hyphens (**--**).
VXLAN ID	This field is not supported in the current software version. ID of the VXLAN to which the ARP entry belongs. VXLAN ID is also called VNI. If the ARP entry does not belong to any VXLAN, this field displays hyphens (**--**).
VSI name	Name of the VSI to which the ARP entry belongs. If the ARP entry does not belong to any VSI, this field displays hyphens (**--**).

Field	Description
VSI interface	This field is not supported in the current software version. Name of the gateway interface of the VSI. If no gateway interface is specified for the VSI, this field displays hyphens (**--**).
MPLS PW ID	This field is not supported in the current software version. ID of the PW to which the ARP entry belongs. This field displays two hyphens (**--**) if the ARP entry does not belong to a PW.
MPLS peer PE address	This field is not supported in the current software version. IP address of the remote PE on the PW. This field displays two hyphens (**--**) if the ARP entry does not belong to a PW.
Nickname	This field is not supported in the current software version. Nickname of the ARP entry. The nickname is a string of four hexadecimal numbers, for example, 0x012a.
Description	Description of the ARP entry. If no description is configured for the ARP entry, this field displays hyphens (**--**).
Total number of entries	Number of ARP entries.

Reth subinterface view

Predefined user roles

network-admin

context-admin

Parameters

interval *interval*: Specifies the sending interval in the range of 200 to 200000 milliseconds. The default value is 2000 milliseconds.

Usage guidelines

This feature takes effect on an interface only when the interface has an IP address and the data link layer state of the interface is up.

This feature can send gratuitous ARP requests only for a VRRP virtual IP address, or the sending interface's primary IP address or manually configured secondary IP address. The primary IP address can be configured manually or automatically, whereas the secondary IP address must be configured manually.

If you change the sending interval for gratuitous ARP packets, the configuration takes effect at the next sending interval.

The sending interval for gratuitous ARP packets might be much longer than the set interval when any of the following conditions exist:

- This feature is enabled on multiple interfaces.
- Each interface is configured with multiple secondary IP addresses.
- A small sending interval is configured in the preceding cases.

Examples

Enable GigabitEthernet 1/0/1 to send gratuitous ARP packets every 300 milliseconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] arp send-gratuitous-arp interval 300
```

gratuitous-arp mac-change retransmit

Use **gratuitous-arp mac-change retransmit** to set the times and the interval for retransmitting a gratuitous ARP packet for the device MAC address change.

Use **undo gratuitous-arp mac-change retransmit** to restore the default.

Syntax

gratuitous-arp mac-change retransmit *times* **interval** *seconds*

undo gratuitous-arp mac-change retransmit

Default

The device sends a gratuitous packet for its MAC address change once only.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

times: Specifies the times of retransmitting a gratuitous packet, in the range of 1 to 10.

interval *seconds*: Specifies the interval for retransmitting a gratuitous packet, in the range of 1 to 10 seconds.

Usage guidelines

The device sends a gratuitous ARP packet to inform other devices of its MAC address change. However, the other devices might fail to receive the packet because the device sends the gratuitous ARP packet once only by default. Use this command to configure gratuitous ARP retransmission parameters to ensure that the other devices can receive the packet.

After you execute this command, the device will retransmit a gratuitous ARP packet for its MAC address change at the specified interval for the specified times.

Examples

Set the times to 3 and the interval to 5 for retransmitting a gratuitous ARP packet for the device MAC address change.

```
<Sysname> system-view
[Sysname] gratuitous-arp mac-change retransmit 3 interval 5
```

gratuitous-arp-learning enable

Use **gratuitous-arp-learning enable** to enable learning of gratuitous ARP packets.

Use **undo gratuitous-arp-learning enable** to disable learning of gratuitous ARP packets.

Syntax

```
gratuitous-arp-learning enable
undo gratuitous-arp-learning enable
```

Default

Learning of gratuitous ARP packets is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The learning of gratuitous ARP packets feature allows a device to maintain its ARP table by creating or updating ARP entries based on received gratuitous ARP packets.

When this feature is disabled, the device uses received gratuitous ARP packets to update existing ARP entries only. ARP entries are not created based on the received gratuitous ARP packets, which saves ARP table space.

Examples

Enable learning of gratuitous ARP packets.

```
<Sysname> system-view
[Sysname] gratuitous-arp-learning enable
```

gratuitous-arp-sending enable

Use **gratuitous-arp-sending enable** to enable sending gratuitous ARP packets upon receiving ARP requests whose sender IP address is on a different subnet.

Use **undo gratuitous-arp-sending enable** to disable sending gratuitous ARP packets upon receiving ARP requests whose sender IP address is on a different subnet.

Syntax

gratuitous-arp-sending enable

undo gratuitous-arp-sending enable

Default

A device does not send gratuitous ARP packets when it receives ARP requests whose sender IP address is on a different subnet.

Views

System view

Predefined user roles

network-admin

context-admin

Examples

Disable a device from sending gratuitous ARP packets upon receiving ARP requests whose sender IP address is on a different subnet.

```
<Sysname> system-view
[Sysname] undo gratuitous-arp-sending enable
```

Proxy ARP commands

display local-proxy-arp

Use **display local-proxy-arp** to display the local proxy ARP status.

Syntax

display local-proxy-arp [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays the local proxy ARP status for all interfaces.

Usage guidelines

You can use this command to check whether local proxy ARP is enabled or disabled.

Examples

Display the local proxy ARP status for GigabitEthernet 1/0/1.

```
<Sysname> display local-proxy-arp interface gigabitethernet 1/0/1
Interface GigabitEthernet1/0/1
 Local Proxy ARP status: enabled
```

Related commands

local-proxy-arp enable

display proxy-arp

Use **display proxy-arp** to display the proxy ARP status.

Syntax

display proxy-arp [**interface** *interface-type interface-number*]

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays the proxy ARP status for all interfaces.

Usage guidelines

You can use this command to check whether proxy ARP is enabled or disabled.

Examples

Display the proxy ARP status on GigabitEthernet 1/0/1.

```
<Sysname> display proxy-arp interface gigabitethernet 1/0/1
Interface GigabitEthernet1/0/1
 Proxy ARP status: disabled
```

Related commands

proxy-arp enable

local-proxy-arp enable

Use **local-proxy-arp enable** to enable local proxy ARP.

Use **undo local-proxy-arp enable** to disable local proxy ARP.

Syntax

local-proxy-arp enable [**ip-range** *start-ip-address* **to** *end-ip-address*]

undo local-proxy-arp enable

Default

Local proxy ARP is disabled.

Predefined user roles

network-admin

context-admin

Parameters

ip-range *start-ip-address* **to** *end-ip-address*: Specifies the IP address range for which local proxy ARP is enabled. The start IP address must be lower than or equal to the end IP address.

Usage guidelines

Proxy ARP enables a device on a network to answer ARP requests for an IP address not on that network. With proxy ARP, hosts in different broadcast domains can communicate with each other as they do on the same network.

Proxy ARP includes common proxy ARP and local proxy ARP.

Common proxy ARP allows communication between hosts that connect to different Layer 3 interfaces and reside in different broadcast domains.

Local proxy ARP allows communication between hosts that connect to the same Layer 3 interface and reside in different broadcast domains.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Enable local proxy ARP on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] local-proxy-arp enable
```

Enable local proxy ARP on GigabitEthernet 1/0/1 for an IP address range.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] local-proxy-arp enable ip-range 1.1.1.1 to 1.1.1.20
```

context-operator

Parameters

vlan *vlan-id*: Displays ARP snooping entries for a VLAN. The *vlan-id* argument is in the range of 1 to 4094.

count: Displays the number of the ARP snooping entries.

ip *ip-address*: Displays the ARP snooping entry for the specified IP address.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays ARP snooping entries for the master device.

Examples

Display ARP snooping entries for VLAN 2.

```
<Sysname> display arp snooping vlan 2
IP Address   MAC Address    VLAN ID Interface  Aging       Status
3.3.3.3      0003-0003-0003 2       GE1/0/1    20          Valid
3.3.3.4      0004-0004-0004 2       GE1/0/2    5           Invalid
```

Display the number of the ARP snooping entries.

```
<Sysname> display arp snooping count
Total entries: 2
```

Table 2 Command output

Field	Description
IP Address	IP address in an ARP snooping entry.
MAC Address	MAC address in an ARP snooping entry.
VLAN ID	ID of the VLAN to which the ARP snooping entry belongs.
Interface	Input interface in an ARP snooping entry.
Aging	Aging time for an ARP snooping entry in minutes.
Status	Status of an ARP snooping entry: **Valid**, **Invalid**, **Collision**.
Total entries	Number of ARP snooping entries.

Related commands

reset arp snooping

reset arp snooping

Use **reset arp snooping** to delete ARP snooping entries.

Syntax

reset arp snooping [**ip** *ip-address* | **vlan** *vlan-id*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

ip *ip-address*: Deletes the ARP snooping entry for the specified IP address.

vlan *vlan-id*: Deletes ARP snooping entries for the specified VLAN. The value range for the *vlan-id* argument is 1 to 4094.

Usage guidelines

If you do not specify any option, the command deletes all ARP snooping entries.

Examples

Delete ARP snooping entries for VLAN 2.

```
<Sysname> reset arp snooping vlan 2
```

IPv6 basics commands

display ipv6 fib

Use **display ipv6 fib** to display IPv6 FIB entries.

Syntax

display ipv6 fib [**vpn-instance** *vpn-instance-name*] [*ipv6-address* [*prefix-length*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays IPv6 FIB entries for the public network.

ipv6-address: Displays IPv6 FIB entries for a destination IPv6 address. If you do not specify an IPv6 address, this command displays all IPv6 FIB entries.

prefix-length: Specifies a prefix length for the IPv6 address, in the range of 0 to 128. If you do not specify the prefix length, this command displays the IPv6 FIB entry longest matching the IPv6 address.

Examples

Display all IPv6 FIB entries for the public network.

```
<Sysname> display ipv6 fib

Destination count: 1 FIB entry count: 1

Flag:
  U:Useable   G:Gateway   H:Host   B:Blackhole   D:Dynamic   S:Static
  R:Relay     F:FRR

Destination: ::1                                    Prefix length: 128
Nexthop    : ::1                                    Flags: UH
Time stamp : 0x1                                    Label: Null
Interface  : InLoop0                                Token: Invalid
```

Table 1 Command output

Field	Description
Destination count	Total number of destination addresses.
FIB entry count	Total number of IPv6 FIB entries.

Field	Description
Destination	Destination address.
Prefix length	Prefix length of the destination address.
Nexthop	Next hop address.
Flags	Route flag: • **U**—Usable route. • **G**—Gateway route. • **H**—Host route. • **B**—Black hole route. • **D**—Dynamic route. • **S**—Static route. • **R**—Recursive route. • **F**—Fast re-route.
Time stamp	Time when the IPv6 FIB entry was generated.
Label	This field is not supported in the current software version. Inner MPLS label. For IPv6 FIB entries for the public network, this field displays **Null**.
Interface	Outgoing interface.
Token	Label switched path index number.

display ipv6 icmp statistics

Use **display ipv6 icmp statistics** to display ICMPv6 packet statistics.

Syntax

display ipv6 icmp statistics [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays ICMPv6 packet statistics for all member devices.

Examples

Display ICMPv6 packet statistics.

```
<Sysname> display ipv6 icmp statistics
  Input: bad code              0         too short               0
         checksum error        0         bad length              0
         path MTU changed      0         destination unreachable 0
         too big               0         parameter problem       0
```

```
        echo request           0         echo reply              0
        neighbor solicit       0         neighbor advertisement  0
        router solicit         0         router advertisement    0
        redirect               0         router renumbering      0
output: parameter problem      0         echo request            0
        echo reply             0         unreachable no route    0
        unreachable admin      0         unreachable beyond scope 0
        unreachable address    0         unreachable no port     0
        too big                0         time exceed transit     0
        time exceed reassembly 0         redirect                0
        ratelimited            0         other errors            0
```

Table 2 Command output

Field	Description
bad code	Number of received packets with error codes.
too short	Number of received packets with the length too short.
checksum error	Number of received packets with checksum errors.
bad length	Number of received packets with incorrect packet size.
path MTU changed	Number of received packets with path MTU changed.
destination unreachable	Number of destination unreachable packets that have been received.
too big	Number of received or sent oversized packets.
parameter problem	Number of received or sent packets with incorrect parameters.
echo request	Number of received or sent echo request packets.
echo reply	Number of received or sent echo reply packets.
neighbor solicit	Number of received NS packets.
neighbor advertisement	Number of received NA packets.
router solicit	Number of received RS packets.
router advertisement	Number of received RA packets.
redirect	Number of received or sent redirect packets.
router renumbering	Number of received packets with router renumbering.
unreachable no route	Number of sent packets to report the error that no route is available to the destination.
unreachable admin	Number of sent packets to report the error that the communication with the destination is administratively prohibited.
unreachable beyondscope	Number of sent packets to report the error that the source addresses is beyond the scope.
unreachable address	Number of address unreachable packets that have been sent.

unreachable no port	Number of port unreachable packets that have been sent.
time exceed transit	Number of sent packets to report the time exceeded in transmit error.
time exceed reassembly	Number of sent packets to report the fragment reassembly time exceeded error.
ratelimited	Number of packets that were not sent out because of the rate limit.
other errors	Number of sent packets with other errors.

display ipv6 interface

Use **`display ipv6 interface`** to display IPv6 interface information.

Syntax

`display ipv6 interface` [*`interface-type`* [*`interface-number`*]] [**`brief`**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`interface-type`: Specifies an interface by its type.

`interface-number`: Specifies an interface by its number.

`brief`: Displays brief IPv6 interface information, including physical status, link-layer protocols, and IPv6 address. If you do not specify the keyword, this command displays detailed IPv6 interface information, including IPv6 configuration and operating information, and IPv6 packet statistics.

Usage guidelines

If you do not specify an interface, this command displays IPv6 information about all interfaces except VA interfaces.

If you specify only the *`interface-type`* argument, this command displays IPv6 information about the interfaces of the specified type.

If you specify both the *`interface-type`* and the *`interface-number`* arguments, this command displays IPv6 information about the specified interface.

Examples

Display IPv6 information about GigabitEthernet 1/0/1.

```
<Sysname> display ipv6 interface gigabitethernet 1/0/1
GigabitEthernet1/0/1 current state: UP
Line protocol current state: UP
IPv6 is enabled, link-local address is FE80::200:1FF:FE04:5D00 [TENTATIVE]
  Global unicast address(es):
    10::1234:56FF:FE65:4322, subnet is 10::/64 [TENTATIVE] [AUTOCFG]
```

```
    [valid lifetime 4641s/preferred lifetime 4637s]
   20::1234:56ff:fe65:4322, subnet is 20::/64 [TENTATIVE] [EUI-64]
   30::1, subnet is 30::/64 [TENTATIVE] [ANYCAST]
   40::2, subnet is 40::/64 [TENTATIVE] [DHCP]
   50::3, subnet is 50::/64 [TENTATIVE]
  Joined group address(es):
   FF02::1
   FF02::2
   FF02::1:FF00:1
   FF02::1:FF04:5D00
  MTU is 1500 bytes
  ND DAD is enabled, number of DAD attempts: 1
  ND reachable time is 30000 milliseconds
  ND retransmit interval is 1000 milliseconds
  Hosts use stateless autoconfig for addresses
IPv6 Packet statistics:
  InReceives:                0
  InTooShorts:               0
  InTruncatedPkts:           0
  InHopLimitExceeds:         0
  InBadHeaders:              0
  InBadOptions:              0
  ReasmReqds:                0
  ReasmOKs:                  0
  InFragDrops:               0
  InFragTimeouts:            0
  OutFragFails:              0
  InUnknownProtos:           0
  InDelivers:                0
  OutRequests:               0
  OutForwDatagrams:          0
  InNoRoutes:                0
  InTooBigErrors:            0
  OutFragOKs:                0
  OutFragCreates:            0
  InMcastPkts:               0
  InMcastNotMembers:         0
  OutMcastPkts:              0
  InAddrErrors:              0
  InDiscards:                0
  OutDiscards:               0
```

Table 3 Command output

Field	Description
GigabitEthernet1/0/1 current state	Physical state of the interface: • **Administratively DOWN**—The interface has been administratively shut down by using the **shutdown** command. • **DOWN**—The interface is administratively up but its physical state is down, possibly because of a connection or link failure.

Field	Description
	• **UP**—The administrative and physical states of the interface are both up.
Line protocol current state	Link layer state of the interface: • **DOWN**—The link layer protocol state of the interface is down. • **UP**—The link layer protocol state of the interface is up.
IPv6 is enabled	IPv6 is enabled on the interface. This feature is automatically enabled after an IPv6 address is configured for an interface.
link-local address	Link-local address of the interface.
Global unicast address(es)	Global unicast addresses of the interface. IPv6 address states: • **TENTATIVE**—Initial state. DAD is being performed or is to be performed on the address. • **DUPLICATE**—The address is not unique on the link. • **PREFERRED**—The address is preferred and can be used as the source or destination address of a packet. If an address is in this state, the command does not display the address state. • **DEPRECATED**—The address is beyond the preferred lifetime but in the valid lifetime. It is valid, but it cannot be used as the source address for a new connection. Packets destined for the address are processed correctly. If a global unicast address is not manually configured, the following notations indicate how the address is obtained: • **AUTOCFG**—Stateless autoconfigured. • **DHCP**—Assigned by a DHCPv6 server. • **EUI-64**—Manually configured EUI-64 IPv6 address. • **RANDOM**—Random address automatically generated. If the address is a manually configured anycast address, it is noted with **ANYCAST**.
valid lifetime	Specifies how long autoconfigured global unicast addresses using a prefix are valid.
preferred lifetime	Specifies how long autoconfigured global unicast addresses using a prefix are preferred.
Joined group address(es)	Addresses of the multicast groups that the interface has joined.
MTU	MTU of the interface.
ND DAD is enabled, number of DAD attempts	DAD is enabled. • If DAD is enabled, this field displays the number of attempts to send an NS message for DAD (set by using the **ipv6 nd dad attempts** command). • If DAD is disabled, this field displays **ND DAD is disabled**. To disable DAD, set the number of attempts to 0.
ND reachable time	Time during which a neighboring device is reachable.
ND retransmit interval	Interval for retransmitting an NS message.
Hosts use stateless autoconfig for addresses	Hosts obtained IPv6 addresses through stateless autoconfiguration.
InReceives	Received IPv6 packets, including error messages.
InTooShorts	Received IPv6 packets that are too short. For example, the received IPv6 packet is less than 40 bytes.
InTruncatedPkts	Received IPv6 packets with a length less than the payload length field

Field	Description
	specified in the packet header.
InHopLimitExceeds	Received IPv6 packets with a hop count exceeding the hop limit field specified in the packet header.
InBadHeaders	Received IPv6 packets with incorrect basic headers.
InBadOptions	Received IPv6 packets with incorrect extension headers.
ReasmReqds	Received IPv6 fragments.
ReasmOKs	Number of reassembled IPv6 packets.
InFragDrops	Received IPv6 fragments that are discarded because of certain errors.
InFragTimeouts	Received IPv6 fragments that are discarded because the amount of time they stay in the system buffer exceeds the specified interval.
OutFragFails	IPv6 packets that fail to be fragmented on the output interface.
InUnknownProtos	Received IPv6 packets with unknown or unsupported protocol type.
InDelivers	Received IPv6 packets that are delivered to user protocols (such as ICMPv6, TCP, and UDP).
OutRequests	Local IPv6 packets sent by IPv6 user protocols.
OutForwDatagrams	IPv6 packets forwarded by the interface.
InNoRoutes	Received IPv6 packets that are discarded because no matching route can be found.
InTooBigErrors	Received IPv6 packets that fail to be forwarded because they exceeded the Path MTU.
OutFragOKs	Fragmented IPv6 packets on the output interface.
OutFragCreates	Number of IPv6 fragments on the output interface.
InMcastPkts	Received IPv6 multicast packets.
InMcastNotMembers	Received IPv6 multicast packets that are discarded because the interface is not in the multicast group.
OutMcastPkts	IPv6 multicast packets sent by the interface.
InAddrErrors	Received IPv6 packets that are discarded due to invalid destination addresses.
InDiscards	Received IPv6 packets that are discarded due to resource problems rather than packet errors.
OutDiscards	IPv6 packets that fail to be sent due to resource problems rather than packet errors.

Display brief IPv6 information about all interfaces.

```
<Sysname> display ipv6 interface brief
*down: administratively down
(s): spoofing
Interface                         Physical Protocol IPv6 Address
GigabitEthernet1/0/1              up       up       2001::1
GigabitEthernet1/0/2              up       up       Unassigned
GigabitEthernet1/0/3              down     down     Unassigned
```

Table 4 Command output

Field	Description
*down: administratively down	The interface has been administratively shut down by using the **shutdown** command.
(s): spoofing	Spoofing attribute of the interface. The link protocol state of the interface is up, but the link is temporarily established on demand or does not exist.
Interface	Name of the interface.
Physical	Physical state of the interface: • ***down**—The interface has been administratively shut down by using the **shutdown** command. • **down**—The interface is administratively up but its physical state is down, possibly because of a connection or link failure. • **up**—The administrative and physical states of the interface are both up.
Protocol	Link layer protocol state of the interface: • **down**—The network layer protocol state of the interface is down. • **up**—The network layer protocol state of the interface is up.
IPv6 Address	IPv6 address of the interface. • If multiple global unicast addresses are configured, this field displays the lowest address. • If no global unicast address is configured, this field displays the link-local address. • If no address is configured, this field displays **Unassigned**.

display ipv6 interface prefix

Use **display ipv6 interface prefix** to display IPv6 prefix information for an interface.

Syntax

display ipv6 interface *interface-type interface-number* **prefix**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number.

Examples

Display IPv6 prefix information for GigabitEthernet 1/0/1.

```
<Sysname> display ipv6 interface gigabitethernet 1/0/1prefix
Prefix: 1001::/65                                  Origin: ADDRESS
Age:    -                                           Flag:   AL
Lifetime(Valid/Preferred): 2592000/604800
```

```
Prefix: 2001::/64                                   Origin: STATIC
Age:    -                                            Flag:   L
Lifetime(Valid/Preferred): 3000/2000

Prefix: 3001::/64                                   Origin: RA
Age:    600                                          Flag:   A
Lifetime(Valid/Preferred): -
```

Table 5 Command output

Filed	Description
Prefix	IPv6 address prefix.
Origin	How the prefix is generated: • **STATIC**—Manually configured by using the **ipv6 nd ra prefix** command. • **RA**—Advertised in RA messages after stateless autoconfiguration is enabled. • **ADDRESS**—Generated by a manually configured address.
Age	Aging time in seconds. If the prefix does not age out, this field displays a hyphen (-).
Flag	Flags carried in RA messages. If no flags are available, this field displays a hyphen (-). • **L**—The address with the prefix is directly reachable on the link. • **A**—The prefix is used for stateless autoconfiguration.
Lifetime	Lifetime in seconds advertised in RA messages. If the prefix does not need to be advertised, this field displays a hyphen (-). • **Valid**—Valid lifetime of the prefix. • **Preferred**—Preferred lifetime of the prefix.

context-operator

Parameters

ipv6-address: Specifies the IPv6 address of a neighbor whose information is displayed.

all: Displays information about all neighbors, including neighbors acquired dynamically and configured statically on the public network and all private networks.

dynamic: Displays information about all neighbors acquired dynamically.

static: Displays information about all neighbors configured statically.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv6 neighbor information for all member devices.

interface *interface-type interface-number*: Specifies an interface by its type and number.

vlan *vlan-id*: Displays information about neighbors in the specified VLAN. The value range for VLAN ID is 1 to 4094.

verbose: Displays detailed neighbor information.

Examples

Display all neighbor information.

```
<Sysname> display ipv6 neighbors all
Type: S-Static   D-Dynamic   O-Openflow    R-Rule   IS-Invalid static
IPv6 address            MAC address   VID  Interface         State T  Age
FE80::200:5EFF:FE32:B800  0000-5e32-b800 --   GE1/0/1           REACH S  --
```

Display detailed information about all neighbors.

```
<Sysname> display ipv6 neighbors all verbose
IPv6 address : FE80::200:5EFF:FE32:B800
MAC address  : 0000-5e32-b800          Type  : Static
State       : REACH                 Age   : --
Interface    : GE1/0/1               VID   : --
VPN instance : vpn1
Nickname     : 0x0
```

Table 6 Command output

Field	Description
IPv6 address	IPv6 address of the neighbor.
MAC address	MAC address of the neighbor.
VID	VLAN or virtual switch instance (VSI) to which the interface connected to a neighbor belongs.
Interface	Interface connected to the neighbor.
State	State of the neighbor: • **INCMP**—The address is being resolved. The link layer address of the neighbor is unknown. • **REACH**—The neighbor is reachable. • **STALE**—Whether the neighbor is reachable is unknown. The device does not verify the reachability any longer unless data is sent to the neighbor. • **DELAY**—Whether the neighbor is reachable is unknown. The device sends an NS message after a delay. • **PROBE**—Whether the neighbor is reachable is unknown. The device sends an NS message to verify the reachability of the neighbor.
Type	Neighbor information type: • **Static**—Statically configured. • **Dynamic**—Dynamically obtained. • **Openflow**—Learned from the OpenFlow module. This field is not supported in the

Field	Description
	current software version. • **Rule**—Learned from IPoE or Portal module. • **Invalid static**—Invalid static entries.
Age	A hyphen (-) indicates a static entry. For a dynamic entry, this field displays the elapsed time in seconds. If the neighbor is never reachable, this field displays a pound sign (#).
VPN instance	Name of a VPN instance. If no VPN instance is configured, this field displays a hyphen (-).
Nickname	This field is not supported in the current software version. Nickname of a neighbor entry. The name is a string of four hexadecimal numbers, such as 012a.

Parameters

all: Displays the total number of all neighbor entries, including neighbor entries created dynamically and configured statically.

dynamic: Displays the total number of neighbor entries created dynamically.

static: Displays the total number of neighbor entries configured statically.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays the number of neighbor entries for all member devices.

interface *interface-type interface-number*: Specifies an interface by its type and number.

vlan *vlan-id*: Displays the total number of neighbor entries in the specified VLAN. The value range for VLAN ID is 1 to 4094.

Examples

Display the total number of neighbor entries created dynamically.

```
<Sysname> display ipv6 neighbors dynamic count
 Total number of dynamic entries: 2
```

display ipv6 neighbors vpn-instance

Use **display ipv6 neighbors vpn-instance** to display neighbor information about a VPN instance.

Parameters

vpn-instance-name: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. The VPN instance must already exist.

count: Displays the total number of neighbor entries in the specified VPN instance.

Examples

Display neighbor information about the VPN instance **vpn1**.

```
<Sysname> display ipv6 neighbors vpn-instance vpn1
Type: S-Static   D-Dynamic   O-Openflow    R-Rule   IS-Invalid static
IPv6 address            MAC address   VID  Interface         State T  Age
FE80::200:5EFF:FE32:B800  0000-5e32-b800 --   GE1/0/1           REACH IS --
```

Table 7 Command output

Field	Description
IPv6 address	IPv6 address of a neighbor.
MAC address	MAC address of a neighbor.
VID	VLAN to which the interface connected to a neighbor belongs.
Interface	Interface connected to a neighbor.
State	Neighbor state: • **INCMP**—The address is being resolved. The link layer address of the neighbor is unknown. • **REACH**—The neighbor is reachable. • **STALE**—Whether the neighbor is reachable is unknown. The device does not verify the reachability any longer unless data is sent to the neighbor. • **DELAY**—Whether the neighbor is reachable is unknown. The device sends an NS message after a delay. • **PROBE**—Whether the neighbor is reachable is unknown. The device sends an NS message to verify the reachability of the neighbor.
T	Neighbor information type: • **Static**—Statically configured.

Field	Description
	• **Dynamic**—Dynamically obtained. • **Openflow**—Learned from the OpenFlow module. This type is not supported in the current software version. • **Rule**—Learned from the IPoE or portal module. • **Invalid static**—Invalid static entry.
Age	A hyphen (-) indicates a static entry. For a dynamic entry, this field displays the elapsed time in seconds. If the neighbor is never reachable, this field displays a pound sign (#).

display ipv6 pathmtu

Use the **display ipv6 pathmtu** command to display IPv6 Path MTU information.

Syntax

display ipv6 pathmtu [**vpn-instance** *vpn-instance-name*] { *ipv6-address* | { **all** | **dynamic** | **static** } [**count**] }

Views

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays IPv6 Path MTU information about the public network.

ipv6-address: Specifies the destination IPv6 address for which the Path MTU information is to be displayed.

all: Displays all Path MTU information for the public network.

dynamic: Displays all dynamic Path MTU information.

static: Displays all static Path MTU information.

count: Displays the total number of Path MTU entries.

Examples

Display all Path MTU information.

```
<Sysname> display ipv6 pathmtu all
IPv6 destination address             PathMTU   Age   Type
1:2::3:2                             1800      -     Static
1:2::4:2                             1400      10    Dynamic
1:2::5:2                             1280      10    Dynamic
```

Displays the total number of Path MTU entries.

```
<Sysname> display ipv6 pathmtu all count
Total number of entries: 3
```

Table 8 Command output

Field	Description
PathMTU	Path MTU value on the network path to an IPv6 address.
Age	Time for a Path MTU to live. For a static Path MTU, this field displays a hyphen (-).
Type	Path MTU type: • **Dynamic**—Dynamically negotiated. • **Static**—Statically configured.
Total number of entries	Total number of Path MTU entries.

Related commands

ipv6 pathmtu

reset ipv6 pathmtu

display ipv6 prefix

Use **display ipv6 prefix** to display information about IPv6 prefixes, including dynamic and static prefixes.

Syntax

display ipv6 prefix [*prefix-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

prefix-number: Specifies the ID of an IPv6 prefix, in the range of 1 to 1024. If you do not specify an IPv6 prefix ID, this command displays information about all IPv6 prefixes.

Usage guidelines

A static IPv6 prefix is configured by using the **ipv6 prefix** command.

A dynamic IPv6 prefix is obtained from the DHCPv6 server, and its prefix ID is configured by using the **ipv6 dhcp client pd** command. For more information about prefix generation, see DHCPv6 client configuration in *Layer 3—IP Services Configuration Guide*.

Examples

Display information about all IPv6 prefixes.

```
<Sysname> display ipv6 prefix
Number  Prefix                                  Type
1       1::/16                                  Static
2       11:77::/32                              Dynamic
```

Display information about the IPv6 prefix with prefix ID 1.

```
<Sysname> display ipv6 prefix 1
Number: 1
Type  : Dynamic
Prefix: ABCD:77D8::/32
Preferred lifetime 90 sec, valid lifetime 120 sec
```

Table 9 Command output

Field	Description
Number	Prefix ID.
Type	Prefix type: • **Static**—Static IPv6 prefix. • **Dynamic**—Dynamic IPv6 prefix.
Prefix	Prefix and its length. If no prefix is obtained, this field displays **Not-available**.
Preferred lifetime 90 sec	Preferred lifetime in seconds. For a static IPv6 prefix, this field is not displayed.
valid lifetime 120 sec	Valid lifetime in seconds. For a static IPv6 prefix, this field is not displayed.

 Type: 3
```

```
Protocol: 58
Inpcb flags: N/A
Inpcb extflag: N/A
Inpcb vflag: INP_IPV6
Hop limit: 255 (minimum hop limit: 0)
Send VRF: 0xffff
Receive VRF: 0xffff
```

Table 11 Command output

Field	Description
Total RawIP socket number	Total number of IPv6 RawIP sockets.
Connection info	Connection information, including the source and destination IPv6 addresses.
Location	Socket location.
Creator	Task name of the socket. The process number is in the square brackets.
State	Socket state: • **NOFDREF**—The user has closed the connection. • **ISCONNECTED**—The connection has been established. • **ISCONNECTING**—The connection is being established. • **ISDISCONNECTING**—The connection is being interrupted. • **ASYNC**—Asynchronous mode. • **ISDISCONNECTED**—The connection has been terminated. • **ISSMOOTHING**—Cross-card data smoothing is in progress. • **CANBIND**—The socket supports the bind operation. • **PROTOREF**—Indicates strong protocol reference. • **ISPCBSYNCING**—Cross-card PCB synchronization is in progress • **N/A**—None of above state.
Options	Socket options: • **SO_DEBUG**—Records socket debugging information. • **SO_ACCEPTCONN**—Enables the server to listen connection requests. • **SO_REUSEADDR**—Allows the local address reuse. • **SO_KEEPALIVE**—Requires the protocol to test whether the connection is still alive. • **SO_DONTROUTE**—Bypasses the routing table query for outgoing packets because the destination is in a directly connected network. • **SO_BROADCAST**—Supports broadcast packets. • **SO_LINGER**—Closes the socket. The system can still send remaining data in the socket send buffer. • **SO_OOBINLINE**—Stores the out-of-band data in the input queue. • **SO_REUSEPORT**—Allows the local port reuse. • **SO_TIMESTAMP**—Records the timestamps of the input packets, accurate to milliseconds. This option is applicable to protocols that are not connection orientated. • **SO_NOSIGPIPE**—Disables the socket from sending data. As a result, a sigpipe cannot be established when a return failure occurs. • **SO_TIMESTAMPNS**—Has a similar function with the timestamp, accurate to nanoseconds. • **SO_KEEPALIVETIME**—Sets a keepalive time. This option is supported in TCP. • **SO_FILTER**—Supports setting the packet filter criterion. This option

Field	Description
	is available for OSI Socket and RawIP. • **SO_SEQPACKET**—Preserves the boundaries of packets sent to the socket buffer. • **SO_FILLTWAMPTIME**—Sets the timestamp for TWAMP. • **SO_LOCAL**—Local socket option. • **SO_NBMAADDR**—Obtains the remote NBMA address of the ADVPN tunnel. • **SO_DONTDELIVER**—Do not deliver the data to the application. • **N/A**—No options are set.
Error	Error code.

Receiving buffer(cc/hiwat/lowat/drop/state)	Displays receive buffer information in the following order:
	• **cc**—Used space.
	• **hiwat**—Maximum space.
	• **lowat**—Minimum space.
	• **drop**—Number of dropped packets.
	• **state**—Buffer state:
	  ○ **CANTSENDMORE**—Unable to send data to the peer.
	  ○ **CANTRCVMORE**—Unable to receive data from the peer.
	  ○ **RCVATMARK**—Receiving tag.
	  ○ **N/A**—None of the above states.

Sending buffer(cc/hiwat/lowat/state)	Displays send buffer information in the following order:
	• **cc**—Used space.
	• **hiwat**—Maximum space.
	• **lowat**—Minimum space.
	• **state**—Buffer state:
	  ○ **CANTSENDMORE**—Unable to send data to the peer.
	  ○ **CANTRCVMORE**—Unable to receive data from the peer.
	  ○ **RCVATMARK**—Receiving tag.
	  ○ **N/A**—None of the above states.

Type	Socket type: • **1**—**SOCK_STREAM**. This socket uses TCP to provide reliable transmission of byte streams. • **2**—**SOCK_DGRAM**. This socket uses UDP to provide datagram transmission. • **3**—**SOCK_RAW**. This socket allows an application to change the next upper-layer protocol header. • **N/A**—None of the above types.
Protocol	Number of protocol using the socket. 58 represents ICMP.
Inpcb flags	Flags in the Internet PCB: • **INP_RECVOPTS**—Receives IPv6 options. • **INP_RECVRETOPTS**—Receives replied IPv6 options. • **INP_RECVDSTADDR**—Receives destination IPv6 address. • **INP_HDRINCL**—Provides the entire IPv6 header. • **INP_REUSEADDR**—Reuses the IPv6 address. • **INP_REUSEPORT**—Reuses the port number. • **INP_ANONPORT**—Port number not specified. • **INP_PROTOCOL_PACKET**—Identifies a protocol packet. • **INP_RCVVLANID**—Receives the VLAN ID of the packet. Only UDP and RawIP support this flag. • **IN6P_IPV6_V6ONLY**—Only supports IPv6 protocol stack.

Field	Description
	• **IN6P_PKTINFO**—Receives the source IPv6 address and input interface of the packet. • **IN6P_HOPLIMIT**—Receives the hop limit. • **IN6P_HOPOPTS**—Receives the hop-by-hop options extension header. • **IN6P_DSTOPTS**—Receives the destination options extension header. • **IN6P_RTHDR**—Receives the routing extension header. • **IN6P_RTHDRDSTOPTS**—Receives the destination options extension header preceding the routing extension header. • **IN6P_TCLASS**—Receives the traffic class of the packet. • **IN6P_AUTOFLOWLABEL**—Attaches a flow label automatically. • **IN6P_RFC2292**—Uses the API specified in RFC 2292. • **IN6P_MTU**—Discovers differences in the MTU size of every link along a given data path. TCP does not support this flag. • **INP_RCVMACADDR**—Receives the MAC address of the frame. • **INP_USEICMPSRC**—Uses the specified IPv6 address as the source IPv6 address for outgoing ICMP packets. • **INP_SYNCPCB**—Waits until Internet PCB is synchronized. • **INP_LOCAL**—Preferentially matches the INPCB with this flag on the same card. • **N/A**—None of the above flags.
Inpcb extflag	Extension flags in the Internet PCB: • **INP_EXTRCVPVCIDX**—Records the PVC index of the received packet. • **INP_RCVPWID**—Records the PW ID of the received packet. • **INP_EXTRCVICMPERR**—Receives an ICMP error packet. • **INP_EXTFILTER**—Filters the contents in the received packets. • **INP_EXTDONTDROP**—Does not drop the received packet. • **INP_EXLISTEN**—Adds the INPCB carrying this flag to the listen hash table. • **INP_SELECTMATCHSRCBYFIB**—Uses the FIB table to select a matching source. • **INP_EXTPRIVATESOCKET**—Associates the INPCB with the NSR private socket. • **INP_EXLISTENNET**—Sets this flag when the connection information is added to the network segment linked list. • **N/A**—None of the above flags.
Inpcb vflag	IP version flag in the Internet PCB: • **INP_IPV4**—IPv4 protocol. • **INP_IPV6**—IPv6 protocol. • **INP_IPV6PROTO**—Creates an Internet PCB based on IPv6 protocol. • **INP_TIMEWAIT**—In **TIMEWAIT** state. • **INP_ONESBCAST**—Sends broadcast packets. • **INP_DROPPED**—Protocol dropped flag. • **INP_SOCKREF**—Strong socket reference. • **INP_DONTBLOCK**—Do not block synchronization of the Internet PCB. • **N/A**—None of the above flags.
Hop limit	Hop limit in the Internet PCB.
Send VRF	VRF from which packets are sent.

Field	Description
Receive VRF	VRF from which packets are received.

display ipv6 statistics

Use **display ipv6 statistics** to display IPv6 and ICMPv6 packet statistics.

Syntax

display ipv6 statistics [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv6 and ICMPv6 packet statistics for all member devices.

Examples

Display IPv6 and ICMPv6 packet statistics.

```
<Sysname> display ipv6 statistics
  IPv6 statistics:

    Sent packets:
      Total:     0
        Sent locally:        0          Forwarded:            0
        Raw packets:         0          Discarded:            0
        Fragments:           0          Fragments failed:     0
        Routing failed:      0

    Received packets:
      Total:     0
        Received locally:    0          Hop limit exceeded:  0
        Fragments:           0          Reassembled:         0
        Reassembly failures:  0          Reassembly timeout:  0
        Format errors:       0          Option errors:       0
        Protocol errors:     0

  ICMPv6 statistics:

    Sent packets:
      Total:     0
        Unreachable:         0           Too big:             0
        Hop limit exceeded:  0           Reassembly timeouts: 0
```

```
    Parameter problems:   0
    Echo requests:        0          Echo replies:         0
    Neighbor solicits:    0          Neighbor adverts:     0
    Router solicits:      0          Router adverts:       0
    Redirects:            0          Router renumbering:   0
  Send failed:
    Rate limitation:      0          Other errors:         0

Received packets:

    Bad length:           0
```

Table 12 Command output

Field	Description
IPv6 statistics:	IPv6 packet statistics.
Sent packets: Total: Sent locally: Forwarded: Raw packets: Discarded: Fragments: Fragments failed: Routing failed:	Statistics for sent IPv6 packets: • **Total**—Total number of packets that have been locally sent and forwarded. • **Sent locally**—Number of locally sent packets. • **Forwarded**—Number of forwarded packets. • **Raw packets**—Number of packets sent by using a raw socket. • **Discarded**—Number of discarded packets. • **Fragments**—Number of sent fragments. • **Fragments failed**—Number of fragments that were failed to send. • **Routing failed**—Number of packets with routing failures.
Received packets: Total: Received locally: Hop limit exceeded: Fragments: Reassembled: Reassembly failures: Reassembly timeout: Format errors:	Statistics for received IPv6 packets: • **Total**—Total number of received packets. • **Received locally**—Number of received packets that are destined for the device. • **Hop limit exceeded**—Number of packets with hop limit exceeded. • **Fragments**—Number of received fragments. • **Reassembled**—Number of reassembled packets. • **Reassembly failures**—Number of packets with reassembly failures.

Option errors: Protocol errors:	• **Reassembly timeout**—Number of packets with reassembly timed out. • **Format errors**—Number of packets with format errors. • **Option errors**—Number of packets with option errors. • **Protocol errors**—Number of packets with protocol errors.
ICMPv6 statistics:	ICMPv6 message statistics.
Sent packets: Total: Unreached: Too big: Hop limit exceeded: Reassembly timeouts: Parameter problems: Echo requests: Echo replies: Neighbor solicits: Neighbor adverts: Router solicits: Router adverts: Redirects: Router renumbering Sent failed: Rate limitation: Other errors:	Statistics for sent ICMPv6 messages: • **Total**—Total number of sent messages. • **Unreached**—Number of Destination Unreachable messages. • **Too big**—Number of Packet Too Big messages. • **Hop limit exceeded**—Number of Hop Limit Exceeded messages. • **Reassembly timeouts**—Number of Fragment Reassembly Time Exceeded messages. • **Parameter problems**—Number of Parameter Problem messages. • **Echo requests**—Number of Echo Requests. • **Echo replies**—Number of Echo Replies. • **Neighbor solicits**—Number of Neighbor Solicitation messages. • **Neighbor adverts**—Number of Neighbor Advertisement messages. • **Router solicits**—Number of Router Solicitation messages. • **Router adverts**—Number of Router Advertisement messages. • **Redirects**—Number of Redirect messages. • **Router renumbering**—Number of Router Renumbering messages. This value is not supported in the current software version. • **Sent failed**—Number of messages that were failed to send locally. • **Rate limitation**—Number of unsent messages because of rate limiting. • **Other errors**—Number of messages with other errors.
Received packets: Total: Checksum errors: Too short: Bad codes: Unreachable: Too big: Hop limit exceeded: Reassembly timeouts: Parameter problems: Unknown error types: Echo requests:	Statistics for received ICMPv6 messages: • **Total**—Total number of received messages. • **Checksum errors**—Number of messages with checksum errors. • **Too short**—Number of messages with a too short length. • **Bad codes**—Number of messages with error codes. • **Unreached**—Number of Destination Unreachable messages. • **Too big**—Number of Packet Too Big messages. • **Hop limit exceeded**—Number of Hop Limit Exceeded messages.

Echo replies: Neighbor solicits: Neighbor adverts: Router solicits: Router adverts: Redirects: Router renumbering: Unknown info types: Deliver failed: Bad length:	• **Reassembly timeouts**—Number of Fragment Reassembly Time Exceeded messages. • **Parameter problems**—Number of Parameter Problem messages. • **Unknown error types**—Number of messages with unknown error types. • **Echo requests**—Number of Echo Requests. • **Echo replies**—Number of Echo Replies. • **Neighbor solicits**—Number of Neighbor Solicitation messages. • **Neighbor adverts**—Number of Neighbor Advertisement messages. • **Router solicits**—Number of Router Solicitation messages. • **Router adverts**—Number of Router Advertisement messages. • **Redirects**—Number of Redirect messages. **Router renumbering**—Number of Router Renumbering messages. This field is not supported in the current software version. • **Unknown info types**—Number of messages with unknown information types. • **Deliver failed**—Number of messages with local delivery failures. • **Bad length**—Number of messages with error length.

Related commands

`reset ipv6 statistics`

display ipv6 tcp

Use **`display ipv6 tcp`** to display brief information about IPv6 TCP connections.

Syntax

`display ipv6 tcp` [**`slot`** *`slot-number`*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`slot` *`slot-number`*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays brief information about IPv6 TCP connections for all member devices.

Examples

Display brief information about IPv6 TCP connections.

```
<Sysname> display ipv6 tcp
*: TCP MD5 Connection
 LAddr->port        FAddr->port      State       Slot  PCB
*2001:2002:2003:2   3001:3002:3003:3 ESTABLISHED 1    0x000000000000c387
004:2005:2006:20    004:3005:3006:30
07:2008->1200       07:3008->1200
2001::1->23         2001::5->1284    ESTABLISHED 1    0x0000000000000008
2003::1->25         2001::2->1283    LISTEN      1    0x0000000000000009
```

Table 13 Command output

Field	Description
*	Indicates that the TCP connection uses MD5 authentication.
LAddr->port	Local IPv6 address and port number.
FAddr->port	Peer IPv6 address and port number.
State	IPv6 TCP connection state: • **CLOSED**—The server receives a disconnection request's reply from the client. • **LISTEN**—The server is waiting for connection requests. • **SYN_SENT**—The client is waiting for the server to reply to the connection request. • **SYN_RCVD**—The server receives a connection request. • **ESTABLISHED**—The server and client have established connections and can transmit data bidirectionally. • **CLOSE_WAIT**—The server receives a disconnection request from the client. • **FIN_WAIT_1**—The client is waiting for the server to reply to a disconnection request. • **CLOSING**—The server and client are waiting for peer's disconnection reply when receiving disconnection requests from each other. • **LAST_ACK**—The server is waiting for the client to reply to a disconnection request. • **FIN_WAIT_2**—The client receives a disconnection reply from the server. • **TIME_WAIT**—The client receives a disconnection request from the server.
PCB	PCB index.

display ipv6 tcp verbose

Use **display ipv6 tcp verbose** to display detailed information about IPv6 TCP connections.

Syntax

display ipv6 tcp verbose [**slot** *slot-number* [**pcb** *pcb-index*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays detailed information about IPv6 TCP connections for all member devices.

pcb *pcb-index*: Displays detailed information about IPv6 TCP connections of the specified PCB. The value range for the *pcb-index* argument is 1 to 16.

Examples

Display detailed information about an IPv6 TCP connection.

```
<Sysname> display ipv6 tcp verbose
TCP inpcb number: 1(tcpcb number: 1)

 Connection info: src = 2001::1->179 ,  dst = 2001::2->4181
 Location: Slot:2

 Creator: bgpd[199]
 State: ISCONNECTED
 Options: N/A
 Error: 0
 Receiving buffer(cc/hiwat/lowat/drop/state): 0 / 65536 / 1 / 0 / N/A
 Sending buffer(cc/hiwat/lowat/state): 0 / 65536 / 512 / N/A
 Type: 1
 Protocol: 6
 Inpcb flags: N/A
 Inpcb extflag: N/A
 Inpcb vflag: INP_IPV6
 Hop limit: 255 (minimum hop limit: 0)
 Connection state: ESTABLISHED
 TCP options: TF_REQ_SCALE TF_REQ_TSTMP TF_SACK_PERMIT TF_NSR
 NSR state: READY(M)
 Send VRF: 0x0
 Receive VRF: 0x0
```

Table 14 Command output

Field	Description
TCP inpcb number	Number of IPv6 TCP Internet PCBs.
Connection info	Connection information, including source IPv6 address, source port number, destination IPv6 address, and destination port number.
Location	Socket location.
tcpcb number	Number of IPv6 TCP PCBs (excluding PCBs of TCP in TIME_WAIT state).
NSR standby	ID of the IRF member device and number of the slot where the NSR standby card resides. This field displays **N/A** if no NSR standby card is present.
Creator	Task name of the socket. The process number is in the square brackets.
State	Socket state:

Field	Description
	• **NOFDREF**—The user has closed the connection. • **ISCONNECTED**—The connection has been established. • **ISCONNECTING**—The connection is being established. • **ISDISCONNECTING**—The connection is being interrupted. • **ASYNC**—Asynchronous mode. • **ISDISCONNECTED**—The connection has been terminated. • **ISSMOOTHING**—Cross-card data smoothing is in progress. • **CANBIND**—The socket supports the bind operation. • **PROTOREF**—Indicates strong protocol reference. • **ISPCBSYNCING**—Cross-card PCB synchronization is in progress • **N/A**—None of above state.
Options	Socket options: • **SO_DEBUG**—Records socket debugging information. • **SO_ACCEPTCONN**—Enables the server to listen connection requests. • **SO_REUSEADDR**—Allows the local address reuse. • **SO_KEEPALIVE**—Requires the protocol to test whether the connection is still alive. • **SO_DONTROUTE**—Bypasses the routing table query for outgoing packets because the destination is in a directly connected network. • **SO_BROADCAST**—Supports broadcast packets. • **SO_LINGER**—Closes the socket. The system can still send remaining data in the socket send buffer. • **SO_OOBINLINE**—Stores the out-of-band data in the input queue. • **SO_REUSEPORT**—Allows the local port reuse. • **SO_TIMESTAMP**—Records the timestamps of the input packets, accurate to milliseconds. This option is applicable to protocols that are not connection orientated. • **SO_NOSIGPIPE**—Disables the socket from sending data. As a result, a sigpipe cannot be established when a return failure occurs. • **SO_TIMESTAMPNS**—Has a similar function with the timestamp, accurate to nanoseconds. • **SO_KEEPALIVETIME**—Sets a keepalive time. This option is supported in TCP. • **SO_FILTER**—Supports setting the packet filter criterion. This option is available for OSI Socket and RawIP. • **SO_SEQPACKET**—Preserves the boundaries of packets sent to the socket buffer. • **SO_FILLTWAMPTIME**—Sets the timestamp for TWAMP. • **SO_LOCAL**—Local socket option. • **SO_NBMAADDR**—Obtains the remote NBMA address of the ADVPN tunnel. • **SO_DONTDELIVER**—Do not deliver the data to the application. • **N/A**—No options are set.
Error	Error code.
Receiving buffer(cc/hiwat/lowat/drop/state)	Displays receive buffer information in the following order: • **cc**—Used space. • **hiwat**—Maximum space. • **lowat**—Minimum space. • **drop**—Number of dropped packets. • **state**—Buffer state. Buffer states include the following:

Field	Description
	• **CANTSENDMORE**—Unable to send data to the peer. • **CANTRCVMORE**—Unable to receive data from the peer. • **RCVATMARK**—Receiving tag. • **N/A**—None of the above states.

Sending buffer(cc/hiwat/lowat/state)	Displays send buffer information in the following order:
	• **cc**—Used space.
	• **hiwat**—Maximum space.
	• **lowat**—Minimum space.
	• **state**—Buffer state:
	  ○ **CANTSENDMORE**—Unable to send data to the peer.
	  ○ **CANTRCVMORE**—Unable to receive data from the peer.
	  ○ **RCVATMARK**—Receiving tag.
	  ○ **N/A**—None of the above states.

Type	Socket type: • **1**—**SOCK_STREAM**. This socket uses TCP to provide reliable transmission of byte streams. • **2**—**SOCK_DGRAM**. This socket uses UDP to provide datagram transmission. • **3**—**SOCK_RAW**. This socket allows an application to change the next upper-layer protocol header. • **N/A**—None of the above types.
Protocol	Number of the protocol using the socket. 6 represents TCP.
Inpcb flags	Flags in the Internet PCB: • **INP_RECVOPTS**—Receives IPv6 options. • **INP_RECVRETOPTS**—Receives replied IPv6 options. • **INP_RECVDSTADDR**—Receives destination IPv6 address. • **INP_HDRINCL**—Provides the entire IPv6 header. • **INP_REUSEADDR**—Reuses the IPv6 address. • **INP_REUSEPORT**—Reuses the port number. • **INP_ANONPORT**—Port number not specified. • **INP_PROTOCOL_PACKET**—Identifies a protocol packet. • **INP_RCVVLANID**—Receives the VLAN ID of the packet. Only UDP and RawIP support this flag. • **IN6P_IPV6_V6ONLY**—Only supports IPv6 protocol stack. • **IN6P_PKTINFO**—Receives the source IPv6 address and input interface of the packet. • **IN6P_HOPLIMIT**—Receives the hop limit. • **IN6P_HOPOPTS**—Receives the hop-by-hop options extension header. • **IN6P_DSTOPTS**—Receives the destination options extension header. • **IN6P_RTHDR**—Receives the routing extension header. • **IN6P_RTHDRDSTOPTS**—Receives the destination options extension header preceding the routing extension header. • **IN6P_TCLASS**—Receives the traffic class of the packet. • **IN6P_AUTOFLOWLABEL**—Attaches a flow label automatically. • **IN6P_RFC2292**—Uses the API specified in RFC 2292. • **IN6P_MTU**—Discovers differences in the MTU size of every link along a given data path. TCP does not support this flag. • **INP_RCVMACADDR**—Receives the MAC address of the frame. • **INP_SYNCPCB**—Waits until Internet PCB is synchronized.

Field	Description
	• **INP_LOCAL**—Preferentially matches the INPCB with this flag on the same card. • **N/A**—None of the above flags.
Inpcb extflag	Extension flags in the Internet PCB: • **INP_EXTRCVPVCIDX**—Records the PVC index of the received packet. • **INP_RCVPWID**—Records the PW ID of the received packet. • **INP_EXTDONTDROP**—Does not drop the received packet. • **INP_EXLISTEN**—Listening socket. • **INP_EXTFILTER**—Filters the contents in the received packets. • **INP_SELECTMATCHSRCBYFIB**—Uses the FIB table to select a matching source. • **INP_EXTRCVICMPERR**—Receives an ICMP error packet. • **INP_EXTPRIVATESOCKET**—Associates the INPCB with the NSR private socket. • **INP_EXLISTENNET**—Sets this flag when the connection information is added to the network segment linked list. • **N/A**—None of the above flags.
Inpcb vflag	IP version flags in the Internet PCB: • **INP_IPV4**—IPv4 protocol. • **INP_IPV6**—IPv6 protocol. • **INP_IPV6PROTO**—Creates an Internet PCB based on IPv6 protocol. • **INP_TIMEWAIT**—In **TIMEWAIT** state. • **INP_ONESBCAST**—Sends broadcast packets. • **INP_DROPPED**—Protocol dropped flag. • **INP_SOCKREF**—Strong socket reference. • **INP_DONTBLOCK**—Do not block synchronization of the Internet PCB. • **N/A**—None of the above flags.
Hop limit	Hop limit in the Internet PCB.
Connection state	TCP connection state: • **CLOSED**—The server receives a disconnection request's reply from the client. • **LISTEN**—The server is waiting for connection requests. • **SYN_SENT**—The client is waiting for the server to reply to the connection request. • **SYN_RCVD**—The server receives a connection request. • **ESTABLISHED**—The server and client have established connections and can transmit data bidirectionally. • **CLOSE_WAIT**—The server receives a disconnection request from the client. • **FIN_WAIT_1**—The client is waiting for the server to reply to a disconnection request. • **CLOSING**—The server and client are waiting for peer's disconnection reply when receiving disconnection requests from each other. • **LAST_ACK**—The server is waiting for the client to reply to a disconnection request. • **FIN_WAIT_2**—The client receives a disconnection reply from the server. • **TIME_WAIT**—The client receives a disconnection request from the

Field	Description
	server.
TCP options	TCP options: • **TF_ACKNOW**—Immediately replies an ACK packet to the peer. • **TF_DELACK**—Delays sending ACK packets. • **TF_SENTFIN**—A FIN packet has been sent. • **TF_RCVD_SCALE**—Requests the receive window size scale factor. • **TF_RCVD_TSTMP**—A timestamp was received in the SYN packet. • **TF_NEEDSYN**—Sends a SYN packet. • **TF_NEEDFIN**—Sends a FIN packet. • **TF_MORETOCOME**—More data is to be added to the socket. • **TF_LQ_OVERFLOW**—The listening queue overflows. • **TF_LASTIDLE**—Idle connection. • **TF_RXWIN0SENT**—A reply with receive window size 0 was sent. • **TF_FASTRECOVERY**—Enters NewReno fast recovery mode. • **TF_WASFRECOVERY**—In NewReno fast recovery mode. • **TF_SIGNATURE**—MD5 signature. • **TF_FORCEDATA**—Forces to send one byte. • **TF_TSO**—TSO is enabled. • **TF_PMTU**—Supports RFC 1191. • **TF_PMTUD**—Starts Path MTU discovery. • **TF_PASSIVE_CONN**—Passive connection. • **TF_APP_SEND**—The application sends data. • **TF_NODELAY**—Disables the Nagle algorithm that buffers the sent data inside the TCP. • **TF_NOOPT**—No TCP options. • **TF_NOPUSH**—Forces TCP to delay sending any TCP data until a full sized segment is buffered in the TCP buffers. • **TF_NSR**—Enables TCP NSR. • **TF_REQ_SCALE**—Enables the TCP window scale option. • **TF_REQ_TSTMP**—Enables the time stamp option. • **TF_SACK_PERMIT**—Enables the TCP selective acknowledgement option. • **TF_ENHANCED_AUTH**—Enables the enhanced authentication option.
NSR state	NSR state of the TCP connection: • **CLOSED**—Closed (initial) state. • **CLOSING**—The connection is to be closed. • **ENABLED**—The connection backup is enabled. • **OPEN**—The connection synchronization has started. • **PENDING**—The connection backup is not ready. • **READY**—The connection backup is ready. • **SMOOTH**—The connection data is being smoothed. Between the parentheses is the role of the connection: • **M**—Main connection. • **S**—Standby connection.
Send VRF	VRF from which packets are sent.
Receive VRF	VRF from which packets are received.

display ipv6 tcp-proxy

Use **display ipv6 tcp-proxy** to display brief information about IPv6 TCP proxy.

Syntax

display ipv6 tcp-proxy slot *slot-number*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID.

Examples

Display brief information about IPv6 TCP proxy.

```
<Sysname> display ipv6 tcp-proxy slot 1
LAddr->port          FAddr->port           State       Service type
2001::1->45          11:22:33:44->54602     ESTABLISHED LB
11:22:33:44->54602    2001::1->45           ESTABLISHED LB
```

Table 15 Command output

Field	Description
LAddr->port	Local IPv6 address and port number.
Faddr->port	Peer IPv6 address and port number.
State	IPv6 TCP connection state: • **CLOSED**—The server receives a disconnection request's reply from the client. • **LISTEN**—The server is waiting for connection requests. • **SYN_SENT**—The client is waiting for the server to reply to the connection request. • **SYN_RECEIVED**—The server receives a connection request. • **ESTABLISHED**—The server and client have established connections and can transmit data bidirectionally. • **CLOSE_WAIT**—The server receives a disconnection request from the client. • **FIN_WAIT_1**—The client is waiting for the server to reply to a disconnection request. • **CLOSING**—The server and client are waiting for peer's disconnection reply when receiving disconnection requests from each other. • **LAST_ACK**—The server is waiting for the client to reply to a disconnection request. • **FIN_WAIT_2**—The client receives a disconnection reply from the server. • **TIME_WAIT**—The client receives a disconnection request from the server.
Service type	Type of services that the IPv6 TCP proxy is used for: • **NONE**—No service type is specified. • **LB**—Load balancing services.

Field	Description
	• **SSL VPN**—SSL VPN services. • **APPPROXY**—Application proxy services.

display ipv6 tcp-proxy port-info

Use **display ipv6 tcp-proxy port-info** to display the usage of non-well known ports for IPv6 TCP proxy.

Syntax

display ipv6 tcp-proxy port-info slot *slot-number*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays non-well known port usage for all member devices.

Usage guidelines

The TCP ports are divided into well-known ports (port numbers from 0 through 1023) and non-well known ports (port numbers from 1024 through 65535).

- Well known ports are for certain services, for example, port 23 for Telnet service, ports 20 and 21 for FTP service, and port 80 for HTTP service.
- Non-well known ports are available for various services. You can use the **display ipv6 tcp-proxy port-info** command to display the usage of these ports.

Examples

Display the usage of non-well known ports for IPv6 TCP proxy.

```
<Sysname> display ipv6 tcp-proxy port-info slot 1
Index  Range          State
16     [1024, 1087]    USABLE
17     [1088, 1151]    USABLE
18     [1152, 1215]    USABLE
19     [1216, 1279]    USABLE
20     [1280, 1343]    USABLE
...
1020   [65280, 65343]   USABLE
1021   [65344, 65407]   USABLE
1022   [65408, 65471]   USABLE
1023   [65472, 65535]   USABLE
```

Table 16 Command output

Field	Description
Index	Index of the port range.
Range	Start port number and end port number.
State	State of the port range: • **USABLE**—The ports are assignable. • **ASSIGNED**—Some ports are dynamically assigned and some ports are not. • **ALLASSIGNED**—All ports are dynamically assigned. The assigned ports can be reclaimed. • **TO RECLAIM**—Some ports are statically assigned. The assigned ports can be reclaimed. • **RESERVED**—The ports are reserved. The reserved ports cannot be dynamically assigned.

display ipv6 udp

Use **display ipv6 udp** to display brief information about IPv6 UDP connections.

Syntax

display ipv6 udp [**slot** *slot-number*]

Views

Any view

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays brief information about IPv6 UDP connections for all member devices.

Examples

Displays brief information about IPv6 UDP connections.

```
<Sysname> display ipv6 udp
 LAddr->port        FAddr->port        Slot  PCB
 2001:2002:2003:2   3001:3002:3003:3   1     0x000000000000c387
 004:2005:2006:20   004:3005:3006:30
 07:2008->1200      07:3008->1200
 2001::1->23        2001::5->1284      1     0x0000000000000008
 2003::1->25        2001::2->1283      1     0x0000000000000009
```

Table 17 Command output

Field	Description
LAddr->port	Local IPv6 address and port number.

Field	Description
FAddr->port	Peer IPv6 address and port number.
PCB	PCB index.

display ipv6 udp verbose

Use **display ipv6 udp verbose** to display detailed information about IPv6 UDP connections.

Syntax

display ipv6 udp verbose [**slot** *slot-number* [**pcb** *pcb-index*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays detailed information about IPv6 UDP connections for all member devices.

pcb *pcb-index*: Displays detailed information about IPv6 UDP connections of the specified PCB. The value range for the *pcb-index* argument is 1 to 16.

Examples

Display detailed information about an IPv6 UDP connection.

```
<Sysname> display ipv6 udp verbose
Total UDP socket number: 1

 Connection info: src = ::->69, dst = ::->0
 Location: slot: 1
 Creator: sock_test_mips[250]
 State: N/A
 Options: N/A
 Error: 0
 Receiving buffer(cc/hiwat/lowat/drop/state): 0 / 41600 / 1 / 0 / N/A
 Sending buffer(cc/hiwat/lowat/state): 0 / 9216 / 512 / N/A
 Type: 2
 Protocol: 17
 Inpcb flags: N/A
 Inpcb extflag: N/A
 Inpcb vflag: INP_IPV6
 Hop limit: 255 (minimum hop limit: 0)
 Send VRF: 0xffff
 Receive VRF: 0xffff
```

Table 18 Command output

Field	Description
Total UDP socket number	Total number of IPv6 UDP sockets.
Connection info	Connection information, including source IPv6 address, source port number, destination IPv6 address, and destination port number.
Location	Socket location.
Creator	Task name of the socket. The progress number is in the square brackets.
State	Socket state: • **NOFDREF**—The user has closed the connection. • **ISCONNECTED**—The connection has been established. • **ISCONNECTING**—The connection is being established. • **ISDISCONNECTING**—The connection is being interrupted. • **ASYNC**—Asynchronous mode. • **ISDISCONNECTED**—The connection has been terminated. • **ISSMOOTHING**—Cross-card data smoothing is in progress. • **CANBIND**—The socket supports the bind operation. • **PROTOREF**—Indicates strong protocol reference. • **ISPCBSYNCING**—Cross-card PCB synchronization is in progress. • **N/A**—None of above state.
Options	Socket options: • **SO_DEBUG**—Records socket debugging information. • **SO_ACCEPTCONN**—Enables the server to listen connection requests. • **SO_REUSEADDR**—Allows the local address reuse. • **SO_KEEPALIVE**—Requires the protocol to test whether the connection is still alive. • **SO_DONTROUTE**—Bypasses the routing table query for outgoing packets because the destination is in a directly connected network. • **SO_BROADCAST**—Supports broadcast packets. • **SO_LINGER**—Closes the socket. The system can still send remaining data in the socket send buffer. • **SO_OOBINLINE**—Stores the out-of-band data in the input queue. • **SO_REUSEPORT**—Allows the local port reuse. • **SO_TIMESTAMP**—Records the timestamps of the input packets, accurate to milliseconds. This option is applicable to protocols that are not connection orientated. • **SO_NOSIGPIPE**—Disables the socket from sending data. As a result, a sigpipe cannot be established when a return failure occurs. • **SO_TIMESTAMPNS**—Has a similar function with the timestamp, accurate to nanoseconds. • **SO_KEEPALIVETIME**—Sets a keepalive time. This option is supported in TCP. • **SO_FILTER**—Supports setting the packet filter criterion. This option is available for OSI Socket and RawIP. • **SO_SEQPACKET**—Preserves the boundaries of packets sent to the socket buffer. • **SO_FILLTWAMPTIME**—Sets the timestamp for TWAMP. • **SO_LOCAL**—Local socket option. • **SO_NBMAADDR**—Obtains the remote NBMA address of the ADVPN tunnel. • **SO_DONTDELIVER**—Do not deliver the data to the application.

Field	Description
	• **N/A**—No options are set.
Error	Error code.

Receiving buffer(cc/hiwat/lowat/drop/state)	Displays receive buffer information in the following order:
	• **cc**—Used space.
	• **hiwat**—Maximum space.
	• **lowat**—Minimum space.
	• **drop**—Number of dropped packets.
	• **state**—Buffer state:
	  ○ **CANTSENDMORE**—Unable to send data to the peer.
	  ○ **CANTRCVMORE**—Unable to receive data from the peer.
	  ○ **RCVATMARK**—Receiving tag.
	  ○ **N/A**—None of the above states.

Sending buffer(cc/hiwat/lowat/state)	Displays send buffer information in the following order:
	• **cc**—Used space.
	• **hiwat**—Maximum space.
	• **lowat**—Minimum space.
	• **state**—Buffer state:
	  ○ **CANTSENDMORE**—Unable to send data to the peer.
	  ○ **CANTRCVMORE**—Unable to receive data from the peer.
	  ○ **RCVATMARK**—Receiving tag.
	  ○ **N/A**—None of the above states.

Type	Socket type: • **1**—**SOCK_STREAM**. This socket uses TCP to provide reliable transmission of byte streams. • **2**—**SOCK_DGRAM**. This socket uses UDP to provide datagram transmission. • **3**—**SOCK_RAW**. This socket allows an application to change the next upper-layer protocol header. • **N/A**—None of the above types.
Protocol	Number of the protocol using the socket. 17 represents UDP.
Inpcb flags	Flags in the Internet PCB: • **INP_RECVOPTS**—Receives IPv6 options. • **INP_RECVRETOPTS**—Receives replied IPv6 options. • **INP_RECVDSTADDR**—Receives destination IPv6 address. • **INP_HDRINCL**—Provides the entire IPv6 header. • **INP_REUSEADDR**—Reuses the IPv6 address. • **INP_REUSEPORT**—Reuses the port number. • **INP_ANONPORT**—Port number not specified. • **INP_PROTOCOL_PACKET**—Identifies a protocol packet. • **INP_RCVVLANID**—Receives the VLAN ID of the packet. Only UDP and RawIP support this flag. • **IN6P_IPV6_V6ONLY**—Only supports IPv6 protocol stack. • **IN6P_PKTINFO**—Receives the source IPv6 address and input interface of the packet. • **IN6P_HOPLIMIT**—Receives the hop limit. • **IN6P_HOPOPTS**—Receives the hop-by-hop options extension header. • **IN6P_DSTOPTS**—Receives the destination options extension header. • **IN6P_RTHDR**—Receives the routing extension header.

Field	Description
	• **IN6P_RTHDRDSTOPTS**—Receives the destination options extension header preceding the routing extension header. • **IN6P_TCLASS**—Receives the traffic class of the packet. • **IN6P_AUTOFLOWLABEL**—Attaches a flow label automatically. • **IN6P_RFC2292**—Uses the API specified in RFC 2292. • **IN6P_MTU**—Discovers differences in the MTU size of every link along a given data path. TCP does not support this flag. • **INP_RCVMACADDR**—Receives the MAC address of the frame. • **INP_SYNCPCB**—Waits until Internet PCB is synchronized. • **INP_LOCAL**—Preferentially matches the INPCB with this flag on the same card. • **N/A**—None of the above flags.
Inpcb extflag	Extension flags in the Internet PCB: • **INP_EXTRCVPVCIDX**—Records the PVC index of the received packet. • **INP_RCVPWID**—Records the PW ID of the received packet. • **INP_EXTDONTDROP**—Do not drop the received packet. • **INP_EXLISTEN**—Adds the INPCB carrying this flag to the listen hash table. • **INP_EXTFILTER**—Filters the contents in the received packets. • **INP_SELECTMATCHSRCBYFIB**—Uses the FIB table to select a matching source. • **INP_EXTRCVICMPERR**—Receives an ICMP error packet. • **INP_EXTPRIVATESOCKET**—Associates the INPCB with the NSR private socket. • **INP_EXLISTENNET**—Sets this flag when the connection information is added to the network segment linked list. • **N/A**—None of the above flags.
Inpcb vflag	IP version flags in the Internet PCB: • **INP_IPV4**—IPv4 protocol. • **INP_IPV6**—IPv6 protocol. • **INP_IPV6PROTO**—Creates an Internet PCB based on IPv6 protocol. • **INP_TIMEWAIT**—In **TIMEWAIT** state. • **INP_ONESBCAST**—Sends broadcast packets. • **INP_DROPPED**—Protocol dropped flag. • **INP_SOCKREF**—Strong socket reference. • **INP_DONTBLOCK**—Do not block synchronization of the Internet PCB. • **N/A**—None of the above flags.
Hop limit	Hop limit in the Internet PCB.
Send VRF	VRF from which packets are sent.
Receive VRF	VRF from which packets are received.

ipv6 address

Use **ipv6 address** to configure an IPv6 global unicast address for an interface.

Use **undo ipv6 address** to delete an IPv6 global unicast address of the interface.

Syntax

ipv6 address { *ipv6-address prefix-length* | *ipv6-address*/*prefix-length* }

undo ipv6 address [*ipv6-address prefix-length* | *ipv6-address*/*prefix-length*]

Default

No IPv6 global unicast address is configured for an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies an IPv6 address.

prefix-length: Specifies a prefix length in the range of 1 to 128.

Usage guidelines

Like public IPv4 addresses, IPv6 global unicast addresses are assigned to ISPs. This type of address allows for prefix aggregation to reduce the number of global routing entries.

If you do not specify any parameters, the **undo ipv6 address** command deletes all IPv6 addresses of an interface.

Examples

Set the IPv6 global unicast address of GigabitEthernet 1/0/1 to 2001::1 with prefix length 64.

Method 1:

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address 2001::1/64
```

Method 2:

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address 2001::1 64
```

ipv6 address anycast

Use **ipv6 address anycast** to configure an IPv6 anycast address for an interface.

Use **undo ipv6 address anycast** to delete the IPv6 anycast address of the interface.

Syntax

ipv6 address { *ipv6-address prefix-length* | *ipv6-address*/*prefix-length* } **anycast**

undo ipv6 address { *ipv6-address prefix-length* | *ipv6-address*/*prefix-length* } **anycast**

Default

No IPv6 anycast address is configured for an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies an IPv6 anycast address.

prefix-length: Specifies a prefix length in the range of 1 to 128.

Examples

Set the IPv6 anycast address of interface GigabitEthernet 1/0/1 to 2001::1 with prefix length 64.

Method 1:

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address 2001::1/64 anycast
```

Method 2:

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address 2001::1 64 anycast
```

ipv6 address auto

Use **ipv6 address auto** to enable the stateless address autoconfiguration feature on an interface, so that the interface can automatically generate a global unicast address.

Use **undo ipv6 address auto** to disable this feature.

Syntax

ipv6 address auto

undo ipv6 address auto

Default

The stateless address autoconfiguration feature is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

After a global unicast address is generated through stateless autoconfiguration, a link-local address is generated automatically.

To delete the global unicast address and the link-local address that are automatically generated, use either of the following commands:

- **undo ipv6 address auto**
- **undo ipv6 address**

Examples

Enable stateless address autoconfiguration on interface GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address auto
```

ipv6 address auto link-local

Use **ipv6 address auto link-local** to automatically generate a link-local address for an interface.

Use **undo ipv6 address auto link-local** to restore the default.

Syntax

ipv6 address auto link-local

undo ipv6 address auto link-local

Default

No link-local address is configured on an interface. A link-local address is automatically generated after an IPv6 global unicast address is configured for the interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

Link-local addresses are used for neighbor discovery and stateless autoconfiguration on the local link. Packets using link-local addresses as the source or destination addresses cannot be forwarded to other links.

After an IPv6 global unicast address is configured for an interface, a link-local address is automatically generated. This link-local address is the same as the one generated by using the **ipv6 address auto link-local** command.

The **undo ipv6 address auto link-local** command deletes only the link-local addresses generated through the **ipv6 address auto link-local** command. If the **undo** command is executed on an interface with an IPv6 global unicast address configured, the interface still has a link-local address.

You can also manually assign an IPv6 link-local address for an interface by using the **ipv6 address link-local** command. Manual assignment takes precedence over automatic generation for IPv6 link-local addresses.

- If you first use automatic generation and then manual assignment, the manually assigned link-local address overwrites the automatically generated address.
- If you first use manual assignment and then automatic generation, both of the following occur:
  - The automatically generated link-local address does not take effect.
  - The link-local address of an interface is still the manually assigned address.

  If you delete the manually assigned address, the automatically generated link-local address takes effect.

Examples

Configure GigabitEthernet 1/0/1 to automatically generate a link-local address.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address auto link-local
```

Related commands

ipv6 address link-local

ipv6 address eui-64

Use **ipv6 address eui-64** to configure an EUI-64 IPv6 address for an interface.

Use **undo ipv6 address eui-64** to delete an EUI-64 IPv6 address from an interface.

Syntax

ipv6 address { *ipv6-address prefix-length* | *ipv6-address/prefix-length* } **eui-64**

undo ipv6 address { *ipv6-address prefix-length* | *ipv6-address/prefix-length* } **eui-64**

Default

No EUI-64 IPv6 address is configured for an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address prefix-length: Specifies an IPv6 address and IPv6 prefix length. The *ipv6-address* and *prefix-length* arguments specify the prefix of an EUI-64 IPv6 address. The value range for the *prefix-length* argument is 1 to 64. The IPv6 address and IPv6 prefix length support the following formats:

- *ipv6-address/prefix-length*. For example: 2001::1/64.
- *ipv6-address prefix-length*. For example: 2001::1 64.

Usage guidelines

An EUI-64 IPv6 address is generated based on the specified prefix and the automatically generated interface ID. To display the EUI-64 IPv6 address, use the **display ipv6 interface** command.

The prefix length of an EUI-64 IPv6 address cannot be greater than 64.

Examples

Configure an EUI-64 IPv6 address for interface GigabitEthernet 1/0/1. The prefix of the address is the same as that of 2001::1/64, and the interface ID is generated based on the MAC address of the device.

Method 1:

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address 2001::1/64 eui-64
```

Method 2:

```
<Sysname> system-view
```

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address 2001::1 64 eui-64
```

Related commands

display ipv6 interface

ipv6 address link-local

Use **ipv6 address link-local** to configure a link-local address for the interface.

Use **undo ipv6 address link-local** to restore the default.

Syntax

ipv6 address *ipv6-address* **link-local**

undo ipv6 address *ipv6-address* **link-local**

Default

No link-local address is configured for the interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies an IPv6 link-local address. The first 10 bits of an address must be 1111111010 (binary). The first group of hexadecimals in the address must be FE80 to FEBF.

Usage guidelines

Manual assignment takes precedence over automatic generation.

If you use automatic generation, and then use manual assignment, the manually assigned link-local address overwrites the one that is automatically generated.

If you use manual assignment and then use automatic generation, both of the following occur:

- The automatically generated link-local address does not take effect.
- The manually assigned link-local address of an interface remains.

After you delete the manually assigned address, the automatically generated link-local address takes effect. For automatic generation of an IPv6 link-local address, see the **ipv6 address auto link-local** command.

Examples

Configure a link-local address for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address fe80::1 link-local
```

Related commands

ipv6 address auto link-local

ipv6 address *prefix-number*

Use **ipv6 address** *prefix-number* to specify an IPv6 prefix for an interface to automatically generate an IPv6 global unicast address and advertise the prefix.

Use **undo ipv6 address** *prefix-number* to restore the default.

Syntax

ipv6 address *prefix-number sub-prefix/prefix-length*

undo ipv6 address *prefix-number*

Default

No IPv6 prefix is specified for IPv6 address autoconfiguration.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

prefix-number: Specifies an IPv6 prefix by its ID in the range of 1 to 1024. The specified IPv6 prefix can be manually configured or obtained through DHCPv6.

sub-prefix: Specifies the sub-prefix bit and host bit for the IPv6 global unicast address.

prefix-length: Specifies the sub-prefix length in the range of 1 to 128.

Usage guidelines

This command enables an interface to automatically generate an IPv6 global unicast address based on the specified IPv6 prefix, sub-prefix bit, and host bit.

An interface can generate only one IPv6 global unicast address based on the prefix specified by using the **ipv6 address** command. To configure the interface to generate a new IPv6 address, execute the **undo ipv6 address** command to delete the configuration, and then execute the **ipv6 address** command.

Examples

Configure a static IPv6 prefix AAAA::/16 and assign ID 1 to the prefix. Configure GigabitEthernet 1/0/1 to use this prefix to generate the IPv6 address AAAA:CCCC:DDDD::10/32 and advertise this prefix.

```
<Sysname> system-view
[Sysname] ipv6 prefix 1 AAAA::/16
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address 1 BBBB:CCCC:DDDD::10/32
```

Configure GigabitEthernet 1/0/2 to obtain an IPv6 prefix through DHCPv6 and assign ID 2 to the obtained prefix. Configure GigabitEthernet 1/0/1 to use the obtained prefix to generate the IPv6 address AAAA:CCCC:DDDD::10/32 and advertise the prefix.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] ipv6 dhcp client pd 2 rapid-commit option-group 1
[Sysname-GigabitEthernet1/0/2] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address 2 BBBB:CCCC:DDDD::10/32
```

Related commands

ipv6 prefix

ipv6 dhcp client pd

ipv6 extension-header drop enable

Use **ipv6 extension-header drop enable** to enable a device to discard IPv6 packets that contain extension headers.

Use **undo ipv6 extension-header drop enable** to disable a device from discarding IPv6 packets that contain extension headers.

Syntax

ipv6 extension-header drop enable

undo ipv6 extension-header drop enable

Default

A device does not discard IPv6 packets that contain extension headers.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables a device to discard a received IPv6 packet in which the extension headers cannot be processed by the device.

Examples

Enable the device to discard IPv6 packets that contain extension headers.

```
<Sysname> system-view
[Sysname] ipv6 extension-header drop enable
```

ipv6 hop-limit

Use **ipv6 hop-limit** to set the Hop Limit field in the IPv6 header.

Use **undo ipv6 hop-limit** to restore the default.

Syntax

ipv6 hop-limit *value*

undo ipv6 hop-limit

Default

The hop limit is 64.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies the number of hops, in the range of 1 to 255.

Usage guidelines

The hop limit determines the number of hops that an IPv6 packet generated by the device can travel.

The device advertises the hop limit in RA messages. All RA message receivers use the advertised value to fill in the Hop Limit field for IPv6 packets to be sent. To disable the device from advertising the hop limit, use the **ipv6 nd ra hop-limit unspecified** command.

Examples

Set the maximum number of hops to 100.

```
<Sysname> system-view
[Sysname] ipv6 hop-limit 100
```

Related commands

ipv6 nd ra hop-limit unspecified

ipv6 hoplimit-expires enable

Use **ipv6 hoplimit-expires enable** to enable sending ICMPv6 time exceeded messages.

Use **undo ipv6 hoplimit-expires** to disable sending ICMPv6 time exceeded messages.

Syntax

ipv6 hoplimit-expires enable

undo ipv6 hoplimit-expires enable

Default

Sending ICMPv6 time exceeded messages is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

ICMPv6 time exceeded messages are sent to the source of IPv6 packets after the device discards IPv6 packets because hop or reassembly times out.

To prevent too many ICMPv6 error messages from affecting device performance, disable this feature. Even with the feature disabled, the device still sends fragment reassembly time exceeded messages.

Examples

Disable sending ICMPv6 time exceeded messages.

```
<Sysname> system-view
[Sysname] undo ipv6 hoplimit-expires enable
```

ipv6 icmpv6 error-interval

Use **ipv6 icmpv6 error-interval** to set the bucket size and the interval for tokens to arrive in the bucket for ICMPv6 error messages.

Use **undo ipv6 icmpv6 error-interval** to restore the default.

Syntax

ipv6 icmpv6 error-interval *interval* [*bucketsize*]

undo ipv6 icmpv6 error-interval

Default

The bucket allows a maximum of 10 tokens, and a token is placed in the bucket every 100 milliseconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the interval for tokens to arrive in the bucket. The value range is 0 to 2147483647 milliseconds. To disable the ICMPv6 rate limit, set the value to 0.

bucketsize: Specifies the maximum number of tokens allowed in the bucket. The value range is 1 to 200.

Usage guidelines

This command limits the rate at which ICMPv6 error messages are sent. Use this command to prevent network congestion caused by excessive ICMPv6 error messages generated within a short period. A token bucket algorithm is used with one token representing one ICMPv6 error message.

A token is placed in the bucket at intervals until the maximum number of tokens that the bucket can hold is reached.

A token is removed from the bucket when an ICMPv6 error message is sent. When the bucket is empty, ICMPv6 error messages are not sent until a new token is placed in the bucket.

Examples

Set the bucket size to 40 tokens and the interval for tokens to arrive in the bucket to 200 milliseconds for ICMPv6 error messages.

```
<Sysname> system-view
[Sysname] ipv6 icmpv6 error-interval 200 40
```

ipv6 icmpv6 multicast-echo-reply enable

Use **ipv6 icmpv6 multicast-echo-reply enable** to enable replying to multicast echo requests.

Use **undo ipv6 icmpv6 multicast-echo-reply** to restore the default.

Syntax

ipv6 icmpv6 multicast-echo-reply enable

undo ipv6 icmpv6 multicast-echo-reply enable

Default

The device is disabled from replying to multicast echo requests.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

If a host is configured to reply to multicast echo requests, an attacker can use this mechanism to attack the host. For example, the attacker can send an echo request to a multicast address with Host A as the source. All hosts in the multicast group will send echo replies to Host A.

To prevent attacks, do not enable the device to reply to multicast echo requests unless necessary.

Examples

Enable replying to multicast echo requests.

```
<Sysname> system-view
[Sysname] ipv6 icmpv6 multicast-echo-reply enable
```

ipv6 icmpv6 source

Use **ipv6 icmpv6 source** to specify an IPv6 address as the source address for outgoing ICMPv6 packets.

Use **undo ipv6 icmpv6 source** to remove the specified IPv6 source address for outgoing ICMPv6 packets.

Syntax

ipv6 icmpv6 source [**vpn-instance** *vpn-instance-name*] *ipv6-address*

undo ipv6 icmpv6 source [**vpn-instance** *vpn-instance-name*]

Default

No IPv6 source address for outgoing ICMPv6 packets is specified. The device uses the IPv6 address of the sending interface as the source IPv6 address for outgoing ICMPv6 packets.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the specified address belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the *ipv6-address* argument specifies an IPv6 address on the public network. The specified VPN instance must already exist.

ipv6-address: Specifies an IPv6 address.

Usage guidelines

It is a good practice to specify the IPv6 address of the loopback interface as the source IPv6 address for outgoing ping echo request and ICMPv6 error messages. This feature helps users to easily locate the sending device.

Examples

Specify IPv6 address 1::1 as the source address for outgoing ICMPv6 packets.

```
<Sysname> system-view
[Sysname] ipv6 icmpv6 source 1::1
```

ipv6 last-hop hold

Use **ipv6 last-hop hold** to enable IPv6 last hop holding.

Use **undo ipv6 last-hop hold** to disable IPv6 last hop holding.

Syntax

ipv6 last-hop hold

undo ipv6 last-hop hold

Default

IPv6 last hop holding is disabled.

Views

Layer 3 Ethernet interface view

Layer 3 Ethernet subinterface view

Dialer interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

Last hop holding implements symmetric routing.

When the interface enabled with this feature receives the first IPv6 packet of a forward flow, this feature implements the following operations:

- Obtains the forward flow information and last hop information of the packet.
- Based on the information, creates an IPv6 fast forwarding entry for the reverse flow.

When packets of the reverse flow arrive at the device, the device forwards those packets based on the entry.

Last hop holding is based on IPv6 fast forwarding entries. If the MAC address of a last hop changes on an Ethernet link, this feature can function correctly only after the fast forwarding entry is updated for the MAC address.

Examples

Enable the IPv6 last hop holding feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 last-hop hold
```

Enable the IPv6 last hop holding feature on Dialer 0.

```
<Sysname> system-view
```

```
[Sysname] interface dialer 0
[Sysname-Dialer0] ipv6 last-hop hold
```

ipv6 mtu

Use **ipv6 mtu** to configure the interface MTU for IPv6 packets.

Use **undo ipv6 mtu** to restore the default MTU.

Syntax

ipv6 mtu *size*

undo ipv6 mtu

Default

The interface MTU is not configured.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

size: Specifies the MTU size in bytes. The value range is 1280 to 1500 for VLAN interfaces and 1280 to 1560 for other interfaces.

Usage guidelines

IPv6 routers do not support packet fragmentation. After an IPv6 router receives an IPv6 packet, if the packet size is larger than the MTU of the forwarding interface, the router discards the packet. Meanwhile, the router sends the MTU to the source host through an ICMPv6 packet — Packet Too Big message. The source host fragments the packet according to the MTU and resends it. To reduce the extra flow overhead resulting from packet drops, set an appropriate interface MTU for your network.

Examples

Set the interface MTU for IPv6 packets to 1280 bytes on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 mtu 1280
```

ipv6 nd autoconfig managed-address-flag

Use **ipv6 nd autoconfig managed-address-flag** to set the managed address configuration flag (M) to 1 in RA advertisements to be sent.

Use **undo ipv6 nd autoconfig managed-address-flag** to restore the default.

Syntax

ipv6 nd autoconfig managed-address-flag

undo ipv6 nd autoconfig managed-address-flag

Default

The M flag is set to **0** in RA advertisements. Hosts receiving the advertisements will obtain IPv6 addresses through stateless autoconfiguration.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

The M flag in RA advertisements determines whether receiving hosts use stateful autoconfiguration to obtain IPv6 addresses.

- If the M flag is set to 1 in RA advertisements, receiving hosts use stateful autoconfiguration (for example, from an DHCPv6 server) to obtain IPv6 addresses.
- If the M flag is set to 0 in RA advertisements, receiving hosts use stateless autoconfiguration. Stateless autoconfiguration generates IPv6 addresses according to link-layer addresses and the prefix information in the RA advertisements.

Examples

Set the M flag to 1 in RA advertisements to be sent.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd autoconfig managed-address-flag
```

ipv6 nd autoconfig other-flag

Use **ipv6 nd autoconfig other-flag** to set the other stateful configuration flag (O) to 1 in RA advertisements to be sent.

Use **undo ipv6 nd autoconfig other-flag** to restore the default.

Syntax

ipv6 nd autoconfig other-flag

undo ipv6 nd autoconfig other-flag

Default

The O flag is set to **0** in RA advertisements. Hosts receiving the advertisements will acquire other information through stateless autoconfiguration.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

The O flag in RA advertisements determines whether receiving hosts use stateful autoconfiguration to obtain configuration information other than IPv6 addresses.

- If the O flag is set to 1 in RA advertisements, receiving hosts use stateful autoconfiguration (for example, from a DHCPv6 server) to obtain configuration information other than IPv6 addresses.
- If the O flag is set to 0 in RA advertisements, receiving hosts use stateless autoconfiguration to obtain configuration information other than IPv6 addresses.

Examples

Set the O flag to 0 in RA advertisements to be sent.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] undo ipv6 nd autoconfig other-flag
```

ipv6 nd dad attempts

Use **ipv6 nd dad attempts** to set the number of attempts to send an NS message for DAD.

Use **undo ipv6 nd dad attempts** to restore the default.

Syntax

ipv6 nd dad attempts *times*

undo ipv6 nd dad attempts

Default

The number of attempts to send an NS message for DAD is 1.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

times: Specifies the number of attempts to send an NS message for DAD, in the range of 0 to 600. If it is set to 0, DAD is disabled.

Usage guidelines

An interface sends an NS message for DAD after obtaining an IPv6 address.

If the interface does not receive a response within the time specified by using **ipv6 nd ns retrans-timer**, it resends an NS message.

If the interface receives no response after making the maximum sending attempts, the interface uses the obtained address.

Examples

Set the number of attempts to send an NS message for DAD to 20.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd dad attempts 20
```

Related commands

display ipv6 interface

ipv6 nd ns retrans-timer

ipv6 nd ns retrans-timer

Use **ipv6 nd ns retrans-timer** to set the interval for retransmitting an NS message.

Use **undo ipv6 nd ns retrans-timer** to restore the default.

Syntax

ipv6 nd ns retrans-timer *value*

undo ipv6 nd ns retrans-timer

Default

The local interface sends NS messages at every an interval of 1000 milliseconds, and the Retrans Timer field in the RA messages sent is 0. The interval for retransmitting an NS message is determined by the receiving device.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies the interval value in the range of 1000 to 4294967295 milliseconds.

Usage guidelines

If a device does not receive a response from the peer within the specified interval, the device resends an NS message. The device retransmits an NS message at the specified interval and uses the interval value to fill the Retrans Timer field in RA messages to be sent.

Examples

Specify GigabitEthernet 1/0/1 to retransmit NS messages every 10000 milliseconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd ns retrans-timer 10000
```

Related commands

display ipv6 interface

ipv6 nd nud reachable-time

Use **ipv6 nd nud reachable-time** to set the neighbor reachable time on an interface.

Use **undo ipv6 nd nud reachable-time** to restore the default.

Syntax

ipv6 nd nud reachable-time *time*

undo ipv6 nd nud reachable-time

Default

The neighbor reachable time on the local interface is 30000 milliseconds, and the value of the Reachable Time field in RA messages is 0. The reachable time is determined by the receiving device.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the neighbor reachable time in the range of 1 to 3600000 milliseconds.

Usage guidelines

If the neighbor reachability detection shows that a neighbor is reachable, the device considers the neighbor reachable within the specified reachable time. If the device must send a packet to the neighbor after the specified reachable time expires, the device reconfirms whether the neighbor is reachable. The device sets the specified value as the neighbor reachable time on the local interface and uses the value to fill the Reachable Time field in RA messages to be sent.

Examples

Set the neighbor reachable time on GigabitEthernet 1/0/1 to 10000 milliseconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd nud reachable-time 10000
```

Related commands

ipv6 nd ra dns search-list

Use **ipv6 nd ra dns search-list** to specify DNS suffix information to be advertised in RA messages.

Use **undo ipv6 nd ra dns search-list** to remove a DNS suffix from RA message advertisement.

Syntax

ipv6 nd ra dns search-list *domain-name* [*seconds* | **infinite**] **sequence** *seqno*

undo ipv6 nd ra dns search-list *domain-name*

Default

DNS suffix information is not specified and RA messages do not contain DNS suffix options.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a DNS suffix. It is a dot-separated, case-insensitive string that can include letters, digits, hyphens (-), underscores (_), and dots (.), for example, aabbcc.com. The DNS suffix can include a maximum of 253 characters, and each separated string includes no more than 63 characters.

seconds: Specifies the lifetime of the DNS suffix, in seconds. The value range is 4 to 4294967295. Value 4294967295 indicates that the lifetime of the DNS suffix is infinite.

infinite: Sets the lifetime of the DNS suffix to infinite.

seqno: Specifies the sequence number of the DNS suffix, in the range of 0 to 4294967295. The sequence number for a DNS suffix must be unique. A smaller sequence number represents a higher priority.

Usage guidelines

The DNS search list (DNSSL) option in RA messages provides DNS suffix information for hosts. The RA messages allow hosts to obtain their IPv6 addresses and the DNS suffix through stateless autoconfiguration. This method is useful in a network where DHCPv6 infrastructure is not provided.

The default lifetime of the DNS suffix is three times the maximum interval for advertising RA messages. To set the maximum interval, use the **ipv6 nd ra interval** command.

You can configure a maximum of eight DNS suffixes on an interface. One DNSSL option contains one DNS suffix. All DNSSL options are sorted in ascending order of the sequence number of the DNS suffix.

The sequence number uniquely identifies a DNS suffix. To modify a DNS suffix or its sequence number, you must first use the **undo ipv6 nd ra dns search-list** command to remove the DNS suffix from RA message advertisement.

After you execute the **ipv6 nd ra dns search-list** command, the device immediately sends an RA message with the existing and newly specified DNS suffix information.

After you execute the **undo ipv6 nd ra dns search-list** command, the device immediately sends two RA messages.

- The first RA message contains information about all DNS suffixes, including DNS suffixes specified in the **undo** command with their lifetime set to 0 seconds.
- The second RA message contains information about remaining DNS suffixes.

Each time the device sends an RA message from an interface, it immediately refreshes the RA message advertisement interval for that interface.

Examples

Specify the DNS suffix as **com**, the suffix lifetime as **3600** seconds, and the sequence number as **1** for RA messages on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd ra dns search-list com 3600 sequence 1
```

Use **ipv6 nd ra dns search-list suppress** to enable DNS suffix suppression in RA messages.

Use **undo ipv6 nd ra dns search-list suppress** to disable DNS suffix suppression in RA messages.

Syntax

ipv6 nd ra dns search-list suppress

undo ipv6 nd ra dns search-list suppress

Default

DNS suffix suppression in RA messages is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command suppresses advertising DNS suffixes in RA messages on an interface. If you specify a new DNS suffix or remove a DNS suffix on the interface, the device immediately sends an RA message without any DNSSL options.

RA messages are suppressed by default. To disable RA message suppression, use the **undo ipv6 nd ra halt** command.

Whether enabling this feature on an interface will trigger sending RA message immediately depends on the interface configuration:

- If the interface has DNS suffix information configured, the device immediately sends two RA messages. In the first message, the lifetime for DNS suffixes is 0 seconds. The second RA message does not contain any DNSSL options.
- If the interface has no DNS suffix information specified, no RA messages are triggered.

Whether disabling this feature on an interface will trigger sending RA message immediately depends on the interface configuration:

- If the interface has DNS suffix information configured, the device immediately sends an RA message containing the DNS suffix information.
- If the interface has no DNS suffix information specified, no RA messages are triggered.

Each time the device sends an RA message from an interface, it immediately refreshes the RA message advertisement interval for that interface.

Examples

Enable DNS suffix suppression in RA messages on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd ra dns search-list suppress
```

Related commands

ipv6 nd ra dns search-list

ipv6 nd ra dns server

Use **ipv6 nd ra dns server** to specify DNS server information to be advertised in RA messages.

Use **undo ipv6 nd ra dns server** to remove a DNS server from RA message advertisement.

Syntax

ipv6 nd ra dns server *ipv6-address* [*seconds* | **infinite**] **sequence** *seqno*

undo ipv6 nd ra dns server *ipv6-address*

Default

DNS server information is not specified and RA messages do not contain DNS server options.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies the IPv6 address of the DNS server, which must be a global unicast address or a link-local address.

seconds: Specifies the lifetime of the DNS server, in seconds. The value range is 4 to 4294967295. Value 4294967295 indicates that the lifetime of the DNS server is infinite.

infinite: Sets the lifetime of the DNS server to infinite.

sequence *seqno*: Specifies the sequence number of the DNS server, in the range of 0 to 4294967295. The sequence number for a DNS server must be unique. A smaller sequence number represents a higher priority.

Usage guidelines

The DNS server option in RA messages provides DNS server information for hosts. The RA messages allow hosts to obtain their IPv6 addresses and the DNS server through stateless autoconfiguration. This method is useful in a network where DHCPv6 infrastructure is not provided.

The default lifetime of the DNS server is three times the maximum interval for advertising RA messages. To set the maximum interval, use the **ipv6 nd ra interval** command.

You can configure a maximum of eight DNS servers on an interface. One DNS server option contains one DNS server. All DNS server options are sorted in ascending order of the DNS server sequence number.

The sequence number uniquely identifies a DNS server. To modify the IPv6 address or sequence number of a DNS server, you must first use the **undo ipv6 nd ra dns server** command to remove the DNS server from RA message advertisement.

After you execute the **ipv6 nd ra dns server** command, the device immediately sends an RA message with the existing and newly specified DNS server options.

After you execute the **undo ipv6 nd ra dns server** command, the device immediately sends two RA messages.

- The first RA message contains information about all DNS servers, including the DNS servers specified in the **undo** command with their lifetime set to 0 seconds.
- The second RA message contains information about remaining DNS servers.

Each time the device sends an RA message from an interface, it immediately refreshes the RA message advertisement interval for that interface.

In an IPv6 environment, PPP users and IPoE IPv6-ND-RS users can obtain the IPv6 DNS server address through AAA authorization. This AAA-authorized IPv6 DNS server address is also carried in RA messages. If an interface obtains the AAA-authorized and manually specified IPv6 DNS server addresses, the RA messages contain both, with the AAA-authorized address in the front. When the two addresses conflict, the AAA-authorized DNS-related attributes are used.

For more information about the PPP support for IPv6, see PPP configuration in *Layer 2—WAN Access Configuration Guide*.

For more information about IPoE IPv6-ND-RS users, see IPoE configuration in *Security Configuration Guide*.

Examples

Specify the DNS server address as **2001:10::100**, the server lifetime as **3600** seconds, and the sequence number as **1** for RA messages on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd ra dns server 2001:10::100 3600 sequence 1
```

[Sysname-GigabitEthernet1/0/1] undo ipv6 nd ra halt
```

ipv6 nd ra hop-limit unspecified

Use **ipv6 nd ra hop-limit unspecified** to specify unlimited hops in RA messages.

Use **undo ipv6 nd ra hop-limit unspecified** to restore the default.

Syntax

ipv6 nd ra hop-limit unspecified

undo ipv6 nd ra hop-limit unspecified

Default

The maximum number of hops in the RA messages is limited to 64.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

To set the maximum number of hops to a value rather than the default setting, use the **ipv6 hop-limit** command.

Examples

Specify unlimited hops in the RA messages on interface GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd ra hop-limit unspecified
```

Related commands

ipv6 hop-limit

ipv6 nd ra interval

Use **ipv6 nd ra interval** to set the maximum and minimum intervals for advertising RA messages.

Use **undo ipv6 nd ra interval** to restore the default.

Syntax

ipv6 nd ra interval *max-interval min-interval*

undo ipv6 nd ra interval

Default

The maximum interval between RA messages is 600 seconds, and the minimum interval is 200 seconds.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

max-interval: Specifies the maximum interval value in seconds, in the range of 4 to 1800.

min-interval: Specifies the minimum interval value in the range of 3 seconds to three-fourths of the maximum interval.

Usage guidelines

The device advertises RA messages randomly between the maximum interval and the minimum interval.

The maximum interval for sending RA messages should be less than or equal to the router lifetime in RA messages.

Examples

Set the maximum interval for advertising RA messages to 1000 seconds and the minimum interval to 700 seconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd ra interval 1000 700
```

Related commands

ipv6 nd ra router-lifetime

ipv6 nd ra no-advlinkmtu

Use **ipv6 nd ra no-advlinkmtu** to turn off the MTU option in RA messages.

Use **undo ipv6 nd ra no-advlinkmtu** to restore the default.

Syntax

ipv6 nd ra no-advlinkmtu

undo ipv6 nd ra no-advlinkmtu

Default

RA messages contain the MTU option.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

The MTU option in the RA messages specifies the link MTU to ensure that all nodes on the link use the same MTU.

Examples

Turn off the MTU option in RA messages on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd ra no-advlinkmtu
```

ipv6 nd ra prefix

Use **ipv6 nd ra prefix** to configure the prefix information in RA messages.

Use **undo ipv6 nd ra prefix** to restore the default.

Syntax

ipv6 nd ra prefix { *ipv6-prefix prefix-length* | *ipv6-prefix*/*prefix-length* } [*valid-lifetime preferred-lifetime* [**no-autoconfig** | **off-link**] * | **no-advertise**]

undo ipv6 nd ra prefix { *ipv6-prefix* | *ipv6-prefix/prefix-length* }

Default

No prefix information is configured for RA messages. Instead, the IPv6 address of the interface sending RA messages is used as the prefix information.

If the IPv6 address is manually configured, the prefix uses the fixed valid lifetime 2592000 seconds (30 days) and preferred lifetime 604800 seconds (7 days).

If the IPv6 address is automatically obtained (through DHCP, for example), the prefix uses the valid and preferred lifetime of the IPv6 address.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-prefix: Specifies the IPv6 prefix.

prefix-length: Specifies the prefix length of the IPv6 address.

valid-lifetime: Specifies the valid lifetime of a prefix, in the range of 0 to 4294967295 seconds. The default value is 2592000 seconds (30 days).

preferred-lifetime: Specifies the preferred lifetime of a prefix used for stateless autoconfiguration, in the range of 0 to 4294967295 seconds. The preferred lifetime cannot be longer than the valid lifetime. The default value is 604800 seconds (7 days).

no-autoconfig: Specifies a prefix not to be used for stateless autoconfiguration. If you do not specify this keyword, the prefix is used for stateless autoconfiguration.

off-link: Indicates that the address with the prefix is not directly reachable on the link. If you do not specify this keyword, the address with the prefix is directly reachable on the link.

no-advertise: Disables the device from advertising the prefix specified in this command. If you do not specify this keyword, the device advertises the prefix specified in this command.

Usage guidelines

After hosts on the same link receive RA messages, they can use the prefix information in the RA messages for stateless autoconfiguration.

A prefix specified without a parameter in this command preferentially uses the default settings configured by using the **ipv6 nd ra prefix default** command. If the default settings are unavailable, the prefix uses the following settings:

- Valid lifetime of 2592000 seconds (30 days).
- Preferred lifetime of 604800 seconds (7 days).
- The prefix is used for stateless autoconfiguration.
- The address with the prefix is directly reachable on the link.
- The prefix is advertised in RA messages.

Examples

Configure the prefix information in RA messages on GigabitEthernet 1/0/1.

Method 1:

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd ra prefix 2001:10::100/64 100 10
```

Method 2:

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd ra prefix 2001:10::100 64 100 10
```

ipv6 nd ra prefix default

Use **ipv6 nd ra prefix default** to configure the default settings for prefixes advertised in RA messages.

Use **undo ipv6 nd ra prefix default** to restore the default.

Syntax

ipv6 nd ra prefix default [*valid-lifetime preferred-lifetime* [**no-autoconfig** | **off-link**] * | **no-advertise**]

undo ipv6 nd ra prefix default

Default

No default settings are configured for prefixes advertised in RA messages.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

valid-lifetime: Specifies the valid lifetime of a prefix, in the range of 0 to 4294967295 seconds. The default value is 2592000 seconds (30 days).

preferred-lifetime: Specifies the preferred lifetime of a prefix used for stateless autoconfiguration, in the range of 0 to 4294967295 seconds. The preferred lifetime cannot be longer than the valid lifetime. The default value is 604800 seconds (7 days).

no-autoconfig: Specifies a prefix not to be used for stateless autoconfiguration. If you do not specify this keyword, the prefix is used for stateless autoconfiguration.

off-link: Indicates that the address with the prefix is not directly reachable on the link. If you do not specify this keyword, the address with the prefix is directly reachable on the link.

no-advertise: Disables the device from advertising the prefix specified in this command. If you do not specify this keyword, the device advertises the prefix specified in this command.

Usage guidelines

This command specifies the default settings for the prefix specified by using the **ipv6 nd ra prefix** command. If none of the parameters (*valid-lifetime*, *preferred-lifetime*, **no-autoconfig**, **off-link**, and **no-advertise**) is configured in the **ipv6 nd ra prefix** command, the prefix uses the default settings.

Examples

Configure the default settings for prefixes advertised in RA messages on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd ra prefix default 100 10
```

ipv6 nd ra router-lifetime

Use **ipv6 nd ra router-lifetime** to set the router lifetime in RA messages.

Use **undo ipv6 nd ra router-lifetime** to restore the default.

Syntax

ipv6 nd ra router-lifetime *time*

undo ipv6 nd ra router-lifetime

Default

The router lifetime in RA messages is three times as long as the maximum interval for advertising RA messages.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the router lifetime in the range of 0 to 9000 seconds. If the value is set to 0, the router does not act as the default router.

Usage guidelines

The router lifetime in RA messages specifies how long the router sending the RA messages acts as the default router. Hosts receiving the RA messages check this value to determine whether to use the sending router as the default router. If the router lifetime is 0, the router cannot be used as the default router.

The router lifetime in RA messages must be greater than or equal to the advertising interval.

Examples

Set the router lifetime in RA messages on GigabitEthernet 1/0/1 to 1000 seconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd ra router-lifetime 1000
```

Related commands

ipv6 nd ra interval

ipv6 nd router-preference

Use **ipv6 nd router-preference** to set a router preference in RA messages.

Use **undo ipv6 nd router-preference** to restore the default.

Syntax

ipv6 nd router-preference { **high** | **low** | **medium** }

undo ipv6 nd router-preference

Default

The router preference is **medium**.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

high: Sets the router preference to the highest setting.

low: Sets the router preference to the lowest setting.

medium: Sets the router preference to the medium setting.

Usage guidelines

A hosts selects a router with the highest preference as the default router.

When router preferences are the same in RA messages, a host selects the router corresponding to the first received RA message as the default gateway.

Examples

Set the router preference in RA messages to the lowest on interface GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd router-preference low
```

ipv6 nd unsolicited-na-learning enable

Use **ipv6 nd unsolicited-na-learning enable** to enable unsolicited NA learning.

Use **undo ipv6 nd unsolicited-na-learning enable** to disable unsolicited NA learning.

Syntax

ipv6 nd unsolicited-na-learning enable

undo ipv6 nd unsolicited-na-learning enable

Default

Unsolicited NA learning is disabled.

Views

Layer 3 interface view

Predefined user roles

network-admin

context-admin

context-operator

Usage guidelines

With this feature enabled, the device can learns ND entries from unsolicited NA messages. The ND entries generated by using this method are in stale state. To ensure that the device learns ND entries from trusted NA messages, enable this feature only on a secure network.

This feature might cause the device to learn excessive ND entries that consume too many system resources. As a best practice, execute the **ipv6 neighbor stale-aging** command to set a smaller aging timer before you enable this feature. The smaller aging timer accelerates the aging of ND entries in stale state.

Examples

Enable unsolicited NA learning on Layer 3 Ethernet interface GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface GigabitEthernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 nd unsolicited-na-learning enable
```

Related commands

ipv6 neighbor stale-aging

ipv6 neighbor

Use **ipv6 neighbor** to configure a static neighbor entry.

Use **undo ipv6 neighbor** to delete a neighbor entry.

Syntax

ipv6 neighbor *ipv6-address mac-address* { *vlan-id port-type port-number* | **interface** *interface-type interface-number* } [**vpn-instance** *vpn-instance-name*]

undo ipv6 neighbor *ipv6-address interface-type interface-number*

Default

No static neighbor entries exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies the IPv6 address of the static neighbor entry.

mac-address: Specifies the MAC address (48 bits) of the static neighbor entry, in the format of H-H-H.

vlan-id: Specifies the VLAN ID of the static neighbor entry, in the range of 1 to 4094.

port-type port-number: Specifies a Layer 2 port of the static neighbor entry by its type and number.

interface *interface-type interface-number*: Specifies a Layer 3 interface of the static neighbor entry by its type and number.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the static neighbor entry belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command configures a static neighbor entry for the public network.

Usage guidelines

A neighbor entry stores information about a link-local node. The entry can be created dynamically through NS and NA messages, or configured statically.

The device uniquely identifies a static neighbor entry by using the neighbor's IPv6 address and the number of the Layer 3 interface that connects to the neighbor. You can configure a static neighbor entry by using either of the following methods:

- **Method 1**—Associate a neighbor IPv6 address and link-layer address with the Layer 3 interface of the local node.
- **Method 2**—Associate a neighbor IPv6 address and link-layer address with a Layer 2 port in a VLAN containing the local node.

You can use either of the previous configuration methods to configure a static neighbor entry for a VLAN interface.

- If Method 1 is used, the neighbor entry is in INCMP state. After the device obtains the corresponding Layer 2 port information, the neighbor entry goes into REACH state.
- If Method 2 is used, the port specified by *port-type port-number* must belong to the VLAN specified by *vlan-id* and the corresponding VLAN interface must already exist. After the static neighbor entry is configured, the device associates the VLAN interface with the IPv6 address to uniquely identify the static neighbor entry. The entry will be in REACH state.

You can use the **undo ipv6 neighbor** command to delete both static and dynamic neighbor entries.

To delete a neighbor entry for a VLAN interface, specify only the corresponding VLAN interface.

Do not specify a Reth interface as the outgoing interface in IPv6 static neighbor entries if its member interfaces contain subinterfaces. For more information about Reth interfaces, see *Virtual Technologies Configuration Guide*.

Examples

Configure a static neighbor entry for Layer 3 interface GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] ipv6 neighbor 2000::1 fe-e0-89 interface gigabitethernet 1/0/1
```

Related commands

display ipv6 neighbors

reset ipv6 neighbors

ipv6 neighbor link-local minimize

Use **ipv6 neighbor link-local minimize** to minimize link-local ND entries.

Use **undo ipv6 neighbor link-local minimize** to restore the default.

Syntax

ipv6 neighbor link-local minimize

undo ipv6 neighbor link-local minimize

Default

All ND entries are assigned to the driver.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Perform this command to minimize link-local ND entries assigned to the driver. Link-local ND entries refer to ND entries that contain link-local addresses.

With this feature enabled, the device does not add newly learned link-local ND entries whose link local addresses are not the next hop of any route to the driver. This saves driver resources.

This feature affects only newly learned link-local ND entries rather than existing ND entries.

Examples

Minimize link-local ND entries.

```
<Sysname> system-view
[Sysname] ipv6 neighbor link-local minimize
```

ipv6 neighbor stale-aging

Use **ipv6 neighbor stale-aging** to set the aging timer for ND entries in stale state.

Use **undo ipv6 neighbor stale-aging** to restore the default.

Syntax

ipv6 neighbor stale-aging *aging-time*

undo ipv6 neighbor stale-aging

Default

The aging timer for ND entries in stale state is 240 minutes.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

aging-time: Specifies the aging timer for ND entries in stale state, in the range of 1 to 1440 minutes.

Usage guidelines

This aging time applies to all ND entries in stale state. If an ND entry in stale state is not updated before the timer expires, it moves to the delay state. If it is still not updated in 5 seconds, the ND entry moves to the probe state. The device sends an NS message for detection a maximum of three times. If no response is received, the device deletes the ND entry.

Examples

Set the aging timer for ND entries in stale state to 120 minutes.

```
<Sysname> system-view
[Sysname] ipv6 neighbor stale-aging 120
```

ipv6 neighbors max-learning-num

Use **ipv6 neighbors max-learning-num** to set the maximum number of dynamic neighbor entries that an interface can learn. This prevents the interface from occupying too many neighbor table resources.

Use **undo ipv6 neighbors max-learning-num** to restore the default.

Syntax

ipv6 neighbors max-learning-num *max-number*

undo ipv6 neighbors max-learning-num

Default

An interface can learn a maximum of 65536 dynamic neighbor entries.

Views

Layer 2/Layer 3 interface view

Layer 2 aggregate interface view

Layer 3 aggregate interface view

Predefined user roles

network-admin

context-admin

Parameters

max-number: Specifies the maximum number of dynamic neighbor entries that an interface can learn. The value range for this argument is 0 to 65536.

Usage guidelines

The device can dynamically acquire the link-layer address of a neighboring node through NS and NA messages and add it into the neighbor table.

When the number of dynamic neighbor entries reaches the threshold, the interface stops learning neighbor information.

To disable the device from learning neighbor entries, set the learning limit to 0.

Examples

Set the maximum number of dynamic neighbor entries that GigabitEthernet 1/0/1 can learn to 10.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 neighbors max-learning-num 10
```

ipv6 pathmtu

Use **ipv6 pathmtu** to set a static Path MTU for an IPv6 address.

Use **undo ipv6 pathmtu** to delete the Path MTU configuration for an IPv6 address.

Syntax

ipv6 pathmtu [**vpn-instance** *vpn-instance-name*] *ipv6-address value*

undo ipv6 pathmtu [**vpn-instance** *vpn-instance-name*] *ipv6-address*

Default

No static Path MTU is set.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the Path MTU belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command sets the Path MTU for the public network.

ipv6-address: Specifies an IPv6 address.

value: Specifies the Path MTU of the specified IPv6 address, in the range of 1280 to 10240 bytes.

Usage guidelines

You can set a static Path MTU for a destination IPv6 address. When a source host sends a packet through an interface, it compares the interface MTU with the static Path MTU of the specified destination IPv6 address. If the packet size is larger than the smaller one of the two values, the host fragments the packet according to the smaller value.

Examples

Set a static Path MTU for an IPv6 address.

```
<Sysname> system-view
[Sysname] ipv6 pathmtu fe80::12 1300
```

Related commands

display ipv6 pathmtu

reset ipv6 pathmtu

ipv6 pathmtu age

Use **ipv6 pathmtu age** to set the aging time for a dynamic Path MTU.

Use **undo ipv6 pathmtu age** to restore the default.

Syntax

ipv6 pathmtu age *age-time*

undo ipv6 pathmtu age

Default

The aging time for dynamic Path MTU is 10 minutes.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

age-time: Specifies the aging time for Path MTU in minutes, in the range of 10 to 100.

Usage guidelines

After the path MTU from a source host to a destination host is dynamically determined, the source host sends subsequent packets to the destination host based on this MTU. After the aging time expires, the following events occur:

- The dynamic Path MTU is removed.
- The source host determines a dynamic path MTU through the Path MTU mechanism again.

The aging time is invalid for a static Path MTU.

Examples

Set the aging time for a dynamic Path MTU to 40 minutes.

```
<Sysname> system-view
[Sysname] ipv6 pathmtu age 40
```

Related commands

display ipv6 pathmtu

ipv6 prefer temporary-address

Use **ipv6 prefer temporary-address** to enable the system to preferentially use the temporary IPv6 address of the sending interface as the source address of a packet.

Use **undo ipv6 prefer temporary-address** to disable the system to preferentially use the temporary IPv6 address of the sending interface as the source address of a packet.

Syntax

ipv6 prefer temporary-address

undo ipv6 prefer temporary-address

Default

The system is disabled to preferentially use the temporary IPv6 address of the sending interface as the source address of a packet.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The temporary address feature enables the system to generate and preferentially use the temporary IPv6 address of the sending interface as the source address of a packet. If the temporary IPv6 address cannot be used because of a DAD conflict, the system uses the public IPv6 address.

Examples

Enable the system to preferentially use the temporary IPv6 address of the sending interface as the source address of the packet.

```
<Sysname> system-view
[Sysname] ipv6 prefer temporary-address
```

Related commands

ipv6 address auto

ipv6 nd ra prefix

ipv6 temporary-address

ipv6 prefix

Use **ipv6 prefix** to configure a static IPv6 prefix.

Use **undo ipv6 prefix** to delete a static IPv6 prefix.

Syntax

ipv6 prefix *prefix-number ipv6-prefix/prefix-length*

undo ipv6 prefix *prefix-number*

Default

No static IPv6 prefix is configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

prefix-number: Specifies a prefix ID in the range of 1 to 1024.

ipv6-prefix/prefix-length: Specifies a prefix and its length. The value range for the *prefix-length* argument is 1 to 128.

Usage guidelines

To modify an existing static prefix, execute the **undo ipv6 prefix** command to delete the existing static prefix, and then execute the **ipv6 prefix** command.

Dynamic IPv6 prefixes obtained from DHCPv6 servers cannot be manually removed or modified.

A static IPv6 prefix can have the same prefix ID with a dynamic IPv6 prefix, but the static one takes precedence over the dynamic one.

Examples

Create static IPv6 prefix 2001:0410::/32 with prefix ID 1.

```
<Sysname> system-view
[Sysname] ipv6 prefix 1 2001:0410::/32
```

Related commands

display ipv6 prefix

ipv6 reassemble local enable

Use **ipv6 reassemble local enable** to enable IPv6 local fragment reassembly.

Use **undo ipv6 reassemble local enable** to disable IPv6 local fragment reassembly.

Syntax

ipv6 reassemble local enable

undo ipv6 reassemble local enable

Default

IPv6 local fragment reassembly is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Configure this command on a multichassis IRF fabric to improve fragment reassembly efficiency. The command enables the subordinate to reassemble the IPv6 fragments of a packet if all the fragments arrive at it. If this feature is disabled, all IPv6 fragments are delivered to the master for reassembly. The command applies only to fragments destined for the same subordinate.

Examples

Enable IPv6 local fragment reassembly.

```
<Sysname> system-view
[Sysname] ipv6 reassemble local enable
```

ipv6 redirects enable

Use **ipv6 redirects enable** to enable sending ICMPv6 redirect messages.

Use **undo ipv6 redirects enable** to disable sending ICMPv6 redirect messages.

Syntax

ipv6 redirects enable

undo ipv6 redirects enable

Default

Sending ICMPv6 redirect messages is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The default gateway sends an ICMPv6 redirect message to the source of an IPv6 packet to inform the source of a better first hop.

Sending ICMPv6 redirect messages enables hosts that hold few routes to establish routing tables and find the best route. Because this feature adds host routes into the routing tables, host performance degrades when there are too many host routes. As a result, sending ICMPv6 redirect messages is disabled by default.

Examples

Enable sending ICMPv6 redirect messages.

```
<Sysname> system-view
[Sysname] ipv6 redirects enable
```

ipv6 temporary-address

Use **ipv6 temporary-address** to enable the temporary IPv6 address feature.

Use **undo ipv6 temporary-address** to restore the default.

Syntax

ipv6 temporary-address [*valid-lifetime preferred-lifetime*]

undo ipv6 temporary-address

Default

The system does not generate any temporary IPv6 address.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

valid-lifetime: Specifies the valid lifetime for temporary IPv6 addresses, in the range of 600 to 4294967295 seconds. The default valid lifetime is 604800 seconds (7 days).

preferred-lifetime: Specifies the preferred lifetime for temporary IPv6 addresses, in the range of 600 to 4294967295 seconds. The default preferred lifetime is 86400 seconds (1 day).

Usage guidelines

You must enable stateless autoconfiguration before enabling the temporary address feature.

The valid lifetime for temporary IPv6 addresses must be greater than or equal to the preferred lifetime for temporary IPv6 addresses.

In stateless address autoconfiguration, an interface automatically generates an IPv6 global unicast address by using the address prefix in the received RA message and the interface ID. On an IEEE 802 interface (such as an Ethernet interface or a VLAN interface), the interface ID is generated based on the interface's MAC address and is globally unique. An attacker can exploit this rule to easily identify the sending device.

To fix the vulnerability, you can enable the temporary address feature. An IEEE 802 interface generates the following addresses:

- **Public IPv6 address**—Includes an address prefix in the RA message and a fixed interface ID generated based on the interface's MAC address.
- **Temporary IPv6 address**—Includes an address prefix in the RA message and a random interface ID generated through MD5.

When the valid lifetime of a temporary IPv6 address expires, the system deletes the address and generates a new one. This enables the system to send packets with different source addresses through the same interface. The preferred lifetime and valid lifetime for a temporary IPv6 address are determined as follows:

- The preferred lifetime of a temporary IPv6 address takes the smaller of the following values:
  - The preferred lifetime of the address prefix in the RA message.
  - The preferred lifetime configured for temporary IPv6 addresses minus DESYNC_FACTOR (a random number in the range of 0 to 600 seconds).
- The valid lifetime of a temporary IPv6 address takes the smaller of the following values:
  - The valid lifetime of the address prefix.
  - The valid lifetime configured for temporary IPv6 addresses.

Examples

Enable the system to generate a temporary IPv6 address.

```
<Sysname> system-view
[Sysname] ipv6 temporary-address
```

Related commands

ipv6 unreachables enable

Use **ipv6 unreachables enable** to enable sending ICMPv6 destination unreachable messages.

Use **undo ipv6 unreachables** to disable sending ICMPv6 destination unreachable messages.

Syntax

ipv6 unreachables enable

undo ipv6 unreachables enable

Default

Sending ICMPv6 destination unreachable messages is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

If the device fails to forward a received IPv6 packet because of a destination unreachable error, it performs the following operations:

- Drops the packet.
- Sends an ICMPv6 destination unreachable message to the source.

If the device is generating ICMPv6 destination unreachable messages incorrectly, disable sending ICMPv6 destination unreachable messages to prevent attack risks.

Examples

Enable sending ICMPv6 destination unreachable messages.

```
<Sysname> system-view
[Sysname] ipv6 unreachables enable
```

local-proxy-nd enable

Use **local-proxy-nd enable** to enable local ND proxy.

ID	Fragment ID.
Relay_flag	Fragment pass-through flag: • **0**—Not pass through. • **1**—Pass through.

ipv6 fast-forwarding enable

Use **ipv6 fast-forwarding enable** to enable IPv6 fast forwarding.

Use **undo ipv6 fast-forwarding enable** to disable IPv6 fast forwarding.

Syntax

ipv6 fast-forwarding enable

undo ipv6 fast-forwarding enable

Default

IPv6 fast forwarding is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The IPv6 fast forwarding feature will create fast forwarding entries for the device to speed up packet forwarding. When the traffic volume is high, the device will generate a large number of fast forwarding entries. These entries will cause high memory usage, which eventually leads to memory allocation failure for other services. In this case, you can disable this feature temporarily to free up device memory.

Do not disable IPv6 fast forwarding if the device runs session-based services. Disabling fast forwarding will make these services become ineffective:

- NAT.
- ASPF.
- Attack detection and prevention.

Examples

Disable IPv6 fast forwarding.

```
<Sysname> system-view
[Sysname] undo ipv6 fast-forwarding enable
```

Related commands

display ipv6 fast-forwarding cache

reset ipv6 fast-forwarding cache

ipv6 fast-forwarding load-sharing

Use **ipv6 fast-forwarding load-sharing** to enable IPv6 fast forwarding load sharing.

Use **undo ipv6 fast-forwarding load-sharing** to disable IPv6 fast forwarding load sharing.

Syntax

ipv6 fast-forwarding load-sharing

undo ipv6 fast-forwarding load-sharing

Default

IPv6 fast forwarding load sharing is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

IPv6 fast forwarding load sharing enables the device to load share packets of the same flow. This feature identifies a data flow by using the packet information.

If IPv6 fast forwarding load sharing is disabled, the device identifies a data flow by the packet information and the input interface. No load sharing is implemented.

Examples

Enable IPv6 fast forwarding load sharing.

```
<Sysname> system-Views
[Sysname] ipv6 fast-forwarding load-sharing
```

reset ipv6 fast-forwarding cache

Use **reset ipv6 fast-forwarding cache** to clear the IPv6 fast forwarding table.

Contents

DHCP commands

Common DHCP commands

dhcp client-detect

Use **dhcp client-detect** to enable client offline detection on the DHCP server or DHCP relay agent.

Use **undo dhcp client-detect** to disable client offline detection on the DHCP server or DHCP relay agent.

Syntax

dhcp client-detect

undo dhcp client-detect

Default

Client offline detection is disabled on the DHCP server or DHCP relay agent.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

The client offline detection feature on the DHCP server reclaims an assigned IP address and deletes the binding entry when the ARP entry ages out for the IP address.

This feature on the DHCP relay agent deletes the related relay entry and sends a RELEASE message to the DHCP server when an ARP entry ages out.

Examples

Enable client offline detection.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dhcp client-detect
```

dhcp dscp

Use **dhcp dscp** to set the DSCP value for DHCP packets sent by the DHCP server or the DHCP relay agent.

Use **undo dhcp dscp** to restore the default.

Syntax

dhcp dscp *dscp-value*

undo dhcp dscp

Default

The DSCP value is 56 in DHCP packets sent by the DHCP server or the DHCP relay agent.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Specifies the DSCP value for DHCP packets, in the range of 0 to 63.

Usage guidelines

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Examples

Set the DSCP value to 30 for DHCP packets sent by the DHCP server or the DHCP relay agent.

```
<Sysname> system-view
[Sysname] dhcp dscp 30
```

dhcp enable

Use **dhcp enable** to enable DHCP.

Use **undo dhcp enable** to disable DHCP.

Syntax

dhcp enable

undo dhcp enable

Default

DHCP is disabled.

context-admin

Usage guidelines

DHCP related configuration takes effect only after you enable DHCP.

Enable DHCP before you configure the DHCP server or relay agent.

Examples

Enable DHCP.

```
<Sysname> system-view
[Sysname] dhcp enable
```

dhcp log enable

Use **dhcp log enable** to enable DHCP server logging.

Use **undo dhcp log enable** to disable DHCP server logging.

Syntax

dhcp log enable

undo dhcp log enable

Default

DHCP server logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command enables the DHCP server to generate DHCP logs and send them to the information center. The information helps administrators to locate and solve problems. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

As a best practice, disable this feature if the log generation affects the device performance or reduces the address allocation efficiency. For example, this situation might occur when a large number of clients frequently come online or go offline.

Examples

Enable DHCP server logging.

```
<Sysname> system-view
[Sysname] dhcp log enable
```

dhcp select

Use **dhcp select** to enable the DHCP server or DHCP relay agent on an interface.

Use **undo dhcp select** to disable the DHCP server or DHCP relay agent on an interface. The interface will discard incoming DHCP packets.

Syntax

dhcp select { **relay** | **server** }

undo dhcp select { **relay** | **server** }

Default

The interface operates in the DHCP server mode and responds to DHCP requests with configuration parameters.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

relay: Enables the DHCP relay agent on the interface.

server: Enables the DHCP server on the interface.

Usage guidelines

Before enabling a DHCP server to operate as a DHCP relay agent, use the **reset dhcp server ip-in-use** command to clear address bindings and authorized ARP entries. These authorized ARP entries might conflict with ARP entries that are created after the DHCP relay agent is enabled.

Examples

Enable the DHCP relay agent on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dhcp select relay
```

Related commands

dhcp smart-relay enable

DHCP server commands

address range

Use **address range** to configure an IP address range in a DHCP address pool for dynamic allocation.

Use **undo address range** to restore the default.

Syntax

address range *start-ip-address end-ip-address*

undo address range

Default

No IP address range exists.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

start-ip-address: Specifies the start IP address.

end-ip-address: Specifies the end IP address.

Usage guidelines

If no IP address range is specified, all IP addresses in the subnet specified by the **network** command in address pool view are assignable. If an IP address range is specified, only the IP addresses in the IP address range are assignable.

After you use the **address range** command, you cannot use the **network secondary** command to specify a secondary subnet in the address pool.

If you execute this command multiple times, the most recent configuration takes effect.

The address range specified by the **address range** command must be within the subnet specified by the **network** command. The addresses outside of the subnet cannot be assigned.

Examples

Specify an address range of 192.168.8.1 through 192.168.8.150 in address pool 1.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 1
[Sysname-dhcp-pool-1] network 192.168.8.1 mask 255.255.255.0
[Sysname-dhcp-pool-1] address range 192.168.8.1 192.168.8.150
```

network

bims-server

Use **bims-server** to specify the IP address, port number, and shared key of the BIMS server in a DHCP address pool.

Use **undo bims-server** to restore the default.

Syntax

bims-server ip *ip-address* [**port** *port-number*] **sharekey** { **cipher** | **simple** } *string*

undo bims-server

Default

No BIMS server information is specified.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

ip *ip-address*: Specifies the IP address of the BIMS server.

port *port-number*: Specifies the port number of the BIMS server, in the range of 1 to 65534.

cipher: Specifies a key in encrypted form.

simple: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key string. Its plaintext form is a case-sensitive string of 1 to 16 characters. Its encrypted form is a case-sensitive string of 1 to 53 characters. The DHCP client uses the shared key to encrypt packets sent to the BIMS server.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify BIMS server IP address 1.1.1.1, port number 80, and shared key **aabbcc** in address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] bims-server ip 1.1.1.1 port 80 sharekey simple aabbcc
```

bootfile-name

Use **bootfile-name** to specify a configuration file name or URL.

Use **undo bootfile-name** to restore the default.

Syntax

bootfile-name { *bootfile-name* | *url* }

undo bootfile-name

Default

No configuration file name or URL is specified.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

bootfile-name: Specifies the configuration file name, a case-sensitive string of 1 to 63 characters.

url: Specifies the HTTP URL of the configuration file. It is a case-sensitive string of 1 to 63 characters.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

To specify a configuration file on a TFTP server, use the *bootfile-name* argument.

To specify a configuration file on an HTTP server, use the *url* argument.

Examples

Specify configuration file name **boot.cfg** in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] bootfile-name boot.cfg
```

Specify configuration file URL **http://10.1.1.1/boot.cfg** in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] bootfile-name http://10.1.1.1/boot.cfg
```

class ip-pool

Use **class ip-pool** to specify a DHCP address pool for a DHCP user class.

Use **undo class ip-pool** to remove the DHCP address pool specified for a DHCP user class.

Syntax

class *class-name* **ip-pool** *pool-name*

undo class *class-name* **ip-pool**

Default

No DHCP address pool is specified for a DHCP user class.

Views

DHCP policy view

Predefined user roles

network-admin

context-admin

Parameters

class-name: Specifies a DHCP user class by its name, a case-insensitive string of 1 to 63 characters.

pool-name: Specifies a DHCP address pool by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

You can specify only one DHCP address pool for a DHCP user class in a DHCP policy. If you execute this command multiple times for a user class, the most recent configuration takes effect.

Examples

Specify DHCP address pool **pool1** for DHCP user class **test** in DHCP policy 1.

```
<Sysname> system-view
[Sysname] dhcp policy 1
[Sysname-dhcp-policy-1] class test ip-pool pool1
```

class option-group

Use **class option-group** to specify a DHCP option group for a DHCP user class.

Use **undo class option-group** to remove the configuration.

Syntax

class *class-name* **option-group** *option-group-number*

undo class *class-name* **option-group**

Default

No DHCP option group is specified for a DHCP user class.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

class-name: Specifies a DHCP user class by its name, a case-insensitive string of 1 to 63 characters.

option-group-number: Specifies a DHCP option group by its number in the range of 1 to 32768.

Usage guidelines

When receiving a DHCP-DISCOVER message, the server compares the client against the user classes in the order that they are specified by this command. If a match is found, the server assigns the client the DHCP options in the option group. If multiple matches are found, the server selects option groups by using the following methods:

- If the option groups have options in common, the server selects the option group specified for the first matching user class.
- If the option groups have different options, the server selects all the matching option groups.

You can specify only one option group for a DHCP user class in a DHCP address pool. If you execute this command multiple times for a user class, the most recent configuration takes effect.

Examples

Specify DHCP option group 1 for user class **user** in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] class user option-group 1
```

Related commands

dhcp option-group

class range

Use **class range** to specify an IP address range for a DHCP user class.

Use **undo class range** to remove the IP address range for the DHCP user class.

Syntax

class *class-name* **range** *start-ip-address end-ip-address*

undo class *class-name* **range**

Default

No IP address range is specified for a DHCP user class.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

class-name: Specifies a DHCP user class name, a case-insensitive string of 1 to 63 characters. If the specified user class does not exist, the DHCP server will not assign the addresses in the address range specified for the user class to any clients.

start-ip-address: Specifies the start IP address.

end-ip-address: Specifies the end IP address.

Usage guidelines

The **class range** command allows you to divide an address range into multiple address ranges for different DHCP user classes. The address range for a user class must be within the primary subnet specified by the **network** command. If the DHCP client does not match any DHCP user class, the DHCP server selects an address in the IP address range specified by the **address range** command. If the address range has no assignable IP addresses or no address range is configured, the address allocation fails.

After you specify an address range for a user class, you cannot use the **network secondary** command to specify a secondary subnet in the address pool.

You can specify only one address range for a DHCP user class in an address pool. If you execute this command multiple times for a DHCP user class, the most recent configuration takes effect.

Examples

Specify an IP address range of 192.168.8.1 through 192.168.8.150 for DHCP user class **user** in DHCP address pool 1.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 1
[Sysname-dhcp-pool-1] class user range 192.168.8.1 192.168.8.150
```

default ip-pool

Use **default ip-pool** to specify the default DHCP address pool.

Use **undo default ip-pool** to restore the default.

Syntax

default ip-pool *pool-name*

undo default ip-pool

Default

No default DHCP address pool is specified.

Views

DHCP policy view

Predefined user roles

network-admin

context-admin

Parameters

pool-name: Specifies a DHCP address pool by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

In a DHCP policy, the DHCP server uses the default DHCP address pool to assign IP addresses and other parameters to clients that do not match any user classes. If no default address pool is specified or the default address pool does not have assignable IP addresses, the address assignment fails.

You can specify only one default address pool in a DHCP policy. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify DHCP address pool **pool1** as the default DHCP address pool in DHCP policy 1.

```
<Sysname> system-view
[Sysname] dhcp policy 1
[Sysname-dhcp-policy-1] default ip-pool pool1
```

dhcp policy

Use **dhcp policy** to create a DHCP policy and enter its view, or enter the view of an existing DHCP policy.

Use **undo dhcp policy** to delete a DHCP policy.

Syntax

dhcp policy *policy-name*

undo dhcp policy *policy-name*

Default

No DHCP policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Assigns a name to the DHCP policy. The policy name is a case-insensitive string of 1 to 63 characters.

Usage guidelines

In DHCP policy view, you can specify address pools for different user classes. Clients matching a user class will obtain IP addresses and other parameters from the specified address pool.

For a DHCP policy to take effect, you must apply it to an interface.

Examples

Create DHCP policy **test** and enter its view.

```
<Sysname> system-view
[Sysname] dhcp policy test
[Sysname-dhcp-policy-test]
```

Related commands

class ip-pool

default ip-pool

dhcp apply-policy

dhcp class

dhcp server always-broadcast

Use **dhcp server always-broadcast** to enable the DHCP server to broadcast all responses.

Use **undo dhcp server always-broadcast** to restore the default.

Syntax

dhcp server always-broadcast

undo dhcp server always-broadcast

Default

The DHCP server reads the broadcast flag in a DHCP request to decide whether to broadcast or unicast the response.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command enables the DHCP server to ignore the broadcast flag in DHCP requests and broadcast all responses.

The DHCP server always unicasts a response in the following situations, regardless of whether this command is executed:

- The DHCP request is from a DHCP client that has an IP address (the **ciaddr** field is not 0).
- The DHCP request is forwarded by a DHCP relay agent from a DHCP client (the **giaddr** field is not 0).

Examples

Enable the DHCP server to broadcast all responses.

```
<Sysname> system-view
[Sysname] dhcp server always-broadcast
```

dhcp server apply ip-pool

Use **dhcp server apply ip-pool** to apply an address pool to an interface.

Use **undo dhcp server apply ip-pool** to restore the default.

Syntax

dhcp server apply ip-pool *pool-name*

undo dhcp server apply ip-pool

Default

No address pool is applied to an interface

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

pool-name: Specifies the name of a DHCP address pool, a case-insensitive string of 1 to 63 characters.

Usage guidelines

Upon receiving a DHCP request from the interface, the DHCP server searches for a static binding for the client from all address pools. If no static binding is found, the server assigns configuration parameters from the address pool applied on the interface to the client. If the address pool has no assignable IP address or does not exist, the DHCP client cannot obtain an IP address.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Apply DHCP address pool 0 to GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dhcp server apply ip-pool 0
```

Related commands

dhcp server ip-pool

dhcp server bootp ignore

Use **dhcp server bootp ignore** to configure the DHCP server to ignore BOOTP requests.

Use **undo dhcp server bootp ignore** to restore the default.

Syntax

dhcp server bootp ignore

undo dhcp server bootp ignore

Default

The DHCP server does not ignore BOOTP requests.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The lease duration of IP addresses obtained by BOOTP clients is unlimited. For scenarios that do not allow unlimited leases, you can configure the DHCP server to ignore BOOTP requests.

Examples

Configure the DHCP server to ignore BOOTP requests.

```
<Sysname> system-view
[Sysname] dhcp server bootp ignore
```

dhcp server bootp reply-rfc-1048

Use **dhcp server bootp reply-rfc-1048** to enable the sending of BOOTP responses in RFC 1048 format.

Use **undo dhcp server bootp reply-rfc-1048** to disable this feature.

Syntax

dhcp server bootp reply-rfc-1048

undo dhcp server bootp reply-rfc-1048

Default

This feature is disabled. The DHCP server does not process the Vend field of RFC 1048-incompliant requests but copies the Vend field into responses.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Not all BOOTP clients can send requests compliant with RFC 1048. This command enables the DHCP server to fill the Vend field in RFC 1048-compliant format in DHCP responses to RFC 1048-incompliant requests sent by BOOTP clients.

Examples

Enable the sending of BOOTP responses in RFC 1048 format on the DHCP server.

```
<Sysname> system-view
[Sysname] dhcp server bootp reply-rfc-1048
```

dhcp server database filename

Use **dhcp server database filename** to configure the DHCP server to back up the DHCP bindings to a file.

Use **undo dhcp server database filename** to restore the default.

Syntax

dhcp server database filename { *filename* | **url** *url* [**username** *username* [**password** { **cipher** | **simple** } *string*]] }

undo dhcp server database filename

Default

The DHCP server does not back up the DHCP bindings.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

filename: Specifies the name of a local backup file. For information about the *filename* argument, see *Fundamentals Configuration Guide*.

url *url*: Specifies the URL of a remote backup file, a case-sensitive string of 1 to 255 characters. Do not include a username or password in the URL.

username *username*: Specifies the username for accessing the URL of the remote backup file, a case-sensitive string of 1 to 32 characters. Do not specify this option if a username is not required for accessing the URL of the remote backup file.

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 32 characters. Its encrypted form is a case-sensitive string of 1 to 73 characters. Do not specify this argument if a password is not required for accessing the URL of the remote backup file.

Usage guidelines

The command automatically creates the file if you specify a nonexistent file.

With this command executed, the DHCP server backs up its bindings immediately and runs auto backup. The server, by default, waits 300 seconds after a binding change to update the backup file. You can use the **dhcp server database update interval** command to change the waiting time. If no DHCP binding changes, the backup file is not updated.

As a best practice, back up the bindings to a remote file. If you use the local storage medium, the frequent erasing and writing might damage the medium and then cause the DHCP server to malfunction.

When the backup file is on a remote device, follow these restrictions and guidelines to specify the URL, username, and password:

If the file is on an FTP server, enter URL in the following format: ftp://*server address:port/file path*, where the port number is optional.

If the file is on a TFTP server, enter URL in the following format: tftp://*server address:port/file path*, where the port number is optional.

- The username and password must be the same as those configured on the FTP server. If the server authenticates only the username, the password can be omitted.
- If the IP address of the server is an IPv6 address, enclose the address in a pair of brackets, for example, **ftp://[1::1]/database.dhcp**.
- You can also specify the DNS domain name for the server address field, for example, **ftp://company/database.dhcp**.

Examples

Configure the DHCP server to back up its bindings to file **database.dhcp**.

```
<Sysname> system-view
[Sysname] dhcp server database filename database.dhcp
```

Configure the DHCP server to back up its bindings to file **database.dhcp** in the working directory of the FTP server at 10.1.1.1.

```
<Sysname> system-view
[Sysname] dhcp server database filename url ftp://10.1.1.1/database.dhcp username 1
password simple 1
```

Related commands

dhcp server database update interval

dhcp server database update now

dhcp server database update stop

dhcp server database update interval

Use **dhcp server database update interval** to set the waiting time for the DHCP server to update the backup file after a DHCP binding change.

Use **undo dhcp server database update interval** to restore the default.

Syntax

dhcp server database update interval *interval*

undo dhcp server database update interval

Default

The DHCP server waits 300 seconds to update the backup file after a DHCP binding change. If no DHCP binding changes, the backup file is not updated.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the waiting time in the range of 60 to 864000 seconds.

Usage guidelines

When a DHCP binding is created, updated, or removed, the waiting period starts. The DHCP server updates the backup file when the waiting period is reached. All bindings changed during the period will be saved to the backup file.

The waiting time takes effect only after you configure the DHCP binding auto backup by using the **dhcp server database filename** command.

Examples

Set the waiting time to 10 minutes for the DHCP server to update the backup file.

```
<Sysname> system-view
[Sysname] dhcp server database update interval 600
```

Related commands

dhcp server database filename

dhcp server database update now

Use **dhcp server database update now** to manually save the DHCP bindings to the backup file.

Syntax

dhcp server database update now

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Each time this command is executed, the DHCP bindings are saved to the backup file.

For this command to take effect, you must configure the DHCP auto backup by using the **dhcp server database filename** command.

Examples

Manually save the DHCP bindings to the backup file.

```
<Sysname> system-view
[Sysname] dhcp server database update now
```

Related commands

dhcp server database filename

dhcp server database update interval

dhcp server database update stop

dhcp server database update stop

Use **dhcp server database update stop** to terminate the download of DHCP bindings from the backup file.

Syntax

dhcp server database update stop

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The DHCP server does not provide services during the binding download process. If the connection disconnects during the process, the waiting timeout timer is 60 minutes. When the timer expires, the DHCP server stops waiting and starts providing address allocation services.

To enable the DHCP server to provide services without waiting for the connection to be repaired, use this command to terminate the download immediately. The IP addresses associated with the undownloaded bindings will be assigned to clients. Address conflicts might occur.

Examples

Terminate the download of the backup DHCP bindings.

```
<Sysname> system-view
[Sysname] dhcp server database update stop
```

Related commands

dhcp server database filename

dhcp server database update interval

dhcp server database update now

dhcp server forbidden-ip

Use **dhcp server forbidden-ip** to exclude IP addresses from dynamic allocation globally.

Use **undo dhcp server forbidden-ip** to remove the configuration.

Syntax

dhcp server forbidden-ip *start-ip-address* [*end-ip-address*] [**vpn-instance** *vpn-instance-name*]

undo dhcp server forbidden-ip *start-ip-address* [*end-ip-address*] [**vpn-instance** *vpn-instance-name*]

Default

No IP addresses are excluded from dynamic allocation globally.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

start-ip-address: Specifies the start IP address.

end-ip-address: Specifies the end IP address, which cannot be lower than the *start-ip-address*. If you do not specify this argument, only the *start-ip-address* is excluded from dynamic allocation.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If the excluded IP addresses belong to the public network, do not specify this option.

Usage guidelines

The IP addresses of some devices such as the gateway and FTP server cannot be assigned to clients. Use this command to exclude such addresses from dynamic allocation.

If the excluded IP address is in a static DHCP binding, the address can still be assigned to the client.

The address or address range specified in the **undo dhcp server forbidden-ip** command must be the same as that specified in the **dhcp server forbidden-ip** command. To remove an IP address from the specified address range, you must remove the entire address range.

You can execute this command multiple times to exclude multiple IP address ranges from dynamic allocation.

Examples

Exclude the IP addresses of 10.110.1.1 through 10.110.1.63 from dynamic allocation globally.

```
<Sysname> system-view
[Sysname] dhcp server forbidden-ip 10.110.1.1 10.110.1.63
```

dhcp server ping packets

Use **dhcp server ping packets** to set the maximum number of ping packets.

Use **undo dhcp server ping packets** to restore the default.

Syntax

dhcp server ping packets *number*

undo dhcp server ping packets

Default

The maximum number of ping packets is 1.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

number: Sets the maximum number of ping packets, in the range of 0 to 10. To disable the address conflict detection, set the value to 0.

Usage guidelines

To avoid IP address conflicts, the DHCP server pings an IP address before assigning it to a DHCP client.

If a ping attempt succeeds, the server determines that the IP address is in use and picks a new IP address. If all the ping attempts fail, the server assigns the IP address to the requesting DHCP client.

Examples

Set the maximum number of ping packets to 10.

```
<Sysname> system-view
[Sysname] dhcp server ping packets 10
```

Related commands

dhcp server ping timeout

dhcp server ping timeout

Use **dhcp server ping timeout** to set the ping response timeout time on the DHCP server.

Use **undo dhcp server ping timeout** to restore the default.

Syntax

dhcp server ping timeout *milliseconds*

undo dhcp server ping timeout

Default

The ping response timeout time is 500 milliseconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

milliseconds: Specifies the timeout time in the range of 0 to 10000 milliseconds. To disable the ping operation for address conflict detection, set the value to 0 milliseconds.

Usage guidelines

To avoid IP address conflicts, the DHCP server pings an IP address before assigning it to a DHCP client.

If a ping attempt succeeds, the server determines that the IP address is in use and picks a new IP address. If all the ping attempts fail, the server assigns the IP address to the requesting DHCP client.

Examples

Set the response timeout time to 1000 milliseconds.

```
<Sysname> system-view
[Sysname] dhcp server ping timeout 1000
```

Related commands

dhcp server ping packets

display dhcp server conflict

dhcp server relay information enable

Use **dhcp server relay information enable** to enable the DHCP server to handle Option 82.

Use **undo dhcp server relay information enable** to configure the DHCP server to ignore Option 82.

Syntax

dhcp server relay information enable

undo dhcp server relay information enable

Default

The DHCP server handles Option 82.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Upon receiving a DHCP request that contains Option 82, the server copies the original Option 82 into the response. If the server is configured to ignore Option 82, the response will not contain Option 82.

Examples

Configure the DHCP server to ignore Option 82.

```
<Sysname> system-view
[Sysname] undo dhcp server relay information enable
```

dhcp server reply-exclude-option60

Use **dhcp server reply-exclude-option60** to disable the DHCP server from encapsulating Option 60 in DHCP replies.

Use **undo dhcp server reply-exclude-option60** to restore the default.

Syntax

dhcp server reply-exclude-option60

undo dhcp server reply-exclude-option60

Default

The DHCP server can encapsulate Option 60 in DHCP replies.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

If you do not disable the capability, the DHCP server encapsulates Option 60 in a DHCP reply in the following situations:

- The received DHCP packet contains Option 60.
- Option 60 is configured for the address pool.

If you disable the capability, the DHCP server does not encapsulate Option 60 in DHCP replies.

Examples

Disable the DHCP server from encapsulating Option 60 in DHCP replies.

```
<Sysname> system-view
[Sysname] dhcp server reply-exclude-option60
```

display dhcp server conflict

Use **display dhcp server conflict** to display information about IP address conflicts.

Syntax

display dhcp server conflict [**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ip *ip-address*: Displays conflict information about the specified IP address. If you do not specify this option, this command displays information about all IP address conflicts.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays IP address conflict information for the public network.

Usage guidelines

The DHCP server generates IP address conflict information in the following situations:

- Before assigning an IP address to a DHCP client, the DHCP server pings the IP address and discovers that another host is using the address.
- The DHCP client sends a DECLINE packet to the DHCP server to inform the server of an IP address conflict.
- The DHCP server discovers that the only assignable address in the address pool is its own IP address.

Examples

Display information about all IP address conflicts.

```
<Sysname> display dhcp server conflict
IP address          Detect time
4.4.4.1             Apr 25 16:57:20 2019
4.4.4.2             Apr 25 17:00:10 2019
```

 Password                :
 Update interval         :   600 seconds
 Latest write time       :   Feb  8 16:09:53 2014
 Status                  :   Last write succeeded.
```

Table 2 Command output

Field	Description
File name	Name of the DHCP binding backup file.
Username	Username for accessing the URL of the remote backup file.
Password	Password for accessing the URL of the remote backup file. This field displays ********** if a password is configured.
Update interval	Waiting time in seconds after a DHCP binding change for the DHCP server to update the backup file.
Latest write time	Time of the latest update.
Status	Status of the update: • **Writing**—The backup file is being updated. • **Last write succeeded**—The backup file was successfully updated. • **Last write failed**—The backup file failed to be updated.

display dhcp server expired

Use **display dhcp server expired** to display the lease expiration information.

Syntax

display dhcp server expired [[**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ip *ip-address*: Displays lease expiration information about the specified IP address. If you do not specify an IP address, this command displays lease expiration information about all IP addresses.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays lease expiration information about IP addresses for the public network.

pool *pool-name*: Displays lease expiration information about the specified address pool. The pool name is a case-insensitive string of 1 to 63 characters. If you do not specify an address pool, this command displays lease expiration information about all address pools.

Usage guidelines

DHCP assigns these expired IP addresses to DHCP clients when all available addresses have been assigned.

Examples

Display all lease expiration information.

```
<Sysname> display dhcp server expired
IP address       Client-identifier/Hardware address    Lease expiration
4.4.4.6          3030-3066-2e65-3230-302e-3130-3234    Apr 25 17:10:47 2019
                 -2d45-7468-6572-6e65-7430-2f31
```

Table 3 Command output

Field	Description
IP address	Expired IP address.
Client-identifier/Hardware address	Client ID or MAC address. For the client ID: • If an ASCII string is used as the client ID value, the type value is 00. • If the MAC address of an interface is used as the client ID value, the type value is 01. • If a hexadecimal string is used as the client ID value, the type value is the first two digits of the string.
Lease expiration	Time when the lease expired.

Related commands

reset dhcp server expired

display dhcp server free-ip

Use **display dhcp server free-ip** to display information about assignable IP addresses.

Syntax

display dhcp server free-ip [**pool** *pool-name* | **vpn-instance** *vpn-instance-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

pool *pool-name*: Displays assignable IP addresses in the specified address pool. The pool name is a case-insensitive string of 1 to 63 characters. If you do not specify an address pool, this command displays all assignable IP addresses for all address pools.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays assignable IP addresses in address pools for the public network.

Examples

Display assignable IP addresses in all address pools.

```
<Sysname> display dhcp server free-ip
Pool name: 1
  Network: 10.0.0.0 mask 255.0.0.0
    IP ranges from 10.0.0.10 to 10.0.0.100
    IP ranges from 10.0.0.105 to 10.0.0.255
  Secondary networks:
    10.1.0.0 mask 255.255.0.0
      IP ranges from 10.1.0.0 to 10.1.0.255
    10.2.0.0 mask 255.255.0.0
      IP Ranges from 10.2.0.0 to 10.2.0.255

Pool name: 2
  Network: 20.1.1.0 mask 255.255.255.0
    IP ranges from 20.1.1.0 to 20.1.1.255
```

Table 4 Command output

Field	Description
Pool name	Name of the address pool.
Network	Assignable network.
IP ranges	Assignable IP address range.
Secondary networks	Assignable secondary networks.

Related commands

display dhcp server ip-in-use

Use **display dhcp server ip-in-use** to display binding information about assigned IP addresses.

Syntax

display dhcp server ip-in-use [[**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ip *ip-address*: Displays binding information about the specified assigned IP address. If you do not specify an IP address, this command displays binding information about all assigned IP addresses.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays binding information about assigned IP addresses for the public network.

pool *pool-name*: Displays binding information about assigned IP addresses in the specified address pool. The pool name is a case-insensitive string of 1 to 63 characters. If you do not specify an address pool, this command displays binding information about assigned IP addresses in all address pools.

Usage guidelines

The binding information can be used by other security modules only when the DHCP server is configured on the gateway of DHCP clients.

If the lease deadline exceeds the year 2100, the lease expiration time is displayed as **After 2100**.

Examples

Display binding information about all assigned DHCP addresses.

```
<Sysname> display dhcp server ip-in-use
IP address       Client identifier/    Lease expiration      Type
                 Hardware address
10.1.1.1         4444-4444-4444        Not used              Static(F)
10.1.1.2         0030-3030-302e-3030-  May 1 14:02:49 2015   Auto(C)
                 3066-2e30-3030-332d-
                 4574-6865-726e-6574
10.1.1.3         1111-1111-1111        After 2100            Static(C)
```

Table 5 Command output

Field	Description
IP address	IP address assigned.
Client identifier/Hardware address	Client ID or hardware address. Client ID is specified as a string of hexadecimal numbers, in which the first two characters represents the hardware type value. • If an ASCII string is used, the hardware type value is 00, which means no type. • If the hardware type is Ethernet, the type value is 01. • If the hardware type is token ring, the type value is 06.

Field	Description
Lease expiration	Lease expiration time: • **Exact time (May 1 14:02:49 2015 in this example)**—Time when the lease will expire. • **Not used**—The IP address of the static binding has not been assigned to the specific client. • **Unlimited**—Infinite lease expiration time. • **After 2100**—The lease will expire after 2100.
Type	Binding types: • **Static(F)**—A free static binding whose IP address has not been assigned. • **Static(O)**—An offered static binding whose IP address has been selected and sent by the DHCP server in a DHCP-OFFER packet to the client. **Static(C)**—A committed static binding whose IP address has been assigned to the DHCP client. • **Auto(O)**—An offered dynamic binding whose IP address has been dynamically selected by the DHCP server and sent in a DHCP-OFFER packet to the DHCP client. • **Auto(C)**—A committed dynamic binding whose IP address has been dynamically assigned to the DHCP client.

Related commands

`reset dhcp server ip-in-use`

display dhcp server pool

Use **`display dhcp server pool`** to display information about a DHCP address pool.

Syntax

`display dhcp server pool` [*`pool-name`* | **`vpn-instance`** *`vpn-instance-name`*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`pool-name`: Displays information about the specified address pool. The pool name is a case-insensitive string of 1 to 63 characters. If you do not specify the *`pool-name`* argument, this command displays information about all address pools.

`vpn-instance` *`vpn-instance-name`*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays information about address pools for the public network.

Examples

Display information about all DHCP address pools.

```
<Sysname> display dhcp server pool
Pool name: 0
```

```

Table 6 Command output

Field	Description
Pool name	Name of an address pool.
Network	Assignable network.
secondary networks	Assignable secondary networks.
address range	Assignable address range.
class *class-name* range	DHCP user class and its address range.
static bindings	Static IP-to-MAC/client ID bindings.
ip-address mask	IP address and mask in the static binding.
hardware-address	Hardware address in the static binding.
client-identifier	Client ID in the static binding.
description	Description of the static binding.
option	Customized DHCP option.
expired	Lease duration.
bootfile-name	Boot file name
dns-list	DNS server IP address.
domain-name	Domain name suffix.
bims-server	BIMS server information.
forbidden-ip	IP addresses excluded from dynamic allocation.
forbidden-ip-range	IP address range excluded from dynamic allocation.
gateway-list	Gateway addresses.
nbns-list	WINS server addresses.
netbios-type	NetBIOS node type.
next-server	Next server IP address.
tftp-server domain-name	TFTP server name.
tftp-server ip-address	TFTP server address.
voice-config ncp-ip	Primary network calling processor address.
voice-config as-ip	Backup network calling processor address.
voice-config voice-vlan	Voice VLAN.
voice-config fail-over	Failover route.

display dhcp server statistics

Use **display dhcp server statistics** to display the DHCP server statistics.

Syntax

display dhcp server statistics [**pool** *pool-name* | **vpn-instance** *vpn-instance-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

pool *pool-name*: Specifies an address pool by its name, a case-insensitive string of 1 to 63 characters. If you do not specify this option, this command displays information about all address pools.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays DHCP server statistics for the public network.

Examples

Display the DHCP server statistics.

```
<Sysname> display dhcp server statistics
    Pool number:                    1
    Pool utilization:               0.39%
    Bindings:
      Automatic:                    1
      Manual:                       0
      Expired:                      0
    Conflict:                       1
    Messages received:              10
      DHCPDISCOVER:                 5
      DHCPREQUEST:                  3
      DHCPDECLINE:                  0
      DHCPRELEASE:                  2
      DHCPINFORM:                   0
      BOOTPREQUEST:                 0
    Messages sent:                  6
      DHCPOFFER:                    3
      DHCPACK:                      3
      DHCPNAK:                      0
      BOOTPREPLY:                   0
    Bad Messages:                   0
```

Table 7 Command output

Field	Description
Pool number	Total number of address pools. This field is not displayed when you display statistics for a specific address pool.

Field	Description
Pool utilization	Pool usage rate: • If you display statistics for all address pools, this field displays the usage rate of all address pools. • If you display statistics for an address pool, this field displays the pool usage rate of the specified address pool.
Bindings	Bindings include the following types: • **Automatic**—Number of dynamic bindings. • **Manual**—Number of static bindings. • **Expired**—Number of expired bindings.
Conflict	Total number of conflict addresses. This field is not displayed if you display statistics for a specific address pool.
Messages received	DHCP packets received from clients: • DHCPDISCOVER. • DHCPREQUEST. • DHCPDECLINE. • DHCPRELEASE. • DHCPINFORM. • BOOTPREQUEST. This field is not displayed if you display statistics for a specific address pool.
Messages sent	DHCP packets sent to clients: • DHCPOFFER. • DHCPACK. • DHCPNAK. • BOOTPREPLY. This field is not displayed if statistics about a specific address pool are displayed.
Bad Messages	Number of bad messages. This field is not displayed if you display statistics for a specific address pool.

Related commands

reset dhcp server statistics

dns-list

Use **dns-list** to specify DNS server addresses in a DHCP address pool.

Use **undo dns-list** to remove DNS server addresses from a DHCP address pool.

Syntax

dns-list *ip-address*&<1-8>

undo dns-list [*ip-address*&<1-8>]

Default

No DNS server address is specified.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

ip-address&<1-8>: Specifies a space-separated list of up to eight DNS servers.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

If you do not specify any parameters, the **undo dns-list** command deletes all DNS server addresses in the DHCP address pool.

Examples

Specify DNS server address 10.1.1.254 in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] dns-list 10.1.1.254
```

Related commands

display dhcp server pool

domain-name

Use **domain-name** to specify a domain name in a DHCP address pool.

Use **undo domain-name** to restore the default.

Syntax

domain-name *domain-name*

undo domain-name

Default

No domain name is specified.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies the domain name, a case-sensitive string of 1 to 50 characters.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify domain name **company.com** in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] domain-name company.com
```

Related commands

display dhcp server pool

expired

Use **expired** to set the lease duration in a DHCP address pool.

Use **undo expired** to restore the default lease duration for a DHCP address pool.

Syntax

expired { **day** *day* [**hour** *hour* [**minute** *minute* [**second** *second*]]] | **unlimited** }

undo expired

Default

The lease duration of a dynamic DHCP address pool is one day.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

day *day*: Specifies the number of days, in the range of 0 to 365.

hour *hour*: Specifies the number of hours, in the range of 0 to 23. The default is 0.

minute *minute*: Specifies the number of minutes, in the range of 0 to 59. The default is 0.

second *second*: Specifies the number of seconds, in the range of 0 to 59. The default is 0.

unlimited: Specifies the unlimited lease duration, which is actually 136 years.

Usage guidelines

The DHCP server assigns an IP address together with the lease duration to the DHCP client. Before the lease expires, the DHCP client must extend the lease duration.

- If the lease extension operation succeeds, the DHCP client can continue to use the IP address.
- If the lease extension operation does not succeed, both of the following events occur:
  - The DHCP client cannot use the IP address after the lease duration expires.
  - The DHCP server will label the IP address as an expired address.

Examples

Set the lease duration to 1 day, 2 hours, 3 minutes, and 4 seconds in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] expired day 1 hour 2 minute 3 second 4
```

Related commands

display dhcp server expired

display dhcp server pool

reset dhcp server expired

forbidden-ip

Use **forbidden-ip** to exclude IP addresses from dynamic allocation in an address pool.

Use **undo forbidden-ip** to remove the configuration.

Syntax

forbidden-ip *ip-address*&<1-8>

undo forbidden-ip [*ip-address*&<1-8>]

Default

No IP addresses are excluded from dynamic allocation in an address pool.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

ip-address&<1-8>: Specifies a space-separated list of up to eight excluded IP addresses.

Usage guidelines

The excluded IP addresses in an address pool are still assignable in other address pools.

You can exclude a maximum of 4096 IP addresses in an address pool by executing this command multiple times.

If you do not specify any parameters, the **undo forbidden-ip** command removes all excluded IP addresses.

Examples

Exclude IP addresses 192.168.1.3 and 192.168.1.10 from dynamic allocation in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] forbidden-ip 192.168.1.3 192.168.1.10
```

Related commands

dhcp server forbidden-ip

display dhcp server pool

forbidden-ip-range

Use **forbidden-ip-range** to exclude an IP address range from dynamic allocation in an address pool.

Use **undo forbidden-ip-range** to remove the configuration.

Syntax

forbidden-ip-range *start-ip-address* [*end-ip-address*]

undo forbidden-ip-range [*start-ip-address* [*end-ip-address*]]

Default

No IP address ranges are excluded from dynamic allocation in an address pool.

Views

DHCP address pool view

Predefined user roles

network-admin

contextmdc-admin

Parameters

start-ip-address: Specifies a start IP address.

end-ip-address: Specifies an end IP address. The end IP address cannot be lower than the start IP address. If you do not specify this argument, the excluded IP range includes only the start IP address.

Usage guidelines

The excluded IP address range in an address pool is still assignable in other address pools.

To specify multiple excluded IP address ranges, execute the **forbidden-ip-range** command multiple times. IP addresses in excluded IP address ranges can overlap.

If you do not specify any parameters, the **undo forbidden-ip-range** command removes all excluded IP address ranges.

If the **undo** command specifies an address range smaller than the existing excluded address range, the **undo** command removes only the specified address range. If the **undo** command specifies an address range broader than the existing excluded address range, the existing excluded range is removed.

Examples

Exclude IP address range 192.168.1.3 to 192.168.1.10 from dynamic allocation in DHCP address pool **0**.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] forbidden-ip-range 192.168.1.3 192.168.1.10
```

Related commands

display dhcp server pool

gateway-list

Use **gateway-list** to specify gateway addresses in a DHCP address pool or a DHCP secondary subnet.

Use **undo gateway-list** to remove the specified gateway addresses from a DHCP address pool or a DHCP secondary subnet.

Syntax

gateway-list *ip-address*&<1-64> [**export-route**]

undo gateway-list [*ip-address*&<1-64>] [**export-route**]

Default

No gateway address is configured in a DHCP address pool or a DHCP secondary subnet.

Views

DHCP address pool view

DHCP secondary subnet view

Predefined user roles

network-admin

context-admin

Parameters

ip-address&<1-64>: Specifies a space-separated list of up to 64 gateway addresses. Gateway addresses must reside on the same subnet as the assignable IP addresses.

export-route: Binds the gateways to the device's MAC address in the address management module. The ARP module will use the entries to reply to ARP requests from the DHCP clients. If you do not specify this keyword, the gateways will not be bound to the device's MAC address.

Usage guidelines

The DHCP server assigns gateway addresses to clients on a secondary subnet in the following ways:

- If gateways are specified in both address pool view and secondary subnet view, DHCP assigns those specified in the secondary subnet view.
- If gateways are specified in address pool view but not in secondary subnet view, DHCP assigns those specified in address pool view.

If you do not specify any parameters, the **undo gateway-list** command deletes all gateway addresses.

Examples

Specify gateway address 10.1.1.1 in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] gateway-list 10.1.1.1
```

Related commands

display dhcp server pool

if-match

Use **if-match** to configure a match rule for a DHCP user class.

Use **undo if-match** to delete a match rule for a DHCP user class.

Syntax

if-match rule *rule-number* { **hardware-address** *hardware-address* **mask** *hardware-address-mask* | **option** *option-code* [**ascii** *ascii-string* [**offset** *offset* | **partial**] | **hex** *hex-string* [**mask** *mask* | **offset** *offset* **length** *length* | **partial**]] | **relay-agent** *gateway-address* }

undo if-match rule *rule-number*

Default

No match rules are configured for the DHCP user class.

Views

DHCP user class view

Predefined user roles

network-admin

context-admin

Parameters

rule *rule-number*: Assigns the match rule an ID in the range of 1 to 128. A smaller ID represents a higher match priority.

hardware-address *hardware-address*: Specifies a hardware address, a string of 4 to 39 characters. The string contains hyphen-separated hexadecimal numbers. The last hexadecimal number can be a two-digit or four-digit number, and the other hexadecimal numbers must be four-digit numbers. For example, **aabb-ccdd-ee** is valid, and **aabb-c-dddd** or **aabb-cc-dddd** is invalid.

mask *hardware-address-mask*: Specifies the mask to be ANDed with the specified hardware address for the match operation. The length of the mask must be the same as that of the hardware address.

option *option-code*: Specifies a DHCP option by its number in the range of 1 to 254.

ascii *ascii-string*: Specifies an ASCII string of 1 to 128 characters.

offset *offset*: Specifies the offset in bytes after which the match operation starts. The value range is 0 to 254. If you do not specify an offset value, the match starts from the first byte of the option content. If you specify an ASCII string, a packet matches the rule if the option content after the offset is the same as the ASCII string. If you specify a hexadecimal number, a packet matches the rule if the option content of the specified length after the offset is the same as the hexadecimal number.

partial: Enables partial match. A packet matches a rule if the specified option in the packet contains the ASCII string or hexadecimal number specified in the rule. For example, if you specify **abc** in the rule, option content **xabc**, **xyzabca**, **xabcyz**, and **abcxyz** all match the rule.

hex *hex-string*: Specifies a hexadecimal number. The length of the hexadecimal number must be an even number in the range of 2 to 256.

mask *mask*: Specifies a hexadecimal mask for the match operation. The mask length must be an even number in the range of 2 to 256 and be the same as the *hex-string* length. The DHCP server selects option content of the mask length from the start and ANDs the selected option content and the specified hexadecimal number with the mask. The packet matches the rule if the two AND operation results are the same.

length *length*: Specifies the length of the option content to be matched, in the range of 1 to 128 bytes. The length must be the same as the *hex-string* length.

relay-agent *gateway-address*: Specifies a **giaddr** field value. The value is an IPv4 address in the dotted decimal notation. A packet matches the rule if its **giaddr** field value is the same as that in the rule.

Usage guidelines

If a DHCP request sent by a DHCP client matches a rule in a DHCP user class, the DHCP client matches the user class.

You can configure multiple match rules for a DHCP user class. Each match rule is uniquely identified by a rule ID within its type (hardware address, option, or relay agent address).

- If the rule that you are configuring has the same ID and type as an existing rule, the new rule overwrites the existing rule.
- If the rule that you are configuring has the same ID as an existing rule but a different type, the new rule takes effect and coexists with the existing rule. As a best practice, do not assign the same ID to rules of different types.
- Rules of different IDs cannot have the same rule content.

When you configure an **if-match hardware-address** rule, follow these guidelines:

- The hardware address type supports only the MAC address. A rule does not match clients with hardware addresses of other types.
- The specified hardware address must be of the same length as the client hardware addresses to be matched. To match MAC addresses, the specified hardware address must be six bytes long.
- The fs and 0s in the mask for the hardware match operation can be noncontiguous. For example, the rule **if-match rule** 1 **hardware-address** 0094-0000-1100 **mask** ffff-0000-ff00 matches hardware addresses in which the first two bytes are 0094 and the fifth byte is 11.

When you configure an **if-match option** rule, follow these guidelines:

- To match packets that contain an option, specify only the *option-code* argument.
- To match a hexadecimal number by AND operations, specify the **option** *option-code* **hex** *hex-string* **mask** *mask* options.
- To match a hexadecimal number directly, specify the **option** *option-code* **hex** *hex-string* [**offset** *offset* **length** *length* | **partial**] options. If you do not specify the **offset**, **length**, or **partial** parameter, a packet matches a rule if the option content starts with the hexadecimal number.
- To match an ASCII string, specify the **option** *option-code* **ascii** *ascii-string* [**offset** *offset* | **partial**] options. If you do not specify the **offset** or **partial** parameter, a packet matches a rule if the option content starts with the ASCII string.

Examples

Configure match rule **1** for DHCP user class **exam** to match DHCP requests in which the hardware address is six bytes long and begins with **0094**.

```
<Sysname> system-view
[Sysname] dhcp class exam
[Sysname-dhcp-class-exam] if-match rule 1 hardware-address 0094-0000-0101 mask
ffff-0000-0000
```

Configure match rule **2** for DHCP user class **exam** to match DHCP requests that contain Option 82.

```
<Sysname> system-view
[Sysname] dhcp class exam
[Sysname-dhcp-class-exam] if-match rule 2 option 82
```

Configure match rule **3** for DHCP user class **exam**. The rule matches DHCP requests in which the highest bit of the fourth byte in Option 82 is the hexadecimal number **1**.

```
<Sysname> system-view
[Sysname] dhcp class exam
[Sysname-dhcp-class-exam] if-match rule 3 option 82 hex 00000080 mask 00000080
```

Configure match rule **4** for DHCP user class **exam**. The rule matches DHCP requests in which the first three bytes of Option 82 are the hexadecimal number **13ae92**.

```
<Sysname> system-view
[Sysname] dhcp class exam
[Sysname-dhcp-class-exam] if-match rule 4 option 82 hex 13ae92 offset 0 length 3
```

Configure match rule **5** for DHCP user class **exam**. The rule matches DHCP requests in which the Option 82 contains the hexadecimal number **13ae**.

```
<Sysname> system-view
[Sysname] dhcp class exam
[Sysname-dhcp-class-exam] if-match rule 5 option 82 hex 13ae partial
```

Configure match rule **6** for DHCP user class **exam** to match DHCP requests in which the **giaddr** field is 10.1.1.1.

```
<Sysname> system-view
[Sysname] dhcp class exam
[Sysname-dhcp-class-exam] if-match rule 6 relay-agent 10.1.1.1
```

Related commands

dhcp class

ip-in-use threshold

Use **ip-in-use threshold** to set a threshold for the address pool usage alarming.

Use **undo ip-in-use threshold** to restore the default.

Syntax

ip-in-use threshold *threshold-value*

undo ip-in-use threshold

Default

The address pool usage threshold is 100%.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

threshold-value: Specifies the threshold for the address pool usage percentage. The value range is 1 to 100.

Usage guidelines

If you execute this command in the same address pool view multiple times, the most recent configuration takes effect.

When the address pool usage exceeds the threshold, the system sends notifications to the SNMP module. For DHCP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Examples

Set the address pool usage threshold to 85%.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool p1
[Sysname-dhcp-pool-p1] ip-in-use threshold 85
```

nbns-list

Use **nbns-list** to specify WINS server addresses in a DHCP address pool.

Use **undo nbns-list** to remove the specified WINS server addresses.

Syntax

nbns-list *ip-address*&<1-8>

undo nbns-list [*ip-address*&<1-8>]

Default

No WINS server address is specified.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

ip-address&<1-8>: Specifies a space-separated list of up to eight WINS server IP addresses.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

If you do not specify any parameters, the **undo nbns-list** command deletes all WINS server addresses.

Examples

Specify WINS server address 10.1.1.1 in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] nbns-list 10.1.1.1
```

Related commands

display dhcp server pool

netbios-type

netbios-type

Use **netbios-type** to specify the NetBIOS node type in a DHCP address pool.

Use **undo netbios-type** to restore the default.

Syntax

netbios-type { **b-node** | **h-node** | **m-node** | **p-node** }

undo netbios-type

Default

No NetBIOS node type is specified.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

b-node: Specifies the broadcast node. A b-node client sends the destination name in a broadcast message to get the name-to-IP mapping from a server.

h-node: Specifies the hybrid node. An h-node client unicasts the destination name to a WINS server. If it does not receive a response, the h-node client broadcasts the destination name to get the mapping from a server.

m-node: Specifies the mixed node. An m-node client broadcasts the destination name. If it does not receive a response, the m-node client unicasts the destination name to the WINS server to get the mapping.

p-node: Specifies the peer-to-peer node. A p-node client sends the destination name in a unicast message to get the mapping from the WINS server.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the NetBIOS node type as p-node in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] netbios-type p-node
```

Related commands

display dhcp server pool

nbns-list

network

Use **network** to specify the subnet for dynamic allocation in a DHCP address pool.

Use **undo network** to remove the specified subnet.

Syntax

network *network-address* [*mask-length* | **mask** *mask*] [**secondary**] [**export-route**]

undo network *network-address* [*mask-length* | **mask** *mask*] [**secondary**]

Default

No subnet is specified in a DHCP address pool.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

network-address: Specifies the subnet for dynamic allocation. If no mask length or mask is specified, the natural mask will be used.

mask-length: Specifies the mask length in the range of 1 to 30.

mask *mask*: Specifies the mask in dotted decimal format.

secondary: Specifies the subnet as a secondary subnet. If you do not specify this keyword, this command specifies the primary subnet. If the addresses in the primary subnet are used up, the DHCP server can select addresses from a secondary subnet for clients.

export-route: Advertises the subnet assigned to DHCP clients. If you do not specify this keyword, the subnet will not be advertised.

Usage guidelines

You can use the **secondary** keyword to specify a secondary subnet and enter its view. In secondary subnet view, you can specify gateways by using the **gateway-list** command for DHCP clients in the secondary subnet.

You can specify only one primary subnet for a DHCP address pool. If you execute the **network** command multiple times, the most recent configuration takes effect.

You can specify up to 32 secondary subnets for a DHCP address pool.

The primary subnet and secondary subnets in a DHCP address pool must not have the same network address and mask.

If you have used the **address range** or **class** command in an address pool, you cannot specify a secondary subnet in the same address pool.

Modifying or removing the **network** configuration deletes the assigned addresses from the current address pool.

If you execute the **network export-route** command multiple times, the most recent configuration takes effect.

Examples

Specify primary subnet 192.168.8.0/24 and secondary subnet 192.168.10.0/24 in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] network 192.168.8.0 mask 255.255.255.0
[Sysname-dhcp-pool-0] network 192.168.10.0 mask 255.255.255.0 secondary
[Sysname-dhcp-pool-0-secondary]
```

Related commands

display dhcp server pool

gateway-list

next-server

Use **next-server** to specify the IP address of a server in a DHCP address pool.

Use **undo next-server** to restore the default.

Syntax

next-server *ip-address*

undo next-server

Default

No server's IP address is specified in a DHCP address pool.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IP address of a server.

Usage guidelines

Upon startup, the DHCP client obtains an IP address and the specified server IP address. Then it contacts the specified server, such as a TFTP server, to get other boot information.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify a server's IP address 10.1.1.254 in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] next-server 10.1.1.254
```

Related commands

display dhcp server pool

option

Use **option** to customize a DHCP option.

Use **undo option** to remove a customized DHCP option.

Syntax

option *code* { **ascii** *ascii-string* | **hex** *hex-string* | **ip-address** *ip-address*&<1-8> }

undo option *code*

Default

No DHCP option is customized.

Views

DHCP address pool view

DHCP option group view

Predefined user roles

network-admin

context-admin

Parameters

code: Specifies the number of the customized option, in the range of 2 to 254, excluding 50 through 54, 56, 58, 59, 61, and 82.

ascii *ascii-string*: Specifies a case-sensitive ASCII string of 1 to 255 characters as the option content.

hex *hex-string*: Specifies a hexadecimal number as the option content. The length of the hexadecimal number must be an even number in the range of 2 to 256.

ip-address *ip-address*&<1-8>: Specifies a space-separated list of up to eight IP addresses as the option content.

Usage guidelines

The DHCP server fills the customized option with the specified ASCII string, hexadecimal number, or IP addresses, and sends it in a response to the client.

You can customize options for the following purposes:

- Add newly released options.
- Add options for which the vendor defines the contents, for example, Option 43.
- Add options for which the CLI does not provide a dedicated configuration command. For example, you can use the **`option 4 ip-address 1.1.1.1`** command to define the time server address 1.1.1.1 for DHCP clients.
- Add all option values if the actual requirement exceeds the limit for a dedicated option configuration command. For example, the **`dns-list`** command can specify up to eight DNS servers. To specify more than eight DNS server, you must use the **`option 6`** command to define all DNS servers.

DHCP options specified by dedicated commands take precedence over those specified by the **`option`** commands. For example, if a DNS server address is specified by both the **`dns-list`** command and the **`option 6`** command, the server uses the address specified by the **`dns-list`** command.

DHCP options specified in DHCP option groups take precedence over those specified in DHCP address pools.

If you execute this command multiple times with the same *`code`* specified, the most recent configuration takes effect.

Examples

Configure Option 7 to specify log server address 2.2.2.2 in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] option 7 ip-address 2.2.2.2
```

Related commands

`display dhcp server pool`

reset dhcp server conflict

Use **`reset dhcp server conflict`** to clear IP address conflict information.

Syntax

`reset dhcp server conflict` [**`ip`** *`ip-address`*] [**`vpn-instance`** *`vpn-instance-name`*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

`ip` *`ip-address`*: Clears conflict information about the specified IP address. If you do not specify this option, this command clears all address conflict information.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command clears conflict information about IP addresses for the public network.

Usage guidelines

Address conflicts occur when dynamically assigned IP addresses have been statically configured for other hosts. After you modify the address pool configuration, the conflicted addresses might become assignable. To assign these addresses, use the **reset dhcp server conflict** command to clear the conflict information first.

Examples

Clear all IP address conflict information.

```
<Sysname> reset dhcp server conflict
```

Related commands

display dhcp server conflict

reset dhcp server expired

Use **reset dhcp server expired** to clear binding information about expired IP addresses.

Syntax

reset dhcp server expired [[**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

ip *ip-address*: Clears binding information about the specified expired IP address. If you do not specify an IP address, this command clears binding information about all expired IP addresses.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command clears lease expiration information about IP addresses for the public network.

pool *pool-name*: Clears binding information about the expired IP addresses in the specified address pool. The pool name is a case-insensitive string of 1 to 63 characters. If you do not specify an address pool, this command clears binding information about expired IP addresses in all address pools.

Examples

Clear binding information about all expired IP addresses.

```
<Sysname> reset dhcp server expired
```

Related commands

display dhcp server expired

reset dhcp server ip-in-use

Use **reset dhcp server ip-in-use** to clear binding information about assigned IP addresses.

Syntax

reset dhcp server ip-in-use [[**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

ip *ip-address*: Clears binding information about the specified assigned IP address. If you do not specify an IP address, this command clears binding information about all assigned IP addresses.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command clears binding information for the public network.

pool *pool-name*: Clears binding information about assigned IP addresses in the specified address pool. The pool name is a case-insensitive string of 1 to 63 characters. If you do not specify an address pool, this command clears binding information about assigned IP addresses in all address pools.

Usage guidelines

If you use this command to clear information about an assigned static binding, the static binding becomes a free static binding.

Examples

Clear binding information about IP address 10.110.1.1.

```
<Sysname> reset dhcp server ip-in-use ip 10.110.1.1
```

Related commands

display dhcp server ip-in-use

reset dhcp server statistics

Use **reset dhcp server statistics** to clear DHCP server statistics.

Syntax

reset dhcp server statistics [**vpn-instance** *vpn-instance-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command clears DHCP server statistics for the public network.

Examples

Clear DHCP server statistics.

```
<Sysname> reset dhcp server statistics
```

Related commands

display dhcp server statistics

static-bind

Use **static-bind** to statically bind a client ID or MAC address to an IP address.

Use **undo static-bind** to remove a static binding.

Syntax

static-bind ip-address *ip-address* [*mask-length* | **mask** *mask*] { **client-identifier** *client-identifier* | **hardware-address** *hardware-address* [**ethernet** | **token-ring**] } [**description** *description-text*]

undo static-bind ip-address *ip-address*

Default

No static binding is specified in a DHCP address pool.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

ip-address *ip-address*: Specifies the IP address of the static binding. The natural mask is used if no mask length or mask is specified.

mask-length: Specifies the mask length in the range of 1 to 30.

mask *mask*: Specifies the mask, in dotted decimal format.

client-identifier *client-identifier*: Specifies the client ID of the static binding, a string of 4 to 254 characters. The string can contain only hexadecimal numbers and hyphen (-), in the format of H-H-H…. The last H can be a two-digit or four-digit hexadecimal number while the other Hs must be all four-digit hexadecimal numbers. For example, aabb-cccc-dd is correct, and aabb-c-dddd and aabb-cc-dddd are not correct.

hardware-address *hardware-address*: Specifies the client hardware address of the static binding, a string of 4 to 39 characters. The string can contain only hexadecimal numbers and hyphen (-), in the format of H-H-H…. The last H can be a two-digit or four-digit hexadecimal number while the other Hs must be all four-digit hexadecimal numbers. For example, aabb-cccc-dd is correct, and aabb-c-dddd and aabb-cc-dddd are not correct.

ethernet: Specifies the client hardware address type as Ethernet. The default type is Ethernet.

token-ring: Specifies the client hardware address type as token ring.

description *description-text*: Specifies a description for the static binding, a case-sensitive string of 1 to 255 characters.

Usage guidelines

The IP address of a static binding must not be an interface address of the DHCP server. Otherwise, an IP address conflict occurs, and the bound client cannot obtain the IP address.

You can specify multiple static bindings in an address pool. The total number of static bindings in all address pools cannot exceed 8192.

An IP address can be bound to only one DHCP client. To modify the binding for a DHCP client, first execute the **undo** form of the command to delete the existing binding and then create a new binding.

Examples

Bind IP address 10.1.1.1/24 to client ID **00aa-aabb** in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] static-bind ip-address 10.1.1.1 mask 255.255.255.0
client-identifier 00aa-aabb
```

valid class

Use **valid class** to add DHCP user classes to the whitelist.

Use **undo valid class** to remove DHCP user classes from the whitelist.

Syntax

valid class *class-name*&<1-8>

undo valid class *class-name*&<1-8>

Default

No DHCP user class is listed on the whitelist.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

class-name&<1-8>: Specifies a space-separated list of up to eight DHCP user classes by their names, a case-insensitive string of 1 to 63 characters.

Usage guidelines

For this command to take effect, you must enable the DHCP user class whitelist.

Examples

Add DHCP user classes **test1** and **test2** to the whitelist in DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] valid class test1 test2
```

Related commands

dhcp class

verify class

verify class

Use **verify class** to enable the DHCP user class whitelist.

Use **undo verify class** to disable the DHCP user class whitelist.

Syntax

verify class

undo verify class

Default

The DHCP user class whitelist is disabled.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Usage guidelines

After you enable the DHCP user class whitelist, the DHCP server processes requests only from clients on the DHCP user class whitelist.

The DHCP user class whitelist does not take effect on clients that request static IP addresses, and the server always processes their requests.

Examples

Enable the DHCP user class whitelist in DHCP address pool 0.

```
[Sysname] system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] verify class
```

Related commands

voice-config

Use **voice-config** to configure the content for Option 184 in a DHCP address pool.

Use **undo voice-config** to remove the Option 184 content from a DHCP address pool.

Syntax

voice-config { **as-ip** *ip-address* | **fail-over** *ip-address dialer-string* | **ncp-ip** *ip-address* | **voice-vlan** *vlan-id* { **disable** | **enable** } }

undo voice-config [**as-ip** | **fail-over** | **ncp-ip** | **voice-vlan**]

Default

No Option 184 content is configured in a DHCP address pool.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

as-ip *ip-address*: Specifies the IP address of the backup network calling processor.

fail-over *ip-address dialer-string*: Specifies the failover IP address and dialer string. The *dialer-string* is a string of 1 to 39 characters. Valid characters are digits and asterisk (*).

ncp-ip *ip-address*: Specifies the IP address of the primary network calling processor.

voice-vlan *vlan-id*: Specifies the voice VLAN ID in the range of 2 to 4094.

- **disable**: Disables the specified VLAN. DHCP clients will not take this VLAN as their voice VLAN.
- **enable**: Enables the specified VLAN. DHCP clients will take this VLAN as their voice VLAN.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure Option 184 in DHCP address pool 0. The primary and backup network calling processors are at 10.1.1.1 and 10.2.2.2, respectively. The voice VLAN 3 is enabled. The failover IP address is 10.3.3.3. The dialer string is 99*.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] voice-config ncp-ip 10.1.1.1
[Sysname-dhcp-pool-0] voice-config as-ip 10.2.2.2
[Sysname-dhcp-pool-0] voice-config voice-vlan 3 enable
[Sysname-dhcp-pool-0] voice-config fail-over 10.3.3.3 99*
```

Related commands

display dhcp server pool

vpn-instance

Use **vpn-instance** to apply a DHCP address pool to a VPN instance.

Use **undo vpn-instance** to restore the default.

Syntax

vpn-instance *vpn-instance-name*

undo vpn-instance

Default

The DHCP address pool is not applied to any VPN instance.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance-name: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

If a DHCP address pool is applied to a VPN instance, the DHCP server assigns IP addresses in this address pool to clients in the specified VPN instance.

The DHCP server identifies the VPN instance to which a DHCP client belongs according to the following information:

- The client's VPN information stored in authentication modules.
- The VPN information of the DHCP server's interface that receives DHCP packets from the client.

The VPN information from authentication modules takes priority over the VPN information of the receiving interface.

Examples

Apply DHCP address pool 0 to VPN instance **abc**.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] vpn-instance abc
```

DHCP relay agent commands

dhcp relay check mac-address

Use **dhcp relay check mac-address** to enable MAC address check on the relay agent.

Use **undo dhcp relay check mac-address** to disable MAC address check on the relay agent.

Syntax

dhcp relay check mac-address

undo dhcp relay check mac-address

Default

The MAC address check feature is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the DHCP relay agent to compare the **chaddr** field of a received DHCP request with the source MAC address in the frame header. If they are the same, the DHCP relay agent forwards the request to the DHCP server. If they are not the same, the DHCP relay agent discards the request.

The MAC address check feature takes effect only when the **dhcp select relay** command has already been configured on the interface.

Enable the MAC address check feature only on the DHCP relay agent directly connected to the DHCP clients. A DHCP relay agent changes the source MAC address of DHCP packets before sending them.

Examples

Enable MAC address check on the DHCP relay agent.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dhcp relay check mac-address
```

dhcp select relay

dhcp relay check mac-address aging-time

Use **dhcp relay check mac-address aging-time** to set the aging time for MAC address check entries on the DHCP relay agent.

Use **undo dhcp relay check mac-address aging-time** to restore the default.

Syntax

dhcp relay check mac-address aging-time *time*

undo dhcp relay check mac-address aging-time

Default

The aging time is 30 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the aging time for MAC address check entries, in the range of 30 to 600 seconds.

Usage guidelines

This command takes effect only after you execute the **dhcp relay check mac-address** command.

Examples

Set the aging time to 60 seconds for MAC address check entries on the DHCP relay agent.

```
<Sysname> system-view
[Sysname] dhcp relay check mac-address aging-time 60
```

dhcp relay client-information record

Use **dhcp relay client-information record** to enable recording client information in relay entries.

Use **undo dhcp relay client-information record** to disable the feature.

Syntax

dhcp relay client-information record

undo dhcp relay client-information record

Default

The DHCP relay agent does not record client information in relay entries.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Client information is recorded only when the DHCP relay agent is configured on the gateway of DHCP clients. A relay entry contains information about a client such as the client's IP and MAC addresses.

Disabling the recording of client information deletes all recorded relay entries.

Examples

Enable the recording of relay entries on the relay agent.

```
<Sysname> system-view
[Sysname] dhcp relay client-information record
```

Related commands

dhcp relay client-information refresh

dhcp relay client-information refresh enable

dhcp relay client-information refresh

Use **dhcp relay client-information refresh** to set the interval at which the DHCP relay agent refreshes relay entries.

Use **undo dhcp relay client-information refresh** to restore the default.

Syntax

dhcp relay client-information refresh [**auto** | **interval** *interval*]

undo dhcp relay client-information refresh

Default

The refresh interval is automatically calculated based on the number of relay entries.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

auto: Automatically calculates the refresh interval. The more the entries, the shorter the refresh interval. The shortest interval is 50 ms.

interval *interval*: Specifies the refresh interval in the range of 1 to 120 seconds.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Set the refresh interval to 100 seconds.

```
<Sysname> system-view
[Sysname] dhcp relay client-information refresh interval 100
```

Related commands

dhcp relay client-information record

dhcp relay client-information refresh enable

dhcp relay client-information refresh enable

Use **dhcp relay client-information refresh enable** to enable the DHCP relay agent to periodically refresh dynamic relay entries.

Use **undo dhcp relay client-information refresh enable** to disable the DHCP relay agent to periodically refresh dynamic relay entries.

Syntax

dhcp relay client-information refresh enable

undo dhcp relay client-information refresh enable

Default

The DHCP relay agent periodically refreshes relay entries.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

A DHCP client unicasts a DHCP-RELEASE message to the DHCP server to release its IP address. The DHCP relay agent conveys the message to the DHCP server and does not remove the IP-to-MAC entry of the client.

With this feature, the DHCP relay agent uses a client's IP address to periodically send a DHCP-REQUEST message to the DHCP server.

- If the server returns a DHCP-ACK message or does not return any message within an interval, the DHCP relay agent performs the following operations:
  - Removes the relay entry.
  - Sends a DHCP-RELEASE message to the DHCP server to release the IP address.
- If the server returns a DHCP-NAK message, the relay agent keeps the entry.

With this feature disabled, the DHCP relay agent does not remove relay entries automatically. After a DHCP client releases its IP address, you must use the **reset dhcp relay client-information** on the relay agent to remove the corresponding relay entry.

Examples

Disable periodic refresh of relay entries.

```
<Sysname> system-view
[Sysname] undo dhcp relay client-information refresh enable
```

dhcp relay gateway

Use **dhcp relay gateway** to specify the DHCP relay agent address to be inserted in DHCP requests.

Use **undo dhcp relay gateway** to restore the default.

Syntax

dhcp relay gateway *ip-address*

undo dhcp relay gateway

Default

The primary IP address of the interface is inserted in DHCP requests as the DHCP relay agent address.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the DHCP relay agent address. It must be an IP address of the interface.

Usage guidelines

The DHCP relay agent uses the specified IP address instead of the primary IP address of the relay interface as the DHCP relay agent address.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify 10.1.1.1 as the DHCP relay agent address to be inserted in DHCP requests on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dhcp relay gateway 10.1.1.1
```

dhcp relay information circuit-id

Use **dhcp relay information circuit-id** to configure the padding mode and padding format for the Circuit ID sub-option of Option 82.

Use **undo dhcp relay information circuit-id** to restore the default.

Syntax

dhcp relay information circuit-id { **bas** [**sub-interface-vlan**] | **string** *circuit-id* | { **normal** | **verbose** [**node-identifier** { **mac** | **sysname** | **user-defined** *node-identifier* }] [**interface**] } [**sub-interface-vlan**] [**format** { **ascii** | **hex** }] }

undo dhcp relay information circuit-id

Default

The padding mode is **normal** and the padding format is **hex**.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

bas: Specifies the bas mode that fills in the Circuit ID sub-option with the interface and VLAN information. The device fills the information in the format of *interface-type slot/subslot/port vxlan_id.vlan_id.subvlan_id*.

sub-interface-vlan: Specifies the VLAN ID of the L2VE subinterface as the content for the Circuit ID sub-option. If you do not specify this keyword, the VLAN ID of the interface on which you configure this command is written to the sub-option. This keyword is available only for L3VE interfaces.

string *circuit-id*: Specifies the string mode that uses a case-sensitive string of 3 to 63 characters as the content of the Circuit ID sub-option.

normal: Specifies the normal mode, in which the padding content consists of the VLAN ID and port number.

verbose: Specifies the verbose mode. The padding content includes the node identifier, interface information, and VLAN ID. The default node identifier is the MAC address of the access node. The default interface information consists of the Ethernet type (fixed to **eth**), chassis number, slot number, sub-slot number, and interface number.

node-identifier { **mac** | **sysname** | **user-defined** *node-identifier* }: Specifies the access node identifier.

- **mac**: Uses the MAC address of the access node as the node identifier.
- **sysname**: Uses the device name as the node identifier. You can set the device name by using the **sysname** command in system view. The padding format for the device name is always ASCII regardless of the specified padding format. If you specify this keyword, do not include any spaces when you set the device name. Otherwise, the DHCP relay agent fails to add or replace Option 82.
- **user-defined** *node-identifier:* Uses a case-sensitive string of 1 to 50 characters as the node identifier. The padding format for the specified character string is always ASCII regardless of the specified padding format.

interface: Uses the interface name as the interface information. The padding format for the interface name is always ASCII regardless of the specified padding format.

format: Specifies the padding format for the Circuit ID sub-option.

ascii: Specifies the ASCII padding format.

hex: Specifies the hex padding format.

Usage guidelines

The Circuit ID sub-option cannot carry information about interface splitting or subinterfaces. For more information about interface splitting and subinterfaces, see *Interface Configuration Guide*.

If you execute this command multiple times, the most recent configuration takes effect.

The padding format for the string mode, the normal mode, or the verbose mode varies by command configuration. Table 8 shows how the padding format is determined for different modes.

Table 8 Padding format for different modes

Keyword (mode)	If no padding format is set	If the padding format is ascii	If the padding format is hex
string *circuit-id*	The padding format is ASCII, and is not configurable.	N/A	N/A
normal	Hex.	ASCII.	Hex.
verbose	Hex for the VLAN ID. ASCII for the node identifier, Ethernet type, chassis number, slot number, sub-slot number, and interface number.	ASCII.	ASCII for the node identifier and Ethernet type. Hex for the chassis number, slot number, sub-slot number, interface number, and VLAN ID.

Examples

Specify the content mode as verbose, node identifier as the device name, and the padding format as ASCII for the Circuit ID sub-option.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dhcp relay information enable
[Sysname-GigabitEthernet1/0/1] dhcp relay information strategy replace
[Sysname-GigabitEthernet1/0/1] dhcp relay information circuit-id verbose node-identifier sysname format ascii
```

Related commands

dhcp relay forward reply by-option82

dhcp relay information enable

dhcp relay information strategy

display dhcp relay information

dhcp relay information enable

Use **dhcp relay information enable** to enable the DHCP relay agent to support Option 82.

Use **undo dhcp relay information enable** to disable Option 82 support.

Syntax

dhcp relay information enable

undo dhcp relay information enable

Default

The DHCP relay agent does not support Option 82.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command enables the DHCP relay agent to add Option 82 to DHCP requests that do not contain Option 82 before forwarding the requests to the DHCP server. The content of Option 82 is determined by the **dhcp relay information circuit-id** and **dhcp relay information remote-id** commands. If the DHCP requests contain Option 82, the relay agent handles the requests according to the strategy configured with the **dhcp relay information strategy** command.

If this feature is disabled, the relay agent forwards requests that contain or do not contain Option 82 to the DHCP server.

Examples

Enable Option 82 support on the relay agent.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dhcp relay information enable
```

Related commands

dhcp relay information remote-id

dhcp relay information strategy

display dhcp relay information

dhcp relay information remote-id

Use **dhcp relay information remote-id** to configure the padding mode and padding format for the Remote ID sub-option of Option 82.

Use **undo dhcp relay information remote-id** to restore the default.

Syntax

dhcp relay information remote-id { **normal** [**format** { **ascii** | **hex** }] | **string** *remote-id* | **sysname** }

undo dhcp relay information remote-id

Default

The padding mode is **normal** and the padding format is **hex**.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

normal: Specifies the normal mode in which the padding content is the MAC address of the receiving interface.

format: Specifies the padding format for the Remote ID sub-option. The default padding format is hex.

ascii: Specifies the ASCII padding format.

hex: Specifies the hex padding format.

string *remote-id*: Specifies the string mode that uses a case-sensitive string of 1 to 63 characters as the content of the Remote ID sub-option.

sysname: Specifies the sysname mode that uses the device name as the content of the Remote ID sub-option. You can set the device name by using the **sysname** command.

Usage guidelines

The padding format is always ASCII for the specified character string (**string**), and the device name (**sysname**).

The padding format for the **normal** mode is determined by the command.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the padding content for the Remote ID sub-option of Option 82 as **device001**.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dhcp relay information enable
[Sysname-GigabitEthernet1/0/1] dhcp relay information strategy replace
[Sysname-GigabitEthernet1/0/1] dhcp relay information remote-id string device001
```

Related commands

dhcp relay information enable

dhcp relay information strategy

display dhcp relay information

dhcp relay information strategy

Use **dhcp relay information strategy** to configure the strategy for the DHCP relay agent to handle messages containing Option 82.

Use **undo dhcp relay information strategy** to restore the default handling strategy.

Syntax

dhcp relay information strategy { **drop** | **keep** | **replace** }

undo dhcp relay information strategy

Default

The handling strategy for messages that contain Option 82 is **replace**.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

drop: Drops DHCP messages that contain Option 82 messages.

keep: Keeps the original Option 82 intact and forwards the DHCP messages.

replace: Replaces the original Option 82 with the configured Option 82 before forwarding the DHCP messages.

Usage guidelines

This command takes effect only on DHCP requests that contain Option 82.

For DHCP requests that do not contain Option 82, the DHCP relay agent always adds Option 82 to the requests before forwarding the requests to the DHCP server.

If the handling strategy is **replace**, configure a padding mode and padding format for Option 82. If the handling strategy is **keep** or **drop**, you do not need to configure any padding mode or padding format. The settings do not take effect even if you configure them.

Examples

Specify the handling strategy for Option 82 as **keep**.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dhcp relay information enable
[Sysname-GigabitEthernet1/0/1] dhcp relay information strategy keep
```

Related commands

dhcp relay information enable

display dhcp relay information

dhcp relay release ip

Use **dhcp relay release ip** to release a client IP address.

Syntax

dhcp relay release ip *ip-address* [**vpn-instance** *vpn-instance-name*]

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IP address to be released.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the specified IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command releases the IP address on the public network.

Usage guidelines

After you execute this command, the relay agent sends a DHCP-RELEASE packet to the DHCP server and removes the relay entry of the IP address. Upon receiving the packet, the server removes binding information about the specified IP address to release the IP address.

Examples

Release IP address 1.1.1.1.

```
<Sysname> system-view
[Sysname] dhcp relay release ip 1.1.1.1
```

dhcp relay server-address

Use **dhcp relay server-address** to specify DHCP servers on the DHCP relay agent.

Use **undo dhcp relay server-address** to remove DHCP servers.

Syntax

dhcp relay server-address *ip-address*

undo dhcp relay server-address [*ip-address*]

Default

No DHCP server is specified on the DHCP relay agent.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IP address of a DHCP server. The DHCP relay agent forwards DHCP packets received from DHCP clients to this DHCP server.

Usage guidelines

The specified IP address of the DHCP server must not reside on the same subnet as the IP address of the DHCP relay agent interface. Otherwise, the DHCP clients might fail to obtain IP addresses.

You can specify a maximum of eight DHCP servers on an interface. After receiving a DHCP request, the DHCP relay agent forwards the packets to all the specified DHCP servers.

If you do not specify an IP address, the **undo dhcp relay server-address** command removes all DHCP servers on the interface.

Examples

Specify DHCP server address 1.1.1.1 on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dhcp relay server-address 1.1.1.1
```

Related commands

dhcp select relay

display dhcp relay interface

dhcp relay source-address

Use **dhcp relay source-address** to specify the source IP address for relayed DHCP requests.

Use **undo dhcp relay source-address** to restore the default.

Syntax

dhcp relay source-address { *ip-address* | **gateway** | **relay-interface** }

undo dhcp relay source-address

Default

The relay agent chooses the default source IP address for relayed requests depending on whether its server-side interface and the DHCP server belong to the same VPN instance:

- If they belong to the same VPN instance, the relay agent uses the IP address of the output interface for relayed requests as the default source IP address.
- If they belong to different VPN instances, the relay agent uses the lowest IP address that is in the same VPN instance as the DHCP server as the default source address.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the source IP address.

gateway: Uses the IP address in the **giaddr** field as the source IP address of the relayed DHCP requests. If the **giaddr** field is empty, the relay agent follows the default rule to specify the source IP address for relayed DHCP requests.

relay-interface: Uses the primary IP address of the relay interface as the source IP address. If this interface does not have an IP address, the relay agent follows the default rule to specify the source IP address for relayed DHCP requests.

Usage guidelines

This command is required if multiple relay interfaces share the same IP address or if a relay interface does not have routes to DHCP servers. You can use this command to specify the IP address of another interface, typically the loopback interface, on the DHCP relay agent as the source IP address for DHCP requests. The relay interface inserts the source IP address in the source IP address field as well as the **giaddr** field in DHCP requests.

If multiple relay interfaces share the same IP address, you must also configure the relay interface to support Option 82. Upon receiving a DHCP request, the relay interface inserts the subnet information in sub-option 5 in Option 82. The DHCP server assigns an IP address according to sub-option 5. The DHCP relay agent looks up the output interface in the MAC address table to forward the DHCP reply.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify 1.1.1.1 as the source IP address for relayed DHCP requests on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dhcp relay source-address 1.1.1.1
```

Related commands

dhcp select relay

dhcp smart-relay enable

Use **dhcp smart-relay enable** to enable the DHCP smart relay feature.

Use **undo dhcp smart-relay enable** to disable the DHCP smart relay feature.

Syntax

dhcp smart-relay enable

undo dhcp smart-relay enable

Default

The DHCP smart relay feature is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The smart relay feature allows the relay agent to use secondary IP addresses as the gateway address when the DHCP server does not reply the DHCP-OFFER message. The relay agent initially inserts its primary IP address in the **giaddr** field before forwarding a request to the DHCP server. If no DHCP-OFFER is returned after two retries, the relay agent switches to secondary IP addresses.

Without this feature, the relay agent always uses the primary IP address as the gateway address.

Examples

Enable the DHCP smart relay feature.

```
<Sysname> system-view
[Sysname] dhcp smart-relay enable
```

Aging-time	Aging time of the MAC address check entry, in seconds.

display dhcp relay client-information

Use **display dhcp relay client-information** to display relay entries on the relay agent.

Syntax

display dhcp relay client-information [**interface** *interface-type interface-number* | **ip** *ip-address* [**vpn-instance** *vpn-instance-name*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Displays relay entries on the specified interface. If you do not specify an interface, this command displays relay entries on all interfaces.

ip *ip-address*: Displays the relay entry for the specified IP address. If you do not specify an IP address, this command displays relay entries for all IP addresses.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the specified IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays the relay entry for the specified IP address on the public network.

Usage guidelines

The DHCP relay agent records relay entries only after you configure the **dhcp relay client-information record** command.

Examples

Display all relay entries on the relay agent.

```
<Sysname> display dhcp relay client-information
Total number of client-information items: 2
Total number of dynamic items: 1
Total number of temporary items: 1
IP address       MAC address      Type        Interface           VPN name
10.1.1.1         00e0-0000-0001   Dynamic     GE1/0/1             N/A
10.1.1.5         00e0-0000-0000   Temporary   GE1/0/1             N/A
```

Table 10 Command output

Field	Description
Total number of client-information items	Total number of relay entries.
Total number of dynamic items	Total number of dynamic relay entries.
Total number of temporary items	Total number of temporary relay entries.
IP address	IP address of the DHCP client.
MAC address	MAC address of the DHCP client.
Type	Relay entry type: • **Dynamic**—The relay agent creates a dynamic relay entry upon receiving an ACK response from the DHCP server. • **Temporary**—The relay agent creates a temporary relay entry upon receiving a REQUEST packet from a DHCP client.
Interface	Layer 3 interface connected to the DHCP client. **N/A** is displayed for relay entries without interface information.
VPN name	Name of the VPN instance to which the DHCP client belongs. If the DHCP client does not belong to any VPN, this field displays **N/A**.

Related commands

reset dhcp relay statistics

gateway-list

Use **gateway-list** to specify gateway addresses for DHCP clients in a DHCP address pool.

Use **undo gateway-list** to remove gateway addresses from a DHCP address pool.

Syntax

gateway-list *ip-address*&<1-64> [**export-route**]

undo gateway-list [*ip-address*&<1-64>] [**export-route**]

Default

No gateway address is specified in a DHCP address pool.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

ip-address&<1-64>: Specifies a space-separated list of up to 64 addresses.

export-route: Binds the gateways to the device's MAC address in the address management module. The ARP module will use the entries to reply to ARP requests from the DHCP clients. If you do not specify this keyword, the gateways will not be bound to the device's MAC address.

Usage guidelines

DHCP clients of the same access type can be classified into different types by their locations. In this case, the relay interface typically has no IP address configured. You can use the **gateway-list** command to specify gateway addresses for clients matching the same DHCP address pool and bind the gateway addresses to the device's MAC address.

Upon receiving a DHCP DISCOVER or REQUEST from a client that matches a DHCP address pool, the relay agent processes the packet as follows:

1. Fills the **giaddr** field of the packet with the specified gateway address.
2. Forwards the packet to all DHCP servers in the matching DHCP address pool.

The DHCP servers select a DHCP address pool according to the gateway address.

Examples

Specify gateway address 10.1.1.1 in DHCP address pool 0.

```
<Sysname> system-view
```

```
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] gateway-list 10.1.1.1
```

Related commands

dhcp smart-relay enable

remote-server

Use **remote-server** to specify DHCP servers for a DHCP relay address pool.

Use **undo remote-server** to remove DHCP servers from a DHCP relay address pool.

Syntax

remote-server *ip-address*&<1-8>

undo remote-server [*ip-address*&<1-8>]

Default

No DHCP server is specified for the DHCP relay address pool.

Views

DHCP address pool view

Predefined user roles

network-admin

context-admin

Parameters

ip-address&<1-8>: Specifies a space-separated list of up to eight DHCP server addresses.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

If you do not specify a DHCP server address, the **undo remote-server** command removes all DHCP servers in the DHCP address pool.

Examples

Specify DHCP server 10.1.1.1 for DHCP address pool 0.

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] remote-server 10.1.1.1
```

reset dhcp relay client-information

Use **reset dhcp relay client-information** to clear relay entries on the DHCP relay agent.

Syntax

reset dhcp relay client-information [**interface** *interface-type interface-number* | **ip** *ip-address* [**vpn-instance** *vpn-instance-name*]]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Clears relay entries on the specified interface. If you do not specify an interface, this command clears relay entries on all interfaces.

ip *ip-address*: Clears the relay entry for the specified IP address. If you do not specify an IP address, this command clears relay entries for all IP addresses.

vpn-instance *vpn-instance-name*: Specifies the MPLS L3VPN instance to which the specified IP address belongs. The *vpn-instance-name* argument is a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command clears the relay entry for the specified IP address on the public network.

Examples

Clear all relay entries on the DHCP relay agent.

```
<Sysname> reset dhcp relay client-information
```

Related commands

display dhcp relay client-information

reset dhcp relay statistics

Use **reset dhcp relay statistics** to clear relay agent statistics.

Syntax

reset dhcp relay statistics [**interface** *interface-type interface-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command clears all DHCP relay agent statistics.

Examples

Clear all DHCP relay agent statistics.

```
<Sysname> reset dhcp relay statistics
```

Related commands

display dhcp relay statistics

DHCP client commands

dhcp client dad enable

Use **dhcp client dad enable** to enable duplicate address detection.

Use **undo dhcp client dad enable** to disable duplicate address detection.

Syntax

dhcp client dad enable

undo dhcp client dad enable

Default

Duplicate address detection is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

DHCP client detects IP address conflict through ARP packets. An attacker can act as the IP address owner to send an ARP reply. This makes the client unable to use the IP address assigned by the server. As a best practice, disable duplicate address detection when ARP attacks exist on the network.

Examples

Disable the duplicate address.

```
<Sysname> system-view
[Sysname] undo dhcp client dad enable
```

dhcp client dscp

Use **dhcp client dscp** to set the DSCP value for DHCP packets sent by the DHCP client.

Use **undo dhcp client dscp** to restore the default.

Syntax

dhcp client dscp *dscp-value*

undo dhcp client dscp

Default

The DSCP value is 56 in DHCP packets sent by the DHCP client.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Sets the DSCP value for DHCP packets, in the range of 0 to 63.

Usage guidelines

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Examples

Set the DSCP value to 30 for DHCP packets sent by the DHCP client.

```
<Sysname> system-view
[Sysname] dhcp client dscp 30
```

dhcp client identifier

Use **dhcp client identifier** to configure a DHCP client ID for an interface.

Use **undo dhcp client identifier** to restore the default.

Syntax

dhcp client identifier { **ascii** *ascii-string* | **hex** *hex-string* | **mac** *interface-type interface-number* }

undo dhcp client identifier

Default

An interface generates the DHCP client ID based on its MAC address. If the interface has no MAC address, it uses the MAC address of the first Ethernet interface to generate its client ID.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ascii *ascii-string*: Specifies a case-sensitive ASCII string of 1 to 63 characters as the client ID.

hex *hex-string*: Specifies a hexadecimal number of 4 to 64 characters as the client ID.

mac *interface-type interface-number*: Uses the MAC address of the specified interface as a DHCP client ID. The *interface-type interface-number* argument specifies an interface by its type and number.

Usage guidelines

A DHCP client ID is added to the DHCP option 61. A DHCP server can specify IP addresses for clients based on the DHCP client ID. You can specify a DHCP client ID by performing one of the following operations:

- Naming an ASCII string or hexadecimal number as the client ID.
- Using the MAC address of an interface to generate a client ID.

Whichever method you use, make sure the IDs for different DHCP clients are unique.

Examples

Use the MAC address of GigabitEthernet 1/0/2 as the DHCP client ID for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dhcp client identifier mac gigabitethernet 1/0/2
```

Related commands

display dhcp client

display dhcp client

Use **display dhcp client** to display DHCP client information.

Syntax

display dhcp client [**verbose**] [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

verbose: Displays detailed DHCP client information. If you do not specify this keyword, the command displays brief DHCP client information.

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays DHCP client information on all interfaces.

Examples

Display brief DHCP client information on all interfaces.

```
<Sysname> display dhcp client
GigabitEthernet1/0/1 DHCP client information:
 Current state: BOUND
 Allocated IP: 40.1.1.20 255.255.255.0
 Allocated lease: 259200 seconds, T1: 129600 seconds, T2: 226800 seconds
 DHCP server: 40.1.1.2
```

Display detailed DHCP client information on all interfaces.

```
<Sysname> display dhcp client verbose
GigabitEthernet1/0/1 DHCP client information:
 Current state: BOUND
 Allocated IP: 40.1.1.20 255.255.255.0
 Allocated lease: 259200 seconds, T1: 129600 seconds, T2: 226800 seconds
 Lease from May 21 19:00:29 2012   to   May 31 19:00:29 2012
 DHCP server: 40.1.1.2
 Transaction ID: 0x1c09322d
 Default router: 40.1.1.2
Classless static routes:
   Destination: 1.1.0.1, Mask: 255.0.0.0, NextHop: 192.168.40.16
   Destination: 10.198.122.63, Mask: 255.255.255.255, NextHop: 192.168.40.16
 DNS servers: 44.1.1.11 44.1.1.12
 Domain name: ddd.com

 ACS parameter:
   URL: http://192.168.1.1:7547/acs
```

```
  Username: bims
  Password: ******
Client ID type: acsii(type value=00)
Client ID value: 000c.29d3.8659-GE1/0/1
Client ID (with type) hex: 0030-3030-632e-3239-
                           6433-2e38-3635-392d-
                           4574-6830-2f30-2f32
T1 will timeout in 1 day 11 hours 58 minutes 52 seconds.
```

Table 13 Command output

Field	Description
DHCP client information	Information about the interface that acts as the DHCP client.
Current state	Current state of the DHCP client: • **HALT**—The client stops applying for an IP address. • **INIT**—The initialization state. • **SELECTING**—The client has sent out a DHCP-DISCOVER message in search for a DHCP server and is waiting for the response from DHCP servers. • **REQUESTING**—The client has sent out a DHCP-REQUEST message requesting for an IP address and is waiting for the response from DHCP servers. • **BOUND**—The client has received the DHCP-ACK message from a DHCP server and obtained an IP address successfully. • **RENEWING**—The T1 timer expires. • **REBOUNDING**—The T2 timer expires.
Allocated IP	IP address allocated by the DHCP server.
Allocated lease	Allocated lease time.
T1	1/2 lease time (in seconds) of the DHCP client IP address.
T2	7/8 lease time (in seconds) of the DHCP client IP address.
Lease from….to….	Start and end time of the lease.
DHCP server	DHCP server IP address that assigned the IP address.
Transaction ID	Transaction ID, a random number chosen by the client to identify an IP address allocation.
Default router	Gateway address assigned to the client.
Classless static routes	Classless static routes assigned to the client.
Static routes	Classful static routes assigned to the client.
DNS servers	DNS server address assigned to the client.
Domain name	Domain name suffix assigned to the client.
Boot servers	PXE server addresses (up to 16 addresses) specified for the DHCP client, which are obtained through Option 43.
ACS parameter	Parameters about the ACS.
URL	URL of the ACS.
Username	Username for logging in to the ACS.

Field	Description
Password	Password for logging in to the ACS. If a password is configured, this field displays **********. If no password is configured, this field is not displayed.
Client ID type	DHCP client ID type: • If an ASCII string is used as the client ID value, the type value is 00. • If the MAC address of a specific interface is used as the client ID value, the type value is 01. • If a hexadecimal number is used as the client ID value, the type value is the first two characters in the string.
Client ID value	Value of the DHCP client ID.
Client ID (with type) hex	DHCP client ID with the type field, a hexadecimal number.
T1 will timeout in 1 day 11 hours 58 minutes 52 seconds.	How long the T1 (1/2 lease time) timer will timeout.

Related commands

dhcp client identifier

ip address dhcp-alloc

ip address dhcp-alloc

Use **ip address dhcp-alloc** to configure an interface to use DHCP for IP address acquisition.

Use **undo ip address dhcp-alloc** to cancel an interface from using DHCP.

Syntax

ip address dhcp-alloc

undo ip address dhcp-alloc

Default

An interface does not use DHCP for IP address acquisition.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

When you execute the **undo ip address dhcp-alloc** command, the interface sends a DHCP-RELEASE message to release the IP address obtained through DHCP. If the interface is down, the message cannot be sent out. This situation can occur when a subinterface obtained an IP address through DHCP, and the **shutdown** command is executed on its primary interface. The subinterface will fail to send a DHCP-RELEASE message.

Examples

Configure GigabitEthernet 1/0/1 to use DHCP for IP address acquisition.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
```

```
[Sysname-GigabitEthernet1/0/1] ip address dhcp-alloc
```

BOOTP client commands

display bootp client

Use **display bootp client** to display information about a BOOTP client.

Syntax

display bootp client [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays BOOTP client information on all interfaces.

Examples

Display BOOTP client information on GigabitEthernet 1/0/1.

```
<Sysname> display bootp client interface gigabitethernet 1/0/1
GigabitEthernet1/0/1 BOOTP client information:
Allocated IP: 169.254.0.2 255.255.0.0
Transaction ID: 0x3d8a7431
MAC Address: 00e0-fc0a-c3ef
```

Table 14 Command output

Field	Description
BOOTP client information	Information about the interface that acts as a BOOTP client.
Allocated IP	BOOTP client's IP address allocated by the BOOTP server.
Transaction ID	Value of the **XID** field in a BOOTP message. The BOOTP client chooses a random number for the **XID** field when sending a BOOTP request to the BOOTP server. It is used to match a response message from the BOOTP server. If the values of the **XID** field are different in the BOOTP response and request, the BOOTP client drops the BOOTP response.
Mac Address	MAC address of a BOOTP client.

Related commands

ip address bootp-alloc

ip address bootp-alloc

Use **ip address bootp-alloc** to configure an interface to use BOOTP for IP address acquisition.

Use **undo ip address bootp-alloc** to cancel an interface from using BOOTP.

Syntax

ip address bootp-alloc

undo ip address bootp-alloc

Default

An interface does not use BOOTP for IP address acquisition.

Views

Interface view

Predefined user roles

network-admin

DHCPv6 commands

Common DHCPv6 commands

display ipv6 dhcp duid

Use **display ipv6 dhcp duid** to display the DUID of the local device.

Syntax

display ipv6 dhcp duid

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Usage guidelines

A DHCP unique identifier (DUID) uniquely identifies a DHCPv6 device (DHCPv6 client, server, or relay agent). A DHCPv6 device adds its DUID in a sent packet.

This command displays output only after the DHCPv6 process is running on the device.

Examples

Display the DUID of the local device.

```
<Sysname> display ipv6 dhcp duid
The DUID of this device: 0003000100e0fc005552.
```

ipv6 dhcp dscp

Use **ipv6 dhcp dscp** to set the DSCP value for the DHCPv6 packets sent by the DHCPv6 server or the DHCPv6 relay agent.

Use **undo ipv6 dhcp dscp** to restore the default.

Syntax

ipv6 dhcp dscp *dscp-value*

undo ipv6 dhcp dscp

Default

The DSCP value is 56 in DHCPv6 packets sent by the DHCPv6 server or the DHCPv6 relay agent.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Specifies the DSCP value for DHCPv6 packets, in the range of 0 to 63.

Usage guidelines

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Examples

Set the DSCP value to 30 for DHCPv6 packets sent by the DHCPv6 server or the DHCPv6 relay agent.

```
<Sysname> system-view
[Sysname] ipv6 dhcp dscp 30
```

ipv6 dhcp log enable

Use **ipv6 dhcp log enable** to enable DHCPv6 server logging.

Use **undo ipv6 dhcp log enable** to disable DHCPv6 server logging.

Syntax

ipv6 dhcp log enable

undo ipv6 dhcp log enable

Default

DHCPv6 server logging is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command enables the DHCPv6 server to generate DHCPv6 logs and send them to the information center. The log information helps administrators locate and solve problems. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

As a best practice, disable this feature if the log generation affects the device performance or reduces the address and prefix allocation efficiency. For example, this situation might occur when a large number of clients frequently come online or go offline.

Examples

Enable DHCPv6 server logging.

```
<Sysname> system-view
[Sysname] ipv6 dhcp log enable
```

ipv6 dhcp select

Use **ipv6 dhcp select** to enable the DHCPv6 server or DHCPv6 relay agent on an interface.

Use **undo ipv6 dhcp select** to restore the default.

Syntax

ipv6 dhcp select { **relay** | **server** }

undo ipv6 dhcp select

Default

An interface does not work in the DHCPv6 server mode or in the DHCPv6 relay agent mode. It discards DHCPv6 packets from DHCPv6 clients.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

relay: Enables the DHCPv6 relay agent on the interface.

server: Enables the DHCPv6 server on the interface.

Usage guidelines

Before changing the DHCPv6 server mode to the DHCPv6 relay agent mode on an interface, use the following commands to remove IPv6 address/prefix bindings:

- **reset ipv6 dhcp server ip-in-use**
- **reset ipv6 dhcp server pd-in-use**

Do not configure the DHCPv6 client on the interface that has been configured as the DHCPv6 relay agent or DHCPv6 server.

Examples

Enable the DHCPv6 server on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 dhcp select server
```

Enable the DHCPv6 relay agent on GigabitEthernet 1/0/2.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] ipv6 dhcp select relay
```

Related commands

display ipv6 dhcp relay server-address

display ipv6 dhcp server

DHCPv6 server commands

address range

Use **address range** to specify a non-temporary IPv6 address range in a DHCPv6 address pool for dynamic allocation.

Use **undo address range** to restore the default.

Syntax

address range *start-ipv6-address end-ipv6-address* [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

undo address range

Default

No non-temporary IPv6 address range exists.

Views

DHCPv6 address pool view

Predefined user roles

network-admin

context-admin

Parameters

start-ipv6-address: Specifies the start IPv6 address.

end-ipv6-address: Specifies the end IPv6 address.

preferred-lifetime *preferred-lifetime*: Specifies the preferred lifetime for the non-temporary IPv6 addresses. The value range is 60 to 4294967295 seconds, and the default is 604800 seconds (7 days).

valid-lifetime *valid-lifetime*: Specifies the valid lifetime for the non-temporary IPv6 addresses. The value range is 60 to 4294967295 seconds, and the default is 2592000 seconds (30 days). The valid lifetime cannot be shorter than the preferred lifetime.

Usage guidelines

If you do not specify a non-temporary IPv6 address range, all unicast addresses on the subnet specified by the **network** command in address pool view are assignable. If you specify a non-temporary IPv6 address range, only the IPv6 addresses in the specified IPv6 address range are assignable.

You can specify only one non-temporary IPv6 address range in an address pool. If you execute this command multiple times, the most recent configuration takes effect.

The non-temporary IPv6 address range specified by the **address range** command must be on the subnet specified by the **network** command.

Examples

Configure a non-temporary IPv6 address range from 3ffe:501:ffff:100::10 through 3ffe:501:ffff:100::31 in address pool 1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] network 3ffe:501:ffff:100::/64
[Sysname-dhcp6-pool-1] address range 3ffe:501:ffff:100::10 3ffe:501:ffff:100::31
```

class pool

Use **class pool** to specify a DHCPv6 address pool for a DHCPv6 user class.

Use **undo class pool** to restore the default.

Syntax

class *class-name* **pool** *pool-name*

undo class *class-name* **pool**

Default

No DHCPv6 address pool is specified for a DHCPv6 user class.

Views

DHCPv6 policy view

Predefined user roles

network-admin

context-admin

Parameters

class-name: Specifies a DHCPv6 user class by its name, a case-insensitive string of 1 to 63 characters.

pool-name: Specifies a DHCPv6 address pool by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

You can specify only one DHCPv6 address pool for a DHCPv6 user class in a DHCPv6 policy. If you execute this command multiple times for a user class, the most recent configuration takes effect.

Examples

Specify DHCPv6 address pool **pool1** for DHCPv6 user class **test** in DHCPv6 policy 1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp policy 1
[Sysname-dhcp6-policy-1] class test pool pool1
```

Related commands

default pool

ipv6 dhcp policy

ipv6 dhcp pool

default pool

Use **default pool** to specify the default DHCPv6 address pool.

Use **undo default pool** to restore the default.

Syntax

default pool *pool-name*

undo default pool

Default

No default DHCPv6 address pool is specified.

Views

DHCPv6 policy view

Predefined user roles

network-admin

context-admin

Parameters

pool-name: Specifies a DHCPv6 address pool by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

In a DHCPv6 policy, the DHCPv6 server uses the default address pool to assign IPv6 address, IPv6 prefix, or other parameters to clients that do not match any user classes. If no default address pool is specified or the default address pool does not have assignable IPv6 addresses or prefixes, the assignment fails.

You can specify only one default address pool in a DHCPv6 policy. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the DHCPv6 address pool **pool1** as the default DHCPv6 address pool in DHCPv6 policy 1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp policy 1
[Sysname-dhcp6-policy-1] default pool pool1
```

display ipv6 dhcp option-group

Use **display ipv6 dhcp option-group** to display information about a DHCPv6 option group.

Syntax

display ipv6 dhcp option-group [*option-group-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

option-group-number: Specifies a static or dynamic DHCPv6 option group by its ID. The value range for the option group ID is 1 to 100. If you do not specify an option group, this command displays information about all DHCPv6 option groups.

Usage guidelines

A static DHCPv6 option group is created by using the **ipv6 dhcp option-group** command.

A dynamic DHCPv6 option group is created automatically by a DHCPv6 client after it obtains the DHCPv6 configuration parameters. Dynamic option groups cannot be manually modified or deleted.

Examples

Display information about all DHCPv6 option groups.

```
<Sysname> display ipv6 dhcp option-group
DHCPv6 option group: 1
  DNS server addresses:
    Type: Static
    Interface: N/A
    1::1
  DNS server addresses:
    Type: Dynamic (DHCPv6 address allocation)
    Interface: GigabitEthernet1/0/1
    1::1

Table 1 Command output

Field	Description
DHCPv6 option group	ID of the DHCPv6 option group.
Type	Types of the DHCPv6 option: • **Static**—Parameter in a static DHCPv6 option group. • **Dynamic (DHCPv6 address allocation)**—Parameter in a dynamic DHCPv6 option group created during IPv6 address acquisition. • **Dynamic (DHCPv6 prefix allocation)**—Parameters in a dynamic DHCPv6 option group created during IPv6 prefix acquisition. • **Dynamic (DHCPv6 address and prefix allocation)**—Parameters in a dynamic DHCPv6 option group created during IPv6 address and prefix acquisition.
Interface	Interface name.
DNS server addresses	IPv6 address of the DNS server.
Domain name	Domain name suffix.
SIP server addresses	IPv6 address of the SIP server.
SIP server domain names	Domain name of the SIP server.
Options	Self-defined options.
Code	Code of the self-defined option.
Length	Self-defined option length in bytes.
Hex	Self-defined option content represented by a hexadecimal number.

display ipv6 dhcp pool

Use **display ipv6 dhcp pool** to display information about a DHCPv6 address pool.

Syntax

display ipv6 dhcp pool [*pool-name* | **vpn-instance** *vpn-instance-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

pool-name: Displays information about the specified DHCPv6 address pool. The pool name is a case-insensitive string of 1 to 63 characters. If you do not specify a DHCPv6 address pool, this command displays information about all DHCPv6 address pools.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays information about DHCPv6 address pools for the public network.

Examples

Display information about DHCPv6 address pool 1.

```
<Sysname> display ipv6 dhcp pool 1
DHCPv6 pool: 1
  Network: 3FFE:501:FFFF:100::/64
    Preferred lifetime 604800 seconds, valid lifetime 2592000 seconds
  Prefix pool: 1
    Preferred lifetime 24000 seconds, valid lifetime 36000 seconds
  Addresses:
    Range: from 3FFE:501:FFFF:100::1
           to 3FFE:501:FFFF:100::99
    Preferred lifetime 70480 seconds, valid lifetime 200000 seconds
    Total address number: 153
    Available: 153
    In-use: 0
  Temporary addresses:
    Range: from 3FFE:501:FFFF:100::200
           to 3FFE:501:FFFF:100::210
    Preferred lifetime 60480 seconds, valid lifetime 259200 seconds
    Total address number: 17
    Available: 17
    In-use: 0
  Static bindings:
    DUID: 0003000100e0fc000001
    IAID: 0000003f
    Prefix: 3FFE:501:FFFF:200::/64
      Preferred lifetime 604800 seconds, valid lifetime 2592000 seconds
    Description: ClientA
    DUID: 0003000100e0fc00cff1
    IAID: 00000001
    Address: 3FFE:501:FFFF:2001::1/64
      Preferred lifetime 604800 seconds, valid lifetime 2592000 seconds
    Description: ClientB
  DNS server addresses:
    2::2
  Domain name:
    aaa.com
  SIP server addresses:
    5::1
  SIP server domain names:
    bbb.com
```

Display information about DHCPv6 address pool 1.

```
<Sysname> display ipv6 dhcp pool 1
DHCPv6 pool: 1
  Network: Not-available
    Preferred lifetime 604800 seconds, valid lifetime 2592000 seconds
```

Display information about DHCPv6 address pool 1.

```
<Sysname> display ipv6 dhcp pool 1
DHCPv6 pool: 1
  Network: 1::/64(Zombie)
    Preferred lifetime 604800 seconds, valid lifetime 2592000 seconds
```

Table 2 Command output

Field	Description
DHCPv6 pool	Name of the DHCPv6 address pool.
Network	IPv6 subnet for dynamic IPv6 address allocation. If the subnet prefix is ineffective, this field displays **Not-available**. If the subnet prefix becomes ineffective after a configuration recovery (for example, a switchover from the backup to the master), the prefix is marked **(Zombie)**.
Prefix pool	Prefix pool referenced by the address pool.
Preferred lifetime	Preferred lifetime in seconds.
valid lifetime	Valid lifetime in seconds.
Addresses	Non-temporary IPv6 address range.
Range	IPv6 address range for dynamic allocation.
Total address number	Total number of IPv6 addresses.
Available	Total number of available IPv6 addresses.
In-use	Total number of assigned IPv6 addresses.
Temporary addresses	Temporary IPv6 address range for dynamic allocation.
Static bindings	Static bindings configured in the address pool.
DUID	Client DUID.
IAID	Client IAID. If no IAID is configured, this field displays **Not configured**.
Prefix	IPv6 address prefix.
Address	Static IPv6 address.
Description	Description of the static binding.
DNS server addresses	DNS server address.
Domain name	Domain name.
SIP server addresses	SIP server address.
SIP server domain names	Domain name of the SIP server.

display ipv6 dhcp prefix-pool

Use **`display ipv6 dhcp prefix-pool`** to display information about a prefix pool.

Syntax

display ipv6 dhcp prefix-pool [*prefix-pool-number*] [**vpn-instance** *vpn-instance-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

prefix-pool-number: Displays detailed information about a prefix pool specified by its number in the range of 1 to 128. If you do not specify a prefix pool, this command displays brief information about all prefix pools.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays information about prefix pools for the public network.

Examples

Display brief information about all prefix pools.

```
<Sysname> display ipv6 dhcp prefix-pool
Prefix-pool Prefix                                  Available In-use Static
1           5::/64                                  64        0      0
```

Display brief information about all prefix pools.

```
<Sysname> display ipv6 dhcp  prefix-pool
Prefix-pool Prefix                                  Available In-use Static
2           Not-available                           0         0      0
```

Display brief information about all prefix pools.

```
<Sysname> display ipv6 dhcp  prefix-pool
Prefix-pool Prefix                                  Available In-use Static
11          21::/112(Zombie)                        0         64     0
```

Display detailed information about prefix pool 1.

```
<Sysname> display ipv6 dhcp prefix-pool 1
Prefix: 5::/64
Assigned length: 70
Total prefix number: 64
Available: 64
In-use: 0
Static: 0
```

Display detailed information about prefix pool 1.

```
<Sysname> display ipv6 dhcp prefix-pool 1
Prefix: Not-available
Assigned length: 70
Total prefix number: 0
Available: 0
In-use: 0
```

```
Static: 0
```

Display detailed information about prefix pool 1.

```
<Sysname> display ipv6 dhcp prefix-pool 1
Prefix: 5::/64(Zombie)
Assigned length: 70
Total prefix number: 10
Available: 0
In-use: 10
Static: 0
```

Table 3 Command output

Field	Description
Prefix-pool	Prefix pool number.
Prefix	Prefix specified in the prefix pool. If the prefix is ineffective, this field displays **Not-available**. If the prefix becomes ineffective after a configuration recovery (for example, a switchover from the backup to the master), the prefix is marked **(Zombie)**.
Available	Number of available prefixes.
In-use	Number of assigned prefixes.
Static	Number of statically bound prefixes.
Assigned length	Length of assigned prefixes.
Total prefix number	Number of prefixes.

display ipv6 dhcp server

Use **display ipv6 dhcp server** to display DHCPv6 server configuration information.

Syntax

display ipv6 dhcp server [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Displays DHCPv6 server configuration information for the specified interface. If you do not specify an interface, this command displays DHCPv6 server configuration information for all interfaces.

Examples

Display DHCPv6 server configuration information for all interfaces.

```
<Sysname> display ipv6 dhcp server
```

```
Interface             Pool
GigabitEthernet1/0/1  1
GigabitEthernet1/0/2  global
```

Display DHCPv6 server configuration information for the interface GigabitEthernet 1/0/1.

```
<Sysname> display ipv6 dhcp server interface gigabitethernet 1/0/1
Using pool: 1
Preference value: 0
Allow-hint: Enabled
Rapid-commit: Disabled
```

Table 4 Command output

Field	Description
Interface	Interface enabled with DHCPv6 server.
Pool	Address pool applied to the interface. If no address pool is applied to the interface, **global** is displayed. The DHCPv6 server selects a global address pool to assign a prefix, an address, and other configuration parameters to a client.
Using pool	Address pool applied to the interface. If no address pool is applied to the interface, **global** is displayed. The DHCPv6 server selects a global address pool to assign a prefix, an address, and other configuration parameters to a client.
Preference value	Server preference in the DHCPv6 Advertise message. The value range is 0 to 255. The bigger the value is, the higher preference the server has.
Allow-hint	Indicates whether desired address/prefix assignment is enabled.
Rapid-commit	Indicates whether rapid address/prefix assignment is enabled.

display ipv6 dhcp server conflict

Use **display ipv6 dhcp server conflict** to display information about IPv6 address conflicts.

Syntax

display ipv6 dhcp server conflict [**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

address *ipv6-address*: Displays conflict information for the specified IPv6 address. If you do not specify an IPv6 address, this command displays information about all IPv6 address conflicts.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays IPv6 address conflict information for the public network.

Usage guidelines

The DHCPv6 server creates IP address conflict information in the following conditions:

- The DHCPv6 client sends a DECLINE packet to the DHCPv6 server to inform the server of an IPv6 address conflict.
- The DHCPv6 server discovers that the only assignable address in the address pool is its own IPv6 address.

Examples

Display information about all address conflicts.

```
<Sysname> display ipv6 dhcp server conflict
IPv6 address                                Detect time
2001::1                                     Apr 25 16:57:20 2019
1::1:2                                      Apr 25 17:00:10 2019
```

Table 5 Command output

Field	Description
IPv6 address	Conflicted IPv6 address.
Detect time	Time when the conflict was discovered.

Related commands

reset ipv6 dhcp server conflict

display ipv6 dhcp server database

Use **display ipv6 dhcp server database** to display information about DHCPv6 binding auto backup.

Syntax

display ipv6 dhcp server database

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display information about DHCPv6 binding auto backup.

```
<Sysname> display ipv6 dhcp server database
 File name               :   database.dhcp
 Username                :
 Password                :
 Update interval         :   600 seconds
```

```
Latest write time       :   Feb  8 16:02:23 2014
Status                  :   Last write succeeded.
```

Table 6 Command output

Field	Description
File name	Name of the DHCPv6 binding backup file.
Username	Username for accessing the URL of the remote backup file.
Password	Password for accessing the URL of the remote backup file. This field displays ********** if a password is configured.
Update interval	Waiting time in seconds after a DHCPv6 binding change for the DHCPv6 server to update the backup file.
Latest write time	Time of the latest update.
Status	Status of the update: • **Writing**—The backup file is being updated. • **Last write succeeded**—The backup file was successfully updated. • **Last write failed**—The backup file failed to be updated.

display ipv6 dhcp server expired

Use **display ipv6 dhcp server expired** to display lease expiration information.

Syntax

display ipv6 dhcp server expired [[**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

address *ipv6-address*: Displays lease expiration information for the specified IPv6 address. If you do not specify an IPv6 address, this command displays lease expiration information for all IPv6 addresses.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays lease expiration information about IPv6 addresses for the public network.

pool *pool-name*: Displays lease expiration information for the DHCPv6 address pool specified by its name, a case-insensitive string of 1 to 63 characters. If you do not specify a DHCPv6 address pool, this command displays lease expiration information for all DHCPv6 address pools.

Usage guidelines

DHCPv6 assigns the expired IPv6 addresses to DHCPv6 clients when all available addresses have been assigned.

Examples

Display all lease expiration information.

```
<Sysname> display ipv6 dhcp server expired
IPv6 address           DUID                          Lease expiration
2001:3eff:fe80:4caa:   3030-3066-2e65-3230-302e-     Apr 25 17:10:47 2019
37ee:7::1              3130-3234-2d45-7468-6572-
                       6e65-7430-2f31
```

Table 7 Command output

Field	Description
IPv6 address	Expired IPv6 address.
DUID	Client DUID bound to the expired IPv6 address.
Lease expiration	Time when the lease expired.

Related commands

reset ipv6 dhcp server expired

display ipv6 dhcp server ip-in-use

Use **display ipv6 dhcp server ip-in-use** to display binding information for assigned IPv6 addresses.

```

Display binding information for the specified IPv6 address.

```
<Sysname> display ipv6 dhcp server ip-in-use address 2:1::3
Pool: 1
Client: FE80::C800:CFF0:FE18:0
Hardware address: 3674-0832-eab3
Type: Auto(O)
DUID: 00030001CA000C180000
IAID: 0x00030001
  IPv6 address: 2:1::3
  Preferred lifetime 400 seconds, valid lifetime 500 seconds
  Expires at Jul 10 09:45:01 2019 (288 seconds left)
```

Table 8 Command output

Field	Description
Pool	DHCPv6 address pool.
IPv6 address	IPv6 address assigned.
Hardware address	Hardware address of a DHCPv6 client. In a network with DHCPv6 relay agent, this field displays **N/A** because the DHCPv6 server cannot obtain the hardware address of the client.

Field	Description
Type	IPv6 address binding types: • **Static(F)**—Free static binding whose IPv6 address has not been assigned. • **Static(O)**—Offered static binding whose IPv6 address has been selected and sent by the DHCPv6 server in a DHCPv6-OFFER packet to the client. • **Static(C)**—Committed static binding whose IPv6 address has been assigned to the client. • **Auto(O)**—Offered dynamic binding whose IPv6 address has been dynamically selected by the DHCPv6 server and sent in a DHCPv6-OFFER packet to the DHCPv6 client. • **Auto(C)**—Committed dynamic binding whose IPv6 address has been dynamically assigned to the DHCPv6 client. • **Auto(Z)**—Zombie dynamic binding whose IPv6 address has been dynamically assigned to the DHCPv6 client. The binding becomes zombie because the subnet prefix goes invalid for address allocation after a configuration recovery, for example, after a switchover from the backup to the master.
Lease-expiration	Time when the lease of the IPv6 address will expire. If the lease expires after the year 2100, this field displays **Expires after 2100**. For an unassigned static binding, this field displays **Not available**.
Client	IPv6 address of the DHCPv6 client. For an unassigned static binding, this field is blank.
DUID	Client DUID.
IAID	Client IAID. For an unassigned static binding without IAID specified, this field displays **N/A**.
Preferred lifetime	Preferred lifetime in seconds of the IPv6 address.
valid lifetime	Valid lifetime in seconds of the IPv6 address.
Expires at	Time when the lease of an IPv6 address will expire. If the lease expires after the year 2100, this field displays **Expires after 2100**.

Parameters

pool *pool-name*: Displays IPv6 prefix binding information for the DHCPv6 address pool specified by its name, a case-insensitive string of 1 to 63 characters. If you do not specify a DHCPv6 address pool, this command displays IPv6 prefix binding information for all DHCPv6 address pools.

prefix *prefix/prefix-len*: Displays binding information for the specified IPv6 prefix. The value range for the prefix length is 1 to 128. If you do not specify an IPv6 prefix, this command displays binding information for all IPv6 prefixes.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays binding information about IPv6 prefixes for the public network.

Examples

Display all IPv6 prefix binding information.

```
<Sysname> display ipv6 dhcp server pd-in-use
Pool: 1
 IPv6 prefix             Hardware address     Type      Lease expiration
 2:1::/24                0125-0354-aab2       Auto(O)   Jul 10 19:45:01 2019
Pool: 2
 IPv6 prefix             Hardware address     Type      Lease expiration

IAID: 0x00030001
  IPv6 prefix: 2:1::/24
   Preferred lifetime 400 seconds, valid lifetime 500 seconds
  Expires at Jul 10 09:45:01 2019 (288 seconds left)
```

Table 9 Command output

Field	Description
IPv6 prefix	IPv6 prefix assigned.

Field	Description
Hardware address	Hardware address of a DHCPv6 client. In a network with DHCPv6 relay agent, this field displays **N/A** because the DHCPv6 server cannot obtain the hardware address of the client.
Type	Prefix binding types: • **Static(F)**—Free static binding whose IPv6 prefix has not been assigned. • **Static(O)**—Offered static binding whose IPv6 prefix has been selected and sent by the DHCPv6 server in a DHCPv6-OFFER packet to the client. • **Static(C)**—Committed static binding whose IPv6 prefix has been assigned to the client. • **Auto(O)**—Offered dynamic binding whose IPv6 prefix has been dynamically selected by the DHCPv6 server and sent in a DHCPv6-OFFER packet to the DHCPv6 client. • **Auto(C)**—Committed dynamic binding whose IPv6 prefix has been dynamically assigned to the DHCPv6 client. • **Auto(Z)**—Zombie dynamic binding whose IPv6 prefix has been dynamically assigned to the DHCPv6 client. The binding becomes zombie because the prefix in the prefix pool goes invalid after a configuration recovery, for example, after a switchover from the backup to the master.
Pool	Address pool.
Lease-expiration	Time when the lease of the IPv6 prefix will expire. If the lease will expire after the year 2100, this field displays **Expires after 2100**. For an unassigned static binding, this field displays **Not available**.
Client	IPv6 address of the DHCPv6 client. For an unassigned static binding, this field is blank.
DUID	Client DUID.
IAID	Client IAID. For an unassigned static binding without IAID, this field displays **N/A**.
Preferred lifetime	Preferred lifetime in seconds of the IPv6 prefix.
valid lifetime	Valid lifetime in seconds of the IPv6 prefix.
Expires at	Time when the lease of the prefix will expire. If the lease expires after the year 2100, this field displays **Expires after 2100**.

Related commands

reset ipv6 dhcp server pd-in-use

display ipv6 dhcp server statistics

Use **display ipv6 dhcp server statistics to** display DHCPv6 packet statistics on the DHCPv6 server.

Syntax

display ipv6 dhcp server statistics [**pool** *pool-name* | **vpn-instance** *vpn-instance-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

pool *pool-name*: Displays DHCPv6 packet statistics for the DHCPv6 address pool specified by its name, a case-insensitive string of 1 to 63 characters. If you do not specify an address pool, this command displays DHCPv6 packet statistics for all address pools.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays DHCPv6 server statistics for the public network.

Examples

Display all DHCPv6 packet statistics on the DHCPv6 server.

```
<Sysname> display ipv6 dhcp server statistics
Bindings:
    Ip-in-use               :  1
    Pd-in-use               :  0
    Expired                 :  0
Conflict                    :  0
Packets received            :  1
    Solicit                 :  1
    Request                 :  0
    Confirm                 :  0
    Renew                   :  0
    Rebind                  :  0
    Release                 :  0
    Decline                 :  0
    Information-request     :  0
    Relay-forward           :  0
Packets dropped             :  0
Packets sent                :  0
    Advertise               :  0
    Reconfigure             :  0
    Reply                   :  0
    Relay-reply             :  0
```

Table 10 Command output

Field	Description
Bindings	Number of bindings: • **Ip-in-use**—Total number of address bindings. • **Pd-in-use**—Total number of prefix bindings. • **Expired**—Total number of expired address bindings.
Conflict	Total number of conflicted addresses. If statistics about an address pool are displayed, this field is not displayed.

Field	Description
Packets received	Number of messages received by the DHCPv6 server. The message types include: • Solicit. • Request. • Confirm. • Renew. • Rebind. • Release. • Decline. • Information-request. • Relay-forward. If statistics about an address pool are displayed, this field is not displayed.
Packets dropped	Number of packets discarded. If statistics about an address pool are displayed, this field is not displayed.
Packets sent	Number of messages sent by the DHCPv6 server. The message types include: • Advertise. • Reconfigure. • Reply. • Relay-reply. If statistics about an address pool are displayed, this field is not displayed.

Related commands

`reset ipv6 dhcp server statistics`

dns-server

Use **`dns-server`** to specify a DNS server in a DHCPv6 address pool.

Use **`undo dns-server`** to remove the specified DNS server from a DHCPv6 address pool.

Syntax

`dns-server` *`ipv6-address`*

`undo dns-server` *`ipv6-address`*

Default

No DNS server address is specified.

Views

DHCPv6 address pool view

DHCPv6 option group view

Predefined user roles

network-admin

context-admin

Parameters

`ipv6-address`: Specifies the IPv6 address of a DNS server.

Usage guidelines

You can use the **dns-server** command to specify up to eight DNS servers in an address pool. A DNS server specified earlier has a higher preference.

Examples

Specify the DNS server address 2:2::3 in DHCPv6 address pool 1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] dns-server 2:2::3
```

Related commands

display ipv6 dhcp pool

domain-name

Use **domain-name** to specify a domain name in a DHCPv6 address pool.

Use **undo domain-name** to restore the default.

Syntax

domain-name *domain-name*

undo domain-name

Default

No domain name is specified.

Views

DHCPv6 address pool view

DHCPv6 option group view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a domain name, a case-sensitive string of 1 to 50 characters.

Usage guidelines

You can configure only one domain name in an address pool. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the domain name **aaa.com** in DHCPv6 address pool 1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] domain-name aaa.com
```

Related commands

display ipv6 dhcp pool

if-match

Use **if-match** to configure a match rule for a DHCPv6 user class.

Use **undo if-match** to delete a match rule for a DHCP user class.

Syntax

if-match rule *rule-number* { **option** *option-code* [**ascii** *ascii-string* [**offset** *offset* | **partial**] | **hex** *hex-string* [**mask** *mask* | **offset** *offset* **length** *length* | **partial**]] | **relay-agent** *gateway-ipv6-address* }

undo if-match rule *rule-number*

Default

No match rules are configured for the DHCPv6 user class.

Views

DHCPv6 user class view

Predefined user roles

network-admin

context-admin

Parameters

rule *rule-number*: Assigns the match rule an ID in the range of 1 to 128. A smaller ID represents a higher match priority.

option *option-code*: Specifies a DHCPv6 option by its number in the range of 1 to 65535.

ascii *ascii-string*: Specifies an ASCII string of 1 to 128 characters.

offset *offset*: Specifies the offset in bytes after which the match operation starts. The value range is 0 to 65534. If you specify an ASCII string, a packet matches the rule if the option content after the offset is the same as the ASCII string. If you specify a hexadecimal number, a packet matches the rule if the option content of the specified length after the offset is the same as the hexadecimal number.

partial: Enables partial match. A packet matches the rule if the specified option in the packet contains the ASCII string or hexadecimal number specified in the rule. For example, if you specify **abc** in the rule, option content **xabc**, **xyzabca**, **xabcyz**, and **abcxyz** all match the rule.

hex *hex-string*: Specifies a hexadecimal number. The length of the hexadecimal number must be an even number in the range of 2 to 256.

mask *mask*: Specifies the mask for the match operation. The mask is a hexadecimal number whose length is an even number in the range of 2 to 256 and must be the same as the *hex-string* length. The DHCPv6 server selects option content of the mask length from the start and ANDs the selected option content and the specified hexadecimal number with the mask. The packet matches the rule if the two AND operation results are the same.

length *length*: Specifies the length of the option content to be matched, in the range of 1 to 128 bytes. The length must be the same as the *hex-string* length.

relay-agent *gateway-ipv6-address*: Specifies a **link-address** field value. The value is an IPv6 address. A packet matches the rule if its **link-address** field value is the same as that in the rule.

Usage guidelines

If a DHCPv6 request sent by a DHCPv6 client matches a rule in a DHCPv6 user class, the DHCPv6 client matches the user class.

You can configure multiple match rules for a DHCPv6 user class. Each match rule is uniquely identified by a rule ID within its type (option or relay agent address).

- If the rule that you are configuring has the same ID and type as an existing rule, the new rule overwrites the existing rule.

- If the rule that you are configuring has the same ID as an existing rule but a different type, the new rule takes effect and coexists with the existing rule. As a best practice, do not assign the same ID to rules of different types.
- Rules of different IDs cannot have the same rule content.

When you configure an **if-match option** rule, follow these guidelines:

- To match packets that contain an option, specify only the *option-code* argument.
- To match a hexadecimal number by AND operations, specify the **option** *option-code* **hex** *hex-string* **mask** *mask* options.
- To match a hexadecimal number directly, specify the **option** *option-code* **hex** *hex-string* [**offset** *offset* **length** *length* | **partial**] options. If you do not specify the **offset**, **length**, or **partial** parameter, a packet matches a rule if the option content starts with the hexadecimal number.
- To match an ASCII string, specify the **option** *option-code* **ascii** *ascii-string* [**offset** *offset* | **partial**] options. If you do not specify the **offset** or **partial** parameter, a packet matches a rule if the option content starts with the ASCII string.

Examples

Configure match rule **1** for the DHCPv6 user class **exam** to match DHCPv6 requests that contain Option 16.

```
<Sysname> system-view
[Sysname] ipv6 dhcp class exam
[Sysname-dhcp6-class-exam] if-match rule 1 option 16
```

Configure match rule **2** for the DHCPv6 user class **exam**. The rule matches DHCPv6 requests in which the highest bit of the fourth byte in Option 16 is the hexadecimal number **1**.

```
<Sysname> system-view
[Sysname] ipv6 dhcp class exam
[Sysname-dhcp6-class-exam] if-match rule 2 option 16 hex 00000080 mask 00000080
```

Configure match rule **3** for the DHCPv6 user class **exam**. The rule matches DHCPv6 requests in which the first three bytes of Option 16 are the hexadecimal number **13ae92**.

```
<Sysname> system-view
[Sysname] ipv6 dhcp class exam
[Sysname-dhcp6-class-exam] if-match rule 3 option 16 hex 13ae92 offset 0 length 3
```

Configure match rule **4** for the DHCPv6 user class **exam**. The rule matches DHCPv6 requests in which the Option 16 contains the hexadecimal number **13ae**.

```
<Sysname> system-view
[Sysname] ipv6 dhcp class exam
[Sysname-dhcp6-class-exam] if-match rule 5 option 16 hex 13ae partial
```

Configure match rule **5** for the DHCPv6 user class **exam** to match DHCPv6 requests in which the **link-address** field is 2001::1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp class exam
[Sysname-dhcp6-class-exam] if-match rule 5 relay-agent 2001::1
```

Related commands

ipv6 dhcp class

ipv6 dhcp apply-policy

Use **ipv6 dhcp apply-policy** to apply a DHCPv6 policy to an interface.

Use **undo ipv6 dhcp apply-policy** to restore the default.

Syntax

ipv6 dhcp apply-policy *policy-name*

undo ipv6 dhcp apply-policy

Default

No DHCPv6 policy is applied to an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies a DHCPv6 policy by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

You can apply only one DHCPv6 policy to an interface. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Apply the DHCPv6 policy **test** to GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 dhcp apply-policy test
```

ipv6 dhcp option-group

Use **ipv6 dhcp option-group** to create a static DHCPv6 option group and enter its view.

Use **undo ipv6 dhcp option-group** to delete the specified static DHCPv6 option group.

Syntax

ipv6 dhcp option-group *option-group-number*

undo ipv6 dhcp option-group *option-group-number*

Default

No static DHCPv6 option groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

option-group-number: Assigns an ID to the static option group, in the range of 1 to 100.

Usage guidelines

A static DHCPv6 option group can use the same ID as a dynamic DHCPv6 option group. If a static DHCPv6 option group and a dynamic DHCPv6 option group use the same ID, the static one takes precedence over the dynamic one.

Examples

Create static DHCPv6 option group 1 and enter its view.

```
<Sysname> system-view
[Sysname] ipv6 dhcp option-group 1
[Sysname-dhcp6-option-group-1]
```

Related commands

display ipv6 dhcp option-group

ipv6 dhcp policy

Use **ipv6 dhcp policy** to create a DHCPv6 policy and enter its view, or enter the view of an existing DHCPv6 policy.

Use **undo ipv6 dhcp policy** to delete a DHCPv6 policy.

Syntax

ipv6 dhcp policy *policy-name*

undo ipv6 dhcp policy *policy-name*

Default

No DHCPv6 policies exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Assigns a name to the DHCPv6 policy. The policy name is a case-insensitive string of 1 to 63 characters.

Usage guidelines

In DHCP policy view, you can specify address pools for different user classes. Clients matching a user class will obtain IPv6 addresses and other parameters from the specified address pool.

For a DHCPv6 policy to take effect, you must apply it to an interface.

Examples

Create DHCPv6 policy **test** and enter its view.

```
<Sysname> system-view
[Sysname] ipv6 dhcp policy test
[Sysname-dhcp6-policy-test]
```

ipv6 dhcp pool

Use **ipv6 dhcp pool** to create a DHCPv6 address pool and enter its view, or enter the view of an existing DHCPv6 address pool.

Use **undo ipv6 dhcp pool** to delete the specified DHCPv6 address pool.

Syntax

ipv6 dhcp pool *pool-name*

undo ipv6 dhcp pool *pool-name*

Default

No DHCPv6 address pools exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

pool-name: Specifies a name for the DHCPv6 address pool, a case-insensitive string of 1 to 63 characters.

Usage guidelines

A DHCPv6 address pool stores IPv6 address/prefix and other configuration parameters to be assigned to DHCPv6 clients.

When you delete a DHCPv6 address pool, binding information for the assigned IPv6 addresses and prefixes in the address pool is also deleted.

Examples

Create a DHCPv6 address pool named **pool1** and enter its view.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool pool1
[Sysname-dhcp6-pool-pool1]
```

Related commands

class pool

display ipv6 dhcp pool

ipv6 dhcp server apply pool

ipv6 dhcp prefix-pool

Use **ipv6 dhcp prefix-pool** to create a prefix pool and specify the prefix and the assigned prefix length for the pool.

Use **undo ipv6 dhcp prefix-pool** to delete the specified prefix pool.

Syntax

ipv6 dhcp prefix-pool *prefix-pool-number* **prefix** { *prefix-number* | *prefix/prefix-len* } **assign-len** *assign-len* [**vpn-instance** *vpn-instance-name*]

undo ipv6 dhcp prefix-pool *prefix-pool-number* [**vpn-instance** *vpn-instance-name*]

Default

No prefix pools exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

prefix-pool-number: Specifies a prefix pool number in the range of 1 to 128.

prefix { *prefix-number* | *prefix/prefix-len* }: Specifies a prefix by its ID or in the format of *prefix*/*prefix length*. The value range for the *prefix-number* argument is 1 to 1024. The value range for the *prefix-len* argument is 1 to 128.

assign-len *assign-len*: Specifies the assigned prefix length. The value range is 1 to 128, and the value must be greater than or equal to *prefix-len*. The difference between *assign-len* and *prefix-len* must be no more than 16.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. To create a prefix pool for the public network, do not specify this option.

Usage guidelines

Different prefix pools cannot overlap.

To modify a prefix pool, execute the **undo ipv6 dhcp prefix-pool** command to delete the prefix pool, and then execute the **ipv6 dhcp prefix-pool** command.

Deleting a prefix pool clears all prefix bindings from the prefix pool.

When you specify a prefix by its ID, follow these restrictions and guidelines:

- This command does not take effect if the prefix does not exist. This command takes effect after the prefix is created.
- Do not specify the same prefix for different prefix pools in a VPN.
- If the prefix that the ID represents is changed, the prefix range in the prefix pool accordingly changes.

Examples

Create IPv6 prefix 88:99::/32 with ID 3. Configure prefix pool 2 with IPv6 prefix 3 and an assigned prefix length of 42. Prefix pool 2 contains 1024 prefixes from 88:99::/42 to 88:99:FFC0::/42.

```
<Sysname> system-view
[Sysname] ipv6 prefix 3 88:99::/32
[Sysname] ipv6 dhcp prefix-pool 2 prefix 3 assign-len 42
```

Create prefix pool 1, and specify prefix 2001:0410::/32 with an assigned prefix length of 42. Prefix pool 1 contains 1024 prefixes from 2001:0410::/42 to 2001:0410:FFC0::/42.

```
<Sysname> system-view
[Sysname] ipv6 dhcp prefix-pool 1 prefix 2001:0410::/32 assign-len 42
```

Related commands

display ipv6 dhcp prefix-pool

prefix-pool

ipv6 dhcp server

Use **ipv6 dhcp server** to configure global address assignment on an interface. The server on the interface uses a global address pool to assign configuration information to a client.

Use **undo ipv6 dhcp server** to restore the default.

Syntax

ipv6 dhcp server { **allow-hint** | **preference** *preference-value* | **rapid-commit** } *

undo ipv6 dhcp server

Default

The server supports global address assignment on an interface, but does not support desired address/prefix assignment or rapid address/prefix assignment. No server preference is set.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

allow-hint: Enables desired address/prefix assignment.

preference *preference-value*: Specifies the server preference in Advertise messages, in the range of 0 to 255. A greater value represents a higher preference.

rapid-commit: Enables rapid address/prefix assignment involving two messages.

Usage guidelines

The **allow-hint** keyword enables the server to assign the desired address or prefix to the requesting client. If the desired address or prefix is not included in any global address pool, or is already assigned to another client, the server assigns the client a free address or a prefix. If the **allow-hint** keyword is not specified, the server ignores the desired address or prefix, and selects an address or prefix from a global address pool.

If you use the **ipv6 dhcp server** and **ipv6 dhcp server apply pool** commands on the same interface, the **ipv6 dhcp server apply pool** command takes effect.

Examples

Configure global address assignment on the interface GigabitEthernet 1/0/1. Use the desired address/prefix assignment and rapid address/prefix assignment, and set the server preference to the highest 255.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 dhcp server allow-hint preference 255 rapid-commit
```

Related commands

display ipv6 dhcp server

ipv6 dhcp select

ipv6 dhcp server apply pool

Use **ipv6 dhcp server apply pool** to apply a DHCPv6 address pool to an interface.

Use **undo ipv6 dhcp server apply pool** to restore the default.

Syntax

ipv6 dhcp server apply pool *pool-name* [**allow-hint** | **preference** *preference-value* | **rapid-commit**] *

undo ipv6 dhcp server apply pool

Default

No DHCPv6 address pool is applied to an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

pool-name: Specifies a DHCPv6 address pool by its name, a case-insensitive string of 1 to 63 characters.

allow-hint: Enables desired address/prefix assignment.

preference *preference-value*: Specifies the server preference in Advertise messages, in the range of 0 to 255. A greater value represents a higher preference. By default, no server preference is set.

rapid-commit: Enables rapid address/prefix assignment involving two messages.

Usage guidelines

Upon receiving a DHCPv6 request, the DHCPv6 server selects an IPv6 address or prefix from the address pool applied to the receiving interface. If no address pool is applied, the server selects an IPv6 address or prefix from a global address pool that matches the IPv6 address of the receiving interface or the DHCPv6 relay agent.

The **allow-hint** keyword enables the server to assign the desired address or prefix to the client. If the desired address or prefix does not exist or is already assigned to another client, the server assigns a free address or prefix. If **allow-hint** is not specified, the server ignores the desired address or prefix, and assigns a free address or prefix.

Only one address pool can be applied to an interface. If you execute this command multiple times, the most recent configuration takes effect.

A non-existing address pool can be applied to an interface, but the server cannot assign any prefix, address, or other configuration information from the address pool until the address pool is created.

Examples

Apply address pool 1 to GigabitEthernet 1/0/1, configure the address pool to support desired address/prefix assignment and address/prefix rapid assignment, and set the preference to 255.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 dhcp server apply pool 1 allow-hint preference 255
rapid-commit
```

Related commands

display ipv6 dhcp server

ipv6 dhcp pool

ipv6 dhcp select

ipv6 dhcp server database filename

Use **ipv6 dhcp server database filename** to configure the DHCPv6 server to back up the DHCPv6 bindings to a file.

Use **undo ipv6 dhcp server database filename** to restore the default.

Syntax

ipv6 dhcp server database filename { *filename* | **url** *url* [**username** *username* [**password** { **cipher** | **simple** } *string*]] }

undo ipv6 dhcp server database filename

Default

The DHCPv6 server does not back up the DHCPv6 bindings.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

filename: Specifies the name of a local backup file. For information about the *filename* argument, see *Fundamentals Configuration Guide*.

url *url*: Specifies the URL of a remote backup file. The URL is a case-sensitive string of 1 to 255 characters. Do not include a username or password in the URL.

username *username*: Specifies the username for accessing the URL of the remote backup file, a case-sensitive string of 1 to 32 characters. Do not specify this option if a username is not required for accessing the URL of the remote backup file.

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 32 characters. Its encrypted form is a case-sensitive string of 1 to 73 characters. Do not specify this argument if a password is not required for accessing the URL of the remote backup file.

Usage guidelines

The command automatically creates the file if you specify a nonexistent file.

With this command executed, the DHCPv6 server backs up its bindings immediately and runs auto backup. The server, by default, waits 300 seconds after a binding change to update the backup file. You can use the **ipv6 dhcp server database update interval** command to change the waiting time. If no DHCPv6 binding changes, the backup file is not updated.

As a best practice, back up the bindings to a remote file. If you use the local storage medium, the frequent erasing and writing might damage the medium and then cause the DHCPv6 server to malfunction.

When the backup file is on a remote device, follow these restrictions and guidelines to specify the URL, username, and password:

- If the file is on an FTP server, enter URL in the format of ftp:*//server address:port/file path*, where the port number is optional.
- If the file is on a TFTP server, enter URL in the format of tftp:*//server address:port/file path*, where the port number is optional.
- The username and password must be the same as those configured on the FTP server. If the server authenticates only the username, the password can be omitted.
- If the IP address of the server is an IPv6 address, enclose the address in a pair of brackets, for example, **ftp://[1::1]/database.dhcp**.
- You can also specify the DNS domain name for the server address field, for example, **ftp://company/database.dhcp**.

Examples

Configure the DHCPv6 server to back up its bindings to the file **database.dhcp**

```
<Sysname> system-view
[Sysname] ipv6 dhcp server database filename database.dhcp
```

Configure the DHCPv6 server to back up its bindings to the file **database.dhcp** in the working directory of the FTP server at 10::1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp server database filename url ftp://[10::1]/database.dhcp username 1
password simple 1
```

Related commands

ipv6 dhcp server database update interval

ipv6 dhcp server database update now

ipv6 dhcp server database update stop

ipv6 dhcp server database update interval

Use **ipv6 dhcp server database update interval** to set the waiting time for the DHCPv6 server to update the backup file after a DHCPv6 binding change.

Use **undo ipv6 dhcp server database update interval** to restore the default.

Syntax

ipv6 dhcp server database update interval *interval*

undo ipv6 dhcp server database update interval

Default

The DHCPv6 server waits 300 seconds to update the backup file after a DHCPv6 binding change. If no DHCPv6 binding changes, the backup file is not updated.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Sets the waiting time in the range of 60 to 864000 seconds.

Usage guidelines

When a DHCPv6 binding is created, updated, or removed, the waiting period starts. The DHCPv6 server updates the backup file when the waiting period is reached. All bindings changed during the period will be saved to the backup file.

The waiting time takes effect only after you configure the DHCPv6 binding auto backup by using the **ipv6 dhcp server database filename** command.

Examples

Set the waiting time to 600 seconds for the DHCPv6 server to update the backup file.

```
<Sysname> system-view
[Sysname] ipv6 dhcp server database update interval 600
```

Use **ipv6 dhcp server database update now** to manually save the DHCPv6 bindings to the backup file.

Syntax

ipv6 dhcp server database update now

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Each time this command is executed, the DHCPv6 bindings are saved to the backup file.

For this command to take effect, you must configure the DHCPv6 auto backup by using the **ipv6 dhcp server database filename** command.

Examples

Manually save the DHCPv6 bindings to the backup file.

```
<Sysname> system-view
[Sysname] ipv6 dhcp server database update now
```

Related commands

ipv6 dhcp server database filename

ipv6 dhcp server database update interval

ipv6 dhcp server database update stop

ipv6 dhcp server database update stop

Use **ipv6 dhcp server database update stop** to terminate the download of DHCPv6 bindings from the backup file.

Syntax

ipv6 dhcp server database update stop

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The DHCPv6 server does not provide services during the binding download process. If the connection breaks up during the process, the waiting timeout timer is 60 minutes. When the timer expires, the DHCPv6 server stops waiting and starts providing address allocation services. You can execute this command to terminate the download immediately.

Manual termination allows the DHCPv6 server to provide services without waiting for the connection to be repaired. The IPv6 addresses and prefixes associated with the undownloaded bindings will be assigned to clients and address conflicts might occur.

Examples

Terminate the download of the backup DHCPv6 bindings.

```
<Sysname> system-view
[Sysname] ipv6 dhcp server database update stop
```

ipv6 dhcp server forbidden-address

Use **ipv6 dhcp server forbidden-address** to exclude IPv6 addresses in the DHCPv6 address pool from dynamic allocation.

Use **undo ipv6 dhcp server forbidden-address** to remove the configuration.

Syntax

ipv6 dhcp server forbidden-address *start-ipv6-address* [*end-ipv6-address*] [**vpn-instance** *vpn-instance-name*]

undo ipv6 dhcp server forbidden-address *start-ipv6-address* [*end-ipv6-address*] [**vpn-instance** *vpn-instance-name*]

Default

Except for the DHCPv6 server address, all IPv6 addresses in a DHCPv6 address pool are assignable.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

start-ipv6-address: Specifies the start IPv6 address.

end-ipv6-address: Specifies the end IPv6 address, which cannot be lower than *start-ipv6-address*. If you do not specify an end IPv6 address, only the start IPv6 address is excluded from dynamic allocation. If you specify an end IPv6 address, the IP addresses from *start-ipv6-address* through *end-ipv6-address* are all excluded from dynamic allocation.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If the excluded IPv6 addresses belong to the public network, do not specify this option.

Usage guidelines

The IPv6 addresses of some devices such as the gateway and FTP server cannot be assigned to clients. Use this command to exclude such addresses from dynamic allocation.

If the excluded IPv6 address is in a static DHCPv6 binding, the address can still be assigned to the client.

The address or address range specified in the **undo** form of the command must be the same as the address or address range specified in the command. To remove an IP address that has been specified as part of an address range, you must remove the entire address range.

You can execute this command multiple times to exclude multiple IPv6 address ranges from dynamic allocation.

Examples

Exclude IPv6 addresses of 2001:10:110::1 through 2001:10:110::20 from dynamic assignment.

```
<Sysname> system-view
[Sysname] ipv6 dhcp server forbidden-address 2001:10:110::1 2001:10:110::20
```

Related commands

ipv6 dhcp server forbidden-prefix

static-bind

ipv6 dhcp server forbidden-prefix

Use **ipv6 dhcp server forbidden-prefix** to exclude IPv6 prefixes in the DHCPv6 prefix pool from dynamic allocation.

Use **undo ipv6 dhcp server forbidden-prefix** to remove the configuration.

Syntax

ipv6 dhcp server forbidden-prefix *start-prefix/prefix-len* [*end-prefix/prefix-len*] [**vpn-instance** *vpn-instance-name*]

undo ipv6 dhcp server forbidden-prefix *start-prefix/prefix-len* [*end-prefix/prefix-len*] [**vpn-instance** *vpn-instance-name*]

Default

No IPv6 prefixes in the DHCPv6 prefix pool are excluded from dynamic allocation.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

start-prefix/prefix-len: Specifies the start IPv6 prefix. The *prefix-len* argument specifies the prefix length in the range of 1 to 128.

end-prefix/prefix-len: Specifies the end IPv6 prefix. The *prefix-len* argument specifies the prefix length in the range of 1 to 128. The value for *end-prefix* cannot be lower than that for *start-prefix*. If you do not specify this argument, only the *start-prefix/prefix-len* is excluded from dynamic allocation. If you specify this argument, the prefixes from *start-prefix/prefix-len* to *end-prefix/prefix-len* are all excluded.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If the excluded IPv6 prefixes belong to the public network, do not specify this option.

Usage guidelines

If the excluded IPv6 prefix is in a static binding, the prefix can still be assigned to the client.

The prefix or prefix range specified in the **undo** form of the command must be the same as the prefix or prefix range specified in the command. To remove a prefix that has been specified as part of a prefix range, you must remove the entire prefix range.

You can execute this command multiple times to exclude multiple IPv6 prefix ranges from dynamic allocation.

Examples

Exclude IPv6 prefixes from 2001:3e11::/32 through 2001:3eff::/32 from dynamic allocation.

```
<Sysname> system-view
[Sysname] ipv6 dhcp server forbidden-prefix 2001:3e11::/32 2001:3eff::/32
```

Related commands

ipv6 dhcp server forbidden-address

static-bind

network

Use **network** to specify an IPv6 subnet for dynamic allocation in a DHCPv6 address pool.

Use **undo network** to restore the default.

Syntax

network { *prefix/prefix-length* | **prefix** *prefix-number* [*sub-prefix/sub-prefix-length*] } [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*] [**export-route**]

undo network

Default

No IPv6 subnet is specified in a DHCPv6 address pool.

Views

DHCPv6 address pool view

Predefined user roles

network-admin

context-admin

Parameters

prefix/prefix-length: Specifies the IPv6 subnet for dynamic allocation. The value range for the *prefix-length* argument is 1 to 128.

prefix *prefix-number*: Specifies an IPv6 prefix by its ID in the range of 1 to 1024.

sub-prefix/*sub-prefix-length*: Specifies an IPv6 sub-prefix and its length. The value range for the *sub-prefix-length* argument is 1 to 128. If the IPv6 prefix is longer than the IPv6 sub-prefix or if you do not specify an IPv6 sub-prefix, the IPv6 subnet defined by the IPv6 prefix is used for dynamic allocation.

preferred-lifetime *preferred-lifetime*: Sets the preferred lifetime. The value range is 60 to 4294967295 seconds, and the default is 604800 seconds (7 days).

valid-lifetime *valid-lifetime*: Sets the valid lifetime. The value range is 60 to 4294967295 seconds, and the default is 2592000 seconds (30 days). The valid lifetime must be longer than or equal to the preferred lifetime.

export-route: Advertises the subnet assigned to DHCPv6 clients. If you do not specify this keyword, the subnet will not be advertised.

Usage guidelines

You can specify only one subnet for a DHCPv6 address pool. If you execute the **network** command multiple times, the most recent configuration takes effect.

Modifying or removing the **network** command configuration removes assigned addresses in the current address pool.

If you execute the **network export-route** command multiple times, the most recent configuration takes effect.

The **network prefix** command does not take effect if the specified IPv6 prefix does not exist. This command takes effect after the IPv6 prefix is created.

The **network** command defines the IPv6 subnet for dynamic allocation through the *prefix/prefix-length* arguments or the *prefix-number* [*sub-prefix*/*sub-prefix-length*] arguments. The IPv6 subnets cannot be the same in different DHCPv6 address pools.

If the prefix that the ID represents is changed, the IPv6 subnet in this command accordingly changes, and the assigned prefix and address bindings are cleared.

Examples

Specify the subnet 3ffe:501:ffff:100::/64 in DHCPv6 address pool 1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] network 3ffe:501:ffff:100::/64
```

Create IPv6 prefix 88:99::/32 with the prefix ID 3. Create DHCPv6 address pool 1 and use the IPv6 subnet defined by the IPv6 prefix for dynamic allocation.

```
<Sysname> system-view
[Sysname] ipv6 prefix 3 88:99::/32
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] network prefix 3
```

Create IPv6 prefix 88:99::/32 with the prefix ID 3. Create DHCPv6 address pool 1 and use IPv6 subnet 88:99:ffff:100::/64 defined by IPv6 prefix 3 and IPv6 sub-prefix 3ffe:501:ffff:100::/64 for dynamic allocation. The first 32 bits of the IPv6 subnet are determined by IPv6 prefix 3. The bits 33 to 64 of the IPv6 subnet are determined by the IPv6 sub-prefix and its length. The prefix length of the IPv6 subnet is the IPv6 sub-prefix length.

```
<Sysname> system-view
```

```
[Sysname] ipv6 prefix 3 88:99::/32
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] network prefix 3 3ffe:501:ffff:100::/64
```

option

Use **option** to configure a self-defined DHCPv6 option in a DHCPv6 address pool.

Use **undo option** to remove a self-defined DHCPv6 option from a DHCPv6 address pool.

Syntax

option *code* **hex** *hex-string*

undo option *code*

Default

No self-defined DHCPv6 option is configured in a DHCPv6 address pool.

Views

DHCPv6 address pool view

DHCPv6 option group view

Predefined user roles

network-admin

context-admin

Parameters

code: Specifies a number for the self-defined option, in the range of 21 to 65535, excluding 25 through 26, 37 through 40, and 43 through 48.

hex *hex-string*: Specifies the content of the option, a hexadecimal number whose length is an even number in the range of 2 to 256.

Usage guidelines

The DHCPv6 server fills the self-defined option with the specified hexadecimal number and sends it in a response to the client.

You can self-define options for the following purposes:

- Add newly released options.
- Add options for which the vendor defines the contents, for example, Option 43.
- Add options for which the CLI does not provide a dedicated configuration command like **dns-server**. For example, you can use the **option 31 hex 02000000000000000000000000000001** command to define the NTP server address 200::1 for DHCP clients.

If a DHCPv6 option is specified by both the dedicated command and the **option** command, the DHCPv6 server preferentially assigns the content specified by the dedicated command. For example, if a DNS server address is specified by the **dns-server** command and the **option 23** command, the server uses the address specified by **dns-server** command.

If you execute this command multiple times with the same *code* specified, the most recent configuration takes effect.

Examples

Configure Option 23 that specifies a DNS server address 2001:f3e0::1 in DHCPv6 address pool 1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] option 23 hex 2001f3e000000000000000000000001
```

option-group

Use **option-group** to specify a DHCPv6 option group for a DHCPv6 address pool.

Use **undo option-group** to restore the default.

Syntax

option-group *option-group-number*

undo option-group

Default

No DHCPv6 option group is specified for a DHCPv6 address pool.

Views

DHCPv6 address pool view

Predefined user roles

network-admin

context-admin

Parameters

option-group--number: Specifies a DHCPv6 option group by its number in the range of 1 to 100.

Examples

Specify DHCPv6 option group 1 for DHCPv6 address pool 1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] option-group 1
```

Related commands

display ipv6 dhcp pool

ipv6 dhcp option-group

prefix-pool

Use **prefix-pool** to apply a prefix pool to a DHCPv6 address pool, so the DHCPv6 server can dynamically select a prefix from the prefix pool for a client.

Use **undo prefix-pool** to remove the prefix pool.

Syntax

prefix-pool *prefix-pool-number* [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

undo prefix-pool *prefix-pool-number*

Default

No prefix pool is applied to a DHCPv6 address pool.

Views

DHCPv6 address pool view

Predefined user roles

network-admin

context-admin

Parameters

prefix-pool-number: Specifies a prefix pool by its number in the range of 1 to 128.

preferred-lifetime *preferred-lifetime*: Sets the preferred lifetime in the range of 60 to 4294967295 seconds. The default value is 604800 seconds (7 days).

valid-lifetime *valid-lifetime*: Sets the valid lifetime in the range of 60 to 4294967295 seconds. The default value is 2592000 seconds (30 days). The valid lifetime must be longer than or equal to the preferred lifetime.

Usage guidelines

Only one prefix pool can be applied to an address pool.

You can apply a prefix pool that has not been created to an address pool. The setting takes effect after the prefix pool is created.

To modify the prefix pool in a DHCPv6 address pool, execute the **undo prefix-pool** command to remove the prefix pool, and then execute the **prefix-pool** command.

Examples

Apply prefix pool 1 to address pool 1, and use the default preferred lifetime and valid lifetime.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] prefix-pool 1
```

Apply prefix pool 2 to address pool 2, and set the preferred lifetime to one day and the valid lifetime to three days.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 2
[Sysname-dhcp6-pool-2] prefix-pool 2 preferred-lifetime 86400 valid-lifetime 259200
```

reset ipv6 dhcp server conflict

Use **reset ipv6 dhcp server conflict** to clear IPv6 address conflict information.

Syntax

reset ipv6 dhcp server conflict [**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

address *ipv6-address*: Clears conflict information for the specified IPv6 address. If you do not specify an IPv6 address, this command clears all IPv6 address conflict information.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command clears conflict information about IPv6 addresses for the public network.

Usage guidelines

Address conflicts occur when dynamically assigned IP addresses have been statically configured for other hosts. After the conflicts are resolved, you can use the **reset ipv6 dhcp server conflict** command to clear conflict information so that the conflicted addresses can be assigned to clients.

Examples

Clear all IPv6 address conflict information.

```
<Sysname> reset ipv6 dhcp server conflict
```

Related commands

display ipv6 dhcp server conflict

reset ipv6 dhcp server expired

Use **reset ipv6 dhcp server expired** to clear binding information for lease-expired IPv6 addresses.

Syntax

reset ipv6 dhcp server expired [[**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

address *ipv6-address*: Clears binding information for the specified lease-expired IPv6 address. If you do not specify an IPv6 address, this command clears binding information for all lease-expired IPv6 address.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command clears binding information about lease-expired IPv6 addresses for the public network.

pool *pool-name*: Clears binding information for lease-expired IPv6 addresses in the address pool specified by its name, a case-insensitive string of 1 to 63 characters. If you do not specify an address pool, this command clears binding information for lease-expired IPv6 addresses in all address pools.

Examples

Clear binding information for expired IPv6 address 2001:f3e0::1.

```
<Sysname> reset ipv6 dhcp server expired address 2001:f3e0::1
```

Related commands

reset ipv6 dhcp server ip-in-use

Use **reset ipv6 dhcp server ip-in-use** to clear binding information for assigned IPv6 addresses.

Syntax

reset ipv6 dhcp server ip-in-use [[**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

address *ipv6-address*: Clears binding information for the specified assigned IPv6 address. If you do not specify an IPv6 address, this command clears binding information for all assigned IPv6 addresses.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command clears binding information about assigned IPv6 addresses for the public network.

pool *pool-name*: Clears binding information for assigned IPv6 addresses in the address pool specified by its name, a case-insensitive string of 1 to 63 characters. If you do not specify an address pool, this command clears binding information for assigned IPv6 addresses in all address pools.

Usage guidelines

If you execute this command to clear information about an assigned static binding, the static binding becomes a free static binding.

Examples

Clear binding information for all assigned IPv6 addresses.

```
<Sysname> reset ipv6 dhcp server ip-in-use
```

Clears binding information for assigned IPv6 addresses in DHCPv6 address pool 1.

```
<Sysname> reset ipv6 dhcp server ip-in-use pool 1
```

Clears binding information for the assigned IPv6 address 2001:0:0:1::1.

```
<Sysname> reset ipv6 dhcp server ip-in-use address 2001:0:0:1::1
```

display ipv6 dhcp server statistics

sip-server

Use **sip-server** to specify the IPv6 address or domain name of a SIP server in the DHCPv6 address pool.

Use **undo sip-server** to remove a SIP server.

Syntax

sip-server { **address** *ipv6-address* | **domain-name** *domain-name* }

undo sip-server { **address** *ipv6-address* | **domain-name** *domain-name* }

Default

No SIP server address or domain name is specified.

Views

DHCPv6 address pool view

DHCPv6 option group view

Predefined user roles

network-admin

context-admin

Parameters

address *ipv6-address*: Specifies the IPv6 address of a SIP server.

domain-name *domain-name*: Specifies the domain name of a SIP server, a case-insensitive string of 1 to 50 characters.

Usage guidelines

You can specify up to eight SIP server addresses and eight SIP server domain names in an address pool. A SIP server that is specified earlier has a higher preference.

Examples

Specify the SIP server address **2:2::4** in DHCPv6 address pool 1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] sip-server address 2:2::4
```

Specify the SIP server domain name **bbb.com** in DHCPv6 address pool 1.

```
[Sysname-dhcp6-pool-1] sip-server domain-name bbb.com
```

Related commands

display ipv6 dhcp pool

static-bind

Use **static-bind** to statically bind an IPv6 address or prefix to a client in the DHCPv6 address pool.

Use **undo static-bind** to delete a static binding.

Syntax

static-bind { **address** *ipv6-address*/*addr-prefix-length* | **prefix** *prefix*/*prefix-len* } **duid** *duid* [**iaid** *iaid*] [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*] [**description** *description-text*]

undo static-bind { **address** *ipv6-address*/*addr-prefix-length* | **prefix** *prefix*/*prefix-len* }

Default

No static binding is configured in a DHCPv6 address pool.

Views

DHCPv6 address pool view

Predefined user roles

network-admin

context-admin

Parameters

address *ipv6-address*/*addr-prefix-length*: Specifies the IPv6 address and prefix length. The value range for the prefix length is 1 to 128.

prefix *prefix*/*prefix-len*: Specifies the prefix and prefix length. The value range for the prefix length is 1 to 128.

duid *duid*: Specifies a client DUID. The value is an even hexadecimal number in the range of 2 to 256.

iaid *iaid*: Specifies a client IAID. The value is a hexadecimal number in the range of 0 to FFFFFFFF. If you do not specify an IAID, the server does not match the client IAID for prefix assignment.

preferred-lifetime *preferred-lifetime*: Sets the preferred lifetime of the address or prefix. The value range is 60 to 4294967295 seconds, and the default is 604800 seconds (7 days).

valid-lifetime *valid-lifetime*: Sets the valid lifetime of the address or prefix. The value range is 60 to 4294967295 seconds, and the default is 2592000 seconds (30 days). The valid lifetime cannot be shorter than the preferred lifetime.

description *description-text*: Specifies a description for the static binding, a case-sensitive string of 1 to 255 characters.

Usage guidelines

You can specify multiple static bindings in a DHCPv6 address pool.

An IPv6 address or prefix can be bound to only one DHCPv6 client.

To modify a static binding, execute the **undo static-bind** command to delete the binding, and then execute the **static-bind** command.

Examples

In address pool 1, bind IPv6 address 2001:0410::/35 to the client DUID 0003000100e0fc005552 and IAID A1A1A1A1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] static-bind address 2001:0410::/35 duid 0003000100e0fc005552 iaid A1A1A1A1
```

In address pool 1, bind prefix 2001:0410::/35 to the client DUID 00030001CA0006A400 and IAID A1A1A1A1.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] static-bind prefix 2001:0410::/35 duid 00030001CA0006A400 iaid A1A1A1A1
```

Related commands

display ipv6 dhcp pool

temporary address range

Use **temporary address range** to configure a temporary IPv6 address range in a DHCPv6 address pool for dynamic allocation.

Use **undo temporary address range** to restore the default.

Syntax

temporary address range *start-ipv6-address end-ipv6-address* [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

undo temporary address range

Default

No temporary IPv6 address range is configured in a DHCPv6 address pool.

Views

DHCPv6 address pool view

Predefined user roles

network-admin

context-admin

Parameters

start-ipv6-address: Specifies the start IPv6 address.

end-ipv6-address: Specifies the end IPv6 address.

preferred-lifetime *preferred-lifetime*: Sets the preferred lifetime. The value range is 60 to 4294967295 seconds, and the default is 604800 seconds (7 days).

valid-lifetime *valid-lifetime*: Sets the valid lifetime. The value range is 60 to 4294967295 seconds, and the default is 2592000 seconds (30 days). The valid lifetime cannot be shorter than the preferred lifetime.

Usage guidelines

If you do not execute the **temporary address range** command, the DHCPv6 server does not support temporary address assignment.

You can configure only one temporary IPv6 address range in an address pool. If you execute this command multiple times, the most recent configuration takes effect.

Examples

In DHCPv6 address pool 1, configure a temporary IPv6 address range from 3ffe:501:ffff:100::50 to 3ffe:501:ffff:100::60.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 1
[Sysname-dhcp6-pool-1] network 3ffe:501:ffff:100::/64
[Sysname-dhcp6-pool-1] temporary address range 3ffe:501:ffff:100::50
3ffe:501:ffff:100::60
```

Default

The DHCPv6 address pool is not applied to any VPN instance.

Views

DHCPv6 address pool view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance-name: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the DHCPv6 address pool belongs to the public network.

Usage guidelines

If a DHCPv6 address pool is applied to a VPN instance, the DHCPv6 server assigns IPv6 addresses in this address pool to clients in the specified VPN instance.

The DHCPv6 server identifies the VPN instance to which a DHCPv6 client belongs according to the following information:

- The client's VPN information stored in authentication modules.
- The VPN information of the DHCPv6 server's interface that receives DHCPv6 packets from the client.

The VPN information from authentication modules takes priority over the VPN information of the receiving interface.

Examples

Apply DHCPv6 address pool 0 to the VPN instance **abc**.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 0
[Sysname-dhcp6-pool-0] vpn-instance abc
```

DHCPv6 relay agent commands

display ipv6 dhcp relay server-address

Use **display ipv6 dhcp relay server-address** to display DHCPv6 server addresses specified on the DHCPv6 relay agent.

Syntax

display ipv6 dhcp relay server-address [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays DHCPv6 server addresses on all interfaces enabled with DHCPv6 relay agent.

Examples

Display DHCPv6 server addresses on all interfaces enabled with DHCPv6 relay agent.

```
<Sysname> display ipv6 dhcp relay server-address
Interface: GigabitEthernet1/0/1
 Server address                              Outgoing Interface
 2::3
 3::4                                        GigabitEthernet1/0/3
```

```
Interface: GigabitEthernet1/0/2
 Server address                              Outgoing Interface
 2::3
 3::4                                        GigabitEthernet1/0/3
```

Display DHCPv6 server addresses on GigabitEthernet 1/0/1.

```
<Sysname> display ipv6 dhcp relay server-address interface gigabitethernet 1/0/1
Interface: GigabitEthernet1/0/1
 Server address                              Outgoing Interface
 2::3
 3::4                                        GigabitEthernet1/0/3
```

Table 11 Command output

Field	Description
Server address	DHCPv6 server address specified on the DHCP relay agent.
Outgoing Interface	Output interface of DHCPv6 packets. If no output interface is specified, the device searches the routing table for the output interface.

Related commands

ipv6 dhcp relay server-address

    Relay-forward            :  8
    Relay-reply              :  0
```

Table 12 Command output

Field	Description
Packets dropped	Number of discarded packets.
Packets received	Number of received packets.
Solicit	Number of received solicit packets.
Request	Number of received request packets.
Confirm	Number of received confirm packets.
Renew	Number of received renew packets.
Rebind	Number of received rebind packets.
Release	Number of received release packets.

Field	Description
Decline	Number of received decline packets.
Information-request	Number of received information request packets.
Relay-forward	Number of received relay-forward packets.
Relay-reply	Number of received relay-reply packets.
Packets sent	Number of sent packets.
Advertise	Number of sent advertise packets.
Reconfigure	Number of sent reconfigure packets.
Reply	Number of sent reply packets.
Relay-forward	Number of sent Relay-forward packets.
Relay-reply	Number of sent Relay-reply packets.

Related commands

reset ipv6 dhcp relay statistics

gateway-list

Use **gateway-list** to specify gateway addresses for DHCPv6 clients in a DHCPv6 address pool.

Use **undo gateway-list** to remove gateway addresses from a DHCPv6 address pool.

Syntax

gateway-list *ipv6-address*&<1-8>

undo gateway-list [*ipv6-address*&<1-8>]

Default

No gateway address is specified in a DHCPv6 address pool.

Views

DHCPv6 address pool view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address&<1-8>: Specifies a space-separated list of up to eight addresses.

Usage guidelines

DHCPv6 clients of the same access type can be classified into different types by their locations. In this case, the relay interface typically has no IPv6 address configured. You can use the **gateway-list** command to specify gateway addresses for clients matching the same DHCPv6 address pool.

Upon receiving a DHCPv6 Solicit or Request from a client that matches a DHCPv6 address pool, the relay agent processes the packet as follows:

- Fills the **link-address** field of the packet with a specified gateway address.
- Forwards the packet to all DHCPv6 servers in the matching DHCPv6 address pool.

The DHCPv6 servers select a DHCPv6 address pool according to the gateway address.

Examples

Specify the gateway address 10::1 in the DHCPv6 address pool **p1**.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool p1
[Sysname-dhcp6-pool-p1] gateway-list 10::1
```

ipv6 dhcp relay gateway

Use **ipv6 dhcp relay gateway** to specify a gateway address for DHCPv6 clients on the DHCPv6 relay interface.

Use **undo ipv6 dhcp relay gateway** to restore the default.

Syntax

ipv6 dhcp relay gateway *ipv6-address*

undo ipv6 dhcp relay gateway

Default

The first IPv6 address of the relay interface is used as the gateway address for DHCPv6 clients.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies a gateway address. The IPv6 address must be an IPv6 address of the relay interface.

Usage guidelines

The DHCPv6 relay agent uses the specified IPv6 address instead of the first IPv6 address of the relay interface as the gateway address for DHCPv6 clients.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify 10::1 as the gateway address for DHCPv6 clients on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 dhcp relay gateway 10::1
```

Related commands

gateway-list

ipv6 dhcp relay interface-id

Use **ipv6 dhcp relay interface-id** to specify a padding mode for the Interface-ID option.

Use **undo ipv6 dhcp relay interface-id** to restore the default.

Syntax

ipv6 dhcp relay interface-id { **bas** | **interface** }

undo ipv6 dhcp relay interface-id

Default

The DHCPv6 relay agent fills the Interface-ID option with the interface index of the interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

bas: Specifies the BAS mode.

interface: Specifies the interface name mode. This mode pads the Interface-ID option in ASCII code with the interface name and VLAN ID of the interface.

Usage guidelines

Enable the DHCPv6 relay agent on the interface before executing this command. Otherwise, the command does not take effect.

Examples

Specify the BAS mode as the padding mode for the Interface-ID option on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 dhcp relay interface-id bas
```

Specify the interface name mode as the padding mode for the Interface-ID option on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 dhcp relay interface-id interface
```

ipv6 dhcp relay server-address

Use **ipv6 dhcp relay server-address** to specify a DHCPv6 server on the DHCPv6 relay agent.

Use **undo ipv6 dhcp relay server-address** to remove DHCPv6 server addresses.

Syntax

ipv6 dhcp relay server-address *ipv6-address* [**interface** *interface-type interface-number*]

undo ipv6 dhcp relay server-address [*ipv6-address* [**interface** *interface-type interface-number*]]

Default

No DHCPv6 server address is specified on the DHCPv6 relay agent.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies the IPv6 address of a DHCPv6 server.

interface *interface-type interface-number*: Specifies an output interface through which the relay agent forwards the DHCPv6 requests to the DHCPv6 server. If you do not specify an output interface, the relay agent looks up the routing table for an output interface.

Usage guidelines

Upon receiving a request from a DHCPv6 client, the interface encapsulates the request into a Relay-forward message and forwards the message to the specified DHCPv6 server.

You can specify a maximum of eight DHCPv6 servers on an interface. The DHCPv6 relay agent forwards DHCP requests to all the specified DHCPv6 servers.

If the DHCPv6 server address is a link-local address or multicast address, you must specify an output interface. If you do not specify an output interface, DHCPv6 packets might fail to reach the DHCPv6 server.

If you do not specify an IPv6 address, the **undo ipv6 dhcp relay server-address** command removes all DHCPv6 server addresses specified on the interface.

Do not enable the DHCPv6 client and the DHCPv6 relay agent on the same interface.

Examples

Enable the DHCPv6 relay agent on GigabitEthernet 1/0/1 and specify the DHCPv6 server address 2001:1::3.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 dhcp select relay
[Sysname-GigabitEthernet1/0/1] ipv6 dhcp relay server-address 2001:1::3
```

Related commands

display ipv6 dhcp relay server-address

ipv6 dhcp select

remote-server

Use **remote-server** to specify DHCPv6 servers for a DHCPv6 address pool.

Use **undo remote-server** to remove DHCPv6 servers from a DHCPv6 address pool.

Syntax

remote-server *ipv6-address* [**interface** *interface-type interface-number*]

undo remote-server [*ipv6-address* [**interface** *interface-type interface-number*]]

Default

No DHCPv6 server is specified for the DHCPv6 address pool.

Views

DHCPv6 address pool view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies a DHCPv6 server address.

interface *interface-type interface-number*: Specifies the outgoing interface by its type and number for the DHCPv6 relay agent to forward packets to the DHCPv6 server. If you do not specify an outgoing interface, the DHCPv6 relay agent performs a routing table lookup.

Usage guidelines

You can specify a maximum of eight DHCPv6 servers in one DHCPv6 address pool.

If you do not specify any parameters, the **undo remote-server** command removes all DHCPv6 servers in the DHCPv6 address pool.

If a DHCPv6 server address is a link-local address, you must specify an outgoing interface by using the **interface** keyword in this command. If you do not specify an outgoing interface, DHCPv6 packets might fail to reach the DHCPv6 server.

Examples

Specify DHCPv6 server 10::1 for DHCPv6 address pool 0.

```
<Sysname> system-view
[Sysname] ipv6 dhcp pool 0
[Sysname-dhcp6-pool-0] remote-server 10::1
```

reset ipv6 dhcp relay statistics

Use **reset ipv6 dhcp relay statistics** to clear packets statistics on the DHCPv6 relay agent.

Syntax

reset ipv6 dhcp relay statistics [**interface** *interface-type interface-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command clears all relay agent statistics.

Examples

Clear packet statistics on the DHCPv6 relay agent.

```
<Sysname> reset ipv6 dhcp relay statistics
```

Table 13 Command output

Field	Description
Type	Types of DHCPv6 client: • **Stateful client requesting address**—A DHCPv6 client that requests an IPv6 address. • **Stateful client requesting prefix**—A DHCPv6 client that requests an IPv6 prefix. • **Stateful client requesting address and prefix**—A DHCPv6 client that requests an IPv6 address and prefix. • **Stateless client**—A DHCPv6 client that requests configuration parameters other than an IPv6 address and prefix through stateless DHCPv6.
State	Current state of the DHCPv6 client: • **IDLE**—The client is in idle state. • **SOLICIT**—The client is locating a DHCPv6 server. • **REQUEST**—The client is requesting an IPv6 address or prefix. • **OPEN**—The client has obtained an IPv6 address or prefix. • **RENEW**—The client is extending the lease (after T1 and before T2). • **REBIND**—The client is extending the lease (after T2 and before the lease expires). • **RELEASE**—The client is releasing an IPv6 address or prefix. • **DECLINE**—The client is declining an IPv6 address or prefix because of an address or prefix conflict. • **INFO-REQUESTING**—The client is requesting configuration parameters through stateless DHCPv6.
Client DUID	DUID of the DHCPv6 client.
Preferred server	Information about the DHCPv6 server selected by the DHCPv6 client.
Reachable via address	Reachable address for the DHCPv6 client. It is the link local address of the DHCPv6 server or DHCPv6 relay agent.
Server DUID	DUID of the DHCPv6 server.
IA_NA	IA_NA information.
IA_PD	IA_PD information.
IAID	IA identifier.
T1	T1 value in seconds.
T2	T2 value in seconds.
Address	IPv6 address obtained. This field is displayed only when the DHCPv6 client type is **Stateful client requesting address**.
Prefix	IPv6 prefix obtained. This field is displayed only when the DHCPv6 client type is **Stateful client requesting prefix**.
Preferred lifetime	Preferred lifetime in seconds.
valid lifetime	Valid lifetime in seconds.

Field	Description
Will expire on Feb 4 2014 at 15:37:20 (288 seconds left)	Time when the lease expires and the remaining time of the lease. If the lease expires after the year 2100, this field displays **Will expire after 2100**.
DNS server addresses	IPv6 address of the DNS server.
Domain name	Domain name suffix.
SIP server addresses	IPv6 address of the SIP server.
SIP server domain names	Domain name of the SIP server.
Options	Self-defined options.
Code	Code of the self-defined option.
Length	Self-defined option length in bytes.
Hex	Self-defined option content represented by a hexadecimal number.

network-operator

context-admin

context-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays statistics for all DHCPv6 clients.

Examples

Display DHCPv6 client statistics on GigabitEthernet 1/0/1.

```
<Sysname> display ipv6 dhcp client statistics interface gigabitethernet 1/0/1
Interface                    :  GigabitEthernet1/0/1
Packets received             :  1
        Reply                :  1
        Advertise            :  0
```

```
         Reconfigure         :   0
         Invalid             :  0
Packets sent                 :  5
         Solicit             :  0
         Request             :  0
         Renew               :  0
         Rebind              :  0
         Information-request  :  5
         Release             :  0
         Decline             :  0
```

Table 14 Command output

Field	Description
Interface	Interface that acts as the DHCPv6 client.
Packets Received	Number of received packets.
Reply	Number of received reply packets.
Advertise	Number of received advertise packets.
Reconfigure	Number of received reconfigure packets.
Invalid	Number of invalid packets.
Packets sent	Number of sent packets.
Solicit	Number of sent solicit packets.
Request	Number of sent request packets.
Renew	Number of sent renew packets.
Rebind	Number of sent rebind packets.
Information-request	Number of sent information request packets.
Release	Number of sent release packets.
Decline	Number of sent decline packets.

Related commands

`reset ipv6 dhcp client statistics`

ipv6 address dhcp-alloc

Use **`ipv6 address dhcp-alloc`** to configure an interface to use DHCPv6 for IPv6 address acquisition.

Use **`undo ipv6 address dhcp-alloc`** to cancel an interface from using DHCPv6, and clear the obtained IPv6 address and other configuration parameters.

Syntax

`ipv6 address dhcp-alloc` [**`option-group`** *`option-group-number`* | **`rapid-commit`**] *

`undo ipv6 address dhcp-alloc`

Default

An interface does not use DHCPv6 for IPv6 address acquisition.

Views

Layer 3 Ethernet interface view

Layer 3 Ethernet subinterface view

Layer 3 aggregate interface view

Layer 3 aggregate subinterface view

VLAN interface view

Reth interface view

Reth subinterface view

Predefined user roles

network-admin

context-admin

Parameters

option-group *option-group-number*: Enables the DHCPv6 client to create a dynamic DHCPv6 option group for saving the configuration parameters, and assigns an ID to the option group. The value range for the ID is 1 to 100. If you do not specify this option, the DHCPv6 client does not create any dynamic DHCPv6 option groups.

rapid-commit: Supports rapid address or prefix assignment.

Examples

Configure GigabitEthernet 1/0/1 to use DHCPv6 for IPv6 address acquisition. Configure the DHCPv6 client to support rapid address assignment and create dynamic DHCPv6 option group 1 for the configuration parameters obtained.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address dhcp-alloc rapid-commit option-group 1
```

Related commands

display ipv6 dhcp client

ipv6 dhcp client dscp

Use **ipv6 dhcp client dscp** to set the DSCP value for DHCPv6 packets sent by the DHCPv6 client.

Use **undo ipv6 dhcp client dscp** to restore the default.

Syntax

ipv6 dhcp client dscp *dscp-value*

undo ipv6 dhcp client dscp

Default

The DSCP value in DHCPv6 packets is 56.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Sets the DSCP value for DHCP packets, in the range of 0 to 63.

Usage guidelines

The DSCP value is carried in the Traffic class field of a DHCPv6 packet. It specifies the priority level of the packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Examples

Set the DSCP value to 30 for DHCPv6 packets sent by the DHCPv6 client.

```
<Sysname> system-view
[Sysname] ipv6 dhcp client dscp 30
```

ipv6 dhcp client duid

Use **ipv6 dhcp client duid** to configure the DHCPv6 client DUID for an interface.

Use **undo ipv6 dhcp client duid** to restore the default.

Syntax

ipv6 dhcp client duid { **ascii** *ascii-string* | **hex** *hex-string* | **mac** *interface-type interface-number* }

undo ipv6 dhcp client duid

Default

The interface uses the device bridge MAC address to generate its DHCPv6 client DUID.

Views

Layer 3 Ethernet subinterface view

Layer 3 aggregate interface view

Layer 3 aggregate subinterface view

VLAN interface view

Reth interface view

Reth subinterface view

Predefined user roles

network-admin

context-admin

Parameters

ascii *ascii-string*: Specifies a case-sensitive ASCII string of 1 to 130 characters as the DHCPv6 client DUID.

hex *hex-string*: Specifies a hexadecimal number of 2 to 260 characters as the DHCPv6 client DUID.

mac *interface-type interface-number*: Specifies the MAC address of the specified interface as the DHCPv6 client DUID. The *interface-type interface-number* arguments specify an interface by its type and number.

Usage guidelines

A DHCPv6 client pads its DUID into the Option 1 of the DHCPv6 packet that it sends to the DHCPv6 server. The DHCPv6 server can assign specific IPv6 addresses or prefixes to DHCPv6 clients with specific DUIDs.

The DUID of a DHCPv6 client is the globally unique identifier of the client, so make sure the DUID that you configure is unique.

Examples

Specify the MAC address of GigabitEthernet 1/0/2 as the DHCPv6 client DUID for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 dhcp client duid mac gigabitethernet 1/0/2
```

Related commands

display ipv6 dhcp client

ipv6 dhcp client pd

Use **ipv6 dhcp client pd** to configure an interface to use DHCPv6 for IPv6 prefix acquisition.

Use **undo ipv6 dhcp client pd** to cancel an interface from using DHCPv6, and clear the obtained IPv6 prefix and other configuration parameters.

Syntax

ipv6 dhcp client pd *prefix-number* [**option-group** *option-group-number* | **rapid-commit**]*

undo ipv6 dhcp client pd

Default

An interface does not use DHCPv6 for IPv6 prefix acquisition.

Layer 3 aggregate subinterface view

VLAN interface view

Reth interface view

Reth subinterface view

Predefined user roles

network-admin

context-admin

Parameters

prefix-number: Specifies an IPv6 prefix ID in the range of 1 to 1024. After obtaining an IPv6 prefix, the client assigns the ID to the IPv6 prefix.

rapid-commit: Supports rapid address or prefix assignment.

option-group *option-group-number*: Enables the DHCPv6 client to create a dynamic DHCPv6 option group for saving the configuration parameters, and assigns an ID to the option group. The value range for the ID is 1 to 100. If you do not specify this option, the DHCPv6 client does not create any dynamic DHCPv6 option groups.

Examples

Configure GigabitEthernet 1/0/1 to use DHCPv6 for IPv6 prefix acquisition. Specify IDs for the dynamic IPv6 prefix and dynamic DHCPv6 option group, and configure the client to support rapid prefix assignment.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 dhcp client pd 1 rapid-commit option-group 1
```

Related commands

display ipv6 dhcp client

ipv6 dhcp client stateful

Use **ipv6 dhcp client stateful** to configure an interface to use DHCPv6 for IPv6 address and prefix acquisition.

Use **undo ipv6 dhcp client stateful** to cancel an interface from using DHCPv6, and clear the obtained IPv6 address, prefix, and other configuration parameters.

Syntax

ipv6 dhcp client stateful prefix *prefix-number* [**option-group** *option-group-number* | **rapid-commit**] *

undo ipv6 dhcp client stateful

Default

An interface does not use DHCPv6 for IPv6 address and prefix acquisition.

Predefined user roles

network-admin

context-admin

Parameters

prefix *prefix-number*: Specifies an IPv6 prefix ID in the range of 1 to 1024. After obtaining an IPv6 prefix, the client assigns the ID to the IPv6 prefix.

rapid-commit: Supports rapid address and prefix assignment.

option-group *option-group-number*: Enables the DHCPv6 client to create a dynamic DHCPv6 option group for saving the configuration parameters, and assigns an ID to the option group.

The value range for the ID is 1 to 100. If you do not specify this option, the DHCPv6 client does not create any dynamic DHCPv6 option groups.

Usage guidelines

The **ipv6 dhcp client stateful** command takes effect if it is configured with the **ipv6 address dhcp-alloc** and **ipv6 dhcp client pd** commands on an interface. You must execute the **undo ipv6 dhcp client stateful** command to have the **ipv6 address dhcp-alloc** and **ipv6 dhcp client pd** commands take effect.

Examples

Configure GigabitEthernet 1/0/1 to use DHCPv6 for IPv6 address and prefix acquisition. Specify IDs for the dynamic IPv6 prefix and dynamic DHCPv6 option group, and configure the client to support rapid address and prefix assignment.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 dhcp client stateful prefix 1 rapid-commit
option-group 1
```

context-operator

Parameters

dynamic: Displays the domain name suffixes dynamically obtained through DHCP or other protocols. If you do not specify this keyword, the command displays the statically configured and dynamically obtained domain name suffixes.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays domain name suffixes for the public network.

Examples

Display the statically configured and dynamically obtained domain name suffixes for the public network.

```
<Sysname> display dns domain
Type:
  D: Dynamic    S: Static

No.    Type   Domain suffix
1      S      com
2      D      net
```

Table 1 Command output

Field	Description
No.	Sequence number.
Type	Domain name suffix type: • **S**—A statically configured domain name suffix. • **D**—A domain name suffix dynamically obtained through DHCP or other protocols.
Domain suffix	Domain name suffixes.

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ip: Specifies type A queries. A type A query resolves a domain name to the mapped IPv4 address.

ipv6: Specifies type AAAA queries. A type AAAA query resolves a domain name to the mapped IPv6 address.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays domain name-to-IP address mappings for the public network.

Usage guidelines

If you do not specify the **ip** or **ipv6** keyword, this command displays domain name-to-IP address mappings of all query types.

Examples

Display domain name-to-IP address mappings of all query types.

```
<Sysname> display dns host
Type:
  D: Dynamic    S: Static

Total number: 3
No.  Host name         Type  TTL        Query type   IP addresses
1    sample.com        D     3132       A            192.168.10.1
                                                     192.168.10.2
                                                     192.168.10.3
2    zig.sample.com    S     -          A            192.168.1.1
3    sample.net        S     -          AAAA         FE80::4904:4448
```

Table 2 Command output

Field	Description
No.	Sequence number.
Host name	Domain name.
Type	Domain name-to-IP address mapping type: • **S**—A static mapping configured by the **ip host** or **ipv6 host** command.

Field	Description
	• **D**—A mapping dynamically obtained through dynamic domain name resolution.
TTL	Time in seconds that a mapping can be stored in the cache. For a static mapping, a hyphen (-) is displayed.
Query type	Query type: A and AAAA.
IP addresses	Replied IP address: • For a type A query, the replied IP address is an IPv4 address. • For a type AAAA query, the replied IP address is an IPv6 address.

Outgoing Interface	Output interface.

Related commands

ipv6 dns server

dns cache ttl

Use **dns cache ttl** to set the TTL value for DNS entries.

Use **undo dns cache ttl** to cancel the TTL configuration for DNS entries.

Syntax

dns cache ttl { **maximum** *max-value* | **minimum** *min-value* } *

undo dns cache ttl { **maximum** | **minimum** }

Default

The TTL value for DNS entries is the TTL value in the DNS reply.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

maximum *max-value*: Specifies the maximum TTL value for DNS entries, in the range of 60 to 3600 seconds.

minimum *min-value*: Specifies the minimum TTL value for DNS entries, in the range of 60 to 3600 seconds. The value for the *min-value* argument must be smaller than that for the *max-value* argument.

Usage guidelines

The device periodically sends a DNS request to the DNS server according to the TTL for DNS entries, which consumes CPU resources. If the TTL value is too small, the device sends DNS requests frequently to the DNS server, which consumes more CPU resources. If the TTL value is too large, DNS mappings cannot be updated in time. To avoid such issues, you can use this command to set the TTL value for DNS entries.

By default, the DNS client obtains the TTL for the following DNS entries from the DNS reply:

- DNS entries generated from DNS transparent proxy.
- DNS entries generated from DNS snooping.
- Dynamic domain name resolution cache generated from the DNS server/DNS server group.

After you set the TTL value for DNS entries, the device specifies the TTL for DNS entries as follows:

- If the TTL value in the DNS reply is smaller than the minimum TTL value, the device uses the minimum TTL value as the TTL for DNS entries. Otherwise, the device uses the TTL value in the DNS reply as the TTL for DNS entries.
- If the TTL value in the DNS reply is larger than the maximum TTL value, the device uses the maximum TTL value as the TTL for DNS entries. Otherwise, the device uses the TTL value in the DNS reply as the TTL for DNS entries.

After you execute this command, the configuration only takes effect on the subsequent DNS entries generated from DNS transparent proxy, DNS snooping, and DNS server/DNS server group.

After you execute the **undo dns cache ttl** command, the current TTL for the existing DNS entries still works.

If you execute the **dns cache ttl minimum**, **dns cache ttl maximum**, or **dns cache ttl minimum maximum** command multiple times, the most recent configuration takes effect.

Examples

Set the minimum TTL value for DNS entries to 180 seconds and the maximum TTL value for DNS entries to 3600 seconds.

```
<Sysname> system-view
[Sysname] dns cache ttl maximum 3600 minimum 180
```

Related commands

dns server
dns snooping enable
dns transparent-proxy enable

dns domain

Use **dns domain** to configure a domain name suffix.

Use **undo dns domain** to delete the specified domain name suffix.

Syntax

dns domain *domain-name* [**vpn-instance** *vpn-instance-name*]

undo dns domain *domain-name* [**vpn-instance** *vpn-instance-name*]

Default

No domain name suffix is configured. Only the provided domain name is resolved.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

domain-name: Specifies a domain name suffix. It is a dot-separated, case-insensitive string that can include letters, digits, hyphens (-), underscores (_), and dots (.), for example, aabbcc.com. The domain name suffix can include a maximum of 253 characters, and each separated string includes no more than 63 characters.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. To configure a domain name suffix for the public network, do not specify this option.

Usage guidelines

For domain name resolution, the resolver automatically uses the suffix list to supply the missing part of an incomplete name entered by a user.

A domain name suffix applies to both IPv4 DNS and IPv6 DNS.

The system allows a maximum of 16 domain name suffixes for the public network or each VPN instance. You can specify domain name suffixes for both public network and VPN instances.

Examples

Configure domain name suffix **com** for the public network.

```
<Sysname> system-view
[Sysname] dns domain com
```

Related commands

display dns domain

dns dscp

Use **dns dscp** to set the DSCP value for DNS packets sent by a DNS client or DNS proxy.

Use **undo dns dscp** to restore the default.

Syntax

dns dscp *dscp-value*

undo dns dscp

Default

The DSCP value is 0 in DNS packets sent by a DNS client or DNS proxy.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Specifies the DSCP value in the range of 0 to 63.

Usage guidelines

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Examples

Set the DSCP value to 30 for outgoing DNS packets.

```
<Sysname> system-view
[Sysname] dns dscp 30
```

dns filter

Use **dns filter** to enable DNS filtering and add a host name to the denylist or allowlist.

Use **undo dns filter** to disable DNS filtering and delete a host name from the denylist or allowlist.

Syntax

dns filter { **allowlist** | **denylist** } *hostname*

undo dns filter { **allowlist** | **denylist** } *hostname*

Default

DNS filtering is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

allowlist: Adds a host name to the allowlist.

denylist: Adds a host name to the denylist.

hostname: Specifies a host name, a case-insensitive string of 1 to 253 characters. The string can contain letters, digits, hyphens (-), underscores (_), and dots (.). This argument supports fuzzy match by adding the character (*) to the start or end of the string. For example, to match a host name including **abc**, specify the *hostname* argument as **abc**, **abc*, or *abc**. To exactly match a host name, do not add the character (*).

Usage guidelines

The DNS proxy uses DNS filtering to filter DNS requests as follows:

- If the allowlist has a matching host name or the denylist has no matching host name with the domain name in the received DNS request, the DNS proxy filters in the request. After receiving a DNS reply, the DNS proxy records the DNS mapping and forwards the reply to the DNS client.
- If the denylist has a matching host name or the allowlist has no matching host name with the domain name in the received DNS request, the DNS proxy discards the DNS request.

To implement a strict access control, use an allowlist to filter DNS requests. To implement a loose access control, use a denylist to filter DNS requests.

To add multiple host names to the allowlist or denylist, repeat this command. However, a host name cannot be added to both the denylist and allowlist.

Examples

Enable DNS filtering and add the host names with **.abc** to the allowlist.

```
<Sysname> system-view
[Sysname] dns filter allowlist *.abc
```

dns proxy enable

Use **dns proxy enable** to enable DNS proxy.

Use **undo dns proxy enable** to disable DNS proxy.

Syntax

dns proxy enable

undo dns proxy enable

Default

DNS proxy is disabled.

Views

System view

Predefined user roles

network-admin

This configuration applies to both IPv4 DNS and IPv6 DNS.

Examples

Enable DNS proxy.

```
<Sysname> system-view
[Sysname] dns proxy enable
```

dns server

Use **dns server** to specify the IPv4 address of a DNS server.

Use **undo dns server** to remove the IPv4 address of a DNS server.

Syntax

dns server *ip-address* [**vpn-instance** *vpn-instance-name*]

undo dns server [*ip-address*] [**vpn-instance** *vpn-instance-name*]

Default

No DNS server IPv4 address is specified.

Views

System view

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IPv4 address of a DNS server. When you execute the **undo** form of the command in interface view, you must specify this argument.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. To specify a DNS server IPv4 address for the public network, do not use this option.

Usage guidelines

The device sends a DNS query request to the DNS servers in the order their IPv4 addresses are specified.

The system allows a maximum of six DNS server IPv4 addresses for the public network or each VPN instance. You can specify DNS server IPv4 addresses for both public network and VPN instances.

If you do not specify an IPv4 address, the **undo dns server** command removes all DNS server IPv4 addresses for the public network or the specified VPN instance.

Examples

Specify DNS server IPv4 address 172.16.1.1.

```
<Sysname> system-view
[Sysname] dns server 172.16.1.1
```

Specify DNS server IPv4 address 172.16.1.1 on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dns server 172.16.1.1
```

Related commands

display dns server

dns snooping enable

Use **dns snooping enable** to enable DNS snooping.

Use **undo dns snooping enable** to disable DNS snooping.

Syntax

dns snooping enable

undo dns snooping enable

Default

DNS snooping is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

DNS snooping is applicable to the scenario where traffic filtering is based on domain names. To filter traffic based on domain names, the DNS mapping is required. The device enabled with DNS snooping monitors received DNS requests and replies. If the domain name in a DNS request matches a filtering rule, the device records the DNS mapping after receiving a DNS reply and reports the mapping to the rule for traffic filtering. If the domain name does not match a filtering rule, the device does not record the DNS mapping.

DNS snooping only works between the DNS client and DNS server, or the DNS client and DNS proxy.

The DNS snooping and DNS transparent proxy features cannot be both configured.

The DNS snooping feature is not VPN-aware. The input interface and output interface of DNS packets must belong to the same VPN.

Examples

Enable DNS snooping.

```
<Sysname> system-view
[Sysname] dns snooping enable
```

Related commands

dns transparent-proxy enable

dns snooping log enable

Use **dns snooping log enable** to enable DNS snooping logging.

Use **undo dns snooping log enable** to disable DNS snooping logging.

Syntax

dns snooping log enable

undo dns snooping log enable

Default

DNS snooping logging is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The DNS proxy searches the static domain name resolution table and dynamic domain name resolution cache after receiving a request.

- If the requested information is found, the DNS proxy returns a DNS reply to the client.
- If the requested information is not found, the DNS proxy sends the request to the designated DNS server.

Too many requests received at the same time will increase network load and affect the performance of the DNS proxy and DNS server.

To avoid this issue, you can have DNS snooping work between the DNS client and DNS proxy, or the DNS client and DNS server. The DNS snooping logging feature enables the DNS snooping device to generate DNS snooping logs and send them to the fast log module. The administrator can locate and troubleshoot issues based on the logs. For information about the fast log output configuration, see *Network Management and Monitoring Configuration Guide*.

Examples

Enable DNS snooping logging.

```
<Sysname> system-view
[Sysname] dns snooping log enable
```

dns snooping rate-limit

Use **dns snooping rate-limit** to configure a rate limit of incoming DNS packets on interfaces.

Use **undo dns snooping rate-limit** to disable DNS snooping packet rate limit.

Syntax

dns snooping rate-limit *rate*

undo dns snooping rate-limit

Default

The rate of incoming DNS packets is not limited.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

rate: Specifies the maximum rate in pps. The value range for this argument is 64 to 512

Usage guidelines

An interface will discard DNS packets exceeding the specified rate limit.

This command takes effect only when the DNS transparent proxy or DNS snooping logging feature is enabled.

Examples

Set the DNS packet rate limit to 64 pps.

```
<Sysname> system-view
[Sysname] dns snooping rate-limit 64
```

Related commands

dns snooping log enable

dns transparent-proxy enable

dns source-interface

Use **dns source-interface** to specify the source interface for DNS packets.

Use **undo dns source-interface** to restore the default.

Syntax

dns source-interface *interface-type interface-number* [**vpn-instance** *vpn-instance-name*]

undo dns source-interface *interface-type interface-number* [**vpn-instance** *vpn-instance-name*]

Default

No source interface is specified for DNS packets. The device uses the primary IP address of the output interface of the matching route as the source IP address for a DNS request.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface-type interface-number: Specifies an interface by its type and number.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. To specify a source interface for the public network, do not use this option.

Usage guidelines

This configuration applies to both IPv4 and IPv6.

In IPv4 DNS, the device uses the primary IPv4 address of the specified source interface as the source IP address of a DNS query. In IPv6 DNS, the device selects an IPv6 address of the specified source interface as the source IP address of a DNS query. The method of selecting the IPv6 address is defined in RFC 3484.

The system allows only one source interface for the public network or each VPN instance. If you execute this command multiple times, the most recent configuration takes effect. You can specify source interfaces for both public network and VPN instances.

This command takes effect whether the source interface belongs to the VPN instance or not. As a best practice, specify an interface that belongs to the VPN instance as the source interface.

Examples

Specify GigabitEthernet 1/0/1 as the source interface for DNS packets on the public network.

```
<Sysname> system-view
[Sysname] dns source-interface gigabitethernet 1/0/1
```

dns spoofing

Use **dns spoofing** to enable DNS spoofing and specify the IPv4 address for spoofing DNS requests.

Use **undo dns spoofing** to disable DNS spoofing.

Syntax

dns spoofing *ip-address* [**vpn-instance** *vpn-instance-name*]

undo dns spoofing *ip-address* [**vpn-instance** *vpn-instance-name*]

Default

DNS spoofing is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IPv4 address used to spoof DNS requests.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. To enable DNS spoofing for the public network, do not specify this option.

Usage guidelines

Use the **dns spoofing** command together with the **dns proxy enable** command.

DNS spoofing functions when the DNS proxy does not know the DNS server address or cannot reach the DNS server. It enables the DNS proxy to spoof DNS queries of type A by responding with the specified IPv4 address.

The system allows only one replied IPv4 address for the public network or each VPN instance. If you execute this command multiple times, the most recent configuration takes effect. You can configure DNS spoofing for both public network and VPN instances.

Examples

Enable DNS spoofing for the public network and specify IPv4 address 1.1.1.1 for spoofing DNS requests.

```
<Sysname> system-view
[Sysname] dns proxy enable
[Sysname] dns spoofing 1.1.1.1
```

Related commands

dns proxy enable

dns transparent-proxy enable

Use **dns transparent-proxy enable** to enable DNS transparent proxy.

Use **undo dns transparent-proxy enable** to disable DNS transparent proxy.

Syntax

dns transparent-proxy enable

undo dns transparent-proxy enable

Default

DNS transparent proxy is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

DNS transparent proxy modifies the source address in the DNS request so that the DNS client seems to receive a DNS reply directly from the DNS server. This feature is applicable to domain name-based policies, such as security policies and bandwidth policies.

The DNS client does not configure the DNS server address as the DNS transparent proxy address, which simplifies DNS client configurations. As a best practice, enable DNS transparent proxy in some load balancing scenarios.

The device enabled with DNS transparent proxy monitors received DNS requests and replies and records the DNS mapping as follows:

1. The DNS transparent proxy monitors all received DNS packets. After receiving a DNS request, the DNS transparent proxy specifies a local IP address that can reach the DNS server as the source IP address in the request.
2. After receiving the DNS reply, the DNS transparent proxy records the DNS mapping and forwards the reply to the DNS client.
3. The DNS transparent proxy searches the local entries after receiving another request. If the requested information is found, the DNS transparent proxy returns a DNS reply to the client. If the requested information is not found, the DNS proxy forwards the query to the DNS server for domain name resolution.

The DNS transparent proxy and DNS snooping features cannot be both configured.

The DNS transparent proxy is not VPN-aware. The input interface and output interface of DNS packets must belong to the same VPN.

Examples

Enable DNS transparent proxy.

```
<Sysname> system-view
[Sysname] dns transparent-proxy enable
```

Related commands

dns proxy enable

dns snooping enable

dns trust-interface

Use **dns trust-interface** to specify a DNS trusted interface.

Use **undo dns trust-interface** to remove a DNS trusted interface.

Syntax

dns trust-interface *interface-type interface-number*

undo dns trust-interface [*interface-type interface-number*]

Default

No DNS trusted interface is specified.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interface-type interface-number: Specifies an interface by its type and number.

Usage guidelines

By default, an interface obtains DNS suffix and DNS server information from DHCP. A network attacker might act as the DHCP server to assign a wrong DNS suffix and DNS server address to the device. As a result, the device fails to obtain the resolved IP address or might get the wrong IP address. With the DNS trusted interface specified, the device only uses the DNS suffix and DNS server information obtained through the trusted interface to avoid attacks.

This configuration applies to both IPv4 DNS and IPv6 DNS.

You can configure a maximum of 128 DNS trusted interfaces on the device.

If you do not specify an interface, the **undo dns trust-interface** command removes all DNS trusted interfaces and restores the default.

Examples

Specify GigabitEthernet 1/0/1 as a DNS trusted interface.

```
<Sysname> system-view
[Sysname] dns trust-interface gigabitethernet 1/0/1
```

ip host

Use **ip host** to create a host name-to-IPv4 address mapping.

Use **undo ip host** to remove a host name-to-IPv4 address mapping.

Syntax

ip host *host-name ip-address* [**vpn-instance** *vpn-instance-name*]

undo ip host *host-name ip-address* [**vpn-instance** *vpn-instance-name*]

Default

No host name-to-IPv4 address mappings exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

host-name: Specifies a host name, a case-insensitive string of 1 to 253 characters. Valid characters are letters, digits, hyphens (-), underscores (_), and dots (.).

ip-address: Specifies the IPv4 address of the host.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. To create a host name-to-IP address mapping for the public network, do not specify this option.

Usage guidelines

The system allows a maximum of 1024 host name-to-IPv4 address mappings for the public network or each VPN instance. You can configure host name-to-IPv4 address mappings for both public network and VPN instances.

For the public network or a VPN instance, each host name maps to only one IPv4 address. If you execute this command multiple times, the most recent configuration takes effect.

Do not use the **ping** command parameter **ip**, **-a**, **-c**, **-f**, **-h**, **-i**, **-m**, **-n**, **-p**, **-q**, **-r**, **-s**, **-t**, **-tos**, **-v**, or **-vpn-instance** as the host name. For more information about the **ping** command parameters, see *Network Management and Monitoring Command Reference*.

Examples

Map IPv4 address 10.110.0.1 to host name **aaa** for the public network.

```
<Sysname> system-view
[Sysname] ip host aaa 10.110.0.1
```

Related commands

display dns host

ipv6 dns dscp

Use **ipv6 dns dscp** to set the DSCP value for IPv6 DNS packets sent by an IPv6 DNS client or IPv6 DNS proxy.

Use **undo ipv6 dns dscp** to restore the default.

Syntax

ipv6 dns dscp *dscp-value*

undo ipv6 dns dscp

Default

The DSCP value is 0 in IPv6 DNS packets sent by an IPv6 DNS client or IPv6 DNS proxy.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Specifies the DSCP value in the range of 0 to 63.

Usage guidelines

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Examples

Set the DSCP value to 30 for outgoing IPv6 DNS packets.

```
<Sysname> system-view
[Sysname] ipv6 dns dscp 30
```

ipv6 dns server

Use **ipv6 dns server** to specify the IPv6 address of a DNS server.

Use **undo ipv6 dns server** to remove the IPv6 address of a DNS server.

Syntax

ipv6 dns server *ipv6-address* [*interface-type interface-number*] [**vpn-instance** *vpn-instance-name*]

undo ipv6 dns server [*ipv6-address* [*interface-type interface-number*]] [**vpn-instance** *vpn-instance-name*]

Default

No DNS server IPv6 address is specified.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies the IPv6 address of a DNS server.

interface-type interface-number: Specifies the output interface by its type and number. If you do not specify an interface, the device forwards DNS packets out of the output interface of the

matching route. Specify this argument if the IPv6 address of the DNS server is a link-local address. Do not specify this argument if the IPv6 address of the DNS server is a global unicast address.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. To specify a DNS server IPv6 address for the public network, do not use this option.

Usage guidelines

The device sends a DNS query request to the DNS servers in the order their IPv6 addresses are specified.

The system allows a maximum of six DNS server IPv6 addresses for the public network or each VPN instance. You can specify DNS server IPv6 addresses for both public network and VPN instances.

If you do not specify an IPv6 address, the **undo ipv6 dns server** command removes all DNS server IPv6 addresses for the public network or the specified VPN instance.

Examples

Specify DNS server IPv6 address 2002::1 for the public network.

```
<Sysname> system-view
[Sysname] ipv6 dns server 2002::1
```

Related commands

display ipv6 dns server

ipv6 dns spoofing

Use **ipv6 dns spoofing** to enable DNS spoofing and specify the IPv6 address to spoof DNS requests.

Use **undo ipv6 dns spoofing** to disable DNS spoofing.

Syntax

ipv6 dns spoofing *ipv6-address* [**vpn-instance** *vpn-instance-name*]

undo ipv6 dns spoofing *ipv6-address* [**vpn-instance** *vpn-instance-name*]

Default

DNS spoofing is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies the IPv6 address used to spoof DNS requests.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. To enable DNS spoofing for the public network, do not specify this option.

Usage guidelines

Use the **ipv6 dns spoofing** command together with the **dns proxy enable** command.

DNS spoofing functions when the DNS proxy does not know the DNS server address or cannot reach the DNS server. It enables the DNS proxy to spoof DNS queries of type AAAA by responding with the specified IPv6 address.

The system allows only one replied IPv6 address for the public network or each VPN instance. If you execute this command multiple times, the most recent configuration takes effect. You can configure DNS spoofing for both public network and VPN instances.

Examples

Enable DNS spoofing for the public network and specify IPv6 address 2001::1 for spoofing DNS requests.

```
<Sysname> system-view
[Sysname] dns proxy enable
[Sysname] ipv6 dns spoofing 2001::1
```

Related commands

dns proxy enable

ipv6 host

Use **ipv6 host** to create a host name-to-IPv6 address mapping.

Use **undo ipv6 host** to remove a host name-to-IPv6 address mapping.

Syntax

ipv6 host *host-name ipv6-address* [**vpn-instance** *vpn-instance-name*]

undo ipv6 host *host-name ipv6-address* [**vpn-instance** *vpn-instance-name*]

Default

No host name-to-IPv6 address mappings exist.

Parameters

host-name: Specifies a host name, a case-insensitive string of 1 to 253 characters. It can include letters, digits, hyphens (-), underscores (_), and dots (.).

ipv6-address: Specifies the IPv6 address of the host.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. To create a host name-to-IPv6 address mapping for the public network, do not specify this option.

Usage guidelines

The system allows a maximum of 1024 host name-to-IPv6 address mappings for the public network or each VPN instance. You can configure host name-to-IPv6 address mappings for both public network and VPN instances.

For the public network or a VPN instance, each host name maps to only one IPv6 address. If you execute this command multiple times, the most recent configuration takes effect.

Do not use the **ping ipv6** command parameter **-a**, **-c**, **-i**, **-m**, **-q**, **-s**, **-t**, **-tc**, **-v**, or **-vpn-instance** as the host name. For more information about the **ping ipv6** command parameters, see *Network Management and Monitoring Command Reference*.

Examples

Map IPv6 address 2001::1 to host name **aaa** for the public network.

```
<Sysname> system-view
[Sysname] ipv6 host aaa 2001::1
```

Related commands

ip host

reset dns host

Use **reset dns host** to clear dynamic DNS entries.

Syntax

reset dns host [**ip** | **ipv6**] [**vpn-instance** *vpn-instance-name*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

ip: Specifies type A queries. A type A query resolves a domain name to the mapped IPv4 address.

ipv6: Specifies type AAAA queries. A type AAAA query resolves a domain name to the mapped IPv6 address.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command clears dynamic DNS entries for the public network.

Usage guidelines

If you do not specify the **ip** or **ipv6** keyword, the **reset dns host** command clears dynamic DNS entries of all query types.

Use this command to clear the following dynamic DNS entries:

- Dynamic DNS entries on the DNS client.
- Dynamic DNS entries on the device enabled with DNS transparent proxy.

Examples

Clear dynamic DNS entries of all query types for the public network.

```
<Sysname> reset dns host
```

DDNS commands

ddns apply policy

Use **ddns apply policy** to apply a DDNS policy to an interface and enable DDNS update. DDNS updates the mapping between the FQDN and the primary IP address of the interface.

Use **undo ddns apply policy** to remove the application of a DDNS policy from an interface and to stop DDNS update.

Syntax

ddns apply policy *policy-name* [**fqdn** *domain-name*]

undo ddns apply policy *policy-name*

Default

No DDNS policy and FQDN are specified on the interface, and DDNS update is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies a DDNS policy by its name, a case-insensitive string of 1 to 32 characters.

fqdn *domain-name*: Specifies the FQDN to replace <h> in the URL for DDNS update. The *domain-name* argument specifies a case-insensitive string of 1 to 253 characters. It can include letters, digits, hyphens (-), underscores (_), and dots (.).

Usage guidelines

You can apply a maximum of four DDNS policies to an interface.

If you execute this command multiple times with the same DDNS policy name but different FQDNs, both of the following occur:

- The most recent configuration takes effect.
- The device initiates a DDNS update request immediately.

Examples

Apply DDNS policy **steven_policy** to GigabitEthernet 1/0/1 to update the domain name-to-IP address mapping for FQDN **www.whatever.com** and enable DDNS update.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ddns apply policy steven_policy fqdn www.whatever.com
```

DDNS policy: u-policy
  URL              : oray://phddns60.oray.net
  Username         : username
  Password         :
  Method           : -
  SSL client policy:
  Interval         : 0 days 0 hours 15 minutes
```

Table 5 Command output

Field	Description
DDNS policy	DDNS policy name.
URL	URL address for a DDNS update request. This field is empty if no URL address is configured.
Username	Username for logging in to the DDNS server. This field is empty if no username is configured.
Password	Password for logging in to the DDNS server. This field is empty if no password is configured and displays ********** if a password is configured.
Method	Parameter transmission method used to send HTTP/HTTPS-based DDNS update requests. Method types include GET and POST.
SSL client policy	Name of the associated SSL client policy. This field is empty if no SSL client policy is associated.
Interval	Interval for sending DDNS update requests.

Related commands

ddns policy

interval

Use **interval** to set the interval for sending DDNS update requests.

Use **undo interval** to restore the default.

Syntax

interval *days* [*hours* [*minutes*]]

undo interval

Default

The DDNS update request interval is 1 hour.

Views

DDNS policy view

Predefined user roles

network-admin

context-admin

Parameters

days: Days in the range of 0 to 365.

hours: Hours in the range of 0 to 23.

minutes: Minutes in the range of 0 to 59.

Usage guidelines

The interface always sends a DDNS update request in one of the following conditions:

- The primary IP address of the interface changes.
- The link state of the interface changes from down to up.

If you set the interval to 0, the device does not periodically initiate DDNS update requests.

If you execute this command multiple times, the most recent configuration takes effect. If you change the interval for an applied DDNS policy, the device immediately initiates a DDNS update request and sets the interval as the update interval.

Examples

Set the interval to 1 day and 1 minute for sending DDNS update requests for DDNS policy **steven_policy**.

```
<Sysname> system-view
[Sysname] ddns policy steven_policy
[Sysname-ddns-policy-steven_policy] interval 1 0 1
```

Related commands

ddns policy

display ddns policy

method

Use **method** to specify the parameter transmission method for sending DDNS update requests to HTTP/HTTPS-based DDNS servers.

Use **undo method** to restore the default.

Syntax

method { **http-get** | **http-post** }

undo method

Default

The method **http-get** applies.

Views

DDNS policy view

Predefined user roles

network-admin

context-admin

Parameters

http-get: Uses the get operation.

http-post: Uses the post operation.

Usage guidelines

This command applies to DDNS updates in HTTP/HTTPS. If the DDNS server uses HTTP or HTTPS service, choose a parameter transmission method compatible with the DDNS server. For example, a DHS server supports the **http-post** method.

If the DDNS policy has been applied to an interface, a DDNS update is sent immediately after the parameter transmission is changed.

Examples

Specify the parameter transmission method as **http-post** for DDNS update requests for DDNS policy **steven_policy**.

```
<Sysname> system-view
[Sysname] ddns policy steven_policy
[Sysname-ddns-policy-steven_policy] method http-post
```

Related commands

ddns policy

display ddns policy

password

Use **password** to specify the password for logging in to the DDNS server.

Use **undo password** to restore the default.

Syntax

password { **cipher** | **simple** } *string*

undo password

Default

No password is specified for logging in to the DDNS server.

Views

DDNS policy view

Predefined user roles

network-admin

context-admin

Parameters

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 32 characters. Its encrypted form is a case-sensitive string of 1 to 73 characters.

Examples

In DDNS policy **steven_policy**, specify **nevets** as the password for logging in to the DDNS server.

```
<Sysname> system-view
[Sysname] ddns policy steven_policy
[Sysname-ddns-policy-steven_policy] password simple nevets
```

ssl-client-policy

Use **ssl-client-policy** to associate an SSL client policy with a DDNS policy.

Use **undo ssl-client-policy** to restore the default.

Syntax

ssl-client-policy *policy-name*

undo ssl-client-policy

Default

No SSL client policy is associated with a DDNS policy.

Views

DDNS policy view

Predefined user roles

network-admin

context-admin

Parameters

policy-name: Specifies a SSL client policy by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

The SSL client policy is effective only for HTTPS-based DDNS update requests.

If you execute this command multiple times with different SSL client policies, the most recent configuration takes effect.

Examples

Associate SSL client policy **ssl_policy** with DDNS policy **steven_policy**.

```
<Sysname> system-view
```

```
[Sysname] ddns policy steven_policy
[Sysname-ddns-policy-steven_policy] ssl-client-policy ssl_policy
```

url

Use **url** to specify the URL address for DDNS update requests.

Use **undo url** to restore the default.

Syntax

url *request-url*

undo url

Default

No URL address is specified for DDNS update requests.

Views

DDNS policy view

Predefined user roles

network-admin

context-admin

Parameters

request-url: Specifies the URL address, a case-sensitive string of 1 to 240 characters.

Usage guidelines

The URL addresses configured for update requests vary by DDNS server. Common DDNS server URL address formats are shown in Table 6.

Table 6 Common URL addresses for DDNS update request

DDNS server	URL addresses for DDNS update requests
www.3322.org	http://members.3322.org/dyndns/update?system=dyndns&hostname=<h>&myip=<a>
DYNDNS	http://members.dyndns.org/nic/update?system=dyndns&hostname=<h>&myip=<a>
DYNS	http://www.dyns.cx/postscript.php?host=<h>&ip=<a>
ZONEEDIT	http://dynamic.zoneedit.com/auth/dynamic.html?host=<h>&dnsto=<a>
TZO	http://cgi.tzo.com/webclient/signedon.html?TZOName=<h>IPAddress=<a>
EASYDNS	http://members.easydns.com/dyn/ez-ipupdate.php?action=edit&myip=<a>&host_id=<h>
HEIPV6TB	http://dyn.dns.he.net/nic/update?hostname=<h>&myip=<a>
CHANGE-IP	http://nic.changeip.com/nic/update?hostname=<h>&offline=1
NO-IP	http://dynupdate.no-ip.com/nic/update?hostname=<h>&myip=<a>

DDNS server	URL addresses for DDNS update requests
DHS	http://members.dhs.org/nic/hosts?domain=dyn.dhs.org&hostname=<h>&hostscmd=edit&hostscmdstage=2&type=1&ip=<a>
HP	https://*server-name*/nic/update?group=*group-name*&myip=<a>
ODS	ods://update.ods.org
GNUDIP	gnudip://*server-name*
PeanutHull	• oray://phddns60.oray.net • oray://phservice2.oray.net • http://ddns.oray.com/ph/update?hostname=<h>&myip=<a>

The URL address cannot contain the username or password. To configure the username and password, use the **username** command and the **password** command.

HP and GNUDIP are common DDNS update protocols. The *server-name* parameter is the domain name or IP address of the service provider's server using one of the update protocols.

The URL address for an update request can start with:

- **http://**—The HTTP-based DDNS server.
- **https://**—The HTTPS-based DDNS server.
- **ods://**—The TCP-based ODS server.
- **gnudip://**—The TCP-based GNUDIP server.
- **oray://**—The TCP-based DDNS server.

The domain names of DDNS servers are members.3322.org and phddns60.oray.net. The domain names of PeanutHull DDNS servers can be phddns60.oray.net and phservice2.oray.net. The domain name phservice2.oray.net maps to the public IP address of the old version PeanutHull DDNS server, which is not maintained any more. You might need to try several times upon failures to connect to the server. As a best practice, register a new account and a domain name on the PeanutHull DDNS of a new version. Determine the domain name in the URL according to the actual situation.

The port number in the URL address is optional. If you do not specify a port number, the default port number is used. HTTP uses port 80, HTTPS uses port 443, and the PeanutHull server uses port 6060.

The system automatically performs the following tasks:

- Fills <h> with the FQDN that is specified when the DDNS policy is applied to an interface.
- Fills <a> with the primary IP address of the interface to which the DDNS policy is applied.

You can also manually specify an FQDN and an IP address in <h> and <a>, respectively. In this case, the FQDN that is specified when the DDNS policy is applied to an interface will not take effect. As a best practice, do not manually change the <h> and <a> because your configuration might be incorrect.

You cannot specify an FQDN and IP address in the URL address for contacting the PeanutHull server. Alternatively, you can specify an FQDN when applying the DDNS policy to an interface. The system automatically uses the primary IP address of the interface to which the DDNS policy is applied as the IP address for DDNS update.

To avoid misinterpretation, do not include colons (:), at signs (@), and question marks (?) in your login username or password, even if you can do so.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify the URL address for DDNS update requests for DDNS policy **steven_policy**. The device contacts **www.3322.org** for DDNS update.

```
<Sysname> system-view
[Sysname] ddns policy steven_policy
[Sysname-ddns-policy-steven_policy] url http://
members.3322.org/dyndns/update?system=dyndns&hostname=<h>&myip=<a>

display ip statistics

Use **display ip statistics** to display IP packet statistics.

Syntax

display ip statistics [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IP packet statistics for all member devices.

Usage guidelines

IP statistics include information about received and sent packets, fragments, and reassembly.

Examples

Display IP packet statistics.

```
<Sysname> display ip statistics
  Input:           sum            7120          local             112
                   bad protocol   0             bad format        0
                   bad checksum   0             bad options       0
                   dropped        0
  Output:          forwarding     0             local             27
                   dropped        0             no route          2
                   compress fails 0
  Reassembling:    fragments      0             reassembled       0
                   dropped        0             timeouts          0
  Fragment:        fragmented     0             couldn't fragment 0
                   output frags   0
  Forwarded Frags: sum            0
```

Table 1 Command output

Field	Description
Input	Statistics about received packets: • **sum**—Total number of packets received. • **local**—Total number of packets destined for the device. • **bad protocol**—Total number of unknown protocol packets. • **bad format**—Total number of packets with incorrect format. • **bad checksum**—Total number of packets with incorrect checksum. • **bad options**—Total number of packets with incorrect option.
Reassembling	Statistics about reassembling: • **fragments**—Total number of fragments that need reassembling. • **reassembled**—Total number of packets that are reassembled. • **dropped**—Total number of dropped fragments that fail the reassembling. • **timeouts**—Total number of reassembly timeouts.

Field	Description
Fragment	Statistics about fragments: • **fragmented**—Total number of packets successfully fragmented. • **couldn't fragment**—Total number of packets that failed to be fragmented. • **output**—Total number of fragments sent.
Forwarded Frags	Statistics about forwarded fragments: **sum**—Total number of fragments that are directly forwarded.

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`slot` *`slot-number`*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays brief information about RawIP connections for all member devices.

Usage guidelines

Brief RawIP connection information includes local and peer addresses, protocol, and PCB.

Examples

Display brief information about RawIP connections.

```
<Sysname> display rawip
 Local Addr       Foreign Addr     Protocol  Slot  PCB
 0.0.0.0          0.0.0.0          1         1     0x0000000000000009
 0.0.0.0          0.0.0.0          1         1     0x0000000000000008
 0.0.0.0          0.0.0.0          1         5     0x0000000000000002
```

Table 2 Command output

Field	Description
Local Addr	Local IP address.
Foreign Addr	Peer IP address.

Field	Description
Protocol	Protocol number.
PCB	Protocol control block.

display rawip verbose

Use **display rawip verbose** to display detailed information about RawIP connections.

Syntax

display rawip verbose [**slot** *slot-number* [**pcb** *pcb-index*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

pcb *pcb-index*: Displays detailed RawIP connection information for the specified PCB. The *pcb-index* argument specifies the index of the PCB. The index value range is 1 to 16.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays detailed information about RawIP connections for all member devices.

Usage guidelines

The detailed information includes socket creator, state, option, type, protocol number, and the source and destination IP addresses of RawIP connections.

Examples

Display detailed information about RawIP connections.

```
<Sysname> display rawip verbose
Total RawIP socket number: 1

 Connection info: src = 0.0.0.0, dst = 0.0.0.0
 Location: slot 6
 Creator: ping[320]
 State: N/A
 Options: N/A
 Error: 0
 Receiving buffer(cc/hiwat/lowat/drop/state): 0 / 9216 / 1 / 0 / N/A
 Sending buffer(cc/hiwat/lowat/state): 0 / 9216 / 512 / N/A
 Type: 3
 Protocol: 1
 Inpcb flags: N/A
 Inpcb extflag: N/A
 Inpcb vflag: INP_IPV4
```

```
TTL: 255(minimum TTL: 0)
Send VRF: 0xffff
Receive VRF: 0xffff
```

Table 3 Command output

Field	Description
Total RawIP socket number	Total number of RawIP sockets.
Connection info	Connection information, including source IP address and destination IP address.
Location	Socket location.
Creator	Name of the operation that created the socket. The number in brackets is the process number of the creator.
State	Socket state: • **NOFDREF**—The user has closed the connection. • **ISCONNECTED**—The connection has been established. • **ISCONNECTING**—The connection is being established. • **ISDISCONNECTING**—The connection is being interrupted. • **ISSMOOTHING**—Cross-card data smoothing is in progress. • **CANBIND**—The socket supports the bind operation. • **ASYNC**—Asynchronous mode. • **ISDISCONNECTED**—The connection has been terminated. • **PROTOREF**—Indicates strong protocol reference. • **ISPCBSYNCING**—Cross-card PCB synchronization is in progress. • **N/A**—None of above state.

Field	Description
Options	Socket options: • **SO_DEBUG**—Records socket debugging information. • **SO_ACCEPTCONN**—Enables the server to listen connection requests. • **SO_REUSEADDR**—Allows the local address reuse. • **SO_KEEPALIVE**—Requires the protocol to test whether the connection is still alive. • **SO_DONTROUTE**—Bypasses the routing table query for outgoing packets because the destination is in a directly connected network. • **SO_BROADCAST**—Supports broadcast packets. • **SO_LINGER**—Closes the socket. The system can still send remaining data in the socket send buffer. • **SO_OOBINLINE**—Stores the out-of-band data in the input queue. • **SO_REUSEPORT**—Allows the local port reuse. • **SO_TIMESTAMP**—Records the timestamps of the incoming packets, accurate to milliseconds. This option is applicable to protocols that are not connection orientated. • **SO_NOSIGPIPE**—Disables the socket from sending data. As a result, a sigpipe cannot be established when a return failure occurs. • **SO_FILTER**—Supports setting the packet filter criterion. This option takes effect on the incoming packets. • **SO_TIMESTAMPNS**—Has a similar function with the timestamp, accurate to nanoseconds. • **SO_SEQPACKET**—Preserves the boundaries of packets sent to the socket buffer. • **SO_FILLTWAMPTIME**—Sets the timestamp for TWAMP. • **SO_LOCAL**—Local socket option. • **SO_NBMAADDR**—Obtains the remote NBMA address of the ADVPN tunnel. • **SO_DONTDELIVER**—Do not deliver the data to the application. • **N/A**—No options are set.
Error	Error code.

Receiving buffer (cc/hiwat/lowat/drop/state)	Displays receive buffer information in the following order:
	• **cc**—Used space.
	• **hiwat**—Maximum space.
	• **lowat**—Minimum space.
	• **drop**—Number of dropped packets.
	• **state**—Buffer state:
	  ○ **CANTSENDMORE**—Unable to send data to the peer.
	  ○ **CANTRCVMORE**—Unable to receive data from the peer.
	  ○ **RCVATMARK**—Receiving tag.
	  ○ **N/A**—None of the above states.

Field	Description

Sending buffer (cc/hiwat/lowat/state)	Displays send buffer information in the following order:
	• **cc**—Used space.
	• **hiwat**—Maximum space.
	• **lowat**—Minimum space.
	• **state**—Buffer state:
	  ○ **CANTSENDMORE**—Unable to send data to the peer.
	  ○ **CANTRCVMORE**—Unable to receive data from the peer.
	  ○ **RCVATMARK**—Receiving tag.
	  ○ **N/A**—None of the above states.

Type	Socket type: • **1**—**SOCK_STREAM**. This socket uses TCP to provide reliable transmission of byte streams. • **2**—**SOCK_DGRAM**. This socket uses UDP to provide datagram transmission. • **3**—**SOCK_RAW**. This socket allows an application to change the next upper-layer protocol header. • **N/A**—None of the above types.
Protocol	Number of the protocol using the socket.
Inpcb flags	Flags in the Internet PCB: • **INP_RECVOPTS**—Receives IP options. • **INP_RECVRETOPTS**—Receives replied IP options. • **INP_RECVDSTADDR**—Receives destination IP address. • **INP_HDRINCL**—Provides the entire IP header. • **INP_REUSEADDR**—Reuses the IP address. • **INP_REUSEPORT**—Reuses the port number. • **INP_ANONPORT**—Port number not specified. • I**NP_RECVIF**—Records the input interface of the packet. • **INP_RECVTTL**—Receives TTL of the packet. Only UDP and RawIP support this flag. • **INP_DONTFRAG**—Sets the **Don't Fragment** flag. • **INP_ROUTER_ALERT**—Receives packets with the router alert option. Only RawIP supports this flag. • **INP_PROTOCOL_PACKET**—Identifies a protocol packet. • **INP_RCVVLANID**—Receives the VLAN ID of the packet. Only UDP and RawIP support this flag. • **INP_RCVMACADDR**—Receives the MAC address of the frame. • **INP_RECVTOS**—Receives TOS of the packet. Only UDP and RawIP support this flag. • **INP_USEICMPSRC**—Uses the specified IP address as the source IP address for outgoing ICMP packets. • **INP_SYNCPCB**—Waits until Internet PCB is synchronized. • **INP_LOCAL**—Preferentially matches the INPCB with this flag on the same card. • **N/A**—None of the above flags.

Field	Description
Inpcb extflag	Extension flags in the Internet PCB: • **INP_EXTRCVPVCIDX**—Records the PVC index of the received packet. • **INP_RCVPWID**—Records the PW ID of the received packet. • **INP_EXTRCVICMPERR**—Receives an ICMP error packet. • **INP_EXTFILTER**—Filters the contents in the received packet. • **INP_EXTDONTDROP**—Do not drop the received packet. • **INP_EXLISTEN**—Adds the INPCB carrying this flag to the listen hash table. • **INP_SELECTMATCHSRCBYFIB**—Uses the FIB table to select a matching source. • **INP_EXTPRIVATESOCKET**—Associates the INPCB with the NSR private socket. • **INP_EXLISTENNET**—Sets this flag when the connection information is added to the network segment linked list. • **N/A**—None of the above flags.
Inpcb vflag	IP version flags in the Internet PCB: • **INP_IPV4**—IPv4 protocol. • **INP_TIMEWAIT**—In **TIMEWAIT** state. • **INP_ONESBCAST**—Sends broadcast packets. • **INP_DROPPED**—Protocol dropped flag. • **INP_SOCKREF**—Strong socket reference. • **INP_DONTBLOCK**—Do not block synchronization of the Internet PCB. • **N/A**—None of the above flags.
TTL	TTL value in the Internet PCB.
Send VRF	VRF from which packets are sent.
Receive VRF	VRF from which packets are received.

display tcp

Use **`display tcp`** to display brief information about TCP connections.

Syntax

`display tcp` [**`slot`** *`slot-number`*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`slot` *`slot-number`*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays brief information about TCP connections for all member devices.

Usage guidelines

Brief TCP connection information includes local IP address, local port number, peer IP address, peer port number, and TCP connection state.

Examples

Display brief information about TCP connections.

```
<Sysname> display tcp
 *: TCP MD5 Connection
 Local Addr:port       Foreign Addr:port     State       Slot  PCB
*0.0.0.0:21            0.0.0.0:0             LISTEN      1     0x000000000000c387
 192.168.20.200:23     192.168.20.14:1284    ESTABLISHED 1     0x0000000000000009
 192.168.20.200:23     192.168.20.14:1283    ESTABLISHED 1     0x0000000000000002
```

Table 4 Command output

Field	Description
*	Indicates that the TCP connection uses authentication.
Local Addr:port	Local IP address and port number.
Foreign Addr:port	Peer IP address and port number.
State	TCP connection state.
PCB	PCB index.

display tcp statistics

Use **display tcp statistics** to display TCP traffic statistics.

Syntax

display tcp statistics [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays TCP traffic statistics for all member devices.

Usage guidelines

TCP traffic statistics include information about received and sent TCP packets and Syncache/syncookie.

Examples

Display TCP traffic statistics.

```
<Sysname> display tcp statistics
Received packets:
```

```
    Total: 4150
    packets in sequence: 1366 (134675 bytes)
    window probe packets: 0, window update packets: 0
    checksum error: 0, offset error: 0, short error: 0
    packets dropped for lack of memory: 0
    packets dropped due to PAWS: 0
    duplicate packets: 12 (36 bytes), partially duplicate packets: 0 (0 bytes)
    out-of-order packets: 0 (0 bytes)
    packets with data after window: 0 (0 bytes)
    packets after close: 0
    ACK packets: 3531 (795048 bytes)
    duplicate ACK packets: 33, ACK packets for unsent data: 0

Sent packets:
    Total: 4058
    urgent packets: 0
    control packets: 50
    window probe packets: 3, window update packets: 11
    data packets: 3862 (795012 bytes), data packets retransmitted: 0 (0 bytes)
    ACK-only packets: 150 (52 delayed)
    unnecessary packet retransmissions: 0

Syncache/syncookie related statistics:
    entries added to syncache: 12
    syncache entries retransmitted: 0
    duplicate SYN packets: 0
    reply failures: 0
    successfully build new socket: 12
    bucket overflows: 0
    zone failures: 0
    syncache entries removed due to RST: 0
    syncache entries removed due to timed out: 0
    ACK checked by syncache or syncookie failures: 0
    syncache entries aborted: 0
    syncache entries removed due to bad ACK: 0
    syncache entries removed due to ICMP unreachable: 0
    SYN cookies sent: 0
    SYN cookies received: 0

SACK related statistics:
    SACK recoveries: 1
    SACK retransmitted segments: 0 (0 bytes)
    SACK blocks (options) received: 0
    SACK blocks (options) sent: 0
    SACK scoreboard overflows: 0

Other statistics:
    retransmitted timeout: 0, connections dropped in retransmitted timeout: 0
```

```
    persist timeout: 0
    keepalive timeout: 21, keepalive probe: 0
    keepalive timeout, so connections disconnected: 0
    fin_wait_2 timeout, so connections disconnected: 0
    initiated connections: 29, accepted connections: 12, established connections:
23
    closed connections: 50051 (dropped: 0, initiated dropped: 0)
    bad connection attempt: 0
    ignored RSTs in the window: 0
    listen queue overflows: 0
    RTT updates: 3518(attempt segment: 3537)
    correct ACK header predictions: 0
    correct data packet header predictions: 568
    resends due to MTU discovery: 0
    packets dropped due to MD5 authentication failure: 0
    packets that passed MD5 authentication: 0
    sent Keychain-encrypted packets: 0
    packets that passed Keychain authentication: 0
    packets dropped due to Keychain authentication failure: 0
    packets dropped with MD5 authentication: 0
    packets permitted with MD5 authentication: 0
```

Related commands

reset tcp statistics

display tcp verbose

Use **display tcp verbose** to display detailed information about TCP connections.

Syntax

display tcp verbose [**slot** *slot-number* [**pcb** *pcb-index*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

pcb *pcb-index*: Displays detailed TCP connection information for the specified PCB. The index value range is 1 to 16.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays detailed information about TCP connections for all member devices.

Usage guidelines

The detailed TCP connection information includes socket creator, state, option, type, protocol number, source IP address and port number, destination IP address and port number, and connection state.

Examples

Display detailed information about TCP connections.

```
<Sysname> display tcp verbose
TCP inpcb number: 1(tcpcb number: 1)

 Connection info: src = 192.168.20.200:179 ,  dst = 192.168.20.14:4181
 Location: slot 6
 NSR standby: N/A
 Creator: bgpd[199]
 State: ISCONNECTED
 Options: N/A
 Error: 0
 Receiving buffer(cc/hiwat/lowat/drop/state): 0 / 65700 / 1 / 0 / N/A
 Sending buffer(cc/hiwat/lowat /state): 0 / 65700 / 512 / N/A
 Type: 1
 Protocol: 6
 Inpcb flags: N/A
 Inpcb extflag: N/A
 Inpcb vflag: INP_IPV4
 TTL: 255(minimum TTL: 0)
 Connection state: ESTABLISHED
 TCP options: TF_REQ_SCALE TF_REQ_TSTMP TF_SACK_PERMIT TF_NSR
 NSR state: READY(M)
 Send VRF: 0x0
 Receive VRF: 0x0
```

Table 5 Command output

Field	Description
TCP inpcb number	Number of TCP IP PCBs.
Connection info	Connection information, including source IP address, source port number, destination IP address, and destination port number.
Location	Socket location.
NSR standby	ID of the IRF member device and number of the slot where the NSR standby card resides. This field displays **N/A** if no NSR standby card is present.
tcpcb number	Number of TCP PCBs. This field is not displayed if the state of the TCP connection is **TIME_WAIT**.
Creator	Name of the operation that created the socket. The number in brackets is the process number of the creator.

Field	Description
State	Socket state: • **NOFDREF**—The user has closed the connection. • **ISCONNECTED**—The connection has been established. • **ISSMOOTHING**—Cross-card data smoothing is in progress. • **CANBIND**—The socket supports the bind operation. • **ISCONNECTING**—The connection is being established. • **ISDISCONNECTING**—The connection is being interrupted. • **ASYNC**—Asynchronous mode. • **ISDISCONNECTED**—The connection has been terminated. • **PROTOREF**—Indicates strong protocol reference. • **ISPCBSYNCING**—Cross-card PCB synchronization is in progress. • **N/A**—None of above state.
Options	Socket options: • **SO_DEBUG**—Records socket debugging information. • **SO_ACCEPTCONN**—Enables the server to listen connection requests. • **SO_REUSEADDR**—Allows the local address reuse. • **SO_KEEPALIVE**—Requires the protocol to test whether the connection is still alive. • **SO_DONTROUTE**—Bypasses the routing table query for outgoing packets because the destination is in a directly connected network. • **SO_BROADCAST**—Supports broadcast packets. • **SO_LINGER**—Closes the socket. The system can still send remaining data in the socket send buffer. • **SO_OOBINLINE**—Stores the out-of-band data in the input queue. • **SO_REUSEPORT**—Allows the local port reuse. • **SO_TIMESTAMP**—Records the timestamps of the incoming packets, accurate to milliseconds. This option is applicable to protocols that are not connection orientated. • **SO_NOSIGPIPE**—Disables the socket from sending data. As a result, a sigpipe cannot be established when a return failure occurs. • **SO_TIMESTAMPNS**—Has a similar function with the timestamp, accurate to nanoseconds. • **SO_KEEPALIVETIME**—Sets a keepalive time. • **SO_SEQPACKET**—Preserves the boundaries of packets sent to the socket buffer. • **SO_FILLTWAMPTIME**—Sets the timestamp for TWAMP. • **SO_LOCAL**—Local socket option. • **SO_NBMAADDR**—Obtains the remote NBMA address of the ADVPN tunnel. • **SO_DONTDELIVER**—Do not deliver the data to the application. • **N/A**—No options are set.
Error	Error code.

Field	Description

Receiving buffer (cc/hiwat/lowat/drop/state)	Displays receive buffer information in the following order:
	• **cc**—Used space.
	• **hiwat**—Maximum space.
	• **lowat**—Minimum space.
	• **drop**—Number of dropped packets.
	• **state**—Buffer state:
	  ○ **CANTSENDMORE**—Unable to send data to the peer.
	  ○ **CANTRCVMORE**—Unable to receive data from the peer.
	  ○ **RCVATMARK**—Receiving tag.
	  ○ **N/A**—None of the above states.

Sending buffer (cc/hiwat/lowat/state)	Displays send buffer information in the following order:
	• **cc**—Used space.
	• **hiwat**—Maximum space.
	• **lowat**—Minimum space.
	• **state**—Buffer state:
	  ○ **CANTSENDMORE**—Unable to send data to the peer.
	  ○ **CANTRCVMORE**—Unable to receive data from the peer.
	  ○ **RCVATMARK**—Receiving tag.
	  ○ **N/A**—None of the above states.

Type	Socket type: • **1**—**SOCK_STREAM**. This socket uses TCP to provide reliable transmission of byte streams. • **2**—**SOCK_DGRAM**. This socket uses UDP to provide datagram transmission. • **3**—**SOCK_RAW**. This socket allows an application to change the next upper-layer protocol header. • **N/A**—None of the above types.
Protocol	Number of the protocol using the socket.

Field	Description
Inpcb flags	Flags in the Internet PCB: • **INP_RECVOPTS**—Receives IP options. • **INP_RECVRETOPTS**—Receives replied IP options. • **INP_RECVDSTADDR**—Receives destination IP address. • **INP_HDRINCL**—Provides the entire IP header. • **INP_REUSEADDR**—Reuses the IP address. • **INP_REUSEPORT**—Reuses the port number. • **INP_ANONPORT**—Port number not specified. • I**NP_RECVIF**—Records the input interface of the packet. • **INP_RECVTTL**—Receives TTL of the packet. Only UDP and RawIP support this flag. • **INP_DONTFRAG**—Sets the **Don't Fragment** flag. • **INP_ROUTER_ALERT**—Receives packets with the router alert option. Only RawIP supports this flag. • **INP_PROTOCOL_PACKET**—Identifies a protocol packet. • **INP_RCVVLANID**—Receives the VLAN ID of the packet. Only UDP and RawIP support this flag. • **INP_RCVMACADDR**—Receives the MAC address of the frame. • **INP_RECVTOS**—Receives TOS of the packet. Only UDP and RawIP support this flag. • **INP_SYNCPCB**—Waits until Internet PCB is synchronized. • **INP_LOCAL**—Preferentially matches the INPCB with this flag on the same card. • **N/A**—None of the above flags.
Inpcb extflag	Extension flags in the Internet PCB: • **INP_EXTRCVPVCIDX**—Records the PVC index of the received packet. • **INP_RCVPWID**—Records the PW ID of the received packet. • **INP_EXTFILTER**—Filters the contents in the received packets. • **INP_SELECTMATCHSRCBYFIB**—Uses the FIB table to select a matching source. • **INP_EXTRCVICMPERR**—Receives an ICMP error packet. • **INP_EXTPRIVATESOCKET**—Associates the INPCB with the NSR private socket. • **INP_EXLISTENNET**—Sets this flag when the connection information is added to the network segment linked list. • **N/A**—None of the above flags.
Inpcb vflag	IP version flags in the Internet PCB: • **INP_IPV4**—IPv4 protocol. • **INP_TIMEWAIT**—In **TIMEWAIT** state. • **INP_ONESBCAST**—Sends broadcast packets. • **INP_DROPPED**—Protocol dropped flag. • **INP_SOCKREF**—Strong socket reference. • **INP_DONTBLOCK**—Do not block synchronization of the Internet PCB. • **N/A**—None of the above flags.
TTL	TTL value in the Internet PCB.

Field	Description
TCP options	TCP options: • **TF_ACKNOW**—Immediately replies an ACK packet to the peer. • **TF_DELACK**—Delays sending ACK packets. • **TF_SENTFIN**—A FIN packet has been sent. • **TF_RCVD_SCALE**—Requests the receive window size scale factor. • **TF_RCVD_TSTMP**—A timestamp was received in the SYN packet. • **TF_NEEDSYN**—Sends a SYN packet. • **TF_NEEDFIN**—Sends a FIN packet. • **TF_MORETOCOME**—More data is to be added to the socket. • **TF_LQ_OVERFLOW**—The listening queue overflows. • **TF_LASTIDLE**—Idle connection. • **TF_RXWIN0SENT**—A reply with receive window size 0 was sent. • **TF_FASTRECOVERY**—Enters NewReno fast recovery mode. • **TF_WASFRECOVERY**—In NewReno fast recovery mode. • **TF_SIGNATURE**—MD5 signature. • **TF_FORCEDATA**—Forces to send one byte. • **TF_TSO**—TSO is enabled. • **TF_PMTU**—Supports RFC 1191. • **TF_PMTUD**—Starts Path MTU discovery. • **TF_PASSIVE_CONN**—Passive connection. • **TF_APP_SEND**—The application sends data. • **TF_NODELAY**—Disables the Nagle algorithm that buffers the sent data inside the TCP. • **TF_NOOPT**—No TCP options. • **TF_NOPUSH**—Forces TCP to delay sending any TCP data until a full sized segment is buffered in the TCP buffers. • **TF_NSR**—Enables TCP NSR. • **TF_REQ_SCALE**—Enables the TCP window scale option. • **TF_REQ_TSTMP**—Enables the time stamp option. • **TF_SACK_PERMIT**—Enables the TCP selective acknowledgement option. • **TF_ENHANCED_AUTH**—Enables the enhanced authentication option.
NSR state	State of the TCP connections. Between the parentheses is the role of the connection: • **M**—Main connection. • **S**—Standby connection.
Send VRF	VRF from which packets are sent.
Receive VRF	VRF from which packets are received.

display tcp-proxy

Use **display tcp-proxy** to display brief information about TCP proxy.

Syntax

display tcp-proxy slot *slot-number*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID.

Usage guidelines

TCP proxy splits every TCP connection that passes through it into two TCP connections to relay data packets between clients and servers. The split is transparent to the servers and clients. This feature reduces bandwidth use and improves TCP performance. It is used for services such as load balancing and SSL VPN.

Examples

Display brief information about TCP proxy for the specified slot.

```
<Sysname> display tcp-proxy slot 1
Local Addr:port       Foreign Addr:port     State        Service type
192.168.56.25:1111    111.111.111.125:8080  ESTABLISHED  LB
111.111.111.125:8080  192.168.56.25:1111    ESTABLISHED  LB
```

Table 6 Command output

Field	Description
Local Addr:port	Local IP address and port number.
Foreign Addr:port	Peer IP address and port number.
State	TCP connection state.
Service type	Type of services that the TCP proxy is used for: • **LB**—Load balancing services. • **SSL VPN**—SSL VPN services. • **WAAS**—WAAS services. • **APPPROXY**—Application proxy services.

display tcp-proxy port-info

Use **display tcp-proxy port-info** to display the usage of non-well known ports for TCP proxy.

Syntax

display tcp-proxy port-info slot *slot-number*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays non-well known port usage for all member devices.

Usage guidelines

The TCP ports are divided into well-known ports (port numbers from 0 through 1023) and non-well known ports (port numbers from 1024 through 65535).

- Well known ports are for certain services, for example, port 23 for Telnet service, ports 20 and 21 for FTP service, and port 80 for HTTP service.
- Non-well known ports are available for various services. You can use the **display tcp-proxy port-info** command to display the usage of these ports.

Examples

Display the usage of non-well known ports for TCP proxy for the specified slot.

```
<Sysname> display tcp-proxy port-info slot 1
Index  Range            State
16     [1024, 1087]     USABLE
17     [1088, 1151]     USABLE
18     [1152, 1215]     USABLE
19     [1216, 1279]     USABLE
20     [1280, 1343]     USABLE
...
1020   [65280, 65343]   USABLE
1021   [65344, 65407]   USABLE
1022   [65408, 65471]   USABLE
1023   [65472, 65535]   USABLE
```

Table 7 Command output

Field	Description
Index	Index of the port range.
Range	Start port number and end port number.
State	State of the port range: • **USABLE**—The ports are assignable. • **ASSIGNED**—Some ports are dynamically assigned and some ports are not. • **ALLASSIGNED**—All ports are dynamically assigned. The assigned ports can be reclaimed. • **TO RECLAIM**—Some ports are statically assigned. The assigned ports can be reclaimed. • **RESERVED**—The ports are reserved. The reserved ports cannot be dynamically assigned.

display udp

Use **display udp** to display brief information about UDP connections.

Syntax

display udp [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays brief information about UDP connections for all member devices.

Usage guidelines

Brief UDP connection information includes local IP address and port number, and peer IP address and port number.

Examples

Display brief information about UDP connections.

```
<Sysname> display udp
 Local Addr:port        Foreign Addr:port     Slot  PCB
 0.0.0.0:69             0.0.0.0:0             1     0x0000000000000003
 192.168.20.200:1024    192.168.20.14:69      5     0x0000000000000002
```

Table 8 Command output

Field	Description
Local Addr:port	Local IP address and port number.
Foreign Addr:port	Peer IP address and port number.
PCB	PCB index.

display udp statistics

Use **display udp statistics** to display UDP traffic statistics.

Syntax

display udp statistics [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays UDP traffic statistics for all member devices.

Usage guidelines

UDP traffic statistics include information about received and sent UDP packets.

Examples

Display UDP traffic statistics.

```
<Sysname> display udp statistics
Received packets:
     Total: 240
     checksum error: 0, no checksum: 0
     shorter than header: 0, data length larger than packet: 0
     no socket on port(unicast): 0
     no socket on port(broadcast/multicast): 240
     not delivered, input socket full: 0
Sent packets:
     Total: 0
```

Related commands

reset udp statistics

display udp verbose

Use **display udp verbose** to display detailed information about UDP connections.

Syntax

display udp verbose [**slot** *slot-number* [**pcb** *pcb-index*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

pcb *pcb-index*: Displays detailed UDP connection information for the specified PCB. The value range for the *pcb-index* argument is 1 to 16.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays detailed information about UDP connections for all member devices.

Usage guidelines

The detailed information includes socket creator, status, option, type, protocol number, source IP address and port number, and destination IP address and port number for UDP connections.

Examples

Display detailed UDP connection information.

```
<Sysname> display udp verbose
Total UDP socket number: 1

 Connection info: src = 0.0.0.0:69, dst = 0.0.0.0:0
 Location: slot 6
 Creator: sock_test_mips[250]
 State: N/A
 Options: N/A
 Error: 0
 Receiving buffer(cc/hiwat/lowat/drop/state): 0 / 41600 / 1 / 0 / N/A
 Sending buffer(cc/hiwat/lowat/state): 0 / 9216 / 512 / N/A
 Type: 2
 Protocol: 17
 Inpcb flags: N/A
 Inpcb extflag: N/A
 Inpcb vflag: INP_IPV4
 TTL: 255(minimum TTL: 0)
 Send VRF: 0xffff
 Receive VRF: 0xffff
```

Table 9 Command output

Field	Description
Total UDP socket number	Total number of UDP sockets.
Connection info	Connection information, including source IP address, source port number, destination IP address, and destination port number.
Location	Socket location.
Creator	Name of the operation that created the socket. The number in brackets is the process number of the creator.
State	Socket state: • **NOFDREF**—The user has closed the connection. • **ISCONNECTED**—The connection has been established. • **ISCONNECTING**—The connection is being established. • **ISDISCONNECTING**—The connection is being interrupted. • **ASYNC**—Asynchronous mode. • **ISDISCONNECTED**—The connection has been terminated. • **ISSMOOTHING**—Cross-card data smoothing is in progress. • **CANBIND**—The socket supports the bind operation. • **PROTOREF**—Indicates strong protocol reference. • **ISPCBSYNCING**—Cross-card PCB synchronization is in progress. • **N/A**—None of above state.

Field	Description
Options	Socket options: • **SO_DEBUG**—Records socket debugging information. • **SO_ACCEPTCONN**—Enables the server to listen connection requests. • **SO_REUSEADDR**—Allows the local address reuse. • **SO_KEEPALIVE**—Requires the protocol to test whether the connection is still alive. • **SO_DONTROUTE**—Bypasses the routing table query for outgoing packets because the destination is in a directly connected network. • **SO_BROADCAST**—Supports broadcast packets. • **SO_LINGER**—Closes the socket. The system can still send remaining data in the socket send buffer. • **SO_OOBINLINE**—Stores the out-of-band data in the input queue. • **SO_REUSEPORT**—Allows the local port reuse. • **SO_TIMESTAMP**—Records the timestamps of the incoming packets, accurate to milliseconds. This option is applicable to protocols that are not connection orientated. • **SO_NOSIGPIPE**—Disables the socket from sending data. As a result, a sigpipe cannot be established when a return failure occurs. • **SO_TIMESTAMPNS**—Has a similar function with the timestamp, accurate to nanoseconds. • **SO_SEQPACKET**—Preserves the boundaries of packets sent to the socket buffer. • **SO_FILLTWAMPTIME**—Sets the timestamp for TWAMP. • **SO_LOCAL**—Local socket option. • **SO_NBMAADDR**—Obtains the remote NBMA address of the ADVPN tunnel. • **SO_DONTDELIVER**—Do not deliver the data to the application. • **N/A**—No options are set.
Error	Error code.

Receiving buffer(cc/hiwat/lowat/drop/state)	Displays receive buffer information in the following order:
	• **cc**—Used space.
	• **hiwat**—Maximum space.
	• **lowat**—Minimum space.
	• **drop**—Number of dropped packets.
	• **state**—Buffer state:
	  ○ **CANTSENDMORE**—Unable to send data to the peer.
	  ○ **CANTRCVMORE**—Unable to receive data from the peer.
	  ○ **RCVATMARK**—Receiving tag.
	  ○ **N/A**—None of the above states.

Sending buffer(cc/hiwat/lowat/state)	Displays send buffer information in the following order:
	• **cc**—Used space.
	• **hiwat**—Maximum space.
	• **lowat**—Minimum space.
	• **state**—Buffer state:
	  ○ **CANTSENDMORE**—Unable to send data to the peer.
	  ○ **CANTRCVMORE**—Unable to receive data from the peer.
	  ○ **RCVATMARK**—Receiving tag.
	  ○ **N/A**—None of the above states.

Field	Description
Type	Socket type: • **1**—**SOCK_STREAM**. This socket uses TCP to provide reliable transmission of byte streams. • **2**—**SOCK_DGRAM**. This socket uses UDP to provide datagram transmission. • **3**—**SOCK_RAW**. This socket allows an application to change the next upper-layer protocol header. • **N/A**—None of the above types.
Protocol	Number of the protocol using the socket.
Connection info	Connection information, including source IP address, source port number, destination IP address, and destination port number.
Inpcb flags	Flags in the Internet PCB: • **INP_RECVOPTS**—Receives IP options. • **INP_RECVRETOPTS**—Receives replied IP options. • **INP_RECVDSTADDR**—Receives destination IP address. • **INP_HDRINCL**—Provides the entire IP header. • **INP_REUSEADDR**—Reuses the IP address. • **INP_REUSEPORT**—Reuses the port number. • **INP_ANONPORT**—Port number not specified. • I**NP_RECVIF**—Records the input interface of the packet. • **INP_RECVTTL**—Receives TTL of the packet. Only UDP and RawIP support this flag. • **INP_DONTFRAG**—Sets the **Don't Fragment** flag. • **INP_ROUTER_ALERT**—Receives packets with the router alert option. Only RawIP supports this flag. • **INP_PROTOCOL_PACKET**—Identifies a protocol packet. • **INP_RCVVLANID**—Receives the VLAN ID of the packet. Only UDP and RawIP support this flag. • **INP_RCVMACADDR**—Receives the MAC address of the frame. • **INP_RECVTOS**—Receives TOS of the packet. Only UDP and RawIP support this flag. • **INP_SYNCPCB**—Waits until Internet PCB is synchronized. • **INP_LOCAL**—Preferentially matches the INPCB with this flag on the same card. • **N/A**—None of the above flags.
Inpcb extflag	Extension flags in the Internet PCB: • **INP_EXTRCVPVCIDX**—Records the PVC index of the received packet. • **INP_RCVPWID**—Records the PW ID of the received packet. • **INP_EXTDONTDROP**—Do not drop the received packet. • **INP_EXLISTEN**—Adds the INPCB carrying this flag to the listen hash table. • **INP_EXTFILTER**—Filters the contents in the received packets. • **INP_SELECTMATCHSRCBYFIB**—Uses the FIB table to select a matching source. • **INP_EXTRCVICMPERR**—Receives an ICMP error packet. • **INP_EXTPRIVATESOCKET**—Associates the INPCB with the NSR private socket. • **INP_EXLISTENNET**—Sets this flag when the connection information is added to the network segment linked list. • **N/A**—None of the above flags.

Field	Description
Inpcb vflag	IP version flags in the Internet PCB: • **INP_IPV4**—IPv4 protocol. • **INP_TIMEWAIT**—In **TIMEWAIT** state. • **INP_ONESBCAST**—Sends broadcast packets. • **INP_DROPPED**—Protocol dropped flag. • **INP_SOCKREF**—Strong socket reference. • **INP_DONTBLOCK**—Do not block synchronization of the Internet PCB. • **N/A**—None of the above flags.
TTL	TTL value in the Internet PCB.
Send VRF	VRF from which packets are sent.
Receive VRF	VRF from which packets are received.

ip df-bit

Use **ip df-bit** to configure the DF bit for IP packets.

Use **undo ip df-bit** to restore the default.

Syntax

ip df-bit { **clear** | **set** }

undo ip df-bit

The following compatibility matrixes show the support of hardware platforms for this command:

Models	Command compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB1180, NFNX3-HDB1480	No

Default

The DF bit value of IP packets is retained as it is.

Views

System view

Predefined user roles

network-admin

context-adminn

Parameters

clear: Sets the DF bit to 0 for IP packets. The IP packets can be fragmented.

set: Sets the DF bit to 1 for IP packets. The IP packets cannot be fragmented.

Examples

Clear the DF bit for IP packets.

```
<Sysname> system-view
```

```
[Sysname] ip df-bit clear
```

ip forward-broadcast

Use **ip forward-broadcast** to enable an interface to receive and forward directed broadcast packets destined for the directly connected network.

Use **undo ip forward-broadcast** to disable an interface from receiving and forwarding directed broadcast packets destined for the directly connected network.

Syntax

ip forward-broadcast

undo ip forward-broadcast

Default

An interface cannot forward directed broadcasts destined for the directly connected network, and can receive directed broadcasts destined for the directly connected network.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

acl *acl-number*: Specifies an ACL by its number. The interface forwards only the directed broadcasts permitted by the ACL. The value range for basic ACLs is 2000 to 2999. The value range for advanced ACLs is 3000 to 3999.

Usage guidelines

A directed broadcast packet is destined for all hosts on a specific network. In the destination IP address of the directed broadcast, the network ID identifies the target network, and the host ID is made up of all ones.

Examples

Enable GigabitEthernet 1/0/1 to receive and forward directed broadcast packets destined for the directly connected network.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip forward-broadcast
```

ip icmp error-interval

Use **ip icmp error-interval** to set the interval for tokens to arrive in the bucket and the bucket size for ICMP error messages.

Use **undo ip icmp error-interval** to restore the default.

Syntax

ip icmp error-interval *interval* [*bucketsize*]

undo ip icmp error-interval

Default

A token is placed in the bucket every 100 milliseconds, and the bucket allows a maximum of 10 tokens.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the interval for tokens to arrive in the bucket. The value range is 0 to 2147483647 milliseconds. To disable the ICMP rate limit, set the value to 0.

bucketsize: Specifies the maximum number of tokens allowed in the bucket. The value range is 1 to 200.

Usage guidelines

This command limits the rate at which ICMP error messages are sent. Use this command to avoid sending excessive ICMP error messages within a short period that might cause network congestion. A token bucket algorithm is used with one token representing one ICMP error message.

A token is placed in the bucket at intervals until the maximum number of tokens that the bucket can hold is reached.

A token is removed from the bucket when an ICMP error message is sent. When the bucket is empty, ICMP error messages are not sent until a new token is placed in the bucket.

Examples

Set the interval to 200 milliseconds for tokens to arrive in the bucket and set the bucket size to 40 tokens for ICMP error messages.

```
<Sysname> system-view
[Sysname] ip icmp error-interval 200 40
```

ip icmp source

Use **ip icmp source** to specify the source address for outgoing ICMP packets.

Use **undo ip icmp source** to remove the specified source address for outgoing ICMP packets.

Syntax

ip icmp source [**vpn-instance** *vpn-instance-name*] *ip-address*

undo ip icmp source [**vpn-instance** *vpn-instance-name*]

Default

No source address is specified for outgoing ICMP packets. The default source IP addresses for different types of ICMP packets vary as follows:

- For an ICMP error message, the source IP address is the IP address of the receiving interface of the packet that triggers the ICMP error message. ICMP error messages include Time Exceeded, Port Unreachable, and Parameter Problem messages.
- For an ICMP echo request, the source IP address is the IP address of the sending interface.
- For an ICMP echo reply, the source IP address is the destination IP address of the ICMP echo request specific to this reply.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance to which the specified address belongs. The *vpn-instance-name* argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. The specified VPN instance must exist. If you do not specify a VPN instance, the *ip-address* argument specifies an IP address on the public network.

ip-address: Specifies an IP address.

Usage guidelines

It is a good practice to specify the IP address of the loopback interface as the source IP address for outgoing ping echo request and ICMP error messages. This feature helps users to locate the sending device easily.

Examples

Specify 1.1.1.1 as the source address for outgoing ICMP packets.

```
<Sysname> system-view
[Sysname] ip icmp source 1.1.1.1
```

ip mtu

Use **ip mtu** to set the interface MTU for IPv4 packets. The MTU defines the largest size of an IPv4 packet that an interface can transmit without fragmentation.

Use **undo ip mtu** to restore the default.

Syntax

ip mtu *mtu-size*

undo ip mtu

Default

The interface MTU is not set.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

mtu-size: Specifies the MTU in bytes. The value range for the *mtu-size* argument depends on the interface type.

Usage guidelines

When a packet exceeds the MTU of the sending interface, the device processes the packet in one of the following ways:

- If the packet disallows fragmentation, the device discards it.
- If the packet allows fragmentation, the device fragments it and forwards the fragments.

Fragmentation and reassembling consume system resources, so set an appropriate MTU to avoid fragmentation.

If an interface supports both the **mtu** and **ip mtu** commands, the device fragments a packet based on the MTU set by the **ip mtu** command.

Examples

Set the interface MTU to 1280 bytes for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip mtu 1280
```

ip reassemble local enable

Use **ip reassemble local enable** to enable IPv4 local fragment reassembly.

Use **undo ip reassemble local enable** to disable local fragment reassembly.

Syntax

ip reassemble local enable

undo ip reassemble local enable

Default

IPv4 local fragment reassembly is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this feature on a multichassis IRF fabric to improve fragment reassembly efficiency. This feature enables a subordinate to reassemble the IPv4 fragments of a packet if all the fragments arrive at it. If this feature is disabled, all IPv4 fragments are delivered to the master device for reassembly. The feature applies only to fragments destined for the same subordinate.

Examples

Enable IPv4 local fragment reassembly.

```
<Sysname> system-view
[Sysname] ip reassemble local enable
```

ip redirects enable

Use **ip redirects enable** to enable sending ICMP redirect messages.

Use **undo ip redirects enable** to disable sending ICMP redirect messages.

Syntax

ip redirects enable

undo ip redirects enable

Default

Sending ICMP redirect messages is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

ICMP redirect messages simplify host management and enable hosts to gradually optimize their routing tables.

A host that has only one route destined for the default gateway sends all packets to the default gateway. The default gateway sends an ICMP redirect message to inform the host of a correct next hop when the following conditions are met:

- The receiving and sending interfaces are the same.
- The packet source IP address and the IP address of the packet receiving interface are on the same segment.
- There is no source route option in the received packet.

Examples

Enable sending ICMP redirect messages.

```
<Sysname> system-view
[Sysname] ip redirects enable
```

ip ttl-expires enable

Use **ip ttl-expires enable** to enable sending ICMP time exceeded messages.

Use **undo ip ttl-expires enable** to disable sending ICMP time exceeded messages.

Syntax

ip ttl-expires enable

undo ip ttl-expires enable

Default

Sending ICMP time exceeded messages is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

A device sends ICMP time exceeded messages by following these rules:

- The device sends an ICMP TTL exceeded in transit message to the source when the following conditions are met:
  - The received packet is not destined for the device.
  - The TTL field of the packet is 1.

- When the device receives the first fragment of an IP datagram destined for the device itself, it starts a timer. If the timer expires before all the fragments of the datagram are received, the device sends an ICMP fragment reassembly time exceeded message to the source.

A device disabled from sending ICMP time exceeded messages does not send ICMP TTL exceeded in transit messages but can still send ICMP fragment reassembly time exceeded messages.

Examples

Enable sending ICMP time exceeded messages.

```
<Sysname> system-view
[Sysname] ip ttl-expires enable
```

ip unreachables enable

Use **ip unreachables enable** to enable sending ICMP destination unreachable messages.

Use **undo ip unreachables enable** to disable sending ICMP destination unreachable messages.

Syntax

ip unreachables enable

undo ip unreachables enable

Default

Sending ICMP destination unreachable messages is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

A device sends ICMP destination unreachable messages by following these rules:

- The device sends the source an ICMP network unreachable message when the following conditions are met:
  - The received packet does not match any route.
  - No default route exists in the routing table.
- The device sends the source an ICMP protocol unreachable message when the following conditions are met:
  - The received packet is destined for the device.
  - The transport layer protocol of the packet is not supported by the device.
- The device sends the source an ICMP port unreachable message when the following conditions are met:
  - The received UDP packet is destined for the device.
  - The packet's port number does not match the running process.
- The device sends the source an ICMP source route failed message when the following conditions are met:
  - The source uses Strict Source Routing to send packets.
  - The intermediate device finds that the next hop specified by the source is not directly connected.

- The device sends the source an ICMP fragmentation needed and DF set message when the following conditions are met:
  - The MTU of the sending interface is smaller than the packet.
  - The packet has Don't Fragment set.

Examples

Enable sending ICMP destination unreachable messages.

```
<Sysname> system-view
[Sysname] ip unreachables enable
```

ip virtual-reassembly centralize

Use **ip virtual-reassembly centralize** to enable fragment centralization for IPv4 VFR.

Use **undo ip virtual-reassembly centralize** to disable fragment centralization for IPv4 VFR.

Syntax

ip virtual-reassembly centralize

undo ip virtual-reassembly centralize

Default

Fragment centralization is disabled for IPv4 VFR.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

On an HA network, if an HA device enabled with IPv4 VFR does not receive all fragments of a datagram, it cannot reassemble the datagram and will discard the received fragments. To resolve this issue, you can enable this feature. Devices that do not receive the first fragment of a datagram forward the received fragments of this datagram to the device that receives the first fragment for VFR.

This feature is applicable to devices enabled with IPv4 VFR on an HA network.

For more information about HA networking, see high availability group configuration in *High Availability Configuration Guide*.

Examples

Enable fragment centralization for IPv4 VFR.

```
<Sysname> system-view
[Sysname] ip virtual-reassembly centralize
```

Related commands

undo ip virtual-reassembly suppress

ip virtual-reassembly enable

Use **ip virtual-reassembly enable** to enable IPv4 virtual fragment reassembly (VFR).

Use **undo ip virtual-reassembly enable** to disable IPv4 virtual fragment reassembly.

Syntax

ip virtual-reassembly enable

undo ip virtual-reassembly enable

Default

IPv4 virtual fragment reassembly is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

To prevent each service module from processing packet fragments that do not arrive in order, you can enable the virtual fragment reassembly feature. This feature virtually reassembles the fragments of a datagram through fragment check, sequencing, and caching, ensuring fragments arrive at each service module in order.

VFR can detect and prevent the following types of attacks:

- **Tiny fragment attack**—The first fragment size is too small to hold the Layer 4 (such as TCP and UDP) header field, which is forced into the second fragment. VFR discards all tiny fragments.
- **Overlapping fragment attack**—Two consecutive incoming fragments are identical or overlap with each other. If an overlapping fragment is detected, VFR discards all fragments within a fragment chain.
- **Fragment flooding attack**—The maximum number of concurrent preassemblies or the number of fragments per datagram exceeds the upper limits. VFR discards subsequent fragments if the upper limit is reached.

The enabling status of VFR can be managed at CLI or the enabling status of a service module that can call VFR. VRF is enabled in either of the following conditions:

- A service module that can call it is enabled.
- The **ip virtual-reassembly enable** command is executed.

If fragment reassembly is required, but a service module cannot call it, execute this command at CLI.

Examples

Enable IPv4 virtual fragment reassembly

```
<Sysname> system-view
[Sysname] ip virtual-reassembly enable
```

ip virtual-reassembly suppress

Use **ip virtual-reassembly suppress** to forcibly disable IPv4 VFR.

Use **undo ip virtual-reassembly suppress** to restore the default.

Syntax

ip virtual-reassembly suppress

undo ip virtual-reassembly suppress

Default

Forcibly disabling IPv4 VFR is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

IMPORTANT:

Use this feature according to the demands of VFR.

IPv4 VFR checks, sequences, and caches fragments upon fragment receiving to ensure that these fragments will be assembled in the correct order. By default, IPv4 VFR is enabled.

On an HA network, if an HA device does not receive all fragments of a datagram, it cannot reassemble the datagram and will discard the received fragments. For the device to permit the received fragments to pass, you can forcibly disable IPv4 VFR.

After you enable VFR through service calling or CLI, you can use the **ip virtual-reassembly suppress** command to forcibly disable VFR.

With IPv4 VFR forcibly disabled, ASPF and connection limit do not take effect on the received IPv4 fragments and the fragments will be forwarded directly.

For more information about HA networking, see high availability group configuration in *High Availability Configuration Guide*.

Examples

Forcibly disable IPv4 VFR.

```
<Sysname> system-view
[Sysname] ip virtual-reassembly suppress
```

ipv6 virtual-reassembly centralize

Use **ipv6 virtual-reassembly centralize** to enable fragment centralization for IPv6 VFR.

Use **undo ipv6 virtual-reassembly centralize** to disable fragment centralization for IPv6 VFR.

Syntax

ipv6 virtual-reassembly centralize

undo ipv6 virtual-reassembly centralize

Default

Fragment centralization is disabled for IPv6 VFR.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

On an HA network, if an HA device enabled with IPv6 VFR does not receive all fragments of a datagram, it cannot reassemble the datagram and will discard all the received fragments. To resolve this issue, you can enable this feature. Devices that do not receive the first fragment of a datagram forward the received fragments of this datagram to the device that receives the first fragment for VFR.

This feature is applicable to devices enabled with IPv6 VFR on an HA network.

For more information about HA networking, see high availability group configuration in *High Availability Configuration Guide*.

Examples

Enable fragment centralization for IPv6 VFR.

```
<Sysname> system-view
[Sysname] ipv6 virtual-reassembly centralize
```

ipv6 virtual-reassembly suppress

Use **ipv6 virtual-reassembly suppress** to forcibly disable IPv6 VFR.

Use **undo ipv6 virtual-reassembly suppress** to restore the default.

Syntax

ipv6 virtual-reassembly suppress

undo ipv6 virtual-reassembly suppress

Default

Forcibly disabling IPv6 VFR is disabled.

reset ip statistics

Use **reset ip statistics** to clear IP traffic statistics.

Syntax

reset ip statistics [**slot** *slot-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command clears IP traffic statistics for all member devices.

Usage guidelines

Use this command to clear history IP traffic statistics before you collect IP traffic statistics for a time period.

Examples

Clear IP traffic statistics.

```
<Sysname> reset ip statistics
```

Related commands

display ip interface

display ip statistics

reset tcp statistics

Use **reset tcp statistics** to clear TCP traffic statistics.

Clear UDP traffic statistics.

```
<Sysname> reset udp statistics
```

Related commands

display udp statistics

tcp mss

Use **tcp mss** to set the TCP maximum segment size (MSS).

Use **undo tcp mss** to restore the default.

Syntax

tcp mss *value*

undo tcp mss

Default

The TCP MSS is not set.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies the TCP MSS in bytes. The minimum value is 128 bytes. The maximum value equals the maximum MTU that the interface supports minus 40.

Usage guidelines

The MSS option informs the receiver of the largest segment that the sender can accept. Each end announces its MSS during TCP connection establishment. If the size of a TCP segment is smaller than the MSS of the receiver, TCP sends the TCP segment without fragmentation. If not, TCP fragments the segment according to the receiver's MSS.

If you set the TCP MSS on an interface, the size of each TCP segment received or sent on the interface cannot exceed the MSS value.

This configuration takes effect only on TCP connections that are established after the configuration and not on the TCP connections that already exist.

This configuration is effective only on IP packets.

Examples

Set the TCP MSS to 300 bytes on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] tcp mss 300
```

tcp path-mtu-discovery

Use **tcp path-mtu-discovery** to enable TCP path MTU discovery.

Use **undo tcp path-mtu-discovery** to disable TCP path MTU discovery.

Syntax

tcp path-mtu-discovery [**aging** *age-time* | **no-aging**]

undo tcp path-mtu-discovery

Default

TCP path MTU discovery is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

aging *age-time*: Specifies the aging time for the path MTU, in the range of 10 to 30 minutes. The default aging time is 10 minutes.

no-aging: Does not age out the path MTU.

Usage guidelines

After you enable TCP path MTU discovery, all new TCP connections detect the path MTU. The device uses the path MTU to calculate the MSS to avoid IP fragmentation.

After you disable TCP path MTU discovery, the system stops all path MTU timers. The TCP connections established later do not detect the path MTU, but the TCP connections previously established still can detect the path MTU.

Examples

Enable TCP path MTU discovery and set the path MTU aging time to 20 minutes.

```
<Sysname> system-view
[Sysname] tcp path-mtu-discovery aging 20
```

tcp syn-cookie enable

Use **tcp syn-cookie enable** to enable SYN Cookie to protect the device from SYN flood attacks.

Use **undo tcp syn-cookie enable** to disable SYN Cookie.

Syntax

tcp syn-cookie enable

undo tcp syn-cookie enable

Default

SYN Cookie is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

A TCP connection is established through a three-way handshake:

1. The sender sends a SYN packet to the server.
2. The server receives the SYN packet, establishes a TCP semi-connection in SYN_RECEIVED state, and replies with a SYN ACK packet to the sender.
3. The sender receives the SYN ACK packet and replies with an ACK packet. Then, a TCP connection is established.

An attacker can exploit this mechanism to mount SYN flood attacks. The attacker sends a large number of SYN packets, but they do not respond to the SYN ACK packets from the server. As a result, the server establishes a large number of TCP semi-connections and cannot handle normal services.

SYN Cookie can protect the server from SYN flood attacks. When the server receives a SYN packet, it responds to the request with a SYN ACK packet without establishing a TCP semi-connection.

The server establishes a TCP connection and enters ESTABLISHED state only when it receives an ACK packet from the sender.

Examples

Enable SYN Cookie.

```
<Sysname> system-view
[Sysname] tcp syn-cookie enable
```

tcp timer fin-timeout

Use **tcp timer fin-timeout** to set the TCP FIN wait timer.

Use **undo tcp timer fin-timeout** to restore the default.

Syntax

tcp timer fin-timeout *time-value*

undo tcp timer fin-timeout

Default

The TCP FIN wait timer is 675 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

time-value: Specifies the TCP FIN wait timer in the range of 76 to 3600 seconds.

Usage guidelines

TCP starts the FIN wait timer when the state of a TCP connection changes to FIN_WAIT_2. If no FIN packet is received within the timer interval, the TCP connection is terminated.

If a FIN packet is received, TCP changes the connection state to TIME_WAIT. If a non-FIN packet is received, TCP restarts the timer and tears down the connection when the timer expires.

Examples

Set the TCP FIN wait timer to 800 seconds.

```
<Sysname> system-view
[Sysname] tcp timer fin-timeout 800
```

tcp timer syn-timeout

Use **tcp timer syn-timeout** to set the TCP SYN wait timer.

Use **undo tcp timer syn-timeout** to restore the default.

Syntax

tcp timer syn-timeout *time-value*

undo tcp timer syn-timeout

Default

The TCP SYN wait timer is 75 seconds.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

time-value: Specifies the TCP SYN wait timer in the range of 2 to 600 seconds.

Usage guidelines

TCP starts the SYN wait timer after sending a SYN packet. Within the SYN wait timer if no response is received or the upper limit on TCP connection tries is reached, TCP fails to establish the connection.

Examples

Set the TCP SYN wait timer to 80 seconds.

```
<Sysname> system-view
[Sysname] tcp timer syn-timeout 80
```

tcp timestamps enable

Use **tcp timestamps enable** to enable carrying the TCP timestamp option in outgoing TCP packets.

Use **undo tcp timestamps enable** to disable carrying the TCP timestamp option in outgoing TCP packets.

Syntax

tcp timestamps enable

undo tcp timestamps enable

Default

The device adds the TCP timestamp option in outgoing TCP packets.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

The TCP timestamp option in TCP packets is used to calculate the RTT between two communicating devices. In some networks, it is required to prevent the intermediate devices from obtaining the TCP timestamps in packets passing through. Then you can disable carrying the TCP timestamp option in outgoing packets on a device at either end.

This command takes effect on TCP connections established only after the execution of the command.

Examples

Enable carrying the TCP timestamp option in outgoing TCP packets.

```
<Sysname> system-view
[Sysname] undo tcp timestamps enable
```

tcp window

Use **tcp window** to set the size of the TCP receive/send buffer.

Use **undo tcp window** to restore the default.

Syntax

tcp window *window-size*

undo tcp window

Default

The size of the TCP receive/send buffer is 63 KB.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

window-size: Specifies the size of the TCP receive/send buffer, in the range of 1 to 64 KB.

Examples

Set the size of the TCP receive/send buffer to 3 KB.

```
<Sysname> system-view
[Sysname] tcp window 3
```

Contents

Multi-CPU packet distribution commands

forwarding policy

Use **forwarding policy** to specify a multi-CPU packet distribution policy.

Use **undo forwarding policy** to restore the default.

Syntax

forwarding policy { **per-flow** [**three-tuple | mode { source-ip | destination-ip | source-port | destination-port }**] | **per-packet** }

undo forwarding policy

Default

The device uses the flow-based policy that identifies a flow by source IP address, destination IP address, source port number, destination port number, and protocol number.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

per-flow: Specifies the flow-based forwarding. The device identifies a data flow by the five-tuple, and forwards packets of the same flow to one CPU. The CPU processes flow packets by following the first-in first-out rule.

three-tuple: Identifies a data flow by the three-tuple (source IP address, destination IP address, and protocol number). If you do not specify this keyword, the device identifies a data flow by the five-tuple.

The following compatibility matrixes show the support of hardware platforms for the **three-tuple** keyword:

Models	Parameter compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No

mode: Specifies a flow-based forwarding mode.

source-ip: Identifies a flow by source IP address.

destination-ip: Identifies a flow by destination IP address.

source-port: Identifies a flow by source port.

destination-port: Identifies a flow by destination port.

per-packet: Specifies the packet-based forwarding. The device forwards packets in sequence to different CPUs, even though they are the same flow. This policy does not ensure packet order.

Usage guidelines

If you do not specify any keyword for flow identification, the device identifies a flow by source IP address, destination IP address, source port number, destination port number, and protocol number.

Examples

Specify the flow-based policy.

```
<Sysname> system-view
[Sysname] forwarding policy per-flow
```

Adjacency table commands

IPv4 adjacency table commands

display adjacent-table

Use **display adjacent-table** to display IPv4 adjacency entries.

Syntax

display adjacent-table { **all** | **physical-interface** *interface-type interface-number* | **routing-interface** *interface-type interface-number* | **slot** *slot-number* } [**count** | **verbose**]

View

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

all: Displays all IPv4 adjacency entries.

physical-interface *interface-type interface-number*: Displays IPv4 adjacency entries about the specified physical interface.

routing-interface *interface-type interface-number*: Displays IPv4 adjacency entries about the specified routing interface.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv4 adjacency entries for all member devices.

count: Displays the number of IPv4 adjacency entries.

verbose: Displays detailed information about IPv4 adjacency entries.

Examples

Display detailed information about all IPv4 adjacency entries.

```
<Sysname> display adjacent-table all verbose
   IP address                      : 0.0.0.0
   Routing interface               : Tunnel1
   Physical interface              : Tunnel1
   Logical interface               : N/A
   Service type                    : Tunnel
   Action type                     : Forwarding
   Link media type                 : P2P
   Slot                            : 0
   Cpu                             : 0
   VPN index                       : 0
```

```
  Virtual circuit information   : N/A
  Link head information(IP)      : 450000000000000ff2f0000020202010202020200000
                                   0800
  Link head information(MPLS)    : 450000000000000ff2f0000020202010202020200000
                                   0800
```

Display IPv4 adjacency entries for the specified slot.

```
<Sysname> display adjacent-table slot 1
IP address        Routing interface         Physical interface      Type
0.0.0.0           Tun1                         Tun1                       Tunnel
```

Display the number of IPv4 adjacency entries for the specified slot.

```
<Sysname> display adjacent-table slot 1 count
 Total entries on slot 1: 1
```

Table 1 Command output

Field	Description
IP address	IP address of the next hop. • For a P2P link, the IP address of the next hop is not needed. This field displays **0.0.0.0**. • For an NBMA link, the value 0.0.0.0 indicates the default adjacency entry. Packets are forwarded through the default virtual circuit.
Routing interface	Output interface of the matching route entry.
Physical interface	Physical interface of which the outgoing packets are sent out.
Logical interface	Logical interface for sending the packets. If the entry has no logical interface, this field displays **N/A**.
Service type/Type	Link layer protocol type.
Action type	Packet processing type, **Forwarding** or **Drop**.
Link media type	Link media type: • **P2P**—Point-to-point link. • **NBMA**—Non-broadcast multi-access link.
Cpu	This field is not supported in the current software version. Number of the CPU.
VPN index	Index of the VPN.
Virtual circuit information	Information about the virtual circuit, such as PVC or DLCI. If the entry has no virtual circuit, this field displays **N/A**.
Link head information(IP)	Link layer header for IPv4.
Link head information(MPLS)	This field is not supported in the current software version. Link layer header for MPLS.

IPv6 adjacency table commands

display ipv6 adjacent-table

Use **display ipv6 adjacent-table** to display IPv6 adjacency entries.

Syntax

display ipv6 adjacent-table { **all** | **physical-interface** *interface-type interface-number* | **routing-interface** *interface-type interface-number* | **slot** *slot-number* } [**count** | **verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

   Link head information(IPv6)   : 450000000000000ff2f000002020201020202020000
                                   86dd
   Link head information(MPLS)   : 450000000000000ff2f000002020201020202020000
```

```
                                    86dd
```

Display IPv6 adjacency entries for the specified slot.

```
<Sysname> display ipv6 adjacent-table slot 1
IPv6 address          Routing interface     Physical interface    Type
N/A                     Tun1                     Tun1                    Tunnel
```

Display the number of IPv6 adjacency entries for the specified slot.

```
<Sysname> display ipv6 adjacent-table slot 1 count
 Total entries on slot 1: 1
```

Table 2 Command output

Field	Description
IPv6 address	IPv6 address of the next hop. • For a P2P link, the IPv6 address of the next hop is not needed. This field has the value 0::0, and displays **N/A**. • For an NBMA link, the value 0.0.0.0 indicates a default adjacency table. Packets are forwarded through the default virtual circuit.
Routing interface	Output interface of the matching route entry.
Physical interface	Physical interface of which the outgoing packets are sent out.
Logical interface	Logical interface that sends the packets. If the entry has no logical interface, this field displays **N/A**.
Service type/Type	Link layer protocol type.
Action type	Packet processing type, **Forwarding** or **Drop**.
Link media type	Link media type: • **P2P**—Point-to-point link. • **NBMA**—Non-broadcast multi-access link.
Cpu	This field is not supported in the current software version. Number of the CPU.
VPN index	Index of the VPN.
Virtual circuit information	Information about the virtual circuit, such as PVC or DLCI. If the entry has no virtual circuit, this field displays **N/A**.
Link head information(IPv6)	Link layer header for IPv6.
Link head information(MPLS)	This field is not supported in the current software version. Link layer header for MPLS.

Web caching commands

Web caching is supported only in RXX60P20 and later.

backup

Use **backup** to specify a backup Web caching slot.

Use **undo backup** to restore the default.

Syntax

backup slot *slot-number*

undo backup

Default

No backup Web caching slot is specified.

Views

Web cache view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID.

Usage guidelines

To enhance the high availability of Web caching, configure the Web cache backup feature. You can use this command to specify a backup Web caching slot. When the primary slot (specified by using the **web-cache** command) fails, the backup slot will take over to provide the Web caching service to ensure service continuity. When the primary slot recovers, the Web caching service switches back to the primary slot.

Examples

Specify slot 1 as the backup Web caching slot.

```
<Sysname> system-view
[Sysname] web-cache slot 1
[Sysname-web-cache-slot1] backup slot 2
```

cached-data

Use **cached-data** to specify the types of the webpage files to be cached.

Use **undo cached-data** to restore the default.

Syntax

cached-data { **apk** | **bmp** | **doc** | **docx** | **gif** | **gzip** | **ipa** | **jar** | **jpg** | **jpeg** | **mp4** | **pdf** | **png** | **ppt** | **pptx** | **rar** | **swf** | **tar** | **txt** | **xls** | **xlsx** | **zip** } *

undo cached-data

Default

No webpage file types are specified.

Views

Web cache view

Predefined user roles

network-admin

context-admin

Parameters

`apk`: Specifies .apk files.

`bmp`: Specifies .bmp files.

`doc`: Specifies .doc files.

`docx`: Specifies .docx files.

`gif`: Specifies .gif files.

`gzip`: Specifies .gzip files.

`ipa`: Specifies .ipa files.

`jar`: Specifies .jar files.

`jpg`: Specifies .jpg files.

`jpeg`: Specifies .jpeg files.

`mp4`: Specifies .mp4 files.

`pdf`: Specifies .pdf files.

`png`: Specifies .png files.

`ppt`: Specifies .ppt files.

`pptx`: Specifies .pptx files.

`rar`: Specifies .rar files.

`swf`: Specifies .swf files.

`tar`: Specifies .tar files.

`txt`: Specifies .txt files.

`xls`: Specifies .xls files.

`xlsx`: Specifies .xlsx files.

`zip`: Specifies .zip files.

Usage guidelines

If you do not specify the types of the webpage files to be cached, the Web caching feature does not cache any types of files on webpages.

Execute this command before enabling Web caching.

Before configuring or modifying file type settings, you must disable Web caching. After configuring or modifying file type settings, enable Web caching again.

Execution of the **`undo cached-data`** command will not delete webpage files saved in the Web cache directory. The Web caching feature can still cache webpage files specified by using the **`cached-file`** command.

Examples

Configure the Web caching feature to cache .doc and .docx files on webpages.

```
<Sysname> system-view
[Sysname] web-cache slot 1
[Sysname-web-cache-slot1] cached-data doc docx
```

Related commands

http enable

https enable

cached-file

Use **cached-file** to specify a webpage file to be cached.

Use **undo cached-file** to remove a webpage file to be cached.

Syntax

cached-file *file-name*

undo cached-file [*file-name*]

Default

No webpage files can be cached.

Views

Web cache view

Predefined user roles

network-admin

context-admin

Parameters

file-name: Specifies a webpage file by its name, a case-sensitive string of 1 to 127 characters.

Usage guidelines

You can repeat this command to specify multiple webpage files to be cached.

If you specify both webpage files and types of the webpage files to be cached, the device caches the matching webpage files of the specified types.

Before you add or delete a webpage file to be cached, you must disable Web caching. After adding or deleting the webpage file, enable Web caching again.

Execution of the **undo cached-data** command will not delete webpage files saved in the Web cache directory.

Examples

Specify file **test1.doc** as a webpage file to be cached.

```
<Sysname> system-view
[Sysname] web-cache slot 1
[Sysname-web-cache-slot1] cached-file test1.doc
```

Related commands

cached-data

cache-limit

Use **cache-limit** to set the maximum total size for Web cache files.

Use **undo cache-limit** to restore the default.

Syntax

cache-limit *size*

undo cache-limit

Default

The maximum total size of Web cache files is 4 GB.

Views

Web cache view

Predefined user roles

network-admin

context-admin

Parameters

size: Specifies the maximum total size for Web cache files in GB. The value range is 1 to 4095. The default is 4.

Usage guidelines

Before changing the maximum total file size setting, you must disable Web caching. After changing the maximum total file size setting, enable Web caching again.

The maximum total size for Web cache files must be smaller than the maximum storage space size in the working directory. To display the maximum size of storage space in the working directory, execute the **display web-cache** command. After the effective maximum total size is reached, the device deletes the oldest Web cache file to save the new Web cache file.

The aging time for Web cache files is fixed at 30 days. When the device reboots or receives a request for the content in a Web cache file, it restarts the aging timer. If no users request the content in a file before the aging timer expires, the device deletes the file.

Examples

Set the maximum total size for Web cache files to 3 GB.

```
<Sysname> system-view
[Sysname] web-cache slot 1
[Sysname-web-cache-slot1] cache-limit 3
```

display web-cache

Use **display web-cache** to display Web caching information.

Syntax

display web-cache [**history** [**last** { **day** | **30-days** | **365-days** | **hour** | **minute** | **week** } | **verbose**]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

history: Displays history information. If you specify this keyword but do not specify any following keywords, the command displays the current statistics, which is collected at 1-second intervals. If you do not specify this keyword, the command displays Web cache configuration and statistics for the most recent time ranges.

last: Displays statistics for a specific period of time in the past.

minute: Displays statistics for the most recent one minute.

hour: Displays statistics for the most recent one hour.

day: Displays statistics for the most recent one day.

week: Displays statistics for the most recent one week.

30-days: Displays statistics for the most recent 30 days.

365-days: Displays statistics for the most recent 365 days.

verbose: Displays detailed information. If you do not specify this keyword, the command displays brief information.

Examples

Display the current Web caching statistics.

```
<Sysname> display web-cache history
Date TimeRange ConnectTop CacheTop BandwidthSaved CacheHitRate
2018/06/20 14:43:02-14:43:03 3 16.0KB 0 0%
2018/06/20 14:43:01-14:43:02 3 16.0KB 96.0Kbps 100%
```

Display all Web caching information.

```
<Sysname> display web-cache
Web-cache configurations
  Cache path: flash:/var/web-cache/proxy/cache
  Max connections: 1022
  Max cache size: 3GB

Table 1 Command output

Field	Description
Cache path	Web cache directory.
Max connections	Maximum number of connections allowed.
Max cache size	Current maximum storage space size.
Cache memory	Current total size of Web cache files.
Cache count	Number of Web cache files.
Statistics for past 1 minute	Web caching statistics for the most recent one minute.
Statistics for past 1 hour	Web caching statistics for the most recent one hour.
Statistics for past 1 day	Web caching statistics for the most recent one day.
Statistics for past 30 days	Web caching statistics for the most recent 30 days.
Statistics for past 365 days	Web caching statistics for the most recent 365 days.
ConnectTop	Maximum number of connections during the specified period of time.
CacheTop	Maximum total size of Web cache files during the specified period of time, in KB, MB, GB, or TB.
Bandwidth saved	Bandwidth saved during the specified period of time, in Kbps, Mbps, Gbps, or Tbps.
Cached data transmission speed	Speed at which cached data was transferred to users during the specified period of time, in Kbps, Mbps, Gbps, or Tbps.
Cached data transmitted	Amount of cached data that was transferred to users during the specified period of time, in KB, MB, GB, or TB.
Download speed	Speed at which cached data was downloaded from Web servers during the specified period of time, in Kbps, Mbps, Gbps, or Tbps.

Field	Description
Download size	Amount of cached data that was downloaded from Web servers during the specified period of time, in KB, MB, GB, or TB.
CacheHitRate	Percentage of hits of cached data.
Hit count	Number of hits of cached data.
Miss count	Number of times that cached data was not matched.

file-directory

Use **file-directory** to set the primary Web cache directory.

Use **undo file-directory** to restore the default.

Syntax

file-directory *directory*

undo file-directory

Default

The primary Web cache directory is not set.

Views

Web cache view

Predefined user roles

network-admin

context-admin

Parameters

directory: Specifies the primary Web cache directory, starting from the storage medium location information **slot***n*#. The slot number *n* must be the same as the slot number of the Web cache view.

Usage guidelines

Before changing the Web cache directory, you must disable Web caching. After changing the Web cache directory, enable Web caching again.

Make sure the storage medium where the Web cache directory resides has sufficient storage space. The Web caching feature saves its operation data and the Web content to be cached to files in the directory. The directory typically needs a storage space of over 1 GB.

Before specifying a Web cache directory, make sure all files in the upper-level directory are using a different name than the Web cache directory or have a file extension. For example, if you want to specify **flash:/web-cache** as the Web cache directory, files without a file extension in the **flash:** directory cannot use **web-cache** as the file name.

The primary Web cache directory for a Web cache view must reside on the same slot as the Web view.

Examples

Set the primary Web cache directory.

```
<Sysname> system-view
[Sysname] web-cache slot 1
[Sysname-web-cache-slot1] file-directory slot1#flash:/aaa
```

file-directory backup

Use **file-directory backup** to set the backup Web cache directory.

Use **undo file-directory backup** to restore the default.

Syntax

file-directory backup *directory*

undo file-directory backup

Default

No backup Web cache directory is set.

Views

Web cache view

Predefined user roles

network-admin

context-admin

Parameters

directory: Specifies the backup Web cache directory, starting from the storage medium location information **slot***n*#. The slot number *n* must be the same as the slot number of the Web cache view.

Usage guidelines

To implement Web cache backup, use this command to specify the backup Web cache directory. When the device uses the primary slot for Web caching, it saves webpage files to the primary Web cache directory. When the device uses the backup Web caching slot, it saves webpage files to the backup Web cache directory.

Make sure the storage medium where the Web cache directory resides has sufficient storage space. The Web caching feature saves its operation data and the Web content to be cached to files in the directory. The directory typically needs a storage space of over 1 GB.

The backup Web cache directory for a Web cache view must reside on the backup slot. After the backup Web cache directory is created, the device will not synchronize cache files under the primary directory to the backup directory.

Before specifying a Web cache directory, make sure all files in the upper-level directory are using a different name than the Web cache directory or have a file extension. For example, if you want to specify **flash:/web-cache** as the Web cache directory, files without a file extension in the **flash:** directory cannot use **web-cache** as the file name.

Before changing the Web cache directory, you must disable Web caching. After changing the Web cache directory, enable Web caching again.

You must specify a directory on the slot same as the backup Web caching slot specified by using the **backup** command.

Examples

Set the backup Web cache directory.

```
<Sysname> system-view
[Sysname] web-cache slot 1
[Sysname-web-cache-slot1] file-directory backup slot4#flash:/webcache
```

Related commands

backup

http enable

Use **http enable** to enable HTTP-based Web caching.

Use **undo http enable** to disable HTTP-based Web caching.

Syntax

http enable

undo http enable

Default

HTTP-based Web caching is disabled.

Views

Web cache view

Predefined user roles

network-admin

context-admin

Usage guidelines

Before enabling HTTP-based Web caching, you must configure the types of the webpage files to be cached and the Web cache directory.

Examples

Enable HTTP-based Web caching.

```
<Sysname> system-view
[Sysname] web-cache slot 1
[Sysname-web-cache-slot1] http enable
```

Related commands

cached-data

file-directory

listen-port

https enable

Use **https enable** to enable HTTPS-based Web caching.

Use **undo https enable** to disable HTTP-based Web caching.

Syntax

https enable

undo https enable

Default

HTTPS-based Web caching is disabled.

Views

Web cache view

Predefined user roles

network-admin

context-admin

Usage guidelines

Before enabling HTTPS-based Web caching, you must configure the types of the webpage files to be cached and the Web cache directory.

Examples

Enable HTTPS-based Web caching.

```
<Sysname> system-view
[Sysname] web-cache slot 1
[Sysname-web-cache-slot1] https enable
```

Related commands

file-directory

cached-data

https listen-port

Use **https listen-port** to set the port number for Web caching to listen for HTTPS packets.

Use **undo https listen-port** to restore the default.

Syntax

https listen-port *port-number*

undo https listen-port

Default

Web caching listens to port 443 for HTTPS packets.

Views

Web cache view

Predefined user roles

network-admin

context-admin

Parameters

port-number: Specifies a TCP port number in the range of 1 to 65535.

Usage guidelines

Make sure the specified TCP port number is not being used by any other services on the device. To display TCP port numbers in use, execute the **display tcp verbose** command.

Before changing the listening port setting, you must disable Web caching. After changing the listening port setting, enable Web caching again.

Examples

Set the port number to 655 for Web caching to listen for HTTPS packets.

```
<Sysname> system-view
[Sysname] web-cache slot 1
[Sysname-web-cache-slot1] https listen-port 655
```

Related commands

https enable

listen-port

Use **listen-port** to set the port number for Web caching to listen for HTTP packets.

Use **undo listen-port** to restore the default.

Syntax

listen-port *port-number*

undo listen-port

Default

Web caching listens to port 80 for HTTP packets.

Views

Web cache view

Predefined user roles

network-admin

context-admin

Parameters

port-number: Specifies a TCP port number in the range of 1 to 65535.

Usage guidelines

Make sure the specified TCP port number is not being used by any other services on the device. To display TCP port numbers in use, execute the **display tcp verbose** command.

Before changing the listening port setting, you must disable Web caching. After changing the listening port setting, enable Web caching again.

Examples

Set the port number to 655 for Web caching to listen for HTTP packets.

```
<Sysname> system-view
[Sysname] web-cache slot 1
[Sysname-web-cache-slot1] listen-port 655
```

Related commands

http enable

object-group

Use **object-group** to specify an IPv4 object group used to filter Web content to be cached.

Use **undo object-group** to remove an IPv4 object group used to filter Web content to be cached.

Syntax

object-group [**source**] **ip** *object-group-name*

undo object-group [**source**]

Default

No IPv4 object group is specified for filtering Web content. The Web caching feature caches webpage content from all Web servers.

Views

Web cache view

Predefined user roles

network-admin

context-admin

Parameters

source: Caches Web content requested by specific Web clients. If you do not specify this keyword, the Web caching feature caches Web content from specific Web servers.

ip: Uses an IPv4 object group to specify Web clients or Web servers. For more information about IPv4 object groups, see *Security Configuration Guide*.

object-group-name: Specifies an IPv4 object group by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

Use this command to configure the Web caching feature to cache only Web content requested by specific Web clients or sent from specific Web servers.

This command requires the cooperation of the IPv4 object group feature. For more information about the IPv4 object group feature, see object group configuration in *Security Configuration Guide*.

Execute this command before enabling Web caching.

Before changing the IPv4 object group setting, you must disable Web caching. After changing the IPv4 object group setting, enable Web caching again.

Examples

Configure the Web caching feature to cache only Web content from Web servers specified by IPv4 object group **aaa**.

```
<Sysname> system-view
[Sysname] web-cache slot 1
[Sysname-web-cache-slot1] object-group ip aaa
```

Related commands

object-group (*Security Command Reference*)

web-cache

Use **web-cache** to create a Web cache view and enter its view, or enter an existing Web cache view.

Use **undo web-cache** to delete a Web cache view and all settings in the view.

Syntax

web-cache slot *slot-number*

undo web-cache slot

Default

No Web cache views exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID.

Examples

Create a Web cache view and enter its view.

```
<Sysname> system-view
[Sysname] web-cache slot 1
[Sysname-web-cache-slot1]
```

NSFOCUS Firewall Series

NF Layer 3—IP Routing

Command Reference

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

This command reference describes the commands for configuring routing protocols, including basic IP routing, static routing, RIP, OSPF, IS-IS, BGP, policy-based routing, IPv6 static routing, IPv6 policy-based routing, RIPng, OSPFv3, Guard route , RIR and routing policies.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Basic IP routing commands

address-family ipv4

Use **address-family ipv4** to create the RIB IPv4 address family and enter its view, or enter the view of the existing RIB IPv4 address family.

Use **undo address-family ipv4** to delete the RIB IPv4 address family and all settings in the view.

Syntax

address-family ipv4

undo address-family ipv4

Default

No RIB IPv4 address family exists.

Views

RIB view

Predefined user roles

network-admin

context-admin

Examples

Create the RIB IPv4 address family and enter its view.

```
<Sysname> system-view
[Sysname] rib
[Sysname-rib] address-family ipv4
[Sysname-rib-ipv4]
```

address-family ipv6

Use **address-family ipv6** to create the RIB IPv6 address family and enter its view, or enter the view of the existing RIB IPv6 address family.

Use **undo address-family ipv6** to delete the RIB IPv6 address family and all settings in the view.

Syntax

address-family ipv6

undo address-family ipv6

Default

No RIB IPv6 address family exists.

Views

network-admin

context-admin

Examples

Create the RIB IPv6 address family and enter its view.

```
<Sysname> system-view
[Sysname] rib
[Sysname-rib] address-family ipv6
[Sysname-rib-ipv6]
```

display ip routing-table

Use **display ip routing-table** to display routing table information.

Syntax

display ip routing-table [**vpn-instance** *vpn-instance-name*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters.

verbose: Displays detailed routing table information, including information about both active and inactive routes. If you do not specify this keyword, the command displays only brief information about active routes.

Usage guidelines

If you do not specify any parameters, the command displays routing table information for the public network.

Examples

Display brief information about active routes in the routing table.

```
<Sysname> display ip routing-table

Destinations : 10        Routes : 10

Destination/Mask   Proto   Pre Cost        NextHop         Interface
0.0.0.0/32         Direct  0   0           127.0.0.1       InLoop0

```

Table 2 Command output

Field	Description
Destinations	Number of destination addresses.
Routes	Number of routes.
Destination	Destination address/mask length.
Protocol	Protocol that installed the route.
SubProtID	ID of the subprotocol for routing.
Age	Time for which the route has been in the routing table.
Cost	Cost of the route.
Preference	Preference of the route.
IpPre	IP precedence.
QosLocalID	Local QoS ID.
Tag	Route tag.
State	Route status: • **Active**—Active unicast route. • **Adv**—Route that can be advertised. • **Inactive**—Inactive route. • **NoAdv**—Route that the router must not advertise. • **Vrrp**—Routes generated by VRRP. This state is not supported in the current software version. • **Nat**—Routes generated by NAT. • **TunE**—Tunnel.
OrigTblID	Original routing table ID.
OrigVrf	Original VPN instance that the route belongs to. This field displays **default-vrf** if the route is on the public network.
TableID	ID of the routing table.
OrigAs	Original AS number.

Field	Description
NibID	ID of the next hop.
LastAs	Last AS number.
AttrID	Attribute ID.
Neighbor	Address of the neighbor determined by the routing protocol.
Flags	Flags of the route.
OrigNextHop	Next hop address of the route.
Label	This field is not supported in the current software version. Label of the route.
RealNextHop	Real next hop of the route.
BkLabel	This field is not supported in the current software version. Backup label.
BkNexthop	Backup next hop.
SRLabel	This field is not supported in the current software version. Segment routing (SR) label.
BkSRLabel	This field is not supported in the current software version. Backup segment routing (SR) label.
SIDIndex	This field is not supported in the current software version. SID index value.
InLabel	This field is not supported in the current software version. Input label.
Tunnel ID	Tunnel ID.
Interface	Output interface for packets to be forwarded along the route.
BkTunnel ID	Backup tunnel ID.
BkInterface	Backup output interface.
FtnIndex	Index of the FTN entry.
TrafficIndex	Traffic index in the range of 1 to 64. This field displays **N/A** when the value is invalid.
Connector	BGP connector attribute exchanged between BGP peers along with a VPN IPv4 route. The value of the attribute is the IP address of the remote PE device. The BGP connector attribute is used for MD VPN. This field displays **N/A** if the BGP connector attribute is not supported.
VpnPeerId	This field is not supported in the current software version. ID of the VPN peer to which the route belongs, in the range of 1 to 134217727. This field displays **N/A** when the value is invalid.
Dscp	DSCP value of the route, in the range of 0 to 63. This field displays **N/A** when the value is invalid.
Exp	MPLS EXP value of the route, which is supported only by BGP. This field displays **N/A** when the value is invalid.
Summary count	Number of routes.

display ip routing-table acl

Use **display ip routing-table acl** to display information about routes permitted by a basic ACL.

Syntax

display ip routing-table [**vpn-instance** *vpn-instance-name*] **acl** *ipv4-acl-number* [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command displays routing information for the public network.

ipv4-acl-number: Specifies a basic ACL by its number in the range of 2000 to 2999.

verbose: Displays detailed information about all routes permitted by the basic ACL. If you do not specify this keyword, the command displays only brief information about active routes permitted by the basic ACL.

Usage guidelines

If the specified ACL does not exist or has no rules configured, the command displays information about all routes.

Examples

Define basic ACL 2000 and set the route filtering rules.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule permit source 192.168.1.0 0.0.0.255
[Sysname-acl-ipv4-basic-2000] rule deny source any
```

Display brief information about active routes permitted by basic ACL 2000.

```
[Sysname-acl-ipv4-basic-2000] display ip routing-table acl 2000

Summary count : 4

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
192.168.1.0/24      Direct 0    0            192.168.1.111   GE1/0/1
192.168.1.0/32      Direct 0    0            192.168.1.111   GE1/0/1
192.168.1.111/32    Direct 0    0            127.0.0.1       InLoop0
192.168.1.255/32    Direct 0    0            192.168.1.111   GE1/0/1
```

For command output, see Table 1.

Display detailed information about all routes permitted by basic ACL 2000.

```
<Sysname> display ip routing-table acl 2000 verbose
```

```

For command output, see Table 2.

display ip routing-table *ip-address*

Use **display ip routing-table** *ip-address* to display information about routes to a specific destination address.

Use **display ip routing-table** *ip-address1* **to** *ip-address2* to display information about routes to a range of destination addresses.

Syntax

display ip routing-table [**vpn-instance** *vpn-instance-name*] *ip-address* [*mask-length* | *mask*] [**longer-match**] [**verbose**]

display ip routing-table [**vpn-instance** *vpn-instance-name*] *ip-address1* **to** *ip-address2* [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command displays routing information for the public network.

ip-address: Specifies a destination IP address in dotted decimal notation.

mask-length: Specifies the mask length, an integer in the range of 0 to 32.

mask: Specifies the IP address mask in dotted decimal notation.

longer-match: Displays the route entry with the longest mask.

ip-address1 **to** *ip-address2*: Specifies a destination IP address range.

verbose: Displays detailed routing table information, including information about both active and inactive routes. If you do not specify this keyword, the command displays brief information about active routes.

Usage guidelines

Executing the command with different parameters yields different outputs.

- **display ip routing-table** *ip-address*
  - The system ANDs the entered destination IP address with the subnet mask in each active route entry.
  - The system ANDs the destination IP address in each active route entry with its own subnet mask.

  If the two operations yield the same result for an entry, the entry is displayed.
- **display ip routing-table** *ip-address mask*
  - The system ANDs the entered destination IP address with the entered subnet mask.
  - The system ANDs the destination IP address in each active route entry with the entered subnet mask.

  If the two operations yield the same result for an entry with a subnet mask not greater than the entered subnet mask, the entry is displayed.
- **display ip routing-table** *ip-address* **longer-match**
  - The system ANDs the entered destination IP address with the subnet mask in each active route entry.

- The system ANDs the destination IP address in each active route entry with its own subnet mask.

If the two operations yield the same result for multiple entries, the entry with the longest mask length is displayed.

- **display ip routing-table** *ip-address mask* **longer-match**
  - The system ANDs the entered destination IP address with the entered subnet mask.
  - The system ANDs the destination IP address in each active route entry with the entered subnet mask.

  If the two operations yield the same result for multiple entries with a mask not greater than the entered subnet mask, the entry with the longest mask length is displayed.
- **display ip routing-table** *ip-address1* **to** *ip-address2*

  The system displays active route entries with destinations in the range of *ip-address1*/32 to *ip-address2*/32.

Examples

Display brief information about the routes to the destination IP address 11.0.0.1.

```
<Sysname> display ip routing-table 11.0.0.1

Summary count : 3

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
11.0.0.0/8          Static 60   0            0.0.0.0         NULL0
11.0.0.0/16         Static 60   0            0.0.0.0         NULL0
11.0.0.0/24         Static 60   0            0.0.0.0         NULL0
```

Display brief information about the routes to the destination IP address 11.0.0.1 and mask length 20.

```
<Sysname> display ip routing-table 11.0.0.1 20

Summary count : 2

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
11.0.0.0/8          Static 60   0            0.0.0.0         NULL0
11.0.0.0/16         Static 60   0            0.0.0.0         NULL0
```

Display brief information about the most specific route to the destination address 11.0.0.1.

```
<Sysname> display ip routing-table 11.0.0.1 longer-match

Summary count : 1

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
11.0.0.0/24         Static 60   0            0.0.0.0         NULL0
```

Display brief information about the most specific route to the destination IP address 11.0.0.1 and mask length 20.

```
<Sysname> display ip routing-table 11.0.0.1 20 longer-match

Summary count : 1

```

For command output, see Table 2.

display ip routing-table prefix-list

Use **display ip routing-table prefix-list** to display routes permitted by an IP prefix list.

Syntax

display ip routing-table [**vpn-instance** *vpn-instance-name*] **prefix-list** *prefix-list-name* [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command displays routing information for the public network.

prefix-list-name: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters.

verbose: Displays detailed information about all routes permitted by the IP prefix list. If you do not specify this keyword, the command displays brief information about active routes permitted by the IP prefix list.

Usage guidelines

If the specified IP prefix list does not exist, the command displays information about all routes.

Examples

Create an IP prefix list named **test** to permit the route 1.1.1.0/24.

```
<Sysname> system-view
[Sysname] ip prefix-list test permit 1.1.1.0 24
```

Display brief information about the active route permitted by the IP prefix list.

```
[Sysname] display ip routing-table prefix-list test

Summary count : 1

BkTunnel ID: Invalid        BkInterface: N/A
   FtnIndex: 0x0           TrafficIndex: N/A
  Connector: N/A              VpnPeerId: N/A
       Dscp: N/A                    Exp: N/A
```

For command output, see Table 2.

display ip routing-table protocol

Use **display ip routing-table protocol** to display information about routes installed by a protocol.

Syntax

display ip routing-table [**vpn-instance** *vpn-instance-name*] **protocol** *protocol* [**inactive** | **verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command displays routing information for the public network.

protocol: Specifies a routing protocol.

inactive: Displays information about inactive routes. If you do not specify this keyword, the command displays information about both active and inactive routes.

verbose: Displays detailed routing table information. If you do not specify this keyword, the command displays brief routing information.

Examples

Display brief information about direct routes.

```
<Sysname> display ip routing-table protocol direct

Summary count : 9

Direct Routing table status : <Active>
Summary count : 9
```

```
Destination/Mask    Proto  Pre  Cost         NextHop         Interface
0.0.0.0/32          Direct 0    0            127.0.0.1       InLoop0
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.0/32        Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
127.255.255.255/32  Direct 0    0            127.0.0.1       InLoop0
192.168.80.0/24     Direct 0    0            192.168.80.10   GE1/0/1
192.168.80.0/32     Direct 0    0            192.168.80.10   GE1/0/1
192.168.80.10/32    Direct 0    0            127.0.0.1       InLoop0
192.168.80.255/32   Direct 0    0            192.168.80.10   GE1/0/1

Direct Routing table status : <Inactive>
Summary count : 0
```

Display brief information about static routes.

```
<Sysname> display ip routing-table protocol static

Summary count : 1

Static Routing table status : <Active>
Summary count : 0

Static Routing table status : <Inactive>
Summary count : 1

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
3.0.0.0/8           Static 60   0            2.2.2.2         GE1/0/1
```

Display detailed information about OSPF routes.

```
<Sysname> display ip routing-table protocol ospf verbose

Summary count : 1

Destination: 1.1.1.2/32
   Protocol: O_INTRA
 Process ID: 0
  SubProtID: 0x6                  Age: 00h03m54s

  Connector: N/A              VpnPeerId: N/A
       Dscp: N/A                    Exp: N/A
```

For command output, see Table 2.

display ip routing-table statistics

Use **display ip routing-table statistics** to display IPv4 route statistics, including numbers of total routes, routes installed by the protocol, routes marked as deleted, and active routes.

Syntax

display ip routing-table [**vpn-instance** *vpn-instance-name*] **statistics**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

If you do not specify any parameters, the command displays IPv4 route statistics for the public network.

Examples

Display IPv4 route statistics for the public network.

```
<Sysname> display ip routing-table statistics

Total prefixes: 15        Active prefixes: 15

Proto      route       active      added       deleted
DIRECT     12          12          30          18
STATIC     3           3           5           2
RIP        0           0           0           0
OSPF       0           0           0           0
IS-IS      0           0           0           0
LISP       0           0           0           0
BGP        0           0           0           0
Total      15          15          35          20
```

Table 3 Command output

Field	Description
Proto	Protocol that installed the route.
route	Number of routes installed by the protocol.
active	Number of active routes.
added	Number of routes added to the routing table after the router started up or the routing table was cleared most recently.
deleted	Number of routes marked as deleted, which will be cleared after a period.
Total	Total number of routes.

display ip routing-table summary

Use **display ip routing-table summary** to display brief routing table information, including maximum number of ECMP routes, maximum number of active routes, and number of remaining active routes.

Syntax

display ip routing-table [**vpn-instance** *vpn-instance-name*] **summary**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command displays brief routing table information for the public network.

Examples

Display brief routing table information for the public network.

```
<Sysname> display ip routing-table summary

Max ECMP: 32
Max Active Route: 262144
Remain Active Route: 262126
```

Display brief routing table information for the MPLS L3VPN instance **vpn1**.

```
<Sysname> display ip routing-table vpn-instance vpn1 summary

Max ECMP: 32
Max Active Route: 262144
Remain Active Route: 262134
Threshold value percentage of max active routes: 100%
```

Table 4 Command output

Field	Description
Max ECMP	Maximum number of ECMP routes supported by the system.
Max Active Route	Maximum number of supported routes.
Remain Active Route	Number of the remaining inactive routes.
Threshold value xxx	Alarm threshold of active routes specified by using the **routing-table limit** command in a VPN instance: • **Threshold value of active routes alert**—This field is displayed when the alarm threshold is specified by using the **routing-table limit** *number* **simply-alert** command. When the number of active routes exceeds the alarm threshold, the system logs the event and sends traps but still accepts active routes. • **Threshold value percentage of max active routes**—This field is displayed when the **routing-table limit** *number* **simply-alert** command is not configured or when the alarm threshold is specified by using the **routing-table limit** *number* *warn-threshold* command. The value range for the alarm threshold is 1 to 100 in percentage. When the percentage of active routes exceeds the alarm threshold, the system logs the event and sends traps but still accepts active routes. If the number of active routes reaches the maximum number, no more routes can be added. The percentage of active routes equals the number of active routes divided by the maximum number of active routes supported in a VPN instance, and multiplied by 100.

display ipv6 rib attribute

Use **display ipv6 rib attribute** to display route attribute information in the IPv6 RIB.

Syntax

display ipv6 rib attribute [*attribute-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

attribute-id: Specifies a route attribute by its ID, a hexadecimal string in the range of 0 to ffffffff.

Examples

Display route attribute information in the IPv6 RIB.

```
<Sysname> display ipv6 rib attribute
Total number of attribute(s): 1
```

```
Detailed information of attribute 0x9:
                  Flag: 0x0
              Protocol: BGP4+ instance default
        Address family: IPv6
       Reference count: 0
      Local preference: 0
Ext-communities number: 0
 Ext-communities value: N/A
    Communities number: 0
     Communities value: N/A
        AS-path number: 0
         AS-path value: N/A
```

For command output, see Table 8.

display ipv6 rib graceful-restart

Use **`display ipv6 rib graceful-restart`** to display IPv6 RIB GR state information.

Syntax

`display ipv6 rib graceful-restart`

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display IPv6 RIB GR state information.

```
<Sysname> display ipv6 rib graceful-restart
RIB GR state     : Phase2-calculation end
RCOM GR state    : Flush end
Protocol GR state:
 No.  Protocol   Lifetime FD   State    Start/End
-------------------------------------------------
 1    DIRECT6    480      29   End      No/No
 2    STATIC6    480      32   End      No/No
 3    ISISV6     480      30   End      No/No
 4    BGP4+ instance default
                 480      31   End      No/No
 5    BGP4+ instance ebcdefg
                 480      32   End      No/No
```

For command output, see Table 9.

display ipv6 rib nib

Use **display ipv6 rib nib** to display next hop information in the IPv6 RIB.

Syntax

display ipv6 rib nib [**self-originated**] [*nib-id*] [**verbose**]

display ipv6 rib nib protocol *protocol* [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

self-originated: Displays information about next hops of self-originated routes in the IPv6 RIB.

nib-id: Specifies a NIB by its ID, a hexadecimal string in the range of 1 to ffffffff.

verbose: Displays detailed next hop information in the IPv6 RIB. If you do not specify this keyword, the command displays brief next hop information in the IPv6 RIB.

protocol *protocol*: Specifies a protocol by its name.

Examples

Display brief next hop information in the IPv6 RIB.

```
<Sysname> display ipv6 rib nib
Total number of nexthop(s): 151

      NibID: 0x20000000        Sequence: 0
       Type: 0x1                Flushed: Yes
   UserKey0: 0x0                VrfNthp: 0
   UserKey1: 0x0                Nexthop: ::
    IFIndex: 0x111            LocalAddr: ::
   TopoNthp: Invalid

      NibID: 0x20000001        Sequence: 1
       Type: 0x1                Flushed: Yes
   UserKey0: 0x0                VrfNthp: 0
   UserKey1: 0x0                Nexthop: ::1
    IFIndex: 0x112            LocalAddr: ::1
   TopoNthp: Invalid

...
```

Display detailed next hop information in the IPv6 RIB.

```
<Sysname> display ipv6 rib nib verbose
Total number of nexthop(s): 151
```

```
      NibID: 0x20000000        Sequence: 0

   Instance: abc
```

...

For command output, see Table 10 and Table 11.

display ipv6 route-direct nib

Use **display ipv6 route-direct nib** to display next hop information for IPv6 direct routes.

Syntax

display ipv6 route-direct nib [*nib-id*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

nib-id: Specifies a NIB by its ID, a hexadecimal string in the range of 1 to ffffffff.

verbose: Displays detailed next hop information for IPv6 direct routes. If you do not specify this keyword, the command displays brief next hop information for IPv6 direct routes.

Examples

Display brief next hop information for IPv6 direct routes.

```
<Sysname> display ipv6 route-direct nib
Total number of nexthop(s): 115

      NibID: 0x20000000        Sequence: 0
       Type: 0x1                Flushed: Yes
   UserKey0: 0x0                VrfNthp: 0
   UserKey1: 0x0                Nexthop: ::
    IFIndex: 0x111             LocalAddr: ::
   TopoNthp: Invalid

...
```

For command output, see Table 12 and Table 13.

display ipv6 routing-table

Use **display ipv6 routing-table** to display IPv6 routing table information.

Syntax

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters.

verbose: Displays detailed routing table information, including information about both active and inactive routes. If you do not specify this keyword, the command displays only brief information about active routes.

Usage guidelines

If you do not specify any parameters, the command displays IPv6 routing table information for the public network.

Examples

Display brief information about active routes in the IPv6 routing table.

```
<Sysname> display ipv6 routing-table

Destinations : 4        Routes : 4

Destination: ::1/128                                    Protocol  : Direct
NextHop    : ::1                                        Preference: 0
Interface  : InLoop0                                    Cost      : 0

Destination: 1:1:2::/64                                 Protocol  : Guard
NextHop    : ::                                         Preference: 254
Interface  : NULL0                                      Cost      : 0

Destination: FE80::/10                                  Protocol  : Direct
NextHop    : ::                                         Preference: 0
Interface  : InLoop0                                    Cost      : 0

Destination: FF00::/8                                   Protocol  : Direct
NextHop    : ::                                         Preference: 0
Interface  : NULL0                                      Cost      : 0
```

Table 5 Command output

Field	Description
Destinations	Number of destination addresses.
Routes	Number of routes.
Destination	IPv6 address and prefix of the destination network or host.
NextHop	Next hop address of the route.
Preference	Preference of the route.
Interface	Output interface for packets to be forwarded along the route.
Protocol	Protocol that installed the route.
Cost	Cost of the route.
Summary count	Number of routes.

Display detailed information about all routes in the IPv6 routing table.

```
<Sysname> display ipv6 routing-table verbose
```

```

Table 6 Command output

Field	Description
Destination	IPv6 address and prefix of the destination network or host.
Protocol	Protocol that installed the route.
SubProtID	ID of the subprotocol for routing.
Age	Time for which the route has been in the routing table.
Cost	Cost of the route.
Preference	Preference of the route.
IpPre	IP precedence.
QosLocalID	Local QoS ID.
Tag	Tag of the route.
State	Route status: • **Active**—Active unicast route. • **Adv**—Route that can be advertised. • **Inactive**—Inactive route. • **NoAdv**—Route that the router must not advertise. • **Vrrp**—Routes generated by VRRP. This state is not supported in the current software version. • **Nat**—Routes generated by NAT. • **TunE**—Tunnel.
OrigTblID	Original routing table ID.
OrigVrf	Original VPN instance that the route belongs to. This field displays **default-vrf** if the route is on the public network.
TableID	ID of the routing table.
OrigAs	Original AS number.
NibID	ID of the next hop.
LastAs	Last AS number.
AttrID	Attribute ID.
Neighbor	Address of the neighbor determined by the routing protocol.
Flags	Flags of the route.
OrigNextHop	Next hop address of the route.
Label	This field is not supported in the current software version. Label of the route.
RealNextHop	Real next hop of the route.
BkLabel	This field is not supported in the current software version. Backup label.
BkNexthop	Backup next hop.
SRLabel	This field is not supported in the current software version. SR label.
BkSRLabel	This field is not supported in the current software version. Backup SR label.

Field	Description
Tunnel ID	Tunnel ID.
Interface	Output interface for packets to be forwarded along the route.
BkTunnel ID	Backup tunnel ID.
BkInterface	Backup output interface.
FtnIndex	Index of the FTN entry.
TrafficIndex	Traffic index in the range of 1 to 64. This field displays **N/A** when the value is invalid.
Connector	BGP connector attribute exchanged between BGP peers along with a VPN IPv4 route. The value of the attribute is the IP address of the remote PE device. The BGP connector attribute is used for MD VPN. This field displays **N/A** if BGP connector attribute is not supported.
VpnPeerId	This field is not supported in the current software version. ID of the VPN peer to which the route belongs, in the range of 1 to 134217727. This field displays **N/A** when the value is invalid.
Dscp	DSCP value of the route, in the range of 0 to 63. This field displays **N/A** when the value is invalid.
Exp	MPLS EXP value of the route, which is supported only by BGP. This field displays **N/A** when the value is invalid.
Summary count	Number of routes.

display ipv6 routing-table acl

Use **display ipv6 routing-table acl** to display routing information permitted by an IPv6 basic ACL.

Syntax

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] **acl** *ipv6-acl-number* [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command displays routing information for the public network.

ipv6-acl-number: Specifies a basic IPv6 ACL by its number in the range of 2000 to 2999.

verbose: Displays detailed information about all routes permitted by the basic IPv6 ACL. If you do not specify this keyword, the command displays only brief information about active routes permitted by the basic IPv6 ACL.

Usage guidelines

If the specified IPv6 ACL does not exist or has no rules configured, the command displays information about all IPv6 routes.

Examples

Display brief information about active routes permitted by IPv6 ACL 2000.

```
<Sysname> display ipv6 routing-table acl 2000

Summary count : 6

For command output, see Table 6.

display ipv6 routing-table *ipv6-address*

Use **display ipv6 routing-table** *ipv6-address* to display information about routes to an IPv6 destination address.

Use **display ipv6 routing-table** *ipv6-address1* **to** *ipv6-address2* to display information about routes to a range of IPv6 destination addresses.

Syntax

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] *ipv6-address* [*prefix-length*] [**longer-match**] [**verbose**]

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] *ipv6-address1* **to** *ipv6-address2* [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command displays routing information for the public network.

ipv6-address: Specifies a destination IPv6 address.

prefix-length: Specifies the prefix length in the range of 0 to 128.

longer-match: Displays the route entry with the longest prefix.

ipv6-address1 **to** *ipv6-address2*: Specifies a destination IPv6 address range.

verbose: Displays detailed routing table information, including information about both active and inactive routes. If you do not specify this keyword, the command displays only brief information about active routes.

Usage guidelines

Executing the command with different parameters yields different output.

- **display ipv6 routing-table** *ipv6-address*
  - The system ANDs the entered destination IPv6 address with the prefix length in each active route entry.
  - The system ANDs the destination IPv6 address in each active route entry with the prefix length in the entry.

  If the two operations yield the same result for an entry, the entry is displayed.
- **display ipv6 routing-table** *ipv6-address prefix-length*
  - The system ANDs the entered destination IPv6 address with the entered prefix length.
  - The system ANDs the destination IPv6 address in each active route entry with the entered prefix length.

  If the two operations yield the same result for an entry with a prefix length not greater than the entered prefix length, the entry is displayed.
- **display ipv6 routing-table** *ipv6-address* **longer-match**
  - The system ANDs the entered destination IPv6 address with the prefix length in each active route entry.
  - The system ANDs the destination IPv6 address in each active route entry with the prefix length in the entry.

  If the two operations yield the same result for multiple entries, the entry with the longest prefix length is displayed.
- **display ipv6 routing-table** *ipv6-address prefix-length* **longer-match**
  - The system ANDs the entered destination IPv6 address with the entered prefix length.
  - The system ANDs the destination IPv6 address in each active route entry with the entered prefix length.

  If the two operations yield the same result for multiple entries with a prefix length not greater than the entered prefix length, the entry with the longest prefix length is displayed.
- **display ipv6 routing-table** *ipv6-address1* **to** *ipv6-address2*

  The system displays route entries with destinations in the range of *ipv6-address1*/128 to *ipv6-address2*/128.

Examples

Display brief information about the routes to the destination IPv6 address 10::1 127.

```
<Sysname> display ipv6 routing-table 10::1 127
```

```
Summary count: 3

For command output, see Table 6.

display ipv6 routing-table prefix-list

Use **display ipv6 routing-table prefix-list** to display information about IPv6 routes permitted by an IPv6 prefix list.

Syntax

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] **prefix-list** *prefix-list-name* [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command displays routing information for the public network.

prefix-list-name: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters.

verbose: Displays detailed information about all IPv6 routes permitted by the IPv6 prefix list. If you do not specify this keyword, the command displays brief information about active IPv6 routes permitted by the IPv6 prefix list.

Usage guidelines

If the specified IPv6 prefix list does not exist, the command displays information about all routes.

Examples

Create an IPv6 prefix list named test to permit the prefix ::1/128.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list test permit ::1 128
```

Display brief information about the active IPv6 route permitted by the IPv6 prefix list.

```
[Sysname] display ipv6 routing-table prefix-list test

Summary count : 1

Destination: ::1/128                                    Protocol  : Direct
NextHop    : ::1                                        Preference: 0
Interface  : InLoop0                                    Cost      : 0
```

For command output, see Table 5.

Display detailed information about all routes permitted by the IPv6 prefix list.

```
[Sysname] display ipv6 routing-table prefix-list test verbose

Summary count : 1

Destination: ::1/128
   Protocol: Direct
 Process ID: 0
  SubProtID: 0x0                  Age: 08h57m19s
       Cost: 0              Preference: 0
      IpPre: N/A            QosLocalID: N/A
        Tag: 0                   State: Active NoAdv

  Connector: N/A              VpnPeerId: N/A
       Dscp: N/A                   Exp: N/A
```

For command output, see Table 6.

display ipv6 routing-table protocol

Use **display ipv6 routing-table protocol** to display information about IPv6 routes installed by a protocol.

Syntax

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] **protocol** *protocol* [**inactive** | **verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command displays routing information for the public network.

protocol: Specifies a routing protocol.

inactive: Displays information about inactive routes. If you do not specify this keyword, the command displays information about both active and inactive routes.

verbose: Displays detailed routing table information. If you do not specify this keyword, the command displays brief routing information.

Examples

Display brief information about IPv6 direct routes.

```
<Sysname> display ipv6 routing-table protocol direct

Summary count : 3

Direct Routing table status : <Active>
Summary count : 3

Destination: ::1/128                                Protocol  : Direct

       Dscp: N/A                   Exp: N/A
```

For command output, see Table 6.

display ipv6 routing-table statistics

Use **`display ipv6 routing-table statistics`** to display IPv6 route statistics, including numbers of total routes, routes installed and deleted by the protocol, and active routes.

Syntax

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] **statistics**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

If you do not specify any parameters, the command displays IPv6 route statistics for the public network.

Examples

Display IPv6 route statistics for the public network.

```
<Sysname> display ipv6 routing-table statistics

Total prefixes: 8        Active prefixes: 8

Proto      route       active      added       deleted
DIRECT     5           5           5           0
STATIC     3           3           3           0
RIPng      0           0           0           0
OSPFv3     0           0           0           0
IS-ISv6    0           0           0           0
LISP       0           0           0           0
BGP4+      0           0           0           0
Total      8           8           8           0
```

Table 7 Command output

Field	Description
Proto	Protocol that installed the route.
route	Number of routes installed by the protocol.
active	Number of active routes.
added	Number of routes added to the routing table after the router started up or the routing table was cleared most recently.
deleted	Number of routes marked as deleted, which will be cleared after a period.
Total	Total number of routes.

display ipv6 routing-table summary

Use **display ipv6 routing-table summary** to display brief IPv6 routing table information, including maximum number of ECMP routes, maximum number of active routes, and number of remaining active routes.

Syntax

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] **summary**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command displays brief IPv6 routing table information for the public network.

Examples

Display brief IPv6 routing table information for the public network.

```
<Sysname> display ipv6 routing-table summary

Max ECMP: 32
Max Active Route: 262144
Remain Active Route: 262126
```

Display brief IPv6 routing table information for the MPLS L3VPN instance **vpn1**.

```
<Sysname> display ipv6 routing-table vpn-instance vpn1 summary

Max ECMP: 32
Max Active Route: 262144
Remain Active Route: 262134
Threshold value of active routes alert: 65100
```

For command output, see Table 4.

display rib attribute

Use **display rib attribute** to display route attribute information in the RIB.

Syntax

display rib attribute [*attribute-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

attribute-id: Specifies a route attribute by its ID, a hexadecimal string in the range of 0 to ffffffff.

Examples

Display route attribute information in the RIB.

```
<Sysname> display rib attribute
Total number of attribute(s): 10

Detailed information of attribute 0x0:
                  Flag: 0x0
              Protocol: BGP instance default
        Address family: IPv4
       Reference count: 0
      Local preference: 0
Ext-communities number: 26
 Ext-communities value: <RT: 1:1> <RT: 2:2> <RT: 3:3> <RT: 123.123.123.123:65535
                        > <RT: 1234567890:65535> <RT: 123.123.123.123:65534> <RT
                        : 4:4> <RT: 5:5> <RT: 6:6> <RT: 7:7> <RT: 8:8> <RT: 9:9>
                         <RT: 10:10> <RT: 10:1> <RT: 10:11> <RT: 10:12> <RT: 10:
                        13> <RT: 10:14> <RT: 10:15> <RT: 10:16> ...
    Communities number: 0
     Communities value: N/A
        AS-path number: 0
         AS-path value: N/A

Detailed information of attribute 0x1:
                  Flag: 0x0
              Protocol: BGP
        Address family: IPv4
       Reference count: 0
      Local preference: 0
Ext-communities number: 1
 Ext-communities value: <RT: 1:2>
    Communities number: 0
     Communities value: N/A
        AS-path number: 0
         AS-path value: N/A
```

Table 8 Command output

Field	Description
Protocol	Protocol that generates the attribute.
Ext-communities number	Number of the extended community attribute values.
Ext-communities value	Values of the extended community attribute. This field displays **N/A** when no values exist, and it can display a maximum of 20 values.

Field	Description
Communities number	Number of the COMMUNITY attribute values.
Communities value	Values of the COMMUNITY attribute. This field displays **N/A** when no values exist, and it can display a maximum of 20 values.
AS-path number	Number of ASs in the AS_PATH attribute.
AS-path value	Values of the AS_PATH attribute, including AS_SET, AS_SEQUENCE, confederation AS_SET, and confederation AS_SEQUENCE. This field displays **N/A** when no values exist, and it can display a maximum of 20 values.

display rib graceful-restart

Use **display rib graceful-restart** to display RIB GR state information.

Syntax

display rib graceful-restart

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display RIB GR state information.

```
<Sysname> display rib graceful-restart
RIB GR state     : Phase2-calculation end
RCOM GR state    : Flush end
Protocol GR state:
 No.  Protocol   Lifetime FD   State    Start/End
-------------------------------------------------
 1    DIRECT     100      30   End      No/No
 2    STATIC     480      34   End      No/No
 3    OSPF       480      36   End      No/No
 4    ISIS       480      32   End      No/No
```

Table 9 Command output

Field	Description
RIB GR state	RIB GR status: • **Start**—GR starts. • **IGP end**—All IGP protocols complete GR. • **VPN-triggering end**—Optimal route selection triggered by VPN routes completes. • **VPN-calculation end**—Optimal VPN route selection completes. • **Routing protocol end**—All routing protocols complete GR. • **NSR-calculation unfinished**—NSR has not finished optimal route selection. • **Triggering start**—All triggered optimal route selection starts. • **Triggering end**—All triggered optimal route selection completes. • **Phase1-calculation end**—Optimal route selection phase 1 completes. • **All end**—All protocols complete GR. • **Phase2-calculation end**—Optimal route selection phase 2 completes.
RCOM GR state	RCOM GR status: • **Start**—GR starts. • **VPN-calculation end**—Optimal VPN route selection completes. • **VPN-notification end**—VPN routes have been delivered to the route management module. • **Routing protocol end**—All routing protocols complete GR. • **NSR-calculation unfinished**—NSR has not finished optimal route selection. • **Phase1-calculation end**—Optimal route selection phase 1 completes. • **Notification end**—All routes have been delivered to the route management module. • **Phase2-calculation end**—Optimal route selection phase 2 completes. • **Flush start**—Starts to flush routes to the FIB. • **Flush end**—Completes flushing routes to the FIB.
No.	Protocol number.
Lifetime	Lifetime (in seconds) of routes in the RIB during GR.
FD	Handle between the protocol and the RIB.
State	Protocol GR state: • **Init**—Initialization state. • **Listen**—Listening state. • Idle. • Active. • **Start**—GR starts. • **End**—GR completes.
Start/End	Message sending state: • **No**—The message has not been sent. • **Yes**—The message has been sent.

display rib nib

Use **display rib nib** to display next hop information in the RIB.

Syntax

display rib nib [**self-originated**] [*nib-id*] [**verbose**]

display rib nib protocol *protocol* [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

self-originated: Displays information about next hops of self-originated routes in the RIB.

nib-id: Specifies a NIB by its ID, a hexadecimal string in the range of 1 to ffffffff.

verbose: Displays detailed next hop information in the RIB. If you do not specify this keyword, the command displays brief next hop information in the RIB.

protocol *protocol*: Specifies a protocol by its name.

Examples

Display brief next hop information in the RIB.

```
<Sysname> display rib nib
Total number of nexthop(s): 176

      NibID: 0x10000000        Sequence: 0

Table 10 Command output

Field	Description
NibID	ID of the next hop.
Sequence	Sequence number of the next hop.
Type	Type of the next hop.
Flushed	Indicates whether the route with the next hop has been flushed to the FIB.
UserKey0	Reserved data 1.
UserKey1	Reserved data 2.
VrfNthp	Index of the VPN instance that the next hop belongs to. This field displays **0** if the next hop is on the public network.
Nexthop	Next hop address.
IFIndex	Interface index.
LocalAddr	Local interface address.
TopoNthp	Non-base topologies are not supported in the current software version. Index of the topology that contains the next hop. This field displays **0** if the next hop is on the IPv4 public network. This field displays **Invalid** if the next hop is on an IPv6 network, because the router does not support multiple IPv6 topologies.
Instance	BGP instance name.
SubNibID	ID of the sub-next hop.
SubSeq	Sequence number of the sub-next hop.
NthpCnt	Number of sub-next hops.
Samed	Number of the same sub-next hops.
NthpType	Type of the sub-next hop: **IP**—IP forwarding.

Display detailed next hop information in the RIB.

Table 11 Command output

Field	Description
x nexthop (s)	Number of next hops.
PrefixIndex	Prefix index of the next hop for an ECMP route.
Vrf	VPN instance name. For the public network, this field displays **default-vrf**.
OrigNexthop	Original next hop.
RealNexthop	Real next hop.
Interface	Output interface.
LocalAddr	Local interface address.
RelyDepth	Recursion depth.
TunnelCnt	Number of tunnels after route recursion.
TunnelID	ID of the tunnel after route recursion.
Topology	Non-base topologies are not supported in the current software version. Topology name. The topology name for the IPv4 public network is **base**. This field is blank for IPv6, because IPv6 does not support multiple topologies.
Weight	ECMP route weight. This field displays 0 for non-ECMP routes.
Instance	BGP instance name.
RefCnt	Reference count of the next hop.
FlushRefCnt	Reference count of the next hop that is flushed to the FIB.
Flag	Flag of the next hop.
Version	Version of the next hop.

display route-direct nib

Use **`display route-direct nib`** to display next hop information for direct routes.

Syntax

`display route-direct nib` [*`nib-id`*] [**`verbose`**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`nib-id`: Specifies a NIB by its ID, a hexadecimal string in the range of 1 to ffffffff.

`verbose`: Displays detailed next hop information for direct routes. If you do not specify this keyword, the command displays brief next hop information for direct routes.

Examples

Display brief next hop information for direct routes.

```
<Sysname> display route-direct nib
Total number of nexthop(s): 116

      NibID: 0x10000000        Sequence: 0
       Type: 0x1                Flushed: Yes

RefCnt	Reference count of the next hop.
FlushRefCnt	Reference count of the next hop that is flushed to the FIB.
Flag	Flag of the next hop.
Version	Version of the next hop.

fib lifetime

Use **fib lifetime** to set the maximum lifetime for IPv4 or IPv6 routes in the FIB.

Use **undo fib lifetime** to restore the default.

Syntax

fib lifetime *seconds*

undo fib lifetime

Default

The maximum lifetime for IPv4 or IPv6 routes in the FIB is 600 seconds.

Views

RIB IPv4 address family view

RIB IPv6 address family view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the maximum lifetime for routes in the FIB, in the range of 0 to 6000 seconds. When this argument is set to 0, FIB entries immediately age out after a protocol or RIB process switchover.

Usage guidelines

When a protocol or RIB process switchover occurs and GR or NSR is not configured, FIB entries age out after the time specified in this command.

Examples

Set the maximum lifetime for IPv4 routes in the FIB to 60 seconds.

```
<Sysname> system-view
[Sysname] rib
[Sysname-rib] address-family ipv4
[Sysname-rib-ipv4] fib lifetime 60
```

inter-protocol fast-reroute

Use **inter-protocol fast-reroute** to enable IPv4 or IPv6 RIB inter-protocol FRR.

Use **undo inter-protocol fast-reroute** to disable IPv4 or IPv6 RIB inter-protocol FRR.

Syntax

inter-protocol fast-reroute [**vpn-instance** *vpn-instance-name*]

undo inter-protocol fast-reroute [**vpn-instance** *vpn-instance-name*]

Default

Inter-protocol FRR is disabled.

Views

RIB IPv4 address family view

RIB IPv6 address family view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command enables IPv4 or IPv6 RIB inter-protocol FRR for the public network.

Usage guidelines

This command allows a device to perform fast rerouting between routes of different protocols. A backup next hop is automatically selected to reduce the service interruption time caused by unreachable next hops. When the next hop of the primary link fails, the traffic is redirected to the backup next hop.

This command uses the next hop of a route from a different protocol as the backup next hop for the faulty route, which might cause loops.

Inter-protocol FRR cannot select a backup next hop from routes in the RIB that have the same next hop, output interface, and destination as those of the faulty route.

Examples

Enable IPv4 RIB inter-protocol FRR for the public network.

```
<Sysname> system-view
[Sysname] rib
[Sysname-rib] address-family ipv4
[Sysname-rib-ipv4] inter-protocol fast-reroute
```

ipv6 max-ecmp-num

Use **ipv6 max-ecmp-num** to set the maximum number of IPv6 ECMP routes.

Syntax

ipv6 max-ecmp-num *number*

Default

Models	Default
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1180, NFNX3-HDB1480	16
NFNX3-HDB1780, NFNX3-HDB3080	Not supported
NFNX3-HDB680, NFNX3-HDB1080	32

Views

System view

Predefined user roles

network-admin

Parameters

number: Specifies the maximum number of IPv6 ECMP routes. The value range for this argument is 1 to 128.

Usage guidelines

This command takes effect after a device reboot. Before you reboot the device, make sure you understand the potential impact on the network.

This command is supported only on the default context.

Examples

Set the maximum number of IPv6 ECMP routes to 10.

```
<Sysname> system-view
[Sysname] ipv6 max-ecmp-num 10
The configuration will take effect at the next reboot. Continue? [Y/N]:y
Reboot device to make the configuration take effect.
```

After reboot, the maximum number of IPv6 ECMP routes is 10.

Related commands

display ipv6 max-ecmp-num

max-ecmp-num

Use **max-ecmp-num** to set the maximum number of IPv4 ECMP routes.

Syntax

context-admin

Examples

Enable NSR for the RIB IPv4 address family.

```
<Sysname> system-view
[Sysname] rib
[Sysname-rib] address-family ipv4
[Sysname-rib-ipv4] non-stop-routing
```

protocol lifetime

Use **protocol lifetime** to set the maximum lifetime for IPv4 or IPv6 routes in the RIB.

Use **undo protocol lifetime** to restore the default.

Syntax

protocol *protocol* [**instance** *instance-name*] **lifetime** *seconds*

undo protocol *protocol* [**instance** *instance-name*] **lifetime**

Default

The maximum lifetime for IPv4 or IPv6 routes in the RIB is 480 seconds.

Views

RIB IPv4 address family view

RIB IPv6 address family view

Predefined user roles

network-admin

context-admin

Parameters

protocol: Specifies a routing protocol.

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. This argument applies only to the BGP protocol. If you do not specify a BGP instance, this command sets the maximum lifetime for all BGP routes and labels in the RIB.

seconds: Specifies the maximum lifetime for routes and labels in the RIB, in the range of 1 to 6000 seconds.

Usage guidelines

When GR is enabled, make sure the protocol can complete GR and install all route entries to the RIB within the lifetime configured in this command.

Examples

Set the maximum lifetime for RIP routes in the RIB to 60 seconds.

```
<Sysname> system-view
[Sysname] rib
[Sysname-rib] address-family ipv4
[Sysname-rib-ipv4] protocol rip lifetime 60
```

reset ip routing-table statistics protocol

Use **reset ip routing-table statistics protocol** to clear IPv4 route statistics.

Syntax

reset ip routing-table statistics protocol [**vpn-instance** *vpn-instance-name*] { *protocol* | **all** }

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command clears IPv4 route statistics for the public network.

protocol: Clears route statistics for a routing protocol.

all: Clears route statistics for all IPv4 routing protocols.

Usage guidelines

This command clears only statistics of added and deleted routes for the specified routing protocols.

Examples

Clear all IPv4 route statistics for the public network.

```
<Sysname> reset ip routing-table statistics protocol all
```

reset ipv6 routing-table statistics protocol

Use **reset ipv6 routing-table statistics protocol** to clear IPv6 route statistics.

Syntax

reset ipv6 routing-table statistics protocol [**vpn-instance** *vpn-instance-name*] { *protocol* | **all** }

Views

Contents

Static routing commands

delete static-routes all

Use **delete static-routes all** to delete all static routes.

Syntax

delete [**vpn-instance** *vpn-instance-name*] **static-routes all**

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command deletes all static routes for the public network.

Usage guidelines

CAUTION:

This command might interrupt network communication and cause packet forwarding failure. Before executing the command, make sure you fully understand the potential impact on the network.

When you use this command, the system will prompt you to confirm the operation before deleting all the static routes.

To delete one static route, use the **undo ip route-static** command. To delete all static routes, including the default route, use the **delete static-routes all** command.

Examples

Delete all static routes.

```
<Sysname> system-view
[Sysname] delete static-routes all
This will erase all IPv4 static routes and their configurations, you must reconfigure all static routes.
Are you sure?[Y/N]:y
```

Related commands

Table 2 Command output

Field	Description
NibID	ID of the NIB.
Sequence	Sequence number of the NIB.
Type	Type of the NIB.
Flushed	Indicates whether the route with the NIB has been flushed to the FIB.
UserKey0	Reserved data 1.
VrfNthp	Index of the VPN instance that the next hop belongs to. This field displays **0** if the next hop is on the public network.
UserKey1	Reserved data 2.
Nexthop	Next hop address.
IFIndex	Interface index
LocalAddr	Local interface address.
TopoNthp	Index of the topology that contains the next hop. This field displays **0** if the next hop is on the public network.
RefCnt	Reference count of the next hop.
FlushRefCnt	Reference count of the next hop that is flushed to the FIB.
Flag	Flag of the next hop.
Version	Version of the next hop.
x nexthop(s)	Number of next hops.
PrefixIndex	Prefix index of the next hop for an ECMP route.
OrigNexthop	Original next hop.
RelyDepth	Recursion depth.
RealNexthop	Real next hop.
Interface	Output interface.
localAddr	Local interface address.
TunnelCnt	Number of tunnels after route recursion.
Vrf	VPN instance name. For the public network, this field displays **default-vrf**.
TunnelID	ID of the tunnel after route recursion.
Topology	This field is not supported in the current software version. Topology name. The topology name for the public network is **base**.
Weight	ECMP route weight. This field displays 0 for non-ECMP routes.

display route-static routing-table

Use **display route-static routing-table** to display static routing table information.

Syntax

display route-static routing-table [**vpn-instance** *vpn-instance-name*] [*ip-address* { *mask-length* | *mask* }]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command displays static routing table information for the public network.

ip-address: Specifies the destination IP address in dotted decimal notation. If you do not specify this argument, the command displays all static routing table information.

mask-length: Specifies the mask length, an integer in the range of 0 to 32.

mask: Specifies the subnet mask in dotted decimal notation.

Examples

Display static routing table information.

```
<Sysname> display route-static routing-table
Total number of routes: 24

Status: * - valid

*Destination: 0.0.0.0/0
      NibID: 0x1100000a       NextHop: 2.2.2.10
   MainNibID: N/A           BkNextHop: N/A
     BkNibID: N/A           Interface: GigabitEthernet1/0/1
     TableID: 0x2         BkInterface: GigabitEthernet1/0/2
        Flag: 0x82d01        BfdSrcIp: N/A
     DbIndex: 0xd          BfdIfIndex: 0x0
        Type: Normal       BfdVrfIndex: 0
  TrackIndex: 0xffffffff        Label: NULL
  Preference: 60          vrfIndexDst: 0
     BfdMode: N/A          vrfIndexNH: 0
   Permanent: 0                 Tag: 0

 Destination: 0.0.0.0/0
      NibID: 0x1100000b       NextHop: 2.2.2.11
   MainNibID: N/A           BkNextHop: N/A
```

```
   BkNibID: N/A            Interface: GigabitEthernet1/0/3
   TableID: 0x2          BkInterface: GigabitEthernet1/0/4
      Flag: 0x82d01         BfdSrcIp: N/A
   DbIndex: 0xd           BfdIfIndex: 0x0
      Type: Normal        BfdVrfIndex: 0
 TrackIndex: 0xffffffff         Label: NULL
 Preference: 60           vrfIndexDst: 0
   BfdMode: N/A           vrfIndexNH: 0
  Permanent: 0                  Tag: 0
```

...

Table 3 Command output

Field	Description
destination	Destination address/prefix.
NibID	ID of the NIB.
MainNibID	ID of the primary next hop for static route FRR.
BkNibID	ID of the backup next hop for static route FRR.
NextHop	Next hop address.
BkNextHop	Backup next hop address.
Interface	Output interface of the route.
BkInterface	Backup output interface.
TableID	ID of the table to which the route belongs.
Flag	Flag of the route.
DbIndex	Index of the database to which the route belongs.
Type	Route type: • Normal. • DHCP. • NAT. • IPsec.
BfdSrcIp	Source IP address of the indirect BFD session.
BfdIfIndex	Index of the interface where BFD is enabled.
BfdVrfIndex	Index of the VPN instance where BFD is enabled. This field displays **0** if BFD is enabled for the public network.
BfdMode	BFD session mode: • **N/A**—No BFD session is configured. • **Ctrl**—Control packet mode • **Echo**—Echo packet mode.
TrackIndex	NQA Track index.
Label	This field is not supported in the current software version. Label.
vrfIndexDst	Index of VPN instance that the destination belongs to. For the public network, this field displays **0**.

Field	Description
vrfIndexNH	Index of the VPN instance that the next hop belongs to. For the public network, this field displays **0**.
Permanent	Permanent static route flag. 1 indicates a permanent static route.

ip route-static

Use **ip route-static** to configure a static route.

Use **undo ip route-static** to delete a static route.

Syntax

ip route-static { *dest-address* { *mask-length* | *mask* } | **group** *group-name* } *interface-type interface-number* [**dhcp** | *next-hop-address*] [**backup-interface** *interface-type interface-number* [**backup-nexthop** *backup-nexthop-address*] [**permanent**] | **bfd** { **control-packet** | **echo-packet** | **static** *session-name* } | **permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

ip route-static { *dest-address* { *mask-length* | *mask* } | **group** *group-name* } *next-hop-address* [**bfd control-packet bfd-source** *ip-address* | **permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

ip route-static { *dest-address* { *mask-length* | *mask* } | **group** *group-name* } **vpn-instance** *d-vpn-instance-name next-hop-address* [**bfd control-packet bfd-source** *ip-address* | **permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

undo ip route-static { *dest-address* { *mask-length* | *mask* } | **group** *group-name* } [*interface-type interface-number* [**dhcp** | *next-hop-address*] | *next-hop-address* | **vpn-instance** *d-vpn-instance-name next-hop-address*] [**preference** *preference*]

Default

No static route is configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

dest-address: Specifies the destination IP address of the static route, in dotted decimal notation.

mask-length: Specifies the mask length, an integer in the range of 0 to 32.

mask: Specifies the subnet mask in dotted decimal notation.

group *group-name*: Specifies a static route group by its name, a case-sensitive string of 1 to 31 characters.

vpn-instance *d-vpn-instance-name*: Specifies a destination MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If a destination VPN instance is specified, packets will search for the output interface in the destination VPN instance based on the configured next hop address.

interface-type interface-number: Specifies an output interface by its type and number. For more information, see *Layer 3—IP Routing Configuration Guide*.

dhcp: Specifies the default router designated by the DHCP server for the output interface as the next hop of the static route.

next-hop-address: Specifies the IP address of the next hop, in dotted decimal notation. For more information, see *Layer 3—IP Routing Configuration Guide*.

backup-interface *interface-type interface-number*: Specifies a backup output interface by its type and number. If the backup output interface is a broadcast interface, you must specify the backup next hop address.

backup-nexthop *backup-nexthop-address*: Specifies a backup next hop address.

bfd: Enables BFD to detect reachability of the static route's next hop. When the next hop is unreachable, the system immediately switches to the backup route.

control-packet: Specifies the BFD control mode.

bfd-source *ip-address*: Specifies the source IP address of BFD packets. As a best practice, specify the loopback interface address.

echo-packet: Specifies the BFD echo mode.

static *session-name*: Specifies a static BFD session by its name, a case-sensitive string of 1 to 64 characters. You can specify a nonexistent static BFD session. For the configuration to take effect, you must create the static BFD session.

permanent: Specifies the route as a permanent static route. If the output interface is down, the permanent static route is still active.

track *track-entry-number*: Associates the static route with a track entry specified by its number in the range of 1 to 1024. For more information about Track, see *Network Management and Monitoring Configuration Guide*.

preference *preference*: Specifies a preference for the static route, in the range of 1 to 255. The default is 60.

tag *tag-value*: Sets a tag value for marking the static route, in the range of 1 to 4294967295. The default is 0. Tags of routes are used for route control in routing policies. For more information about routing policies, see *Layer 3—IP Routing Configuration Guide*.

description *text*: Configures a description of 1 to 60 characters for the static route. The description can include special characters, such as the space, except the question mark (?).

Usage guidelines

If the destination IP address and the mask are both 0.0.0.0 (or 0), the configured route is a default route. The default route is used for forwarding a packet matching no entry in the routing table.

Implement different routing policies to configure different route preferences. For example, to enable load sharing for multiple routes to the same destination, assign the same preference to the routes. To enable the routes to back up one another, assign different preferences to them.

Follow these guidelines when you specify the output interface or the next hop address of the static route:

- If the output interface is a Null 0 interface, no next hop address is required.
- If the output interface is a point-to-point interface, you can specify only the output interface. You do not need to change the configuration of the route even if the peer address is changed.

- Multiple next hops might exist if the output interface is a broadcast interface (for example, an Ethernet interface or VLAN interface). You must specify both the output interface and next hop IP address for the static route.

Follow these guidelines when you configure a static route:

- Enabling BFD for a flapping route could worsen the route flapping situation. Therefore, use it with caution. For more information about BFD, see *Network Management and Monitoring Configuration Guide*.
- For static routing-Track-NQA collaboration, you must configure the same VPN instance ID for the next hop to be detected and the NQA operation.
- If a static route needs route recursion, the associated track entry must monitor the next hop of the recursive route instead of that of the static route. Otherwise, a valid route might be mistakenly considered invalid.

If you specify a static route group, all prefixes in the static route group will be assigned the next hop and output interface specified by using this command.

After an interface obtains an IP address and gateway address through DHCP, the device automatically generates a static route with the interface as the output interface. The destination address of the static route is 0.0.0.0/0 and the next hop of the static route is the default router (the gateway address designated by the DHCP server). This static route cannot form ECMP routes with manually configured static routes. The device uses this static route to guide traffic forwarding only after the manually configured static routes become invalid.

Specify the **dhcp** keyword to use both the automatically generated static route and the manually configured static routes to guide traffic forwarding. This keyword is applicable when the device has dual egress WAN links.

The **dhcp** keyword enables the device to automatically generate a static route destined for the specified network with the DHCP-designated default router of the output interface as the next hop. This static route takes effect only after the output interface obtains an IP address and gateway address through DHCP, and becomes invalid upon the DHCP lease expiration. The next hop of this static route changes as the gateway address of the output interface changes. In addition, this static route can form ECMP routes with manually configured static routes.

To specify the **dhcp** keyword, make sure the output interface of the static route is a broadcast interface.

Examples

Configure a static route, whose destination address is 1.1.1.1/24, next hop address is 2.2.2.2, tag value is 45, and description information is **for internet**.

```
<Sysname> system-view
[Sysname] ip route-static 1.1.1.1 24 2.2.2.2 tag 45 description for internet
```

Related commands

display ip routing-table protocol

ip route-static-group

prefix

ip route-static default-preference

Use **ip route-static default-preference** to configure a default preference for static routes.

Use **undo ip route-static default-preference** to restore the default.

Syntax

ip route-static default-preference *default-preference*

undo ip route-static default-preference

Default

The default preference of static routes is 60.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

default-preference: Specifies a default preference for static routes, in the range of 1 to 255.

Usage guidelines

If no preference is specified for a static route, the default preference applies.

When the default preference is reconfigured, it applies only to newly added static routes.

Examples

Set a default preference of 120 for static routes.

```
<Sysname> system-view
[Sysname] ip route-static default-preference 120
```

Related commands

ip route-static fast-reroute auto

Use **ip route-static fast-reroute auto** to configure static route FRR to automatically select a backup next hop.

Use **undo ip route-static fast-reroute auto** to disable static route FRR from automatically selecting a backup next hop.

Syntax

ip route-static fast-reroute auto

undo ip route-static fast-reroute auto

Default

Static route FRR is disabled from automatically selecting a backup next hop.

Views

System view

Predefined user roles

network-admin

context-admin

Examples

Configure static route FRR to automatically select a backup next hop.

```
<Sysname> system-view
[Sysname] ip route-static fast-reroute auto
```

ip route-static primary-path-detect bfd echo

Use **ip route-static primary-path-detect bfd echo** to enable BFD echo packet mode for static route FRR.

Use **undo ip route-static primary-path-detect bfd** to disable BFD echo packet mode for static route FRR.

Syntax

ip route-static primary-path-detect bfd echo

undo ip route-static primary-path-detect bfd

Default

BFD echo packet mode for static route FRR is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command enables static route FRR to use BFD echo packet mode for fast failure detection on the primary link.

Examples

Enable BFD echo packet mode for static route FRR.

```
<Sysname> system-view
[Sysname] ip route-static 1.1.1.1 32 gigabitethernet 1/0/1 2.2.2.2 backup-interface
gigabitethernet 1/0/2 backup-nexthop 3.3.3.3
[Sysname] ip route-static primary-path-detect bfd echo
```

Default

No static route is configured in a VPN instance.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

s-vpn-instance-name: Specifies a source MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. Each VPN instance has its own routing table, and the configured static route is installed in the routing tables of the specified VPN instances.

dest-address: Specifies the destination IP address of the static route, in dotted decimal notation.

mask-length: Specifies the mask length, an integer in the range of 0 to 32.

mask: Specifies the subnet mask in dotted decimal notation.

group *group-name*: Specifies a static route group by its name, a case-sensitive string of 1 to 31 characters.

vpn-instance *d-vpn-instance-name*: Specifies a destination MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If a destination VPN instance is specified, packets will search for the output interface in the destination VPN instance based on the configured next hop address.

interface-type interface-number: Specifies an output interface by its type and number. For more information, see *Layer 3—IP Routing Configuration Guide*.

dhcp: Specifies the default router designated by the DHCP server for the output interface as the next hop of the static route.

next-hop-address: Specifies the IP address of the next hop, in dotted decimal notation. For more information, see *Layer 3—IP Routing Configuration Guide*.

backup-interface *interface-type interface-number*: Specifies a backup output interface by its type and number. If the backup output interface is a non-P2P interface (an NBMA interface or broadcast interface), you must specify the backup next hop address.

backup-nexthop *backup-nexthop-address*: Specifies a backup next hop address.

bfd: Enables BFD to detect reachability of the static route's next hop. When the next hop is unreachable, the system immediately switches to the backup route.

control-packet: Specifies the BFD control mode.

bfd-source *ip-address*: Specifies the source IP address of BFD packets. As a best practice, specify the loopback interface address.

echo-packet: Specifies the BFD echo mode.

static *session-name*: Specifies a static BFD session by its name, a case-sensitive string of 1 to 64 characters. You can specify a nonexistent static BFD session. For the configuration to take effect, you must create the static BFD session.

permanent: Specifies the route as a permanent static route. If the output interface is down, the permanent static route is still active.

track *track-entry-number*: Associates the static route with a track entry specified by its number in the range of 1 to 1024. For more information about Track, see *Network Management and Monitoring Configuration Guide*.

public: Specifies the public network, which indicates that the specified next hop address is on the public network. The device searches for the output interface in the public network based on the next hop address for packets matching the static route. If you do not specify this keyword or the destination VPN instance, the specified next hop address is in the source VPN instance. The device searches for the output interface in the source VPN instance based on the next hop address for packets matching the static route.

preference *preference*: Specifies a preference for the static route, in the range of 1 to 255. The default is 60.

tag *tag-value*: Sets a tag value for marking the static route, in the range of 1 to 4294967295. The default is 0. Tags of routes are used for route control in routing policies. For more information about routing policies, see *Layer 3—IP Routing Configuration Guide*.

description *text*: Configures a description of 1 to 60 characters for the static route. The description can include special characters, such as the space, except the question mark (?).

Usage guidelines

If the destination IP address and the mask are both 0.0.0.0 (or 0), the configured route is a default route. The default route is used for forwarding a packet matching no entry in the routing table.

Implement different routing policies to configure different route preferences. For example, to enable load sharing for multiple routes to the same destination, assign the same preference to the routes. To enable the routes to back up one another, assign different preferences to them.

Follow these guidelines when you specify the output interface or the next hop address of the static route:

- If the output interface is a Null 0 interface, no next hop address is required.
- If the output interface is a point-to-point interface, you can specify only the output interface. You do not need to change the configuration of the route even if the peer address is changed.
- If the output interface is a broadcast interface (for example, an Ethernet interface or VLAN interface), the device uses the next hop IP address to obtain the MAC address of the next hop. Therefore, you must specify both the output interface and next hop IP address.

Follow these guidelines when you configure a static route:

- Enabling BFD for a flapping route could worsen the route flapping situation. Therefore, use it with caution. For more information about BFD, see *Network Management and Monitoring Configuration Guide*.
- For static routing-Track-NQA collaboration, you must configure the same VPN instance ID for the next hop to be detected and the NQA operation.
- If a static route needs route recursion, the associated track entry must monitor the next hop of the related route instead of that of the recursive static route. Otherwise, a valid route might be mistakenly considered invalid.

If you specify a static route group, all prefixes in the static route group will be assigned the next hop and output interface specified by using this command.

After an interface obtains an IP address and gateway address through DHCP, the device automatically generates a static route with the interface as the output interface. The destination address of the static route is 0.0.0.0/0 and the next hop of the static route is the default router (the gateway address designated by the DHCP server). This static route cannot form ECMP routes with manually configured static routes. The device uses this static route to guide traffic forwarding only after the manually configured static routes become invalid.

Specify the **dhcp** keyword to use both the automatically generated static route and the manually configured static routes to guide traffic forwarding. This keyword is applicable when the device has dual egress WAN links.

The **dhcp** keyword enables the device to automatically generate a static route destined for the specified network with the DHCP-designated default router of the output interface as the next hop. This static route takes effect only after the output interface obtains an IP address and gateway address through DHCP, and becomes invalid upon the DHCP lease expiration. The next hop of this static route changes as the gateway address of the output interface changes. In addition, this static route can form ECMP routes with manually configured static routes.

To specify the **dhcp** keyword, make sure the output interface of the static route is a broadcast interface.

Examples

Configure a static route in VPN instance **vpn1**, whose destination address is 1.1.1.1/24, next hop address is 2.2.2.2 in VPN instance **vpn2**, tag value is 45, and description information is **for internet**.

```
<Sysname> system-view
[Sysname] ip route-static vpn-instance vpn1 1.1.1.1 24 vpn-instance vpn2 2.2.2.2 tag 45
description for internet
```

Related commands

display ip routing-table protocol

ip route-static-group

prefix

ip route-static-group

Use **ip route-static-group** to create a static route group and enter its view, or enter the view of an existing static route group.

Use **undo ip route-static-group** to delete a static route group.

Syntax

ip route-static-group *group-name*

undo ip route-static-group *group-name*

Default

No static route groups exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies the static route group name, a case-sensitive string of 1 to 31 characters.

Examples

Create static route group **test** and enter its view.

```
<Sysname> system-view
[Sysname] ip route-static-group test
[Sysname-route-static-group-test]
```

Related commands

ip route-static

prefix

prefix

Use **prefix** to add a static route prefix to a static route group.

Use **undo prefix** to delete a static route prefix from a static route group.

Syntax

prefix *dest-address* { *mask-length* | *mask* }

undo prefix *dest-address* { *mask-length* | *mask* }

Default

No static route prefix is added to a static route group.

Views

Static route group view

Predefined user roles

network-admin

context-admin

Parameters

dest-address: Specifies the destination IP address of the static route, in dotted decimal notation.

mask-length: Specifies the mask length, an integer in the range of 0 to 32.

mask: Specifies the subnet mask in dotted decimal notation.

Usage guidelines

Execute this command repeatedly to add multiple static route prefixes to a static route group.

After you add static route prefixes to a static route group, you can specify that group in the **ip route-static group** command to configure static routes with the prefixes. To configure more static routes, you only need to add new static route prefixes to the group.

Examples

Add static route prefix 1.1.1.1/32 to static route group **test**.

```
<Sysname> system-view

IPv6 static routing commands

delete ipv6 static-routes all

Use **delete ipv6 static-routes all** to delete all IPv6 static routes.

Syntax

delete ipv6 [**vpn-instance** *vpn-instance-name*] **static-routes all**

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command deletes all IPv6 static routes for the public network.

Usage guidelines

CAUTION:

This command might interrupt network communication and cause packet forwarding failure. Before executing the command, make sure you fully understand the potential impact on the network.

When you use this command, the system will prompt you to confirm the operation before deleting all the IPv6 static routes.

Examples

Delete all IPv6 static routes.

```
<Sysname> system-view
[Sysname] delete ipv6 static-routes all
This will erase all IPv6 static routes and their configurations, you must reconfigure all static routes.
Are you sure?[Y/N]:y
```

Related commands

ipv6 route-static

display ipv6 route-static nib

Use **display ipv6 route-static nib** to display IPv6 static route next hop information.

Syntax

display ipv6 route-static nib [*nib-id*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

nib-id: Specifies a NIB by its ID, a hexadecimal string in the range of 1 to ffffffff.

verbose: Displays detailed IPv6 static route next hop information. If you do not specify this keyword, the command displays brief IPv6 static route next hop information.

Examples

Display brief IPv6 static route next hop information.

```
<Sysname> display ipv6 route-static nib
Total number of nexthop(s): 35

      NibID: 0x21000000        Sequence: 0
       Type: 0x41               Flushed: Yes
   UserKey0: 0x0                VrfNthp: 0
   UserKey1: 0x0                Nexthop: 2::3
    IFIndex: 0x0              LocalAddr: ::
   TopoNthp: Invalid

      NibID: 0x21000001        Sequence: 1
       Type: 0x41               Flushed: Yes
   UserKey0: 0x0                VrfNthp: 0
   UserKey1: 0x0                Nexthop: 3::4
    IFIndex: 0x0              LocalAddr: ::
   TopoNthp: Invalid

...
```

Table 1 Command output

Field	Description
NibID	ID of the NIB.
Sequence	Sequence number of the NIB.
Type	Type of the NIB.
Flushed	Indicates whether the route with the NIB has been flushed to the FIB.
UserKey0	Reserved data 1.
UserKey1	Reserved data 2.
VrfNthp	Index of the VPN instance to which the next hop belongs. This field displays **0** if the next hop is on the public network.
Nexthop	Next hop address.
IFIndex	Interface index
LocalAddr	Local interface address.

Field	Description
TopoNthp	This field is not supported in the current software version. Index of the topology that contains the next hop. This field displays **Invalid** if the next hop is on an IPv6 network, because the router does not support multiple topologies.

Display detailed IPv6 static route next hop information.

```
<Sysname> display ipv6 route-static nib verbose
Total number of nexthop(s): 35

   TunnelID: N/A               Topology:
     Weight: 0

...
```

Table 2 Command output

Field	Description
x nexthop(s)	Number of next hops.

Field	Description
PrefixIndex	Prefix index of the next hop for an ECMP route.
Vrf	VPN instance name. For the public network, this field displays **default-vrf**.
OrigNexthop	Original next hop.
RealNexthop	Real next hop.
Interface	Output interface.
localAddr	Local interface address.
RelyDepth	Recursion depth.
TunnelCnt	Number of tunnels after route recursion.
TunnelID	ID of the tunnel after route recursion.
Topology	This field is not supported in the current software version. Topology name. This field is blank for IPv6, because IPv6 does not support multiple topologies.
Weight	ECMP route weight. This field displays 0 for non-ECMP routes.
RefCnt	Reference count of the next hop.
FlushRefCnt	Reference count of the next hop that is flushed to the FIB.
Flag	Flag of the next hop.
Version	Version of the next hop.

display ipv6 route-static routing-table

Use **display ipv6 route-static routing-table** to display IPv6 static routing table information.

Syntax

display ipv6 route-static routing-table [**vpn-instance** *vpn-instance-name*] [*ipv6-address prefix-length*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the command displays IPv6 static routing table information for the public network.

ipv6-address: Specifies the destination IPv6 address.

prefix-length: Specifies the prefix length in the range of 0 to 128.

Examples

Display IPv6 static routing table information.

```
<Sysname> display ipv6 route-static routing-table
Total number of routes: 5

Status: * - valid

*Destination: 1::1/128
       NibID: 0x21000000        NextHop: 2::2
   MainNibID: N/A             BkNextHop: N/A
     BkNibID: N/A             Interface: GigabitEthernet1/0/1
     TableID: 0xa           BkInterface: N/A
        Flag: 0x80d0a          BfdSrcIp: N/A
     DbIndex: 0x3            BfdIfIndex: 0x0
        Type: Normal        BfdVrfIndex: 0
  TrackIndex: 0xffffffff          Label: NULL
  Preference: 60            vrfIndexDst: 0
     BfdMode: N/A            vrfIndexNH: 0
   Permanent: 0                     Tag: 0

*Destination: 1::1234/128
      NibID: 0x21000000        NextHop: 2::2
   MainNibID: N/A             BkNextHop: N/A
     BkNibID: N/A             Interface: NULL0
     TableID: 0xa           BkInterface: N/A
        Flag: 0x80d0a          BfdSrcIp: N/A
     DbIndex: 0x1            BfdIfIndex: 0x0
        Type: Normal        BfdVrfIndex: 0
  TrackIndex: 0xffffffff          Label: NULL
  Preference: 60            vrfIndexDst: 0
     BfdMode: N/A            vrfIndexNH: 0
   Permanent: 0                     Tag: 0

...
```

Table 3 Command output

Field	Description
Destination	Destination address/prefix.
NibID	ID of the NIB.
MainNibID	ID of the primary next hop for static route FRR.
BkNibID	ID of the backup next hop for static route FRR.
NextHop	Next hop address.
BkNextHop	Backup next hop address.
Interface	Output interface of the route.
BkInterface	Backup output interface.

Field	Description
TableID	ID of the table to which the route belongs.
DbIndex	Index of the database to which the route belongs.
Type	Route type: • Normal. • DHCP. • NAT.
BfdSrcIp	Source IPv6 address of the indirect BFD session.
BfdIfIndex	Index of the interface where BFD is enabled.
BfdVrfIndex	Index of the VPN instance where BFD is enabled. This field displays **0** if BFD is enabled for the public network.
BfdMode	BFD session mode: • **N/A**—No BFD session is configured. • **Ctrl**—Control packet mode. • **Echo**—Echo packet mode.
TrackIndex	NQA Track index.
Label	This field is not supported in the current software version. Label.
vrfIndexDst	Index of the VPN instance to which the destination belongs. For the public network, this field displays **0**.
vrfIndexNH	Index of the VPN instance to which the next hop belongs. For the public network, this field displays **0**.
Permanent	Permanent static route flag. 1 indicates a permanent static route.

ipv6 route-static

Use **ipv6 route-static** to configure an IPv6 static route.

Use **undo ipv6 route-static** to remove an IPv6 static route.

Syntax

ipv6 route-static *ipv6-address prefix-length* { *interface-type interface-number* [*next-hop-address*] [**bfd** { **control-packet** | **echo-packet** } [**bfd-source** *ipv6-address*] | **permanent** | **track** *track-entry-number*] | [**vpn-instance** *d-vpn-instance-name*] *next-hop-address* [**bfd control-packet bfd-source** *ipv6-address* | **permanent** | **track** *track-entry-number*] } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

undo ipv6 route-static *ipv6-address prefix-length* [*interface-type interface-number* [*next-hop-address*] | [**vpn-instance** *d-vpn-instance-name*] *next-hop-address*] [**preference** *preference*]

ipv6 route-static vpn-instance *s-vpn-instance-name ipv6-address prefix-length* { *interface-type interface-number* [*next-hop-address*] [**bfd** { **control-packet** | **echo-packet** } [**bfd-source** *ipv6-address*] | **permanent** | **track** *track-entry-number*] | *next-hop-address* [**public**] [**bfd control-packet bfd-source** *ipv6-address* | **permanent**] | **vpn-instance** *d-vpn-instance-name next-hop-address* [**bfd control-packet bfd-source**

ipv6-address | **permanent** | **track** *track-entry-number*] } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

undo ipv6 route-static vpn-instance *s-vpn-instance-name ipv6-address prefix-length* [*interface-type interface-number* [*next-hop-address*] | *next-hop-address* [**public**] | **vpn-instance** *d-vpn-instance-name next-hop-address*] [**preference** *preference*]

Default

No IPv6 static route is configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address prefix-length: Specifies the IPv6 address and prefix length.

interface-type interface-number: Specifies an output interface by its type and number. If the output interface is an NBMA interface or broadcast interface and not a point-to-point (P2P) interface, the next hop address must be specified.

next-hop-address: Specifies the next hop IPv6 address.

bfd: Enables BFD to detect reachability of the static route's next hop.

control-packet: Specifies the BFD control packet mode.

bfd-source *ipv6-address*: Specifies the source IPv6 address of BFD packets.

echo-packet: Specifies the BFD echo packet mode.

permanent: Specifies the IPv6 route as a permanent IPv6 static route. If the output interface is down, the permanent IPv6 static route is still active.

track *track-entry-number*: Associates the IPv6 static route with a track entry specified by its number in the range of 1 to 1024. For more information about Track, see *Network Management and Monitoring Configuration Guide*.

public: Indicates the next hop is on the public network.

- With this keyword specified, the system searches for an output interface for the IPv6 static route from the public network IPv6 routing table based on the specified next hop.
- Without this keyword and the destination VPN instance specified, the next hop of the IPv6 static route belongs to the source VPN instance. In this case, the system searches for an output interface for the IPv6 static route from the routing table of the source VPN instance based on the specified next hop.

vpn-instance *d-vpn-instance-name*: Specifies a destination MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If a destination VPN is specified, packets will search for the output interface based on the specified next hop (IPv6 address) for the static route.

preference *preference*: Specifies a preference for IPv6 static routes, in the range of 1 to 255. The default is 60.

tag *tag-value*: Sets a tag for marking the static route, in the range of 1 to 4294967295. The default is 0. Tags of routes are used for route control in routing policies. For more information about routing policies, see *Layer 3—IP Routing Configuration Guide*.

description *text*: Configures a description for the IPv6 static route, which consists of 1 to 60 characters, including special characters such as the space, but excluding the question mark (?).

vpn-instance *s-vpn-instance-name*: Specifies a source MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. Each VPN has its own routing table, and the configured static route is installed in the routing tables of the specified VPNs.

Usage guidelines

An IPv6 static route that has the destination address configured as **::/0** (a prefix length of 0) is the default IPv6 route. If the destination address of an IPv6 packet does not match any entry in the routing table, this default route is used to forward the packet.

Follow these guidelines to configure the output interface, next hop address, or both for a static route:

- If the output interface is a broadcast interface or an NBMA interface, the next hop address must be specified.
- If the output interface is a P2P interface, you can specify only the output interface. You do not need to change the configuration of the route even if the peer address is changed.

Follow these guidelines when you configure BFD for IPv6 static routes:

- If you specify the source IPv6 address of BFD packets, you must specify the IPv6 address as the next hop IPv6 address on the peer device.
- If you specify a non-P2P output interface and a direct next hop, specify the **bfd-source** *ipv6-address* option as a best practice. Make sure the source IPv6 address of BFD packets meets the following requirements:
  - The address is the same as the IPv6 address of the output interface.
  - The address is on the same network segment as the next hop IPv6 address of the same type.

    For example, if the next hop IPv6 address is a link-local address, the source IPv6 address of BFD packets must also be a link-local address.

Follow these guidelines when you configure a static route:

- Enabling BFD for a flapping route could worsen the route flapping situation. Therefore, use it with caution. For more information about BFD, see *Network Management and Monitoring Configuration Guide*.
- The next hop IPv6 address of echo packets must be a global unicast address.

For IPv6 static routing-Track-NQA collaboration, you must configure the same VPN instance ID for the next hop to be detected and the NQA operation.

Examples

Configure an IPv6 static route, with the destination address 1:1:2::/64 and next hop 1:1:3::1.

```
<Sysname> system-view
[Sysname] ipv6 route-static 1:1:2:: 64 1:1:3::1
```

Related commands

display ipv6 routing-table protocol

ipv6 route-static default-preference

Use **ipv6 route-static default-preference** to set a default preference for IPv6 static routes.

Use **undo ipv6 route-static default-preference** to restore the default.

Syntax

ipv6 route-static default-preference *default-preference*

undo ipv6 route-static default-preference

Default

The default preference of IPv6 static routes is 60.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

default-preference: Specifies a default preference for IPv6 static routes, in the range of 1 to 255.

Usage guidelines

If no preference is specified for an IPv6 static route, the default preference applies.

When the default preference is reconfigured, it applies only to newly added IPv6 static routes.

Examples

Set a default preference of 120 for IPv6 static routes.

```
<Sysname> system-view
[Sysname] ipv6 route-static default-preference 120
```

Related commands

display ipv6 routing-table protocol

Contents

RIP commands

bfd all-interfaces enable

Use **bfd all-interfaces enable** to enable BFD on all interfaces of a RIP process.

Use **undo bfd all-interfaces enable** to restore the default.

Syntax

bfd all-interfaces enable [**ctrl**]

undo bfd all-interfaces enable

Default

BFD is disabled on the interfaces of a RIP process.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

ctrl: Enables BFD bidirectional control detection for both directly and indirectly connected neighbors. If you do not specify this keyword, RIP uses BFD single-hop echo detection for directly connected neighbors and uses BFD bidirectional control detection for indirectly connected neighbors.

Usage guidelines

RIP supports the following BFD detection modes:

- **Single-hop echo detection**—Detection mode for a directly connected neighbor. In this mode, a BFD session is established only when the directly connected neighbor has route information to send.
- **Single-hop echo detection for a specific destination**—Detection mode for a directly connected neighbor. In this mode, a BFD session is established to the specified RIP neighbor when RIP is enabled on the local interface.
- **Bidirectional control detection**—Detection mode for both directly and indirectly connected neighbors. In this mode, a BFD session is established only when both ends have routes to send and BFD is enabled on the receiving interface.

You must configure bidirectional control detection on both ends of a link for it to take effect.

The BFD session to a neighbor does not come down when you execute the **undo peer** command to delete its address. This is because the RIP neighbor relationship is not immediately deleted when you execute the **undo peer** command.

The BFD setting configured in interface view takes precedence over the BFD setting configured in RIP view.

Examples

Enable BFD on all interfaces of RIP process 1.

```
<Sysname> system-view
[Sysname] rip 1
[Sysname-rip-1] bfd all-interfaces enable
```

Related commands

rip bfd

checkzero

Use **checkzero** to enable zero field check on RIPv1 messages.

Use **undo checkzero** to disable zero field check.

Syntax

checkzero

undo checkzero

Default

The zero field check function is enabled.

Views

RIP view

Predefined user roles

network-admin

context-admin

Usage guidelines

When the zero field check is enabled, the router discards RIPv1 messages in which zero fields contain non-zero values. If all messages are trustworthy, disable this feature to reduce the workload of the CPU.

Examples

Disable zero field check on RIPv1 messages for RIP process 1.

```
<Sysname> system-view
[Sysname] rip
[Sysname-rip-1] undo checkzero
```

default cost

Use **default cost** to configure a default metric for redistributed routes.

Use **undo default cost** to restore the default.

Syntax

default cost *cost-value*

undo default cost

Default

The default metric of redistributed routes is 0.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

cost-value: Specifies a default metric for redistributed routes, in the range of 0 to 16.

Usage guidelines

When you use the **import-route** command to redistribute routes from another routing protocol without specifying a metric, the metric specified by the **default cost** command applies.

Examples

Configure a default metric of 3 for redistributed routes.

```
<Sysname> system-view
[Sysname] rip 1
[Sysname-rip-1] default cost 3
```

Related commands

import-route

default-route

Use **default-route** to configure all interfaces running a RIP process to advertise a default route with a specified metric to RIP neighbors.

Use **undo default-route** to restore the default.

Syntax

default-route { **only** | **originate** } [**cost** *cost-value* | **route-policy** *route-policy-name*]*

undo default-route

Default

No default route is sent to RIP neighbors.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

only: Advertises only a default route.

originate: Advertises both a default route and other routes.

cost-value: Specifies a cost for the default route, in the range of 1 to 15. The default is 1.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case sensitive string of 1 to 63 characters. If you specify this option, the command advertises a default route only when a route in the routing table matches the routing policy.

Usage guidelines

A RIP router configured with this feature does not receive any default route from RIP neighbors.

Examples

Configure all interfaces running RIP process 100 to send only a default route with a metric of 2 to RIP neighbors.

```
<Sysname> system-view
```

```
[Sysname] rip 100
[Sysname-rip-100] default-route only cost 2
```

Related commands

rip default-route

display rip

Use **display rip** to display state and configuration information for a RIP process.

Syntax

display rip [*process-id*]

Views

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIP process by its ID in the range of 1 to 65535. If no process is specified, the command displays state and configuration information for all RIP processes.

Examples

Display current state and configuration information for all RIP processes.

```
<Sysname> display rip
  Public VPN-instance name:
    RIP process: 1
       RIP version: 1
       Preference: 100
           Routing policy: abc
       Fast-reroute:
           Routing policy: frr
       Checkzero: Enabled
       Default cost: 0
       Summary: Enabled
       Host routes: Enabled
       Maximum number of load balanced routes: 8
       Update time   :   30 secs  Timeout time         :  180 secs
       Suppress time :  120 secs  Garbage-collect time :  120 secs
       Update output delay:   20(ms)  Output count:    3
       Graceful-restart interval:   60 secs
       Triggered Interval : 5 50 200
       BFD: Enabled (ctrl)
       Silent interfaces: None
       Default routes: Originate  Default routes cost: 3
       Verify-source: Enabled
```

```
Networks:
    1.0.0.0
Configured peers:
    197.168.6.2
Triggered updates sent: 0
Number of routes changes: 1
Number of replies to queries: 0
```

Table 1 Command output

Field	Description
Public VPN-instance name	The RIP process runs on the public network.
Private VPN-instance name	VPN instance where the RIP process runs.
RIP process	RIP process ID.
RIP version	RIP version 1 or 2.
Preference	RIP preference.
Fast-reroute	RIP FRR.
Checkzero	Indicates whether the zero field check is enabled for RIPv1 messages: **Enabled** or **Disabled**.
Default cost	Default cost of redistributed routes.
Summary	Indicates whether route summarization is enabled: **Enabled** or **Disabled**.
Host routes	Indicates whether to receive host routes: **Enabled** or **Disabled**.
Maximum number of load balanced routes	Maximum number of ECMP routes for load balancing.
Update time	RIP update interval, in seconds.
Timeout time	RIP timeout time, in seconds.
Suppress time	RIP suppress interval, in seconds.
Garbage-collect time	RIP garbage-collect interval, in seconds.
Update output delay	RIP packet sending interval, in seconds.
Output count	Maximum number of RIP packets sent at each interval.
Graceful-restart interval	GR interval, in seconds.
Triggered Interval	Triggered update sending interval.
BFD	Whether BFD is enabled: • **Disabled**—Disabled in RIP view. • **Enabled**—Enabled in RIP view. RIP uses BFD single-hop echo detection for a directly connected neighbor and uses BFD bidirectional control detection for an indirectly connected neighbor. • **Enabled (ctrl)**—Enabled in RIP view. RIP uses BFD bidirectional control detection for both directly and indirectly connected neighbors.
Silent interfaces	Silent interfaces, which do not periodically send updates.

Field	Description
Default routes	Indicates whether a default route is sent to RIP neighbors. • **only**—Only a default route is advertised. • **originate**—A default route is advertised along with other routes. • **disable**—No default route is advertised.
Default routes cost	Metric for a default route.
Verify-source	Indicates whether the source IP address is checked for received RIP routing updates: **Enabled** or **Disabled**.
Networks	Networks enabled with RIP.
Configured peers	Configured neighbors.
Triggered updates sent	Number of triggered updates sent.
Number of routes changes	Number of route changes.
Number of replies to queries	Number of RIP responses.

display rip database

Use **display rip database** to display active routes for a RIP process.

Syntax

display rip *process-id* **database** [*ip-address* { *mask-length* | *mask* }]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIP process by its ID in the range of 1 to 65535.

ip-address { *mask-length* | *mask* }: Displays active routes for the specified IP address. If you do not specify this argument, the command displays all actives routes for a RIP process.

Examples

Display active routes for RIP process 100.

```
<Sysname> display rip 100 database
   1.0.0.0/8, auto-summary
       1.1.1.0/24, cost 16, interface summary
       1.1.1.0/24, cost 0, nexthop 1.1.1.1, RIP-interface
       1.1.2.0/24, cost 0, imported
   2.0.0.0/8, auto-summary
   2.0.0.0/8, cost 1, nexthop 1.1.1.2
```

Display active routes with destination IP address 1.1.1.0 and mask length 24 for RIP process 100.

```
<Sysname> display rip 100 database 1.1.1.0 24
   1.1.1.0/24, cost 16, interface summary
   1.1.1.0/24, cost 0, nexthop 1.1.1.1, RIP-interface
```

Table 2 Command output

Field	Description
cost	Cost of the route.
auto-summary	Indicates that the route is a RIP automatic summary route.
interface summary	Indicates that the route is a RIP interface summary route.
nexthop	Address of the next hop.
RIP-interface	Direct route on a RIP-enabled interface.
imported	Indicates that the route is redistributed from another routing protocol.

display rip graceful-restart

Use **display rip graceful-restart** to display the GR status for a RIP process.

Syntax

display rip [*process-id*] **graceful-restart**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIP process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the GR status for all RIP processes.

Examples

Display the GR status for RIP process 1.

```
<Sysname> display rip 1 graceful-restart
 RIP process: 1
 Graceful Restart capability     : Enabled
 Current GR state                : Normal
 Graceful Restart period         : 60  seconds
 Graceful Restart remaining time : 0   seconds
```

Table 3 Command output

Field	Description
Graceful Restart capability	Indicates whether GR is enabled: **Enabled** or **Disabled**.
Current GR state	GR state: • **Under GR**—GR is in progress.

Field	Description
	• **Normal**—No GR is in progress or GR has completed.
Graceful Restart period	GR interval.

display rip interface

Use **display rip interface** to display RIP interface information for a RIP process.

Syntax

display rip *process-id* **interface** [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIP process by its ID in the range of 1 to 65535.

interface-type interface-number: Specifies an interface by its type and number. If no interface is specified, the command displays information about all RIP interfaces for the RIP process.

Examples

Display information about all interfaces for RIP process 1.

```
<Sysname> display rip 1 interface
Total: 1

 Interface: GigabitEthernet1/0/2
    Address/Mask: 1.1.1.1/24          Version: RIPv1
    MetricIn: 0                       MetricIn route policy: Not designated
    MetricOut: 1                      MetricOut route policy: Not designated
    Split-horizon/Poison-reverse: On/Off  Input/Output: On/On
    Default route: Off
    Update output delay:  20(ms)      Output count: 3
    BFD: Enabled (ctrl), inherited
    Current number of packets/Maximum number of packets: 0/2000
```

Table 4 Command output

Field	Description
Total	Number of interfaces running RIP.
Interface	Name of an interface running RIP.
Address/Mask	IP address and mask of the interface.
Version	RIP version running on the interface.
MetricIn	Additional metric added to incoming routes.

Field	Description
MetricIn route policy	Name of the routing policy used to add an additional metric for incoming routes. If no routing policy is used, the field displays **Not designated**.
MetricOut	Additional metric added to outgoing routes.
MetricOut route policy	Name of the routing policy used to add an additional routing metric for outgoing routes. If no routing policy is used, the field displays **Not designated**.
Split-horizon	Indicates whether split horizon is enabled: • **on**—Enabled. • **off**—Disabled.
Poison-reverse	Indicates whether poison reverse is enabled: • **on**—Enabled. • **off**—Disabled.
Input/Output	Indicates whether the interface is enabled to receive and send RIP messages: • **on**—Enabled. • **off**—Disabled.
Default route	Indicates whether to send a default route to RIP neighbors: • **Only**—Advertises only a default route. • **Originate**—Advertises both a default route and other routes. • **No-originate**—Advertises only non-default routes. • **Off**—Advertises no default route.
Default route cost	Metric for a default route.
Update output delay	RIP packet sending interval.
Output count	Maximum number of RIP packets that can be sent at each interval.
BFD	Whether BFD for RIP is enabled: • **Disabled**—Disabled in interface view and RIP view. • **Enabled**—Enabled on the RIP interface. The interface uses BFD single-hop echo detection for a directly connected neighbor and uses BFD bidirectional control detection for an indirectly connected neighbor. • **Enabled (ctrl)**—Enabled on the RIP interface. The interface uses BFD bidirectional control detection for both directly and indirectly connected neighbors. • **Enabled, inherited**—Enabled in RIP view. RIP uses BFD single-hop echo detection for a directly connected neighbor and uses BFD bidirectional control detection for an indirectly connected neighbor. The RIP interface uses the BFD setting configured in RIP view. • **Enabled (ctrl), inherited**—Enabled in RIP view. RIP uses BFD bidirectional control detection for both directly and indirectly connected neighbors. The RIP interface uses the BFD setting configured in RIP view. • **Enabled (destination)**—Enabled on the RIP interface. The interface uses BFD single-hop echo detection for a specific destination.
Current number of packets /Maximum number of packets	Number of RIP packets to be sent/maximum number of RIP packets that can be sent within a certain interval.

display rip neighbor

Use **display rip neighbor** to display neighbor information for a RIP process.

Syntax

display rip *process-id* **neighbor** [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIP process by its ID in the range of 1 to 65535.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays all neighbor information for the RIP process.

Examples

Display neighbor information for RIP process 1.

```
<Sysname> display rip 1 neighbor
 Neighbor address: 197.168.2.3
     Interface  : GigabitEthernet1/0/2
     Version    : RIPv2     Last update: 00h00m02s
     Relay nbr  : N/A       BFD session: N/A
     Bad packets: 0         Bad routes : 0
```

Table 5 Command output

Field	Description
Interface	Output interface that is connected to the neighbor.
Version	Version of RIP that the neighbor runs.
Last update	Time elapsed since the most recent update.
Relay nbr	Relay neighbor type.
BFD session	BFD session type.
Bad packets	Number of received bad packets.
Bad routes	Number of received bad routes.

display rip non-stop-routing

Use **display rip non-stop-routing** to display the NSR status for a RIP process.

Syntax

display rip [*process-id*] **non-stop-routing**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIP process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the NSR status for all RIP processes.

Examples

Display the NSR status for RIP process 1.

```
<Sysname> display rip 1 non-stop-routing
RIP process: 1
 Nonstop Routing capability: Enabled
 Current NSR state         : Finish
```

Table 6 Command output

Field	Description
Nonstop Routing capability	Indicates whether NSR is enabled: **Enabled** or **Disabled**.
Current NSR state	NSR state: • Initialization. • **Smooth**—Upgrading data. • **Advertising**—Advertising routes. • **Redistribution**—Redistributing routes. • Finish.

display rip route

Use **display rip route** to display routing information for a RIP process.

Syntax

display rip *process-id* **route** [*ip-address* { *mask-length* | *mask* } [**verbose**] | **peer** *ip-address* | **statistics**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIP process by its ID in the range of 1 to 65535.

ip-address { *mask-length* | *mask* }: Displays route information for the specified IP address.

verbose: Displays all routing information for the specified destination IP address. If you do not specify this keyword, the command displays only information about optimal routes with the specified destination IP address.

peer *ip-address*: Displays route information learned from the specified neighbor.

statistics: Displays route statistics, including the total number of routes and number of routes from each neighbor.

Usage guidelines

If no optional parameters are specified, the **display rip** *process-id* **route** command displays all routing information for a RIP process.

Examples

Display all routing information for RIP process 1.

```
<Sysname> display rip 1 route
 Route Flags: R - RIP
              P - Permanent, A - Aging, S - Suppressed, G - Garbage-collect
              D - Direct, O - Optimal, F - Flush to RIB
 ------------------------------------------------------------------------------
 Peer 1.1.1.1 on GigabitEthernet1/0/2
      Destination/Mask        Nexthop           Cost    Tag     Flags   Sec
      3.0.0.0/8               1.1.1.1           1       0       RAOF    24
 Local route
      Destination/Mask        Nexthop           Cost    Tag     Flags   Sec
      4.4.4.4/32              0.0.0.0           0       0       RDOF    -
      1.1.1.0/24              0.0.0.0           0       0       RDOF    -
```

Display specified routing information for RIP process 1.

```
<Sysname> display rip 1 route 3.0.0.0 8 verbose
 Route Flags: R - RIP
              P - Permanent, A - Aging, S - Suppressed, G - Garbage-collect
              D - Direct, O - Optimal, F - Flush to RIB
 ------------------------------------------------------------------------------
 Peer 1.1.1.1 on GigabitEthernet1/0/2
  Destination/Mask    OrigNexthop/RealNexthop          Cost  Tag   Flags Sec
  3.0.0.0/8           1.1.1.1/1.1.1.1                  1     0     RAOF  16
```

Table 7 Command output

Field	Description
Route Flags	• **R**—RIP route. • **P**—The route never ages out. • **A**—The route is aging. • **S**—The route is suppressed. • **G**—The route is in Garbage-collect state. • **D**—The route is a direct route. • **O**—The route is an optimal route. • **F**—The route has been flushed to the RIB.
Peer *X.X.X.X* on *interface-type interface-number*	Routing information learned from a neighbor on a RIP interface.
Local route	Locally generated direct routes.

Field	Description
Destination/Mask	Destination IP address and subnet mask.
Nexthop	Next hop of the route.
OrigNexthop/RealNexthop	If the route is from a directly connected neighbor, the original next hop is the real next hop. If the route is from an indirectly connected neighbor, the **RealNexthop** field displays the recursive next hop for the route. Otherwise, the field is blank.
Cost	Cost of the route.
Tag	Route tag.
Flags	Route state.
Sec	Remaining time of the timer corresponding to the route state.

Display routing statistics for RIP process 1.

```
<Sysname> display rip 1 route statistics
 Peer                    Optimal/Aging       Optimal/Permanent       Garbage
 1.1.1.1                 1/1                 0/0                     0
 Local                   2/0                 0/0                     0
 Total                   3/1                 0/0                     0
```

Table 8 Command output

Field	Description
Peer	IP address of a neighbor.
Optimal	Total number of optimal routes.
Aging	Total number of aging routes.
Permanent	Total number of routes that never age out.
Garbage	Total number of routes in the Garbage-collection state.
Local	Total number of locally generated direct routes.
Total	Total number of routes learned from all RIP neighbors.

fast-reroute

Use **fast-reroute** to configure RIP FRR.

Use **undo fast-reroute** to disable RIP FRR.

Syntax

fast-reroute route-policy *route-policy-name*

undo fast-reroute

Default

RIP FRR is disabled.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

route-policy *route-policy-name*: Specifies a routing policy by its name, a case sensitive string of 1 to 63 characters. If you specify this option, the command designates a backup next hop for the routes that match the routing policy.

Usage guidelines

RIP FRR is available only when the state of primary link (with Layer 3 interfaces staying up) changes from bidirectional to unidirectional or down. A unidirectional link refers to the link through which packets are forwarded only from one end to the other.

RIP FRR is only effective for RIP routes that are learned from directly connected neighbors.

Equal-cost routes do not support RIP FRR.

Examples

Enable RIP FRR and use routing policy **frr** to specify a backup next hop.

```
<Sysname> system-view
[Sysname] ip prefix-list abc index 10 permit 100.1.1.0 24
[Sysname] route-policy frr permit node 10
[Sysname-route-policy-frr-10] if-match ip address prefix-list abc
[Sysname-route-policy-frr-10] apply fast-reroute backup-interface gigabitethernet 1/0/1
backup-nexthop 193.1.1.8
[Sysname-route-policy-frr-10] quit
[Sysname] rip 100
[Sysname-rip-100] fast-reroute route-policy frr
```

filter-policy export

Use **filter-policy export** to configure RIP to filter redistributed routes.

Use **undo filter-policy export** to remove the filtering.

Syntax

filter-policy { *ipv4-acl-number* | **prefix-list** *prefix-list-name* } **export** [*interface-type interface-number* | **bgp** | **direct** | { **isis** | **ospf** | **rip** } [*process-id*] | **static**]

undo filter-policy export [*interface-type interface-number* | **bgp** | **direct** | { **isis** | **ospf** | **rip** } [*process-id*] | **static**]

Default

RIP does not filter redistributed routes.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-acl-number: Specifies an IPv4 ACL by its number in the range of 2000 to 3999 to filter redistributed routes.

prefix-list *prefix-list-name*: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter redistributed routes.

interface-type interface-number: Specifies an interface by its type and number.

bgp: Filters routes redistributed from BGP.

direct: Filters direct routes.

isis: Filters routes redistributed from IS-IS.

ospf: Filters routes redistributed from OSPF.

rip: Filters routes redistributed from RIP.

process-id: Specifies a process ID of OSPF, IS-IS, or RIP, in the range of 1 to 65535. The default value is 1.

Usage guidelines

You can configure only one filtering policy to filter routes redistributed from a routing protocol or an interface. Without any protocol or interface specified, the filtering policy applies globally. If you execute this command multiple times, the most recent configuration takes effect.

To remove the filtering policy configured for a protocol or an interface, use the **undo filter-policy export** command with the protocol or interface specified.

To reference an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following methods:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.
- To deny/permit a route with the specified destination and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the subnet mask of the route. For the mask configuration to take effect, specify a contiguous subnet mask.

Examples

Use basic ACL 2000 to filter redistributed routes.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule deny source 192.168.10.0 0.0.0.255
[Sysname-acl-ipv4-basic-2000] quit
[Sysname] rip 1
[Sysname-rip-1] filter-policy 2000 export
```

Use IP prefix list **abc** to filter redistributed routes.

```
<Sysname> system-view
[Sysname] ip prefix-list abc index 10 permit 11.0.0.0 8
[Sysname] rip 1
[Sysname-rip-1] filter-policy prefix-list abc export
```

Configure advanced ACL 3000 to permit only route 113.0.0.0/16 to pass. Use ACL 3000 to filter redistributed routes.

```
<Sysname> system-view
```

```
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule 10 permit ip source 113.0.0.0 0 destination 255.255.0.0
0
[Sysname-acl-ipv4-adv-3000] rule 100 deny ip
[Sysname-acl-ipv4-adv-3000] quit
[Sysname] rip 1
[Sysname-rip-1] filter-policy 3000 export
```

Related commands

acl (*ACL and QoS Command Reference*)

import-route

ip prefix-list

filter-policy import

Use **filter-policy import** to configure RIP to filter received routes.

Use **undo filter-policy import** to remove the filtering.

Syntax

filter-policy { *ipv4-acl-number* | **gateway** *prefix-list-name* | **prefix-list** *prefix-list-name* [**gateway** *prefix-list-name*] } **import** [*interface-type interface-number*]

undo filter-policy import [*interface-type interface-number*]

Default

RIP does not filter received routes.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-acl-number: Specifies an IPv4 ACL by its number in the range of 2000 to 3999 to filter received routes.

prefix-list *prefix-list-name*: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter received routes.

gateway *prefix-list-name*: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter routes based on their next hops.

interface-type interface-number: Specifies an interface by its type and number.

Usage guidelines

You can configure only one filtering policy to filter routes received on an interface. Without any interface specified, the filtering policy applies globally. If you execute this command multiple times, the most recent configuration takes effect.

To remove the filtering policy configured for an interface, use the **undo filter-policy import** command with the interface specified.

To reference an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following methods:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command
- To deny/permit a route with the specified destination and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the subnet mask of the route. For the mask configuration to take effect, specify a contiguous subnet mask.

Examples

Use basic ACL 2000 to filter received RIP routes.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule deny source 192.168.10.0 0.0.0.255
[Sysname-acl-ipv4-basic-2000] quit
[Sysname] rip 1
[Sysname-rip-1] filter-policy 2000 import
```

Use IP prefix list **abc** to filter received RIP routes.

```
<Sysname> system-view
[Sysname] ip prefix-list abc index 10 permit 11.0.0.0 8
[Sysname] rip 1
[Sysname-rip-1] filter-policy prefix-list abc import
```

Configure advanced ACL 3000 to permit only route 113.0.0.0/16 to pass. Use ACL 3000 to filter received routes.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule 10 permit ip source 113.0.0.0 0 destination 255.255.0.0
0
[Sysname-acl-ipv4-adv-3000] rule 100 deny ip
[Sysname-acl-ipv4-adv-3000] quit
[Sysname] rip 1
[Sysname-rip-1] filter-policy 3000 import
```

Related commands

acl (*ACL and QoS Command Reference*)

ip prefix-list

graceful-restart

Use **graceful-restart** to enable RIP GR.

Use **undo graceful-restart** to disable RIP GR.

Syntax

graceful-restart

undo graceful-restart

Default

RIP GR is disabled.

Views

RIP view

Predefined user roles

network-admin

context-admin

Usage guidelines

The **graceful-restart** command and the **non-stop-routing** command are mutually exclusive.

Examples

Enable GR for RIP process 1.

```
<Sysname> system-view
[Sysname] rip 1
[Sysname-rip-1] graceful-restart
```

graceful-restart interval

Use **graceful-restart interval** to set the GR interval.

Use **undo graceful-restart interval** to restore the default.

Syntax

graceful-restart interval *interval*

undo graceful-restart interval

Default

The GR interval is 60 seconds.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the GR interval in the range of 5 to 360 seconds.

Examples

Set the GR interval to 200 seconds for RIP process 1.

```
<Sysname> system-view
[Sysname] rip 1
[Sysname-rip-1] graceful-restart interval 200
```

host-route

Use **host-route** to enable host route reception.

Use **undo host-route** to disable host route reception.

Syntax

host-route

undo host-route

Default

RIP receives host routes.

Views

RIP view

Predefined user roles

network-admin

context-admin

Usage guidelines

A router might receive many host routes from the same subnet. These routes are not helpful for routing and occupy a large number of resources. To solve this problem, use the **undo host-route** command to disable RIP from receiving host routes.

This command takes effect only for RIPv2 routes.

Examples

Disable RIP from receiving host routes.

```
<Sysname> system-view
[Sysname] rip 1
[Sysname-rip-1] undo host-route
```

import-route

Use **import-route** to enable route redistribution.

Use **undo import-route** to disable route redistribution.

Syntax

import-route bgp [*as-number*] [**allow-ibgp**] [**cost** *cost-value* | **route-policy** *route-policy-name* | **tag** *tag*] *

import-route { **direct** | **static** } [**cost** *cost-value* | **route-policy** *route-policy-name* | **tag** *tag*] *

import-route { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] [**allow-direct** | **cost** *cost-value* | **route-policy** *route-policy-name* | **tag** *tag*] *

undo import-route { **bgp** | **direct** | { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] | **static** }

Default

RIP does not redistribute routes.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

bgp: Redistributes BGP routes.

direct: Redistributes direct routes.

isis: Redistributes IS-IS routes.

ospf: Redistributes OSPF routes.

rip: Redistributes RIP routes.

static: Redistributes static routes.

as-number: Specifies an AS by its number in the range of 1 to 4294967295. This argument applies only to the BGP protocol. If you do not specify the *as-number* argument, this command redistributes all IPv4 EBGP routes. As a best practice, specify the AS number to avoid redistributing excessive IPv4 EBGP routes.

process-id: Specifies a RIP, IS-IS, or OSPF process by its ID in the range of 1 to 65535. The default is 1.

all-processes: Enables route redistribution from all IS-IS, OSPF or RIP processes.

allow-ibgp: Allows redistribution of IBGP routes. The **import-route bgp** command redistributes only EBGP routes. The **import-route bgp allow-ibgp** command additionally redistributes IBGP routes and might cause routing loops. Therefore, use it with caution.

allow-direct: Redistributes the networks of the local interfaces enabled with the specified routing protocol. If you do not specify the **allow-direct** keyword, the networks of the local interfaces are not redistributed. If you specify both the **allow-direct** keyword and the **route-policy** *route-policy-name* option, make sure the **if-match** rule defined in the routing policy does not conflict with the **allow-direct** keyword. For example, if you specify the **allow-direct** keyword, do not configure the **if-match route-type** rule for the routing policy. Otherwise, the **allow-direct** keyword does not take effect.

cost *cost-value*: Specifies a cost for redistributed routes, in the range of 0 to 16. The default cost is 0.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

tag *tag*: Specifies a tag for marking redistributed routes, in the range of 0 to 65535. The default is 0.

Usage guidelines

This command redistributes only active routes. To view route state information, use the **display ip routing-table protocol** command.

When you execute the **undo** form of the command, per-process setting has higher priority than the all-processes setting.

- The **undo import-route** { **isis** | **ospf** | **rip** } **all-processes** command cannot remove the setting configured for a process by using the **import-route** { **isis** | **ospf** | **rip** } *process-id* command. To remove the setting for that process, you must specify the process ID in the **undo** form of the command.

Examples

Redistribute static routes into RIP, and set the cost for redistributed routes to 4.

```
<Sysname> system-view
[Sysname] rip 1
[Sysname-rip-1] import-route static cost 4
```

Related commands

default cost

maximum load-balancing

Use **maximum load-balancing** to set the maximum number of RIP equal-cost multi-path (ECMP) routes for load balancing.

Use **undo maximum load-balancing** to restore the default.

Syntax

maximum load-balancing *number*

undo maximum load-balancing

Default

The maximum number of RIP ECMP routes equals the maximum number of ECMP routes, which is configurable by using the **max-ecmp-num** command.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the maximum number of RIP ECMP routes. Load balancing is not implemented when the value is 1.

The following compatibility matrixes show the value ranges for the maximum number of RIP ECMP routes:

Models	Value range
NFNX5-HD6480	1 to 16
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	1 to 32

Usage guidelines

You can set a smaller value for the **max-ecmp-num** command than the current value for the **maximum load-balancing** command. After a reboot, the value for the **maximum load-balancing** command automatically changes to be the same as the value for the **max-ecmp-num** command.

Examples

Set the maximum number of RIP ECMP routes to 2.

```
<Sysname> system-view
[Sysname] rip
[Sysname-rip-1] maximum load-balancing 2
```

Related commands

max-ecmp-num

network

Use **network** to enable RIP on an interface attached to a specified network.

Use **undo network** to disable RIP on an interface attached to a specified network.

Syntax

network *network-address* [*wildcard-mask*]

undo network *network-address*

Default

RIP is disabled on an interface.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

network-address: Specifies a subnet address where an interface resides.

wildcard-mask: Specifies an IP address wildcard mask. A wildcard mask can be thought of as a subnet mask, with 1s and 0s inverted. For example, a wildcard mask of 255.255.255.0 corresponds to a subnet mask of 0.0.0.255. If you do not specify this argument, the command uses the natural mask.

Usage guidelines

RIP runs only on an interface attached to the specified network, which can be configured with a wildcard mask. An interface not on the specified network does not receive or send RIP routes, or advertise its direct routes.

For a single RIP process, the **network** 0.0.0.0 command can enable RIP on all interfaces. If multiple RIP processes exist, the command is not applicable.

If a physical interface is attached to multiple networks, you cannot advertise these networks in different RIP processes.

Examples

Enable RIP process 100 on the interface attached to the network 129.102.0.0.

```
<Sysname> system-view
[Sysname] rip 100
[Sysname-rip-100] network 129.102.0.0
```

Related commands

rip enable

non-stop-routing

Use **non-stop-routing** to enable RIP NSR.

Use **undo non-stop-routing** to disable RIP NSR.

Syntax

non-stop-routing

undo non-stop-routing

Default

RIP NSR is disabled.

Views

RIP view

Predefined user roles

network-admin

context-admin

Usage guidelines

RIP NSR enabled for a RIP process takes effect only on that process. As a best practice, enable RIP NSR for each process if multiple RIP processes exist.

The **non-stop-routing** command and the **graceful-restart** command are mutually exclusive.

Examples

Enable NSR for RIP process 1.

```
<Sysname> system-view
[Sysname] rip 1
[Sysname-rip-1] non-stop-routing
```

output-delay

Use **output-delay** to set the rate at which an interface sends RIP packets.

Use **undo output-delay** to restore the default.

Syntax

output-delay *time* **count** *count*

undo output-delay

Default

An interface sends up to three RIP packets every 20 milliseconds.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the sending interval in the range of 10 to 100 milliseconds.

count: Specifies the maximum number of RIP packets sent at each interval, in the range of 1 to 30.

Examples

Configure all interfaces running RIP process 1 to send up to 10 RIP packets every 60 milliseconds.

```
<Sysname> system-view
[Sysname] rip 1
[Sysname-rip-1] output-delay 60 count 10
```

peer

Use **peer** to specify a RIP neighbor in the NBMA network, where routing updates destined for the neighbor are only unicasts and not multicast or broadcast.

Use **undo peer** to remove a RIP neighbor.

Syntax

peer *ip-address*

undo peer *ip-address*

Default

RIP does not unicast updates to any neighbor.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IP address of a RIP neighbor, in dotted decimal notation.

Usage guidelines

Do not use the **peer** *ip-address* command when the neighbor is directly connected. Otherwise, the neighbor might receive both unicast and multicast (or broadcast) messages with the same routing information.

This command must be executed together with the **undo validate-source-address** command, which disables source IP address check on inbound RIP routing updates.

Examples

Configure RIP to unicast updates to peer 202.38.165.1.

```
<Sysname> system-view
[Sysname] rip 1
[Sysname-rip-1] peer 202.38.165.1
```

Related commands

validate-source-address

preference

Use **preference** to specify a preference for RIP routes.

Use **undo preference** to restore the default.

Syntax

preference { *preference* | **route-policy** *route-policy-name* } *

undo preference

Default

The preference of RIP routes is 100.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

preference: Specifies a preference for RIP routes, in the range of 1 to 255. The smaller the value, the higher the preference.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

You can specify a routing policy by using the keyword **route-policy** to set a preference for matching RIP routes.

- The preference set by the routing policy applies to all matching RIP routes. The preference of other routes is set by the **preference** command.
- If no preference is set by the routing policy, the preference of all RIP routes is set by the **preference** command.

Examples

Set a preference of 120 for RIP routes.

```
<Sysname> system-view
[Sysname] rip 1
[Sysname-rip-1] preference 120
```

reset rip process

Use **reset rip process** to reset a RIP process.

Syntax

reset rip *process-id* **process**

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies a RIP process by its ID in the range of 1 to 65535.

Usage guidelines

After executing the command, you are prompted to confirm the operation.

Examples

Reset RIP process 100.

```
<Sysname> reset rip 100 process
Reset RIP process? [Y/N]:y
```

reset rip statistics

Use **reset rip statistics** to clear statistics for a RIP process.

Syntax

reset rip *process-id* **statistics**

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies a RIP process by its ID in the range of 1 to 65535.

Examples

Clear statistics for RIP process 100.

```
<Sysname> reset rip 100 statistics
```

rip

Use **rip** to enable RIP and enter RIP view.

Use **undo rip** to disable RIP.

Syntax

rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

undo rip [*process-id*]

Default

RIP is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies a RIP process by its ID in the range of 1 to 65535. The default is 1.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the RIP process runs on the public network.

Usage guidelines

You must enable a RIP process before configuring global parameters for it. This restriction does not apply to configuring interface parameters.

If you disable a RIP process, the configured interface parameters become invalid.

Examples

Enable RIP process 1 and enter RIP view.

```
<Sysname> system-view
[Sysname] rip
[Sysname-rip-1]
```

rip authentication-mode

Use **rip authentication-mode** to configure RIPv2 authentication.

Use **undo rip authentication-mode** to restore the default.

Syntax

rip authentication-mode { **keychain** *keychain-name* { **rfc2453** | **rfc4822** } | **md5** { **rfc2082** { **cipher** | **plain** } *string key-id* | **rfc2453** { **cipher** | **plain** } *string* } | **simple** { **cipher** | **plain** } *string* }

undo rip authentication-mode

Default

RIPv2 authentication is not configured.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

keychain: Specifies keychain authentication.

keychain-name: Specifies a keychain by its name, a case-sensitive string of 1 to 63 characters.

rfc2453: Uses the message format defined in RFC 2453 (IETF standard).

rfc4822: Uses the message format defined in RFC 4822.

md5: Specifies MD5 authentication.

rfc2082: Uses the message format defined in RFC 2082.

cipher: Specifies a password in encrypted form.

plain: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 16 characters. Its encrypted form is a case-sensitive string of 33 to 53 characters.

key-id: Specifies the key ID in the range of 1 to 255.

rfc2453: Uses the message format defined in RFC 2453 (IETF standard).

simple: Specifies the simple authentication mode.

Usage guidelines

A newly configured key overwrites the old one, if any.

Although you can specify an authentication mode for RIPv1 in interface view, the configuration does not take effect because RIPv1 does not support authentication.

RIPv2 sends and receives packets on an interface configured with keychain authentication as follows:

- Before sending a packet, RIPv2 must obtain a valid send key from the keychain to authenticate the packet.

  RIPv2 does not send the packet if no valid send key is available.
- After receiving a packet, RIPv2 performs the following operations:
  - If the **rfc2453** keyword is specified, RIPv2 uses valid accept keys in the keychain to authenticate the packet.
    - RIPv2 accepts the packet if it is successfully authenticated by an accept key.
    - RIPv2 discards the packet if the packet authentication fails.
  - If the **rfc4822** keyword is specified, RIPv2 performs the following operations:
    - Searches the keychain for a valid accept key using the key ID carried in the packet.
    - Uses the authentication algorithm and key string of the key to authenticate the packet.

      RIPv2 accepts the packet if the authentication succeeds. If the packet authentication fails or no valid accept key is available, RIPv2 discards the packet.

Follow these guidelines when you configure keychain authentication for an interface enabled with RIPv2:

- If the **rfc2453** keyword is specified, RIPv2 supports only the MD5 authentication algorithm of the keychain and a key string length of up to 16 characters. If RIPv2 obtains a key string containing more than 16 characters, it uses the first 16 characters of the key string for authentication.
- If the **rfc4822** keyword is specified, RIPv2 supports only the key IDs with a value range of 0 to 255. Any packets carrying a key ID not in the range will be discarded. RIPv2 supports the MD5, HMAC-SHA-1, HMAC-SM3, and HMAC-SHA-256 authentication algorithms of the keychain. The MD5 authentication algorithm can use the message format defined in RFC 2082.

Examples

Configure MD5 authentication on GigabitEthernet 1/0/1, and specify a plaintext key **rose** in the format defined in RFC 2453.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip version 2
[Sysname-GigabitEthernet1/0/1] rip authentication-mode md5 rfc2453 plain rose
```

Related commands

rip version

rip bfd

Use **rip bfd** to configure BFD for RIP on an interface.

Use **undo rip bfd enable** to restore the default.

Syntax

rip bfd { **disable** | **enable** [**ctrl** | **destination** *ip-address*] }

undo rip bfd enable

Default

BFD for RIP is disabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

`disable`: Disables BFD for RIP on the interface. You can do this to avoid network instability when link flapping occurs on the interface.

`enable`: Enables BFD for RIP on the interface.

`ctrl`: Enables BFD bidirectional control detection for both directly and indirectly connected neighbors. If you do not specify this keyword, the interface uses BFD single-hop echo detection for a directly connected neighbor and BFD bidirectional control detection for an indirectly connected neighbor.

`destination` *`ip-address`*: Specifies a destination to which the interface establishes a BFD session. If you do not specify this option, the interface establishes a BFD session to its RIP neighbor.

Usage guidelines

RIP supports the following BFD detection modes:

- **Single-hop echo detection**—Detection mode for a directly connected neighbor. In this mode, a BFD session is established only when the directly connected neighbor has route information to send.
- **Single-hop echo detection for a specific destination**—Detection mode for a directly connected neighbor. In this mode, a BFD session is established to the specified RIP neighbor when RIP is enabled on the local interface.
- **Bidirectional control detection**—Detection mode for both directly and indirectly connected neighbors. In this mode, a BFD session is established only when both ends have routes to send and BFD is enabled on the receiving interface.

If you specify the **`destination`** *`ip-address`* option, the interface uses BFD single-hop echo detection to detect link failure on the link to the specified destination. If a failure is detected on the link, the interface does not send or receive RIP packets anymore.

The **`bfd all-interfaces enable`** command in RIP view enables BFD for RIP on all interfaces of the RIP process. To disable BFD on one of those interfaces, you must use the **`rip bfd disable`** command instead of the **`undo rip bfd enable`** command in interface view.

You must configure bidirectional control detection on both ends of a link for it to take effect.

The BFD session to a neighbor does not come down when you execute the **`undo peer`** command to delete its address. This is because the RIP neighbor relationship is not immediately deleted when you execute the **`undo peer`** command.

Examples

Enable BFD for RIP on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip bfd enable
```

rip default-route

Use **`rip default-route`** to configure a RIP interface to advertise a default route with a specified metric.

Use **undo rip default-route** to disable a RIP interface from sending a default route.

Syntax

rip default-route { { **only** | **originate** } [**cost** *cost-value* | **route-policy** *route-policy-name*] * | **no-originate** }

undo rip default-route

Default

A RIP interface advertises a default route if the RIP process that the interface runs is enabled to advertise a default route.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

only: Advertises only a default route.

originate: Advertises both a default route and other routes.

cost-value: Specifies a cost for the default route, in the range of 1 to 15. The default is 1.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case sensitive string of 1 to 63 characters. If you specify this option, the command advertises a default route only when a route in the routing table matches the routing policy.

no-originate: Advertises only non-default routes.

Usage guidelines

An interface that is enabled to advertise a default route does not receive any default route from RIP neighbors.

Examples

Configure GigabitEthernet 1/0/1 to advertise only a default route with a metric of 2.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip default-route only cost 2
```

Configure GigabitEthernet 1/0/1 to advertise a default route with a metric of 4 and other routes.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip default-route originate cost 4
```

Related commands

default-route

rip enable

Use **rip enable** to enable RIP on an interface.

Use **undo rip enable** to disable RIP on an interface.

Syntax

rip *process-id* **enable** [**exclude-subip**]

undo rip enable

Default

RIP is disabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies a RIP process by its ID in the range of 1 to 65535.

exclude-subip: Excludes secondary IP addresses from being enabled with RIP. If you do not specify this keyword, RIP is also enabled on secondary IP addresses of a RIP-enabled interface.

Usage guidelines

The **rip enable** command has a higher priority than the **network** command.

Examples

Enable RIP process 100 on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip 100 enable
```

Related commands

network

rip input

Use **rip input** to enable an interface to receive RIP messages.

Use **undo rip input** to disable an interface from receiving RIP messages.

Syntax

rip input

undo rip input

Default

An interface is enabled to receive RIP messages.

Views

Interface view

Predefined user roles

network-admin

context-admin

Examples

Disable GigabitEthernet 1/0/1 from receiving RIP messages.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
```

```
[Sysname-GigabitEthernet1/0/1] undo rip input
```

rip max-packet-length

Use **rip max-packet-length** to set the maximum length of RIP packets.

Use **undo rip max-packet-length** to restore the default.

Syntax

rip max-packet-length *value*

undo rip max-packet-length

Default

The maximum length of RIP packets is 512 bytes.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies the maximum length of RIP packets, in the range of 32 to 65535 bytes.

Usage guidelines

The supported maximum length of RIP packets varies by vendor. Use this feature with caution to avoid compatibility issues.

When authentication is enabled, follow these guidelines to ensure packet forwarding:

- For simple authentication, the maximum length of RIP packets must be no less than 52 bytes.
- For MD5 authentication (with packet format defined in RFC 2453), the maximum length of RIP packets must be no less than 56 bytes.
- For MD5 authentication (with packet format defined in RFC 2082), the maximum length of RIP packets must be no less than 72 bytes.

If the configured value in the **rip max-packet-length** command is greater than the MTU of an interface, the interface MTU value is used as the maximum length of RIP packets.

Examples

Set the maximum length of RIP packets on GigabitEthernet 1/0/1 to 1024 bytes.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip max-packet-length 1024
```

rip metricin

Use **rip metricin** to configure an interface to add a metric to inbound routes.

Use **undo rip metricin** to restore the default.

Syntax

rip metricin [**route-policy** *route-policy-name*] *value*

undo rip metricin

Default

The additional metric of an inbound route is 0.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

route-policy *route-policy-name*: Specifies a routing policy by its name, a case sensitive string of 1 to 63 characters. If you specify this option, the command adds an additional metric for the routes that match the routing policy.

value: Adds an additional metric to inbound routes, in the range of 0 to 16.

Usage guidelines

When a valid RIP route is received, the system adds a metric to it and then installs it into the routing table. The metric of the route received on the configured interface is then increased. If the sum of the additional metric and the original metric is greater than 16, the metric of the route will be 16.

If a routing policy is referenced with the **route-policy** keyword, the following operations can be performed:

- Routes matching the policy are added with the metric specified in the **apply cost** command configured in the policy. Routes not matching it are added with the metric specified in the **rip metricin** command. The **rip metricin** command does not support specifying the **+** or **–** keyword in the **apply cost** command to add or reduce a metric.
- If the **apply cost** command is not configured in the policy, all the inbound routes are added with the metric specified in the **rip metricin** command.

Examples

Configure GigabitEthernet 1/0/1 to add a metric of 6 to the inbound route 1.0.0.0/8 and to add a metric of 2 to other inbound routes.

```
<Sysname> system-view
[Sysname] ip prefix-list 123 permit 1.0.0.0 8
[Sysname] route-policy abc permit node 10
[Sysname-route-policy-abc-10] if-match ip address prefix-list 123
[Sysname-route-policy-abc-10] apply cost 6
[Sysname-route-policy-abc-10] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip metricin route-policy abc 2
```

Related commands

apply cost

rip metricout

Use **rip metricout** to configure an interface to add a metric to outbound routes.

Use **undo rip metricout** to restore the default.

Syntax

rip metricout [**route-policy** *route-policy-name*] *value*

undo rip metricout

Default

The additional metric for outbound routes is 1.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

route-policy *route-policy-name*: Specifies a routing policy by its name, a case sensitive string of 1 to 63 characters. If you specify this option, the command adds an additional metric for the routes that match the routing policy.

value: Adds an additional metric to outbound routes, in the range of 1 to 16.

Usage guidelines

With the command configured on an interface, the metric of RIP routes sent on the interface will be increased.

If a routing policy is referenced with the **route-policy** keyword, the following operations can be performed:

- Routes matching the policy is added with the metric specified in the **apply cost** command configured in the policy. Routes not matching it are added with the metric specified in the **rip metricout** command. The **rip metricout** command does not support specifying the **+** or **–** keyword in the **apply cost** command to add or reduce a metric.
- If the **apply cost** command is not configured in the policy, all the outbound routes are added with the metric specified in the **rip metricout** command.

Examples

Configure GigabitEthernet 1/0/1 to add a metric of 6 to the outbound route 1.0.0.0/8 and to add a metric of 2 to other outbound routes.

```
<Sysname> system-view
[Sysname] ip prefix-list 123 permit 1.0.0.0 8
[Sysname] route-policy abc permit node 10
[Sysname-route-policy-abc-10] if-match ip address prefix-list 123
[Sysname-route-policy-abc-10] apply cost 6
[Sysname-route-policy-abc-10] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip metricout route-policy abc 2
```

Related commands

apply cost

rip mib-binding

Use **rip mib-binding** to bind a RIP process to MIB.

Use **undo rip mib-binding** to restore the default.

Syntax

rip mib-binding *process-id*

undo rip mib-binding

Default

MIB operation is bound to the RIP process with the smallest process ID.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies a RIP process by its ID in the range of 1 to 65535.

Usage guidelines

If the specified process ID does not exist, the MIB binding configuration does not take effect.

Deleting a RIP process bound to MIB operation deletes the MIB binding configuration. After the RIP process is deleted, MIB operation is bound to the RIP process with the smallest process ID.

Examples

Bind RIP process 100 to MIB.

```
<Sysname> system-view
[Sysname] rip mib-binding 100
```

rip output

Use **rip output** to enable an interface to send RIP messages.

Use **undo rip output** to disable an interface from sending RIP messages.

Syntax

rip output

undo rip output

Default

An interface sends RIP messages.

Examples

Disable GigabitEthernet 1/0/1 from sending RIP messages.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] undo rip output
```

rip output-delay

Use **rip output-delay** to set the RIP packet sending interval for an interface and the maximum number of RIP packets that can be sent at each interval.

Use **undo rip output-delay** to restore the default.

Syntax

rip output-delay *time* **count** *count*

undo rip output-delay

Default

An interface uses the RIP packet sending rate set for the RIP process that the interface runs.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

Time: Specifies the RIP packet sending interval in the range of 10 to 100 milliseconds.

count: Specifies the maximum number of RIP packets sent at each interval, in the range of 1 to 30.

Examples

Configure GigabitEthernet 1/0/1 to send a maximum of six RIP packets every 30 milliseconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip output-delay 30 count 6
```

Related commands

output-delay

rip poison-reverse

Use **rip poison-reverse** to enable the poison reverse feature.

Use **undo rip poison-reverse** to disable the poison reverse feature.

Syntax

rip poison-reverse

undo rip poison-reverse

Default

The poison reverse feature is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Examples

Enable the poison reverse feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip poison-reverse
```

rip primary-path-detect bfd

Use **rip primary-path-detect bfd** to enable BFD for RIP FRR.

Use **undo rip primary-path-detect bfd** to disable BFD for RIP FRR.

Syntax

rip primary-path-detect bfd { **ctrl** | **echo** }

undo rip primary-path-detect bfd

Default

BFD for RIP FRR is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ctrl: Enables BFD bidirectional control detection for RIP FRR to detect primary link failures.

echo: Enables BFD single-hop echo detection for RIP FRR to detect primary link failures.

Usage guidelines

For quicker RIP FRR, use BFD on the primary link of redundant links to detect link failure.

You must configure bidirectional control detection on both ends of a link for it to take effect.

Examples

Enable BFD single-hop echo detection for RIP FRR on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] rip 1
[Sysname-rip-1] fast-reroute route-policy frr
[Sysname-rip-1] quit
[Sysname] bfd echo-source-ip 1.1.1.1
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip primary-path-detect bfd echo
```

rip split-horizon

Use **rip split-horizon** to enable the split horizon feature.

Use **undo rip split-horizon** to disable the split horizon feature.

Syntax

rip split-horizon

undo rip split-horizon

Default

The split horizon feature is enabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

The split horizon feature prevents routing loops. If you want to disable the feature, make sure the operation is necessary.

If both split horizon and poison reverse are enabled, only the poison reverse feature takes effect.

Examples

Enable the split horizon feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip split-horizon
```

rip summary-address

Use **rip summary-address** to configure a summary route on an interface.

Use **undo rip summary-address** to remove a summary route on an interface.

Syntax

rip summary-address *ip-address* { *mask-length* | *mask* }

undo rip summary-address *ip-address* { *mask-length* | *mask* }

Default

No summary route is configured on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the destination IP address of the summary route.

mask-length: Specifies the subnet mask length of the summary route, in the range of 0 to 32.

mask: Specifies the subnet mask of the summary route, in dotted decimal notation.

Usage guidelines

This command takes effect only when automatic route summarization is disabled.

Examples

Configure a summary route on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip summary-address 10.0.0.0 255.255.255.0
```

Related commands

summary

rip version

Use **rip version** to specify a RIP version on an interface.

Use **undo rip version** to restore the default.

Syntax

rip version { **1** | **2** [**broadcast** | **multicast**] }

undo rip version

Default

No RIP version is configured on an interface. The interface can send RIPv1 broadcasts, and receive RIPv1 broadcasts and unicasts, and RIPv2 broadcasts, multicasts, and unicasts.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

1: Specifies the RIP version as RIPv1.

2: Specifies the RIP version as RIPv2.

[**broadcast** | **multicast**]: Sends RIPv2 messages in broadcast mode or multicast mode (default).

Usage guidelines

If an interface has no RIP version configured, it uses the global RIP version. Otherwise, it uses the RIP version configured on it.

An interface running RIPv1 can perform the following operations:

- Sends RIPv1 broadcast messages.
- Receives RIPv1 broadcast and unicast messages.

An interface running RIPv2 in broadcast mode can perform the following operations:

- Sends RIPv2 broadcast messages.
- Receives RIPv1 broadcast and unicast messages, and RIPv2 broadcast, multicast, and unicast messages.

An interface running RIPv2 in multicast mode can perform the following operations:

- Sends RIPv2 multicast messages.
- Receives RIPv2 broadcast, multicast, and unicast messages.

Examples

Configure RIPv2 in broadcast mode on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rip version 2 broadcast
```

Related commands

version

silent-interface

Use **silent-interface** to disable interfaces from sending RIP messages. The interfaces can still receive RIP messages.

Use **undo silent-interface** to enable interfaces to send RIP messages.

Syntax

silent-interface { *interface-type interface-number* | **all** }

undo silent-interface { *interface-type interface-number* | **all** }

Default

All RIP interfaces can send RIP messages.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

interface-type interface-number: Disables a specified interface from sending RIP messages.

all: Disables all interfaces from sending RIP messages.

Examples

Disable all interfaces from sending RIP messages except GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] rip 100
[Sysname-rip-100] silent-interface all
[Sysname-rip-100] undo silent-interface gigabitethernet 1/0/1
[Sysname-rip-100] network 131.108.0.0
```

summary

Use **summary** to enable automatic RIPv2 route summarization. Natural masks are used to advertise summary routes to reduce the size of routing tables.

Use **undo summary** to disable automatic RIPv2 route summarization to advertise all subnet routes.

Syntax

summary

undo summary

Default

Automatic RIPv2 route summarization is enabled.

Views

RIP view

Predefined user roles

network-admin

context-admin

Usage guidelines

Automatic RIPv2 route summarization can reduce the routing table size to enhance the scalability and efficiency for large networks.

Examples

Disable automatic RIPv2 route summarization.

```
<Sysname> system-view
[Sysname] rip
[Sysname-rip-1] undo summary
```

Related commands

rip summary-address

rip version

timer triggered

Use **timer triggered** to set the interval for sending triggered updates.

Use **undo timer triggered** to restore the default.

Syntax

timer triggered *maximum-interval* [*minimum-interval* [*incremental-interval*]]

undo timer triggered

Default

The maximum interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

maximum-interval: Specifies the maximum interval in the range of 1 to 5 seconds.

minimum-interval: Specifies the minimum interval in the range of 10 to 5000 milliseconds.

incremental-interval: Specifies the incremental interval in the range of 100 to 1000 milliseconds.

Usage guidelines

The *minimum-interval* and *incremental-interval* cannot be greater than the *maximum-interval*.

For a stable network, the *minimum-interval* setting is used. If network changes become frequent, the incremental interval *incremental-interval* is used to extend the triggered update sending interval until the *maximum-interval* is reached.

Examples

For RIP process 1, set the maximum interval, minimum interval, and incremental interval to 2 seconds, 100 milliseconds, and 100 milliseconds, respectively.

```
<Sysname> system-view
[Sysname] rip 1
[Sysname-rip-1] timer triggered 2 100 100
```

timers

Use **timers** to set RIP timers.

Use **undo timers** to restore the default.

Syntax

timers { **garbage-collect** *garbage-collect-value* | **suppress** *suppress-value* | **timeout** *timeout-value* | **update** *update-value* } *

undo timers { **garbage-collect** | **suppress** | **timeout** | **update** } *

Default

The garbage-collect timer is 120 seconds, the suppress timer is 120 seconds, the timeout timer is 180 seconds, and the update timer is 30 seconds.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

garbage-collect-value: Specifies the garbage-collect timer in the range of 1 to 3600 seconds.

suppress-value: Specifies the suppress timer in the range of 0 to 3600 seconds.

timeout-value: Specifies the timeout timer in the range of 1 to 3600 seconds.

update-value: Specifies the update timer in the range of 1 to 3600 seconds.

Usage guidelines

RIP uses the following timers:

- **Update timer**—Specifies the interval between routing updates.
- **Timeout timer**—Specifies the route aging time. If no update for a route is received before the timer expires, RIP sets the metric of the route to 16.
- **Suppress timer**—Specifies how long a RIP route stays in suppressed state. When the metric of a route becomes 16, the route enters the suppressed state. If RIP receives an update for the

route with a metric less than 16 from the same neighbor, RIP uses this route to replace the suppressed route.

- **Garbage-collect timer**—Specifies the interval from when the metric of a route becomes 16 to when it is deleted from the routing table. During the garbage-collect timer length, RIP advertises the route with a metric of 16. If no update is announced for that route before the garbage-collect timer expires, RIP deletes the route from the routing table.

As a best practice, do not change the default values of these timers.

The timer lengths must be consistent on all routers on the network.

The timeout timer must be greater than the update timer.

Examples

Set the update, timeout, suppress, and garbage-collect timers to 5, 15, 15, and 30 seconds.

```
<Sysname> system-view
[Sysname] rip 100
[Sysname-rip-100] timers update 5 timeout 15 suppress 15 garbage-collect 30
```

validate-source-address

Use **validate-source-address** to enable source IP address check on inbound RIP routing updates.

Use **undo validate-source-address** to disable source IP address check on inbound RIP routing updates.

Syntax

validate-source-address

undo validate-source-address

Default

Source IP address check on inbound RIP routing updates is enabled.

Views

RIP view

Predefined user roles

network-admin

context-admin

Examples

Disable source IP address check on inbound RIP routing updates.

```
<Sysname> system-view
[Sysname-rip] rip 100
[Sysname-rip-100] undo validate-source-address
```

version

Use **version** to specify a global RIP version.

Use **undo version** to restore the default.

Syntax

version { **1** | **2** }

undo version

Default

No global RIP version is configured. An RIP interface can send RIPv1 broadcasts and receive RIPv1 broadcasts and unicasts, and RIPv2 broadcasts, multicasts, and unicasts.

Views

RIP view

Predefined user roles

network-admin

context-admin

Parameters

1: Specifies the RIP version as RIPv1.

2: Specifies the RIP version as RIPv2. RIPv2 messages are multicast.

Usage guidelines

An interface prefers the RIP version configured on it over the global RIP version.

If no RIP version is specified for the interface and the global version is RIPv1, the interface uses RIPv1 and can perform the following operations:

- Send RIPv1 broadcasts.
- Receive RIPv1 broadcasts and unicasts.

If no RIP version is specified for the interface and the global version is RIPv2, the interface uses RIPv2 multicast mode and can perform the following operations:

- Send RIPv2 multicasts.
- Receive RIPv2 broadcasts, multicasts, and unicasts.

Examples

Specify the global RIP version as RIPv2.

```
<Sysname> system-view
[Sysname] rip 100
[Sysname-rip-100] version 2
```

Related commands

rip version

Contents

RIPng commands

checkzero

Use **checkzero** to enable zero field check on RIPng packets.

Use **undo checkzero** to disable zero field check.

Syntax

checkzero

undo checkzero

Default

Zero field check is enabled.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Usage guidelines

Some fields in RIPng packet headers must be zero. These fields are called zero fields. You can enable zero field check on incoming RIPng packets. If a zero field of a packet contains a non-zero value, RIPng discards the packet.

Examples

Disable zero field check on RIPng packets for RIPng 100.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100] undo checkzero
```

default cost

Use **default cost** to configure a default metric for redistributed routes.

Use **undo default cost** to restore the default.

Syntax

default cost *cost-value*

undo default cost

Default

The default metric of redistributed routes is 0.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Parameters

cost-value: Specifies a default metric for redistributed routes, in the range of 0 to 16.

Usage guidelines

When you use the **import-route** command to redistribute routes from another routing protocol without specifying a metric, the metric specified by the **default cost** command applies.

Examples

Configure a default metric of 2 for redistributed routes.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100] default cost 2
```

Related commands

import-route

display ripng

Use **display ripng** to display state and configuration information for a RIPng process.

Syntax

display ripng [*process-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays information about all RIPng processes.

Examples

Display state and configuration information for all configured RIPng processes.

```
<Sysname> display ripng
  Public VPN-instance name:

RIPng process: 1
       Preference: 100
           Routing policy: abc
       Fast-reroute:
           Routing policy: abc
       Checkzero: Enabled
       Default cost: 0
       Maximum number of load balanced routes: 6
       Update time   :   30 secs  Timeout time         :  180 secs
       Suppress time :  120 secs  Garbage-collect time :  120 secs
```

```
Update output delay:   20(ms)  Output count:    3
Graceful-restart interval:   60 secs
Triggered Interval : 5 50 200
Number of periodic updates sent: 256
Number of triggered updates sent: 0
```

Table 1 Command output

Field	Description
Public VPN-instance name	Public network where the RIPng process runs.
Private VPN-instance name	VPN where the RIPng process runs.
RIPng process	RIPng process ID.
Preference	RIPng preference.
Checkzero	Indicates whether zero field check for RIPng packet headers is enabled: **Enabled** or **Disabled**.
Default Cost	Default metric of redistributed routes.
Fast-reroute	RIPng FRR.
Maximum number of balanced paths	Maximum number of load-balanced routes.
Update time	RIPng update interval, in seconds.
Timeout time	RIPng timeout interval, in seconds.
Suppress time	RIPng suppress interval, in seconds.
Garbage-collect time	RIPng garbage collection interval, in seconds.
Update output delay	RIPng packet sending interval, in milliseconds.
Output count	Maximum number of RIPng packets that can be sent at each interval.
Graceful-restart interval	GR interval in seconds.
Triggered Interval	Triggered update sending interval.

display ripng database

Use **display ripng database** to display all active routes in the advertising database for a RIPng process.

Syntax

display ripng *process-id* **database** [*ipv6-address prefix-length*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

ipv6-address prefix-length: Specifies an IPv6 address. The *ipv6-address* argument specifies an IPv6 address. The *prefix-length* argument specifies a prefix length in the range of 0 to 128.

Examples

Display active routes for RIPng process 1.

```
<Sysname> display ripng 1 database
   1::/64,
        cost 0, RIPng-interface
   10::/32,
        cost 0, imported
   2::2/128,
       via FE80::20C:29FF:FE7A:E3E4, cost 1
```

Table 2 Command output

Field	Description
cost	Route metric value.
imported	Indicates the route is redistributed from another routing protocol.
RIPng-interface	Route learned from the interface.
via	Next hop IPv6 address.

display ripng graceful-restart

Use **display ripng graceful-restart** to display GR information.

Syntax

display ripng [*process-id*] **graceful-restart**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

Examples

Display GR information for RIPng process 1.

```
<Sysname> display ripng 1 graceful-restart
RIPng process: 1
 Graceful Restart capability    : Enabled
 Current GR state               : Normal
```

```
Graceful Restart period        : 60  seconds
Graceful Restart remaining time: 0   seconds
```

Table 3 Command output

Field	Description
Graceful Restart capability	Indicates whether GR is enabled: **Enabled** or **Disabled**.
Current GR state	GR state: • **Under GR**—GR is in process. • **Normal**—GR is not in progress or has completed.

display ripng interface

Use **display ripng interface** to display interface information for a RIPng process.

Syntax

display ripng *process-id* **interface** [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays information about all interfaces for the RIPng process.

Examples

Display interface information for RIPng process 1.

```
<Sysname> display ripng 1 interface
Total: 1

 Interface: GigabitEthernet1/0/2
        Link-local address: FE80::20C:29FF:FEC8:B4DD
        Split-horizon: On               Poison-reverse: Off
        MetricIn: 0                     MetricOut: 1
        Default route: Off
        Update output delay: 20 (ms)    Output count: 3
        Primary path detection mode: BFD echo
        Summary address:
               1::/16
```

Table 4 Command output

Field	Description
Total	Number of interfaces running RIPng.
Interface	Name of an interface running RIPng.
Link Local Address	Link-local address of an interface running RIPng.
Split-horizon	Indicates whether split horizon is enabled: • **On**—Enabled. • **Off**—Disabled.
Poison-reverse	Indicates whether poison reverse is enabled: • **On**—Enabled. • **Off**—Disabled.
MetricIn/MetricOut	Additional metric to incoming and outgoing routes.
Default route	• **Only**—The interface advertises only a default route. • **Originate**—The interface advertises a default route and other RIPng routes. • **Off**—In this state, the interface does not advertise a default route. • **In garbage-collection status**—In this state, the interface advertises a default route with a metric of 16.
Update output delay	RIPng packet sending interval, in milliseconds.
Output count	Maximum number of RIPng packets that can be sent at each interval.
Default route cost	Cost of the default route.
Primary path detection mode	**BFD echo** indicates that BFD single-hop echo detection is used to detect primary link failures.

display ripng neighbor

Use **`display ripng neighbor`** to display neighbor information for a RIPng process.

Syntax

`display ripng` *`process-id`* **`neighbor`** [*`interface-type interface-number`*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`process-id`: Specifies a RIPng process by its ID in the range of 1 to 65535.

`interface-type interface-number`: Specifies an interface by its type and number. If you do not specify this argument, the command displays information about all neighbors for the RIPng process.

Examples

Display neighbor information for RIPng process 1.

```
<Sysname> display ripng 1 neighbor
Neighbor Address: FE80::230:FF:FE00:0
     Interface  : GigabitEthernet1/0/1
     Version    : RIPng version 1     Last update: 00h00m27s
     Bad packets: 0                   Bad routes : 0
```

Table 5 Command output

Field	Description
Neighbor Address	Link-local address of a neighbor interface.
Interface	Name of a neighbor interface.
Version	Version of RIPng that a neighbor runs.
Last update	Time elapsed since the most recent update.

display ripng non-stop-routing

Use **display ripng non-stop-routing** to display RIPng NSR information.

Syntax

display ripng [*process-id*] **non-stop-routing**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

Examples

Display NSR information for RIPng process 1.

```
<Sysname> display ripng 1 non-stop-routing
RIPng process: 1
 Nonstop Routing capability: Enabled
 Current NSR state         : Finish
```

Table 6 Command output

Field	Description
Nonstop Routing capability	Indicates whether NSR is enabled: **Enabled** or **Disabled**.

Field	Description
Current NSR state	NSR state: • **Initialization**—Initialization state. • **Smooth**—Upgrading data. • **Advertising**—Advertising routes. • **Redistribution**—Redistributing routes. • **Finish**—Finished.

display ripng route

Use **display ripng route** to display all RIPng routes for a RIPng process.

Syntax

display ripng *process-id* **route** [*ipv6-address prefix-length* [**verbose**] | **peer** *ipv6-address* | **statistics**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

ipv6-address prefix-length: Specifies an IPv6 address. The *ipv6-address* argument specifies an IPv6 address. The *prefix-length* argument specifies a prefix length in the range of 0 to 128.

verbose: Displays all routing information for the specified destination IPv6 address. If you do not specify this keyword, the command displays only optimal RIPng routes with the specified destination IPv6 address.

peer *ipv6-address*: Specifies a neighbor by its IPv6 address.

statistics: Displays routing information statistics, including total number of routes and the number of routes learned from each neighbor.

Examples

Display routing information for RIPng process 1.

```
<Sysname> display ripng 1 route
   Route Flags: A - Aging, S - Suppressed, G - Garbage-collect, D – Direct
                O - Optimal, F - Flush to RIB
 ------------------------------------------------------------------

 Peer FE80::20C:29FF:FED4:7171 on GigabitEthernet1/0/2
 Destination 4::4/128,
     via FE80::20C:29FF:FED4:7171, cost 1, tag 0, AOF, 5 secs
 Local route
 Destination 3::3/128,
```

```
     via ::, cost 0, tag 0, DOF
 Destination 6::/64,
     via ::, cost 0, tag 0, DOF
```

Display information about routes with the specified prefix for RIPng process 1.

```
<Sysname> display ripng 1 route 3::3 128 verbose
   Route Flags: A - Aging, S - Suppressed, G - Garbage-collect, D – Direct
                O - Optimal, F - Flush to RIB
 ----------------------------------------------------------------
 Peer FE80::4283:59FF:FE97:205 on GigabitEthernet1/0/2
 Destination 3::3/128,
     via FE80::4283:59FF:FE97:205, cost 1, tag 0, AOF, 28 secs
```

Table 7 Command output

Field	Description
A–Aging	The route is in aging state.
S–Suppressed	The route is in suppressed state.
G–Garbage-collect	The route is in Garbage-collect state.
D–Direct	The route is a direct route.
Local route	The route is a locally generated direct route.
O - Optimal	The route is an optimal route.
F - Flush to RIB	The route has been flushed to the RIB.
Peer	Neighbor connected to the interface.
Destination	IPv6 destination address.
via	Next hop IPv6 address.
cost	Routing metric value.
tag	Route tag.
secs	Time a route entry has stayed in the current state.

Display routing information statistics for RIPng process 1.

```
<Sysname> display ripng 1 route statistics
Peer                                          Optimal/Aging    Garbage
 FE80::20C:29FF:FED4:7171                      1/2              0
 Local                                         2/0              0
 total                                         3/2              0
```

Table 8 Command output

Field	Description
Peer	IPv6 address of the neighbor.
Optimal	Number of optimal routes.
Aging	Number of routes in aging state.
Garbage	Number of routes in Garbage-collection state.
Local	Total number of locally generated direct route.
total	Total number of routes learned from RIPng neighbors.

enable ipsec-profile

Use **enable ipsec-profile** to apply an IPsec profile to a RIPng process.

Use **undo enable ipsec-profile** to remove the IPsec profile from the RIPng process.

Syntax

enable ipsec-profile *profile-name*

undo enable ipsec-profile

Default

No IPsec profile is applied to a RIPng process.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Parameters

profile-name: Specifies an IPsec profile by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

To configure an IPsec profile, see IPsec in *Security Configuration Guide*.

Examples

Apply IPsec profile **profile001** to RIPng process 1.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] enable ipsec-profile profile001
```

fast-reroute

Use **fast-reroute** to configure RIPng FRR.

Use **undo fast-reroute** to disable RIPng FRR.

Syntax

fast-reroute route-policy *route-policy-name*

undo fast-reroute

Default

RIPng FRR is disabled.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Parameters

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

RIPng FRR is available only when the state of primary link (with Layer 3 interfaces in up state) changes from bidirectional to unidirectional or down.

RIPng FRR is effective only for RIPng routes that are learned from directly connected neighbors.

Equal-cost routes do not support RIPng FRR.

Examples

Enable RIPng FRR and use routing policy **frr** to specify a backup next hop.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc index 10 permit 100:: 64
[Sysname] route-policy frr permit node 10
[Sysname-route-policy-frr-10] if-match ipv6 address prefix-list abc
[Sysname-route-policy-frr-10] apply ipv6 fast-reroute backup-interface gigabitethernet
1/0/1 backup-nexthop FE80::8
[Sysname-route-policy-frr-10] quit
[Sysname] ripng 100
[Sysname-ripng-100] fast-reroute route-policy frr
```

filter-policy export

Use **filter-policy export** to configure RIPng to filter redistributed routes.

Use **undo filter-policy export** to remove the filtering.

Syntax

filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* } **export** [*protocol* [*process-id*]]

undo filter-policy export [*protocol* [*process-id*]]

Default

RIPng does not filter redistributed routes.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999 to filter redistributed routes.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a string of 1 to 63 characters, to filter redistributed routes.

protocol: Filters routes redistributed from a routing protocol.

process-id: Specifies the process ID of the specified routing protocol, in the range of 1 to 65535. This argument is available only when the routing protocol is **ripng**, **ospfv3**, or **isisv6**. The default is 1.

Usage guidelines

If the *protocol* argument is specified, RIPng filters only routes redistributed from the specified routing protocol. Otherwise, RIPng filters all redistributed routes.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL in one of the following ways:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix* command.
- To deny/permit a route with the specified destination and prefix, use the **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix* **destination** *dest dest-prefix* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the prefix of the route. For the prefix configuration to take effect, specify a contiguous prefix.

Examples

Use IPv6 prefix list to filter redistributed RIPng updates.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc index 10 permit 100:1:: 32
[Sysname] ripng 100
[Sysname-ripng-100] filter-policy prefix-list abc export
```

Configure advanced IPv6 ACL 3000 to permit only route 2001::1/128 to pass. Use advanced IPv6 ACL 3000 to filter redistributed routes.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3000
[Sysname-acl-ipv6-adv-3000] rule 10 permit ipv6 source 2001::1 128 destination
ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff 128
[Sysname-acl-ipv6-adv-3000] rule 100 deny ipv6
[Sysname-acl-ipv6-adv-3000] quit
[Sysname] ripng 100
[Sysname-ripng-100] filter-policy 3000 export
```

filter-policy import

Use **filter-policy import** to configure RIPng to filter received routes.

Use **undo filter-policy import** to restore the default.

Syntax

filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* } **import**

undo filter-policy import

Default

RIPng does not filter received routes.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999 to filter received routes.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a string of 1 to 63 characters, to filter received routes.

Usage guidelines

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL in one of the following ways:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix* command.
- To deny/permit a route with the specified destination and prefix, use the **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix* **destination** *dest dest-prefix* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the prefix of the route. For the configuration to take effect, specify a contiguous prefix.

Examples

Use the IPv6 prefix list **abc** to filter received RIPng updates.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc index 10 permit 100:1:: 32
[Sysname] ripng 100
[Sysname-ripng-100] filter-policy prefix-list abc import
```

Configure advanced IPv6 ACL 3000 to permit only route 2001::1/128 to pass. Use advanced IPv6 ACL 3000 to filter received routes.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3000
[Sysname-acl-ipv6-adv-3000] rule 10 permit ipv6 source 2001::1 128 destination
ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff 128
[Sysname-acl-ipv6-adv-3000] rule 100 deny ipv6
[Sysname-acl-ipv6-adv-3000] quit
[Sysname] ripng 100
[Sysname-ripng-100] filter-policy 3000 import
```

graceful-restart

Use **graceful-restart** to enable Graceful Restart (GR) for RIPng.

Use **undo graceful-restart** to disable RIPng GR.

Syntax

graceful-restart

undo graceful-restart

Default

RIPng GR is disabled.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Usage guidelines

RIPng GR and RIPng NSR are mutually exclusive. Do not configure the **graceful-restart** command and the **non-stop-routing** command at the same time.

Examples

Enable GR for RIPng process 1.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] graceful-restart
```

graceful-restart interval

Use **graceful-restart interval** to set the GR interval.

Use **undo graceful-restart interval** to restore the default.

Syntax

graceful-restart interval *interval*

undo graceful-restart interval

Default

The GR interval is 60 seconds.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the GR interval in the range of 5 to 360 seconds.

Examples

Set the GR interval to 200 seconds for RIPng process 1.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] graceful-restart interval 200
```

import-route

Use **import-route** to enable route redistribution.

Use **undo import-route** to disable route redistribution.

Syntax

import-route bgp4+ [*as-number*] [**allow-ibgp**] [**cost** *cost-value* | **route-policy** *route-policy-name*] *

undo import-route bgp4+

import-route { **direct** | **static** } [**cost** *cost-value* | **route-policy** *route-policy-name*] *

undo import-route { **direct** | **static** }

import-route { **isisv6** | **ospfv3** | **ripng** } [*process-id*] [**allow-direct** | **cost** *cost-value* | **route-policy** *route-policy-name*] *

undo import-route { **isisv6** | **ospfv3** | **ripng** } [*process-id*]

Default

RIPng does not redistribute routes.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Parameters

bgp4+: Redistributes BGP4+ routes.

direct: Redistributes direct routes.

isisv6: Redistributes IPv6 IS-IS routes.

ospfv3: Redistributes OSPFv3 routes.

ripng: Redistributes RIPng routes.

static: Redistributes static routes.

as-number: Specifies an AS by its number in the range of 1 to 4294967295. If you do not specify the *as-number* argument, this command redistributes all IPv6 EBGP routes. As a best practice, specify the AS number to avoid redistributing excessive IPv6 EBGP routes.

process-id: Specifies an OSPFv3, IPv6 IS-IS, or RIPng process by its ID in the range of 1 to 65535. The default is 1.

allow-ibgp: Allows redistribution of IBGP routes. The **import-route bgp4+** command redistributes only EBGP routes. The **import-route bgp4+ allow-ibgp** command additionally redistributes IBGP routes and might cause routing loops. Therefore, use it with caution.

allow-direct: Redistributes the networks of the local interfaces enabled with the specified routing protocol. If you do not specify this keyword, the networks of the local interfaces are not redistributed. If you specify both the **allow-direct** keyword and the **route-policy** *route-policy-name* option, make sure the **if-match** rule defined in the routing policy does not conflict with the **allow-direct** keyword. For example, if you specify the **allow-direct** keyword, do not configure the **if-match route-type** rule for the routing policy. Otherwise, the **allow-direct** keyword does not take effect.

cost *cost-value*: Specifies a metric for redistributed routes, in the range of 0 to 16. The default metric is 0.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

This command redistributes only active routes. To view route state information, use the **display ipv6 routing-table protocol** command.

Examples

Redistribute routes from IPv6 IS-IS process 7 into RIPng and set the metric for redistributed routes to 7.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100] import-route isisv6 7 cost 7
```

maximum load-balancing

Use **maximum load-balancing** to set the maximum number of equal-cost multi-path (ECMP) routes for load balancing.

Use **undo maximum load-balancing** to restore the default.

Syntax

maximum load-balancing *number*

undo maximum load-balancing

Default

The maximum number of RIPng ECMP routes equals the maximum number of ECMP routes, which is configurable by using the **max-ecmp-num** command.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the maximum number of ECMP routes. When this argument takes a value of 1, RIPng does not perform load balancing.

The following compatibility matrixes show the value ranges for the maximum number of RIPng ECMP routes:

Models	Value range
NFNX5-HD6480	1 to 16
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	1 to 32

Usage guidelines

You can set a smaller value for the **max-ecmp-num** command than the current value for the **maximum load-balancing** command. After a reboot, the value for the **maximum load-balancing** command automatically changes to be the same as the value for the **max-ecmp-num** command.

Examples

Set the maximum number of ECMP routes to 2.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100] maximum load-balancing 2
```

Related commands

max-ecmp-num

non-stop-routing

Use **non-stop-routing** to enable RIPng NSR.

Use **undo non-stop-routing** to disable RIPng NSR.

Syntax

non-stop-routing

undo non-stop-routing

Default

RIPng NSR is disabled.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Usage guidelines

RIPng NSR enabled for a RIPng process takes effect only on that process. If multiple RIPng processes exist, enable RIPng NSR for each process as a best practice.

RIPng NSR and RIPng GR are mutually exclusive. Do not configure the **non-stop-routing** command and the **graceful-restart** command at the same time.

Examples

Enable NSR for RIPng process 1.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] non-stop-routing
```

output-delay

Use **output-delay** to set the RIPng packet sending interval and the maximum number of RIPng packets that can be sent at each interval.

Use **undo output-delay** to restore the default.

Syntax

output-delay *time* **count** *count*

undo output-delay

Default

A RIPng process sends a maximum of three RIPng packets every 20 milliseconds.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the RIPng packet sending interval in the range of 10 to 100 milliseconds.

count: Specifies the maximum number of RIPng packets sent by a RIPng process at each interval, in the range of 1 to 30.

Usage guidelines

If you configure the RIPng packet sending rate for both a RIPng process and an interface running the RIPng process, the configuration on the interface takes effect.

Examples

Configure RIPng process 1 to send a maximum of 10 RIPng packets every 60 milliseconds.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] output-delay 60 count 10
```

Related commands

ripng output-delay

preference

Use **preference** to set the preference for RIPng routes.

Use **undo preference** to restore the default.

Syntax

preference { *preference* | **route-policy** *route-policy-name* } *

undo preference

Default

The preference of RIPng routes is 100.

Views

RIPng view

Predefined user roles

network-admin

context-admin

Parameters

preference: Specifies the preference for RIPng routes, in the range of 1 to 255. The smaller the value, the higher the preference.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

You can specify a routing policy to set a preference for the matching RIPng routes.

- The preference set by the routing policy applies to all matching RIPng routes. The preference of other routes is set by the **preference** command.

- If no preference is set by the routing policy, the preference of all RIPng routes is set by the **preference** command.

Examples

Set the preference for RIPng routes to 120.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100] preference 120
```

reset ripng process

Use **reset ripng process** to restart a RIPng process.

Syntax

reset ripng *process-id* **process**

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

Usage guidelines

After executing the command, you are prompted to confirm the operation.

Examples

Restart RIPng process 100.

```
<Sysname> reset ripng 100 process
Reset RIPng process? [Y/N]:y
```

reset ripng statistics

Use **reset ripng statistics** to clear statistics for a RIPng process.

Syntax

reset ripng *process-id* **statistics**

Views

User view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

Examples

Clear statistics for RIPng process 100.

```
<Sysname> reset ripng 100 statistics
```

ripng

Use **ripng** to enable RIPng and enter RIPng view.

Use **undo ripng** to disable RIPng.

Syntax

ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

undo ripng [*process-id*]

Default

RIPng is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535. The default value is 1.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, the RIPng process runs on the public network.

Usage guidelines

Before you configure global RIPng parameters, you must create a RIPng process. This restriction does not apply to configuring interface RIPng parameters.

If you disable a RIPng process, the configured RIPng parameters become invalid.

Examples

Create RIPng process 100 and enter its view.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100]
```

ripng default-route

Use **ripng default-route** to configure a RIPng interface to advertise a default route with a specified metric.

Use **undo ripng default-route** to disable a RIPng interface from sending a default route.

Syntax

ripng default-route { **only** | **originate** } [**cost** *cost-value* | **route-policy** *route-policy-name*] *

undo ripng default-route

Default

A RIPng process does not advertise a default route.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

only: Advertises only an IPv6 default route (::/0).

originate: Advertises an IPv6 default route (::/0) and other routes.

cost-value: Specifies a cost for the default route, in the range of 1 to 15. The default is 1.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. The command advertises a default route only when a route in the routing table matches the routing policy.

Usage guidelines

This command enables the interface to advertise a RIPng default route in a route update regardless of whether the default route exists in the local IPv6 routing table.

A RIPng interface configured to advertise a default route does not receive any default routes from its neighbors.

Examples

Configure RIPng on GigabitEthernet 1/0/1 to advertise only a default route.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ripng default-route only
```

Configure RIPng on GigabitEthernet 1/0/1 to advertise a default route and other routes.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ripng default-route originate
```

ripng enable

Use **ripng enable** to enable RIPng on an interface.

Use **undo ripng enable** to disable RIPng on an interface.

Syntax

ripng *process-id* **enable**

undo ripng enable

Default

RIPng is disabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

Examples

Enable RIPng 100 on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ripng 100 enable
```

ripng ipsec-profile

Use **ripng ipsec-profile** to apply an IPsec profile to a RIPng interface.

Use **undo ripng ipsec-profile** to remove the IPsec profile from the RIPng interface.

Syntax

ripng ipsec-profile *profile-name*

undo ripng ipsec-profile

Default

No IPsec profile is applied to a RIPng interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

profile-name: Specifies an IPsec profile by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

To configure an IPsec profile, see IPsec in *Security Configuration Guide*.

Examples

Apply IPsec profile **profile001** to GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ripng ipsec-profile profile001
```

ripng metricin

Use **ripng metricin** to configure an interface to add a metric to inbound RIPng routes.

Use **undo ripng metricin** to restore the default.

Syntax

ripng metricin *value*

undo ripng metricin

Default

The additional metric of an inbound route is 0.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

value: Adds an additional metric to inbound routes, in the range of 0 to 16.

Examples

Configure GigabitEthernet 1/0/1 to add a metric of 12 to inbound RIPng routes.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ripng metricin 12
```

ripng metricout

Use **ripng metricout** to configure an interface to add a metric to outbound RIPng routes.

Use **undo ripng metricout** to restore the default.

Syntax

ripng metricout *value*

undo ripng metricout

Default

The additional metric of outbound routes is 1.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

value: Adds an additional metric to outbound routes, in the range of 1 to 16.

Examples

Configure RIPng on GigabitEthernet 1/0/1 to add a metric of 12 to outbound RIPng routes.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ripng metricout 12
```

ripng output-delay

Use **ripng output-delay** to set the RIPng packet sending interval and the maximum number of RIPng packets that can be sent by an interface at each interval.

Use **undo ripng output-delay** to restore the default.

Syntax

ripng output-delay *time* **count** *count*

undo ripng output-delay

Default

An interface uses the RIPng packet sending rate set for the RIPng process that the interface runs.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the RIPng packet sending interval in the range of 10 to 100 milliseconds.

count: Specifies the maximum number of RIPng packets sent at each interval, in the range of 1 to 30.

Usage guidelines

If you set the RIPng packet sending rate for both a RIPng process and an interface running the RIPng process, the configuration on the interface takes effect.

Examples

Configure GigabitEthernet 1/0/1 to send a maximum of six RIPng packets every 30 milliseconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ripng output-delay 30 count 6
```

Related commands

output-delay

ripng poison-reverse

Use **ripng poison-reverse** to enable poison reverse.

Use **undo ripng poison-reverse** to disable poison reverse.

Syntax

ripng poison-reverse

undo ripng poison-reverse

Default

Poison reverse is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Examples

Enable poison reverse for RIPng update messages on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ripng poison-reverse
```

ripng primary-path-detect bfd echo

Use **ripng primary-path-detect bfd echo** to enable BFD single-hop echo detection for RIPng FRR.

Use **undo ripng primary-path-detect bfd** to disable BFD single-hop echo detection for RIPng FRR.

Syntax

ripng primary-path-detect bfd echo

undo ripng primary-path-detect bfd

Default

BFD single-hop echo detection is disabled for RIPng FRR.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

For quicker RIPng FRR, use BFD single-hop echo detection on the primary link of redundant links to detect link failure.

For correct operation of BFD, make sure the interface is configured with an IPv6 global unicast address before you execute this command. For more information about IPv6 global unicast addresses, see IPv6 basics configuration in *Layer 3—IP Services Configuration Guide*.

Examples

Enable BFD single-hop echo detection for RIPng FRR on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] fast-reroute route-policy frr
[Sysname-ripng-1] quit
[Sysname] bfd echo-source-ipv6 1::1
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ripng primary-path-detect bfd echo
```

ripng split-horizon

Use **ripng split-horizon** to enable split horizon.

Use **undo ripng split-horizon** to disable split horizon.

Syntax

ripng split-horizon

undo ripng split-horizon

Default

Split horizon is enabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

Split horizon prevents routing loops. If you want to disable this feature, make sure the operation is indispensable.

If both poison reverse and split horizon are enabled, only poison reverse takes effect.

Examples

Enable split horizon on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ripng split-horizon
```

ripng summary-address

Use **ripng summary-address** to configure a summary network to be advertised through an interface.

Use **undo ripng summary-address** to remove a summary network.

Syntax

ripng summary-address *ipv6-address prefix-length*

undo ripng summary-address *ipv6-address prefix-length*

Default

No summary network is configured to be advertised through an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies the destination IPv6 address of the summary route.

prefix-length: Specifies the prefix length of the destination IPv6 address of the summary route, in the range of 0 to 128. It indicates the number of consecutive 1s of the prefix, which defines the network ID.

Usage guidelines

Networks on the summary network will not be advertised. The cost of the summary route is the lowest cost among summarized routes.

Examples

Assign an IPv6 address with the 64-bit prefix to GigabitEthernet 1/0/1 and configure a summary with the 35-bit prefix.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 address 2001:200::3EFF:FE11:6770/64
[Sysname-GigabitEthernet1/0/1] ripng summary-address 2001:200:: 35
```

timer triggered

Use **timer triggered** to set the interval for sending triggered updates.

Use **undo timer triggered** to restore the default.

Syntax

timer triggered *maximum-interval* [*minimum-interval* [*incremental-interval*]]

undo timer triggered

Default

The maximum, minimum, and incremental intervals for sending triggered updates are 5 seconds, 50 milliseconds, and 200 milliseconds, respectively.

Views

RIPng view

Predefines user roles

network-admin

context-admin

Parameters

maximum-interval: Specifies the maximum interval for sending triggered updates, in the range of 1 to 5 seconds.

minimum-interval: Specifies the minimum interval for sending triggered updates, in the range of 10 to 5000 milliseconds.

incremental-interval: Specifies the incremental interval for sending triggered updates, in the range of 100 to 1000 milliseconds.

Usage guidelines

The minimum interval and the incremental interval cannot be greater than the maximum interval.

For a stable network, the minimum interval is used. If network changes become frequent, the incremental interval *incremental-interval* is used to increase the triggered update sending interval until the *maximum-interval* is reached.

Examples

Set the maximum, minimum, and incremental intervals for sending triggered updates to 2 seconds, 100 milliseconds, and 100 milliseconds, respectively.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100] timer triggered 2 100 100
```

timers

Use **timers** to set RIPng timers.

Use **undo timers** to restore the default.

Syntax

timers { **garbage-collect** *garbage-collect-value* | **suppress** *suppress-value* | **timeout** *timeout-value* | **update** *update-value* } *

undo timers { **garbage-collect** | **suppress** | **timeout** | **update** } *

Default

The garbage-collect timer is 120 seconds, the suppress timer is 120 seconds, the timeout timer is 180 seconds, and the update timer is 30 seconds.

Views

RIPng view

Predefines user roles

network-admin

context-admin

Parameters

garbage-collect-value: Sets the garbage-collect timer in the range of 1 to 86400 seconds.

suppress-value: Sets the suppress timer in the range of 0 to 86400 seconds.

timeout-value: Sets the timeout timer in the range of 1 to 86400 seconds.

update-value: Sets the update timer in the range of 1 to 86400 seconds.

Usage guidelines

RIPng has the following timers:

- **Update timer**—Interval between update messages.
- **Timeout timer**—Route aging time. If no update for a route is received before the timer expires, RIPng sets the metric of the route to 16.
- **Suppress timer**—How long a RIPng route stays in suppressed state. When the metric of a route becomes 16, the route enters the suppressed state. If RIPng receives an update for the route from the same neighbor and the route in the update has a metric less than 16, RIPng uses the route to replace the suppressed route.
- **Garbage-collect timer**—Interval from when the metric of a route becomes 16 to when it is deleted from the routing table. During the garbage-collect timer length, RIPng advertises the route with a metric of 16. If no update is announced for that route before the garbage-collect timer expires, RIPng deletes the route from the routing table.

As a best practice, do not change the default values of these timers.

The timer lengths must be kept consistent on all routers in the network.

Examples

Set the update, timeout, suppress, and garbage-collect timers to 5 seconds, 15 seconds, 15 seconds, and 30 seconds.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] timers update 5 timeout 15 suppress 15 garbage-collect 30
```

Contents

OSPF commands

abr-summary

Use **abr-summary** to configure route summarization on an ABR.

Use **undo abr-summary** to remove the configuration.

Syntax

abr-summary *ip-address* { *mask-length* | *mask* } [**advertise** | **not-advertise**] [**cost** *cost-value*]

undo abr-summary *ip-address* { *mask-length* | *mask* }

Default

Route summarization is not configured on an ABR.

Views

OSPF area view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the destination IP address of the summary route in dotted decimal notation.

mask-length: Specifies the mask length in the range of 0 to 32.

mask: Specifies the mask of the IP address, in dotted decimal notation.

advertise | **not-advertise**: Advertises the summary route or not. By default, the command advertises the summary route.

cost *cost-value*: Specifies the cost of the summary route, in the range of 1 to 16777215. The default cost is the largest cost value among routes that are summarized.

Usage guidelines

This command applies only to an ABR to summarize multiple contiguous networks into one network.

To enable ABR to advertise specific routes that have been summarized, use the **undo abr-summary** command.

Examples

Summarize networks 36.42.10.0/24 and 36.42.110.0/24 in Area 1 into 36.42.0.0/16.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 1
[Sysname-ospf-100-area-0.0.0.1] network 36.42.10.0 0.0.0.255
[Sysname-ospf-100-area-0.0.0.1] network 36.42.110.0 0.0.0.255
[Sysname-ospf-100-area-0.0.0.1] abr-summary 36.42.0.0 255.255.0.0
```

area

Use **area** to create an OSPF area and enter OSPF area view.

Use **undo area** to remove an OSPF area.

Syntax

area *area-id*

undo area *area-id*

Default

No OSPF areas exist.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

area-id: Specifies an area by its ID, an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format.

Examples

Create Area 0 and enter Area 0 view.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 0
[Sysname-ospf-100-area-0.0.0.0]
```

asbr-summary

Use **asbr-summary** to configure route summarization on an ASBR.

Use **undo asbr-summary** to remove the configuration.

Syntax

asbr-summary *ip-address* { *mask-length* | *mask* } [**cost** *cost-value* | **not-advertise** | **nssa-only** | **tag** *tag*] *

undo asbr-summary *ip-address* { *mask-length* | *mask* }

Default

Route summarization is not configured on an ASBR.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the destination IP address of the summary route.

mask-length: Specifies the mask length in the range of 0 to 32.

mask: Specifies the mask in dotted decimal notation.

cost *cost-value*: Specifies the cost of the summary route, in the range of 1 to 16777214. If you do not specify this option, the largest cost among the summarized routes applies. If the routes in Type-5 LSAs translated from Type-7 LSAs are Type-2 external routes, the largest cost among the summarized routes plus 1 applies.

not-advertise: Disables advertising the summary route. If you do not specify this keyword, the command advertises the route.

nssa-only: Limits the route advertisement to the NSSA area by setting the P-bit of Type-7 LSAs to 0. By default, the P-bit of Type-7 LSAs is set to 1. If the ASBR is also an ABR and **FULL** state neighbors exist in the backbone area, the P-bit of Type-7 LSAs originated by the ASBR is set to 0. This keyword applies to the NSSA ASBR.

tag *tag*: Specifies a tag for the summary route, in the range of 0 to 4294967295. The default is 1. The tag can be used by a routing policy to control summary route advertisement.

Usage guidelines

An ASBR can summarize routes in the following LSAs:

- Type-5 LSAs.
- Type-7 LSAs in an NSSA area.
- Type-5 LSAs translated by the ASBR (also an ABR) from Type-7 LSAs in an NSSA area.

  If the ASBR (ABR) is not a translator, it cannot summarize routes in Type-5 LSAs translated from Type-7 LSAs.

To enable ASBR to advertise specific routes that have been summarized, use the **undo asbr-summary** command.

Examples

Summarize redistributed static routes into a single route, and specify a tag value of 2 and a cost of 100 for the summary route.

```
<Sysname> system-view
[Sysname] ip route-static 10.2.1.0 24 null 0
[Sysname] ip route-static 10.2.2.0 24 null 0
[Sysname] ospf 100
[Sysname-ospf-100] import-route static
[Sysname-ospf-100] asbr-summary 10.2.0.0 255.255.0.0 tag 2 cost 100
```

authentication-mode

Use **authentication-mode** to specify an authentication mode for an OSPF area.

Use **undo authentication-mode** to remove the configuration.

Syntax

For MD5/HMAC-MD5/HMAC-SHA-256 authentication:

authentication-mode { **hmac-md5** | **hmac-sha-256** | **md5** } *key-id* { **cipher** | **plain** } *string*

undo authentication-mode [{ **hmac-md5** | **hmac-sha-256** | **md5** } *key-id*]

For simple authentication:

authentication-mode simple { **cipher** | **plain** } *string*

undo authentication-mode

For keychain authentication:

authentication-mode keychain *keychain-name*

undo authentication-mode

Default

No authentication is performed for an area.

Views

OSPF area view

Predefined user roles

network-admin

context-admin

Parameters

hmac-md5: Specifies the HMAC-MD5 authentication mode.

hmac-sha-256: Specifies the HMAC-SHA-256 authentication mode.

md5: Specifies the MD5 authentication mode.

simple: Specifies the simple authentication mode.

key-id: Specifies a key by its ID in the range of 0 to 255.

cipher: Specifies a key in encrypted form.

plain: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive.

- In simple authentication mode, the plaintext form of the key is a string of 1 to 8 characters. The encrypted form of the key is a string of 33 to 41 characters.
- In MD5/HMAC-MD5/HMAC-SHA-256 authentication mode, the plaintext form of the key is a string of 1 to 255 characters. The encrypted form of the key is a string of 33 to 373 characters.

keychain: Specifies the keychain authentication mode.

keychain-name: Specifies a keychain by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

To establish or maintain adjacencies, routers in the same area must have the same authentication mode and key.

If MD5, HMAC-MD5, or HMAC-SHA-256 authentication is configured, you can configure multiple keys, each having a unique key ID and key string. As a best practice to minimize the risk of key compromise, use only one key for an area and delete the old key after key replacement.

To replace the key used for MD5, HMAC-MD5, or HMAC-SHA-256 authentication in an area, you must configure the new key before removing the old key from each router. OSPF uses the key rollover mechanism to ensure that the routers can pass authentication before the replacement is complete across the area. After you configure a new key on a router, the router sends copies of the same packet, each authenticated by a different key, including the new key and the keys in use. This practice continues until the router detects that all its neighbors have the new key.

When keychain authentication is configured for an OSPF area, OSPF performs the following operations before sending a packet:

1. Obtains a valid send key from the keychain.

   OSPF does not send the packet if it fails to obtain a valid send key.
2. Uses the key ID, authentication algorithm, and key string to authenticate the packet.

   If the key ID is greater than 255, OSPF does not send the packet.

When keychain authentication is configured for an OSPF area, OSPF performs the following operations after receiving a packet:

1. Uses the key ID carried in the packet to obtain a valid accept key from the keychain.

   OSPF discards the packet if it fails to obtain a valid accept key.

2. Uses the authentication algorithm and key string for the valid accept key to authenticate the packet.

   If the authentication fails, OSPF discards the packet.

OSPF supports only the MD5, HMAC-SM3, HMAC-MD5, and HMAC-SHA-256 authentication algorithms for keychain authentication.

The ID of keys used for keychain authentication can only be in the range of 0 to 255.

Examples

Configure OSPF Area 0 to use the MD5 authentication mode, and set the key ID to 15 and the key to **abc** in plaintext form.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 0
[Sysname-ospf-100-area-0.0.0.0] authentication-mode md5 15 plain abc
```

Related commands

ospf authentication-mode

bandwidth-reference

Use **bandwidth-reference** to set a reference bandwidth value for link cost calculation.

Use **undo bandwidth-reference** to restore the default value.

Syntax

bandwidth-reference *value*

undo bandwidth-reference

Default

The reference bandwidth value is 100 Mbps for link cost calculation.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies the reference bandwidth value for link cost calculation, in the range of 1 to 4294967 Mbps.

Usage guidelines

If no cost values are configured for links, OSPF calculates their cost values by using the following formula: Cost = Reference bandwidth value / Expected interface bandwidth. The expected bandwidth of an interface is configured with the **bandwidth** command (see *Interface Command Reference*). If the calculated cost is greater than 65535, the value of 65535 is used. If the calculated cost is less than 1, the value of 1 is used.

Examples

Set the reference bandwidth value to 1000 Mbps.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] bandwidth-reference 1000
```

Related commands

ospf cost

database-filter peer

Use **database-filter peer** to filter LSAs for the specified P2MP neighbor.

Use **undo database-filter peer** to restore the default.

Syntax

database-filter peer *ip-address* { **all** | { **ase** [**acl** *ipv4-acl-number*] | **nssa** [**acl** *ipv4-acl-number*] | **summary** [**acl** *ipv4-acl-number*] } * }

undo database-filter peer *ip-address*

Default

The LSAs for the specified P2MP neighbor are not filtered.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies a P2MP neighbor by its IP address.

all: Filters all LSAs except the Grace LSAs.

ase: Filters Type-5 LSAs.

nssa: Filters Type-7 LSAs.

summary: Filters Type-3 LSAs.

acl *ipv4-acl-number*: Specifies an IPv4 ACL by its number in the range of 2000 to 3999.

Usage guidelines

On an P2MP network, a router might have multiple OSPF neighbors with the P2MP type. Use this command to prevent the router from sending LSAs to the specified neighbor.

When you specify an ACL, follow these guidelines:

- If the ACL does not exist or has no rules, OSPF does not filter the LSAs sent to the specified neighbor.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all of the LSAs sent to the specified neighbor.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following methods:

- To deny/permit LSAs with the specified link state ID, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.

- To deny/permit LSAs with the specified link state ID and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the link state ID of an LSA and the **destination** keyword specifies the subnet mask of the LSA. For the mask configuration to take effect, specify a contiguous subnet mask.

If the specified neighbor has already received an LSA, the LSA still exists in the LSDB of the neighbor after you execute the command.

Examples

Filter all LSAs (except the Grace LSAs) for the P2MP neighbor with the IP address 121.20.20.121.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] database-filter peer 121.20.20.121 all
```

Configure advanced ACL 3000 to filter Type-3 LSAs for the P2MP neighbor with the IP address 121.20.20.121.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000]rule 10 deny ip source 121.20.0.0 0 destination 255.255.0.0
0
[Sysname-acl-ipv4-adv-3000] rule 100 permit ip
[Sysname-acl-ipv4-adv-3000] quit
[Sysname] ospf 1
[Sysname-ospf-1] database-filter peer 121.20.20.121 summary acl 3000
```

Related commands

ospf database-filter

default

Use **default** to configure default parameters for redistributed routes.

Use **undo default** to remove the configuration.

Syntax

default { **cost** *cost-value* | **tag** *tag* | **type** *type* } *

undo default { **cost** | **tag** | **type** } *

Default

The cost is 1, the tag is 1, and the route type is 2.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

cost *cost-value*: Specifies a default cost for redistributed routes, in the range of 0 to 16777214.

tag *tag*: Specifies a tag for redistributed routes, in the range of 0 to 4294967295.

type *type*: Specifies a type for redistributed routes: 1 or 2.

Examples

Set the default cost, tag, and type to 10, 100, and 2 for redistributed external routes.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] default cost 10 tag 100 type 2
```

Related commands

import-route

default-cost

Use **default-cost** to set a cost for the default route advertised to the stub or NSSA area.

Use **undo default-cost** to restore the default value.

Syntax

default-cost *cost-value*

undo default-cost

Default

The cost is 1.

Views

OSPF area view

Predefined user roles

network-admin

context-admin

Parameters

cost-value: Specifies a cost for the default route advertised to the Stub or NSSA area, in the range of 0 to 16777214.

Usage guidelines

This command takes effect only on the ABR of a stub area or the ABR or ASBR of an NSSA area.

Examples

Configure Area 1 as a stub area, and set the cost of the default route advertised to the stub area to 20.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 1
[Sysname-ospf-100-area-0.0.0.1] stub
[Sysname-ospf-100-area-0.0.0.1] default-cost 20
```

Related commands

nssa

stub

default-route-advertise

Use **default-route-advertise** to redistribute a default route into the OSPF routing domain.

Use **undo default-route-advertise** to restore the default.

Syntax

default-route-advertise [[**always** | **permit-calculate-other**] | **cost** *cost-value* | **route-policy** *route-policy-name* | **type** *type*] *

default-route-advertise [**summary cost** *cost-value*]

undo default-route-advertise

Default

No default route is redistributed into the OSPF routing domain.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

always: Redistributes a default route in a Type-5 LSA into the OSPF routing domain regardless of whether a default route exists in the routing table. If you do not specify this keyword, the router redistributes a default route only when an active default route that does not belong to the current OSPF process exists in the IP routing table.

permit-calculate-other: Enables OSPF to calculate default routes received from other routers. If you do not specify this keyword, OSPF does not calculate default routes from other routers. If the router does not redistribute any default route in a Type-5 LSA into the OSPF routing domain, the router calculates default routes from other routers. It calculates these routes regardless of whether this keyword is specified.

cost *cost-value*: Specifies a cost for the default route, in the range of 0 to 16777214. If you do not specify this option, the default cost specified by the **default-cost** command applies.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. When the routing policy is matched and one of the following conditions is met, the command redistributes a default route in a Type-5 LSA into the OSPF routing domain:

- A default route exists in the routing table.
- The **always** keyword is specified.

The routing policy modifies values in the Type-5 LSA.

type *type*: Specifies a type for the Type-5 LSA: 1 or 2. If you do not specify this option, the default type for the Type-5 LSA specified by the **default type** command applies.

summary: Advertises the specified default route in a Type-3 LSA. This keyword is available only for VPNs.

Usage guidelines

This command redistributes a default route in a Type-5 LSA, which cannot be redistributed with the **import-route** command. If the local routing table has no default route, you must specify the **always** keyword for the command.

The **default-route-advertise summary cost** command is applicable only to VPNs. It enables a PE router to redistribute a default external route in a Type-3 LSA to CE routers.

Examples

Redistribute a default route into the OSPF routing domain, regardless of whether the default route exists in the local routing table.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] default-route-advertise always
```

Related commands

default

import-route

description

Use **description** to configure a description for an OSPF process or area.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

No description is configured for an OSPF process or area.

Views

OSPF view

OSPF area view

Predefined user roles

network-admin

context-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 80 characters.

Usage guidelines

The description specified by this command is used to identify an OSPF process or area.

Examples

Describe OSPF process 100 as **abc**.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] description abc
```

Describe OSPF Area 0 as **bone area**.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 0
[Sysname-ospf-100-area-0.0.0.0] description bone area
```

discard-route

Use **discard-route** to configure discard routes for summary networks.

Use **undo discard-route** to restore the default.

Syntax

discard-route { **external** { *preference* | **suppression** } | **internal** { *preference* | **suppression** } } *

undo discard-route [**external** | **internal**] *

Default

A device generates discard routes with preference 255 for summary networks.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

external: Specifies discard routes for redistributed summary networks on the ASBR. These discard routes are external discard routes.

preference: Specifies a preference for external discard routes, in the range of 1 to 255.

suppression: Disables the ASBR from generating external discard routes for summary networks.

internal: Specifies discard routes for summary networks on the ABR. These discard routes are internal discard routes.

preference: Specifies a preference for internal discard routes, in the range of 1 to 255.

suppression: Disables the ABR from generating internal discard routes for summary networks.

Examples

Generate external and internal discard routes with preference 100 and 200, respectively.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] discard-route external 100 internal 200
```

display ospf

Use **display ospf** to display OSPF process information.

Syntax

display ospf [*process-id*] [**verbose**]

Views

Any view

Table 1 Command output

Field	Description
OSPF Process 1 with Router ID 192.168.1.2	OSPF process ID and OSPF router ID.
RouterID	Router ID.
Router type	Router type: • ABR. • ASBR. • NSSA. • Null.
Route tag	Tag of redistributed routes.
Multi-VPN-Instance is not enabled	The OSPF process does not support multi-VPN-instance.
Ext-community type	OSPF extended community attribute type codes: • **Domain ID**—Domain ID code.

	• **Route Type**—Route type code. • **Router ID**—Router ID code.
Domain ID	OSPF domain ID (primary ID).
Opaque capable	Opaque LSA advertisement and reception capability is enabled.
Originating router-LSAs with maximum metric	The maximum cost value for router LSAs (excluding stub links) is used.
Condition	Status of the stub router: • Always. • On startup while BGP is converging. • On startup while BGP is converging for *xxx* seconds, where *xxx* is specified by the user. • On startup for *xxx* seconds, where *xxx* is specified by the user.
State	Whether the stub router is active.
Originating LSAs with metric *xxx* controlled by RBM	The device is the backup device in Remote Backup Management (RBM). • **Originating LSAs with metric +*n* controlled by RBM**—When OSPF generates an LSA, the cost is the sum of the original cost and *n.* • **Originating LSAs with metric *n* controlled by RBM**—When OSPF generates an LSA, the cost is *n.* This field is displayed only when RBM has adjusted the OSPF cost.
ECMP group is enabled	ECMP route grouping is enabled. This field is displayed only when ECMP route grouping is enabled.
SPF-schedule-interval	Interval for SPF calculations. If the SPF calculation interval is fixed, this field also displays **in milliseconds** enclosed with brackets.
LSA generation interval	LSA generation interval.
LSA arrival interval	LSA arrival interval.
Transmit pacing	LSU packet transmit rate of the interface: • **Interval**—LSU transmit interval of the interface. • **Count**—Maximum number of LSU packets sent at each interval.
Default ASE parameters	Default ASE parameters: **Metric**, **Tag**, and **Type**.
Route preference	Internal route preference.
ASE route preference	External route preference.
SPF computation count	SPF computation count of the OSPF process.
RFC1583 compatible	Compatible with RFC 1583.
Fast-reroute	FRR type: **LFA**—LFA is enabled.
Node-Protecing Preference	Preference for node protection policy.
Lowest-cost Preference	Preference for lowest-cost policy.
Graceful restart interval	GR interval.
SNMP trap rate limit interval	SNMP notification sending interval.

Count	Number of sent SNMP notifications.
ExChange/Loading neighbors	Neighbors in ExChange/Loading state.
Full neighbors	Neighbors in Full state.
Calculation trigger type	Route calculation trigger type: • **Full**—Calculation of all routes is triggered. • **Area topology change**—Topology change in an area. • **Intra router change**—Incremental intra-area route change. • **ASBR change**—Incremental ASBR route change. • **7to5 translator**—Type-7-to-Type-5 LSA translator role change. • **Full IP prefix**—Calculation of all IP prefixes is triggered. • **Full intra AS**—Calculation of all intra-AS prefixes is triggered. • **Inc intra AS**—Calculation of incremental intra-AS prefixes is triggered. • **Full inter AS**—Calculation of all AS-external prefixes is triggered. • **Inc inter AS**—Calculation of incremental AS-external prefixes is triggered. • **N/A**—Route calculation is not triggered.
Current calculation type	Current route calculation type: • SPF calculation. • **Intra router calculation**—Intra-area route calculation. • **ASBR calculation**—Inter-area ASBR route calculation. • **Inc intra router**—Incremental intra-area route calculation. • **Inc ASBR calculation**—Incremental inter-area ASBR route calculation. • **7to5 translator**—Type-7-to-Type-5 LSA calculation. • **Full intra AS**—Calculation of all intra-AS prefixes. • **Inc intra AS**—Calculation of incremental intra-AS prefixes. • **Full inter AS**—Calculation of all AS-external prefixes. • **Inc inter AS**—Calculation of incremental AS-external prefixes. • **Forward address**—Forwarding address calculation. • **N/A**—Route calculation is not triggered.
Current calculation phase	Current route calculation phase: • **Calculation area topology**—Calculating area topology. • **Calculation router**—Calculating routes on routers. • **Calculation intra AS**—Calculating intra-AS routes. • **7to5 translator**—Calculating Type-7-to-Type-5 LSAs. • **Forward address**—Calculating forwarding addresses. • **Calculation inter AS**—Calculating AS-external routes. • **Calculation end**—Ending phase of calculation. • **N/A**—Route calculation is not triggered.
Process reset state	Process reset state: • **N/A**—The process is not reset. • **Under reset**—The process is in the reset progress. • **Under RIB smooth**—The process is synchronizing the RIB.

Current reset type	Current process reset type: • **N/A**—The process is not reset. • **Normal**—Normal reset. • **GR quit**—Normal reset when GR quits abnormally. • **Delete**—Delete OSPF process. • **VPN delete**—Delete VPN.
Next reset type	Next process reset type: • **N/A**—The process is not reset. • **Normal**—Normal reset. • **GR quit**—Normal reset when GR quits abnormally. • **Delete**—Delete OSPF process. • **VPN delete**—Delete VPN.
Reset prepare message replied	Modules that reply reset prepare messages: • **P**—Neighbor maintenance module. • **L**—LSDB synchronization module. • **C**—Route calculation module. • **R**—Route redistribution module.
Reset process message replied	Modules that reply reset process messages: • **P**—Neighbor maintenance module. • **L**—LSDB synchronization module. • **C**—Route calculation module. • **R**—Route redistribution module.

Reset phase of module	Reset phase of each module:
	• Main control module:
	  ○ **N/A**—Not reset.
	  ○ Delete area.
	  ○ Delete process.
	• Neighbor maintenance (P) module:
	  ○ **N/A**—Not reset.
	  ○ Delete neighbor.
	  ○ Delete interface.
	  ○ **Delete vlink**—Delete virtual link.
	• LSDB synchronization (L) module:
	  ○ **N/A**—Not reset.
	  ○ Stop timer.
	  ○ **Delete ASE**—Delete all ASE LSAs.
	  ○ **Delete ASE maps**—Delete ASE LSA maps.
	  ○ Clear process data.
	  ○ **Delete area LSA**—Delete LSAs and maps from an area.
	  ○ **Delete area interface**—Delete interfaces from an area.
	  ○ **Delete process**—Delete process-related resources.
	  ○ **Restart**—Restart process-related resources.
	• Route calculation (C) module:
	  ○ **N/A**—Not reset.
	  ○ **Delete topology**—Delete area topology.
	  ○ **Delete router**—Delete routes of routers.
	  ○ **Delete intra AS**—Delete intra-AS routes
	  ○ **Delete inter AS**—Delete AS-external routes.
	  ○ **Delete forward address**—Delete forwarding address list.

	○ **Delete advertise**—Delete advertising router list. • Route redistribution (R) module: ○ **N/A**—Not reset. ○ **Delete ABR summary**—Delete summary routes of the ABR. ○ **Delete ASBR summary**—Delete summary routes of the ASBR. ○ **Delete import**—Delete redistributed routes.
Area	Area ID in the IP address format.
Authentication type	Authentication type of the area: • **None**—No authentication. • **Simple**—Simple authentication. • **Cryptographic**—Encrypted authentication. Options include MD5, HMAC-MD5, and HMAC-SHA-256. • **Keychain**—Keychain authentication.
Area flag	Type of the area: • Normal. • Stub. • StubNoSummary (totally stub area). • NSSA. • NSSANoSummary (totally NSSA area).
7/5 translator state	State of the translator that translates Type-7 LSAs to Type-5 LSAs: • **Enabled**—The translator is specified through commands. • **Elected**—The translator is designated through election. • **Disabled**—The device is not a translator.
7/5 translate stability timer interval	Stability interval for Type-7 LSA-to-Type-5 LSA translation.
SPF scheduled Count	SPF calculation count in the OSPF area.
Interface	Interface in the area.
Cost	Interface cost.
State	Interface state.
Type	Interface network type.
MTU	Interface MTU.
Priority	Router priority.
Timers	OSPF timers: • **Hello**—Interval for sending hello packets. • **Dead**—Interval within which the neighbor is down. • **Poll**—Interval for sending hello packets. • **Retransmit**—Interval for retransmitting LSAs.
FRR backup	Whether Loop Free Alternate (LFA) calculation is enabled on an interface.
Enabled by interface configuration (including secondary IP addresses)	OSPF is enabled on the interface. **including secondary IP addresses** indicates that OSPF advertises the direct routes to the primary and secondary addresses of the interface.
Keychain authentication: Enabled (*xx*), inherited	Keychain authentication is enabled. The name of the keychain is *xx*. If the interface uses the authentication mode of its area, this field displays **inherited** after the

	authentication mode.
Cryptographic authentication: Enabled, inherited	Authentication mode used by the interface. If the interface uses the authentication mode of its area, this field displays **inherited** after the authentication mode. Optional authentication modes include: • **Simple**—Simple authentication. • **Cryptographic**—Encrypted authentication. Options include MD5, HMAC-MD5, and HMAC-SHA-256.
The last key is *xx*	The most recent MD5/HMAC-MD5/HMAC-SHA-256 authentication key ID is *xx*.
The rollover is in progress, *xx* neighbor(s) left	Key rollover for MD5/HMAC-MD5/HMAC-SHA-256 authentication is in progress. The number of neighbors that have not completed rollover is *xx*.

display ospf abr-asbr

Use **display ospf abr-asbr** to display routes to the ABR or ASBR.

Syntax

display ospf [*process-id*] **abr-asbr** [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays routes to the ABR and ASBR for all OSPF processes.

verbose: Displays detailed information. If you do not specify this keyword, the command displays brief information.

Usage guidelines

If you use this command on routers in a stub area, the commands displays no ASBR information.

Examples

Display brief information about routes to the ABR or ASBR.

```
<Sysname> display ospf abr-asbr

          OSPF Process 1 with Router ID 192.168.1.2
                 Routing Table to ABR and ASBR

 Type        Destination       Area       Cost  Nexthop         RtType
 Inter       3.3.3.3           0.0.0.0    3124  10.1.1.2        ASBR
 Intra       2.2.2.2           0.0.0.0    1562  10.1.1.2        ABR
```

Display detailed information about routes to the ABR or ASBR.

```
<Sysname> display ospf abr-asbr verbose
```

```
          OSPF Process 10 with Router ID 101.1.1.11
                  Routing Table to ABR and ASBR

Destination: 1.1.1.1            RtType     : ASBR
Area       : 0.0.0.1            Type       : Intra
Nexthop    : 150.0.1.12         BkNexthop  : 0.0.0.0
Interface  : GE1/0/1            BkInterface: N/A
Cost       : 1000
```

Table 2 Command output

Field	Description
Type	Type of the route to the ABR or ASBR: • **Inter**—Inter-area route. • **Intra**—Intra-area route.
Destination	Router ID of an ABR or ASBR.
Area	ID of the area of the next hop.
Cost	Cost from the router to the ABR or ASBR.
Nexthop	Next hop address.
BkNexthop	Backup next hop address.
RtType	Router type: ABR or ASBR.
Interface	Output interface.
BkInterface	Backup output interface.

display ospf abr-summary

Use **display ospf abr-summary** to display ABR summary route information.

Syntax

display ospf [*process-id*] [**area** *area-id*] **abr-summary** [*ip-address* { *mask-length* | *mask* }] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays information about ABR summary routes for all OSPF processes.

area *area-id*: Specifies an OSPF area by its ID. The area ID is an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format. If you do not specify this option, the command displays information about ABR summary routes for all OSPF areas.

ip-address: Specifies a summary route by its IP address.

mask-length: Specifies the mask length in the range of 0 to 32.

mask: Specifies the mask in dotted decimal notation.

verbose: Displays detailed ABR summary route information. If you do not specify this keyword, the command displays brief ABR summary route information.

Usage guidelines

If you do not specify an IP address, this command displays information about all summary routes on the ABR.

Examples

Display brief information about summary routes on the ABR.

```
<Sysname> display ospf abr-summary

          OSPF Process 1 with Router ID 2.2.2.2
                  ABR Summary Addresses

                        Area: 0.0.0.1
 Total summary addresses: 1
 Net             Mask            Status        Count      Cost
 100.0.0.0       255.0.0.0       Advertise     1          (Not Configured)
```

Table 3 Command output

Field	Description
Area	Area to which the summary routes belong.
Total summary addresses	Total number of summary routes.
Net	Address of the summary route.
Mask	Mask of the summary route address.
Status	Advertisement status of the summary route: **Advertise** or **Non-Advertise**.
Count	Number of summarized routes.
Cost	Cost of the summary route.

Display detailed information about summary routes on the ABR.

```
<Sysname> display ospf abr-summary verbose

          OSPF Process 1 with Router ID 2.2.2.2
                  ABR Summary Addresses

                        Area: 0.0.0.1
 Total summary addresses: 1

 Net         : 100.0.0.0
 Mask        : 255.0.0.0
```

```
Status      : Advertise
Cost        : (Not Configured)
Routes count: 1
  Destination            NetMask                Metric
  100.1.1.0              255.255.255.0          1000
```

Table 4 Command output

Field	Description
Destination	Destination address of a summarized route.
NetMask	Network mask of a summarized route.
Metric	Metric of a summarized route.

display ospf asbr-summary

Use **display ospf asbr-summary** to display ASBR summary route information.

Syntax

display ospf [*process-id*] **asbr-summary** [*ip-address* { *mask-length* | *mask* }]

Views

 30.1.1.0        255.255.255.0   OSPF       2         2        1
```

Table 5 Command output

Field	Description
Total Summary Address Count	Total number of summary routes.
Net	Address of the summary route.
Mask	Mask of the summary route address.
Tag	Tag of the summary route.
Status	Advertisement status of the summary route.
Cost	Cost of the summary route.
The Count of Route is	Number of summarized routes.
Destination	Destination address of a summarized route.
Net Mask	Network mask of a summarized route.
Proto	Routing protocol from which the route was redistributed.
Process	Process ID of the routing protocol from which the route was redistributed.
Type	Type of a summarized route.
Metric	Metric of a summarized route.

display ospf event-log

Use **display ospf event-log** to display OSPF log information.

Syntax

display ospf [*process-id*] **event-log** { **lsa-flush** | **peer** [*neighbor-id*] [**slot** *slot-number*] | **spf** }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPF log information for all processes.

lsa-flush: Specifies LSA aging log information.

peer: Specifies neighbor state change log information.

neighbor-id: Specifies a neighbor by its router ID. If you do not specify this argument, the command displays state change log information for all neighbors.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays neighbor state change information on the member device where the active process resides.

spf: Specifies route calculation log information.

Usage guidelines

Route calculation logs show the number of routes newly installed in the IP routing table.

Neighbor logs include information about the following events:

- The OSPF neighbor state goes down.
- The OSPF neighbor state goes backward because the local end receives BadLSReq, SeqNumberMismatch, and 1-Way events.

Examples

Display OSPF LSA aging log information for all processes.

```
<Sysname> display ospf event-log lsa-flush

          OSPF Process 1 with Router ID 1.1.1.1
                  LSA Flush Log

 Date: 2013-09-22 Time: 14:47:33 Received MaxAge LSA from 10.1.1.1
 Type: 1   LS ID: 2.2.2.2         AdvRtr: 2.2.2.2           Seq#: 80000001

 Date: 2013-09-22 Time: 14:47:33 Flushed MaxAge LSA by the self
 Type: 1   LS ID: 1.1.1.1         AdvRtr: 1.1.1.1           Seq#: 80000001

 Date: 2013-09-22 Time: 14:47:33 Received MaxAge LSA from 10.1.2.2
 Type: 1   LS ID: 2.2.2.2         AdvRtr: 2.2.2.2           Seq#: 80000001

 Date: 2013-09-22 Time: 14:47:33 Flushed MaxAge LSA by the self
 Type: 1   LS ID: 1.1.1.1         AdvRtr: 1.1.1.1           Seq#: 80000001
```

Table 6 Command output

Field	Description
Date/Time	Time when the device receives an LSA that has reached the maximum age.
Received MaxAge LSA from *X.X.X.X*	The device received an LSA that has reached the maximum age from *X.X.X.X*.

Flushed MaxAge LSA by the self	The device flushed the LSA that has reached the maximum age.
Type	LSA type.
LS ID	LSA link state ID.
AdvRtr	Advertising router.
Seq#	LSA sequence number.

Display OSPF route calculation log information for all processes.

```
<Sysname> display ospf event-log spf

          OSPF Process 1 with Router ID 1.1.1.2
                  SPF Log

Date       Time     Duration   Intra Inter External Reason
2012-06-27 15:28:26 0.95       1     1     10000    Intra-area LSA
2012-06-27 15:28:23 0.2        0     0     0        Area 0 full neighbor
2012-06-27 15:28:19 0          0     0     0        Intra-area LSA
2012-06-27 15:28:19 0          0     0     0        external LSA
2012-06-27 15:28:19 0.3        0     0     0        Intra-area LSA
2012-06-27 15:28:12 0          1     0     0        Intra-area LSA
2012-06-27 15:28:11 0          0     0     0        Routing policy
2012-06-27 15:28:11 0          0     0     0        Intra-area LSA
```

Table 7 Command output

Field	Description
Date/Time	Time when the route calculation starts.
Duration	Duration of the route calculation, in seconds.
Intra	Number of intra-area routes newly installed in the IP routing table.
Inter	Number of inter-area routes newly installed in the IP routing table.
External	Number of external routes newly installed in the IP routing table.
Reason	Reasons why the route calculation is performed: • **Intra-area LSA**—Intra-area LSA changes. • **Inter-area LSA**—Inter-area LSA changes. • **External LSA**—External LSA changes. • **Configuration**—Configuration changes. • **Area 0 full neighbor**—Number of **FULL**-state neighbors in Area 0 changes. • **Area 0 up interface**—Number of interfaces in up state in Area 0 changes. • **LSDB overflow state**—Overflow status changes. • **AS number**—AS number changes. • **ABR summarization**—ABR summarization changes. • **GR end**—GR ends. • **Routing policy**—Routing policy changes. • **Intra-area tunnel**—Intra-area tunnel changes. • **Others**—Other reasons.

Display OSPF neighbor log information for OSPF process 1.

```
<Sysname> display ospf 1 event-log peer

          OSPF Process 1 with Router ID 1.1.1.1
                  Neighbors Log

Date       Time     Local Address   Remote Address  Router ID       Reason
2012-12-31 12:35:45 197.168.1.1     197.168.1.2     2.2.2.2         IntPhyChange
2012-12-31 12:35:19 197.168.1.1     197.168.1.2     2.2.2.2         ConfNssaArea
2012-12-31 12:34:59 197.168.1.1     197.168.1.2     2.2.2.2         SilentInt
```

Table 8 Command output

Field	Description
Date/Time	Time when the neighbor state changes.
Local Address	Local address of the neighbor relationship.
Remote Address	Peer address of the neighbor relationship.
Router ID	Neighbor router ID.
Reason	Reasons for neighbor state changes: • **ResetConnect**—The connection is lost due to insufficient memory. • **IntChange**—The interface parameter has changed. • **VlinkChange**—The virtual link parameter has changed. • **ResetOspf**—The OSPF process is reset. • **UndoOspf**—The OSPF process is deleted. • **UndoArea**—The OSPF area is deleted. • **UndoNetwork**—The interface is disabled. • **SilentInt**—The interface is configured as a silent interface. • **IntLogChange**—The logical attribute of the interface has changed. • **IntPhyChange**—The physical attribute of the interface has changed. • **IntVliChange**—The virtual link attribute of the interface has changed. • **VlinkDown**—The virtual link goes down. • **DeadExpired**—The dead timer expires. • **ConfStubArea**—The interface is configured with stub area parameters. • **ConfNssaArea**—The interface is configured with NSSA area parameters. • **AuthChange**—The authentication type has changed. • **OpaqueChange**—The Opaque capability has changed. • **Retrans**—Excessive retransmissions. • **LLSChange**—The LLS capability has changed. • **OOBChange**—The OOB capability has changed. • **GRChange**—The GR capability has changed. • **BFDDown**—The interface is shut down by BFD. • **BadLSReq**—The interface receives BadLSReq events. • **SeqMismatch**—The interface receives SeqNumberMismatch events. • **1-Way**—The interface receives 1-Way events.

Related commands

reset ospf event-log

display ospf event-log hello

Use **display ospf event-log hello** to display OSPF log information about received or sent hello packets.

Syntax

display ospf [*process-id*] **event-log hello** { **received** [**abnormal** | **dropped**] | **sent** } [*neighbor-id*] [**slot** *slot-number*]

display ospf [*process-id*] **event-log hello sent** { **abnormal** | **failed** } [*neighbor-address*] [**slot** *slot-number*]

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPF log information for all processes.

received: Specifies log information for received hello packets.

sent: Specifies log information for sent hello packets.

abnormal: Specifies log information for abnormal hello packets received or sent at intervals greater than or equal to 1.5 times the hello interval.

dropped: Specifies log information for received hello packets that were dropped.

failed: Specifies log information for hello packets that failed to be sent.

neighbor-address: Specifies a neighbor by its IP address. If you do not specify this argument, the command displays received or sent hello packet log information for all neighbors.

neighbor-id: Specifies a neighbor by its router ID. If you do not specify this argument, the command displays received or sent hello packet log information for all neighbors.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays received or sent hello packet log information on the member device where the active process resides.

Examples

Display log information for sent hello packets.

```
<Sysname> display ospf event-log hello sent

         OSPF Process 1 with Router ID 5.5.5.5
                 Hello Log

Interface: GE1/0/1
Neighbor address: 10.1.1.2, NbrID: 1.0.0.2
First 4 hello packets sent:
  2018-08-05 20:10:10:121, failed, errno: 132
```

```

  2018-08-06 11:15:50:121, succeeded
```

Table 9 Command output

Field	Description
Interface	Interface that sends the hello packets.
Neighbor address	IP address of the neighbor.
NbrID	Router ID of the neighbor.
First 4 hello packets sent	Time and result (**succeeded** or **failed**) for sending the first four hello packets. For a packet failed to be sent, an error code is displayed in the **errno** field.
Last 4 hello packets sent before Full->Down at 2018-01-06 14:52:10:121	Time and result (**succeeded** or **failed**) for sending the last four hello packets before neighbor state change. For a packet failed to be sent, an error code is displayed in the **errno** field.

Display log information for hello packets that failed to be sent.

```
<Sysname> display ospf event-log hello sent failed

         OSPF Process 1 with Router ID 5.5.5.5
                 Hello Log

Date: 2018-08-06 Time: 14:51:20:121 Interface: GE1/0/1
Destination address: 224.0.0.5, sent failed, errno: 132

Date: 2018-08-06 Time: 11:20:20:116 Interface: GE1/0/2
Destination address: 10.1.1.2, sent failed, errno: 132
```

Table 10 Command output

Field	Description
Date	Date for the hello packet sending failure, in the format of YYYY-MM-DD. YYYY represents the year, MM represents the month, and DD represents the day.
Time	Time for the hello packet sending failure, in the format of hh:mm:ss:xxx. hh represents the hours, mm represents the minutes, and ss represents the seconds, and xxx represents the milliseconds.
Interface	Interface that sends the hello packet.
Destination address	Destination IP address of the hello packet.
error	Error code for the hello packet sending failure.

Display log information for abnormal hello packets sent.

```
<Sysname> display ospf event-log hello sent abnormal

         OSPF Process 1 with Router ID 5.5.5.5
                 Hello Log

Date: 2018-08-06 Time: 11:21:12:121 Interface: GE1/0/2
Destination address: 224.0.0.5, last one sent: 2018-08-06 11:20:51:916

Date: 2018-08-06 Time: 11:56:21:312 Interface: GE1/0/2
Destination address: 10.1.1.2, last one sent: 2018-08-06 11:56:02:691
```

Table 11 Command output

Field	Description
Date	Date for sending the abnormal hello packet, in the format of YYYY-MM-DD. YYYY represents the year, MM represents the month, and DD represents the day.
Time	Time for sending the abnormal hello packet, in the format of hh:mm:ss:xxx. hh represents the hours, mm represents the minutes, and ss represents the seconds, and xxx represents the milliseconds.
Interface	Interface that sends the abnormal hello packet.
Destination address	Destination IP address of the abnormal hello packet.
last one sent	Time for sending the last hello packet before sending the abnormal hello packet.

Display log information for received hello packets.

```
<Sysname> display ospf event-log hello received

         OSPF Process 1 with Router ID 5.5.5.5
                 Hello Log

Interface: GE1/0/1
Neighbor address: 10.1.1.2, NbrID: 1.0.0.2
First 4 hello packets received:
  2018-08-05 20:11:10:121
```

```
  2018-08-05 20:11:30:121
  2018-08-05 20:11:20:121
  2018-08-05 20:11:40:121
Last 4 hello packets received before Exchange->Down at 2018-08-06 14:52:10:121
  2018-08-06 14:51:10:121
  2018-08-06 14:51:30:121
  2018-08-06 14:51:20:121
  2018-08-06 14:51:40:121

Interface: GE1/0/1
Neighbor address: 10.1.1.1, NbrID: 1.0.0.1
First 4 hello packets received:
  2018-08-06 19:11:15:121
  2018-08-06 19:11:35:121
  2018-08-06 19:11:25:121
  2018-08-06 19:11:45:121
Last 4 hello packets received before Full->Init at 2018-08-06 21:16:20:171
  2018-08-06 21:15:45:121
  2018-08-06 21:15:55:121
  2018-08-06 21:16:05:121
  2018-08-06 21:16:15:121
```

Table 12 Command output

Field	Description
Interface	Interface that receives the hello packets.
Neighbor address	IP address of the neighbor.
NbrID	Router ID of the neighbor.
First 4 hello packets received	Time for receiving the first four hello packets.
Last 4 hello packets received before Full->Init at 2018-01-06 21:16:20:171	Time for receiving the last four hello packets before neighbor state change, in the format of YYYY-MM-DD hh:mm:ss:xxx. YYYY represents the year, MM represents the month, and DD represents the day. hh represents the hours, mm represents the minutes, and ss represents the seconds, and xxx represents the milliseconds.

Display log information for received hello packets that were dropped.

```
<Sysname> display ospf event-log hello received dropped

         OSPF Process 1 with Router ID 5.5.5.5
                 Hello Log

Date: 2018-08-06 Time: 14:51:22:791 Interface: GE1/0/1
Source address: 10.1.1.1, NbrID: 1.0.0.1, area: 0.0.0.1
Drop reason: Hello-time mismatch

Date: 2018-08-06 Time: 14:51:20:121 Interface: GE1/0/1
Source address: 10.1.1.2, NbrID: 1.0.0.2, area: 0.0.0.1
Drop reason: NP-bit mismatch
```

Table 13 Command output

Field	Description
Date	Date for dropping the received hello packet, in the format of YYYY-MM-DD. YYYY represents the year, MM represents the month, and DD represents the day.
Time	Time for dropping the received hello packet, in the format of hh:mm:ss:xxx. hh represents the hours, mm represents the minutes, and ss represents the seconds, and xxx represents the milliseconds.
Interface	Interface that receives the hello packet.
Source address	Source IP address of the received hello packet.
NbrID	Router ID of the neighbor.
area	Area to which the neighbor interface belongs.
Drop reason	Reason for dropping the hello packet: • **Area under reset**—The area is in the reset progress. • **Router ID conflict**—Route ID conflict. • **Area mismatch**—Area ID mismatch. • **Unknown virtual link**—The hello packet is from an unknown virtual link. • **Authentication failure**—Authentication check failure. • **Peer address check failure**—Neighbor address check failure. • **Not DR or BDR**—The destination IP address of the hello packet is 224.0.0.6, but the interface is not a DR or BDR. • **Unknown unicast peer**—The hello packet is from an unknown unicast neighbor. • **Option mismatch**—Option mismatch. • **Subnet mask mismatch**—Subnet mask mismatch. • **Address mismatch**—Address range mismatch. • **Hello timer mismatch**—Hello timer mismatch. • **Dead timer mismatch**—Dead timer mismatch. • **Peer change**—The source IP address or router ID has changed.

Display log information for abnormal hello packets received.

```
<Sysname> display ospf event-log hello received abnormal

         OSPF Process 1 with Router ID 5.5.5.5
                 Hello Log

Date: 2018-08-06 Time: 10:12:22:121 Interface: GE1/0/1
Source address: 10.1.1.2, NbrID: 1.0.0.2, area: 0.0.0.1
Last one received: 2018-08-06 10:12:04:212

Date: 2018-08-06 Time: 14:51:20:121 Interface: GE1/0/1
Source address: 10.1.1.2, NbrID: 1.0.0.2, area: 0.0.0.1
Last one received: 2018-08-06 14:51:05:113
```

Table 14 Command output

Field	Description
Date	Date for receiving the abnormal hello packet, in the format of YYYY-MM-DD.

	YYYY represents the year, MM represents the month, and DD represents the day.
Time	Time for receiving the abnormal hello packet, in the format of hh:mm:ss:xxx. hh represents the hours, mm represents the minutes, and ss represents the seconds, and xxx represents the milliseconds.
Interface	Interface that receives the abnormal hello packet.
Source address	Source IP address of the received abnormal hello packet.
NbrID	Router ID of the neighbor.
area	Area to which the neighbor interface belongs.
last one sent	Time for receiving the last hello packet before receiving the abnormal hello packet.

Related commands

reset ospf event-log hello

display ospf fast-reroute lfa-candidate

Use **display ospf fast-reroute lfa-candidate** to display OSPF FRR backup next hop information.

Syntax

display ospf [*process-id*] [**area** *area-id*] **fast-reroute lfa-candidate**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays FRR backup next hop information for all processes.

area *area-id*: Specifies an OSPF area by its ID. The area ID is an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format. If you do not specify this option, the command displays FRR backup next hop information for all OSPF areas.

Examples

Display OSPF FRR backup next hop information.

```
<Sysname> display ospf 1 area 0 fast-reroute lfa-candidate

          OSPF Process 1 with Router ID 2.2.2.2
                  LFA Candidate List

Area: 0.0.0.0
 Candidate nexthop count: 2
 NextHop          IntIP            Interface
```

```
10.0.1.1          10.0.1.2          GE1/0/2
10.0.11.1         10.0.11.2         GE1/0/3
```

Table 15 Command output

Field	Description
Area	Area to which the backup next hops belong.
Candidate nexthop count	Number of backup next hops.
NextHop	Backup next hop address.
IntIP	IP address of the output interface.
Interface	Output interface.

display ospf graceful-restart

Use **display ospf graceful-restart** to display GR information.

Syntax

display ospf [*process-id*] **graceful-restart** [**verbose**]

Views

Any view

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays GR information for all processes.

verbose: Displays detailed GR information. If you do not specify this keyword, the command displays brief GR information.

Examples

Display detailed GR information.

```
<Sysname> display ospf graceful-restart verbose

          OSPF Process 1 with Router ID 1.1.1.1
              Graceful Restart information

Graceful Restart capability     : Enable(IETF)
Graceful Restart support        : Planned and un-planned,Partial
Helper capability               : Enable(IETF)
Helper support                  : Planned and un-planned (IETF),Strict LSA check
Current GR state                : Normal
Graceful Restart period         : 40 seconds
Number of neighbors under Helper: 0
Number of restarting neighbors  : 0
```

Neighbor        IP address      GR state     Last Helper exit reason
4.4.4.4         20.2.0.4        Normal       Reset neighbor
```

Table 16 Command output

Field	Description
OSPF Process 1 with Router ID 1.1.1.1 Graceful Restart information	GR information for OSPF process 1 with router ID 1.1.1.1.
Graceful Restart capability	Whether GR is enabled: • **Enable(IETF)**—IETF GR is enabled. • **Enable(Nonstandard)**—Non-IETF GR is enabled. • **Disable**—GR is disabled.
Graceful Restart support	GR modes that the process supports (displayed only when GR is enabled): • **Planned and un-planned**—Supports both planned and unplanned GR. • **Planned only**—Supports only planned GR. • **Partial**—Supports partial GR. • **Global**—Supports global GR.

Field	Description
Helper capability	Helper capability that the process supports: • **Enable(IETF)**—Supports IETF GR helper capability. • **Enable(Nonstandard)**—Supports non-IETF GR helper capability. • **Enable(IETF and nonstandard)**—Supports both IETF GR helper capability and non-IETF GR helper capability. • **Disable**—Does not support GR helper capability.
Helper support	Policies that the helper supports (displayed only when GR helper is enabled): • **Strict lsa check**—The helper supports strict LSA checking. • **Planned and un-planned**—The helper supports planned and unplanned GR. • **Planned only**—The helper supports only planned GR.
Current GR state	GR state: • **Normal**—GR is not in progress or has completed. • **Under GR**—GR is in process. • **Under Helper**—The process is acting as GR helper.
Last exit reason	Last exit reason: • **Restarter**—Reason that the restarter exited most recently. • **Helper**—Reason that the helper exited most recently.
Area	Area ID in IP address format.
Authtype	Authentication type of the area: • **None**—No authentication. • **Simple**—Simple authentication. • **MD5**—MD5 authentication.
Area flag	Type of the area: • Normal. • Stub. • StubNoSummary (totally stub area). • NSSA. • NSSANoSummary (totally NSSA area).
Area up Interface count	Number of up interfaces in the area.
Interface	Interface in the area.
Restarter state	Restarter state on the interface.
State	Interface state.
Type	Interface network type.
Neighbor count of this interface	Neighbors of an interface.
Neighbor	Neighbor router ID.
IP address	Neighbor IP address.
GR state	Neighbor GR state: • **Normal**—GR is not in progress or has completed. • **Under GR**—GR is in process. • **Under Helper**—The process is acting as GR helper.

Field	Description
Last Helper exit reason	Reason that the helper exited most recently.
Virtual-link Neighbor-ID	Router ID of the virtual link's neighbor.
Neighbor-State	Neighbor state: Down, Init, 2-Way, ExStart, Exchange, Loading, and Full.
Interface	Output interface of the virtual link.

display ospf hostname-table

Use **display ospf hostname-table** to display the router ID-to-host name mapping table.

Syntax

display ospf [*process-id*] **hostname-table**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify an OSPF process, this command displays the router ID-to-host name mapping tables for all OSPF processes.

Examples

Display the router ID-to-host name mapping tables for all OSPF processes.

```
<Sysname> display ospf hostname-table

        OSPF Process 1 with Router ID 192.168.56.21
               Hostname Table Information

                       Area: 0.0.0.1
Router ID           Hostname
192.168.56.21       RouterA
```

display ospf interface

Use **display ospf interface** to display OSPF interface information.

Syntax

display ospf [*process-id*] **interface** [*interface-type interface-number* | **verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process ID in the range of 1 to 65535. If you do not specify this argument, the command displays the OSPF interface information for all OSPF processes.

interface-type interface-number: Specifies an interface by its type and number.

verbose: Displays detailed OSPF information for all interfaces.

Usage guidelines

If you do not specify the *interface-type interface-number* argument or the **verbose** keyword, this command displays OSPF brief information for all interfaces.

Examples

Display all OSPF interface brief information.

```
<Sysname> display ospf interface

          OSPF Process 1 with Router ID 192.168.1.1
                  Interfaces

 Area: 0.0.0.0
 IP Address      Type         State    Cost  Pri   DR              BDR
 192.168.1.1     PTP          P-2-P    1562  1     0.0.0.0         0.0.0.0

 Area: 0.0.0.1
 IP Address      Type         State    Cost  Pri   DR              BDR
 172.16.0.1      Broadcast    DR       1     1     172.16.0.1      0.0.0.0
```

Table 17 Command output

Field	Description
Area	Area ID of the interface.
IP Address	Interface IP address (regardless of whether TE is enabled or not).
Type	Interface network type: PTP (P2P), PTMP (P2MP), Broadcast, or NBMA.
State	Interface state: • **Down**—No protocol traffic can be sent or received on the interface. • **Loopback**—The interface is in loopback state and it cannot forward traffic. • **Waiting**—The interface starts sending and receiving Hello packets. The router is trying to determine the identity of the (Backup) designated router for the network. • **P-2-P**—The interface will send Hello packets at the hello interval, and try to establish an adjacency with the neighbor. • **DR**—The router is the designated router on the network. • **BDR**—The router is the backup designated router on the network. • **DROther**—The router is a DR Other router on the attached network.
Cost	Interface cost.

Field	Description
Pri	Router priority.
DR	DR on the interface's network segment.
BDR	BDR on the interface's network segment.

Display detailed information about GigabitEthernet 1/0/1.

```
<Sysname> display ospf interface gigabitethernet 1/0/1

          OSPF Process 1 with Router ID 192.168.1.1
                  Interfaces

 Area: 0.0.0.0

 Interface: 172.16.0.1 (GigabitEthernet1/0/1)
 Cost: 1       State: DR        Type: Broadcast    MTU: 1500
 Priority: 1
 Designated router: 172.16.0.1
 Backup designated router: 0.0.0.0
 Timers: Hello 10, Dead 40, Poll  40, Retransmit 5, Transmit Delay 1
 FRR backup: Enabled
 Primary path detection mode: BFD ctrl
 Enabled by interface configuration (including secondary IP addresses)
 BFD: echo
 Cryptographic authentication: Enabled, inherited
    The last key is 1.
```

Table 18 Command output

Field	Description
Interface	Information about the interface, such as the IP address.
Timers	OSPF timers (in seconds): **Hello**, **Dead**, **Poll**, and **Retransmit**.
Transmit Delay	LSA transmission delay on the interface, in seconds.
FRR backup	Whether LFA calculation is enabled on an interface.
Primary path detection mode	Primary link detection mode: • **BFD ctrl**—BFD control packet mode. • **BFD echo**—BFD echo packet mode.
Enabled by interface configuration (including secondary IP addresses)	OSPF is enabled on the interface (including secondary IP addresses).
BFD	BFD session mode enabled on the interface: • **ctrl**—BFD control packet mode. • **echo**—BFD echo packet mode.
Keychain authentication: Enabled (*xx*), inherited	Keychain authentication is enabled. The name of the keychain is *xx*. If the interface uses the authentication mode of its area, this field displays **inherited** after the authentication mode.

Field	Description
Cryptographic authentication: Enabled, inherited	Authentication mode used by the interface. If the interface uses the authentication mode of its area, this field displays **inherited** after the authentication mode. Optional authentication modes include: • **Simple**—Simple authentication. • **Cryptographic**—Encrypted authentication. Options include MD5, HMAC-MD5, or HMAC-SHA-256.
The last key is *xx*	The most recent MD5/HMAC-MD5/HMAC-SHA-256 authentication key ID is *xx*.
The rollover is in progress, *xx* neighbor(s) left.	Key rollover for MD5/HMAC-MD5/HMAC-SHA-256 authentication is in progress. The number of neighbors that have not completed rollover is *xx*.
Nexthop	Next hop address. This field displays 0.0.0.0 for a P2P network.

display ospf interface hello

Use **display ospf interface hello** to display information about hello packets sent by OSPF interfaces.

Syntax

display ospf [*process-id*] **interface** [*interface-type interface-number*] **hello**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process ID in the range of 1 to 65535. If you do not specify this argument, the command displays hello packet information for all OSPF processes.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays information about the hello packets sent by all OSPF interfaces.

Usage guidelines

This command displays information for only the hello packets sent in multicast.

Examples

Display information about hello packets sent by all OSPF interfaces.

```
<Sysname> display ospf interface hello

          OSPF Process 1 with Router ID 192.168.1.1
                  Interfaces

 Area: 0.0.0.0
```

```
Interface: 172.16.0.1 (GigabitEthernet1/0/1)
First 4 hello packets sent:
  2018-08-05 11:05:10:121, succeeded
  2018-08-05 11:05:20:121, succeeded
  2018-08-05 11:05:30:121, succeeded
  2018-08-05 11:05:40:121, succeeded
Last 4 hello packets sent:
  2018-08-06 11:15:10:121, succeeded
  2018-08-06 11:15:20:121, succeeded
  2018-08-06 11:15:30:121, succeeded
  2018-08-06 11:15:40:121, succeeded
```

Table 19 Command output

Field	Description
Area	Area to which the interface belongs.
Interface	IP address of the interface.
First 4 hello packets sent	Time and result (**succeeded** or **failed**) for sending the first four hello packets.
Last 4 hello packets sent	Time and result (**succeeded** or **failed**) for sending the last four hello packets when the command is executed.

display ospf lsdb

Use **display ospf lsdb** to display OSPF LSDB information.

Syntax

display ospf [*process-id*] **lsdb** [**brief** | **originate-router** *advertising-router-id* | **self-originate**] [**age** { **max-value** *max-age-value* | **min-value** *min-age-value* } *] [**resolve-hostname**]

display ospf [*process-id*] **lsdb hostname** *host-name* [**age** { **max-value** *max-age-value* | **min-value** *min-age-value* } *]

display ospf [*process-id*] **lsdb** { **ase** | **opaque-as** } [*link-state-id*] [**originate-router** *advertising-router-id* | **self-originate**] [**age** { **max-value** *max-age-value* | **min-value** *min-age-value* } *] [**resolve-hostname**]

display ospf [*process-id*] **lsdb** { **ase** | **opaque-as** } [*link-state-id*] **hostname** *host-name* [**age** { **max-value** *max-age-value* | **min-value** *min-age-value* } *] | **opaque-area**

display ospf [*process-id*] [**area** *area-id*] **lsdb** { **asbr** | **network** | **nssa** | **opaque-link** | **router** | **summary** } [*link-state-id*] [**originate-router** *advertising-router-id* | **self-originate**] [**age** { **max-value** *max-age-value* | **min-value** *min-age-value* } *] [**resolve-hostname**]

display ospf [*process-id*] [**area** *area-id*] **lsdb** { **asbr** | **network** | **nssa** | **opaque-link** | **router** | **summary** } [*link-state-id*] **hostname** *host-name* [**age** { **max-value** *max-age-value* | **min-value** *min-age-value* } *]

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays LSDB information for all OSPF processes.

age: Displays LSAs whose ages are in the specified range. If you do not specify this keyword, the command displays all LSAs in the LSDB.

max-value *max-age-value*: Specifies the maximum age of LSAs, in the range of 0 to 3600 seconds. The default value is 3600.

min-value *min-age-value*: Specifies the minimum age of LSAs, in the range of 0 to 3600 seconds. The default value is 0. The *min-age-value* cannot be greater than the *max-age-value*.

area *area-id*: Specifies an OSPF area by its ID. The area ID is an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format. If you do not specify this option, the command displays LSDB information for all OSPF areas.

brief: Displays brief LSDB information.

asbr: Displays Type-4 LSA (ASBR Summary LSA) information in the LSDB.

ase: Displays Type-5 LSA (AS External LSA) information in the LSDB.

network: Displays Type-2 LSA (Network LSA) information in the LSDB.

nssa: Displays Type-7 LSA (NSSA External LSA) information in the LSDB.

opaque-as: Displays Type-11 LSA (Opaque-AS LSA) information in the LSDB.

opaque-link: Displays Type-9 LSA (Opaque-link LSA) information in the LSDB.

router: Displays Type-1 LSA (Router LSA) information in the LSDB.

summary: Displays Type-3 LSA (Network Summary LSA) information in the LSDB.

link-state-id: Specifies a link state ID in the IP address format.

originate-router *advertising-router-id*: Specifies an advertising router by its ID.

self-originate: Displays information about self-originated LSAs.

hostname *host-name*: Displays LSAs advertised by the router with the specified host name. If you do not specify this option, the command displays all LSAs in the OSPF LSDB.

resolve-hostname: Displays host names in OSPF LSDB information. If you do not specify this keyword, the OSPF LSDB information does not include host names.

Examples

Display OSPF LSDB information.

```
<Sysname> display ospf lsdb
         OSPF Process 1 with Router ID 192.168.0.1
                 Link State Database
```

```

Table 21 Command output

Field	Description
Type	LSA type.
LS ID	DR IP address.
Adv Rtr	Router that advertised the LSA.
Hostname	Host name of the advertising router.
LS age	LSA age time.
Len	LSA length.
Options	LSA options: • **O**—Opaque LSA advertisement capability. • **E**—AS External LSA reception capability. • **EA**—External extended LSA reception capability. • **DC**—On-demand link support. • **N**—NSSA external LSA support. • **P**—Capability of an NSSA ABR to translate Type-7 LSAs into Type-5 LSAs.
Seq#	LSA sequence number.

Field	Description
Checksum	LSA checksum.
Net Mask	Network mask.
Attached Router	ID of the router that established adjacency with the DR, and ID of the DR itself.

Display Type-9 LSA information in the LSDB of OSPF process 1.

```
<Sysname> display ospf 1 lsdb opaque-link

         OSPF Process 1 with Router ID 1.1.1.1
                 Link State Database

                          Area: 0.0.0.0

    Type      : Opq-Link
    LS ID     : 3.0.0.0
    Adv Rtr   : 1.1.1.1

    Seq#      : 80000001
    Checksum  : 0x31cf
      Opaque type: 3(Grace LSA)
      Opaque ID: 0
      IETF Graceful Restart Period: 120
      Restart Reason:    1 - software restart
      Neighbor Interface Address  : 192.168.12.1
```

display ospf nexthop

Use **display ospf nexthop** to display OSPF next hop information.

Syntax

display ospf [*process-id*] **nexthop**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays next hop information for all OSPF processes.

Examples

Display OSPF next hop information.

```
<Sysname> display ospf nexthop

          OSPF Process 1 with Router ID 1.1.1.2
                  Neighbor Nexthop Information

 NbrID           Nexthop         Interface               RefCount   Status
 192.168.12.1    0.0.0.0         GE1/0/2                 4          Valid
 192.168.12.2    192.168.12.2    GE1/0/2                 3          Valid
 192.168.12.1    0.0.0.0         Loop100                 1          Valid
```

Table 22 Command output

Field	Description
NbrID	Neighbor router ID.
Nexthop	Next hop address.
Interface	Output interface.
RefCount	Reference count (routes that use the next hop).
Status	Next hop status: • **Valid**. • **Invalid**.

display ospf non-stop-routing status

Use **display ospf non-stop-routing status** to display OSPF NSR information.

Syntax

display ospf [*process-id*] **non-stop-routing status**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPF NSR information for all OSPF processes.

Examples

Display OSPF NSR information.

```
<Sysname> display ospf non-stop-routing status

                OSPF Process 1 with Router ID 192.168.33.12
                      Non Stop Routing information
```

```
Non Stop Routing capability : Enabled
Upgrade phase : Normal
```

Table 23 Command output

Field	Description
Non Stop Routing capability	NSR status: enabled or disabled.
Upgrade phase	Upgrade phase: • **Prepare**—Upgrade preparation phase. • **Restore Smooth**—Upgrade phase. • **Preroute**—Route pre-calculation phase. • **Calculating**—Route calculation phase. • **Redisting**—Route redistribution phase. • **Original and age**—LSA generation and aging phase. • **Normal**—Normal status.

display ospf peer

Use **`display ospf peer`** to display information about OSPF neighbors.

Syntax

`display ospf` [*`process-id`*] **`peer`** [**`hello`** | **`verbose`**] [*`interface-type interface-number`*] [[*`neighbor-id`*] [**`resolve-hostname`**] | **`hostname`** *`host-name`*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`process-id`: Specifies an OSPF process by ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPF neighbor information for all OSPF processes.

`hello`: Displays information about the hello packets sent to and received from neighbor routers. In scenarios where hello packets are sent in multicast, the command displays information for only the hello packets received from neighbor routers.

`verbose`: Displays detailed neighbor information. If you do not specify this keyword, the command displays brief OSPF neighbor information.

`interface-type interface-number`: Specifies an interface by its type and number. If you do not specify this argument, the command displays neighbor information for all interfaces.

`neighbor-id`: Specifies a neighbor router ID. If you do not specify this argument, the command displays all neighbor information.

`resolve-hostname`: Resolves the host names of the neighbor routers. If you do not specify this keyword, the command cannot resolve the host names of the neighbor routers.

hostname *host-name*: Specifies a neighbor router by its host name, a case-sensitive string of 1 to 255 characters. If you do not specify this option, the command displays information for all neighbors.

Examples

Display detailed OSPF neighbor information.

```
<Sysname> display ospf peer verbose

          OSPF Process 1 with Router ID 1.1.1.1
                  Neighbors

 Area 0.0.0.0 interface 1.1.1.1(GigabitEthernet1/0/1)'s neighbors
 Router ID: 1.1.1.2          Address: 1.1.1.2          GR State: Normal
   State: Full  Mode: Nbr is master  Priority: 1
   DR: 1.1.1.2  BDR: 1.1.1.1  MTU: 0
   Options is 0x02 (-|-|-|-|-|-|E|-)
   Dead timer due in 33  sec
   Neighbor is up for 02:03:35
   Authentication Sequence: [ 0 ]
   Neighbor state change count: 6
   BFD status: Disabled
 Last Neighbor Down Event:
 Router ID: 22.22.22.22
 Local Address: 11.11.11.11
 Remote Address: 22.22.22.22
 Time: Apr  9 03:18:19 2014
 Reason: Ospf_ifachange
```

Table 24 Command output

Field	Description
Area *areaID* interface *IPAddress*(*InterfaceName*)'s neighbors	Neighbor information for the interface in the specified area: • **areaID**—Area to which the neighbor belongs. • **IPAddress**—Interface IP address. • **InterfaceName**—Interface name.
Router ID	Neighbor router ID.
Address	Neighbor router address.
GR State	This field is not supported in the current software version. GR state: • Normal. • Restarter. • Complete. • Helper.
Hostname	Host name of the neighbor router.

Field	Description
State	Neighbor state: • **Down**—Initial state of a neighbor conversation. • **Init**—The router has received a Hello packet from the neighbor. However, the router has not established bidirectional communication with the neighbor. The router did not appear in the neighbor's hello packet. • **Attempt**—Available only in an NBMA network. In this state, the OSPF router has not received any information from a neighbor for a period. The router can send Hello packets at a longer interval to keep the neighbor relationship. • **2-Way**—Communication between the two routers is bidirectional. The local router appears in the neighbor's Hello packet. • **Exstart**—The goal of this state is to decide which router is the master, and to decide upon the initial Database Description (DD) sequence number. • **Exchange**—The router is sending DD packets to the neighbor, describing its entire link-state database. • **Loading**—The router sends LSRs packets to the neighbor, requesting more recent LSAs. • **Full**—The neighboring routers are fully adjacent.
Mode	Neighbor mode for LSDB synchronization.
Priority	Neighboring router priority.
DR	DR on the interface's network segment.
BDR	BDR on the interface's network segment.
MTU	Interface MTU.
Options	LSA options: • **O**—Opaque LSA advertisement capability. • **E**—AS External LSA reception capability. • **EA**—External extended LSA reception capability. • **DC**—On-demand link support. • **N**—NSSA external LSA support. • **P**—Capability of an NSSA ABR to translate Type-7 LSAs into Type-5 LSAs.
Dead timer due in 33 sec	This dead timer will expire in 33 seconds.
Neighbor is up for 02:03:35	The neighbor has been up for 02:03:35.
Authentication Sequence	Authentication sequence number.
Neighbor state change count	Count of neighbor state changes.
BFD status	This field is not supported in the current software version. BFD status: • Disabled. • Enabled (Control mode). • Enabled (Echo mode).
Last Neighbor Down Event	The most recent neighbor down event.
Time	Time when the neighbor went down.
Reason	Reason for the neighbor down event.

Display brief OSPF neighbor information.

```
<Sysname> display ospf peer

          OSPF Process 1 with Router ID 1.1.1.1
               Neighbor Brief Information

 Area: 0.0.0.0
 Router ID       Address         Pri Dead-Time  State             Interface
 1.1.1.2         1.1.1.2         1   40         Full/DR           GE1/0/1
```

Display brief OSPF neighbor information and resolve the host names of the neighbor routers.

```
<Sysname> display ospf peer resolve-hostname
         OSPF Process 1 with Router ID 1.1.1.1
               Neighbor Brief Information
 Area: 0.0.0.0
 Router ID       Address         Pri Dead-Time  State             Interface
 RouterA         1.1.1.2         1   34         Full/DR           GE1/0/1
```

Table 25 Command output

Field	Description
Area	Neighbor area.
Router ID	ID or host name of the neighbor router.
Address	Neighbor interface address.
Pri	Neighboring router priority.
Dead-Time	Dead interval remained.
Interface	Interface connected to the neighbor.
State	Neighbor state: Down, Init, Attempt, 2-Way, Exstart, Exchange, Loading, or Full.

Display information about the hello packets sent to and received from neighbor routers.

```
<Sysname> display ospf peer hello

          OSPF Process 1 with Router ID 1.1.1.1
                  Neighbors

 Area 0.0.0.0 interface 1.1.1.1(GigabitEthernet1/0/1)'s neighbors
 Router ID: 1.1.1.2          Address: 1.1.1.2
 First 4 hello packets received:
   2018-01-06 09:12:10:121
   2018-01-06 09:12:20:121
   2018-01-06 09:12:30:121
   2018-01-06 09:12:40:121
 Last 4 hello packets received:
   2018-01-06 11:15:10:121
   2018-01-06 11:15:20:121
   2018-01-06 11:15:30:121
   2018-01-06 11:15:40:121
 First 4 hello packets sent:
```

```
  2018-01-06 09:12:12:121, failed, errno:132
  2018-01-06 09:12:22:121, succeeded
  2018-01-06 09:12:32:121, succeeded
  2018-01-06 09:12:42:121, succeeded
Last 4 hello packets sent:
  2018-01-06 11:15:12:121, succeeded
  2018-01-06 11:15:22:121, succeeded
  2018-01-06 11:15:32:121, failed, errno:132
  2018-01-06 11:15:42:121, failed, errno:132
```

Table 26 Command output

Field	Description
Router ID	Router ID of the neighbor.
Address	IP address of the neighbor interface.
First 4 hello packets received	Time for receiving the first four hello packets from neighbors.
Last 4 hello packets received	Time for receiving the last four hello packets from neighbors.
First 4 hello packets sent	Time and result (**succeeded** or **failed**) for sending the first four hello packets to neighbors. For a packet failed to be sent, an error code is displayed in the **errno** field. This field is not displayed in scenarios where hello packets are sent in multicast.
Last 4 hello packets sent	Time and result (**succeeded** or **failed**) for sending the last four hello packets to neighbors when the command is executed. For a packet failed to be sent, an error code is displayed in the **errno** field. This field is not displayed in scenarios where hello packets are sent in multicast.

display ospf peer statistics

Use **display ospf peer statistics** to display OSPF neighbor statistics.

Syntax

display ospf [*process-id*] **peer statistics**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPF neighbor statistics for all OSPF processes.

Examples

Display OSPF neighbor statistics.

```
<Sysname> display ospf peer statistics
          OSPF Process 1 with Router ID 10.3.1.1
                    Neighbor Statistics
  Area ID         Down Attempt Init 2-Way ExStart Exchange Loading Full Total
  0.0.0.0         0    0       0    0     0       0        0       1    1
  0.0.0.2         0    0       0    0     0       0        0       1    1

```

Table 27 Command output

Field	Description
Area ID	The state statistics for all the routers in the area to which the router belongs is displayed.
Down	Number of neighboring routers in Down state in the same area.
Attempt	Number of neighboring routers in Attempt state in the same area.
Init	Number of neighboring routers in Init state in the same area.
2-Way	Number of neighboring routers in 2-Way state in the same area.
ExStart	Number of neighboring routers in ExStart state in the same area.
Exchange	Number of neighboring routers in Exchange state in the same area.
Loading	Number of neighboring routers in Loading state in the same area.
Full	Number of neighboring routers in Full state in the same area.
Total	Total number of neighbors in the same state: Down, Attempt, Init, 2-Way, ExStart, Exchange, Loading, or Full.

display ospf request-queue

Use **display ospf request-queue** to display OSPF request queue information.

Syntax

display ospf [*process-id*] **request-queue** [*interface-type interface-number*] [*neighbor-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the OSPF request queue information for all OSPF processes.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays the OSPF request queue information for all interfaces.

neighbor-id: Specifies a neighbor's router ID. If you do not specify this argument, the command displays the OSPF request queue information for all OSPF neighbors.

Examples

Display OSPF request queue information.

```
<Sysname> display ospf request-queue

         OSPF Process 100 with Router ID 192.168.1.59
                 Link State Request List

  The Router's Neighbor is Router ID 2.2.2.2         Address 10.1.1.2
  Interface 10.1.1.1         Area 0.0.0.0
  Request list:
       Type       LinkState ID      AdvRouter         Sequence   Age
       Router     2.2.2.2           1.1.1.1           80000004   1
       Network    192.168.0.1       1.1.1.1           80000003   1
       Sum-Net    192.168.1.0       1.1.1.1           80000002   2
```

Table 28 Command output

Field	Description
The Router's Neighbor is Router ID	Neighbor router ID.
Address	Neighbor interface IP address.
Interface	Local interface IP address.
Area	Area ID.
Retransmit list	Request list information.
Type	LSA type.
LinkState ID	Link state ID.
AdvRouter	Advertising router.
Sequence	LSA sequence number.
Age	LSA age.

display ospf retrans-queue

Use **display ospf retrans-queue** to display retransmission queue information.

Syntax

display ospf [*process-id*] **retrans-queue** [*interface-type interface-number*] [*neighbor-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays retransmission queue information for all OSPF processes.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays retransmission queue information for all interfaces.

neighbor-id: Specifies a neighbor's router ID. If you do not specify this argument, the command displays retransmission queue information for all neighbors.

Examples

Display OSPF retransmission queue information.

```
<Sysname> display ospf retrans-queue

          OSPF Process 100 with Router ID 192.168.1.59
                  Link State Retransmission List

  The Router's Neighbor is Router ID 2.2.2.2         Address 10.1.1.2
  Interface 10.1.1.1         Area 0.0.0.0
  Retransmit list:
       Type       LinkState ID      AdvRouter         Sequence   Age
       Router     2.2.2.2           2.2.2.2           80000004   1
       Network    12.18.0.1         2.2.2.2           80000003   1
       Sum-Net    12.18.1.0         2.2.2.2           80000002   2
```

Table 29 Command output

Field	Description
The Router's Neighbor is Router ID	Neighbor router ID.
Address	Neighbor interface IP address.
Interface	Interface address of the router.
Area	Area ID.
Retrans List	Retransmission list.
Type	LSA type.
LinkState ID	Link state ID.
AdvRouter	Advertising router.
Sequence	LSA sequence number.
Age	LSA age.

display ospf routing

Use **display ospf routing** to display OSPF routing information.

Syntax

display ospf [*process-id*] **routing** [*ip-address* { *mask-length* | *mask* }] [**interface** *interface-type interface-number*] [**nexthop** *nexthop-address*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the routing information for all OSPF processes.

ip-address: Specifies a destination IP address.

mask-length: Specifies mask length in the range of 0 to 32.

mask: Specifies the mask in dotted decimal notation.

interface *interface-type interface-number*: Displays routes passing the specified output interface. If you do not specify this option, the command displays OSPF routing information for all interfaces.

nexthop *nexthop-address*: Displays routes passing the specified next hop. If you do not specify this option, the command displays all OSPF routing information.

verbose: Displays detailed OSPF routing information. If you do not specify this keyword, the command displays brief OSPF routing information.

Examples

Display OSPF routing information.

```
<Sysname> display ospf routing

          OSPF Process 1 with Router ID 192.168.1.2
                   Routing Table

Routing for network
 Destination        Cost  Type       NextHop         AdvRouter     Area

Table 31 Command output

Field	Description
Priority	Prefix priority: critical, high, medium, and low.
Type	Route type: Transit, Stub, Inter, Type1, or Type2.
AdvRouter	Advertising router.
Area	Area ID.
SubProtoID	Sub protocol ID.
Preference	OSPF route preference.
NextHop	Primary next hop IP address.
BkNextHop	Backup next hop IP address.
IfType	Type of the network to which the primary next hop belongs.
BkIfType	Type of the network to which the backup next hop belongs.
Interface	Output interface.
BkInterface	Backup output interface.
NibID	Next hop ID.

Field	Description
Status	Route status: • **Local**—The route is on the local end and is not sent to the route management module. • **Invalid**—The next hop is invalid. • **Stale**—The next hop is stale. • **Normal**—The route is available. • **Delete**—The route is deleted. • **Host-Adv**—The route is a host route. • **Rely**—The route is a recursive route.
Cost	Cost to destination.
ECMP group	ECMP route group ID. This field is displayed only when ECMP route groups exist.
InLabel	This field is not supported in the current software version. Incoming label. A value of 4294967295 indicates that the incoming label is invalid.
Tunnel type	This field is not supported in the current software version. Tunnel type. Only **SR** (which means SR tunnel) is supported in the current software version.
OutLabel	This field is not supported in the current software version. Outgoing label. A value of 4294967295 indicates that the outgoing label is invalid.
OutLabel flag	This field is not supported in the current software version. Outgoing label flag: • **E**—Explicit null flag. The upstream neighbor must replace the SID with an explicit null flag before forwarding the packets. • **I**—Implicit null flag. The upstream neighbor must replace the SID with an implicit null flag before forwarding the packets. This flag is not supported in the current software version. • **N**—Normal flag. • **P**—SR label preferred flag.
BkOutLabel	This field is not supported in the current software version. Backup outgoing label. A value of 4294967295 indicates that the backup outgoing label is invalid.
BkOutLabel flag	This field is not supported in the current software version. Backup outgoing label flag: • **E**—Explicit null flag. The upstream neighbor must replace the SID with an explicit null flag before forwarding the packets. • **I**—Implicit null flag. The upstream neighbor must replace the SID with an implicit null flag before forwarding the packets. • **N**—Normal flag. • **P**—SR label preferred flag.

display ospf spf-tree

Use **display ospf spf-tree** to display SPF tree information.

Syntax

display ospf [*process-id*] [**area** *area-id*] **spf-tree** [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify a process, this command displays SPF tree information for all OSPF processes.

area *area-id*: Specifies an OSPF area by its ID. The area ID is an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format. If you do not specify an area, this command displays SPF tree information for all OSPF areas.

verbose: Displays detailed SPF tree information. If you do not specify this keyword, the command displays brief SPF tree information.

Examples

Display brief SPF tree information for Area 0 in OSPF process 1.

```
<Sysname> display ospf 1 area 0 spf-tree

          OSPF Process 1 with Router ID 100.0.0.4

        Flags: S-Node is on SPF tree       R-Node is directly reachable
               I-Node or Link is init      D-Node or Link is to be deleted
               P-Neighbor is parent        A-Node is in candidate list
               C-Neighbor is child         T-Node is tunnel destination
               H-Nexthop changed           N-Link is a new path
               V-Link is involved          G-Link is in change list

                  Area: 0.0.0.0  Shortest Path Tree

 SpfNode         Type    Flag      SpfLink         Type   Cost  Flag
>192.168.119.130 Network S R
                                 -->114.114.114.111 NET2RT 0     C
                                 -->100.0.0.4       NET2RT 0     P
>114.114.114.111 Router  S
                                 -->192.168.119.130 RT2NET 65535 P
>100.0.0.4       Router  S
                                 -->192.168.119.130 RT2NET 10    C
```

Table 32 Command output

Field	Description
SpfNode	SPF node, represented by a router ID when the node type is **Router**, or the IP address of the DR when the node type is **Network**. Node flag: • **I**—The node is in initialization state. • **A**—The node is on the candidate list. • **S**—The node is on the SPF tree. • **R**—The node is directly connected to the root node. • **D**—The node is to be deleted. • **T**—The node is the tunnel destination.
SpfLink	SPF link, representing the peer node. Link type: • **RT2RT**—Router to router. • **NET2RT**—Network to router. • **RT2NET**—Router to network. Link flag: • **I**—The link is in initialization state. • **P**—The peer is the parent node. • **C**—The peer is the child node. • **D**—The link is to be deleted. • **H**—The next hop is changed. • **V**—When the peer node is deleted or added, the peer node is not on the SPF tree or is deleted. • **N**—The link is newly added, and both end nodes are on the SPF tree. • **G**—The link is on the area change list.

Display detailed SPF tree information for Area 0 in OSPF process 1.

```
<Sysname> display ospf 1 area 0 spf-tree verbose

          OSPF Process 1 with Router ID 100.0.0.4

```

Table 33 Command output

Field	Description
LsId	Link state ID.
AdvId	ID of the advertising router.
NodeType	Node type: • **Network**—Network node. • **Router**—Router node.
Mask	Network mask. Its value is 0 for a router node.
SPFLinkCnt	Number of SPF links.
Distance	Cost to the root node.
VlinkData	Destination address of virtual link packets.
ParentLinkCnt	Number of parent links.
NodeFlag	Node flag: • **I**—The node is in initialization state. • **A**—The node is on the candidate list. • **S**—The node is on the SPF tree. • **R**—The node is directly connected to the root node. • **D**—The node is to be deleted. • **T**—The node is the tunnel destination.
NextHop	Next hop.
Interface	Output interface.
Flag	This field is not supported in the current software version. Identifies the type of the next hop. **SR** means SR tunnel. For other types, this field displays a hyphen (**-**).
Protect	Traffic protection type: **Link** or **Node**.
BkNextHop	Backup next hop.
LinkId	Link ID.
LinkType	Link type: • **RT2RT**—Router to router. • **NET2RT**—Network to router. • **RT2NET**—Router to network.
LinkCost	Link cost.

Field	Description
NextHopCnt	Number of next hops.
LinkData	Link data.
LinkNewCost	New link cost.
LinkFlag	Link flag: • **I**—The link is in initialization state. • **P**—The peer is the parent node. • **C**—The peer is the child node. • **D**—The link is to be deleted. • **H**—The next hop is changed. • **V**—When the peer node is deleted or added, the peer node is not on the SPF tree or is deleted. • **N**—The link is newly added, and both end nodes are on the SPF tree. • **G**—The link is on the area change list.

display ospf statistics

Use **display ospf statistics** to display OSPF statistics.

Syntax

display ospf [*process-id*] **statistics** [**error** | **packet** [**hello** | *interface-type interface-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPF statistics for all OSPF processes.

error: Displays error statistics. If you do not specify this keyword, the command displays OSPF packet, LSA, and route statistics.

packet: Displays OSPF packet statistics.

hello: Displays statistics of the sent and received hello packets. If you do not specify this keyword, the command displays statistics of all types of sent and received packets.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays statistics for all interfaces.

Examples

Display OSPF statistics.

```
<Sysname> display ospf statistics
```

```
         OSPF Process 1 with Router ID 2.2.2.2
                 Statistics

I/O statistics

Table 34 Command output

Field	Description
I/O statistics	Statistics about input/output packets and LSAs.
Type	OSPF packet type.
Input	Packets received.
Output	Packets sent.
Hello	Hell packet.
DB Description	Database Description packet.
Link-State Req	Link-State Request packet.
Link-State Update	Link-State Update packet.
Link-State Ack	Link-State Acknowledge packet.
LSAs originated by this router	LSAs originated by this router.
Router	Number of Type-1 LSAs originated.
Network	Number of Type-2 LSAs originated.
Sum-Net	Number of Type-3 LSAs originated.
Sum-Asbr	Number of Type-4 LSAs originated.
External	Number of Type-5 LSAs originated.

Field	Description
NSSA	Number of Type-7 LSAs originated.
Opq-Link	Number of Type-9 LSAs originated.
Opq-As	Number of Type-11 LSAs originated.
LSA originated	Number of LSAs originated.
LSA received	Number of LSAs received.
Routing table	Routing table information.
Intra area	Number of intra-area routes.
Inter area	Number of inter-area routes.
ASE/NSSA	Number of ASE/NSSA routes.

Display OSPF error statistics.

```
<Sysname> display ospf statistics error

          OSPF Process 1 with Router ID 192.168.1.112
                  OSPF Packet Error Statistics

 0          : Router ID confusion        0          : Bad packet
 0          : Bad version                0          : Bad checksum

```

Table 35 Command output

Field	Description
Router ID confusion	Packets with duplicate router ID.
Bad packet	Packets illegal.
Bad version	Packets with wrong version.
Bad checksum	Packets with wrong checksum.
Bad area ID	Packets with invalid area ID.
Drop on unnumbered link	Packets dropped on the unnumbered interface.
Bad virtual link	Packets on wrong virtual links.
Bad authentication type	Packets with invalid authentication type.
Bad authentication key	Packets with invalid authentication key.

Field	Description
Packet too small	Packets too small in length.
Neighbor state low	Packets received in low neighbor state.
Transmit error	Packets with error when being transmitted.
Interface down	Shutdown times of the interface.
Unknown neighbor	Packets received from unknown neighbors.
HELLO: Netmask mismatch	Hello packets with mismatched mask.
HELLO: Hello-time mismatch	Hello packets with mismatched hello timer.
HELLO: Dead-time mismatch	Hello packets with mismatched dead timer.
HELLO: Ebit option mismatch	Hello packets with mismatched E-bit in the option field.
DD: MTU option mismatch	DD packets with mismatched MTU.
DD: Unknown LSA type	DD packets with unknown LSA type.
DD: Ebit option mismatch	DD packets with mismatched E-bit in the option field.
ACK: Bad ack	Bad LSAck packets for LSU packets.
ACK: Unknown LSA type	LSAck packets with unknown LSA type.
REQ: Empty request	LSR packets with no request information.
REQ: Bad request	Bad LSR packets.
UPD: LSA checksum bad	LSU packets with wrong LSA checksum.
UPD: Unknown LSA type	LSU packets with unknown LSA type.
UPD: Less recent LSA	LSU packets without the most recent LSA.

Display OSPF packet statistics for all processes and interfaces.

```
<Sysname> display ospf statistics packet

          OSPF Process 100 with Router ID 192.168.1.59
                  Packet Statistics

 Waiting to send packet count: 0
         Hello      DD         LSR        LSU        ACK        Total
 Input : 489        6          2          44         40         581
 Output: 492        8          2          45         40         587

 Area: 0.0.0.1
 Interface: 20.1.1.1 (GigabitEthernet1/0/1)
         DD         LSR        LSU        ACK        Total
 Input : 0          0          0          0          0
 Output: 0          0          0          0          0

 Interface: 100.1.1.1 (GigabitEthernet1/0/2)
         DD         LSR        LSU        ACK        Total
 Input : 3          1          22         16         42
 Output: 2          1          19         20         42
```

Table 36 Command output

Field	Description
Waiting to send packet count	Number of packets waiting to be sent.
Total	Total number of packets.
Input	Number of received packets.
Output	Number of sent packets.
Area	Area ID.
Interface	Interface address and interface name.

Display statistics of the sent and received hello packets.

```
<Sysname> display ospf statistics packet hello

          OSPF Process 1 with Router ID 1.1.1.1
                  Hello statistics
   Total sent                            : 201
   Total sent failed                     : 0
   Sent after one and a half intervals   : 0
   Total received                        : 221
   Total received dropped                : 0
   Received after one and a half intervals: 0
```

Table 37 Command output

Field	Description
Total sent	Total number of hello packets sent.
Total sent failed	Total number of hello packets that failed to be sent.
Sent after one and a half intervals	Total number of hello packets sent at intervals greater than 1.5 times the hello interval.
Total received	Total number of hello packets received.
Total received dropped	Total number of received hello packets that were dropped.
Received after one and a half intervals	Total number of hello packets received at intervals greater than 1.5 times the hello interval.

Related commands

`reset ospf statistics`

display ospf vlink

Use **`display ospf vlink`** to display OSPF virtual link information.

Syntax

`display ospf` [*`process-id`*] **`vlink`**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the OSPF virtual link information for all OSPF processes.

Examples

Display OSPF virtual link information.

```
<Sysname> display ospf vlink
          OSPF Process 1 with Router ID 3.3.3.3
                  Virtual Links

 Virtual-link Neighbor-ID  -> 2.2.2.2, Neighbor-State: Full
 Interface: 10.1.2.1 (GigabitEthernet1/0/1)
 Cost: 1562  State: P-2-P  Type: Virtual
 Transit Area: 0.0.0.1
 Timers: Hello 10 , Dead 40 , Retransmit 5 , Transmit Delay 1
 Cryptographic authentication: Enabled
    The last key is 1.
```

Table 38 Command output

Field	Description
Virtual-link Neighbor-ID	ID of the neighbor on the virtual link.
Neighbor-State	Neighbor state: Down, Init, 2-Way, ExStart, Exchange, Loading, Full.
Interface	IP address and name of the local interface on the virtual link.
Cost	Interface route cost.
State	Interface state.
Type	Virtual link.
Transit Area	Transit area ID.
Timers	Values of timers (in seconds): **Hello**, **Dead**, and **Retransmit**.
Transmit Delay	LSA transmission delay on the interface, in seconds.
Keychain authentication: Enabled (*xx*), inherited	Keychain authentication is enabled. **xx** represents the name of the keychain. If the virtual link uses the authentication mode of the backbone area, this field displays **inherited** after the authentication mode.
Cryptographic authentication: Enabled, inherited	Authentication mode used by the virtual link. If the virtual link uses the authentication mode of the backbone area, this field displays **inherited** after the authentication mode. Optional authentication modes include: • **Simple**—Simple authentication. • **Cryptographic**—Encrypted authentication. Options include MD5, HMAC-MD5, or HMAC-SHA-256.
The last key is *xx*	The most recent MD5/HMAC-MD5/HMAC-SHA-256 authentication key ID is *xx*.

Field	Description
The rollover is in progress, *xx* neighbor(s) left	Key rollover for MD5/HMAC-MD5/HMAC-SHA-256 authentication is in progress. The number of neighbors that have not completed rollover is *xx*.

display router id

Use **display router id** to display the global router ID.

Display the global router ID.

```
<Sysname> display router id
         Configured router ID is 1.1.1.1
```

distribute bgp-ls

Use **distribute bgp-ls** to enable the device to advertise OSPF link state information to BGP.

Use **undo distribute bgp-ls** to restore the default.

Syntax

distribute bgp-ls [**instance-id** *id*] [**strict-link-checking**]

undo distribute bgp-ls

Default

The device does not advertise OSPF link state information to BGP.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

instance-id *id*: Specifies an instance by its ID in the range of 0 to 65535. If you do not specify an instance, this command advertises OSPF link state information of instance 0 to BGP.

strict-link-checking: Enables strict checking on link state information advertised to BGP. If you specify this keyword, the local and remote ends of a link must be in the same subnet so that the

link state information can be advertised to BGP. If you do not specify this keyword, the link state information is advertised to BGP even if the local and remote ends of the link are in different subnets. This keyword applies only to P2P links.

Usage guidelines

After the device advertises OSPF link state information to BGP, BGP can advertise the information for intended applications.

If multiple OSPF processes have the same link state information and instance ID, only the link state information of the OSPF process with the smallest process ID is advertised.

To advertise the same link state information of different OSPF processes to BGP, specify a different instance ID for each OSPF process.

As a best practice, enable strict link state information checking when the following conditions exist:

- The link state information advertised to BGP contains multiple equal-cost links.
- The local and remote ends of each equal-cost link are in the same subnet.

This prevents the device from advertising error link state information to BGP when the equal-cost links flap.

Strict link state information checking and prefix suppression are mutually exclusive. Before you enable strict link state information checking, make sure prefix suppression is disabled.

Examples

Enable the device to advertise link state information for OSPF process 1 to BGP.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] distribute bgp-ls
```

dscp

Use **dscp** to set the DSCP value for outgoing OSPF packets.

Use **undo dscp** to restore the default.

Syntax

dscp *dscp-value*

undo dscp

Default

The DSCP value for outgoing OSPF packets is 48.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

dscp-value: Specifies the DSCP value in the range of 0 to 63 for outgoing OSPF packets.

Examples

Set the DSCP value for outgoing OSPF packets to 63 in OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
```

```
[Sysname-ospf-1] dscp 63
```

ecmp-group enable

Use **ecmp-group enable** to enable OSPF to group ECMP routes.

Use **undo ecmp-group enable** to restore the default.

Syntax

ecmp-group enable

undo ecmp-group enable

Default

OSPF does not group ECMP routes.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Usage guidelines

Configure this command to enable OSPF to group ECMP routes by prefix to speed up route convergence.

This command is applicable to a network when the network has a large number of ECMP routes and different route prefixes in the network have the same next hops. For example, OSPF learns 10000 route prefixes and all route prefixes have the same 16 next hops (1.1.1.1 to 1.1.1.16). If you do not configure this command, OSPF has to send all ECMP routes of every route prefix (10000 × 16 routes) to the route management module. After you configure this command, OSPF groups the ECMP routes by prefix and sends the route groups (10000 route groups) to the route management module.

If the output interfaces to the next hops of ECMP routes are TE tunnel interfaces, OSPF groups the ECMP routes regardless of whether you enable this feature or not.

Examples

Enable OSPF process 1 to group ECMP routes.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] ecmp-group enable
```

enable link-local-signaling

Use **enable link-local-signaling** to enable the OSPF link-local signaling (LLS) capability.

Use **undo enable link-local-signaling** to disable the OSPF LLS capability.

Syntax

enable link-local-signaling

undo enable link-local-signaling

Default

OSPF link-local signaling capability is disabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Examples

Enable link-local signaling for OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] enable link-local-signaling
```

enable out-of-band-resynchronization

Use **enable out-of-band-resynchronization** to enable the OSPF out-of-band resynchronization (OOB-Resynch) capability.

Use **undo enable out-of-band-resynchronization** to disable the OSPF out-of-band resynchronization capability.

Syntax

enable out-of-band-resynchronization

undo enable out-of-band-resynchronization

Default

The OSPF out-of-band resynchronization capability is disabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Usage guidelines

Before you configure this command, enable the link-local signaling capability.

Examples

Enable the out-of-band resynchronization capability for OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] enable link-local-signaling
[Sysname-ospf-1] enable out-of-band-resynchronization
```

Related commands

enable link-local-signaling

event-log

Use **event-log** to set the number of OSPF logs.

Use **undo event-log** to remove the configuration.

Syntax

event-log { **hello** { **received** [**abnormal** | **dropped**] | **sent** [**abnormal** | **failed**] } | **lsa-flush** | **peer** | **spf** } **size** *count*

undo event-log { **hello** { **received** [**abnormal** | **dropped**] | **sent** [**abnormal** | **failed**] } | **lsa-flush** | **peer** | **spf** } **size**

Default

The device can generate a maximum of 100 logs for each type.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

hello: Specifies the number of logs for received or sent hello packets.

received: Specifies the number of logs for received hello packets.

sent: Specifies the number of logs for sent hello packets.

abnormal: Specifies the number of logs for abnormal hello packets received or sent at intervals greater than or equal to 1.5 times the hello interval.

dropped: Specifies the number of logs for received hello packets that were dropped.

failed: Specifies the number of logs for hello packets that failed to be sent.

lsa-flush: Specifies the number of LSA aging logs.

peer: Specifies the number of neighbor state change logs.

spf: Specifies the number of route calculation logs.

size *count*: Specifies the number of OSPF logs, in the range of 0 to 65535.

Examples

Set the number of route calculation logs to 50 in OSPF process 100.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] event-log spf size 50
```

fast-reroute

Use **fast-reroute** to configure OSPF FRR.

Use **undo fast-reroute** to restore the default.

Syntax

fast-reroute { **lfa** [**abr-only**] | **route-policy** *route-policy-name* }

undo fast-reroute

Default

OSPF FRR is disabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

lfa: Uses the LFA algorithm to calculate a backup next hop for all routes.

abr-only: Uses the next hop of the route to the ABR as the backup next hop.

route-policy *route-policy-name*: Uses a routing policy to designate a backup next hop. The *route-policy-name* argument is a case-sensitive string of 1 to 63 characters.

Usage guidelines

When both OSPF FRR and PIC are configured, OSPF FRR takes effect.

Do not use the **fast-reroute lfa** command together with the **vlink-peer** command.

Examples

Enable FRR to calculate a backup next hop for all routes by using LFA algorithm in OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] fast-reroute lfa
```

fast-reroute tiebreaker

Use **fast-reroute tiebreaker** to set the priority for the node-protection or lowest-cost backup path selection policy.

Use **undo fast-reroute tiebreaker** to restore the default.

Syntax

fast-reroute tiebreaker { **lowest-cost** | **node-protecting** } **preference** *preference*

undo fast-reroute tiebreaker { **lowest-cost** | **node-protecting** }

Default

The priority values of the node-protection and lowest-cost backup path selection policies are 40 and 20, respectively.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

lowest-cost: Sets a priority value for the lowest-cost backup path selection policy.

node-protecting: Sets a priority value for the node-protection backup path selection policy.

preference *preference*: Specifies a priority value in the range of 1 to 255. A higher value indicates a higher priority.

Usage guidelines

If you execute this command multiple times for a backup path selection policy, the most recent configuration takes effect.

If the node-protection policy has the higher priority but the backup path calculation still fails, OSPF uses the lowest-cost policy for further calculation.

If the lowest-cost policy has the higher priority but the backup path calculation still fails, OSPF does not perform further backup path calculation.

Examples

Set the priority value of the node-protection backup path selection policy to 100.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] fast-reroute tiebreaker node-protecting preference 100
```

Related commands

fast-reroute

filter

Use **filter** to configure OSPF to filter inbound/outbound Type-3 LSAs on an ABR.

Use **undo filter** to disable Type-3 LSA filtering.

Syntax

filter { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } { **export** | **import** }

undo filter { **export** | **import** }

Default

Type-3 LSAs are not filtered.

Views

OSPF area view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-acl-number: Specifies an IPv4 ACL by its number in the range of 2000 to 3999 to filter inbound/outbound Type-3 LSAs.

prefix-list-name: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter inbound/outbound Type-3 LSAs.

route-policy-name: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter inbound/outbound Type-3 LSAs.

export: Filters Type-3 LSAs advertised to other areas.

import: Filters Type-3 LSAs advertised into the local area.

Usage guidelines

This command applies only to an ABR.

When you specify an ACL, follow these guidelines:

- If the ACL does not exist or has no rules, the ABR does not filter Type-3 LSAs.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all Type-3 LSAs.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following methods:

- To deny/permit Type-3 LSAs with the specified link state ID, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.
- To deny/permit Type-3 LSAs with the specified link state ID and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the link state ID of a Type-3 LSA and the **destination** keyword specifies the subnet mask of the LSA. For the mask configuration to take effect, specify a contiguous subnet mask.

Examples

Use IP prefix list **my-prefix-list** to filter inbound Type-3 LSAs. Use basic ACL 2000 to filter outbound Type-3 LSAs in OSPF Area 1.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 1
[Sysname-ospf-100-area-0.0.0.1] filter prefix-list my-prefix-list import
[Sysname-ospf-100-area-0.0.0.1] filter 2000 export
```

filter-policy export

Use **filter-policy export** to configure OSPF to filter redistributed routes.

Use **undo filter-policy export** to remove the configuration.

Syntax

filter-policy { *ipv4-acl-number* | **prefix-list** *prefix-list-name* } **export** [**bgp** | **direct** | { **isis** | **ospf** | **rip** } [*process-id*] | **static**]

undo filter-policy export [**bgp** | **direct** | { **isis** | **ospf** | **rip** } [*process-id*] | **static**]

Default

OSPF does not filter redistributed routes.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-acl-number: Specifies an IPv4 ACL by its number in the range of 2000 to 3999 to filter redistributed routes by destination address.

prefix-list-name: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter redistributed routes by destination address.

bgp: Filters routes redistributed from BGP.

direct: Filters direct routes.

isis: Filters routes redistributed from IS-IS.

ospf: Filters routes redistributed from OSPF.

rip: Filters routes redistributed from RIP.

process-id: Specifies a process by its ID in the range of 1 to 65535. The default value is 1.

Usage guidelines

If you do not specify any parameters, the command filters all redistributed routes.

When you specify an ACL, follow these guidelines:

- If the ACL does not exist or has no rules, OSPF does not filter redistributed routes.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all redistributed routes.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following methods:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.
- To deny/permit a route with the specified destination and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the subnet mask of the destination address. For the mask configuration to take effect, specify a contiguous subnet mask.

Examples

Configure OSPF process 100 to filter redistributed routes by using basic ACL 2000.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule deny source 192.168.10.0 0.0.0.255
[Sysname-acl-ipv4-basic-2000] quit
[Sysname] ospf 100
[Sysname-ospf-100] filter-policy 2000 export
```

Configure advanced ACL 3000 to permit only route 113.0.0.0/16. Configure OSPF process 100 to filter redistributed routes by using advanced ACL 3000.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule 10 permit ip source 113.0.0.0 0 destination 255.255.0.0
0
[Sysname-acl-ipv4-adv-3000] rule 100 deny ip
[Sysname-acl-ipv4-adv-3000] quit
[Sysname] ospf 100
[Sysname-ospf-100] filter-policy 3000 export
```

Related commands

import-route

filter-policy import

Use **filter-policy import** to configure OSPF to filter routes calculated using received LSAs.

Use **undo filter-policy import** to restore the default.

Syntax

filter-policy { *ipv4-acl-number* [**gateway** *prefix-list-name*] | **gateway** *prefix-list-name* | **prefix-list** *prefix-list-name* [**gateway** *prefix-list-name*] | **route-policy** *route-policy-name* } **import**

undo filter-policy import

Default

OSPF does not filter routes calculated using received LSAs.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-acl-number: Specifies an IPv4 ACL by its number in the range of 2000 to 3999 to filter received routes by destination.

gateway *prefix-list-name*: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter received routes by next hop.

prefix-list *prefix-list-name*: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter received routes by destination.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter received routes.

Usage guidelines

When you specify an ACL, follow these guidelines:

- If the ACL does not exist or has no rules, OSPF does not filter calculated routes.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all calculated routes.

To use an advanced ACL (with a number from 3000 to 3999) in the command or in the specified routing policy, configure the ACL in one of the following ways:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.
- To deny/permit a route with the specified destination and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the subnet mask of the destination address. For the mask configuration to take effect, specify a contiguous subnet mask.

Examples

Use basic ACL 2000 to filter received routes.

```
<Sysname> system-view
[Sysname] acl basic 2000
```

```
[Sysname-acl-ipv4-basic-2000] rule deny source 192.168.10.0 0.0.0.255
[Sysname-acl-ipv4-basic-2000] quit
[Sysname] ospf 100
[Sysname-ospf-100] filter-policy 2000 import
```

Configure advanced ACL 3000 to permit only route 113.0.0.0/16. Use ACL 3000 to filter received routes.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule 10 permit ip source 113.0.0.0 0 destination 255.255.0.0
0
[Sysname-acl-ipv4-adv-3000] rule 100 deny ip
[Sysname-acl-ipv4-adv-3000] quit
[Sysname] ospf 100
[Sysname-ospf-100] filter-policy 3000 import
```

graceful-restart

Use **graceful-restart** to enable OSPF GR.

Use **undo graceful-restart** to disable OSPF GR.

Syntax

graceful-restart [**ietf** | **nonstandard**] [**global** | **planned-only**] *

undo graceful-restart

Default

OSPF GR is disabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

ietf: Enables IETF GR.

nonstandard: Enables non-IETF GR.

global: Enables global GR. In global GR mode, a GR process can be completed only when all GR helpers exist. A GR process fails if a GR helper fails (for example, the interface connected to the GR helper goes down). If you do not specify this keyword, the command enables partial GR. In partial GR mode, a GR process can be completed if a GR helper exists.

planned-only: Enables only planned GR. If you do not specify this keyword, the command enables both planned GR and unplanned GR.

Usage guidelines

GR includes planned GR and unplanned GR.

- **Planned GR**—Manually restarts OSPF by using the **reset ospf process** command or performs an active/standby process switchover by using the **placement reoptimize** command. Before OSPF restart or active/standby switchover, the GR restarter sends Grace-LSAs to GR helpers.

- **Unplanned GR**—OSPF restarts or an active/standby switchover occurs because of device failure. Before OSPF restart or active/standby switchover, the GR restarter does not send Grace-LSAs to GR helpers.

Before enabling IETF GR for OSPF, enable Opaque LSA advertisement and reception with the **opaque-capability enable** command.

Before enabling non-IETF GR for OSPF, enable OSPF LLS with the **enable link-local-signaling** command and OOB-Resynch with the **enable out-of-band-resynchronization** command.

If you do not specify the **nonstandard** or **ietf** keyword, this command enables non-IETF GR for OSPF.

OSPF GR and OSPF NSR are mutually exclusive. Do not configure the **graceful-restart** command and the **non-stop-routing** command at the same time.

Examples

Enable IETF GR for OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] opaque-capability enable
[Sysname-ospf-1] graceful-restart ietf
```

Enable non-IETF GR for OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] enable link-local-signaling
[Sysname-ospf-1] enable out-of-band-resynchronization
[Sysname-ospf-1] graceful-restart nonstandard
```

Related commands

enable link-local-signaling

enable out-of-band-resynchronization

opaque-capability enable

graceful-restart helper enable

Use **graceful-restart helper enable** to enable OSPF GR helper capability.

Use **undo graceful-restart helper enable** to disable OSPF GR helper capability.

Syntax

graceful-restart helper enable [**planned-only**]

undo graceful-restart helper enable

Default

OSPF GR helper capability is enabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

planned-only: Enables only planned GR for the GR helper. If you do not specify this keyword, the command enables both planned GR and unplanned GR for the GR helper.

Usage guidelines

The **planned-only** keyword is available only for the IETF GR helper.

Examples

Enable GR helper capability for OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] graceful-restart helper enable
```

graceful-restart helper strict-lsa-checking

Use **graceful-restart helper strict-lsa-checking** to enable strict LSA checking capability for GR helper.

Use **undo graceful-restart helper strict-lsa-checking** to disable strict LSA checking capability for GR helper.

Syntax

graceful-restart helper strict-lsa-checking

undo graceful-restart helper strict-lsa-checking

Default

Strict LSA checking capability for GR helper is disabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Usage guidelines

When an LSA change on the GR helper is detected, the GR helper device exits the GR helper mode.

Examples

Enable strict LSA checking capability for GR helper in OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] graceful-restart helper strict-lsa-checking
```

graceful-restart interval

Use **graceful-restart interval** to set the GR interval.

Use **undo graceful-restart interval** to restore the default.

Syntax

graceful-restart interval *interval*

undo graceful-restart interval

Default

The GR interval is 120 seconds.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the GR interval in the range of 40 to 1800 seconds.

Usage guidelines

For GR restart to succeed, the value of the GR restart interval cannot be smaller than the maximum OSPF neighbor dead time of all the OSPF interfaces.

Examples

Set the GR interval for OSPF process 1 to 100 seconds.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] graceful-restart interval 100
```

Related commands

ospf timer dead

host-advertise

Use **host-advertise** to advertise a host route.

Use **undo host-advertise** to remove a host route.

Syntax

host-advertise *ip-address cost-value*

undo host-advertise *ip-address*

Default

No host route is advertised.

Views

OSPF area view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IP address of a host.

cost-value: Specifies a cost for the route, in the range of 1 to 65535.

Examples

Advertise host route 1.1.1.1 with a cost of 100.

```
<Sysname> system-view
```

```
[Sysname] ospf 100
[Sysname-ospf-100] area 0
[Sysname-ospf-100-area-0.0.0.0] host-advertise 1.1.1.1 100
```

hostname

Use **hostname** to enable the OSPF dynamic host name mapping feature.

Use **undo hostname** to disable the OSPF dynamic host name mapping feature.

Syntax

hostname [*host-name*]

undo hostname

Default

The OSPF dynamic host name mapping feature is disabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

host-name: Specifies the host name mapped to the router ID of the OSPF process, a case-sensitive string of 1 to 255 characters. If you do not specify this argument, the device name is mapped to the router ID of the OSPF process.

Usage guidelines

OSPF uses Type-11 LSAs to carry information about the dynamic host name attribute. Therefore, make sure the opaque LSA reception and advertisement capability is enabled.

Examples

Enable the dynamic host name mapping feature for OSPF process 1, and specify the host name mapped to the router ID as **red**.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] hostname red
```

Related commands

display ospf hostname-table

opaque-capability enable

import-route

Use **import-route** to enable route redistribution.

Use **undo import-route** to disable route redistribution.

Syntax

import-route bgp [*as-number*] [**allow-ibgp**] [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

import-route { **direct** | **guard** | **static** } [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

import-route { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] [**allow-direct** | **cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

undo import-route { **bgp** | **direct** | **guard** | { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] | **static** }

Default

OSPF does not redistribute routes.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

bgp: Redistributes BGP routes.

direct: Redistributes direct routes.

guard: Redistributes guard routes.

isis: Redistributes IS-IS routes.

ospf: Redistributes OSPF routes.

rip: Redistributes RIP routes.

static: Redistributes static routes.

as-number: Redistributes routes in an AS specified by its number in the range of 1 to 4294967295. If you do not specify this argument, this command redistributes all IPv4 EBGP routes. As a best practice, specify an AS number to prevent the system from redistributing excessive IPv4 EBGP routes.

process-id: Specifies a process by its ID in the range of 1 to 65535. The default is 1.

all-processes: Redistributes routes from all the processes of the specified routing protocol.

allow-ibgp: Redistributes IBGP routes. The **import-route bgp** command redistributes only EBGP routes. Because the **import-route bgp allow-ibgp** command redistributes both EBGP and IBGP routes and might cause routing loops, use it with caution.

allow-direct: Redistributes the networks of the local interfaces enabled with the specified routing protocol. If you do not specify this keyword, the networks of the local interfaces are not redistributed. If you specify both the **allow-direct** keyword and the **route-policy** *route-policy-name* option, make sure the **if-match** rule defined in the routing policy does not conflict with the **allow-direct** keyword. For example, if you specify the **allow-direct** keyword, do not configure the **if-match route-type** rule for the routing policy. Otherwise, the **allow-direct** keyword does not take effect.

cost *cost-value*: Specifies a route cost in the range of 0 to 16777214. The default is 1.

nssa-only: Limits the route advertisement to the NSSA area by setting the P-bit of Type-7 LSAs to 0. If you do not specify this keyword, the P-bit of Type-7 LSAs is set to 1. If the router acts as both an ASBR and an ABR and **FULL** state neighbors exist in the backbone area, the P-bit is set to 0. This keyword applies to NSSA routers.

route-policy *route-policy-name*: Specifies a routing policy to filter redistributed routes. The *route-policy-name* argument is a case-sensitive string of 1 to 63 characters.

tag *tag*: Specifies a tag for external LSAs, in the range of 0 to 4294967295. The default is 1.

type *type*: Specifies a cost type, 1 or 2. The default is 2.

Usage guidelines

This command redistributes routes destined for other ASs from another protocol. AS external routes include the following types:

- **Type-1 external routes**—Have high credibility. The cost of Type-1 external routes is comparable with the cost of OSPF internal routes. The cost of a Type-1 external route equals the cost from the router to the ASBR plus the cost from the ASBR to the external route's destination.
- **Type-2 external routes**—Have low credibility. OSPF considers the cost from the ASBR to the destination of a Type-2 external route is much bigger than the cost from the ASBR to an OSPF internal router. The cost of a Type-2 external route equals the cost from the ASBR to the Type-2 external route's destination.

The **import-route** command redistributes only active routes. To display information about active routes, use the **display ip routing-table protocol** command. The **import-route** command cannot redistribute default external routes.

The **import-route nssa-only** command redistributes AS-external routes in Type-7 LSAs only into the NSSA area.

The **undo import-route** { **isis** | **ospf** | **rip** } **all-processes** command removes only the configuration made by the **import-route** { **isis** | **ospf** | **rip** } **all-processes** command, instead of the configuration made by the **import-route** { **isis** | **ospf** | **rip** } *process-id* command.

Examples

Redistribute routes from RIP process 40 and specify the type, tag, and cost as 2, 33, and 50 for redistributed routes.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] import-route rip 40 type 2 tag 33 cost 50
```

Related commands

default-route-advertise

ispf enable

Use **ispf enable** to enable OSPF incremental SPF (ISPF).

Use **undo ispf enable** to disable OSPF ISPF.

Syntax

ispf enable

undo ispf enable

Default

OSPF ISPF is enabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Usage guidelines

Upon topology changes, ISPF recomputes only the affected part of the SPT, instead of the entire SPT.

Examples

Disable ISPF for OSPF process 100.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] undo ispf enable
```

log-peer-change

Use **log-peer-change** to enable logging for OSPF neighbor state changes.

Use **undo log-peer-change** to disable logging for OSPF neighbor state changes.

Syntax

log-peer-change

undo log-peer-change

Default

Logging for OSPF neighbor state changes is enabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command enables output of OSPF neighbor state changes to the information center. The information center processes the logs according to user-defined output rules (whether and where to output logs). For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Disable logging for neighbor state changes for OSPF process 100.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] undo log-peer-change
```

lsa-arrival-interval

Use **lsa-arrival-interval** to set the LSA arrival interval.

Use **undo lsa-arrival-interval** to restore the default.

Syntax

lsa-arrival-interval *interval*

undo lsa-arrival-interval

Default

The LSA arrival interval is 1000 milliseconds.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the LSA arrival interval in the range of 0 to 60000 milliseconds.

Usage guidelines

If an LSA that has the same LSA type, LS ID, and originating router ID as the previous LSA is received within the interval, OSPF discards the LSA. This feature helps avoid overuse of system resources due to frequent network changes.

As a best practice, set the interval with the **lsa-arrival-interval** command to be smaller than or equal to the minimum interval set with the **lsa-generation-interval** command.

Examples

Set the LSA arrival interval to 200 milliseconds.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] lsa-arrival-interval 200
```

Related commands

lsa-generation-interval

lsa-generation-interval

Use **lsa-generation-interval** to set the OSPF LSA generation interval.

Use **undo lsa-generation-interval** to restore the default.

Syntax

lsa-generation-interval *maximum-interval* [*minimum-interval* [*incremental-interval*]]

undo lsa-generation-interval

Default

The maximum interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

maximum-interval: Specifies the maximum LSA generation interval in the range of 1 to 60 seconds.

minimum-interval: Specifies the minimum LSA generation interval in the range of 10 to 60000 milliseconds.

incremental-interval: Specifies the LSA generation incremental interval in the range of 10 to 60000 milliseconds.

Usage guidelines

When network changes are infrequent, LSAs are generated at the minimum interval. If network changes become frequent, the LSA generation interval increases by the incremental interval × 2^{n-2} for each generation until the maximum interval is reached. The value *n* is the number of generation times.

The minimum interval and the incremental interval cannot be greater than the maximum interval.

Examples

Set the maximum LSA generation interval to 2 seconds, minimum interval to 100 milliseconds, and incremental interval to 100 milliseconds.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] lsa-generation-interval 2 100 100
```

Related commands

lsa-arrival-interval

lsdb-overflow-interval

Use **lsdb-overflow-interval** to set the interval that OSPF exits overflow state.

Use **undo lsdb-overflow-interval** to restore the default.

Syntax

lsdb-overflow-interval *interval*

undo lsdb-overflow-interval

Default

The OSPF exit overflow interval is 300 seconds.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies the interval that OSPF exits overflow state, in the range of 0 to 2147483647 seconds.

Usage guidelines

When the number of LSAs in the LSDB exceeds the upper limit, the LSDB is in an overflow state. In this state, OSPF does not receive any external LSAs and deletes the external LSAs generated by itself to save system resources.

You can configure the interval that OSPF exits overflow state. An interval of 0 indicates that the timer is not started and OSPF does not exit overflow state.

Examples

Set the OSPF exit overflow interval to 10 seconds.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] lsdb-overflow-interval 10
```

lsdb-overflow-limit

Use **lsdb-overflow-limit** to set the upper limit of external LSAs in the LSDB.

Use **undo lsdb-overflow-limit** to restore the default.

Syntax

lsdb-overflow-limit *number*

undo lsdb-overflow-limit

Default

The number of external LSAs is not limited.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the upper limit of external LSAs in the LSDB, in the range of 1 to 1000000.

Examples

Set the upper limit of external LSAs to 400000.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] lsdb-overflow-limit 400000
```

maximum load-balancing

Use **maximum load-balancing** to set the maximum number of equal-cost multi-path (ECMP) routes for load balancing.

Use **undo maximum load-balancing** to restore the default.

Syntax

maximum load-balancing *number*

undo maximum load-balancing

Default

The maximum number of OSPF ECMP routes is 32.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the maximum number of ECMP routes. No ECMP load balancing is available when the number is set to 1.

Usage guidelines

The value range for the *number* argument of the **maximum load-balancing** command depends on the maximum number of ECMP routes supported by the system. You can use the **max-ecmp-num** command to set the maximum number of ECMP routes supported by the system to *m*. After a reboot, the value range for the *number* argument is 1 to *m*.

Examples

Set the maximum number of ECMP routes to 2.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] maximum load-balancing 2
```

network

Use **network** to enable OSPF on the interface attached to the specified network in the area.

Use **undo network** to disable OSPF for the interface attached to the specified network in the area.

Syntax

network *ip-address wildcard-mask*

undo network *ip-address wildcard-mask*

Default

OSPF is not enabled for any interface.

Views

OSPF area view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the IP address of a network.

wildcard-mask: Specifies the wildcard mask of the IP address. For example, the wildcard mask of mask 255.0.0.0 is 0.255.255.255.

Usage guidelines

This command enables OSPF on the interface attached to the specified network. The interface's primary IP address must be in the specified network. If only the interface's secondary IP address is on the network, the interface cannot run OSPF.

Examples

Specify the interface whose primary IP address is on network 131.108.20.0/24 to run OSPF in Area 2.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 2
[Sysname-ospf-100-area-0.0.0.2] network 131.108.20.0 0.0.0.255
```

Related commands

ospf

non-stop-routing

Use **non-stop-routing** to enable OSPF NSR.

Use **undo non-stop-routing** to disable OSPF NSR.

Syntax

non-stop-routing

undo non-stop-routing

Default

OSPF NSR is disabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command takes effect only for the current process. As a best practice, enable OSPF NSR for each process if multiple OSPF processes exist.

OSPF NSR and OSPF GR are mutually exclusive. Do not configure the **non-stop-routing** command and the **graceful-restart** command at the same time.

Examples

Enable NSR for OSPF process 100.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] non-stop-routing
```

nssa

Use **nssa** to configure an area as an NSSA area.

Use **undo nssa** to restore the default.

Syntax

nssa [**default-route-advertise** [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **type** *type*] * | **no-import-route** | **no-summary** | **suppress-fa** | [[[**translate-always**] [**translate-ignore-checking-backbone**]] | **translate-never**] | **translator-stability-interval** *value*] *

undo nssa

Default

No area is configured as an NSSA area.

Views

OSPF area view

Predefined user roles

network-admin

context-admin

Parameters

default-route-advertise: Used on an NSSA ABR or an ASBR only. With this keyword, an NSSA ABR redistributes a default route in a Type-7 LSA into the NSSA area. The ABR redistributes a default route regardless of whether a default route exists in the routing table. With this keyword, an ASBR redistributes a default route in a Type-7 LSA only when the default route exists in the routing table.

cost *cost-value*: Specifies a cost for the default route, in the range of 0 to 16777214. If you do not specify this option, the default cost specified by the **default-cost** command applies.

nssa-only: Limits the default route advertisement to the NSSA area by setting the P-bit of Type-7 LSAs to 0. By default, the P-bit of Type-7 LSAs is set to 1. If the router acts as both an ASBR and an ABR and **FULL** state neighbors exist in the backbone area, the P-bit is set to 0.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. When a default route exists in the routing table and the routing policy is matched, the command redistributes a default route in a Type-7 LSA into the OSPF routing domain. The routing policy modifies values in the Type-7 LSA.

type *type*: Specifies a type for the Type-7 LSA, 1 or 2. If you do not specify this option, the default type specified by the **default type** command applies.

no-import-route: Used on an NSSA ABR to control the **import-route** command to not redistribute routes into the NSSA area.

no-summary: Used only on an ABR to advertise a default route in a Type-3 summary LSA into the NSSA area and to not advertise other summary LSAs into the area. The area is a totally NSSA area.

suppress-fa: Suppresses the forwarding address in the Type-7 LSAs from being placed in the Type-5 LSAs.

translate-always: Always translates Type-7 LSAs to Type-5 LSAs. This keyword takes effect only on an NSSA ABR.

translate-ignore-checking-backbone: Ignores checking for FULL state neighbors in the backbone area during the translator election in the NSSA area.

translate-never: Never translates Type-7 LSAs to Type-5 LSAs. This keyword takes effect only on an NSSA ABR.

translator-stability-interval *value*: Specifies the stability interval of the translator. During the interval, the translator can maintain its translating capability after another device becomes the new translator. The *value* argument is the stability interval in the range of 0 to 900 seconds and

defaults to 0. A value of 0 means the translator does not maintain its translating capability when a new translator arises.

Usage guidelines

All routers attached to an NSSA area must be configured with the **nssa** command in area view.

If you specify the **translate-ignore-checking-backbone** keyword for an ABR, you must also specify the keyword for other ABRs in the NSSA area. This ensures that a translator can be elected among the ABRs.

Examples

Configure Area 1 as an NSSA area.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 1
[Sysname-ospf-100-area-0.0.0.1] nssa
```

Related commands

default-cost

opaque-capability enable

Use **opaque-capability enable** to enable opaque LSA advertisement and reception.

Use **undo opaque-capability** to disable opaque LSA advertisement and reception.

Syntax

opaque-capability enable

undo opaque-capability

Default

The feature is enabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Usage guidelines

After the opaque LSA advertisement and reception capability is enabled, OSPF can receive and advertise Type-9 and Type-11 opaque LSAs.

Examples

Disable opaque LSA advertisement and reception.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] undo opaque-capability
```

ospf

Use **ospf** to enable OSPF and enter OSPF view.

Use **undo ospf** to disable OSPF.

Syntax

ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

undo ospf [*process-id*] [**router-id**]

Default

OSPF is disabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535.

router-id: Specifies an OSPF router ID. If you do not specify an OSPF router ID, the global router ID is used.

auto-select: Automatically obtains an OSPF router ID.

router-id: Manually specifies an OSPF router ID in dotted decimal notation. The value range is from 0.0.0.1 to 255.255.255.255.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the OSPF process runs on the public network.

Usage guidelines

Enable an OSPF process before performing other tasks.

You can enable multiple OSPF processes on a router and specify different router IDs for them.

If you specify the **auto-select** keyword, the OSPF process obtains a router ID in the following ways:

- During the startup of the OSPF process, the primary IPv4 address of the first interface that runs the process is specified as the router ID.
- During the reboot of the router, the primary IPv4 address of the first interface that runs the process is specified as the router ID.
- During the restart of the OSPF process, the highest primary IPv4 address of the loopback interface that runs the process is specified as the router ID. If no loopback address is available, the highest primary IPv4 address of the interface that runs the process is used, regardless of the interface state (up or down).

If you do not specify the **router-id** keyword, the **undo ospf** command shuts down an OSPF process. If you specify the **router-id** keyword, the **undo ospf** command specifies the global router ID as the router ID. The setting takes effect after the OSPF process restarts.

Examples

Enable OSPF process 100 and specify router ID 10.10.10.1.

```
<Sysname> system-view
[Sysname] ospf 100 router-id 10.10.10.1
[Sysname-ospf-100]
```

ospf area

Use **ospf area** to enable OSPF on an interface.

Use **undo ospf area** to disable OSPF on an interface.

Syntax

ospf *process-id* **area** *area-id* [**exclude-subip**]

undo ospf *process-id* **area** [**exclude-subip**]

Default

OSPF is not enabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535.

area-id: Specifies an area by its ID, an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format.

exclude-subip: Excludes secondary IP addresses. If you do not specify this keyword, the command enables OSPF also on secondary IP addresses.

Usage guidelines

The **ospf area** command has a higher priority than the **network** command.

If the specified process and area do not exist, the command creates the process and area. Disabling an OSPF process on an interface does not delete the OSPF process or the area.

Examples

Enable OSPF process 1 on GigabitEthernet 1/0/2 that is in Area 2 and exclude secondary IP addresses.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] ospf 1 area 2 exclude-subip
```

Related commands

network

ospf authentication-mode

Use **ospf authentication-mode** to set the authentication mode and key on an interface.

Use **undo ospf authentication-mode** to remove specified configuration.

Syntax

For MD5/HMAC-MD5 authentication:

ospf authentication-mode { **hmac-md5** | **hmac-sha-256** | **md5** } *key-id* { **cipher** | **plain** } *string*

undo ospf authentication-mode { **hmac-md5** | **hmac-sha-256** | **md5** } *key-id*

For simple authentication:

ospf authentication-mode simple { **cipher** | **plain** } *string*

undo ospf authentication-mode simple

For keychain authentication:

ospf authentication-mode keychain *keychain-name*

undo ospf authentication-mode keychain

Default

No authentication is performed for an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

hmac-md5: Specifies HMAC-MD5 authentication.

hmac-sha-256: Specifies HMAC-SHA-256 authentication.

md5: Specifies MD5 authentication.

simple: Specifies simple authentication.

key-id: Specifies a key by its ID in the range of 1 to 255.

cipher: Specifies a key in encrypted form.

plain: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive.

- In simple authentication mode, the plaintext form of the key is a string of 1 to 8 characters. The encrypted form of the key is a string of 33 to 41 characters.
- In MD5/HMAC-MD5/HMAC-SHA-256 authentication mode, the plaintext form of the key is a string of 1 to 255 characters. The encrypted form of the key is a string of 33 to 373 characters.

keychain: Specifies keychain authentication.

keychain-name: Specifies a keychain by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

To establish or maintain adjacencies, interfaces attached to the same network segment must have the same authentication mode and key.

If MD5, HMAC-MD5, or HMAC-SHA-256 authentication is configured, you can configure multiple keys, each having a unique key ID and key string. To minimize the risk of key compromise, use only one key for an interface and delete the old key after key replacement.

To replace the key used for MD5, HMAC-MD5, or HMAC-SHA-256 authentication on an interface, you must configure the new key before removing the old key from each router. OSPF uses the key rollover mechanism to ensure that the routers can pass authentication before the replacement is complete on the interface. After you configure a new key on a router, the router sends copies of the same packet, each authenticated by a different key, including the new key and the keys in use. This practice continues until the router detects that all its neighbors have the new key.

When keychain authentication is configured for an OSPF interface, OSPF performs the following operations before sending a packet:

1. Obtains a valid send key from the keychain.

   OSPF does not send the packet if it fails to obtain a valid send key.

2. Uses the key ID, authentication algorithm, and key string to authenticate the packet.

   If the key ID is greater than 255, OSPF does not send the packet.

When keychain authentication is configured for an OSPF interface, OSPF performs the following operations after receiving a packet:

1. Uses the key ID carried in the packet to obtain a valid accept key from the keychain.

   OSPF discards the packet if it fails to obtain a valid accept key.

2. Uses the authentication algorithm and key string for the valid accept key to authenticate the packet.

   If the authentication fails, OSPF discards the packet.

The authentication algorithm can only be MD5, HMAC-SM3, HMAC-MD5, or HMAC-SHA-256 and the ID of keys used for keychain authentication can only be in the range of 0 to 255.

Examples

On GigabitEthernet 1/0/1, enable MD5 authentication, and set the interface key ID to 15 and the key to **123456** in plaintext form.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf authentication-mode md5 15 plain 123456
```

On GigabitEthernet 1/0/1, enable simple authentication, and set the key to **123456** in plaintext form.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf authentication-mode simple plain 123456
```

Related commands

authentication-mode

ospf bfd enable

Use **ospf bfd enable** to enable BFD on an OSPF interface.

Use **undo ospf bfd enable** to disable BFD on an OSPF interface.

Syntax

ospf bfd enable [**echo**]

undo ospf bfd enable

Default

BFD for OSPF is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

echo: Enables BFD single-hop echo detection. If you do not specify this keyword, the command enables BFD bidirectional control detection.

Examples

Enable BFD for OSPF on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] ospf
[Sysname-ospf-1] area 0
[Sysname-ospf-1-area-0.0.0.0] network 192.168.0.0 0.0.255.255
[Sysname-ospf-1-area-0.0.0.0] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf bfd enable
```

ospf cost (interface view)

Use **ospf cost** to set an OSPF cost for an interface.

Use **undo ospf cost** to restore the default.

Syntax

ospf cost *cost-value*

undo ospf cost

Default

An interface computes its OSPF cost according to the interface bandwidth. For a loopback interface, the cost is 0.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

cost-value: Specifies an OSPF cost in the range of 0 to 65535 for a loopback interface, and in the range of 1 to 65535 for other interfaces.

Usage guidelines

If you do not execute this command, the interface automatically computes its OSPF cost.

Examples

Set the OSPF cost on GigabitEthernet 1/0/1 to 65.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf cost 65
```

Related commands

bandwidth-reference

ospf database-filter

Use **ospf database-filter** to filter outbound LSAs on an interface.

Use **undo ospf database-filter** to restore the default.

Syntax

ospf database-filter { **all** | { **ase** [**acl** *ipv4-acl-number*] | **nssa** [**acl** *ipv4-acl-number*] | **summary** [**acl** *ipv4-acl-number*] } * }

undo ospf database-filter

Default

The outbound LSAs are not filtered on the interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

all: Filters all outbound LSAs except the Grace LSAs.

ase: Filters outbound Type-5 LSAs.

nssa: Filters outbound Type-7 LSAs.

summary: Filters outbound Type-3 LSAs.

acl *ipv4-acl-number*: Specifies an IPv4 ACL by its number in the range of 2000 to 3999.

Usage guidelines

When you specify an ACL, follow these guidelines:

- If the ACL does not exist or has no rules, OSPF does not filter outbound LSAs.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all outbound LSAs.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following methods:

- To deny/permit LSAs with the specified link state ID, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.
- To deny/permit LSAs with the specified link state ID and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the link state ID of an LSA and the **destination** keyword specifies the subnet mask of the LSA. For the mask configuration to take effect, specify a contiguous subnet mask.

If the neighbor has already received an LSA to be filtered, the LSA still exists in the LSDB of the neighbor after you execute the command.

Examples

Filter all outbound LSAs (except the Grace LSAs) on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf database-filter all
```

On GigabitEthernet 1/0/2, configure ACL 2000, 2100, and 2200 to filter outbound Type-5, Type-7, and Type-3 LSAs, respectively.

```
<Sysname> system-view
```

```
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] ospf database-filter ase acl 2000 nssa acl 2100 summary
acl 2200
```

Related commands

database-filter peer

ospf dr-priority

Use **ospf dr-priority** to set the router priority for DR/BDR election on an interface.

Use **undo ospf dr-priority** to restore the default value.

Syntax

ospf dr-priority *priority*

undo ospf dr-priority

Default

The router priority is 1.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

priority: Specifies the router priority for the interface, in the range of 0 to 255.

Usage guidelines

The greater the value, the higher the priority for DR/BDR election. If a device has a priority of 0, it will not be elected as a DR or BDR.

Examples

Set the router priority on GigabitEthernet 1/0/1 to 8.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf dr-priority 8
```

ospf fast-reroute lfa-backup

Use **ospf fast-reroute lfa-backup** to enable LFA on an interface.

Use **undo ospf fast-reroute lfa-backup** to disable LFA on an interface.

Syntax

ospf fast-reroute lfa-backup

undo ospf fast-reroute lfa-backup

Default

LFA is enabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

An interface enabled with LFA can be selected as a backup interface. After you disable LFA on the interface, it cannot be selected as a backup interface.

Examples

Disable GigabitEthernet 1/0/1 from calculating a backup next hop by using the LFA algorithm.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] undo ospf fast-reroute lfa-backup
```

ospf mib-binding

Use **ospf mib-binding** to bind an OSPF process to the public MIB.

Use **undo ospf mib-binding** to restore the default.

Syntax

ospf mib-binding *process-id*

undo ospf mib-binding

Default

The public MIB is bound to the OSPF process with the smallest process ID.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535.

Usage guidelines

To access information or data about an OSPF process in **RFC4750-OSPF.MIB**, use this command. To access information or data about an OSPF process in a private MIB for the device, you do not need to use this command. You can access information or data about all OSPF processes in the private MIBs.

If the specified process ID does not exist, a notification is displayed to report that the MIB binding configuration has failed.

Deleting an OSPF process that has been bound to the public MIB unbinds the OSPF process from the MIB, and re-binds the MIB to the OSPF process with the smallest process ID.

Examples

Bind OSPF process 100 to the public MIB.

```
<Sysname> system-view
```

```
[Sysname] ospf mib-binding 100
```

ospf mtu-enable

Use **ospf mtu-enable** to enable an interface to add the interface MTU into DD packets.

Use **undo ospf mtu-enable** to restore the default.

Syntax

ospf mtu-enable

undo ospf mtu-enable

Default

The MTU in DD packets is 0.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

After a virtual link is established through a Virtual-Template or Tunnel, two devices on the link from different vendors might have different MTU values. To make them consistent, restore the interfaces' MTU to the default value 0.

After you configure this command, the interface checks whether the MTU in a received DD packet is greater than its own MTU. If yes, the interface discards the packet.

Examples

Enable GigabitEthernet 1/0/1 to add the interface MTU value into DD packets.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf mtu-enable
```

ospf network-type

Use **ospf network-type** to specify the network type for an interface.

Use **undo ospf network-type** to restore the default.

Syntax

ospf network-type { **broadcast** | **nbma** | **p2mp** [**unicast**] | **p2p** [**peer-address-check**] }

undo ospf network-type

Default

The network type of an interface is broadcast.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

broadcast: Specifies the network type as broadcast.

nbma: Specifies the network type as NBMA.

p2mp: Specifies the network type as P2MP.

unicast: Specifies the P2MP interface to unicast OSPF packets. By default, a P2MP interface multicasts OSPF packets.

p2p: Specifies the network type as P2P.

peer-address-check: Checks whether the peer interface and the local interface are on the same network segment. Two P2P interfaces can establish a neighbor relationship only when they are on the same network segment.

Usage guidelines

If a router on a broadcast network does not support multicast, configure the network type for the connected interfaces as NBMA.

If any two routers on an NBMA network are directly connected through a virtual link, the network is fully meshed. You can configure the network type for the connected interfaces as NBMA. If two routers are not directly connected, configure the P2MP network type so that the two routers can exchange routing information through another router.

When the network type of an interface is NBMA or P2MP unicast, you must use the **peer** command to specify the neighbor.

If only two routers run OSPF on a network, you can configure the network type for the connected interfaces as P2P.

When the network type of an interface is P2MP unicast, all OSPF packets are unicast by the interface.

Examples

Specify the OSPF network type for GigabitEthernet 1/0/1 as NBMA.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf network-type nbma
```

Related commands

ospf dr-priority

ospf prefix-suppression

Use **ospf prefix-suppression** to disable an OSPF interface from advertising all its IP prefixes, except for the prefixes of secondary IP addresses.

Use **undo ospf prefix-suppression** to restore the default.

Syntax

ospf prefix-suppression [**disable**]

undo ospf prefix-suppression

Default

Prefix suppression is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

disable: Disables prefix suppression for an interface.

Usage guidelines

To disable prefix suppression for an interface associated with an OSPF process that has been enabled with prefix suppression, use the **ospf prefix-suppression disable** command on that interface.

Examples

Enable prefix suppression for GigabitEthernet 1/0/2.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] ospf prefix-suppression
```

Related commands

prefix-suppression

ospf primary-path-detect bfd

Use **ospf primary-path-detect bfd** to enable BFD for primary link failure detection for OSPF.

Use **undo ospf primary-path-detect bfd** to disable BFD for primary link failure detection for OSPF.

Syntax

ospf primary-path-detect bfd { **ctrl** | **echo** }

undo ospf primary-path-detect bfd

Default

BFD is disabled for primary link failure detection for OSPF.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ctrl: Enables BFD control packet mode.

echo: Enables BFD echo packet mode.

Usage guidelines

This command enables OSPF PIC or OSPF FRR to use BFD to detect primary link failures.

Examples

On GigabitEthernet 1/0/1, enable BFD control packet mode for OSPF FRR.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] fast-reroute lfa
[Sysname-ospf-1] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf primary-path-detect bfd ctrl
```

On GigabitEthernet 1/0/2, enable BFD echo packet mode for OSPF PIC.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] pic additional-path-always
[Sysname-ospf-1] quit
[Sysname] bfd echo-source-ip 1.1.1.1
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] ospf primary-path-detect bfd echo
```

ospf timer dead

Use **ospf timer dead** to set the neighbor dead interval.

Use **undo ospf timer dead** to restore the default.

Syntax

ospf timer dead *seconds*

undo ospf timer dead

Default

The dead interval is 40 seconds for broadcast and P2P interfaces. The dead interval is 120 seconds for P2MP and NBMA interfaces.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the dead interval in the range of 1 to 2147483647 seconds.

Usage guidelines

If an interface receives no hello packet from a neighbor within the dead interval, the interface considers the neighbor down. The dead interval on an interface is a minimum of four times longer than the hello interval. Devices attached to the same network segment must have the same dead interval.

By default, the neighbor dead interval is four times longer than the hello interval. If you specify a hello interval and do not specify a dead interval, the default dead interval is four times longer than the specified hello interval. To specify a hello interval, use the **ospf timer hello** command.

When you use the **ospf timer dead** command on an interface, following these guidelines:

- The specified neighbor dead interval can be issued to and can take effect on the interface only when it is not shorter than the hello interval.
- To avoid neighbor flapping, do not set a short dead interval.

Examples

Set the dead interval for GigabitEthernet 1/0/1 to 60 seconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf timer dead 60
```

Related commands

ospf timer hello

ospf timer hello

Use **ospf timer hello** to set the hello interval on an interface.

Use **undo ospf timer hello** to restore the default.

Syntax

ospf timer hello *seconds*

undo ospf timer hello

Default

The hello interval is 10 seconds for P2P and broadcast interfaces, and is 30 seconds for P2MP and NBMA interfaces.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the hello interval in the range of 1 to 65535 seconds.

Usage guidelines

The shorter the hello interval, the faster the topology converges, and the more resources are consumed. Make sure the hello interval on two neighboring interfaces is the same.

Examples

Set the hello interval on GigabitEthernet 1/0/1 to 20 seconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf timer hello 20
```

Related commands

ospf timer dead

ospf timer poll

Use **ospf timer poll** to set the poll interval on an NBMA interface.

Use **undo ospf timer poll** to restore the default.

Syntax

ospf timer poll *seconds*

undo ospf timer poll

Default

The poll interval is 120 seconds on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the poll interval in the range of 1 to 2147483647 seconds.

Usage guidelines

When an NBMA interface finds its neighbor is down, it sends hello packets at the poll interval.

The poll interval must be a minimum of four times the hello interval.

Examples

Set the poll timer interval on GigabitEthernet 1/0/1 to 130 seconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf timer poll 130
```

Related commands

ospf timer hello

ospf timer retransmit

Use **ospf timer retransmit** to set the LSA retransmission interval on an interface.

Use **undo ospf timer retransmit** to restore the default.

Syntax

ospf timer retransmit *seconds*

undo ospf timer retransmit

Default

The LSA retransmission interval is 5 seconds on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the LSA retransmission interval in the range of 1 to 3600 seconds.

Usage guidelines

After sending an LSA, an interface waits for an acknowledgment packet. If the interface receives no acknowledgment within the retransmission interval, it retransmits the LSA.

To avoid unnecessary retransmissions, set an appropriate retransmission interval. For example, you can set a large retransmission interval value on a low-speed link.

Examples

Set the LSA retransmission interval to 8 seconds on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf timer retransmit 8
```

ospf trans-delay

Use **ospf trans-delay** to set the LSA transmission delay on an interface.

Use **undo ospf trans-delay** to restore the default.

Syntax

ospf trans-delay *seconds*

undo ospf trans-delay

Default

The LSA transmission delay is 1 second.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the LSA transmission delay in the range of 1 to 3600 seconds.

Usage guidelines

Each LSA in the LSDB has an age that increases by 1 every second, but the age does not change during transmission. Adding a transmission delay into the age time is important in low speed networks.

Examples

Set the LSA transmission delay to 3 seconds on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf trans-delay 3
```

ospf ttl-security

Use **ospf ttl-security** to enable OSPF GTSM for an interface.

Use **ospf ttl-security disable** to disable OSPF GTSM for an interface.

Use **undo ospf ttl-security** to restore the default.

Syntax

ospf ttl-security [**hops** *hop-count* | **disable**]

undo ospf ttl-security

Default

An interface uses the GTSM configuration of the area to which the interface belongs.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

hops *hop-count*: Specifies the hop limit for checking OSPF packets, in the range of 1 to 254. The default hop limit is 1 for packets from common neighbors, and is 255 for packets from virtual link neighbors.

disable: Disables OSPF GTSM for the interface.

Usage guidelines

GTSM checks OSPF packets from common neighbors and virtual link neighbors.

GTSM protects the device by comparing the TTL value in the IP header of incoming OSPF packets against a valid TTL range. If the TTL value is within the valid TTL range, the packet is accepted. If not, the packet is discarded.

The valid TTL range is from 255 – the configured hop count + 1 to 255.

When GTSM is configured, the OSPF packets sent by the device have a TTL of 255. To use GTSM, you must configure GTSM on both the local and peer devices. You can specify different *hop-count* values for them.

The GTSM configuration in OSPF area view applies to all OSPF interfaces in the area. The GTSM configuration in interface view takes precedence over the configuration in OSPF area view.

If a virtual link exists in an area, you can enable GTSM for the interfaces on the virtual link. If you do not know the interfaces on the virtual link, enable GTSM in area view to prevent packet loss.

Examples

Enable OSPF GTSM for GigabitEthernet 1/0/1 and set the hop limit to 254.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospf ttl-security hops 254
```

Enable GTSM in OSPF area view and disable OSPF GTSM for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 1
[Sysname-ospf-100-area-0.0.0.1] ttl-security
[Sysname-ospf-100-area-0.0.0.1] quit
[Sysname-ospf-100] quit
[Sysname] interface gigabitethernet 1/0/1
```

```
[Sysname-GigabitEthernet1/0/1] ospf ttl-security disable
```

Related commands

ttl-security

peer

Use **peer** to specify a neighbor in an NBMA or P2MP network.

Use **undo peer** to remove a neighbor in an NBMA or P2MP network.

Syntax

peer *ip-address* [**cost** *cost-value* | **dr-priority** *priority*]

undo peer *ip-address*

Default

No neighbor is specified.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies a neighbor by its IP address.

cost *cost-value*: Specifies the cost to reach the neighbor, in the range of 1 to 65535.

dr-priority *priority*: Specifies the DR priority for the neighbor, in the range of 0 to 255. The default neighbor DR priority is 1.

Usage guidelines

On an NBMA or P2MP network, OSPF packets are sent in unicast, so you must use this command to specify neighbors.

The cost set with the **peer** command applies only to P2MP neighbors. If no cost is specified, the cost to the neighbor equals the local interface's cost.

A router uses the priority set with the **peer** command to determine whether to send a hello packet to the neighbor rather than for DR election. The DR priority set with the **ospf dr-priority** command is used for DR election.

Examples

Specify the neighbor 1.1.1.1.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] peer 1.1.1.1
```

Related commands

ospf dr-priority

pic

Use **pic** to enable OSPF PIC.

Use **undo pic** to disable OSPF PIC.

Syntax

pic [**additional-path-always**]

undo pic

Default

OSPF PIC is enabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

additional-path-always: Allows the indirect suboptimal route as the backup route.

Usage guidelines

Prefix Independent Convergence (PIC) enables the device to speed up network convergence by ignoring the number of prefixes. PIC applies only to inter-area routes and external routes.

When both OSPF PIC and OSPF FRR are configured, OSPF FRR takes effect.

Examples

Configure OSPF PIC to support the suboptimal route as the backup route.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] pic additional-path-always
```

preference

Use **preference** to set a preference for OSPF.

Use **undo preference** to remove the configuration.

Syntax

preference [**ase**] { *preference* | **route-policy** *route-policy-name* } *

undo preference [**ase**]

Default

The preference is 10 for OSPF internal routes and 150 for OSPF external routes (ASE routes).

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

ase: Specifies a preference for OSPF external routes. If you do not specify this keyword, the command sets a preference for OSPF internal routes.

preference: Specifies the preference value in the range of 1 to 255. A smaller value represents a higher preference.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to set a preference for the specified routes.

Usage guidelines

If multiple routing protocols find routes to the same destination, the router uses the route found by the protocol with the highest preference.

When the **route-policy** *route-policy-name* option is specified, the following preferences take effect:

- For routes matching the routing policy, the preference set in the routing policy takes effect.
- For other routes, the preference set with the **preference** command takes effect.

Examples

Set a preference of 200 for OSPF external routes.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] preference ase 200
```

Set a preference of 100 for OSPF internal routes matching the specified routing policy, and set a preference of 150 for other routes.

```
<Sysname> system-view
[Sysname] ip prefix-list test index 10 permit 100.1.1.0 24
[Sysname] route-policy pre permit node 10
[Sysname-route-policy-pre-10] if-match ip address prefix-list test
[Sysname-route-policy-pre-10] apply preference 100
[Sysname-route-policy-pre-10] quit
[Sysname] ospf 100
[Sysname-ospf-100] preference route-policy pre 150
```

prefix-priority

Use **prefix-priority** to enable prefix prioritization.

Use **undo prefix-priority** to disable prefix prioritization.

Syntax

prefix-priority route-policy *route-policy-name*

undo prefix-priority

Default

Prefix prioritization is disabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to set a priority for the specified route prefixes.

Usage guidelines

Prefix prioritization enables the device to install prefixes in descending priority order: critical, high, medium, and low. The prefix priorities are assigned through routing policies. When a route is assigned multiple prefix priorities, it uses the highest priority.

By default, the 32-bit OSPF host routes have a medium priority and other routes have a low priority.

Examples

Use a routing policy to assign the medium priority to the specified route prefixes.

```
<Sysname> system-view
[Sysname] ip prefix-list test index 10 permit 100.1.1.0 24
[Sysname] route-policy pre permit node 10
[Sysname-route-policy-pre-10] if-match ip address prefix-list test
[Sysname-route-policy-pre-10] apply prefix-priority medium
[Sysname-route-policy-pre-10] quit
[Sysname] ospf 100
[Sysname-ospf-100] prefix-priority route-policy pre
```

prefix-suppression

Use **prefix-suppression** to disable an OSPF process from advertising all IP prefixes except for the prefixes of loopback interfaces, secondary IP addresses, and passive interfaces.

Use **undo prefix-suppression** to restore the default.

Syntax

prefix-suppression

undo prefix-suppression

Default

An OSPF process advertises all prefixes.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Usage guidelines

By default, an OSPF interface advertises all of its prefixes in LSAs. To speed up OSPF convergence, you can suppress interfaces from advertising all their prefixes. This feature helps improve network security by preventing IP routing to the suppressed networks.

As a best practice, configure prefix suppression on all OSPF routers if you want to use prefix suppression.

To disable an OSPF process from advertising the prefixes of loopback and passive interfaces, configure prefix suppression on the interfaces by using the **ospf prefix-suppression** command.

When prefix suppression is enabled:

- On P2P and P2MP networks, OSPF does not advertise Type-3 links in Type-1 LSAs. Other routing information can still be advertised to ensure traffic forwarding.
- On broadcast and NBMA networks, the DR generates Type-2 LSAs with a mask length of 32 to suppress network routes. Other routing information can still be advertised to ensure traffic forwarding. If no neighbors exist, the DR also does not advertise the primary IP addresses of interfaces in Type-1 LSAs.

Examples

Enable prefix suppression for OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] prefix-suppression
```

Related commands

ospf prefix-suppression

reset ospf event-log

Use **reset ospf event-log** to clear OSPF log information.

Syntax

reset ospf [*process-id*] **event-log** [**lsa-flush** | **peer** [**slot** *slot-number*] | **spf**]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command clears OSPF log information for all OSPF processes.

lsa-flush: Clears LSA aging log information.

peer: Clears neighbor state change log information.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command clears neighbor state change information on the member device where the active process resides.

spf: Clears route calculation log information.

Usage guidelines

If you do not specify a log type, this command clears all log information.

Examples

Clear OSPF route calculation log information for all OSPF processes.

```
<Sysname> reset ospf event-log spf
```

Related commands

display ospf event-log

reset ospf event-log hello

Use **reset ospf event-log hello** to clear OSPF log information about received or sent hello packets.

Syntax

reset ospf [*process-id*] **event-log hello** { **received** [**abnormal** | **dropped**] | **sent** [**abnormal** | **failed**] } [**slot** *slot-number*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command clears OSPF log information for all processes.

received: Specifies log information for received hello packets.

sent: Specifies log information for sent hello packets.

abnormal: Specifies log information for abnormal hello packets received or sent at intervals greater than or equal to 1.5 times the hello interval.

dropped: Specifies log information for received hello packets that were dropped.

failed: Specifies log information for hello packets that failed to be sent.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command clears received or sent hello packet log information on the member device where the active process resides.

Examples

Clear sent hello packet log information for all OSPF processes.

```
<Sysname> reset ospf event-log hello sent
```

Related commands

display ospf event-log hello

reset ospf process

Use **reset ospf process** to restart all OSPF processes or a specified process.

Syntax

reset ospf [*process-id*] **process** [**graceful-restart**]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify a process, this command restarts all OSPF processes.

graceful-restart: Resets the OSPF process by using GR.

Usage guidelines

The **reset ospf process** command performs the following actions:

- Clears all invalid LSAs without waiting for their timeouts.
- Makes a newly configured router ID take effect.
- Starts a new DR/BDR election.
- Keeps previous OSPF configurations.

The system prompts you to select whether to restart OSPF process upon execution of this command.

Examples

Restart all OSPF processes.

```
<Sysname> reset ospf process
Reset OSPF process? [Y/N]:y
```

reset ospf redistribution

Use **reset ospf redistribution** to restart route redistribution.

Syntax

reset ospf [*process-id*] **redistribution**

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify a process, this command restarts route redistribution for all OSPF processes.

Examples

Restart route redistribution.

```
<Sysname> reset ospf redistribution
```

reset ospf statistics

Use **reset ospf statistics** to clear OSPF statistics.

Syntax

reset ospf [*process-id*] **statistics**

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Clears the statistics for an OSPF process specified by its ID in the range of 1 to 65535.

Examples

Clear OSPF statistics for all processes.

```
<Sysname> reset ospf statistics
```

Related commands

display ospf statistics

rfc1583 compatible

Use **rfc1583 compatible** to enable compatibility with RFC 1583.

Use **undo rfc1583 compatible** to disable compatibility with RFC 1583.

Syntax

rfc1583 compatible

undo rfc1583 compatible

Default

Compatibility with RFC 1583 is enabled.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Usage guidelines

RFC 1583 specifies a different method than RFC 2328 for selecting the optimal route to a destination in another AS. When multiple routes are available to the ASBR, OSPF selects the optimal route by using the following procedure:

1. Selects the route with the highest preference.
   - If RFC 2328 is compatible with RFC 1583, all these routes have equal preference.
   - If RFC 2328 is not compatible with RFC 1583, the intra-area route in a non-backbone area is preferred to reduce the burden of the backbone area. The inter-area route and intra-area route in the backbone area have equal preference.
2. Selects the route with lower cost if two routes have equal preference.
3. Selects the route with larger originating area ID if two routes have equal cost.

To avoid routing loops, set identical RFC 1583-compatibility on all routers in a routing domain.

Examples

Disable compatibility with RFC 1583.

```
<Sysname> system-view
[Sysname] ospf 100
```

```
[Sysname-ospf-100] undo rfc1583 compatible
```

router id

Use **router id** to configure a global router ID.

Use **undo router id** to restore the default.

Syntax

router id *router-id*

undo router id

Default

No global router ID is configured.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

router-id: Specifies the router ID, in the format of an IPv4 address.

Usage guidelines

OSPF uses a router ID to identify a device. If no router ID is specified, the global router ID is used.

If no global router ID is configured, the highest loopback interface IP address is used as the router ID. If no loopback interface IP address is available, the highest physical interface IP address is used, regardless of the interface status (up or down).

During an active/standby process switchover, the new active process checks whether the previously backed up router ID is valid. If not, the process selects a new router ID.

A new router ID is selected only when the interface IP address used as the router ID is removed or changed. Other events will not trigger a router ID re-selection. For example, router ID re-selection is not triggered in the following situations:

- The interface goes down.
- You change the router ID to the address of a loopback interface after a physical interface address is selected as the router ID.
- A higher interface IP address is configured as the router ID.

After a router ID is changed, you must use the **reset** command to enable it.

Examples

Configure a global router ID as 1.1.1.1.

```
<Sysname> system-view
[Sysname] router id 1.1.1.1
```

silent-interface

Use **silent-interface** to disable an interface or all interfaces from receiving and sending OSPF packets.

Use **undo silent-interface** to remove the configuration.

Syntax

silent-interface { *interface-type interface-number* | **all** }

undo silent-interface { *interface-type interface-number* | **all** }

Default

An interface can receive and send OSPF packets.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

interface-type interface-number: Specifies an interface by its type and number.

all: Specifies all interfaces.

Usage guidelines

To disable a network from receiving and sending OSPF routes, use the command on the interface connected to the network.

Examples

Disable GigabitEthernet 1/0/1 from receiving and sending OSPF packets.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] silent-interface gigabitethernet 1/0/1
```

snmp trap rate-limit

Use **snmp trap rate-limit** to set the SNMP notification output interval and the maximum number of SNMP notifications that can be output at each interval.

Use **undo snmp trap rate-limit** to restore the default.

Syntax

snmp trap rate-limit interval *trap-interval* **count** *trap-number*

undo snmp trap rate-limit

Default

OSPF outputs a maximum of seven SNMP notifications within 10 seconds.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

interval *trap-interval*: Specifies the SNMP notification output interval in the range of 2 to 60 seconds.

count *trap-number*: Specifies the number of SNMP notifications output by OSPF at each interval, in the range of 0 to 300. The value of 0 indicates that OSPF does not output SNMP notifications.

Examples

Configure OSPF to output a maximum of 10 SNMP notifications within 5 seconds.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] snmp trap rate-limit interval 5 count 10
```

snmp-agent trap enable ospf

Use **snmp-agent trap enable ospf** to enable SNMP notifications for OSPF.

Use **undo snmp-agent trap enable ospf** to disable SNMP notifications for OSPF.

Syntax

snmp-agent trap enable ospf [**authentication-failure** | **bad-packet** | **config-error** | **grhelper-status-change** | **grrestarter-status-change** | **if-state-change** | **lsa-maxage** | **lsa-originate** | **lsdb-approaching-overflow** | **lsdb-overflow** | **neighbor-state-change** | **nssatranslator-status-change** | **retransmit** | **virt-authentication-failure** | **virt-bad-packet** | **virt-config-error** | **virt-retransmit** | **virtgrhelper-status-change** | **virtif-state-change** | **virtneighbor-state-change**] *

undo snmp-agent trap enable ospf [**authentication-failure** | **bad-packet** | **config-error** | **grhelper-status-change** | **grrestarter-status-change** | **if-state-change** | **lsa-maxage** | **lsa-originate** | **lsdb-approaching-overflow** | **lsdb-overflow** | **neighbor-state-change** | **nssatranslator-status-change** | **retransmit** | **virt-authentication-failure** | **virt-bad-packet** | **virt-config-error** | **virt-retransmit** | **virtgrhelper-status-change** | **virtif-state-change** | **virtneighbor-state-change**] *

Default

SNMP notifications for OSPF are enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

authentication-failure: Specifies notifications about authentication failures on an interface.

bad-packet: Specifies notifications about error messages received on an interface.

config-error: Specifies notifications about error configuration of an interface.

grhelper-status-change: Specifies notifications about GR helper state change.

grrestarter-status-change: Specifies notifications about GR restarter state change.

if-state-change: Specifies notifications about interface state change.

lsa-maxage: Specifies LSA max age notifications.

lsa-originate: Specifies notifications about locally generated LSAs.

lsdb-approaching-overflow: Specifies notifications about approaching LSDB overflows.

lsdb-overflow: Specifies LSDB overflow notifications.

neighbor-state-change: Specifies notifications about neighbor state change.

nssatranslator-status-change: Specifies notifications about NSSA translator state change.

retransmit: Specifies notifications about packets that are received and forwarded on an interface.

virt-authentication-failure: Specifies notifications about authentication failures on a virtual interface.

virt-bad-packet: Specifies notifications about error messages received on a virtual interface.

virt-config-error: Specifies notifications about error configuration of a virtual interface.

virt-retransmit: Specifies notifications about packets that are received and forwarded on a virtual interface.

virtgrhelper-status-change: Specifies notifications about neighbor GR helper state changes of a virtual interface.

virtif-state-change: Specifies notifications about virtual interface state change.

virtneighbor-state-change: Specifies notifications about the neighbor state change of a virtual interface.

Examples

Disable SNMP notifications for OSPF.

```
<Sysname> system-view
[Sysname] undo snmp-agent trap enable ospf
```

spf-schedule-interval

Use **spf-schedule-interval** to set the OSPF SPF calculation interval.

Use **undo spf-schedule-interval** to restore the default.

Syntax

spf-schedule-interval { *maximum-interval* [*minimum-interval* [*incremental-interval*]] | **millisecond** *interval* }

undo spf-schedule-interval

Default

The maximum calculation interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

maximum-interval: Specifies the maximum OSPF SPF calculation interval in the range of 1 to 60 seconds.

minimum-interval: Specifies the minimum OSPF SPF calculation interval in the range of 10 to 60000 milliseconds.

incremental-interval: Specifies the incremental OSPF SPF calculation interval in the range of 10 to 60000 milliseconds.

millisecond *interval*: Specifies the fixed OSPF SPF calculation interval in the range of 0 to 10000 milliseconds.

Usage guidelines

Based on the LSDB, an OSPF router uses SPF to calculate a shortest path tree with itself as the root. OSPF uses the shortest path tree to determine the next hop to a destination. By adjusting the SPF calculation interval, you can prevent overconsumption of bandwidth and router resources due to frequent topology changes.

After you execute the **spf-schedule-interval** *maximum-interval* [*minimum-interval* [*incremental-interval*]] command, the minimum interval is used for a stable network. If network changes become frequent, the SPF calculation interval increases by the incremental interval × 2^{n-2} for each calculation until the maximum interval is reached. The value *n* is the number of calculation times.

The minimum interval and the incremental interval cannot be greater than the maximum interval.

For a network that requires fast route convergence, use the **spf-schedule-interval millisecond** *interval* command to set a short SPF calculation interval.

Examples

Set the maximum SPF calculation interval to 10 seconds, minimum interval to 500 milliseconds, and incremental interval to 300 milliseconds.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] spf-schedule-interval 10 500 300
```

stub

Use **stub** to configure an area as a stub area.

Use **undo stub** to restore the default.

Syntax

stub [**default-route-advertise-always** | **no-summary**] *

undo stub

Default

No area is a stub area.

Views

OSPF area view

Predefined user roles

network-admin

context-admin

Parameters

default-route-advertise-always: Enables the ABR to advertise a default route in a Type-3 LSA into the stub area regardless of whether **FULL**-state neighbors exist in the backbone area. If you do not specify this keyword, the ABR advertises a default route in a Type-3 LSA into the stub area only when a minimum of one **FULL**-state neighbor exists in the backbone area.

no-summary: Enables the ABR to advertise only a default route in a Type-3 LSA into the stub area without advertising any other Type-3 LSAs. The area is a totally stub area.

Usage guidelines

To configure an area as a stub area, use the **stub** command on all routers attached to the area.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure Area 1 as a stub area.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 1
[Sysname-ospf-100-area-0.0.0.1] stub
```

Related commands

default-cost

stub-router

Use **stub-router** to configure a router as a stub router.

Use **undo stub-router** to restore the default.

Syntax

stub-router [**external-lsa** [*max-metric-value*] | **include-stub** | **on-startup** { *seconds* | **wait-for-bgp** [*seconds*] } | **summary-lsa** [*max-metric-value*]] *

undo stub-router

Default

The router is not configured as a stub router.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

external-lsa *max-metric-value*: Specifies a cost for the external LSAs, in the range of 1 to 16777215. The default is 16711680.

include-stub: Specifies the cost of the stub links (link type 3) in Router LSAs to the maximum value 65535.

on-startup *seconds*: Specifies the router as a stub router during reboot, and specifies the timeout time in the range of 5 to 86400 seconds.

wait-for-bgp *seconds*: Specifies the router as a stub router during BGP route convergence after reboot, and specifies the timeout time in the range of 5 to 86400 seconds. The default timeout time is 600 seconds.

summary-lsa *max-metric-value*: Specifies a cost for the Type-3 LSAs, in the range of 1 to 16777215. The default cost value is 16711680.

Usage guidelines

The router LSAs sent by the stub router over different links contain different link type values. A value of 3 represents a link to a stub network, and the cost of the link is not changed. A value of 1, 2, or 4 represents a point-to-point link, a link to a transit network, or a virtual link. The cost of these links is set to 65535. Neighbors on such links will not send packets to the stub router as long as they have a route with a smaller cost.

Examples

Configure a stub router.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] stub-router
```

transmit-pacing

Use **transmit-pacing** to set the LSU transmission interval and the maximum number of LSU packets that can be sent at each interval.

Use **undo transmit-pacing** to restore the default.

Syntax

transmit-pacing interval *interval* **count** *count*

undo transmit-pacing

Default

An OSPF interface sends a maximum of three LSU packets every 20 milliseconds.

Views

OSPF view

Predefined user roles

network-admin

context-admin

Parameters

interval *interval*: Specifies an interval at which an interface sends LSU packets, in the range of 0 to 1000 milliseconds. If the router has multiple OSPF interfaces, increase this interval to reduce the total number of LSU packets sent by the router every second. As a best practice to maintain network stability, do not set the interval to 0 milliseconds when the OSPF LSDB is large or network changes are frequent.

count *count*: Specifies the maximum number of LSU packets sent by an interface at each interval, in the range of 1 to 200. If the router has multiple OSPF interfaces, decrease the maximum number to reduce the total number of LSU packets sent by the router every second.

Examples

Configure all the interfaces running OSPF process 1 to send a maximum of 10 LSU packets every 30 milliseconds.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] transmit-pacing interval 30 count 10
```

ttl-security

Use **ttl-security** to enable OSPF GTSM for an area.

Use **undo ttl-security** to disable OSPF GTSM for an area.

Syntax

ttl-security [**hops** *hop-count*]

undo ttl-security

Default

OSPF GTSM is disabled for an OSPF area.

Views

OSPF area view

Predefined user roles

network-admin

context-admin

Parameters

hops *hop-count*: Specifies the hop limit for checking OSPF packets, in the range of 1 to 254. The default hop limit is 1 for packets from common neighbors, and is 255 for packets from virtual link neighbors.

Usage guidelines

After you enable GTSM in area view, GTSM checks OSPF packets from common neighbors and virtual link neighbors.

GTSM protects the device by comparing the TTL value in the IP header of incoming OSPF packets against a valid TTL range. If the TTL value is within the valid TTL range, the packet is accepted. If not, the packet is discarded.

The valid TTL range is from 255 – the configured hop count + 1 to 255.

When GTSM is configured, the OSPF packets sent by the device have a TTL of 255. To use GTSM, you must configure GTSM on both the local and peer devices. You can specify different *hop-count* values for them.

The GTSM configuration in OSPF area view applies to all OSPF interfaces in the area. The GTSM configuration in interface view takes precedence over the configuration in OSPF area view.

As a best practice, set the hop limit if a virtual link exists in an area. You can enable GTSM for the interfaces on the virtual link. If you do not know the interfaces on the virtual link, enable GTSM in area view to prevent packet loss.

Examples

Enable OSPF GTSM for OSPF area 1.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 1
[Sysname-ospf-100-area-0.0.0.1] ttl-security
```

Related commands

ospf ttl-security

vlink-peer

Use **vlink-peer** to configure a virtual link.

Use **undo vlink-peer** to remove a virtual link.

Syntax

vlink-peer *router-id* [**dead** *seconds* | **hello** *seconds* | { { **hmac-md5** | **hmac-sha-256** | **md5** } *key-id* { **cipher** | **plain** } *string* | **keychain** *keychain-name* | **simple** { **cipher** | **plain** } *string* } | **retransmit** *seconds* | **trans-delay** *seconds*] *

undo vlink-peer *router-id* [**dead** | **hello** | { **hmac-md5** | **hmac-sha-256** | **md5** } *key-id* | **keychain** | **retransmit** | **simple** | **trans-delay**] *

Default

No virtual links exist.

Views

OSPF area view

Predefined user roles

network-admin

context-admin

Parameters

router-id: Specifies the router ID of the neighbor on the virtual link.

dead *seconds*: Specifies the dead interval in the range of 1 to 32768 seconds. The default is 40. The dead interval must be identical with that on the virtual link neighbor, and a minimum of four times the hello interval.

hello *seconds*: Specifies the hello interval in the range of 1 to 8192 seconds. The default is 10. It must be identical with the hello interval on the virtual link neighbor.

hmac-md5: Specifies the HMAC-MD5 authentication mode.

hmac-sha-256: Specifies the HMAC-SHA-256 authentication mode.

md5: Specifies the MD5 authentication mode.

simple: Specifies the simple authentication mode.

key-id: Specifies the key ID for MD5 or HMAC-MD5 authentication, in the range of 1 to 255.

cipher: Specifies a key in encrypted form.

plain: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive.

- In simple authentication mode, the plaintext form of the key is a string of 1 to 8 characters. The encrypted form of the key is a string of 33 to 41 characters.
- In MD5/HMAC-MD5/HMAC-SHA-256 authentication mode, the plaintext form of the key is a string of 1 to 255 characters. The encrypted form of the key is a string of 33 to 373 characters.

keychain: Specifies the keychain authentication mode.

keychain-name: Specifies a keychain by its name, a case-sensitive string of 1 to 63 characters.

retransmit *seconds*: Specifies the retransmission interval in the range of 1 to 3600 seconds. The default is 5.

trans-delay *seconds*: Specifies the transmission delay interval in the range of 1 to 3600 seconds. The default is 1.

Usage guidelines

As defined in RFC 2328, all non-backbone areas must maintain connectivity to the backbone. You can use the **vlink-peer** command to configure a virtual link to connect an area to the backbone.

When you configure this command, follow these guidelines:

- The smaller the hello interval is, the faster the network converges, and the more network resources are consumed.
- A retransmission interval that is too small can cause unnecessary retransmissions. A large value is appropriate for a low speed link.
- Specify an appropriate transmission delay with the **trans-delay** keyword.

You can specify either MD5/HMAC-MD5/HMAC-SHA-256 authentication or simple authentication for a virtual link. For MD5/HMAC-MD5/HMAC-SHA-256 authentication, you can configure multiple keys by executing this command multiple times, and each command must have a unique key ID and key string.

To modify the key of a virtual link, perform the following key rollover configurations:

1. Configure a new MD5/HMAC-MD5/HMAC-SHA-256 authentication key for the virtual link on the local device. If the new key is not configured on the neighbor device, MD5/HMAC-MD5/HMAC-SHA-256 authentication key rollover is triggered. During key rollover, OSPF sends multiple packets that contain both the new and old MD5/HMAC-MD5/HMAC-SHA-256 authentication keys to ensure that the neighbor device can pass the authentication.
2. Configure the new MD5/HMAC-MD5/HMAC-SHA-256 authentication key on the neighbor device. When the local device receives packets with the new key from the neighbor device, it exits MD5 key rollover.
3. Delete the old MD5/HMAC-MD5/HMAC-SHA-256 authentication key from the local device and the neighbor. This step helps prevent attacks from devices that use the old key for communication and reduces system resources and bandwidth consumption caused by key rollover.

When keychain authentication is configured for an OSPF virtual link, OSPF performs the following operations before sending a packet:

1. Obtains a valid send key from the keychain.

   OSPF does not send the packet if it fails to obtain a valid send key.
2. Uses the key ID, authentication algorithm, and key string to authenticate the packet.

   If the key ID is greater than 255, OSPF does not send the packet.

When keychain authentication is configured for an OSPF virtual link, OSPF performs the following operations after receiving a packet:

1. Uses the key ID carried in the packet to obtain a valid accept key from the keychain.

   OSPF discards the packet if it fails to obtain a valid accept key.
2. Uses the authentication algorithm and key string for the valid accept key to authenticate the packet.

   If the authentication fails, OSPF discards the packet.

OSPF supports only the MD5, HMAC-SM3, HMAC-MD5, and HMAC-SHA-256 authentication algorithms for keychain authentication.

The ID of keys used for keychain authentication can only be in the range of 0 to 255.

Examples

Configure a virtual link to the neighbor with router ID 1.1.1.1.

```
<Sysname> system-view
```

```
[Sysname] ospf 100
[Sysname-ospf-100] area 2
[Sysname-ospf-100-area-0.0.0.2] vlink-peer 1.1.1.1
```

OSPFv3 commands

abr-summary

Use **abr-summary** to configure route summarization on an ABR.

Use **undo abr-summary** to remove the configuration.

Syntax

abr-summary *ipv6-address prefix-length* [**not-advertise**] [**cost** *cost-value*]

undo abr-summary *ipv6-address prefix-length*

Default

Route summarization is not configured on an ABR.

Views

OSPFv3 area view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies the destination IPv6 address of the summary route.

prefix-length: Specifies the prefix length of the destination IPv6 address, in the range of 0 to 128. This argument specifies the number of consecutive 1s of the prefix, which defines the network ID.

not-advertise: Specifies not to advertise the summary IPv6 route. If you do not specify this keyword, the command advertises the IPv6 summary route.

cost *cost-value*: Specifies the cost of the summary route, in the range of 1 to 16777215. The default cost is the largest cost value among routes that are summarized.

Usage guidelines

This command applies only to an ABR to summarize multiple contiguous networks into one network.

To enable ABR to advertise specific routes that have been summarized, use the **undo abr-summary** command.

Examples

Summarize networks 2000:1:1:1::/64 and 2000:1:1:2::/64 in Area 1 into 2000:1:1::/48.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 1
[Sysname-ospfv3-1-area-0.0.0.1] abr-summary 2000:1:1:: 48
```

area

Use **area** to create an OSPFv3 area and enter OSPFv3 area view.

Use **undo area** to remove an OSPFv3 area.

Syntax

area *area-id*

undo area *area-id*

Default

No OSPFv3 areas exist.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

area-id: Specifies an area by its ID, an IPv4 address or a decimal integer in the range of 0 to 4294967295 that is translated into the IPv4 address format.

Examples

Create OSPFv3 Area 0 and enter its view.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 0
[Sysname-ospfv3-1-area-0.0.0.0]
```

asbr-summary

Use **asbr-summary** to configure route summarization on an ASBR.

Use **undo asbr-summary** to remove the configuration.

Syntax

asbr-summary *ipv6-address prefix-length* [**cost** *cost-value* | **not-advertise** | **nssa-only** | **tag** *tag*] *

undo asbr-summary *ipv6-address prefix-length*

Default

Route summarization is not configured on an ASBR.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies the destination IPv6 address of the summary route.

prefix-length: Specifies the prefix length in the range of 0 to 128.

cost *cost-value*: Specifies the cost of the summary route, in the range of 1 to 16777214. If you do not specify this option, the largest cost among the summarized routes applies. If the routes in

Type-5 LSAs translated from Type-7 LSAs are Type-2 external routes, the largest cost among the summarized routes plus 1 applies.

not-advertise: Disables advertising the summary route. If you do not specify this keyword, the command advertises the route.

nssa-only: Limits the route advertisement to the NSSA area by setting the P-bit of Type-7 LSAs to 0. By default, the P-bit of Type-7 LSAs is set to 1. If the ASBR is also an ABR and **FULL** state neighbors exist in the backbone area, the P-bit of Type-7 LSAs originated by the ASBR is set to 0. This keyword applies to the NSSA ASBR.

tag *tag*: Specifies a tag for the summary route, in the range of 0 to 4294967295.

Usage guidelines

An ASBR can summarize routes in the following LSAs:

- Type-5 LSAs.
- Type-7 LSAs in an NSSA area.
- Type-5 LSAs translated by the ASBR (also an ABR) from Type-7 LSAs in an NSSA area.

  If the ASBR (ABR) is not a translator, it cannot summarize routes in Type-5 LSAs translated from Type-7 LSAs.

To enable ASBR to advertise specific routes that have been summarized, use the **undo asbr-summary** command.

Examples

Configure a summary route 2000::/16, and specify a cost of 100 and a tag value of 2 for the summary route.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] asbr-summary 2000:: 16 cost 100 tag 2
```

authentication-mode

Use **authentication-mode** to specify an authentication mode for an OSPFv3 area.

Use **undo authentication-mode** to restore the default.

Syntax

authentication-mode keychain *keychain-name*

undo authentication-mode

Default

No authentication is performed for an area.

Views

OSPFv3 area view

Predefined user roles

network-admin

context-admin

Parameters

keychain: Specifies the keychain authentication mode.

keychain-name: Specifies a keychain by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

The authentication mode specified for an OSPFv3 interface has a higher priority than the mode specified for an OSPFv3 area.

When keychain authentication is configured for an OSPFv3 area, OSPFv3 performs the following operations before sending a packet:

1. Obtains a valid send key from the keychain.

   OSPFv3 does not send the packet if it fails to obtain a valid send key.
2. Uses the key ID, authentication algorithm, and key string to authenticate the packet.

   If the key ID is greater than 65535, OSPFv3 does not send the packet.

When keychain authentication is configured for an OSPFv3 area, OSPFv3 performs the following operations after receiving a packet:

1. Uses the key ID carried in the packet to obtain a valid accept key from the keychain.

   OSPFv3 discards the packet if it fails to obtain a valid accept key.
2. Uses the authentication algorithm and key string for the valid accept key to authenticate the packet.

   If the authentication fails, OSPFv3 discards the packet.

OSPFv3 supports the HMAC-SHA-256 and HMAC-SM3 authentication algorithms for keychain authentication.

The ID of keys used for keychain authentication can only be in the range of 0 to 65535.

Examples

Configure OSPFv3 area 1 to use keychain **test** for packet authentication.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 1
[Sysname-ospfv3-1-area-0.0.0.1] authentication-mode keychain test
```

bandwidth-reference

Use **bandwidth-reference** to set a reference bandwidth value for link cost calculation.

Use **undo bandwidth-reference** to restore the default.

Syntax

bandwidth-reference *value*

undo bandwidth-reference

Default

The reference bandwidth value is 100 Mbps for link cost calculation.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies the reference bandwidth value for link cost calculation, in the range of 1 to 4294967 Mbps.

Usage guidelines

You can configure an OSPFv3 cost for an interface with one of the following methods:

- Configure the cost value in interface view.
- Configure a bandwidth reference value. OSPFv3 computes the cost automatically based on the bandwidth reference value by using the following formula: Interface OSPFv3 cost = Bandwidth reference value / Interface bandwidth.
  - If the calculated cost is greater than 65535, the value of 65535 is used.
  - If the calculated cost is smaller than 1, the value of 1 is used.

If no cost value is configured for an interface, OSPFv3 computes the interface cost value automatically.

Examples

Set the reference bandwidth value to 1000 Mbps.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] bandwidth-reference 1000
```

default tag

Use **default tag** to set a tag for redistributed routes.

Use **undo default tag** to restore the default.

Syntax

default tag *tag*

undo default tag

Default

The tag of redistributed routes is 1.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

tag: Specifies a tag for redistributed routes, in the range of 0 to 4294967295.

Usage guidelines

If you do not set a tag for redistributed routes by using the **default-route-advertise**, **import-route**, or **route-tag** command, the tag specified by the **default tag** command applies.

Examples

Set the tag for redistributed routes to 2.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] default tag 2
```

Related commands

default-route-advertise

import-route

default-cost

Use **default-cost** to set a cost for the default route advertised to the stub area or NSSA area.

Use **undo default-cost** to restore the default.

Syntax

default-cost *cost*

undo default-cost

Default

The cost is 1.

Views

OSPFv3 area view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies a cost for the default route advertised to the stub area or NSSA area, in the range of 0 to 16777214.

Usage guidelines

This command takes effect only on the ABR of a stub area or the ABR or ASBR of an NSSA area.

Examples

Configure Area 1 as a stub area, and set the cost of the default route advertised to the stub area to 60.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 1
[Sysname-ospfv3-1-area-0.0.0.1] stub
[Sysname-ospfv3-1-area-0.0.0.1] default-cost 60
```

Related commands

nssa

stub

default-route-advertise

Use **default-route-advertise** to redistribute a default route into the OSPFv3 routing domain.

Use **undo default-route-advertise** to restore the default.

Syntax

default-route-advertise [[**always** | **permit-calculate-other**] | **cost** *cost-value* | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

undo default-route-advertise

Default

No default route is redistributed into the OSPFv3 routing domain.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

always: Redistributes a default route in an AS-external-LSA into the OSPFv3 routing domain regardless of whether a default route exists in the routing table. If you do not specify this keyword, the router redistributes a default route in an AS-external-LSA into the OSPFv3 routing domain only when the default route exists in the routing table.

permit-calculate-other: Enables OSPFv3 to calculate default routes received from other routers. If you do not specify this keyword, OSPFv3 does not calculate default routes from other routers. If the router does not redistribute any default route in an AS-external-LSA into the OSPFv3 routing domain, the router calculates default routes from other routers. It calculates these routes regardless of whether this keyword is specified.

cost *cost-value*: Specifies a cost for the default route, in the range of 0 to 16777214. The default is 1.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. When the routing policy is matched and one of the following conditions is met, the command redistributes a default route in an AS-external-LSA into the OSPFv3 routing domain:

- A default route exists in the routing table.
- The **always** keyword is specified.

The routing policy modifies values in the AS-external-LSA.

tag *tag*: Specifies a tag for the default route, in the range of 0 to 4294967295. If you do not specify this option, the tag specified by the **default tag** command applies.

type *type*: Specifies a type for the AS-external-LSA, 1 or 2. The default is 2.

Usage guidelines

This command redistributes a default route in an AS-external-LSA, which cannot be redistributed with the **import-route** command. If the local routing table has no default route, you must provide the **always** keyword for the command.

Examples

Redistribute a default route into the OSPFv3 routing domain. (The default route does not exist in the local router.)

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] default-route-advertise always
```

Table 1 Command output

Field	Description
OSPFv3 Process 1 with Router ID 1.1.1.1	OSPFv3 process is 1, and router ID is 1.1.1.1.
Router type	Router type: • ABR. • ASBR. • NSSA. • Null.
Route tag	Tag of the routes redistributed into the OSPFv3 process.
Route tag check	Whether the check is enabled for the route tag in OSPFv3 LSAs of the OSPFv3 process.
Multi-VPN-Instance	Whether the OSPFv3 process supports multiple VPN instances: • **Multi-VPN-Instance: Disabled**—The process does not support multiple VPN instances. • **Multi-VPN-Instance: Enabled**—The process supports multiple VPN instances.

Field	Description
DN-bit check	Whether the check is enabled for the DN bit in OSPFv3 LSAs of the OSPFv3 process.
DN-bit set	Whether the DN bit is set for OSPFv3 LSAs in the OSPFv3 process.
Condition	Time when the router acts as a stub router: • Always. • On startup while BGP is converging for *xxx* seconds, where *xxx* is specified by the user. • On startup for *xxx* seconds, where *xxx* is specified by the user.
State	State of the stub router: • Active. • Inactive.
Originating LSAs with metric *xxx* controlled by RBM	The device is the backup device in Remote Backup Management (RBM). • **Originating LSAs with metric +*n* controlled by RBM**—When OSPFv3 generates an LSA, the cost is the sum of the original cost and *n.* • **Originating LSAs with metric *n* controlled by RBM**—When OSPFv3 generates an LSA, the cost is *n.* This field is displayed only when RBM has adjusted the OSPFv3 cost.
SPF-schedule-interval	Interval for SPF calculations.
Transmit pacing	LSU advertisement rate: • **Interval**—Specifies the interval for sending LSUs. • **Count**—Specifies the maximum number of LSUs sent at each interval.
Default ASE parameters	Default parameters of redistributed routes. **Tag** represents the route tag of the redistributed routes.
Route preference	Internal route preference.
ASE route preference	AS-external route preference.
FRR backup mode	FRR backup mode: • **LFA**—Uses the LFA algorithm to calculate a backup next hop for all routes. **LFA ABR-only** indicates that only the next hop of the route to the ABR can be used as the backup next hop. • **route-policy** *route-policy-name*—Specifies a backup next hop by using a routing policy.
LSA originated count	Number of originated LSAs.
LSA received count	Number of received LSAs.
SNMP trap rate limit interval: 10 Count: 7	OSPFv3 can output a maximum of 7 SNMP notifications within 10 seconds.
Area count	Total number of areas.
Stub area count	Number of stub areas.
NSSA area count	Number of NSSA areas.
ExChange/Loading neighbors	Neighbors in ExChange/Loading state.

Field	Description
Calculation trigger type	Route calculation trigger type: • **Full**—Calculation of all routes is triggered. • **Area topology change**—Topology change in an area. • **Intra router change**—Incremental intra-area route change. • **ASBR change**—Incremental ASBR route change. • **Full IP prefix**—Calculation of all IP prefixes is triggered. • **Full intra AS**—Calculation of all intra-AS prefixes is triggered. • **Inc intra AS**—Calculation of incremental intra-AS prefixes is triggered. • **Full inter AS**—Calculation of all AS-external prefixes is triggered. • **Inc inter AS**—Calculation of incremental AS-external prefixes is triggered. • **Nexthop calculation**—Calculation of next hops is triggered. • **N/A**—Route calculation is not triggered.
Current calculation type	Current route calculation type: • SPF calculation. • **Intra router calculation**—Intra-area route calculation. • **ASBR calculation**—Inter-area ASBR route calculation. • **Inc intra router**—Incremental intra-area route calculation. • **Inc ASBR calculation**—Incremental inter-area ASBR route calculation. • **Full intra AS**—Calculation of all intra-AS prefixes. • **Inc intra AS**—Calculation of incremental intra-AS prefixes. • **Full inter AS**—Calculation of all AS-external prefixes. • **Inc inter AS**—Calculation of incremental AS-external prefixes. • **N/A**—Route calculation is not triggered.
Current calculation phase	Current route calculation phase: • **Calculation area topology**—Calculating area topology. • **Calculation router**—Calculating routes on routers. • **Calculation intra AS**—Calculating intra-AS routes. • **Calculation ASBR**—Calculating routes on ASBRs. • **Calculation inter AS**—Calculating AS-external routes. • **Calculation end**—Ending phase of calculation. • **N/A**—Route calculation is not triggered.
Redistribute timer	Route redistribution timer status: on or off.
Redistribute schedule type	Route redistribution scheduling type: • **RIB**—Redistribute routes through the RIB table. • **Self**—Redistribute routes through the routing table. • **N/A**—Route redistribution is not triggered.
Redistribute route count	Number of redistributed routes.

Field	Description
Process reset state	Process reset state: • **N/A**—The process is not reset. • **Under reset**—The process is in the reset progress. • **Under RIB smooth**—The process is synchronizing RIB routes.
Current reset type	Current process reset type: • **N/A**—The process is not reset. • **GR quit**—Normal reset when GR quits abnormally. • **Delete**—Delete OSPFv3 process. • **Undo router-id**—Delete router ID. • **Set router-id**—Set router ID.
Next reset type	Next process reset type: • **N/A**—The process is not reset. • **GR quit**—Normal reset when GR quits abnormally. • **Delete**—Delete OSPFv3 process. • **Undo router-id**—Delete router ID. • **Set router-id**—Set router ID.
Reset prepare message replied	Modules that reply reset prepare messages: • **P**—Neighbor maintenance module. • **S**—LSDB synchronization module. • **C**—Route calculation module. • **R**—Route redistribution module.
Reset process message replied	Modules that reply reset process messages: • **P**—Neighbor maintenance module. • **S**—LSDB synchronization module. • **C**—Route calculation module. • **R**—Route redistribution module.

Reset phase of module	Reset phase of each module:
	• LSDB synchronization (S) module:
	  ◦ **N/A**—Not reset.
	  ◦ **Delete ASE**—Delete all ASE LSAs.
	  ◦ **Delete area LSA**—Delete LSAs from an area.
	  ◦ **Delete area IF**—Delete interfaces from an area.
	• Route calculation (C) module:
	  ◦ **N/A**—Not reset.
	  ◦ **Delete topology**—Delete area topology.
	  ◦ **Delete router**—Delete routes of routers.
	  ◦ **Delete intra AS**—Delete intra-AS routes
	  ◦ **Delete inter AS**—Delete AS-external routes.
	  ◦ **Delete ASBR**—Delete ASBR routes.
	• Route redistribution (R) module:
	  ◦ **N/A**—Not reset.
	  ◦ **Delete import**—Delete redistributed routes.

IPsec profile name	IPsec profile applied to the area.
Keychain authentication: Enabled (test)	Keychain authentication is enabled for the area, and keychain **test** is used.
Created by Vlink	The area is created through virtual link.

Field	Description
7/5 translator state	State of the translator that translates Type-7 LSAs to Type-5 LSAs: • **Enabled**—The translator is specified through commands. • **Elected**—The translator is designated through election. • **Disabled**—The device is not a translator.
7/5 translate stability timer interval	Stability interval (in seconds) for Type-7 LSA-to-Type-5 LSA translation.

display ospfv3 abr-asbr

Use **display ospfv3 abr-asbr** to display information about the routes to OSPFv3 ABR and ASBR.

Syntax

display ospfv3 [*process-id*] **abr-asbr**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays information about all the routes to the OSPFv3 ABR and ASBR.

Examples

Display information about all the routes to the OSPFv3 ABR and ASBR.

```
<Sysname> display ospfv3 abr-asbr

              OSPFv3 Process 1 with Router ID 1.1.1.1

Destination : 1.1.1.2                                Rtr Type : ABR
 Area        : 0.0.0.0                                Path Type: Intra
 Interface   : GE1/0/2                               BkInterface: GE1/0/1
 NextHop     : FE80:1:1::1
 BkNexthop   : FE80:1:2::2
 Cost        : 1

 Destination : 1.1.1.3                                Rtr Type : ASBR

Table 2 Command output

Field	Description
OSPFv3 Process 1 with Router ID 1.1.1.1	OSPFv3 process is 1, and router ID is 1.1.1.1.
Destination	Router ID of an ABR or ASBR.
Rtr Type	Router type: ABR or ASBR.
Area	Area ID of the next hop.
Path Type	Type of the route to the ABR or ASBR: • **Intra**—Intra-area route. • **Inter**—Inter-area route.
Interface	Output interface.
BkInterface	Backup output interface.
NextHop	Next hop address.
BkNexthop	Backup next hop address.
Cost	Cost from the router to the ABR or ASBR.

display ospfv3 abr-summary

Use **display ospfv3 abr-summary** to display ABR summary route information.

Syntax

display ospfv3 [*process-id*] [**area** *area-id*] **abr-summary** [*ipv6-address prefix-length*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays information about ABR summary routes for all OSPFv3 processes.

area *area-id*: Specifies an OSPFv3 area by its ID. The area ID is an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format. If you do not specify this option, the command displays information about ABR summary routes for all OSPFv3 areas.

ipv6-address prefix-length: Specifies an IPv6 address. The *ipv6-address* argument specifies an IPv6 prefix. The *prefix-length* argument specifies a prefix length in the range of 0 to 128. If you do not specify this argument, the command displays information about all summary routes on the ABR.

verbose: Displays detailed ABR summary route information. If you do not specify this keyword, the command displays brief ABR summary route information.

Examples

Display brief ABR summary route information in OSPFv3 process 1.

```
<Sysname> display ospfv3 1 abr-summary

            OSPFv3 Process 1 with Router ID 2.2.2.2

                    Area: 1.1.1.1
 Total summary addresses: 1

 Prefix      : 1000:4::/32
 Status      : Advertise
 NULL0       : Active
 Cost        : 1 (Configured)
 Routes count: 2
```

Table 3 Command output

Field	Description
Area	Area to which the summary routes belong.
Total summary addresses	Total number of summary routes.
Prefix	Prefix of the summary route.
Status	Advertisement status of the summary route.
NULL0	Null 0 route.
Cost	Cost of the summary route.
Routes count	Number of summarized routes.

Display detailed ABR summary route information in OSPFv3 process 1.

```
<Sysname> display ospfv3 1 abr-summary verbose

            OSPFv3 Process 1 with Router ID 2.2.2.2

                       Area: 1.1.1.1
Total summary addresses: 1

 Prefix      : 1000:4::/32
 Status      : Advertise
 NULL0       : Active
 Cost        : 1 (Configured)
 Routes count: 2
   Destination                                    Metric
   1000:4:10:3::/96                               1
   1000:4:11:3::/96                               1
```

Table 4 Command output

Field	Description
Destination	Destination address of a summarized route.
Metric	Metric of a summarized route.

display ospfv3 asbr-summary

Use **display ospfv3 asbr-summary** to display ASBR summary route information.

Syntax

display ospfv3 [*process-id*] **asbr-summary** [*ipv6-address prefix-length*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays information about ASBR summary routes for all OSPFv3 processes.

ipv6-address prefix-length: Specifies an IPv6 address. The *ipv6-address* argument specifies an IPv6 prefix. The *prefix-length* argument specifies a prefix length in the range of 0 to 128. If you do not specify this argument, the command displays information about all ASBR summary routes.

verbose: Displays detailed ASBR summary route information. If you do not specify this keyword, the command displays brief ASBR summary route information.

Examples

Display brief ASBR summary route information in OSPFv3 process 1.

```
<Sysname> display ospfv3 1 asbr-summary

              OSPFv3 Process 1 with Router ID 2.2.2.2

 Total summary addresses: 1

 Prefix      : 1000:4::/32
 Status      : Advertise

 Tag         : (Not configured)
 Nssa-only   : (Not configured)
 Routes count: 2
```

Table 5 Command output

Field	Description
Total summary addresses	Total number of summary routes.
Prefix	Prefix and prefix length of the summary route.
Status	Advertisement status of the summary route: • **Advertise**—The summary route has been advertised. • **Not-advertise**—The summary route has not been advertised.
NULL0	Status of the Null 0 route: • Active. • Inactive.
Cost	Cost of the summary route: • Configured. • Not configured.
Tag	Tag of the summary route: • Configured. • Not configured.
Nssa-only	Whether the **nssa-only** attribute is configured: • Configured. • Not configured.
Routes count	Number of summarized routes.

Display detailed ASBR summary route information in OSPFv3 process 1.

```
<Sysname> display ospfv3 1 asbr-summary verbose

              OSPFv3 Process 1 with Router ID 2.2.2.2

 Total summary addresses: 1

 Prefix      : 1000:4::/32
 Status      : Advertise

 Routes count: 2
  Destination                                Protocol Process Type Metric
  1000:4:10:3::/96                           Static   0       2    1
  1000:4:11:3::/96                           Static   0       2    1
```

Table 6 Command output

Field	Description
Destination	Prefix and prefix length of the summarized route.
Protocol	Routing protocol from which the route was redistributed.

Field	Description
Process	Process of the routing protocol from which the route was redistributed.
Type	Type of the summarized route.
Metric	Metric of the summarized route.

display ospfv3 event-log

Use **display ospfv3 event-log** to display OSPFv3 log information.

Syntax

display ospfv3 [*process-id*] **event-log** { **lsa-flush** | **peer** | **spf** }

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPFv3 log information for all processes.

lsa-flush: Specifies LSA aging log information.

peer: Specifies neighbor log information.

spf: Specifies route calculation log information.

Usage guidelines

Route calculation logs show the number of routes newly installed in the IPv6 routing table.

Neighbor logs include information about the following events:

- The OSPFv3 neighbor state goes down.
- The OSPFv3 neighbor state goes backward because the local end receives BadLSReq, SeqNumberMismatch, and 1-Way events.

Examples

Display OSPFv3 LSA aging log information for OSPFv3 process 1.

```
<Sysname>display ospfv3 1 event-log lsa-flush

              OSPFv3 Process 1 with Router ID 1.3.3.3

 2014-09-02 07:55:25 Received MaxAge LSA from 1.1.1.1
 Type: 3   LS ID: 0.0.0.2         AdvRtr: 1.1.1.1          Seq#: 80000001

 2014-09-02 07:55:22 Flushed MaxAge LSA by itself
 Type: 3   LS ID: 0.0.0.2         AdvRtr: 1.3.3.3          Seq#: 80000001
```

```
2014-09-02 07:55:07 Flushed MaxAge LSA by itself
Type: 3   LS ID: 0.0.0.40        AdvRtr: 1.3.3.3          Seq#: 80000001

2014-09-02 07:55:07 Flushed MaxAge LSA by itself
Type: 3   LS ID: 0.0.0.39        AdvRtr: 1.3.3.3          Seq#: 80000001
```

Table 7 Command output

Field	Description
Received MaxAge LSA from X.X.X.X	The device received an LSA that has reached the maximum age from X.X.X.X.
Flushed MaxAge LSA by itself	The device flushed the LSA that has reached the maximum age.
Type	LSA type.
LS ID	LSA link state ID.
AdvRtr	Advertising router.
Seq#	LSA sequence number.

Display OSPFv3 route calculation log information for OSPFv3 process 1.

```
<Sysname>display ospfv3 1 event-log spf

              OSPFv3 Process 1 with Router ID 1.3.3.3

Date       Time     Duration   Intra   Inter   External Reason
2014-09-02 07:55:30 0.258827   0       0       0        Intra-area LSA
2014-09-02 07:55:30 0.679      0       0       0        Intra-area LSA
2014-09-02 07:55:30 0.51576    0       0       0        Intra-area LSA
2014-09-02 07:55:30 0.372      0       0       0        Intra-area LSA
2014-09-02 07:55:25 4.948353   0       0       0        Intra-area LSA
2014-09-02 07:55:25 0.5288     0       0       0        Area 0 full neighbor
2014-09-02 07:55:21 1.66013    0       0       0        Intra-area LSA

2014-09-02 07:55:15 0.253688   0       0       0        Interface state change
2014-09-02 07:55:15 0.5693     0       0       0        Intra-area LSA
```

Table 8 Command output

Field	Description
Date	Date when the route calculation starts, in YYYY-MM-DD format. YYYY represents the year, MM represents the month, and DD represents the day.
Time	Time when the route calculation starts, in hh:mm:ss format. hh represents the hours, mm represents the minutes, and ss represents the seconds.
Duration	Duration of the route calculation, in seconds.
Intra	Number of intra-area routes newly installed in the IPv6 routing table.
Inter	Number of inter-area routes newly installed in the IPv6 routing table.
External	Number of external routes newly installed in the IPv6 routing table.

Field	Description
Reason	Reasons why the route calculation is performed: • **Intra-area LSA**—Intra-area LSA changes. • **Inter-area LSA**—Inter-area LSA changes. • **External LSA**—External LSA changes. • **Configuration**—Configuration changes. • **Area 0 full neighbor**—Number of **FULL**-state neighbors in Area 0 changes. • **Area 0 up interface**—Number of interfaces in up state in Area 0 changes. • **AS number**—AS number changes. • **ABR summarization**—ABR summarization changes. • **GR end**—GR ends. • **Routing policy**—Routing policy changes. • **Intra-area tunnel**—Intra-area tunnel changes. • **Others**—Other reasons.

Display OSPFv3 neighbor log information for OSPFv3 process 1.

```
<Sysname> display ospfv3 1 event-log peer

              OSPFv3 Process 1 with Router ID 1.1.1.1

Date       Time     Router ID       Reason       InstID  Interface
2014-09-02 16:39:13 1.3.3.3         IntPhyChange 0       GE1/0/1
2014-09-02 16:36:46 1.3.3.3         IntPhyChange 0       GE1/0/1
2014-09-02 16:34:49 1.3.3.3         BFDDown      0       GE1/0/1
2014-09-02 10:08:45 1.3.3.3         DeadExpired  0       GE1/0/2
2014-09-02 10:08:39 1.3.3.3         DeadExpired  0       VLINK1
2014-09-02 10:08:08 1.3.3.3         BFDDown      0       GE1/0/1
```

Table 9 Command output

Field	Description
Date	Date when the neighbor state changes, in YYYY-MM-DD format. YYYY represents the year, MM represents the month, and DD represents the day.
Time	Time when the neighbor state changes, in hh:mm:ss format. hh represents the hours, mm represents the minutes, and ss represents the seconds.
Router ID	Neighbor router ID.

Field	Description
Reason	Reasons for neighbor state changes: • **ResetConnect**—The connection is lost due to insufficient memory. • **IntChange**—The interface parameter has changed. • **ResetOspfv3**—The OSPFv3 process is reset. • **UndoOspfv3**—The OSPFv3 process is deleted. • **UndoArea**—The OSPFv3 area is deleted. • **UndoInt**—The interface is disabled. • **IntLogChange**—The logical attribute of the interface has changed. • **IntPhyChange**—The physical attribute of the interface has changed. • **DeadExpired**—The dead timer expires. • **Retrans**—Excessive retransmissions. • **BFDDown**—The interface is shut down by BFD. • **SilentInt**—The interface is configured as a silent interface. • **ConfStubArea**—The interface is configured with stub area parameters. • **ConfNssaArea**—The interface is configured with NSSA area parameters. • **VlinkDown**—The virtual link goes down. • **BadLSReq**—The interface receives BadLSReq events. • **SeqMismatch**—The interface receives SeqNumberMismatch events. • **Way**—The interface receives 1-Way events.
InstID	Instance ID for an interface.
Interface	Interface name.

display ospfv3 graceful-restart

Use **`display ospfv3 graceful-restart`** to display GR information.

Syntax

`display ospfv3` [*`process-id`*] **`graceful-restart`** [**`verbose`**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`process-id`: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays GR information for all processes.

`verbose`: Displays detailed GR information. If you do not specify this keyword, the command displays brief GR information.

Examples

Display brief GR information for all OSPFv3 processes (GR restarter).

```
<Sysname> display ospfv3 graceful-restart

               OSPFv3 Process 1 with Router ID 3.3.3.3

 Graceful-restart capability     : Enable
 Graceful-restart support        : Planned and un-planned, Partial
 Helper capability               : Enable
 Helper support                  : Planned and un-planned
 Current GR state                : Normal
 Graceful-restart period         : 120 seconds
 Number of neighbors under helper: 0
 Number of restarting neighbors  : 0
 Last exit reason:
   Restarter: None
   Helper   : None
```

Table 10 Command output

Field	Description
OSPFv3 Process 1 with Router ID 3.3.3.3	The GR status of OSPFv3 process 1 with router ID 3.3.3.3 is displayed.
Graceful-restart capability	Whether OSPFv3 GR is enabled: • Enabled. • Disabled.
Graceful-restart support	GR modes that the process supports (displayed only when GR is enabled): • **Planned and un-planned**—Supports both planned and unplanned GR. • **Planned only**—Supports only planned GR. • **Partial**—Supports partial GR. • **Global**—Supports global GR.
Helper capability	Whether OSPFv3 GR helper is enabled: • Enabled. • Disabled.
Helper support	Policies and GR modes that the GR helper supports (displayed only when GR helper is enabled): • **Strict LSA check**—The GR helper supports strict LSA checking. • **Planned and un-planned**—The GR helper supports both planned and unplanned GR. • **Planned only**—The GR helper supports only planned GR.
Current GR state	GR status: • **Normal**—GR is not in progress or has completed. • **Under GR**—GR is in progress. • **Under Helper**—The process is acting as GR helper.
Graceful-restart period	GR restart interval.

Field	Description
Number of neighbors under helper	Number of neighbors in GR helper status.
Number of restarting neighbors	Number of neighbors in GR restarter status.

Last exit reason	Last exit reason:
	• **Restarter**—Reason that the restarter exited most recently:
	  ○ None.
	  ○ **Completed**—GR is completed.
	  ○ **Interval timer is fired**—The GR timer expires.
	  ○ **Interface state change**—An interface state change occurs.
	  ○ **Received 1-way hello**—The device receives 1-way hello packets from the neighbor.
	  ○ **Reset neighbor**—The neighbor is reset.
	  ○ **DR or BDR change**—The DR or BDR changes.
	• **Helper**—Reason that the helper exited most recently:
	  ○ None.
	  ○ **Completed**—GR is completed.
	  ○ **Received 1-way hello**—The device receives 1-way hello packets from the neighbor.
	  ○ **Grace Period timer is fired**—The GR timer expires.
	  ○ **Lsa check failed**—An LSA change on the GR helper is detected.
	  ○ **Reset neighbor**—The neighbor is reset.
	  ○ **Received MAXAGE gracelsa but neighbor is not full**—The device receives Grace-LSAs that reached the maximum age, but the neighbor is not in Full state.

Display detailed GR information for all OSPFv3 processes (GR restarter).

```
<Sysname> display ospfv3 graceful-restart verbose

               OSPFv3 Process 1 with Router ID 3.3.3.3

 Graceful-restart capability     : Enable
 Graceful-restart support        : Planned and un-planned, Partial

Area up interface count: 0
```

Table 11 Command output

Field	Description
Area	Area ID.
Area flag	Type of the area: • Normal. • Transit. • Stub. • **StubNoSummary**—Totally stub area. • NSSA. • **NSSANoSummary**—Totally NSSA area. • **NSSANoSummaryNoImportRoute**—Totally NSSA area with the **no-import-route** keyword configured.
7/5 translator state	State of the translator that translates Type-7 LSAs to Type-5 LSAs: • **Enabled**—The translator is specified through commands. • **Elected**—The translator is designated through election. • **Disabled**—The device is not a translator.
7/5 translate stability timer interval	Stability interval (in seconds) for Type-7 LSA-to-Type-5 LSA translation.
Area up interface count	Number of up interfaces in the area.
Interface	Interface in the area, or the output interface of the virtual link.
Restarter state	Restarter state on the interface.
State	Interface state.
Type	Interface network type.
Neighbor count of this interface	Number of neighbors on the interface.
Neighbor	Neighbor router ID.
GR state	Neighbor GR state: • **Normal**—GR is not in progress or has completed. • **Under GR**—GR is in process. • **Under Helper**—The process is acting as GR helper.
Last helper exit reason	Reason that the helper exited most recently.
Virtual-link Neighbor-ID	Router ID of the virtual link's neighbor.
Neighbor-State	Neighbor or virtual link state: Down, Init, 2-Way, ExStart, Exchange, Loading, and Full.
Local IPv6 address	Local IPv6 address of the neighbor relationship.
Remote IPv6 address	Peer IPv6 address of the neighbor relationship.
Transit area	Transit area ID.

display ospfv3 interface

Use **display ospfv3 interface** to display OSPFv3 interface information.

Syntax

display ospfv3 [*process-id*] **interface** [*interface-type interface-number* | **verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535.

interface-type interface-number: Specifies an interface by its type and number.

verbose: Displays detailed information about all OSPFv3 interfaces.

Usage guidelines

If you do not specify a process, this command displays brief OSPFv3 interface information for all processes.

If you do not specify the *interface-type interface-number* argument or the **verbose** keyword, this command displays brief information about all OSPFv3 interfaces.

Examples

Display OSPFv3 information about GigabitEthernet 1/0/1.

```
<Sysname> display ospfv3 interface gigabitethernet 1/0/1

               OSPFv3 Process 1 with Router ID 1.1.1.1

 Area: 0.0.0.0
----------------------------------------------------------------------------
 GigabitEthernet1/0/1 is up, line protocol is up
  Interface ID 3        Instance ID 0
  IPv6 prefixes
    FE80::200:12FF:FE34:1  (Link-Local address)
    2001::1
  Cost: 1       State: BDR       Type: Broadcast    MTU: 1500
  Priority: 1
  Designated router: 2.2.2.2
  Backup designated router: 1.1.1.1
  Timers: Hello 10, Dead 40, Poll 40, Retransmit 5, Transmit delay 1
  FRR backup: Enabled
  Neighbor count is 1, Adjacent neighbor count is 1
  Primary path detection mode: BFD echo
  IPsec profile name: profile001
```

```
Exchanging/Loading neighbors: 0
Wait timer: Off,  LsAck timer: Off
Prefix-suppression is enabled
```

Table 12 Command output

Field	Description
Area	Area ID that the interface belongs to.
Interface ID	Interface ID.
Instance ID	Instance ID.
IPv6 prefixes	IPv6 prefix.
Cost	Cost value of the interface.
State	Interface state: • **DOWN**—No protocol traffic can be sent or received on the interface. • **Waiting**—The interface starts sending and receiving Hello packets. The router is trying to determine the identity of the (Backup) designated router for the network. • **P-2-P**—The interface will send Hello packets at the hello interval, and try to establish an adjacency with the neighbor. • **DR**—The router is the designated router on the network. • **BDR**—The router is the backup designated router on the network. • **DROther**—The router is a DR Other router on the attached network.
Type	Network type of the interface: PTP (P2P), PTMP (P2MP), Broadcast, or NBMA.
MTU	MTU value of the interface.
Priority	DR priority of the interface.
Designated router	DR on this link.
Backup designated router	BDR on this link.
Timers	Time intervals in seconds configured on the interface: • **Hello**—Hello interval. • **Dead**—Dead interval. • **Poll**—Polling interval on an NBMA network. • **Retransmit**—LSA retransmission interval.
Transmit Delay	LSA transmission delay on the interface, in seconds.
FRR backup	Whether LFA calculation is enabled on an interface: • **Enabled**. • **Disabled**.
Neighbor count	Number of neighbors on the interface.
Primary path detection mode	Primary link detection mode: • **BFD ctrl**—BFD control packet mode. • **BFD echo**—BFD echo packet mode.
Adjacent neighbor count	Number of adjacencies on the interface.

Field	Description
IPsec profile name	IPsec profile applied to the interface. The **inherited** attribute indicates that the interface is using the IPsec profile specified for the area to which the interface belongs.

display ospfv3 lsdb

Use **display ospfv3 lsdb** to display OSPFv3 LSDB information.

Syntax

display ospfv3 [*process-id*] **lsdb** [{ **external** | **grace** | **inter-prefix** | **inter-router** | **intra-prefix** | **link** | **network** | **nssa** | **router** | **unknown** [*type*] } [*link-state-id*] [**originate-router** *router-id* | **self-originate**] | **statistics** | **total** | **verbose**]

Views

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays LSDB information for all processes.

external: Displays AS external LSAs (Type-5 LSAs).

grace: Displays Grace-LSAs (Type-11 LSAs).

inter-prefix: Displays Inter-area-prefix LSAs (Type-3 LSAs).

inter-router: Displays Inter-area-router LSAs (Type-4 LSAs).

intra-prefix: Displays Intra-area-prefix LSAs (Type-9 LSAs).

link: Displays Link-LSAs (Type-8 LSAs).

network: Displays Network-LSAs (Type-2 LSAs).

nssa: Displays NSSA LSAs (Type-7 LSAs).

router: Displays Router-LSAs (Type-1 LSAs).

unknown: Displays unknown LSAs.

type: Specifies an LSA type, a hexadecimal string of 0 to ffff. If you do not specify this argument, the command displays all unknown LSAs.

link-state-id: Specifies a link state ID in IPv4 address format.

originate-router *router-id*: Specifies an advertising router by its ID.

self-originate: Displays locally originated LSAs.

statistics: Displays LSA statistics.

total: Displays the total number of LSAs in the LSDB.

verbose: Displays detailed information. If you do not specify this keyword, the command displays brief information.

Examples

Display OSPFv3 LSDB information.

```
<Sysname> display ospfv3 lsdb
               OSPFv3 Process 1 with Router ID 1.1.1.1
                  Link-LSA (Interface GigabitEthernet1/0/1)

                 SendCnt: 0       RxmtCnt: 0       Status: Stale
```

Table 16 Command output

Field	Description
SendCnt	Number of interfaces to send the LSA.
RxmtCnt	Number of LSAs in the link state retransmission list.

Field	Description
Status	LSA status: • Normal. • Delayed. • **Maxage routed**—The LSA has reached its maximum age. • Self originated. • **Stale**—A self-originated LSA is received during the GR process.

display ospfv3 nexthop

Use **display ospfv3 nexthop** to display OSPFv3 next hop information.

Syntax

display ospfv3 [*process-id*] **nexthop**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays next hop information for all OSPFv3 processes.

Examples

Display next hop information for OSPFv3 process 1.

```
<Sysname> display ospfv3 1 nexthop

              OSPFv3 Process 1 with Router ID 1.1.1.1

 Nexthop : FE80::20C:29FF:FED7:F308              Interface: GE1/0/2
 RefCount: 4                                     Status   : Valid
 NbrID   : 1.1.1.1                               NbrIntID : 21

 Nexthop : FE80::20C:29FF:FED7:F312              Interface: GE1/0/3
 RefCount: 3                                     Status   : Valid
 NbrID   : 1.1.1.1                               NbrIntID : 38
```

Table 17 Command output

Field	Description
Nexthop	Next hop address.
Interface	Output interface.

Field	Description
RefCount	Reference count (routes that use the next hop).
Status	Next hop status: valid or invalid.
NbrId	Neighbor router ID.
NbrIntID	Neighbor interface ID.

display ospfv3 non-stop-routing

Use **display ospfv3 non-stop-routing** to display OSPFv3 NSR information.

Syntax

display ospfv3 [*process-id*] **non-stop-routing**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPFv3 NSR information for all OSPFv3 processes.

Examples

Display OSPFv3 NSR information.

```
<Sysname> display ospfv3 non-stop-routing

              OSPFv3 Process 1 with Router ID 3.3.3.3

 Nonstop Routing capability: Enabled
 Upgrade phase             : Normal
```

Table 18 Command output

Field	Description
Nonstop Routing capability	NSR status: enabled or disabled.
Upgrade phase	NSR phase: • **Normal**—Normal status. • **Preparation**—Upgrade preparation phase. • **Smooth**—Upgrade phase. • **Precalculation**—Route pre-calculation phase. • **Calculation**—Route calculation phase. • **Redistribution**—Route redistribution phase.

display ospfv3 peer

Use **display ospfv3 peer** to display information about OSPFv3 neighbors.

Syntax

display ospfv3 [*process-id*] [**area** *area-id*] **peer** [[*interface-type interface-number*] [**verbose**] | *peer-router-id* | **statistics**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify a process, this command displays neighbor information for all processes.

area *area-id*: Specifies an area by its ID, an IPv4 address or a decimal integer in the range of 0 to 4294967295 that is translated into the IPv4 address format. If you do not specify an area, this command displays neighbor information for all areas.

interface-type interface-number: Specifies an interface by its type and number.

verbose: Displays detailed neighbor information.

peer-router-id: Specifies a neighbor.

statistics: Displays OSPFv3 neighbor statistics.

Usage guidelines

If you do not specify an interface and a neighbor, this command displays neighbor information for all interfaces.

Examples

Display neighbor information for OSPFv3 process 1.

```
<Sysname> display ospfv3 1 peer

              OSPFv3 Process 1 with Router ID 1.1.1.1

 Area: 0.0.0.1
----------------------------------------------------------------------------
 Router ID       Pri State            Dead-Time InstID Interface
 2.2.2.2         1   Full/DR          00:00:33  0      GE1/0/1

 Sham link destination: 3::3
 Router ID       Pri State            Dead-Time InstID
 100.1.1.1       1   Full/ -          00:00:39  0
```

Table 19 Command output

Field	Description
Router ID	Neighbor router ID.
Pri	Neighboring router priority.
State	Neighbor state.
Dead-Time	Dead time remained.
InstID	Instance ID.
Interface	Interface connected to the neighbor.
Sham link destination	IPv6 destination address of the OSPFv3 sham link.

Display detailed neighbor information for OSPFv3 process 1.

```
<Sysname> display ospfv3 1 peer verbose

Table 20 Command output

Field	Description
Router ID	Neighbor router ID.
Address	Link-local address of the interface.
State	Neighbor state.
Mode	Neighbor mode for LSDB synchronization.
Priority	Neighboring router priority.
DR	DR on the interface's network segment.
BDR	BDR on the interface's network segment.
MTU	Interface MTU.
Options	LSA options: • **DC**—The originating router supports OSPFv3 over on-demand circuits. • **R**—Whether the originating router is an active router. • **N**—Whether the originating router supports NSSA LSAs. • **x**—Reserved. • **E**—Whether the originating router can receive AS External LSAs. • **V6**—Whether the originating router takes part in IPv6 route calculation.
Dead timer due in hh:mm:ss	Remaining time for the dead timer, in hh:mm:ss format. hh represents the hours, mm represents the minutes, and ss represents the seconds.
Neighbor is up for hh:mm:ss	Uptime for the neighbor, in hh:mm:ss format. hh represents the hours, mm represents the minutes, and ss represents the seconds.
Neighbor state change count	Count of neighbor state changes.
Database Summary List	Number of LSAs sent in DD packet.
Link State Request List	Number of LSAs in the link state request list.
Link State Retransmission List	Number of LSAs in the link state retransmission list.
Neighbor interface ID	Interface ID of the neighbor.
GR state	GR state: • **Normal**—GR is not in progress. • **Doing GR**—Acting as the GR restarter. • Complete GR. • **Helper**—Acting as the GR helper.
Grace period	Grace-LSA sending interval.
Grace period timer	Grace-LSA sending interval timer.
DD Rxmt Timer	DD packet retransmission timer.
LS Rxmt Timer	LSU retransmission timer.
Sham link neighbor with address	IPv6 neighbor address of the OSPFv3 sham link.

Display OSPFv3 neighbor statistics.

```
<Sysname> display ospfv3 peer statistics

               OSPFv3 Process 1 with Router ID 1.1.1.1
--------------------------------------------------------------------------
 Area ID         Down Attempt Init 2-Way ExStart Exchange Loading Full Total
 0.0.0.0         0    0       0    0     0       0        0       1    1
 Total           0    0       0    0     0       0        0       1    1
 Sham links' neighbors(Total: 1):
 Down: 0,Init: 0,2-Way: 0,ExStart: 0,Exchange: 0,Loading: 0,Full: 1
```

Table 21 Command output

Field	Description
Area ID	Area ID.
Down	In this state, neighbor initial state, the router has not received any information from a neighboring router for a period of time.
Attempt	This state is available only in an NBMA network. In this state, the OSPFv3 router has not received any information from a neighbor for a period. The router can send Hello packets at a longer interval to keep the neighbor relationship.
Init	In this state, the device received a Hello packet from the neighbor but the packet contains no router ID of the neighbor. Mutual communication is not setup.
2-Way	Mutual communication between the router and its neighbor is available. DR/BDR election is finished under this state (or higher).
ExStart	In this state, the router decides on the initial DD sequence number and active/standby relationship of the two parties.
Exchange	In this state, the router exchanges DD packets with the neighbor.
Loading	In this state, the router sends LSRs to request the neighbor for needed LSAs.
Full	LSDB synchronization has been accomplished between neighbors.
Total	Total number of neighbors under the same state.
Sham links' neighbors(Total: *xx*)	Statistics about sham links' neighbors. The **Total** field displays the total number of neighbors.

display ospfv3 request-queue

Use **display ospfv3 request-queue** to display OSPFv3 request list information.

Syntax

display ospfv3 [*process-id*] [**area** *area-id*] **request-queue** [*interface-type interface-number*] [*neighbor-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify an OSPFv3 process, this command displays OSPFv3 request list information for all OSPFv3 processes.

area *area-id*: Specifies an area by its ID, an IPv4 address or a decimal integer in the range of 0 to 4294967295 that is translated into the IPv4 address format. If you do not specify an OSPFv3 area, this command displays OSPFv3 request list information for all areas.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays OSPFv3 request list information for all interfaces.

neighbor-id: Specifies a neighbor's router ID. If you do not specify a neighbor, this command displays OSPFv3 request list information for all OSPFv3 neighbors.

Examples

Display OSPFv3 request list information.

```
<Sysname> display ospfv3 request-queue

               OSPFv3 Process 1 with Router ID 1.1.1.1

                   Area: 0.0.0.0
                   Interface GigabitEthernet1/0/1

 0x4005  0.0.34.130      1.3.3.3         0x80000001   0027  0x3935
```

Table 22 Command output

Field	Description
Area	Area ID.
Interface	Interface type and sequence number.
Nbr-ID	Neighbor ID.
Request list	Request list information.
Type	LSA type.
LinkState ID	Link state ID.
AdvRouter	Advertising router.
SeqNum	LSA sequence number.
Age	LSA age.
CkSum	Checksum.

display ospfv3 retrans-queue

Use **display ospfv3 retrans-queue** to display retransmission list information.

Syntax

display ospfv3 [*process-id*] [**area** *area-id*] **retrans-queue** [*interface-type interface-number*] [*neighbor-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify an OSPFv3 process, this command displays retransmission list information for all OSPFv3 processes.

area *area-id*: Specifies an area by its ID, an IPv4 address or a decimal integer in the range of 0 to 4294967295 that is translated into the IPv4 address format. If you do not specify an OSPFv3 area, this command displays retransmission list information for all OSPFv3 areas.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays retransmission list information for all interfaces.

neighbor-id: Specifies a neighbor's router ID. If you do not specify a neighbor, this command displays retransmission list information for all neighbors.

Examples

Display OSPFv3 retransmission list information.

```
<Sysname> display ospfv3 retrans-queue

                OSPFv3 Process 1 with Router ID 1.1.1.1

                    Area: 0.0.0.0
                    Interface GigabitEthernet1/0/1
--------------------------------------------------------------------------
                    Nbr-ID 1.2.2.2 Retransmit List
 Type    LinkState ID    AdvRouter       SeqNum       Age   CkSum
 0x2009  0.0.0.0         1.3.3.3         0x80000001   3600  0x49fb
```

Table 23 Command output

Field	Description
Area	Area ID.
Interface	Interface type and sequence number.
Nbr-ID	Neighbor ID.
Retransmit List	Retransmission list information.
Type	LSA type.
LinkState ID	Link state ID.
AdvRouter	Advertising router.

Field	Description
SeqNum	LSA sequence number.
Age	LSA age.
CkSum	Checksum.

display ospfv3 routing

Use **display ospfv3 routing** to display OSPFv3 route information.

Syntax

display ospfv3 [*process-id*] **routing** [*ipv6-address prefix-length*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the OSPFv3 route information for all processes.

ipv6-address prefix-length: Specifies an IPv6 address. The *ipv6-address* argument specifies an IPv6 prefix. The *prefix-length* argument specifies a prefix length in the range of 0 to 128.

Examples

Display OSPFv3 routing information.

```
<Sysname> display ospfv3 routing

               OSPFv3 Process 1 with Router ID 9.9.9.9
------------------------------------------------------------------------
 I  - Intra area route,  E1 - Type 1 external route,  N1 - Type 1 NSSA route
 IA - Inter area route,  E2 - Type 2 external route,  N2 - Type 2 NSSA route
 *  - Selected route

Inter area	Number of inter-area routes.
ASE	Number of Type-5 external routes.
NSSA	Number of Type-7 external routes.

display ospfv3 spf-tree

Use **display ospfv3 spf-tree** to display OSPFv3 SPF tree information.

Syntax

display ospfv3 [*process-id*] [**area** *area-id*] **spf-tree** [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify a process, this command displays SPF tree information for all OSPFv3 processes.

area *area-id*: Specifies an OSPFv3 area by its ID. The area ID is an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format. If you do not specify an area, this command displays SPF tree information for all OSPFv3 areas.

verbose: Displays detailed OSPFv3 SPF tree information. If you do not specify this keyword, the command displays brief OSPFv3 SPF tree information.

Examples

Display brief SPF tree information for Area 0 in OSPFv3 process 1.

```
<Sysname> display ospfv3 1 area 0 spf-tree

               OSPFv3 Process 1 with Router ID 1.1.1.1

 Flags: S-Node is on SPF tree       R-Node is directly reachable
        I-Node or Link is init      D-Node or Link is to be deleted
        P-Neighbor is parent        A-Node is in candidate list
        C-Neighbor is child         H-Nexthop changed
        N-Link is a new path        V-Link is involved

                 Area: 0.0.0.0  Shortest Path Tree

 SPFNode         Type   Flag         SPFLink         Type   Cost  Flag
>1.1.1.1         Router S R
                                  -->2.2.2.2         RT2RT  1     C
                                  -->2.2.2.2         RT2RT  1     P
```

Table 25 Command output

Field	Description
SPFNode	SPF node, represented by the advertising router ID. Node type: • **Network**—Network node. • **Router**—Router node. Node flag: • **I**—The node is in initialization state. • **A**—The node is on the candidate list. • **S**—The node is on the SPF tree. • **R**—The node is directly connected to the root node. • **D**—The node is to be deleted.
SPFLink	SPF link, representing the advertising router ID. Link type: • **RT2RT**—Router to router. • **NET2RT**—Network to router. • **RT2NET**—Router to network. Link flag: • **I**—The link is in initialization state. • **P**—The peer is the parent node. • **C**—The peer is the child node. • **D**—The link is to be deleted. • **H**—The next hop is changed. • **V**—When the peer node is deleted or added, the peer node is not on the SPF tree or is deleted. • **N**—The link is newly added, and both end nodes are on the SPF tree. • **L**—The link is on the area change list.

Display detailed SPF tree information for Area 0 in OSPFv3 process 1.

```
<Sysname> display ospfv3 1 area 0 spf-tree verbose

               OSPFv3 Process 1 with Router ID 1.1.1.1

```

Table 26 Command output

Field	Description
SPFNode	SPF node.
AdvID	ID of the advertising router.
LsID	Link state ID.
NodeType	Node type.
Distance	Cost to the root node.
NodeFlag	Node flag.
Nexthop count	Number of next hops.
NbrID	Neighbor router ID.
NbrIntID	Neighbor interface ID.
Interface	Output interface.
NhFlag	Next hop flag: valid or invalid.
BkInterface	Backup output interface.
RefCount	Reference count (routes that use the backup next hop).
Nexthop	Next hop.
BkNexthop	Backup next hop.
SPFLink count	Number of SPF links.
IntID	Interface ID.
LinkType	Link type: • **RT2RT**—Router to router. • **NET2RT**—Network to router. • **RT2NET**—Router to network.
LinkCost	Link cost.
LinkNewCost	New link cost.

Field	Description
LinkFlag	Link flag: • **I**—The link is in initialization state. • **P**—The peer is the parent node. • **C**—The peer is the child node. • **D**—The link is to be deleted. • **H**—The next hop is changed. • **V**—When the peer node is deleted or added, the peer node is not on the SPF tree or is deleted. • **N**—The link is newly added, and both end nodes are on the SPF tree. • **L**—The link is on the area change list.
NexthopCnt	Number of next hops.
ParentLinkCnt	Number of parent links.

display ospfv3 statistics

Use **display ospfv3 statistics** to display OSPFv3 statistics.

Syntax

display ospfv3 [*process-id*] **statistics** [**error** | **packet** [*interface-type interface-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPFv3 statistics for all processes.

error: Displays error statistics. If you do not specify this keyword, the command displays OSPFv3 packet, LSA, and route statistics.

packet: Displays packet statistics.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays statistics for all interfaces.

Examples

Display OSPFv3 statistics.

```
<Sysname> display ospfv3 statistics

                OSPFv3 Process 1 with Router ID 1.1.1.1
                    Packet Statistics
----------------------------------------------------------
```

```

Table 28 Command output

Field	Description
Transmit error	Packets with error when being transmitted.
Neighbor state low	Packets received in low neighbor state.
Packet too small	Packets too small in length.
Bad version	Packets with wrong version.
Bad checksum	Packets with wrong checksum.
Unknown neighbor	Packets received from unknown neighbors.

Field	Description
Bad area ID	Packets with invalid area ID.
Bad packet	Packets illegal.
Packet dest error	Packets with wrong destination addresses.
Inactive area packet	Packets received in inactive areas.
Router ID confusion	Packets with duplicate router ID.
Bad virtual link	Packets on wrong virtual links.
HELLO: Hello-time mismatch	Hello packets with mismatched hello timer.
HELLO: Dead-time mismatch	Hello packets with mismatched dead timer.
HELLO: Ebit option mismatch	Hello packets with mismatched E-bit in the option field.
DD: Ebit option mismatch	DD packets with mismatched E-bit in the option field.
DD: Unknown LSA type	DD packets with unknown LSA type.
DD: MTU option mismatch	DD packets with mismatched MTU.
REQ: Empty request	LSR packets with no request information.
REQ: Bad request	Bad LSR packets.
UPD: LSA checksum bad	LSU packets with wrong LSA checksum.
UPD: Unknown LSA type	LSU packets with unknown LSA type.
UPD: Less recent LSA	LSU packets without the most recent LSA.
UPD: LSA length bad	LSU packets with wrong LSA length.
UPD: LSA AdvRtr id bad	LSU packets with wrong LSA advertising router.
ACK: Bad ack packet	Bad LSAck packets for LSU packets.
ACK: Invalid ack	Invalid LSAck packets.
Interface down	Shutdown times of the interface.
Multicast incapable	Failures to join the multicast group.
Authentication failure	Received packets with authentication failures.
AuthSeqNumber error	Received packets with incorrect sequence numbers.

Display OSPFv3 packet statistics for all processes and interfaces.

```
<Sysname> display ospfv3 statistics packet

          OSPFv3 Process 1 with Router ID 1.1.1.1

Input	Number of received packets.
Output	Number of sent packets.
Area	Area ID.
Interface	Interface name.

display ospfv3 vlink

Use **display ospfv3 vlink** to display OSPFv3 virtual link information.

Syntax

display ospfv3 [*process-id*] **vlink**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the OSPFv3 virtual link information for all OSPFv3 processes.

Examples

Display OSPFv3 virtual link information.

```
<Sysname> display ospfv3 vlink

              OSPFv3 Process 1 with Router ID 1.1.1.1

 Virtual-link Neighbor-ID: 12.2.2.2, Neighbor-state: Full
 Interface: 2348 (GigabitEthernet1/0/2), Instance-ID: 0
 Local  IPv6 address: 3:3333::12
 Remote IPv6 address: 2:2222::12
 Cost: 1  State: P-2-P  Type: Virtual
 Transit area: 0.0.0.1
```

```
Timers: Hello 10, Dead 40, Retransmit 5, Transmit delay 1
IPsec profile name: profile001
```

Table 30 Command output

Field	Description
Virtual-link Neighbor-ID	ID of the neighbor on the virtual link.
Neighbor-State	Neighbor state: Down, Init, 2-Way, ExStart, Exchange, Loading, or Full.
Interface	Number and name of the local interface on the virtual link.
Cost	Interface route cost.
State	Interface state.
Type	Virtual link.
Transit Area	Transit area ID. This field is displayed when a virtual link is present on the interface.
Timers	Values of OSPFv3 timers (in seconds): **Hello**, **Dead**, and **Retransmit**.
Transmit delay	LSA transmission delay on the interface, in seconds.
IPsec profile name	IPsec profile applied to the virtual link. The **inherited** attribute indicates that the virtual link is using the IPsec profile specified for the backbone area.
Keychain authentication: Enabled (test)	Keychain authentication is enabled for the virtual link, and keychain **test** is used. The **inherited** attribute indicates that the virtual link is using the authentication mode specified for the backbone area.

enable ipsec-profile

Use **`enable ipsec-profile`** to apply an IPsec profile to an OSPFv3 area.

Use **`undo enable ipsec-profile`** to remove the IPsec profile from the OSPFv3 area.

Syntax

`enable ipsec-profile` *`profile-name`*

`undo enable ipsec-profile`

Default

No IPsec profile is applied to an area.

Views

OSPFv3 area view

Predefined user roles

network-admin

context-admin

Parameters

`profile-name`: Specifies an IPsec profile by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

To protect routing information and prevent attacks, OSPFv3 can authenticate protocol packets by using an IPsec profile. For more information about IPsec profiles, see *Security Configuration Guide*.

Examples

Apply IPsec profile **profile001** to Area 0 in OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 0
[Sysname-ospfv3-1-area-0.0.0.0] enable ipsec-profile profile001
```

event-log

Use **event-log** to set the maximum number of OSPFv3 logs.

Use **undo event-log** to remove the configuration.

Syntax

event-log { **lsa-flush** | **peer** | **spf** } **size** *count*

undo event-log { **lsa-flush** | **peer** | **spf** } **size**

Default

The maximum number of LSA aging logs, neighbor logs, or route calculation logs is 10.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

lsa-flush: Specifies the maximum number of LSA aging logs.

peer: Specifies the maximum number of neighbor logs.

spf: Specifies the maximum number of route calculation logs.

size *count*: Specifies the maximum number of OSPFv3 logs, in the range of 0 to 65535.

Examples

Set the maximum number of route calculation logs to 50 in OSPFv3 process 100.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] event-log spf size 50
```

fast-reroute

Use **fast-reroute** to configure OSPFv3 FRR.

Use **undo fast-reroute** to restore the default.

Syntax

fast-reroute { **lfa** [**abr-only**] | **route-policy** *route-policy-name* }

undo fast-reroute

Default

OSPFv3 FRR is disabled.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

lfa: Uses the LFA algorithm to calculate a backup next hop for all routes.

abr-only: Uses the next hop of the route to the ABR as the backup next hop.

route-policy *route-policy-name*: Uses a routing policy to designate a backup next hop. The *route-policy-name* argument is a case-sensitive string of 1 to 63 characters.

Usage guidelines

Do not use the **fast-reroute lfa** command together with the **vlink-peer** command.

Examples

Enable FRR to calculate a backup next hop for all routes by using LFA algorithm in OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] fast-reroute lfa
```

filter

Use **filter** to configure inbound/outbound Inter-Area-Prefix-LSA filtering on an ABR.

Use **undo filter** to remove the configuration.

Syntax

filter { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } { **export** | **import** }

undo filter { **export** | **import** }

Default

Inter-Area-Prefix-LSAs are not filtered.

Views

OSPFv3 area view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999 to filter inbound/outbound Inter-Area-Prefix-LSAs.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter inbound/outbound Inter-Area-Prefix-LSAs.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter inbound/outbound Inter-Area-Prefix-LSAs.

export: Filters Inter-Area-Prefix-LSAs advertised to other areas.

import: Filters Inter-Area-Prefix-LSAs advertised into the local area.

Usage guidelines

This command applies only to an ABR.

When you specify an ACL, follow these guidelines:

- If the ACL does not exist or has no rules, the ABR does not filter Inter-Area-Prefix-LSAs.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all Inter-Area-Prefix-LSAs.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following methods:

- To deny or permit Inter-Area-Prefix-LSAs with the specified address prefix, use the **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour-addr sour-prefix* command.
- To deny or permit Inter-Area-Prefix-LSAs with the specified address prefix and prefix length, use the **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour-addr sour-prefix* **destination** *dest-addr dest-prefix* command.

The **source** keyword specifies the address prefix in an Inter-Area-Prefix LSA and the **destination** keyword specifies the prefix length of the address prefix. For the prefix length configuration to take effect, specify a contiguous prefix length.

Examples

Use IPv6 prefix list **my-prefix-list** to filter inbound Inter-Area-Prefix-LSAs. Use IPv6 basic ACL 2000 to filter outbound Inter-Area-Prefix-LSAs in OSPFv3 Area 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 1
[Sysname-ospfv3-1-area-0.0.0.1] filter prefix-list my-prefix-list import
[Sysname-ospfv3-1-area-0.0.0.1] filter 2000 export
```

filter-policy export

Use **filter-policy export** to configure OSPFv3 to filter redistributed routes.

Use **undo filter-policy export** to remove the configuration.

Syntax

filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* } **export** [**bgp4+** | **direct** | { **isisv6** | **ospfv3** | **ripng** } [*process-id*] | **static**]

undo filter-policy export [**bgp4+** | **direct** | { **isisv6** | **ospfv3** | **ripng** } [*process-id*] | **static**]

Default

Redistributed routes are not filtered.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999 to filter redistributed routes by destination address.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter redistributed routes by destination address.

bgp4+: Filters redistributed IPv6 BGP routes.

direct: Filters redistributed direct routes.

isisv6: Filters redistributed IPv6 IS-IS routes.

ospfv3: Filters redistributed OSPFv3 routes.

ripng: Filters redistributed RIPng routes.

process-id: Specifies a process by its ID in the range of 1 to 65535. The default value is 1.

static: Filters redistributed static routes.

Usage guidelines

When you specify an ACL, follow these guidelines:

- If the ACL does not exist or has no rules, OSPFv3 does not filter redistributed routes.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all redistributed routes.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL in one of the following ways:

- To deny or permit a route with the specified destination, use **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix*.
- To deny or permit a route with the specified destination and prefix, use **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix* **destination** *dest dest-prefix*.

The **source** keyword specifies the destination address of a route, and the **destination** keyword specifies the prefix of the route. For the configuration to take effect, specify a contiguous prefix.

Using the **filter-policy export** command filters only routes redistributed by the **import-route** command. If the **import-route** command is not configured to redistribute routes from other protocols and other OSPFv3 processes, the **filter-policy export** command does not take effect.

If you do not specify a routing protocol, the command filters all redistributed routes.

Examples

Use IPv6 prefix list **abc** to filter redistributed routes.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc permit 2002:1:: 64
[Sysname] ospfv3
[Sysname-ospfv3-1] filter-policy prefix-list abc export
```

Configure IPv6 advanced ACL 3000 to permit only route 2001::1/128. Use ACL 3000 to filter redistributed routes.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3000
[Sysname-acl-ipv6-adv-3000] rule 10 permit ipv6 source 2001::1 128 destination
ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff 128
[Sysname-acl-ipv6-adv-3000] rule 100 deny ipv6
[Sysname-acl-ipv6-adv-3000] quit
```

```
[Sysname] ospfv3
[Sysname-ospfv3-1] filter-policy 3000 export
```

filter-policy import

Use **filter-policy import** to configure OSPFv3 to filter routes calculated using received LSAs.

Use **undo filter-policy import** to remove the configuration.

Syntax

filter-policy { *ipv6-acl-number* [**gateway** *prefix-list-name*] | **prefix-list** *prefix-list-name* [**gateway** *prefix-list-name*] | **gateway** *prefix-list-name* | **route-policy** *route-policy-name* } **import**

undo filter-policy import

Default

Routes calculated using received LSAs are not filtered.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999 to filter routes by destination.

gateway *prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter routes by next hop. If you do not specify this option, the command does not filter routes by next hop.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter routes by destination.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter received routes.

Usage guidelines

When you specify an ACL, follow these guidelines:

- If the ACL does not exist or has no rules, OSPFv3 does not filter calculated routes.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all calculated routes.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL in one of the following ways:

- To deny or permit a route with the specified destination, use **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix*.
- To deny or permit a route with the specified destination and prefix, use **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix* **destination** *dest dest-prefix*.

The **source** keyword specifies the destination address of a route, and the **destination** keyword specifies the prefix of the route. For the configuration to take effect, specify a contiguous prefix.

Using the **filter-policy import** command filters only routes computed by OSPFv3. Routes that fail to pass the filter are not added to the routing table.

Examples

Use IPv6 prefix list **abc** to filter received routes.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc permit 2002:1:: 64
[Sysname] ospfv3
[Sysname-ospfv3-1] filter-policy prefix-list abc import
```

Configure IPv6 advanced ACL 3000 to permit only route 2001::1/128 to pass. Use ACL 3000 to filter received routes.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3000
[Sysname-acl-ipv6-adv-3000] rule 10 permit ipv6 source 2001::1 128 destination
ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff 128
[Sysname-acl-ipv6-adv-3000] rule 100 deny ipv6
[Sysname-acl-ipv6-adv-3000] quit
[Sysname] ospfv3
[Sysname-ospfv3-1] filter-policy 3000 import
```

graceful-restart enable

Use **graceful-restart enable** to enable the GR capability for OSPFv3.

Use **undo graceful-restart enable** to disable the GR capability for OSPFv3.

Syntax

graceful-restart enable [**global** | **planned-only**] *

undo graceful-restart enable

Default

The GR capability for OSPFv3 is disabled.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

global: Enables global GR. In global GR mode, a GR process can be completed only when all GR helpers exist. A GR process fails if a GR helper fails (for example, the interface connected to the GR helper goes down). If you do not specify this keyword, the command enables partial GR. In partial GR mode, a GR process can be completed as long as one GR helper exists.

planned-only: Enables planned GR only. If you do not specify this keyword, the command enables both planned GR and unplanned GR.

Usage guidelines

GR includes planned GR and unplanned GR.

- **Planned GR**—Manually restarts OSPFv3 or performs an active/standby switchover. Before OSPFv3 restart or active/standby switchover, the GR restarter sends Grace-LSAs to GR helpers.
- **Unplanned GR**—OSPFv3 restarts or an active/standby switchover occurs because of device failure. Before OSPFv3 restart or active/standby switchover, the GR restarter does not send Grace-LSAs to GR helpers.

OSPFv3 GR and OSPFv3 NSR are mutually exclusive. Do not configure the **graceful-restart enable** command and the **non-stop-routing** command at the same time.

To prevent service interruption after a master/backup switchover, a GR restarter running OSPFv3 must perform the following tasks:

- Keep the GR restarter forwarding entries stable during reboot.
- Establish all adjacencies and obtain complete topology information after reboot.

Examples

Enable the GR capability for OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] graceful-restart enable
```

Related commands

graceful-restart helper enable

graceful-restart helper enable

Use **graceful-restart helper enable** to enable the GR helper capability for OSPFv3.

Use **undo graceful-restart helper enable** to disable the GR helper capability for OSPFv3.

Syntax

graceful-restart helper enable [**planned-only**]

undo graceful-restart helper enable

Default

The GR helper capability for OSPFv3 is enabled.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

planned-only: Enables only planned GR for the GR helper. If you do not specify this keyword, the command enables both planned GR and unplanned GR for the GR helper.

Usage guidelines

Upon receiving the Grace-LSA, the neighbors with the GR helper capability enter the helper mode (and are called GR helpers). Then, the GR restarter retrieves its adjacencies and LSDB with the help of the GR helpers.

Examples

Enable the GR helper capability for OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] graceful-restart helper enable
```

Related commands

graceful-restart enable

graceful-restart helper strict-lsa-checking

Use **graceful-restart helper strict-lsa-checking** to enable strict LSA checking for the GR helper.

Use **undo graceful-restart helper strict-lsa-checking** to disable strict LSA checking for the GR helper.

Syntax

graceful-restart helper strict-lsa-checking

undo graceful-restart helper strict-lsa-checking

Default

Strict LSA checking for the GR helper is disabled.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Usage guidelines

With GR helper enabled, when an LSA change on the GR helper is detected, the GR helper device exits the GR helper mode.

Examples

Enable strict LSA checking for the GR helper in OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] graceful-restart helper strict-lsa-checking
```

Related commands

graceful-restart helper enable

graceful-restart interval

Use **graceful-restart interval** to set the GR restart interval.

Use **undo graceful-restart interval** to restore the default.

Syntax

graceful-restart interval *interval*

undo graceful-restart interval

Default

The GR restart interval is 120 seconds.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

interval: Specifies GR restart interval in the range of 40 to 1800 seconds.

Usage guidelines

For GR restart to succeed, the value of the GR restart interval cannot be smaller than the maximum OSPFv3 neighbor dead time of all the OSPFv3 interfaces.

Examples

Set the GR restart interval for OSPFv3 process 1 to 100 seconds.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] graceful-restart interval 100
```

Related commands

ospfv3 timer dead

import-route

Use **import-route** to enable route redistribution.

Use **undo import-route** to disable route redistribution.

Syntax

import-route bgp4+ [*as-number*] [**allow-ibgp**] [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

undo import-route bgp4+

import-route { **direct** | **guard** | **static** } [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

undo import-route { **direct** | **guard** | **static** }

import-route { **isisv6** | **ospfv3** | **ripng** } [*process-id* | **all-processes**] [**allow-direct** | **cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

undo import-route { **isisv6** | **ospfv3** | **ripng** } [*process-id* | **all-processes**]

Default

OSPFv3 does not redistribute routes.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

bgp4+: Redistributes IPv6 BGP routes.

direct: Redistributes direct routes.

guard: Redistributes guard routes.

static: Redistributes static routes.

isisv6: Redistributes IPv6 IS-IS routes.

ospfv3: Redistributes OSPFv3 routes.

ripng: Redistributes RIPng routes.

as-number: Redistributes routes from an AS specified by its number in the range of 1 to 4294967295. If you do not specify this argument, this command redistributes all IPv6 EBGP routes. As a best practice, specify an AS number to prevent the system from redistributing excessive IPv6 EBGP routes.

process-id: Specifies the process ID of a routing protocol, in the range of 1 to 65536. The default is 1.

all-processes: Redistributes routes from all the processes of the specified routing protocol.

allow-ibgp: Redistributes IBGP routes. The **import-route bgp4+** command redistributes only EBGP routes. The **import-route bgp4+ allow-ibgp** command redistributes both EBGP and IBGP routes, and might cause routing loops. Therefore, use it with caution.

allow-direct: Redistributes the networks of the local interfaces enabled with the specified routing protocol. If you do not specify this keyword, the networks of the local interfaces are not redistributed. If you specify both the **allow-direct** keyword and the **route-policy** *route-policy-name* option, make sure the **if-match** rule defined in the routing policy does not conflict with the **allow-direct** keyword. For example, if you specify the **allow-direct** keyword, do not configure the **if-match route-type** rule for the routing policy. Otherwise, the **allow-direct** keyword does not take effect.

cost *cost-value*: Specifies a cost for redistributed routes, in the range of 1 to 16777214. The default is 1.

nssa-only: Limits the route advertisement to the NSSA area by setting the P-bit of Type-7 LSAs to 0. If you do not specify this keyword, the P-bit of Type-7 LSAs is set to 1. If the router acts as both an ASBR and an ABR and **FULL** state neighbors exist in the backbone area, the P-bit of Type-7 LSAs originated by the router is set to 0. This keyword applies to NSSA routers.

route-policy *route-policy-name*: Specifies a routing policy to filter redistributed routes. The *route-policy-name* argument is a case-sensitive string of 1 to 63 characters.

tag *tag*: Specifies a tag for external LSAs, in the range of 0 to 4294967295. If you do not specify this option, the tag specified by the **default tag** command applies.

type *type*: Specifies the type for redistributed routes, 1 or 2. The default is 2.

Usage guidelines

An external route is a route to a destination outside the OSPFv3 AS. External routes include the following types:

- **Type-1 external routes**—Have high credibility. The cost of Type-1 external routes is comparable with the cost of OSPFv3 internal routes. The cost of a Type-1 external route equals the cost from the router to the ASBR plus the cost from the ASBR to the external route's destination.

- **Type-2 external routes**—Have low credibility. OSPFv3 considers the cost from the ASBR to a Type-2 external route is much bigger than the cost from the ASBR to an OSPFv3 internal router. The cost of a Type-2 external route equals the cost from the ASBR to the Type-2 external route's destination.

The **import-route** command cannot redistribute default routes.

The **import-route nssa-only** command redistributes AS-external routes in Type-7 LSAs only into the NSSA area.

Examples

Configure OSPFv3 process 1 to redistribute routes from RIPng and specify the type as type 2 and cost as 50.

```
<Sysname> system-view
[Sysname] ospfv3
[Sysname-ospfv3-1] import-route ripng 10 type 2 cost 50
```

Configure OSPFv3 process 100 to redistribute the routes discovered by OSPFv3 process 160.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] import-route ospfv3 160
```

Related commands

default-route-advertise

log-peer-change

Use **log-peer-change** to enable logging for neighbor state changes.

Use **undo log-peer-change** to disable logging for neighbor state changes.

Syntax

log-peer-change

undo log-peer-change

Default

Logging for neighbor state changes is enabled.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Usage guidelines

This feature enables the device to deliver logs about neighbor state changes to its information center. The information center processes logs according to user-defined output rules (whether and where to output logs). For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Disable logging for neighbor state changes for OSPFv3 process 100.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] undo log-peer-change
```

lsa-generation-interval

Use **lsa-generation-interval** to set the OSPFv3 LSA generation interval.

Use **undo lsa-generation-interval** to restore the default.

Syntax

lsa-generation-interval *maximum-interval* [*minimum-interval* [*incremental-interval*]]

undo lsa-generation-interval

Default

The maximum interval is 5 seconds, the minimum interval is 0 milliseconds, and the incremental interval is 0 milliseconds.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

maximum-interval: Specifies the maximum OSPFv3 LSA generation interval in the range of 1 to 60 seconds.

minimum-interval: Specifies the minimum OSPFv3 LSA generation interval in the range of 10 to 60000 milliseconds. The default is 0, which indicates that the minimum interval can be any value.

incremental-interval: Specifies the OSPFv3 LSA generation incremental interval in the range of 10 to 60000 milliseconds.

Usage guidelines

When network changes are infrequent, LSAs are generated at the minimum interval. If network changes become frequent, the LSA generation interval increases by the incremental interval × 2^{n-2} for each generation until the maximum interval is reached. The value *n* is the number of generation times.

The minimum interval and the incremental interval cannot be greater than the maximum interval.

Examples

Set the maximum LSA generation interval to 2 seconds, minimum interval to 100 milliseconds, and incremental interval to 100 milliseconds.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] lsa-generation-interval 2 100 100
```

maximum load-balancing

Use **maximum load-balancing** to set the maximum number of equal-cost multi-path (ECMP) routes.

Use **undo maximum load-balancing** to restore the default.

Syntax

maximum load-balancing *number*

undo maximum load-balancing

Default

The maximum number of OSPFv3 ECMP routes equals the maximum number of ECMP routes supported by the system.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the maximum number of ECMP routes. When the maximum number is 1, OSPFv3 does not perform load balancing.

Usage guidelines

The value range for the *number* argument of the **maximum load-balancing** command depends on the maximum number of ECMP routes supported by the system. You can use the **max-ecmp-num** command to set the maximum number of ECMP routes supported by the system to *m*. After a reboot, the value range for the *number* argument is 1 to *m*.

Examples

Set the maximum number of ECMP routes to 2.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] maximum load-balancing 2
```

non-stop-routing

Use **non-stop-routing** to enable OSPFv3 NSR.

Use **undo non-stop-routing** to disable OSPFv3 NSR.

Syntax

non-stop-routing

undo non-stop-routing

Default

OSPFv3 NSR is disabled.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command takes effect only for the current process. As a best practice, enable OSPFv3 NSR for each process if multiple OSPFv3 processes exist.

OSPFv3 NSR and OSPFv3 GR are mutually exclusive. Do not configure the **non-stop-routing** command and the **graceful-restart enable** command at the same time.

Examples

Enable NSR for OSPFv3 process 100.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] non-stop-routing
```

nssa

Use **nssa** to configure an area as an NSSA area.

Use **undo nssa** to restore the default.

Syntax

nssa [**default-route-advertise** [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] * | **no-import-route** | **no-summary** | [**translate-always** | **translate-never**] | **suppress-fa** | **translator-stability-interval** *value*] *

undo nssa

Default

No area is configured as an NSSA area.

Views

OSPFv3 area view

Predefined user roles

network-admin

context-admin

Parameters

default-route-advertise: Used on an NSSA ABR or an ASBR only. If it is configured on an NSSA ABR, the ABR redistributes a default route in a Type-7 LSA into the NSSA area. It redistributes a default route regardless of whether a default route exists in the routing table. If it is configured on an ASBR, the ASBR redistributes a default route in a Type-7 LSA only when the default route exists in the routing table.

cost *cost-value*: Specifies a cost for the default route, in the range of 0 to 16777214. If you do not specify this option, the default cost specified by the **default-cost** command applies.

nssa-only: Limits the default route advertisement to the NSSA area by setting the P-bit of Type-7 LSAs to 0. If you do not specify this keyword, the P-bit of Type-7 LSAs is set to 1. If the router acts as both an ASBR and an ABR and **FULL** state neighbors exist in the backbone area, the P-bit is set to 0.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. When the specified routing policy is matched, the command redistributes a default route in a Type-7 LSA into the OSPFv3 routing domain. The routing policy modifies values in the Type-7 LSA.

tag *tag*: Specifies a tag for the default route, in the range of 0 to 4294967295.

type *type*: Specifies a type for the Type-7 LSA, 1 or 2. The default is 2.

no-import-route: Used on an NSSA ABR to control the **import-route** command to not redistribute routes into the NSSA area.

no-summary: Used only on an ABR to advertise a default route in a Type-3 summary LSA into the NSSA area and to not advertise other summary LSAs into the area. The area is a totally NSSA area.

translate-always: Always translates Type-7 LSAs to Type-5 LSAs. This keyword takes effect only on an NSSA ABR.

translate-never: Never translates Type-7 LSAs to Type-5 LSAs. This keyword takes effect only on an NSSA ABR.

suppress-fa: Suppresses the forwarding address in the Type-7 LSAs from being placed in the Type-5 LSAs.

translator-stability-interval *value*: Specifies the stability interval of the translator. During the interval, the translator can maintain its translating capability after another device becomes the new translator. The *value* argument is the stability interval in the range of 0 to 900 seconds. The default interval is 0. A value of 0 means the translator does not maintain its translating capability when a new translator arises.

Usage guidelines

All routers attached to an NSSA area must be configured with the **nssa** command in area view.

Examples

Configure Area 1 as an NSSA area.

```
<Sysname> system-view
[Sysname] ospfv3 120
[Sysname-ospfv3-120] area 1
[Sysname-ospfv3-120-area-0.0.0.1] nssa
```

Related commands

default-cost

ospfv3

Use **ospfv3** to enable an OSPFv3 process and enter OSPFv3 view.

Use **undo ospfv3** to disable an OSPFv3 process.

Syntax

ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

undo ospfv3 [*process-id*]

Default

No OSPFv3 process is enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. The default process ID is 1.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the OSPFv3 process runs on the public network.

Usage guidelines

Specify a router ID for the OSPFv3 process. Otherwise, the OSPFv3 process cannot generate LSAs.

Examples

Enable OSPFv3 process 120 and set the router ID to 1.1.1.1.

```
<Sysname> system-view
[Sysname] ospfv3 120
[Sysname-ospfv3-120] router-id 1.1.1.1
```

ospfv3 area

Use **ospfv3 area** to enable an OSPFv3 process on an interface and specify an area for the interface.

Use **undo ospfv3 area** to disable an OSPFv3 process on an interface.

Syntax

ospfv3 *process-id* **area** *area-id* [**instance** *instance-id*]

undo ospfv3 *process-id* **area** *area-id* [**instance** *instance-id*]

Default

No OSPFv3 processes are enabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535.

area-id: Specifies an area by its ID, an IPv4 address or a decimal integer in the range of 0 to 4294967295 that is translated into the IPv4 address format.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Examples

Configure GigabitEthernet 1/0/1 to run instance 1 of OSPFv3 process 1 in Area 1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 1 area 1 instance 1
```

ospfv3 bfd enable

Use **ospfv3 bfd enable** to enable BFD on an OSPFv3 interface.

Use **undo ospfv3 bfd enable** to disable BFD on an OSPFv3 interface.

Syntax

ospfv3 bfd enable [**instance** *instance-id*]

undo ospfv3 bfd enable [**instance** *instance-id*]

Default

BFD is disabled on an OSPFv3 interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

BFD provides a mechanism to quickly detect the connectivity of links between OSPFv3 neighbors, improving the convergence speed of OSPFv3.

OSPFv3 uses BFD to implement bidirectional control detection.

Examples

Enable BFD on GigabitEthernet 1/0/1 in instance 1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 bfd enable instance 1
```

ospfv3 cost

Use **ospfv3 cost** to set an OSPFv3 cost for an interface in an instance.

Use **undo ospfv3 cost** to remove the configuration.

Syntax

ospfv3 cost *cost-value* [**instance** *instance-id*]

undo ospfv3 cost [**instance** *instance-id*]

Default

The cost is 1 for a VLAN interface, is 0 for a loopback interface, and is computed according to the interface bandwidth for other interfaces.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

cost-value: Specifies an OSPFv3 cost in the range of 0 to 65535 for a loopback interface, and in the range of 1 to 65535 for other interfaces.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Examples

Set the OSPFv3 cost to 33 for GigabitEthernet 1/0/1 in instance 1.

```
<Sysname> system-view
```

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 cost 33 instance 1
```

ospfv3 dr-priority

Use **ospfv3 dr-priority** to set the router priority for an interface in an instance.

Use **undo ospfv3 dr-priority** to remove the configuration.

Syntax

ospfv3 dr-priority *priority* [**instance** *instance-id*]

undo ospfv3 dr-priority [**instance** *instance-id*]

Default

An interface has a router ID of 1.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

priority: Specifies a router priority in the range of 0 to 255.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

An interface's router priority determines its privilege in DR/BDR selection.

Examples

Set the router priority for GigabitEthernet 1/0/1 in instance 1 to 8.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 dr-priority 8 instance 1
```

ospfv3 fast-reroute lfa-backup exclude

Use **ospfv3 fast-reroute lfa-backup exclude** to disable LFA on an interface.

Use **undo ospfv3 fast-reroute lfa-backup exclude** to remove the configuration.

Syntax

ospfv3 fast-reroute lfa-backup exclude [**instance** *instance-id*]

undo ospfv3 fast-reroute lfa-backup exclude [**instance** *instance-id*]

Default

LFA is enabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

An interface enabled with LFA can be selected as a backup interface. After you disable LFA on the interface, it cannot be selected as a backup interface.

Examples

Disable GigabitEthernet 1/0/1 from calculating a backup next hop by using the LFA algorithm.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 fast-reroute lfa-backup exclude
```

ospfv3 ipsec-profile

Use **ospfv3 ipsec-profile** to apply an IPsec profile to an OSPFv3 interface.

Use **undo ospfv3 ipsec-profile** to remove the IPsec profile from the OSPFv3 interface.

Syntax

ospfv3 ipsec-profile *profile-name* [**instance** *instance-id*]

undo ospfv3 ipsec-profile [**instance** *instance-id*]

Default

No IPsec profile is applied to an OSPFv3 interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

profile-name: Specifies an IPsec profile by its name, a case-insensitive string of 1 to 63 characters.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

An IPsec profile must be specified in this command. For more information about IPsec profiles, see *Security Configuration Guide*.

Examples

Apply IPsec profile **profile001** to GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 ipsec-profile profile001
```

ospfv3 mib-binding

Use **ospfv3 mib-binding** to bind an OSPFv3 process to MIB.

Use **undo ospfv3 mib-binding** to restore the default.

Syntax

ospfv3 mib-binding *process-id*

undo ospfv3 mib-binding

Default

MIB is bound to the OSPFv3 process with the smallest process ID.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535.

Usage guidelines

If the specified process ID does not exist, the MIB binding configuration fails.

Deleting an OSPFv3 process that has been bound to MIB unbinds the OSPFv3 process from MIB, and re-binds MIB to the OSPFv3 process with the smallest process ID.

Examples

Bind OSPFv3 process 100 to MIB.

```
<Sysname> system-view
[Sysname] ospfv3 mib-binding 100
```

ospfv3 mtu-ignore

Use **ospfv3 mtu-ignore** to configure an interface to ignore MTU check during DD packet exchange.

Use **undo ospfv3 mtu-ignore** to remove the configuration.

Syntax

ospfv3 mtu-ignore [**instance** *instance-id*]

undo ospfv3 mtu-ignore [**instance** *instance-id*]

Default

An interface performs MTU check during DD packet exchange.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

A neighbor relationship can be established only if the interface's MTU is the same as that of the peer.

Examples

Configure GigabitEthernet 1/0/1 that belongs to instance 1 to ignore MTU check during DD packet exchange.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 mtu-ignore instance 1
```

ospfv3 network-type

Use **ospfv3 network-type** to specify the network type for an OSPFv3 interface.

Use **undo ospfv3 network-type** to remove the configuration.

Syntax

ospfv3 network-type { **broadcast** | **nbma** | **p2mp** [**unicast**] | **p2p** } [**instance** *instance-id*]

undo ospfv3 network-type [**instance** *instance-id*]

Default

The network type of an OSPFv3 interface is broadcast.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

broadcast: Specifies the network type as broadcast.

nbma: Specifies the network type as NBMA.

p2mp: Specifies the network type as P2MP.

unicast: Specifies the P2MP interface to unicast OSPFv3 packets. By default, a P2MP interface multicasts OSPFv3 packets.

p2p: Specifies the network type as P2P.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

If a router on a broadcast network does not support multicast, configure the network type for the connected interfaces as NBMA.

If any two routers on an NBMA network are directly connected through a virtual link, the network is fully meshed. You can configure the network type for the connected interfaces as NBMA. If two routers are not directly connected, configure the P2MP network type so that the two routers can exchange routing information through another router.

When the network type of an interface is NBMA or P2MP unicast, you must use the **peer** command to specify the neighbor.

When the network type of an interface is P2MP unicast, all OSPFv3 packets are unicast by the interface.

Examples

Specify the OSPFv3 network type for GigabitEthernet 1/0/1 as NBMA.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 network-type nbma
```

Related commands

ospfv3 dr-priority

ospfv3 peer

Use **ospfv3 peer** to specify a neighbor and the DR priority of the neighbor.

Use **undo ospfv3 peer** to remove the configuration.

Syntax

ospfv3 peer *ipv6-address* [**cost** *cost-value* | **dr-priority** *priority*] [**instance** *instance-id*]

undo ospfv3 peer *ipv6-address* [**instance** *instance-id*]

Default

No link-local address is specified for the neighbor interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ipv6-address: Specifies the link-local IPv6 address of the neighbor.

cost *cost-value*: Specifies the cost of the neighbor, in the range of 1 to 65535.

dr-priority *priority*: Specifies the DR priority of the neighbor, in the range of 0 to 255. The default is 1.

instance *instance-id:* Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

For NBMA and P2MP interfaces (only when in unicast mode), you must specify the link-local IPv6 addresses of their neighbors because these interfaces cannot find neighbors through broadcasting hello packets. For NBMA interfaces, you can also specify DR priorities for their neighbors.

Examples

On GigabitEthernet 1/0/1, specify the link-local address of its neighbor as FE80::1111.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
```

```
[Sysname-GigabitEthernet1/0/1] ospfv3 peer fe80::1111
```

ospfv3 prefix-suppression

Use **ospfv3 prefix-suppression** to disable an OSPFv3 interface from advertising all its prefixes.

Use **undo ospfv3 prefix-suppression** to remove the configuration.

Syntax

ospfv3 prefix-suppression [**disable**] [**instance** *instance-id*]

undo ospfv3 prefix-suppression [**instance** *instance-id*]

Default

Prefix suppression is disabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

disable: Disables prefix suppression for an interface.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

To disable prefix suppression for an interface associated with an OSPFv3 process that has been enabled with prefix suppression, use the **ospfv3 prefix-suppression disable** command on that interface.

Examples

Enable prefix suppression for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 prefix-suppression
```

Related commands

prefix-suppression

ospfv3 primary-path-detect bfd

Use **ospfv3 primary-path-detect bfd** to enable BFD for OSPFv3 FRR.

Use **undo ospfv3 primary-path-detect bfd** to disable BFD for OSPFv3 FRR.

Syntax

ospfv3 primary-path-detect bfd { **ctrl** | **echo** } [**instance** *instance-id*]

undo ospfv3 primary-path-detect bfd [**instance** *instance-id*]

Default

BFD is disabled for OSPFv3 FRR.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ctrl: Enables BFD control packet mode.

echo: Enables BFD echo packet mode.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

This command enables OSPFv3 FRR to use BFD to detect primary link failures.

For an interface to run the BFD session in echo packet mode correctly, make sure the interface has an IPv6 global unicast address. For more information about IPv6 global unicast addresses, see IPv6 basics configuration in *Layer 3—IP Services Configuration Guide*.

Examples

On GigabitEthernet 1/0/1, enable BFD echo packet mode for OSPFv3 FRR.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] fast-reroute lfa
[Sysname-ospfv3-1] quit
[Sysname] bfd echo-source-ipv6 1::1
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 primary-path-detect bfd echo
```

ospfv3 timer dead

Use **ospfv3 timer dead** to set the OSPFv3 neighbor dead time.

Use **undo ospfv3 timer dead** to remove the configuration.

Syntax

ospfv3 timer dead *seconds* [**instance** *instance-id*]

undo ospfv3 timer dead [**instance** *instance-id*]

Default

The OSPFv3 neighbor dead time is 40 seconds for P2P and broadcast interfaces, and is 120 seconds for P2MP and NBMA interfaces.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the dead time in the range of 1 to 65535 seconds.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

If an interface receives no hello packet from a neighbor within the dead time, the interface determines that the neighbor is down.

The dead time must be a minimum of four times the hello time and must be identical on interfaces attached to the same network segment.

Examples

Set the OSPFv3 neighbor dead time to 60 seconds for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 timer dead 60
```

Related commands

ospfv3 timer hello

ospfv3 timer hello

Use **ospfv3 timer hello** to set the hello interval for an interface.

Use **undo ospfv3 timer hello** to remove the configuration.

Syntax

ospfv3 timer hello *seconds* [**instance** *instance-id*]

undo ospfv3 timer hello [**instance** *instance-id*]

Default

The hello interval is 10 seconds for P2P and broadcast interfaces, and is 30 seconds for P2MP or NBMA interfaces.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the hello interval in the range of 1 to 65535 seconds.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

The shorter the hello interval is, the faster the topology converges and the more resources are consumed. Make sure the hello interval on two neighboring interfaces is the same.

Examples

Set the hello interval to 20 seconds for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 timer hello 20
```

Related commands

ospfv3 timer dead

ospfv3 timer poll

Use **ospfv3 timer poll** to set the poll interval on an NBMA interface.

Use **undo ospfv3 timer poll** to remove the configuration.

Syntax

ospfv3 timer poll *seconds* [**instance** *instance-id*]

undo ospfv3 timer poll [**instance** *instance-id*]

Default

The poll interval is 120 seconds on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the poll interval in the range of 1 to 65535 seconds.

instance *instance-id*: Specifies an interface instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

When an NBMA interface finds its neighbor is down, it sends hello packets at the poll interval.

The poll interval must be a minimum of four times the hello interval.

Examples

Set the poll interval on GigabitEthernet 1/0/1 to 120 seconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 timer poll 120
```

Related commands

ospfv3 timer hello

ospfv3 timer retransmit

Use **ospfv3 timer retransmit** to set the LSA retransmission interval for an interface.

Use **undo ospfv3 timer retransmit** to remove the configuration.

Syntax

ospfv3 timer retransmit *seconds* [**instance** *instance-id*]

undo ospfv3 timer retransmit [**instance** *instance-id*]

Default

The interval is 5 seconds.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the LSA retransmission interval in the range of 1 to 3600 seconds.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

After the device sends an LSA to its neighbor, it waits for an acknowledgment. If the device receives no acknowledgment after the LSA retransmission interval elapses, it will retransmit the LSA.

To avoid unnecessary retransmissions, set an appropriate retransmission interval. For example, you can set a large retransmission interval value on a low-speed link.

Examples

Set the LSA retransmission interval to 12 seconds on GigabitEthernet 1/0/1 in instance 1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 timer retransmit 12 instance 1
```

ospfv3 trans-delay

Use **ospfv3 trans-delay** to set the transmission delay for an interface.

Use **undo ospfv3 trans-delay** to remove the configuration.

Syntax

ospfv3 trans-delay *seconds* [**instance** *instance-id*]

undo ospfv3 trans-delay [**instance** *instance-id*]

Default

The transmission delay is 1 second.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the transmission delay in the range of 1 to 3600 seconds.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

Each LSA in the LSDB has an age that increases by 1 every second, but the age does not change during transmission. Adding a transmission delay into the age time is important in low speed networks.

Examples

Set the transmission delay to 3 seconds for GigabitEthernet 1/0/1 in instance 1.

```
<Sysname> system-view
```

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 trans-delay 3 instance 1
```

preference

Use **preference** to set a preference for OSPFv3 routes.

Use **undo preference** to remove the configuration.

Syntax

preference [**ase**] { *preference* | **route-policy** *route-policy-name* } *

undo preference [**ase**]

Default

The preference is 10 for OSPFv3 internal routes and 150 for OSPFv3 external routes.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

ase: Specifies a preference for OSPFv3 external routes. If you do not specify this keyword, the command sets a preference for OSPFv3 internal routes.

preference: Specifies the preference value in the range of 1 to 255. A smaller value represents a higher preference.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to set a preference for matching routes.

Usage guidelines

If multiple routing protocols find multiple routes to the same destination, the router uses the route found by the protocol with the highest preference.

Examples

Set a preference of 150 for OSPFv3 routes.

```
<Sysname> system-view
[Sysname] OSPFv3
[Sysname-OSPFv3-1] preference 150
```

prefix-suppression

Use **prefix-suppression** to disable an OSPFv3 process from advertising all prefixes except for the prefixes of loopback interfaces and passive interfaces.

Use **undo prefix-suppression** to restore the default.

Syntax

prefix-suppression

undo prefix-suppression

Default

An OSPFv3 process advertises all prefixes.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Usage guidelines

By default, an OSPFv3 interface advertises all of its prefixes in LSAs. To speed up OSPFv3 convergence, you can suppress interfaces from advertising all of their prefixes. This feature helps improve network security by preventing IP routing to the suppressed networks.

To disable an OSPFv3 process from advertising the prefixes of loopback and passive interfaces, configure prefix suppression on the interfaces by using the **ospfv3 prefix-suppression** command.

When prefix suppression is enabled:

- OSPFv3 does not advertise the prefixes of suppressed interfaces in Type-8 LSAs.
- On broadcast and NBMA networks, the DR does not advertise the prefixes of suppressed interfaces in Type-9 LSAs that reference Type-2 LSAs.
- On P2P and P2MP networks, OSPFv3 does not advertise the prefixes of suppressed interfaces in Type-9 LSAs that reference Type-1 LSAs.

Examples

Enable prefix suppression for OSPFv3 process 100.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] prefix-suppression
```

Related commands

ospfv3 prefix-suppression

reset ospfv3 event-log

Use **reset ospfv3 event-log** to clear OSPFv3 log information.

Syntax

reset ospfv3 [*process-id*] **event-log** [**lsa-flush** | **peer** | **spf**]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command clears OSPFv3 log information for all OSPFv3 processes.

lsa-flush: Clears LSA aging log information.

peer: Clears neighbor log information.

spf: Clears route calculation log information.

Usage guidelines

If you do not specify a log type, this command clears all log information.

Examples

Clear OSPFv3 route calculation log information for all OSPFv3 processes.

```
<Sysname> reset ospfv3 event-log spf
```

Related commands

display ospfv3 event-log

reset ospfv3 process

Use **reset ospfv3 process** to restart OSPFv3 processes.

Syntax

reset ospfv3 [*process-id*] **process** [**graceful-restart**]

context-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command restarts all OSPFv3 processes.

graceful-restart: Restarts the OSPFv3 process by using GR.

Usage guidelines

The **reset ospfv3 process** command performs the following actions:

- Clears all invalid LSAs without waiting for their timeouts.
- Starts a new DR/BDR election.
- Keeps previous OSPFv3 configurations.

The system prompts you to select whether to restart OSPFv3 process upon execution of this command.

Examples

Restart all OSPFv3 processes.

```
<Sysname> reset ospfv3 process
Reset OSPFv3 process? [Y/N]:y
```

reset ospfv3 redistribution

Use **reset ospfv3 redistribution** to restart route redistribution.

Syntax

reset ospfv3 [*process-id*] **redistribution**

Views

network-admin

context-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command restarts route redistribution for all OSPFv3 processes.

Examples

Restart route redistribution.

```
<Sysname> reset ospfv3 redistribution
```

reset ospfv3 statistics

Use **reset ospfv3 statistics** to clear OSPFv3 statistics.

Syntax

reset ospfv3 [*process-id*] **statistics**

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command clears statistics for all OSPFv3 processes.

Examples

Clear statistics for all OSPFv3 processes.

```
<Sysname> reset ospfv3 statistics
```

router-id

Use **router-id** to configure a router ID.

Use **undo router-id** to restore the default.

Syntax

router-id *router-id*

undo router-id

Default

No router ID is configured.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

router-id: Specifies a router ID in IPv4 address format.

Usage guidelines

The router ID is the unique identifier for the device to run OSPFv3 in the AS. An OSPFv3 process cannot run without a router ID.

You must specify a unique router ID for each OSPFv3 process in an AS. When you run multiple OSPFv3 processes on a router, specify a unique router ID for each OSPFv3 process as a best practice.

Examples

Configure the router ID 10.1.1.3 for OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] router-id 10.1.1.3
```

Related commands

ospfv3

silent-interface

Use **silent-interface** to disable the specified interface from receiving and sending OSPFv3 packets.

Use **undo silent-interface** to remove the configuration.

Syntax

silent-interface { *interface-type interface-number* | **all** }

undo silent-interface { *interface-type interface-number* | **all** }

Default

An interface can receive and send OSPFv3 packets.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

interface-type interface-number: Specifies an interface by its type and number.

all: Specifies all interfaces.

Usage guidelines

Multiple processes can disable the same interface from receiving and sending OSPFv3 packets. However, the **silent-interface** command takes effect only on interfaces enabled with the current process.

Examples

Disable GigabitEthernet 1/0/1 from receiving and sending OSPFv3 packets in OSPFv3 processes 100 and 200.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] router-id 10.100.1.9
[Sysname-ospfv3-100] silent-interface gigabitethernet 1/0/1
[Sysname-ospfv3-100] quit
[Sysname] ospfv3 200
[Sysname-ospfv3-200] router-id 20.100.1.9
[Sysname-ospfv3-200] silent-interface gigabitethernet 1/0/1
```

snmp context-name

Use **snmp context-name** to configure an SNMP context for OSPFv3.

Use **undo snmp context-name** to restore the default.

Syntax

snmp context-name *context-name*

undo snmp context-name

Default

No SNMP contexts exist for OSPFv3.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

context-name: Specifies a context name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

The standard OSPFv3 MIB provides only single-instance MIB objects. For SNMP to correctly identify OSPFv3 management information in the standard OSPFv3 MIB, you must configure a unique context name for OSPFv3. If multiple OSPFv3 processes exist, you must assign a unique context to each process.

Context is a method introduced to SNMPv3 for multiple-instance management. For SNMPv1/v2c, you must specify a community name as a context name for protocol identification.

Examples

Configure the SNMP context name as **mib** for OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] snmp context-name mib
```

snmp trap rate-limit

Use **snmp trap rate-limit** to set the SNMP notification output interval and the maximum number of SNMP notifications that can be output at each interval.

Use **undo snmp trap rate-limit** to restore the default.

Syntax

snmp trap rate-limit interval *trap-interval* **count** *trap-number*

undo snmp trap rate-limit

Default

OSPFv3 outputs a maximum of seven SNMP notifications within 10 seconds.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

interval *trap-interval*: Specifies the SNMP notification output interval in the range of 2 to 60 seconds.

count *trap-number*: Specifies the number of SNMP notifications output by OSPFv3 at each interval, in the range of 0 to 300. The value of 0 indicates that OSPFv3 does not output SNMP notifications.

Examples

Configure OSPFv3 to output a maximum of 10 SNMP notifications within 5 seconds.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] snmp trap rate-limit interval 5 count 10
```

snmp-agent trap enable ospfv3

Use **snmp-agent trap enable ospfv3** to enable SNMP notifications for OSPFv3.

Use **undo snmp-agent trap enable ospfv3** to disable SNMP notifications for OSPFv3.

Syntax

snmp-agent trap enable ospfv3 [**grrestarter-status-change** | **grhelper-status-change** | **if-state-change** | **if-cfg-error** | **if-bad-pkt** | **neighbor-state-change** | **nssatranslator-status-change** | **virtif-bad-pkt** | **virtif-cfg-error** | **virtif-state-change** | **virtgrhelper-status-change** | **virtneighbor-state-change**] *

undo snmp-agent trap enable ospfv3 [**grrestarter-status-change** | **grhelper-status-change** | **if-state-change** | **if-cfg-error** | **if-bad-pkt** | **neighbor-state-change** | **nssatranslator-status-change** | **virtif-bad-pkt** | **virtif-cfg-error** | **virtif-state-change** | **virtgrhelper-status-change** | **virtneighbor-state-change**] *

Default

SNMP notifications for OSPFv3 are enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

grrestarter-status-change: Specifies notifications about GR restarter state changes.

grhelper-status-change: Specifies notifications about GR helper state changes.

if-state-change: Specifies notifications about interface state changes.

if-cfg-error: Specifies notifications about error configuration of an interface.

if-bad-pkt: Specifies notifications about error messages received on an interface.

neighbor-state-change: Specifies notifications about neighbor state changes.

nssatranslator-status-change: Specifies notifications about NSSA translator state changes.

virtif-bad-pkt: Specifies notifications about error messages received on a virtual interface.

virtif-cfg-error: Specifies notifications about error configuration of a virtual interface.

virtif-state-change: Specifies notifications about virtual interface state changes.

virtgrhelper-status-change: Specifies notifications about neighbor GR helper state changes of a virtual interface.

virtneighbor-state-change: Specifies notifications about the neighbor state changes of a virtual interface.

Examples

Disable SNMP notifications for OSPFv3.

```
<Sysname> system-view
[Sysname] undo snmp-agent trap enable ospfv3
```

spf-schedule-interval

Use **spf-schedule-interval** to set the OSPFv3 SPF calculation interval.

Use **undo spf-schedule-interval** to restore the default.

Syntax

spf-schedule-interval *maximum-interval* [*minimum-interval* [*incremental-interval*]]

undo spf-schedule-interval

Default

The maximum SPF calculation interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

maximum-interval: Specifies the maximum OSPFv3 route calculation interval in the range of 1 to 60 seconds.

minimum-interval: Specifies the minimum OSPFv3 route calculation interval in the range of 10 to 60000 milliseconds.

incremental-interval: Specifies the incremental OSPFv3 route calculation interval in the range of 10 to 60000 milliseconds.

Usage guidelines

Based on the LSDB, an OSPFv3 router uses SPF to calculate a shortest path tree with itself being the root. OSPFv3 uses the shortest path tree to determine the next hop to a destination. By adjusting the SPF calculation interval, you can prevent overconsumption of bandwidth and router resources due to frequent topology changes.

For a stable network, the minimum interval is used. If network changes become frequent, the SPF calculation interval increases by the incremental interval × 2^{n-2} for each calculation until the maximum interval is reached. The value *n* is the number of calculation times.

The minimum interval and the incremental interval cannot be greater than the maximum interval.

Examples

Set the maximum SPF calculation interval to 10 seconds, minimum interval to 500 milliseconds, and incremental interval to 300 milliseconds.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] spf-schedule-interval 10 500 300
```

stub

Use **stub** to configure an area as a stub area.

Use **undo stub** to restore the default.

Syntax

stub [**default-route-advertise-always** | **no-summary**] *

undo stub

Default

No area is configured as a stub area.

Views

OSPFv3 area view

Predefined user roles

network-admin

context-admin

Parameters

default-route-advertise-always: Enables the ABR to always advertise a default route into the stub area.

no-summary: Enables the ABR to advertise only a default route in an Inter-Area-Prefix-LSA into the stub area. No AS-external-LSA, Inter-Area-Prefix-LSA, or other Inter-Area-Router-LSA is advertised in the area. The area is a totally stub area.

Usage guidelines

To remove the **no-summary** configuration on an ABR, execute the **stub** command again to overwrite it.

To configure an area as a stub area, execute the **stub** command on all routers attached to the area.

Examples

Configure OSPFv3 area 1 as a stub area.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 1
[Sysname-ospfv3-1-area-0.0.0.1] stub
```

Related commands

default-cost

stub-router

Use **stub-router** to configure a router as a stub router.

Use **undo stub-router** to restore the default.

Syntax

stub-router r-bit [**include-stub** | **on-startup** { *seconds* | **wait-for-bgp** [*seconds*] }] *

stub-router max-metric [**external-lsa** [*max-metric-value*] | **summary-lsa** [*max-metric-value*] | **include-stub** | **on-startup** { *seconds* | **wait-for-bgp** [*seconds*] }] *

undo stub-router

Default

The router is not configured as a stub router.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

r-bit: Clears the R-bit of the Option field in Type-1 LSAs.

max-metric: Advertises the locally generated Type-1 LSAs with the maximum cost of 65535.

external-lsa *max-metric-value*: Specifies a cost for external LSAs, in the range of 1 to 16777215. The default is 16711680.

summary-lsa *max-metric-value*: Specifies a cost for Type-3 and Type-4 LSAs, in the range of 1 to 16777215. The default is 16711680.

include-stub: Specifies the cost for Type-9 LSAs that reference Type-1 LSAs to the maximum value 65535.

on-startup *seconds*: Specifies the router as a stub router during reboot, and specifies the timeout time in the range of 5 to 86400 seconds.

wait-for-bgp *seconds*: Specifies the router as a stub router during BGP route convergence after reboot, and specifies the timeout time in the range of 5 to 86400 seconds. The default timeout time is 600 seconds.

Usage guidelines

You can use the **stub-router r-bit** command or **stub-router max-metric** command to configure a router as a stub router.

- The **stub-router r-bit** command clears the R-bit of the Option field in Type-1 LSAs. When the R-bit is clear, the OSPFv3 router can participate in OSPFv3 topology distribution without forwarding traffic.
- The **stub-router max-metric** command specifies the OSPFv3 max-metric router LSA feature. This feature enables OSPFv3 to advertise its locally generated Type-1 LSAs with a maximum cost of 65535. Neighbors do not send packets to the stub router as long as they have a route with a smaller cost.

Examples

Configure a stub router.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] stub-router r-bit
```

transmit-pacing

Use **transmit-pacing** to set the LSU transmission interval and the maximum number of LSU packets that can be sent at each interval.

Use **undo transmit-pacing** to restore the default.

Syntax

transmit-pacing interval *interval* **count** *count*

undo transmit-pacing

Default

An OSPFv3 interface sends a maximum of three LSU packets every 20 milliseconds.

Views

OSPFv3 view

Predefined user roles

network-admin

context-admin

Parameters

interval *interval*: Specifies an interval at which an interface sends LSU packets, in the range of 10 to 1000 milliseconds. If the router has multiple OSPFv3 interfaces, increase the interval to reduce the total number of LSU packets sent by the router every second.

count *count*: Specifies the maximum number of LSU packets sent by an interface at each interval, in the range of 1 to 200. If the router has multiple OSPFv3 interfaces, decrease the maximum number to reduce the total number of LSU packets sent by the router every second.

Examples

Configure all the interfaces running OSPFv3 process 1 to send a maximum of 10 LSU packets every 30 milliseconds.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] transmit-pacing interval 30 count 10
```

vlink-peer

Use **vlink-peer** to configure a virtual link.

Use **undo vlink-peer** to remove a virtual link.

Syntax

vlink-peer *router-id* [**dead** *seconds* | **hello** *seconds* | **instance** *instance-id* | **ipsec-profile** *profile-name* | **keychain** *keychain-name* | **retransmit** *seconds* | **trans-delay** *seconds*] *

undo vlink-peer *router-id* [**dead** | **hello** | **ipsec-profile** | **keychain** | **retransmit** | **trans-delay**] *

Default

No virtual links exist.

Views

OSPFv3 area view

Predefined user roles

network-admin

context-admin

Parameters

router-id: Specifies the router ID of the neighbor on the virtual link.

dead *seconds*: Specifies the dead interval in the range of 1 to 32768 seconds. The default is 40. The dead interval must be identical with that on the virtual link neighbor, and must be a minimum of four times the hello interval.

hello *seconds*: Specifies the hello interval in the range of 1 to 8192 seconds. The default is 10. It must be identical with the hello interval on the virtual link neighbor.

instance *instance-id*: Specifies the instance ID of a virtual link, in the range of 0 to 255. The default is 0.

ipsec-profile *profile-name:* Specifies an IPsec profile by its name, a case-insensitive string of 1 to 63 characters. For more information about IPsec profiles, see *Security Configuration Guide*.

keychain: Specifies the keychain authentication mode.

keychain-name: Specifies a keychain by its name, a case-sensitive string of 1 to 63 characters.

retransmit *seconds*: Specifies the retransmission interval in the range of 1 to 3600 seconds. The default is 5.

trans-delay *seconds*: Specifies the transmission delay interval in the range of 1 to 3600 seconds. The default is 1.

Usage guidelines

You can configure a virtual link to maintain connectivity between a non-backbone area and the backbone, or maintain connectivity within the backbone. A virtual link is similar to an interface with OSPFv3 enabled. You can configure parameters such as **hello**, **dead**, **retransmit** and **trans-delay** for the virtual link.

Both ends of a virtual link must be ABRs that are configured with the **vlink-peer** command.

The following guidelines apply to parameters:

- The smaller the hello interval is, the faster the network converges, and the more network resources are consumed.
- For a low speed link, set a large retransmission interval to avoid unnecessary retransmissions.
- Specify a transmission delay with the **trans-delay** keyword depending on the interface delay.

The authentication mode specified for an OSPFv3 virtual link has a higher priority than the mode specified for the backbone area. If no authentication mode is specified for the virtual link, the mode specified for the backbone area applies.

When keychain authentication is configured for an OSPFv3 virtual link, OSPFv3 performs the following operations before sending a packet:

1. Obtains a valid send key from the keychain.

   OSPFv3 does not send the packet if it fails to obtain a valid send key.
2. Uses the key ID, authentication algorithm, and key string to authenticate the packet.

   If the key ID is greater than 65535, OSPFv3 does not send the packet.

When keychain authentication is configured for an OSPFv3 virtual link, OSPFv3 performs the following operations after receiving a packet:

1. Uses the key ID carried in the packet to obtain a valid accept key from the keychain.

   OSPFv3 discards the packet if it fails to obtain a valid accept key.
2. Uses the authentication algorithm and key string for the valid accept key to authenticate the packet.

   If the authentication fails, OSPFv3 discards the packet.

OSPFv3 supports the HMAC-SHA-256 and HMAC-SM3 authentication algorithms for keychain authentication.

The ID of keys used for keychain authentication can only be in the range of 0 to 65535.

Examples

Configure a virtual link to 10.10.0.3.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 1
[Sysname-ospfv3-1-area-0.0.0.1] vlink-peer 10.10.0.3
```

area-authentication send-only

Use **area-authentication send-only** to configure IS-IS not to check the authentication information in the received Level-1 packets, including LSPs, CSNPs, and PSNPs.

Use **undo area-authentication send-only** to restore the default.

Syntax

area-authentication send-only

undo area-authentication send-only

Default

When area authentication mode and key are configured, a Level-1 or Level-1-2 router checks the authentication information in the received packets.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Usage guidelines

When area authentication mode and key are configured, a Level-1 or Level-1-2 router adds the key in the specified mode into transmitted Level-1 packets (including LSPs, CSNPs, and PSNPs). It also checks the key in the received Level-1 packets.

To prevent packet exchange failure in case of an authentication key change, configure IS-IS not to check the authentication information in the received packets.

Examples

Configure IS-IS not to check the authentication information in the received packets.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] area-authentication send-only
```

area-authentication-mode { { **gca** *key-id* { **hmac-sha-1** | **hmac-sha-224** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** } [**nonstandard**] | **md5** | **simple** } { **cipher** | **plain** } *string* | **keychain** *keychain-name* } [**ip** | **osi**]

undo area-authentication-mode

Default

No area authentication mode or key is configured.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

gca: Specifies the Generic Cryptographic Authentication (GCA) mode.

key-id: Uniquely identifies an SA in the range of 1 to 65535. The sender inserts the Key ID into the authentication TLV, and the receiver authenticates the packet by using the SA that is selected based on the Key ID.

hmac-sha-1: Specifies the HMAC-SHA-1 algorithm.

hmac-sha-224: Specifies the HMAC-SHA-224 algorithm.

hmac-sha-256: Specifies the HMAC-SHA-256 algorithm.

hmac-sha-384: Specifies the HMAC-SHA-384 algorithm.

hmac-sha-512: Specifies the HMAC-SHA-512 algorithm.

nonstandard: Specifies the nonstandard GCA mode.

md5: Specifies the MD5 authentication mode.

simple: Specifies the simple authentication mode.

cipher: Specifies a key in encrypted form.

plain: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. Its plaintext form is a case-sensitive string of 1 to 16 characters. Its encrypted form is a case-sensitive string of 33 to 53 characters.

keychain: Specifies the keychain authentication mode.

keychain-name: Specifies a keychain by its name, a case-sensitive string of 1 to 63 characters.

ip: Checks IP-related fields in LSPs.

osi: Checks OSI-related fields in LSPs.

Usage guidelines

Area authentication enables IS-IS to discard routes from untrusted routers.

The key in the specified mode is inserted into all outbound Level-1 packets (LSP, CSNP, and PSNP) and is used to authenticate inbound Level-1 packets.

IS-IS keychain authentication supports the HMAC-MD5 and HMAC-SM3 authentication algorithms. For the HMAC-SM3 authentication algorithm, only key IDs in the range of 0 to 65535 are supported. When keychain authentication is used, IS-IS receives and sends packets as follows:

- Before IS-IS sends a Level-1 packet, it uses the valid send key obtained from the keychain to authenticate the packet. If no valid send key exists or the valid send key does not use the HMAC-MD5 or HMAC-SM3 algorithm, the authentication fails and the packet does not contain authentication information.
- After IS-IS receives a Level-1 packet, it processes the packet as follows:
  - If the authentication algorithm of the packet is HMAC-MD5, IS-IS uses a valid accept key obtained from the keychain to authenticate the packet. If no valid accept key exists or all valid accept keys fail to authenticate the packet, the authentication fails and the packet is discarded.
  - If the authentication algorithm of the packet is HMAC-SM3, IS-IS uses the key ID of the received packet to obtain the corresponding valid accept key from the keychain. Then, IS-IS uses the accept key to authenticate the packet. If IS-IS cannot find a valid accept key based on the key ID of the received packet or the packet fails the authentication, the packet is discarded.

Routers in an area must have the same authentication mode and key.

If neither **ip** nor **osi** is specified, OSI-related fields are checked.

When you specify the GCA mode, follow these guidelines:

- If you do not specify the **nonstandard** keyword, the device can communicate only with devices that use the GCA mode.
- If you specify the **nonstandard** keyword, the device can communicate only with devices that use the nonstandard GCA mode.

Examples

Set the area authentication mode to **simple**, and set the plaintext key to 123456.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] area-authentication-mode simple plain 123456
```

auto-cost enable

Use **auto-cost enable** to enable automatic link cost calculation.

Use **undo auto-cost enable** to disable automatic link cost calculation.

Syntax

auto-cost enable

undo auto-cost enable

Default

Automatic link cost calculation is disabled.

Views

IS-IS view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Usage guidelines

After automatic link cost calculation is enabled, the link cost is automatically calculated based on the bandwidth reference value of an interface. When the **cost-style** is **wide** or **wide-compatible**, the cost value of an interface is calculated by using the following formula: Cost = (Reference bandwidth value / Link bandwidth) × 10. For other cost styles, Table 1 applies.

Table 1 Automatic cost calculation scheme for cost styles other than wide and wide-compatible

Interface bandwidth	Cost
≤10 Mbps	60
≤100 Mbps	50
≤155 Mbps	40
≤622 Mbps	30
≤2500 Mbps	20
>2500 Mbps	10

Examples

Enable automatic link cost calculation for IS-IS process 1.

network-admin

context-admin

Parameters

cost-value: Specifies the link cost value. The value range varies by cost style.

- For styles **narrow**, **narrow-compatible**, and **compatible**, the cost value is in the range of 0 to 63.
- For styles **wide** and **wide-compatible**, the cost value is in the range of 0 to 16777215.

level-1: Applies the link cost to Level-1.

level-2: Applies the link cost to Level-2.

Usage guidelines

If no level is specified, the specified cost applies to both Level-1 and Level-2.

Examples

Set the global Level-1 link cost to 11 for IS-IS process 1.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] circuit-cost 11 level-1
```

Related commands

cost-style

isis cost

cost-style

Use **cost-style** to set a cost style.

Use **undo cost-style** to restore the default.

Syntax

cost-style { **narrow** | **wide** | **wide-compatible** | { **compatible** | **narrow-compatible** } [**relax-spf-limit**] }

undo cost-style

Default

The IS-IS cost style is **narrow**.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

narrow: Receives and sends only narrow cost style packets. The narrow cost is in the range of 0 to 63.

wide: Receives and sends only wide cost style packets. The wide cost is in the range of 0 to 16777215.

compatible: Receives and sends both wide and narrow cost style packets.

narrow-compatible: Receives both narrow and wide cost style packets, but sends only narrow cost style packets.

wide-compatible: Receives both narrow and wide cost style packets, but sends only wide cost style packets.

relax-spf-limit: Allows receiving routes with a cost greater than 1023. If you do not specify this keyword, routes with a cost bigger than 1023 will be discarded. This keyword is available only when **compatible** or **narrow-compatible** is used.

Examples

Configure the router to send only narrow cost style packets, but receive both narrow and wide cost style packets.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] cost-style narrow-compatible
```

Related commands

circuit-cost

isis cost

default-route-advertise

Use **default-route-advertise** to advertise a default route of 0.0.0.0/0.

Use **undo default-route-advertise** to restore the default.

Syntax

default-route-advertise [**avoid-learning** | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

undo default-route-advertise

Default

Default route advertisement is disabled.

Views

IS-IS IPv4 unicast address family view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

avoid-learning: Avoids learning the default route received in LSPs or generated by using the ATT bit to avoid routing loops.

level-1: Advertises a Level-1 default route.

level-1-2: Advertises both Level-1 and Level-2 default routes.

level-2: Advertises a Level-2 default route.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

tag *tag*: Specifies the tag value for the default route, in the range of 1 to 4294967295.

Usage guidelines

If no level is specified, a Level-2 default route is advertised.

The Level-1 default route is advertised to other routers in the same area, and the Level-2 default route is advertised to all the Level-2 and Level-1-2 routers.

You can use a routing policy to specify a level for the default route. The **apply isis level-1** command in routing policy view can generate a Level-1 default route. The **apply isis level-2** command in routing policy view can generate a Level-2 default route. The **apply isis**

level-1-2 command in routing policy view can generate both a Level-1 default route and Level-2 default route.

The tag value specified in the routing policy takes precedence over the tag value specified in this command.

Examples

Configure IS-IS process 1 to advertise a Level-2 default route.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
[Sysname-isis-1-ipv4] default-route-advertise
```

display isis

Use **display isis** to display configuration information for an IS-IS process.

Syntax

display isis [*process-id*]

Views

Parameters

process-id: Specifies a process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays configuration information for all IS-IS processes.

Examples

Display IS-IS configuration information.

```
<Sysname> display isis

Table 2 Command output

Field	Description
Network entity	Network entity name.
IS level	IS-IS routing level.
Cost style	Cost style.

Field	Description
Fast reroute	IS-IS FRR status: • **Disabled**—IS-IS FRR is disabled. • **LFA**—IS-IS FRR automatically calculates a backup next hop. • **Route-policy**—IS-IS FRR specifies a backup next hop by using a routing policy.
ECMP group	ECMP route grouping state: **Disabled** or **Enabled**.
Fast-reroute TI-LFA	Topology independent LFA (TI-LFA) FRR status: Disabled or Enabled.
Microloop-avoidance	Microloop avoidance status: **Disabled** or **Enabled**.
Microloop-avoidance RIB-update-delay	Microloop avoidance delay timer.
Fast-reroute TI-LFA	Remote LFA FRR status: **Disabled** or **Enabled**.
Node-protecting preference	Priority of the node-protection backup path selection policy.
Lowest-cost preference	Priority of the lowest-cost backup path selection policy.
SRLG preference	Priority of the shared risk link group (SRLG)-disjoint backup path selection policy.
Preference	IS-IS route preference.
LSP length receive	Maximum LSP that can be received.
LSP length originate	Maximum LSP that can be generated.
Maximum imported routes	Maximum number of redistributed Level-1/Level-2 IPv4/IPv6 routes.
Timers	Timers: • **LSP-max-age**—Maximum life period of LSPs. • **LSP-refresh**—Refresh interval of LSPs. • **SPF mode**—SPF interval calculation mode. • **SPF intervals**—Interval between SPF calculations.
IPv6 enabled	IPv6 is enabled.
Segment routing	Segment routing is supported.
Configured SRGB	Configured SRGB range. This field is displayed when SRGB is configured.
Effective SRGB	SRGB range that takes effect.
Level-1 tunnel count	Number of Level-1 SR tunnels.
Level-2 tunnel count	Number of Level-2 SR tunnels.
Local block	Minimum and maximum label values of the SRLB.

display isis event-log lsp

Use **display isis event-log lsp** to display IS-IS LSP log information.

Syntax

display isis event-log lsp { **purged** | **refreshed** } [**level-1** | **level-2**] [*process-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

purged: Displays log information about purged LSPs.

refreshed: Displays log information about refreshed LSPs, including generated and received LSPs.

level-1: Displays Level-1 LSP log information.

level-2: Displays Level-2 LSP log information.

process-id: Specifies a process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays LSP log information for all IS-IS processes.

Usage guidelines

If you do not specify a level, the command displays both Level-1 and Level-2 LSP log information.

Examples

Displays log information about purged LSPs.

```
<Sysname> display isis event-log lsp purged

                              LSP log for IS-IS(1)
                              --------------------

                                Level-1 LSP log

Related commands

reset isis event-log lsp

display isis event-log spf

Use **display isis event-log spf** to display IS-IS route calculation log information.

Syntax

display isis event-log spf [**ipv4** | **ipv6**] [[**level-1** | **level-2**] | **verbose**] * [*process-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ipv4: Displays IS-IS IPv4 route calculation log information.

ipv6: Displays IS-IS IPv6 route calculation log information.

level-1: Displays Level-1 route calculation log information.

level-2: Displays Level-2 route calculation log information.

verbose: Displays detailed route calculation log information. If you do not specify this keyword, the command displays brief route calculation log information.

process-id: Specifies a process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays route calculation log information for all IS-IS processes.

Usage guidelines

If you specify neither the **ipv4** nor **ipv6** keyword, the command displays IS-IS IPv4 route calculation log information for the public network.

If you do not specify a level, the command displays both Level-1 and Level-2 route calculation log information.

Examples

Display brief IS-IS route calculation log information.

```
<Sysname> display isis event-log spf

                              SPF Log for IS-IS(1)

Table 4 Command output

Field	Description
Date	Start date of route calculation.
Time	Start time of route calculation.
Duration	Route calculation duration in seconds. The value is accurate to six decimal places.
Count	Number of events that trigger the current route calculation.
Trigger event	Type of the most recent event that triggers route calculation: • NextHop changed. • DIS changed. • Interface metric changed. • SPF link changed. • Default route changed. • Summary route changed. • TE tunnel updated. • TE tunnel metric changed. • IPv6 mode changed. • FRR configuration changed. • Prefix priority configuration changed. • Route preference changed.

	• ISPF configuration changed. • Import filter policy changed. • ECMP configuration changed. • PIC configuration changed. • Interface LFA exclude changed. • ATT configuration changed. • GR/NSR first SPF. • GR over. • T3 timeout. • Direct route changed. • Logic interface changed. • Route leakage configuration changed. • NSR over. • Entered overload state. • Exited overload state. • Area address changed. • Route policy changed. • Redistributed route updated. • LSP updated. • MT disabled. • MT enabled. • TE tunnel configuration changed. • TE tunnel destination changed. • RIB smooth. • Remote LFA configuration changed. • LDP label changed.
Log date	Generation time of the route calculation logs.
Log key	Route calculation log key.
Trigger count	Number of events that trigger the current route calculation.
SPF details	Detailed information about the route calculation phases.
Phase	Route calculation phase: • **TE tunnel ADJ**—TE tunnel adjacency calculation. • **Topology**—Topology calculation. • **BSPF**—Backup SPF calculation. • **TI/R-LFA prepare**—TI-LFA/Remote LFA calculation preparation. • **Link PSPF**—SPF calculation after PSPF convergence for link protection. • **Link PQ**—P space and Q space calculation for link protection. • **Node PSPF**—SPF calculation after PSPF convergence for node protection. • **Node PQ**—P space and Q space calculation for node protection. • **LFA**—LFA calculation. • **Area**—Area calculation. • **PRC**—Prefix calculation. • **Route summary**—Route summarization calculation.
Description	Route calculation phase description: • **TE SPF nodes**—Number of SPF nodes for TE tunnel adjacency calculation. • **SPF nodes**—Number of SPF nodes for topology calculation. • **Candidate NBRs**—Number of candidate neighbors.

	• **TI/R-LFA links**—Number of TI-LFA/remote LFA protected links. • **TI/R-LFA nodes**—Number of TI-LFA/remote LFA protected nodes. • **LFA SPF nodes**—Number of SPF nodes for LFA calculation. • **Area addresses**—Number of area addresses. • **Add**, **modify**, and **delete**—Prefix calculation summary. • **Last 10 routes**—10 routes that are most recently calculated. • **Summary route nodes**—Number of summarized routes.
Total	Total duration time of all route calculation phases.

Table 5 Command output

Field	Description
Date	Start date of route calculation.
Time	Start time of route calculation.
Duration	Route calculation duration in seconds. The value is accurate to six decimal places.
Count	Number of events that trigger the current route calculation.
Trigger event	Type of the most recent event that triggers route calculation: • NextHop changed. • DIS changed. • Interface metric changed. • SPF link changed. • Default route changed. • Summary route changed. • TE tunnel updated. • TE tunnel metric changed. • IPv6 mode changed. • FRR configuration changed. • Prefix priority configuration changed. • Route preference changed. • ISPF configuration changed. • Import filter policy changed. • ECMP configuration changed. • PIC configuration changed. • Interface LFA exclude changed. • ATT configuration changed. • GR/NSR first SPF.

	• GR over. • T3 timeout. • Direct route changed. • Logic interface changed. • Route leakage configuration changed. • NSR over. • Entered overload state. • Exited overload state. • Area address changed. • Route policy changed. • Redistributed route updated. • LSP updated. • MT disabled. • MT enabled. • TE tunnel configuration changed. • TE tunnel destination changed. • RIB smooth.
Log date	Generation time of the route calculation logs.
Log key	Route calculation log key.
Trigger count	Number of events that trigger the current route calculation.
SPF details	Detailed information about the route calculation phases.
Phase	Route calculation phase: • **TE tunnel ADJ**—TE tunnel adjacency calculation. • **Topology**—Topology calculation. • **BSPF**—Backup SPF calculation. • **TI-LFA prepare**—TI-LFA calculation preparation. • **Link PSPF**—SPF calculation after PSPF convergence for link protection. • **Link PQ**—P space and Q space calculation for link protection. • **Node PSPF**—SPF calculation after PSPF convergence for node protection. • **Node PQ**—P space and Q space calculation for node protection. • **LFA**—LFA calculation. • **Area**—Area calculation. • **PRC**—Prefix calculation. • **Route summary**—Route summarization calculation.
Description	Route calculation phase description: • **TE SPF nodes**—Number of SPF nodes for TE tunnel adjacency calculation. • **SPF nodes**—Number of SPF nodes for topology calculation. • **Candidate NBRs**—Number of candidate neighbors. • **TI-LFA links**—Number of TI-LFA protected links. • **TI-LFA nodes**—Number of TI-LFA protected nodes. • **LFA SPF nodes**—Number of SPF nodes for LFA calculation. • **Area addresses**—Number of area addresses. • **Add, modify, and delete**—Prefix calculation summary. • **Last 10 routes**—10 routes that are most recently calculated. • **Summary route nodes**—Number of summarized routes.
Total	Total duration time of all route calculation phases.

Related commands

reset isis event-log spf

display isis graceful-restart event-log

Use **display isis graceful-restart event-log** to display IS-IS GR log information.

Syntax

display isis graceful-restart event-log slot *slot-number*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its ID.

Examples

Display IS-IS GR log information for the specified slot.

```
<Sysname> display isis graceful-restart event-log slot 1
IS-IS loginfo :
Sep 18 08:48:24 2015 slot 1 Process 1 enter GR restarting phase(Initialization).
Sep 18 08:48:24 2015 slot 1 Process 1 enter GR phase (LSDB synchronization).
Sep 18 08:48:24 2015 slot 1 Process 1 enter GR phase (TE tunnel prepare).
Sep 18 08:48:24 2015 slot 1 Process 1 enter GR phase (First SPF computation).
Sep 18 08:48:25 2015 slot 1 Process 1 enter GR phase (Redistribution).
Sep 18 08:48:25 2015 slot 1 Process 1 enter GR phase (Second SPF computation).
Sep 18 08:48:25 2015 slot 1 Process 1 enter GR phase (LSP stability).
Sep 18 08:48:25 2015 slot 1 Process 1 enter GR phase (LSP generation).
Sep 18 08:48:25 2015 slot 1 Process 1 enter GR phase (Finish).
Sep 18 08:48:25 2015 slot 1 Process 1 GR complete.
```

Table 6 Command output

Field	Description
GR phase	GR phase: • **Initialization**. • **LSDB synchronization**. • **TE tunnel prepare**—Preparing for TE tunnel computation. • **First SPF computation**. • **Redistribution**. • **Second SPF computation**. • **LSP stability**—Ready to generate LSPs. • **LSP generation**. • **Finish**.

display isis graceful-restart status

Use **display isis graceful-restart status** to display IS-IS GR state.

Syntax

display isis graceful-restart status [**level-1** | **level-2**] [*process-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

level-1: Displays the IS-IS Level-1 GR state.

level-2: Displays the IS-IS Level-2 GR state.

process-id: Specifies a process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays GR state of all IS-IS processes.

Examples

Display IS-IS GR state.

```
<Sysname> display isis graceful-restart status

                        Restart information for IS-IS(1)
                        --------------------------------
Restart status: COMPLETE
Restart phase: Finish
Restart t1: 3, count 10; Restart t2: 60; Restart t3: 300
SA Bit: supported

                          Level-1 restart information
                          ---------------------------
Total number of interfaces: 1
Number of waiting LSPs: 0

                          Level-2 restart information
                          ---------------------------
Total number of interfaces: 1
Number of waiting LSPs: 0
```

Table 7 Command output

Field	Description
Restart status	Current GR state: • **RESTARTING**—In this state, forwarding can be ensured. • **STARTING**—In this state, forwarding cannot be ensured. • **COMPLETE**—GR is completed.
Restart phase	Current Restart phase: • **Initialization**. • **LSDB synchronization**. • **TE tunnel prepare**. • **First SPF computation**. • **Redistribution**. • **Second SPF computation**. • **LSP stability**—Ready to generate LSPs. • **LSP generation**. • **Finish**.
Restart t1	T1 timer, in seconds.
count	Number of T1 timer expirations.
Restart t2	T2 timer, in seconds.
Restart t3	T3 timer, in seconds.
SA Bit	Whether SA is supported.
Total number of interfaces	Total number of IS-IS interfaces.
Number of waiting LSPs	Number of LSPs not obtained by the GR restarter from GR helpers during LSDB synchronization.

display isis interface

Use **`display isis interface`** to display IS-IS interface information.

Syntax

`display isis interface` [[*`interface-type interface-number`*] [**`verbose`**] | **`statistics`**] [*`process-id`*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`interface-type interface-number`: Displays information for a specified IS-IS interface. If you do not specify this argument, the command displays information about all interfaces.

verbose: Displays detailed information about an interface. If you do not specify this keyword, the command displays brief information about an interface.

statistics: Displays IS-IS interface statistics.

process-id: Displays IS-IS interface information for an IS-IS process specified by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays interface information for all IS-IS processes.

Examples

Display brief IS-IS interface information.

```
<Sysname> display isis interface

                    Interface information for IS-IS(1)
                    ----------------------------------

  Interface:  GigabitEthernet1/0/2
  Index     IPv4 state      IPv6 state     Circuit ID   MTU   Type   DIS
  00001     Up              Down           1            1497  L1/L2  No/No
```

Display detailed IS-IS interface information.

```
<Sysname> display isis interface verbose

                    Interface information for IS-IS(1)
                    ----------------------------------

  Interface:  GigabitEthernet1/0/2

Table 8 Command output

Field	Description
Interface	Interface type and number.
Index	Interface index.

Field	Description
IPv4 state	IPv4 state: • **Up**—The interface is up at both the link layer and network layer. • **Down**—The interface is down at the link layer and network layer. • **Lnk:Up/IP:Dn**—The interface is up at the link layer but is down at the network layer.
IPv6 state	IPv6 state: • **Up**—The interface is up at both the link layer and network layer. • **Down**—The interface is down at the link layer and network layer. • **Lnk:Up/IP:Dn**—The interface is up at the link layer but is down at the network layer.
Circuit ID	Circuit ID.
MTU	Interface MTU.
Type	Interface link adjacency type.
DIS	Indicates whether the interface is elected as the Level-1/Level-2 DIS. On a P2P network, this field displays a hyphen (-) because DIS election is not performed.
SNPA address	Subnet access point address.
IP address	Primary IP address.
Secondary IP address(es)	Secondary IP addresses.
IPv6 link-local address	IPv6 link local address.
Extended circuit ID	Extended circuit ID for a P2P link.
CSNP timer value	Interval for sending CSNP packets.
Hello timer value	Interval for sending Hello packets.
Hello multiplier value	Number of invalid Hello packets.
LSP timer value	Minimum interval for sending LSP packets.
LSP transmit-throttle count	Number of LSP packets sent each time.
Cost	Cost of the interface.
IPv6 cost	IPv6 link cost of the interface.
Priority	DIS priority.
Retransmit timer value	Retransmission interval for LSPs on a P2P link.
IPv4 BFD	Whether BFD for IS-IS is enabled: • **Disabled**. • **Enabled**.
IPv6 BFD	Whether BFD for IPv6 IS-IS is enabled: • **Disabled**. • **Enabled**.
IPv4 BFD session-restrict-adj	Whether IPv4 adjacency establishment and maintenance control based on BFD session state is enabled: • **Disabled**. • **Enabled**.

Field	Description
IPv6 BFD session-restrict-adj	Whether IPv6 adjacency establishment and maintenance control based on BFD session state is enabled: • **Disabled**. • **Enabled**.
IPv4 FRR LFA backup	Whether LFA calculation is enabled for IPv4 FRR: • **Disabled**. • **Enabled**.
IPv6 FRR LFA backup	Whether LFA calculation is enabled for IPv6 FRR: • **Disabled**. • **Enabled**.
IPv4 FRR TI-LFA	IPv4 TI-LFA calculation status: • **Disabled**. • **Enabled**.
IPv4 FRR remote-LFA	IPv4 remote LFA calculation status: • **Disabled**. • **Enabled**.
IPv4 prefix suppression	Whether IPv4 IS-IS prefix suppression is enabled: • **Disabled**. • **Enabled**.
IPv6 prefix suppression	Whether IPv6 IS-IS prefix suppression is enabled: • **Disabled**. • **Enabled**.
IPv4 tag	IPv4 tag value of the interface.
IPv6 tag	IPv6 tag value of the interface.
IPv4 primary path detection mode	IPv4 primary path detection mode: • **BFD ctrl**—BFD control packet mode. • **BFD echo**—BFD echo packet mode.
IPv6 primary path detection mode	IPv6 primary path detection mode: • **BFD ctrl**—BFD control packet mode. • **BFD echo**—BFD echo packet mode.
Prefix-SID type	Prefix SID type: • **Absolute**—Absolute value of the prefix SID. • **Index**—Index value of the prefix SID.
Value	Prefix SID value.
Prefix-SID validity	Whether the prefix SID is valid: • **Invalid**—The prefix SID is invalid because it is out of the SRGB range. • **Valid**—The prefix SID is valid.
Nexthop	Next hop address. This field displays 0.0.0.0 for a P2P network.
Type	Adjacency SID type: • **Absolute**—Absolute value of the adjacency SID. • **Index**—Index value of the adjacency SID.

Display IS-IS interface statistics.

```
<Sysname> display isis interface statistics
```

```
                Interface statistics information for IS-IS(1)
                ----------------------------------------
Type            IPv4 up/down          IPv6 up/down
LAN                   1/0                   0/0
P2P                   0/0                   0/0
```

Table 9 Command output

Field	Description
Type	Network type of the interface: • **LAN**—Broadcast network. • **P2P**—Point-to-point network.
IPv4 up	Number of IS-IS interfaces in up state.
IPv4 down	Number of IS-IS interfaces in down state.
IPv6 up	Number of IS-ISv6 interfaces in up state.
IPv6 down	Number of IS-ISv6 interfaces in down state.

display isis lsdb

Use **display isis lsdb** to display IS-IS LSDB information.

Syntax

display isis lsdb [[**level-1** | **level-2**] | **local** | [**lsp-id** *lspid* | **lsp-name** *lspname*] | **verbose**] * [*process-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

level-1: Displays the level-1 LSDB.

level-2: Displays the level-2 LSDB.

local: Displays LSP information generated locally.

lsp-id *lspid*: Specifies an LSP ID, in the form of *sysID. Pseudo ID-fragment num*, where *sysID* represents the originating node or pseudo node. *Pseudo ID* is separated by a dot from sysID and by a hyphen from *fragment num*.

lsp-name *lspname*: Specifies the LSP name, in the form of *Symbolic name.Pseudo ID-fragment num*, where *Pseudo ID* is separated by a dot from *Symbolic name* and by a hyphen from *fragment num*. If the Pseudo ID is 0, specify the LSP name in the form *Symbolic name-fragment num*.

verbose: Displays LSDB detailed information. If you do not specify this keyword, the command displays brief information about LSDB.

process-id: Specifies an IS-IS process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays LSDBs for all IS-IS processes.

Usage guidelines

If no level is specified, the command displays both Level-1 and Level-2 LSDB information.

Examples

Display brief Level-1 LSDB information.

```
<Sysname> display isis lsdb level-1

                        Database information for IS-IS(1)
                        ---------------------------------

```

Table 10 Command output

Field	Description
LSPID	LSP ID.
Seq Num	LSP sequence number.
Checksum	LSP checksum.
Holdtime	LSP lifetime, which decreases as time elapses.
Length	LSP length.
ATT/P/OL	• **ATT**—Attach bit. • **P**—Partition bit. • **OL**—Overload bit. 1 means the LSP bit is set and 0 means the LSP bit is not set.
Source	System ID of the originating router.
HOST NAME	Dynamic host name of the originating router.
ORG ID	Original system ID of the virtual system of the originating router.
NLPID	Network layer protocol the originating router runs.
Area address	Area address of the originating router.

Field	Description
IPv4 address	IP address of the originating router's IS-IS interface.
IPv6 address	IPv6 address of the originating router's IS-ISv6 interface.
MT ID 0000 (-/-) MT ID 0002 (-/-) MT ID 0006 (-/-)	Topology supported by the originating router (0/0/0 indicates ATT/P/OL): • **0000**—Base topology. • **(-/-)**—Attach bit/overload bit.
NBR ID	Neighbor ID of the originating router.
IPv6 unicast NBR ID	IPv6 unicast neighbor information about the originating router.
Router ID	Router ID.
IP-Internal	Internal IP address and mask of the originating router.
IP-External	External IP address and mask of the originating router.
IP-Extended	Extended IP address and mask of the originating router.
Cost	Cost.
Auth	Authentication information of the originating router.
IPv4 unicast	IPv4 unicast reachability information about the originating router.
LAN-ADJ-SID	SID advertisement information from the LAN adjacency path.
P2P-ADJ-SID	SID advertisement information from the P2P adjacency path.
Flags (F/B/V/L/S)	Adjacency SID flag: • **F**—Address family flag. If set, the adjacency SID refers to an IPv6 adjacency. If not set, the adjacency SID refers to an IPv4 adjacency. • **B**—Backup flag. If set, the adjacency SID is eligible for link protection. • **V**—Value/Index flag. If set, the adjacency SID carries an absolute value. If not set, the adjacency SID carries an index value. • **L**—Local flag. If set, the adjacency SID has local significance. If not set, the adjacency SID has global significance. • **S**—Set flag. If set, the adjacency SID refers to a set of adjacencies.
Weight	Adjacency path weight.
System ID	System ID.
Adjacency SID	SID advertised by the adjacency path.
Prefix-SID flags (R/N/P/E/V/L)	Prefix SID flag: • **R**—Re-advertisement flag. If set, inter-level propagation or route redistribution exists. • **N**—Node-SID flag. If set, the prefix SID is the SID to an SR node. • **P**—No-PHP flag. If set, the penultimate node cannot pop the prefix SID. • **E**—Explicit null flag. If set, the upstream neighbor must replace the prefix SID with an explicit null flag before forwarding the packets. • **V**—Value/Index flag. If set, the prefix SID carries an absolute value. • **L**—Local flag. If set, the prefix SID has local significance.
Perfix-SID	Prefix SID value.
Algorithm	Prefix related algorithm. Only SPF is supported in the current software version.
Router capability	Router capability sub-TLV information.

Field	Description
Flags (D/S)	Inter-level leaking flag: • **D**—D flag. If set, the router capability TLV cannot be leaked from Level-1 to Level-2. • **S**—S flag. If set, the router capability TLV must be flooded across the entire routing domain. If not set, the router capability TLV cannot be leaked between levels.
SRGB base	Minimum label value of the SRGB range.
SRGB range	Number of labels of the SRGB.
SRLB base	Minimum label value of the SRGB range.
SRLB range	Number of labels of the SRGB.
SRLG NBR ID	SRLG neighbor information about the originating router.
Interface IP address	IP address of the local interface.
Neighbor IP address	IP address of the remote interface.
Shared risk link group	Number of the SRLG to which the local interface belongs.
SID binding	Prefix-SID mapping information.
Flags (F/M/S/D/A)	Mapping flags: • **F**—Address family flag. If set, the peer is an IPv6 peer. If not set, the peer is an IPv4 peer. • **M**—Mirror context flag. If set, the SID is used for SR node protection. • **S**—Scope flag. If set, the route capability TLV can be leaked from Level-1 to Level-2. • **D**—Down flag. If set, the SID/Label Binding TLV is advertised from Level-2 to Level-1. • **A**—Attached flag. If set, the prefix and SID are advertised by a directly connected peer.
Range	Number of consecutive SIDs assigned.

display isis name-table

Use **`display isis name-table`** to display the host name-to-system ID mapping table.

Syntax

`display isis name-table` [*`process-id`*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`process-id`: Displays the host name to system ID mapping table for an IS-IS process specified by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the host name to system ID mapping table for all IS-IS processes.

Examples

Display the IS-IS host name to system ID mapping table.

```
<Sysname> display isis name-table
                     Name table information for IS-IS(1)
                     ----------------------------------
 System ID           Hostname                          Type       Level
 6789.0000.0001      RUTA                              DYNAMIC    Level-1
 6789.0000.0001      RUTA                              DYNAMIC    Level-2
 0000.0000.0041      RUTB                              STATIC     Level-1
 0000.0000.0041      RUTB                              STATIC     Level-2
 6789.0000.0001.01   DIS-A                             DYNAMIC    Level-1
 0000.0000.0041.01   DIS-B                             DYNAMIC    Level-2
```

Table 11 Command output

Field	Description
System ID	System ID.
Hostname	Host name.
Type	Mapping type: • **STATIC**. • **DYNAMIC**.
Level	Level on which the system ID-to-host name mapping takes effect: **Level-1** or **Level-2**.

display isis non-stop-routing event-log

Use **display isis non-stop-routing event-log** to display IS-IS NSR log information.

Syntax

display isis non-stop-routing event-log slot *slot-number*

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its ID.

Examples

Display IS-IS NSR log information for the specified slot.

```
<Sysname> display isis non-stop-routing event-log slot 1
IS-IS loginfo :
Sep 18 10:20:44 2015 slot 1 Enter HA Block status
Sep 18 10:20:44 2015 slot 1 Exit HA Block status
```

```
Sep 18 10:24:00 2015 slot 1 Process 100 enter NSR phase (Initialization).
Sep 18 10:24:00 2015 slot 1 Process 100 enter NSR phase (Smooth).
Sep 18 10:24:00 2015 slot 1 Process 100 enter NSR phase (TE tunnel prepare).
Sep 18 10:24:00 2015 slot 1 Process 100 enter NSR phase (First SPF computation).
Sep 18 10:24:00 2015 slot 1 Process 100 enter NSR phase (Redistribution).
Sep 18 10:24:00 2015 slot 1 Process 100 enter NSR phase (Second SPF computation).
Sep 18 10:24:00 2015 slot 1 Process 100 enter NSR phase (LSP stability).
Sep 18 10:24:00 2015 slot 1 Process 100 enter NSR phase (LSP generation).
Sep 18 10:24:00 2015 slot 1 Process 100 enter NSR phase (Finish).
Sep 18 10:24:00 2015 slot 1 Process 100 NSR complete.
```

Table 12 Command output

Field	Description
NSR phase	NSR phase: • **Initialization**. • **Smooth**. • **TE tunnel prepare**—Preparing for TE tunnel computation. • **First SPF computation**. • **Redistribution**. • **Second SPF computation**. • **LSP stability**—Ready to generate LSPs. • **LSP generation**. • **Finish**.

display isis non-stop-routing status

Use **`display isis non-stop-routing status`** to display IS-IS NSR status.

Syntax

`display isis non-stop-routing status`

Views

Any view

network-operator

context-admin

context-operator

Examples

Display IS-IS NSR status.

```
<Sysname> display isis non-stop-routing status

                      Nonstop Routing information for IS-IS(1)
                    ----------------------------------------
NSR phase: Finish
```

Table 13 Command output

Field	Description
NSR phase	NSR phase: • **Initialization**. • **Smooth**. • **TE tunnel prepare**. • **First SPF computation**. • **Redistribution**. • **Second SPF computation**. • **LSP stability**—Ready to generate LSPs. • **LSP generation**. • **Finish**.

display isis peer

Use **display isis peer** to display IS-IS neighbor information.

Syntax

display isis peer [**statistics** | **verbose**] [*process-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

statistics: Displays IS-IS neighbor statistics.

verbose: Displays detailed IS-IS neighbor information. If you do not specify this keyword, the command displays brief IS-IS neighbor information.

process-id: Displays IS-IS neighbor information for an IS-IS process specified by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays neighbor information for all IS-IS processes.

Examples

Display brief IS-IS neighbor information.

```
<Sysname> display isis peer

                        Peer information for IS-IS(1)
                        ------------------------------

 System ID: 0000.0000.0001
 Interface: GE1/0/2                Circuit Id:  0000.0000.0001.01
 State: Up     HoldTime:  27s      Type: L1(L1L2)     PRI: 64

 System ID: 0000.0000.0001
```

```
 Interface: GE1/0/2                Circuit Id:  0000.0000.0001.01
 State: Up     HoldTime:  27s      Type: L2(L1L2)     PRI: 64
```

Display detailed IS-IS neighbor information.

```
<Sysname> display isis peer verbose

                        Peer information for IS-IS(1)
                        ----------------------------

 System ID: 0000.1111.2222
 Interface: GE1/0/2                Circuit Id:  0000.1111.2222.01
 State: Up     Holdtime:   6s      Type: L1(L1L2)     PRI: 64
 Area address(es): 49
 Peer IP address(es): 12.0.0.2
 Peer local circuit ID: 1
 Peer circuit SNPA address: 000c-293b-c4be
 Uptime: 00:05:07
 Adj protocol:  IPv4
 IPv4 adjacency state: Up
 Adj P2P three-way handshake: No
Graceful Restart capable
   Restarting signal: No
   Suppress adjacency advertisement: No
 Local topology:
   0

```

Table 14 Command output

Field	Description
System ID	System ID of the neighbor.
Interface	Interface connecting to the neighbor.
Circuit Id	Circuit ID.
State	Circuit state.
HoldTime	Within the holdtime, if no hellos are received from the neighbor, the neighbor is considered down. If a hello is received, the holdtime is reset to the initial value.
Type	Circuit type: • **L1**—Means the circuit type is Level-1 and the neighbor is a Level-1 router. • **L2**—Means the circuit type is Level-2 and the neighbor is a Level-2 router. • **L1(L1L2)**—Means the circuit type is Level-1 and the neighbor is a Level-1-2 router. • **L2(L1L2)**—Means the circuit type is Level-2 and the neighbor is a Level-1-2 router.
PRI	DIS priority of the neighbor.
Area address(es)	Area address of the neighbor.
Peer IP address(es)	IP address of the neighbor.
Peer IPv6 address(es)	IPv6 address of the neighbor.
Uptime	Time elapsed since the neighbor relationship was formed.
Adj Protocol	Adjacency protocol: IPv4 or IPv6.
IPv4 adjacency state	IPv4 adjacency state: **Up** or **Down**. This field is not displayed if IPv4 is not supported.
IPv6 adjacency state	IPv6 adjacency state: **Up** or **Down**. This field is not displayed if IPv6 is not supported.
Adjacency not up	Reason why the adjacency relationship is down: **Waiting for BFD session to come up**. This field is no longer displayed after the adjacency relationship comes up.
Peer local circuit ID	Circuit ID of the neighbor.
Peer circuit SNPA address	SNPA address of the neighbor.
Adj P2P three-way handshake	Indicates whether the neighbor supports P2P three-way handshake.
Peer extended circuit ID	Extended circuit ID of the neighbor interface. This field is available when the neighbor supports three-way handshake.
Graceful Restart capable	The neighbor has the GR helper capability.

Field	Description
Restarting signal	RR flag.
Suppress adjacency advertisement	SA flag.
Local topology	List of topologies supported by the local interface.
Remote topology	List of topologies supported by the neighbor interface.
Local BFD support	Support of the local end for adjacency establishment and maintenance control based on BFD session state: • **(MTID:0, IPv4)**—Adjacency establishment and maintenance control based on BFD session state is supported in IPv4 unicast topology 0. • **(MTID:0, IPv6)**—Adjacency establishment and maintenance control based on BFD session state is supported in IPv6 unicast topology 0. • **(MTID:2, IPv6)**—Adjacency establishment and maintenance control based on BFD session state is supported in IPv6 unicast topology 2. This field is not displayed if the local end does not support adjacency establishment and maintenance control based on BFD session state.
Remote BFD support	Support of the remote end for adjacency establishment and maintenance control based on BFD session state: • **(MTID:0, IPv4)**—Adjacency establishment and maintenance control based on BFD session state is supported in IPv4 unicast topology 0. • **(MTID:0, IPv6)**—Adjacency establishment and maintenance control based on BFD session state is supported in IPv6 unicast topology 0. • **(MTID:2, IPv6)**—Adjacency establishment and maintenance control based on BFD session state is supported in IPv6 unicast topology 2. This field is not displayed if the remote end does not support adjacency establishment and maintenance control based on BFD session state.

Display IS-IS neighbor statistics.

```
<Sysname> display isis peer statistics

                  Peer Statistics information for IS-IS(1)
                  ----------------------------------------
  Type              IPv4 Up/Init              IPv6 Up/Init
  LAN Level-1             1/0                       0/0
  LAN Level-2             1/0                       0/0
  P2P                     0/0                       0/0
```

Table 15 Command output

Field	Description
Type	Neighbor type: • **LAN Level-1**—Number of Level-1 neighbors whose network type is broadcast. • **LAN Level-2**—Number of Level-2 neighbors whose network type is broadcast. • **P2P**—Number of neighbors whose network type is P2P.
IPv4 Up	Number of IPv4 neighbors in up state.
IPv4 Init	Number of IPv4 neighbors in init state.
IPv6 Up	Number of IPv6 neighbors in up state.
IPv6 Init	Number of IPv6 neighbors in init state.

display isis redistribute

Use **display isis redistribute** to display the redistributed IS-IS routing information.

Syntax

display isis redistribute [**ipv4** [*ip-address mask-length*] | **ipv6** [*ipv6-address prefix-length*]] [**level-1** | **level-2**] [*process-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ipv4: Displays the redistributed IPv4 routing information.

ipv6: Displays the redistributed IPv6 routing information.

ipv6-address prefix-length: Displays redistributed routes for the specified IPv6 address and mask length. The value range for the *prefix-length* argument is 1 to 128.

ip-address mask-length: Specifies the destination IP address and mask length.

process-id: Specifies the IS-IS process by its ID in the range of 1 to 65535.

level-1: Displays the IS-IS Level-1 routing information.

level-2: Displays the IS-IS Level-2 routing information.

Usage guidelines

If you do not specify the **ipv4** or **ipv6** keyword, the command displays redistributed IPv4 routing information.

If you do not specify an IS-IS level, this command displays both Level-1 and Level-2 routing information.

Examples

Display redistributed IPv4 IS-IS routing information.

```
<Sysname> display isis redistribute 1

                        Route information for IS-IS(1)
                        ------------------------------

                       Level-1 IPv4 Redistribute Table
                       -------------------------------
 Type IPv4 Destination     IntCost    ExtCost    Tag        State
--------------------------------------------------------------------------------
 D    192.168.30.0/24      0          0                     Active
 D    11.11.11.11/32       0          0
 D    10.10.10.0/24        0          0
```

Table 16 Command output

Field	Description
Route information for IS-IS(1)	IS-IS process of the redistributed routing information.
Level-1 IPv4 Redistribute Table	Redistributed IPv4 routing information of IS-IS Level-1.
Level-2 IPv4 Redistribute Table	Redistributed IPv4 routing information of IS-IS Level-2.
Type	Redistributed route type.
IPv4 Destination	IPv4 destination address.
IntCost	Internal cost of the route.
ExtCost	External cost of the route.
Tag	Tag value.
State	Indicates whether the route is valid.

Display redistributed IPv6 IS-IS routing information.

```
<Sysname> display isis redistribute ipv6 1

                        Route information for IS-IS(1)
                        ------------------------------

                       Level-1 IPv6 Redistribute Table
                       --------------------------------
Type       : direct    Destination: 12:1::/64
IntCost    : 0         Tag        :
State      : Active

                       Level-2 IPv6 Redistribute Table
                       --------------------------------
Type       : direct    Destination: 12:1::/64
IntCost    : 0         Tag        :
State      : Active
```

Table 17 Command output

Field	Description
Route information for IS-IS(1)	Redistributed routing information for IPv6 IS-IS process 1.
Level-1 IPv6 Redistribute Table	Redistributed IPv6 IS-IS Level-1 routing information.
Level-2 IPv6 Redistribute Table	Redistributed IPv6 IS-IS Level-2 routing information.
Type	Redistributed route types: • Direct. • IS-ISv6. • Static. • OSPFv3. • BGP4+. • RIPng.

Destination	IPv6 destination address.
IntCost	Internal route cost.
Tag	Tag value.
State	Indicates whether the redistributed route is valid.

display isis route

Use **display isis route** to display IS-IS routing information.

Syntax

display isis route [**ipv4** [*ip-address mask-length*] | **ipv6** [*ipv6-address prefix-length*]] [[**level-1** | **level-2**] | **verbose**] * [*process-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ipv4: Displays IPv4 IS-IS routing information.

ip-address mask-length: Displays IPv4 IS-IS routing information for the specified IP address. The *mask-length* argument is in the range of 0 to 32.

ipv6: Displays IPv6 IS-IS routing information.

ipv6-address prefix-length: Displays IPv6 IS-IS routing information for the specified IPv6 address. The *prefix-length* argument is in the range of 0 to 128.

verbose: Displays detailed IS-IS routing information. If you do not specify this keyword, the command displays brief IS-IS routing information

process-id: Displays IS-IS routing information for an IS-IS process specified by its ID in the range of 1 to 65535. If you do not specify an IS-IS process, this command displays routing information for all IS-IS processes.

level-1: Displays Level-1 IS-IS routes.

level-2: Displays Level-2 IS-IS routes.

Usage guidelines

If you do not specify the **ipv4** or **ipv6** keyword, the command displays IPv4 IS-IS routing information.

If you do not specify a level, this command displays both Level-1 and Level-2 routing information.

Examples

Display brief IPv4 IS-IS routing information.

```
<Sysname> display isis route

                        Route information for IS-IS(1)
```

```
                          ----------------------------

                          Level-1 IPv4 Forwarding Table
                          ----------------------------

 IPv4 Destination     IntCost    ExtCost ExitInterface   NextHop         Flags
--------------------------------------------------------------------------------
 8.8.8.0/24           10         NULL    GE1/0/2         Direct          D/L/-
 9.9.9.0/24           20         NULL    GE1/0/2         8.8.8.5         R/L/-

      Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set

                          Level-2 IPv4 Forwarding Table
                          ----------------------------

 IPv4 Destination     IntCost    ExtCost ExitInterface   NextHop         Flags
--------------------------------------------------------------------------------
 8.8.8.0/24           10         NULL                                    D/L/-

      Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set
```

Table 18 Command output

Field	Description
Route information for IS-IS(1)	Route information for IS-IS process 1.
Level-1 IPv4 Forwarding Table	IPv4 IS-IS routing information for Level-1.
Level-2 IPv4 Forwarding Table	IPv4 IS-IS routing information for Level-2.
IPv4 Destination	IPv4 destination address.
IntCost	Internal cost.
ExtCost	External cost.
ExitInterface	Output interface.
NextHop	Next hop.
Flags	Routing state flag: • **D**—Direct route. • **R**—The route has been added into the routing table. • **L**—The route has been advertised in an LSP. • **U**—Penetration flag. Setting it to UP can prevent an LSP sent from L2 to L1 from being sent back to L2.

Display detailed IPv4 IS-IS routing information.

```
<Sysname> display isis route verbose

                          Route information for IS-IS(1)
                          ----------------------------

```

Table 19 Command output

Field	Description
Route information for IS-IS(1)	Route information for IS-IS process 1.
Level-1 IPv4 Forwarding Table	IPv4 IS-IS routing information for Level-1.
Level-2 IPv4 Forwarding Table	IPv4 IS-IS routing information for Level-2.
IPv4 Dest	IPv4 destination.
Int. Cost	Internal cost.
Ext. Cost	External cost.
Admin Tag	Tag.
Src Count	Count of advertising sources.
Flag	Route state flag: • **R**—The route has been installed into the routing table. • **L**—The route has been flooded in an LSP. • **U**—Route leaking flag. Setting it to UP can prevent an LSP sent from L2 to L1 from being sent back to L2.
NextHop	Next hop.
Interface	Output interface.
ExitIndex	Index of the output interface.
Nib ID	ID assigned by the routing management module (next hop index).
ECMP group	ECMP route group ID. This field is displayed only when ECMP route groups exist.
InLabel	Incoming label.
InLabel flag	Incoming label flag: • **R**—Re-advertisement flag. If set, inter-level propagation or route redistribution exists. • **N**—Node-SID flag. If set, the prefix SID is the SID to an SR node. • **P**—No-PHP flag. If set, the penultimate node cannot pop the prefix SID. • **E**—Explicit null flag. If set, the upstream neighbor must replace the prefix SID with an explicit null flag before forwarding the packets. • **V**—Value/Index flag. If set, the prefix SID carries an absolute value. • **L**—Local flag. If set, the prefix SID has local significance.
LabelSrc	Label source: • **SR**—The label is allocated by the SR node. • **SRMS**—The label is allocated by the segment routing mapping server (SRMS). • **N/A**—No label exists.
Delay Flag	Microloop avoidance delay flag: • **D**—Microloop avoidance is configured. Route convergence is delayed. • **N/A**—Microloop avoidance is not configured or the microloop avoidance delay timer has expired. Route convergence is in progress.
OutLabel	Outgoing label.

Field	Description
OutLabelFlag	Outgoing label flag: • **E**—Explicit null flag. The upstream neighbor must replace the SID with an explicit null flag before forwarding the packets. • **I**—Implicit null flag. The upstream neighbor must replace the SID with an implicit null flag before forwarding the packets. This flag is not supported in the current software version. • **N**—Normal flag. • **P**—SR label preferred flag.
TI-LFA	TI-LFA backup information.
BKNextHop	TI-LFA/Remote LFA backup next hop.
LsIndex	Label stack index.
Backup label stack(top->bottom)	Backup path label stack. **N/A** indicates that no label stack exists.
Remote-LFA	Remote LFA backup information.
Tunnel destination address	LDP tunnel destination address.
Backup label	Backup label to the PQ node. **N/A** indicates that no label exists.

Display IPv6 IS-IS routing information.

```
<Sysname> display isis route ipv6

                      Route information for IS-IS(1)
                      ------------------------------

                      Level-1 IPv6 forwarding table
                      ------------------------------

 Destination: 2001:1::                              PrefixLen: 64

 Flag       : D/L/-                                 Cost     : 10
 Next hop   : Direct                                Interface: GE1/0/1

       Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set

                      Level-2 IPv6 forwarding table
                      ------------------------------

 Destination: 2001:1::                              PrefixLen: 64
 Flag       : -/-/-                                 Cost     : 20

 Destination: 2001:2::                              PrefixLen: 64
 Flag       : D/L/-                                 Cost     : 10

       Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set
```

Table 20 Command output

Field	Description
Destination	IPv6 destination prefix.
PrefixLen	Length of the prefix.
Flag/Flags	Route flag: • **D**—This is a direct route. • **R**—The route has been added into the routing table. • **L**—The route has been advertised in an LSP. • **U**—Route leaking flag, indicating that the Level-1 route is from Level-2. **U** means the route will not be returned to Level-2.
Cost	Route cost.
Next hop	Next hop.
Interface	Output interface.

Display detailed IPv6 IS-IS routing information.

```
<Sysname> display isis route ipv6 verbose

                      Route information for IS-IS(1)

Table 21 Command output

Field	Description
IPv6 dest	IPv6 destination address and prefix.

Flag/Flags	Route flag: • **D**—This is a direct route. • **R**—The route has been added into the routing table. • **L**—The route has been advertised in an LSP. • **U**—Route leaking flag, indicating the Level-1 route is from Level-2. **U** means the route will not be returned to Level-2.
Cost	Route cost.
Admin tag	Administrative tag.
Src count	Number of advertisement sources.
ECMP group	ECMP route group ID. This field is displayed only when ECMP route groups exist.
Nexthop	Next hop.
Interface	Output interface.
BkNexthop	Backup next hop.
BkInterface	Backup output interface.
Nib ID	Next hop index assigned by the routing management module.

display isis spf-tree

Use **display isis spf-tree** to display IS-IS SPF tree information.

Syntax

display isis spf-tree [**ipv4** | **ipv6**] [[**level-1** | **level-2**] | [**source-id** *source-id* | **verbose**]] * [*process-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ipv4: Displays IPv4 IS-IS SPF tree information.

ipv6: Displays IPv6 IS-IS SPF tree information.

level-1: Displays Level-1 IS-IS SPF tree information. If you do not specify a level, the command displays both Level-1 and Level-2 SPF tree information.

level-2: Displays Level-2 SPF tree information. If you do not specify a level, the command displays both Level-1 and Level-2 SPF tree information.

source-id *source-id*: Displays detailed information about an SPF node. The *source-id* argument represents the system ID of the SPF node, in XXXX.XXXX.XXXX.XX format.

verbose: Displays detailed IS-IS SPF tree information. If you do not specify this keyword, the command displays brief IS-IS SPF tree information.

process-id: Specifies an IS-IS process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays SPF tree information for all IS-IS processes.

Usage guidelines

If you do not specify the **ipv4** or **ipv6** keyword, the command displays IPv4 IS-IS SPF tree information.

Examples

Display brief IPv4 IS-IS SPF tree information.

```
<Sysname> display isis spf-tree

                      Shortest Path Tree for IS-IS(1)
                      -------------------------------

      Flags: S-Node is on SPF tree       T-Node is on tent list
             O-Node is overload          R-Node is directly reachable
             I-Node or Link is isolated  D-Node or Link is to be deleted
             C-Neighbor is child         P-Neighbor is parent
             V-Link is involved          N-Link is a new path
             L-Link is on change list    U-Protocol usage is changed
             H-Nexthop is changed

                         Level-1 Shortest Path Tree

Table 22 Command output

Field	Description
SpfNode	ID of the topology node.
Distance	Shortest distance from the root node to the local node.
TE distance	Shortest distance from the root node to the local node (including tunnel links). If tunnel is not configured, TE distance equals to Distance.
NodeFlag	Node flag: • **S**—The node is on the SPF tree. • **T**—The node is on the tent list. • **O**—The node is overloaded. • **R**—The node is directly connected. • **I**—The node is isolated. • **D**—The node is to be deleted.
RelayNibID	Next hop ID of the node after route recursion.
TE tunnel count	Number of tunnels destined to this node.
Destination	Destination router.
Nexthop count	Next hop count.
Nexthop	Primary next hop of the node or the link advertising source.
AdvMtID	Topology from which the routing information is learned: • **0**—Base topology. • **6-4094**—Other topologies.
Interface	Primary output interface of the node or the link advertising source.
BkNexthop	Backup next hop.
BkInterface	Backup output interface.
Neighbor	ID of the primary next hop neighbor.
BkNeighbor	ID of the backup next hop neighbor.

Field	Description
TiLfaNeighbor	ID of the TI-LFA backup next hop neighbor.
TiLfaInterface	Output interface of the TI-LFA backup next hop.
TiLfaNexthop	TI-LFA backup next hop.
PNode SrcID	Source ID of the P node.
QNode SrcID	Source ID of the Q node.
PNode prefix	Prefix of the P node. **N/A** indicates that the prefix of the destination node is not displayed in the P space.
PNode SidIndex	Index value of the prefix SID for the P node. **N/A** indicates that the prefix SID of the destination node is not displayed in the P space.

Protect	TI-LFA/Remote LFA traffic protection type:
	• **Link**—Link protection that excludes the direct primary link from backup path calculation.
	• **Node**—Node protection that excludes the primary next hop node from backup path calculation.
	• **SrlgLink**—SRLG-disjoint link protection that excludes the following links from backup path calculation:
	  ○ Direct primary link.
	  ○ Local links in the same SRLG as the direct primary link.
	• **SrlgNode**—SRLG-disjoint node protection that excludes the following nodes from backup path calculation:
	  ○ Primary next hop node.
	  ○ Local links in the same SRLG as the direct primary link.

Label stack	Label stack. **N/A** indicates that no label stack exists.
SpfLink	Topology link.
SpfLink count	Number of topology links.
LinkCost	Link cost.
LinkNewCost	New link cost.
LinkFlag	Link flag: • **I**—The link is isolated. • **D**—The link is to be deleted. • **C**—The neighbor is a child node. • **P**—The neighbor is the parent node. • **V**—The link is involved. • **N**—The link is a new path. • **L**—The link is on the change list. • **U**—The protocol usage of the link is changed. • **H**—The next hop of the link is changed.
LinkSrcCnt	Number of link advertising sources.
Type	Type of the link advertising source: • **Adjacent**—The link advertising source is a local neighbor. • **Remote**—The link advertising source is advertised by a remote node in an LSP.
Cost	Cost of the link advertising source.
InterfaceIP	Interface IP address.
NeighborIP	Neighbor IP address.

Field	Description
Remote-LFA	Remote LFA backup information.
RLfaNeighbor	System ID of the remote LFA backup next hop.
PQNode	System ID of the PQ node.
PQNodePrefix	PQ node prefix.
OutLabel	Backup label to the PQ node.

Display brief IPv6 IS-IS SPF tree information.

```
<Sysname> display isis spf-tree ipv6

Table 23 Command output

Field	Description
SpfNode	ID of the topology node.
Distance	Shortest distance from the root node to the current node.
TE distance	Shortest distance from the root node to the current node (including tunnel links). If no tunnels are configured, TE distance equals Distance.
NodeFlag	Node flag: • **S**—The node is on the SPF tree. • **T**—The node is on the tent list. • **O**—The node is overloaded. • **R**—The node is directly connected. • **I**—The node is isolated. • **D**—The node is to be deleted.
TE tunnel count	Number of tunnels destined for this node.
Nexthop count	Number of next hops.
NextHop	Primary next hop of the node or the link advertising source.
AdvMtID	Topology from which the routing information is learned: • **2**—IPv6 unicast topology. • **6-4094**—Other topologies.
Interface	Primary output interface of the node or the link advertising source.
BkNextHop	Backup next hop.
BkInterface	Backup output interface.
Neighbor	ID of the primary next hop neighbor.
BkNeighbor	ID of the backup next hop neighbor.
SpfLink	Topology link.
SpfLink count	Number of topology links.
LinkCost	Link cost.
LinkNewCost	New link cost.
LinkFlag	Link flag: • **I**—The link is isolated. • **D**—The link is to be deleted. • **C**—The neighbor is a child node. • **P**—The neighbor is the parent node. • **V**—The link is involved. • **N**—The link is a new path.

	• **L**—The link is on the change list. • **U**—The protocol of the link is changed. • **H**—The next hop of the link is changed.
LinkSrcCnt	Number of link advertising sources.
Type	Type of the link advertising source: • **Adjacent**—The link advertising source is a local neighbor. • **Remote**—The link advertising source is advertised by a remote node in an LSP.
Cost	Cost of the link advertising source.

display isis statistics

Use **display isis statistics** to display IS-IS statistics.

Syntax

display isis statistics [**ipv4** | **ipv6**] [**level-1** | **level-1-2** | **level-2**] [*process-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

ipv4: Displays IPv4 IS-IS statistics. If you do not specify this option, the command displays both IPv4 and IPv6 statistics.

ipv6: Displays IPv6 IS-IS statistics.

level-1: Displays IS-IS Level-1 statistics.

level-1-2: Displays IS-IS Level-1-2 statistics.

level-2: Displays IS-IS Level-2 statistics.

process-id: Displays statistics for an IS-IS process specified by its ID in the range of 1 to 65535. If you do not specify an IS-IS process, this command displays the statistics for all IS-IS processes.

Usage guidelines

If you do not specify a level, this command displays both Level-1 and Level-2 routing information.

Examples

Display IS-IS statistics.

```
<Sysname> display isis statistics

                    Statistics information for IS-IS(1)
                    -----------------------------------

                           Level-1 Statistics
```

```
                              ------------------

Learnt routes information:
        Total IPv4 Learnt Routes in IPv4 Routing Table: 1

```

Table 24 Command output

Field	Description
Statistics information for IS-IS(*processid*)	Statistics for the IS-IS process.

Field	Description
Level-1 Statistics	Level-1 statistics.
Level-2 Statistics	Level-2 statistics.
Learnt routes information	• **Total IPv4 Learnt Routes in IPv4 Routing Table**—Number of learned IPv4 routes. • **Total IPv6 Learnt Routes in IPv6 Routing Table**—Number of learned IPv6 routes.
IPv4 Imported Routes	Numbers of different types of redistributed IPv4 routes, including static, direct, IS-IS, BGP, RIP, OSPF, and EIGRP routes. EIGRP routes are not supported in the current software version.
IPv6 Imported Routes	Numbers of different types of redistributed IPv6 routes, including static, direct, IS-ISv6, BGP4+, RIPng, and OSPFv3 routes.
Lsp information	LSP information: • **LSP Source ID**—ID of the source system. • **No. of used LSPs**—Number of used LSPs.

display osi

Use **display osi** to display OSI connection information.

Syntax

display osi [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays OSI connection information for all member devices.

Examples

Display OSI connection information.

```
<Sysname> display osi
Total OSI socket number: 2

 Location: slot 0
 Creator: isisd[1539]
 State: N/A
 Options: SO_FILTER
 Error: 0
 Receiving buffer(cc/hiwat/lowat/drop/state): 0 / 1048576 / 1 / 0 / N/A
 Sending buffer(cc/hiwat/lowat/state): 0 / 262144 / 512 / N/A
```

```
Type: 2
Enabled interfaces:
 GigabitEthernet1/0/1
  MAC address: 0180-c200-0014

Location: slot 0
Creator: isisd[1539]
State: N/A
Options: SO_FILTER
Error: 0
Receiving buffer(cc/hiwat/lowat/drop/state): 0 / 1048576 / 1 / 0 / N/A
Sending buffer(cc/hiwat/lowat/state): 0 / 262144 / 512 / N/A
Type: 2
Enabled interfaces:
 GigabitEthernet1/0/1
  MAC address: 0180-c200-0014
```

Table 25 Command output

Field	Description
Total OSI socket number	Total number of OSI sockets.
Creator	Name of the socket creator. The process ID of the creator is displayed in the square brackets.
State	This field always displays **N/A**.
Options	Socket options: • **SO_FILTER**—Filter option is configured. • **N/A**—No option is configured.
Error	Number of errors that affect the socket session.
Receiving buffer(cc/hiwat/lowat/drop/state)	Receiving buffer information, including the current used space, maximum space, minimum space, number of dropped packets, and status.
Sending buffer(cc/hiwat/lowat/state)	Sending buffer information, including the current used space, maximum space, minimum space, and status.
Type	Type 2 socket, corresponding to unreliable connectionless-oriented transport layer protocols.
Enabled interfaces	Input interfaces and matched multicast MAC addresses. Only packets received from Ethernet link-layer interfaces need to match the multicast MAC addresses.

display osi statistics

Use **display osi statistics** to display OSI packet statistics.

Syntax

display osi statistics [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays OSI packet statistics for all member devices.

Examples

Display OSI packet statistics.

```
<Sysname> display osi statistics
Received packets:
     Total: 35
     Relay received: 35
     Relay forwarded: 35
     Invalid service slot: 0
     No matched socket: 0
     Not delivered, input socket full: 0
Sent packets:
     Total: 19
     Relay forwarded: 19
     Relay received: 19
     Failed: 0
```

Table 26 Command output

Field	Description
Received packets	Statistics of received packets: • **Total**—Total number of received link layer packets. • **Relay received**—Number of inbound packets on LPUs relayed from other cards. This count is not included in the total count of received packets. • **Relay forwarded**—Number of inbound packets relayed to LPUs. • **Invalid service slot**—Number of discarded packets due to unavailable LPUs. • **No matched socket**—Number of discarded packets due to mismatches in input interfaces, MAC addresses, or connection filter criteria. • **Not delivered, input socket full**—Number of undelivered packets due to a socket receiving buffer overflow.

Field	Description
Sent packets	Statistics of sent packets: • **Total**—Total number of packets that IS-IS sent over OSI connections. • **Relay forwarded**—Number of outbound packets relayed to the cards that hosts the output interfaces. This count is not included in the total count of sent packets. • **Relay received**—Number of outbound packets on the cards that hosts the output interfaces. These packets are relayed from other cards. • **Failed**—Number of packets failed to be sent.

Related commands

`reset osi statistics`

distribute bgp-ls

Use **`distribute bgp-ls`** to advertise IS-IS link state information to BGP.

Use **`undo distribute bgp-ls`** to restore the default.

Syntax

`distribute bgp-ls` [**`instance-id`** *`id`*] [**`level-1`** | **`level-2`**]

`undo distribute bgp-ls` [**`level-1`** | **`level-2`**]

Default

The device does not advertise IS-IS link state information to BGP.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

`instance-id` *`id`*: Specifies an instance by its ID in the range of 0 to 65535. If you do not specify this option, the command advertises IS-IS link state information of instance 0 to BGP.

`level-1`: Advertises the Level-1 IS-IS link state information to BGP.

`level-2`: Advertises the Level-2 IS-IS link state information to BGP.

Usage guidelines

After the device advertises IS-IS link state information to BGP, BGP can advertise the information for intended applications.

If multiple IS-IS processes have the same instance ID and link state information, only the link state information of the IS-IS process with the smallest process ID is advertised.

To advertise the same link state information of different IS-IS processes to BGP, specify different instance IDs for the IS-IS processes.

If you do not specify a level for the **`distribute bgp-ls`** command, both Level-1 and Level-2 IS-IS link state information are advertised to BGP.

If you do not specify a level for the **undo distribute bgp-ls** command, neither Level-1 nor Level-2 IS-IS link state information can be advertised to BGP.

Examples

Advertise link state information of IS-IS process 1 to BGP.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] distribute bgp-ls
```

domain-authentication send-only

Use **domain-authentication send-only** to configure IS-IS not to check the authentication information in the received Level-2 packets, including LSPs, CSNPs, and PSNPs.

Use **undo domain-authentication send-only** to restore the default.

Syntax

domain-authentication send-only

undo domain-authentication send-only

Default

When domain authentication mode and key are configured, a Level-2 or Level-1-2 router checks the authentication information in the received packets.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Usage guidelines

When domain authentication mode and key are configured, a Level-2 or Level-1-2 router adds the key in the specified mode into transmitted Level-2 packets (including LSPs, CSNPs, and PSNPs). It also checks the key in the received Level-2 packets.

To prevent packet exchange failure in case of an authentication key change, configure IS-IS not to check the authentication information in the received packets.

Examples

Configure IS-IS not to check the authentication information in the received packets.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] domain-authentication send-only
```

domain-authentication-mode

Use **domain-authentication-mode** to specify the routing domain authentication mode and a key.

Use **undo domain-authentication-mode** to restore the default.

Syntax

domain-authentication-mode { { **gca** *key-id* { **hmac-sha-1** | **hmac-sha-224** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** } [**nonstandard**] | **md5** | **simple** } { **cipher** | **plain** } *string* | **keychain** *keychain-name* } [**ip** | **osi**]

undo domain-authentication-mode

Default

No routing domain authentication mode or key is configured.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

gca: Specifies the GCA mode.

key-id: Uniquely identifies an SA in the range of 1 to 65535. The sender inserts the Key ID into the authentication TLV, and the receiver authenticates the packet by using the SA that is selected based on the Key ID.

hmac-sha-1: Specifies the HMAC-SHA-1 algorithm.

hmac-sha-224: Specifies the HMAC-SHA-224 algorithm.

hmac-sha-256: Specifies the HMAC-SHA-256 algorithm.

hmac-sha-384: Specifies the HMAC-SHA-384 algorithm.

hmac-sha-512: Specifies the HMAC-SHA-512 algorithm.

nonstandard: Specifies the nonstandard GCA authentication mode.

md5: Specifies the MD5 authentication mode.

simple: Specifies the simple authentication mode.

cipher: Specifies a key in encrypted form.

plain: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. Its plaintext form is a case-sensitive string of 1 to 16 characters. Its encrypted form is a case-sensitive string of 33 to 53 characters.

keychain: Specifies the keychain authentication mode.

keychain-name: Specifies a keychain by its name, a case-sensitive string of 1 to 63 characters.

ip: Checks IP-related fields in LSPs.

osi: Checks OSI-related fields in LSPs.

Usage guidelines

The configured key in the specified mode is inserted into all outgoing Level-2 packets (LSP, CSNP, and PSNP) and is used for authenticating the incoming Level-2 packets.

IS-IS keychain authentication supports the HMAC-MD5 and HMAC-SM3 authentication algorithms. For the HMAC-SM3 authentication algorithm, only key IDs in the range of 0 to 65535 are supported. When keychain authentication is used, IS-IS receives and sends packets as follows:

- Before IS-IS sends a Level-2 packet, it uses the valid send key obtained from the keychain to authenticate the packet. If no valid send key exists or the valid send key does not use the HMAC-MD5 or HMAC-SM3 algorithm, the authentication fails and the packet does not contain the authentication information.
- After IS-IS receives a Level-2 packet, it processes the packet as follows:
  - If the authentication algorithm of the packet is HMAC-MD5, IS-IS uses a valid accept key obtained from the keychain to authenticate the packet. If no valid accept key exists or all valid accept keys fail to authenticate the packet, the authentication fails and the packet is discarded.
  - If the authentication algorithm of the packet is HMAC-SM3, IS-IS uses the key ID of the received packet to obtain the corresponding valid accept key from the keychain. Then, IS-IS uses the accept key to authenticate the packet. If IS-IS cannot find a valid accept key based on the key ID of the received packet or the packet fails the authentication, the packet is discarded.

All the backbone routers must have the same authentication mode and key.

If neither **ip** nor **osi** is specified, the OSI-related fields in LSPs are checked.

When you specify the GCA mode, follow these guidelines:

- If you do not specify the **nonstandard** keyword, the device can communicate only with devices that use the GCA mode.
- If you specify the **nonstandard** keyword, the device can communicate only with devices that use the nonstandard GCA mode.

Examples

Set the routing domain authentication mode to **simple**, and set the plaintext key to **123456**.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] domain-authentication-mode plain 123456
```

ecmp-group enable

Use **ecmp-group enable** to enable IS-IS to group ECMP routes.

Use **undo ecmp-group enable** to restore the default.

Syntax

ecmp-group enable

undo ecmp-group enable

Default

IS-IS does not group ECMP routes.

Views

IS-IS IPv4 unicast address family view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Usage guidelines

Configure this command to enable IS-IS to group ECMP routes by prefix to speed up route convergence.

This command is applicable to a network when the network has a large number of ECMP routes and different route prefixes in the network have the same next hops. For example, IS-IS learns 10000 route prefixes and all route prefixes have the same 16 next hops (1.1.1.1 to 1.1.1.16). If you do not configure this command, IS-IS has to send all ECMP routes of every route prefix (10000 × 16 routes) to the route management module. After you configure this command, IS-IS groups the ECMP routes by prefix and sends the route groups (10000 route groups) to the route management module.

If the output interfaces to the next hops of ECMP routes are TE tunnel interfaces, IS-IS groups the ECMP routes regardless of whether you enable this feature or not.

Examples

Enable IS-IS process 1 to group ECMP routes.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
[Sysname-isis-1-ipv4] ecmp-group enable
```

fast-reroute

Use **fast-reroute** to configure IS-IS FRR.

Use **undo fast-reroute** to disable IS-IS FRR.

Syntax

fast-reroute { **lfa** [**level-1** | **level-2**] | **route-policy** *route-policy-name* }

undo fast-reroute { **lfa** [**level-1** | **level-2**] | **route-policy** }

Default

IS-IS FRR is disabled.

Views

IS-IS IPv4 unicast address family view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

lfa: Calculates a backup next hop through Loop Free Alternate (LFA) calculation for all routes.

level-1: Specifies Level-1 routes.

level-2: Specifies Level-2 routes.

route-policy *route-policy-name*: Uses the specified routing policy to designate a backup next hop. The *route-policy-name* argument is a case-sensitive string of 1 to 63 characters.

Usage guidelines

ECMP routes do not support FRR.

The LFA calculation of FRR and IS-IS TE are mutually exclusive.

Example

Enable FRR for IS-IS process 1 and configure IS-IS FRR to calculate a backup next hop through LFA calculation for all routes.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
[Sysname-isis-1-ipv4] fast-reroute lfa
```

fast-reroute tiebreaker

Use **fast-reroute tiebreaker** to set the priority for the node-protection or lowest-cost backup path selection policy.

Use **undo fast-reroute tiebreaker** to restore the default.

Syntax

In IS-IS IPv4 unicast address family view:

fast-reroute tiebreaker { **lowest-cost** | **node-protecting** | **srlg-disjoint** } **preference** *preference* [**level-1** | **level-2**]

undo fast-reroute tiebreaker { **lowest-cost** | **node-protecting** | **srlg-disjoint** } [**level-1** | **level-2**]

In IS-IS IPv6 unicast address family view:

fast-reroute tiebreaker { **lowest-cost** | **node-protecting** } **preference** *preference* [**level-1** | **level-2**]

undo fast-reroute tiebreaker { **lowest-cost** | **node-protecting** } [**level-1** | **level-2**]

Default

The priority values of the node-protection, lowest-cost, and SRLG-disjoint backup path selection policies are 40, 20, and 10, respectively.

Views

IS-IS IPv4 unicast address family view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

lowest-cost: Sets a priority value for the lowest-cost backup path selection policy.

node-protecting: Sets a priority value for the node-protection backup path selection policy.

srlg-disjoint: Sets a priority value for the SRLG-disjoint backup path selection policy.

preference *preference*: Specifies a priority value in the range of 1 to 255. A higher value indicates a higher priority.

level-1: Applies the configuration to Level-1 areas.

level-2: Applies the configuration to the Level-2 area.

Usage guidelines

IS-IS FRR uses specific policies for backup path calculation. This command defines the priority for the backup path selection policy. The higher the value, the higher the priority of the associated backup path selection policy. Changing the backup path selection policy priority can affect the backup path calculation result for IS-IS FRR. The backup paths can provide node protection or link protection for traffic, or provide both node protection and link protection.

IS-IS FRR supports the following backup path selection policies that are used to generate different topologies for backup path calculation:

- **Node protection**—IS-IS FRR performs backup path calculation after excluding the primary next hop node.
- **Lowest cost**—IS-IS FRR performs backup path calculation after excluding the direct primary link.
- **SRLG disjoint**—When one link in the SRLG fails, the other links in the SRLG might also fail. If you use a link in this SRLG as the backup link for the failed link, protection does not take effect. To avoid this issue, IS-IS FRR excludes the local links in the same SRLG as the direct primary link and then performs backup path calculation.

For IS-IS FRR, the SRLG disjoint policy depends on the node protection and lowest cost policies.

If multiple backup path selection policies exist in an IS-IS process, the policy with the highest priority is used to calculate the backup path. If the policy fails to calculate the backup path, another policy with higher priority is used. IS-IS performs backup path calculation by using the node protection and lowest cost policies as follows:

- If the node protection policy has higher priority and fails to calculate the backup path, IS-IS uses the lowest cost policy to calculate the backup path. If the lowest cost policy still fails to calculate the backup path, reliability cannot be ensured upon primary link failure.
- If the lowest cost policy has higher priority and fails to calculate the backup path, IS-IS does not perform further backup path calculation with the node protection policy. Reliability cannot be ensured upon primary link failure.

You can execute this command multiple times to specify the priorities for the lowest cost, node protection, and SRLG disjoint policies, respectively.

If you execute this command multiple times for a backup path selection policy, the most recent configuration takes effect.

If you do not specify a level, the command takes effect on both Level-1 and Level-2 areas.

Examples

Set the priority value of the node-protection backup path selection policy to 100.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
[Sysname-isis-1-ipv4] fast-reroute tiebreaker node-protecting preference 100
```

filter-policy export

Use **filter-policy export** to configure IS-IS to filter redistributed routes.

Use **undo filter-policy export** to remove the configuration.

Syntax

In IS-IS IPv4 unicast address family view:

filter-policy { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **export** [**bgp** | **direct** | { **isis** | **ospf** | **rip** } *process-id* | **static**]

undo filter-policy export [**bgp** | **direct** | { **isis** | **ospf** | **rip** } *process-id* | **static**]

In IS-IS IPv6 unicast address family view:

filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **export** [**bgp4+** | **direct** | { **isisv6** | **ospfv3** | **ripng** } *process-id* | **static**]

undo filter-policy export [**bgp4+** | **direct** | { **isisv6** | **ospfv3** | **ripng** } *process-id* | **static**]

Default

IS-IS does not filter redistributed routes.

Views

IS-IS IPv4 unicast address family view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-acl-number: Specifies an IPv4 ACL by its number in the range of 2000 to 3999 to filter redistributed routes.

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999 to filter redistributed routes.

prefix-list *prefix-list-name*: Specifies a prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter redistributed routes by destination address.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter redistributed routes.

bgp: Filters redistributed BGP routes.

direct: Filters redistributed direct routes.

isis: Filters redistributed IS-IS routes.

ospf: Filters redistributed OSPF routes.

rip: Filters redistributed RIP routes.

static: Filters redistributed static routes.

bgp4+: Filters redistributed IPv6 BGP routes.

isisv6: Filters redistributed IPv6 IS-IS routes.

ospfv3: Filters redistributed OSPFv3 routes.

ripng: Filters redistributed RIPng routes.

process-id: Specifies a process by its ID in the range of 1 to 65535.

Usage guidelines

This command filters routes redistributed by the **import-route** command. Only routes that have not been filtered can be advertised.

When you specify an ACL, follow these guidelines:

- If the ACL does not exist or has no rules, IS-IS does not filter redistributed routes.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all redistributed routes.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following methods:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.
- To deny/permit a route with the specified destination and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the subnet mask of the route. For the configuration to take effect, specify a contiguous subnet mask.

Examples

Use basic ACL 2000 to filter redistributed routes.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule deny source 192.168.10.0 0.0.0.255
[Sysname-acl-ipv4-basic-2000] quit
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
[Sysname-isis-1-ipv4] filter-policy 2000 export
```

Configure advanced ACL 3000 to permit only route 113.0.0.0/16 to pass. Use advanced ACL 3000 to filter redistributed routes.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule 10 permit ip source 113.0.0.0 0 destination 255.255.0.0
0
[Sysname-acl-ipv4-adv-3000] rule 100 deny ip
[Sysname-acl-ipv4-adv-3000] quit
[Sysname] isis 1
[Sysname-isis 1] address-family ipv4
[Sysname-isis-1-ipv4] filter-policy 3000 export
```

Related commands

display isis route

filter-policy import

Use **filter-policy import** to configure IS-IS to filter routes calculated using received LSPs.

Use **undo filter-policy import** to restore the default.

Syntax

In IS-IS IPv4 unicast address family view:

filter-policy { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **import**

undo filter-policy import

In IS-IS IPv6 unicast address family view:

filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **import**

undo filter-policy import

Default

IS-IS does not filter routes calculated using received LSPs.

Views

IS-IS IPv4 unicast address family view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-acl-number: Specifies an IPv4 ACL by its number in the range of 2000 to 3999 to filter routes calculated using received LSPs.

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999 to filter routes calculated using received LSPs.

prefix-list *prefix-list-name*: Specifies a prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter routes calculated using received LSPs by destination address.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter received routes.

Usage guidelines

This command filters received routes. Only routes that have not been filtered can be added into the routing table.

When you specify an ACL, follow these guidelines:

- If the ACL does not exist or has no rules, IS-IS does not filter received routes.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all received routes.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following methods:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.

- To deny/permit a route with the specified destination and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the subnet mask of the route. For the configuration to take effect, specify a contiguous subnet mask.

Examples

Use basic ACL 2000 to filter routes calculated using received LSPs.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule deny source 192.168.10.0 0.0.0.255
[Sysname-acl-ipv4-basic-2000] quit
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
[Sysname-isis-1-ipv4] filter-policy 2000 import
```

Use advanced ACL 3000 to filter routes calculated using received LSPs and install only route 113.0.0.0/16 to the IP routing table.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule 10 permit ip source 113.0.0.0 0 destination 255.255.0.0
0
[Sysname-acl-ipv4-adv-3000] rule 100 deny ip
[Sysname-acl-ipv4-adv-3000] quit
[Sysname] isis 1
[Sysname-isis 1] address-family ipv4
[Sysname-isis-1-ipv4] filter-policy 3000 import
```

flash-flood

Use **flash-flood** to enable IS-IS LSP flash flooding.

Use **undo flash-flood** to disable IS-IS LSP flash flooding.

Syntax

flash-flood [**flood-count** *flooding-count* | **max-timer-interval** *flooding-interval* | [**level-1** | **level-2**]] *

undo flash-flood [**level-1** | **level-2**]

Default

IS-IS LSP flash flooding is disabled.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

flood-count *flooding-count*: Specifies the maximum number of LSPs to be flooded before the next SPF calculation, in the range of 1 to 15. The default is 5.

max-timer-interval *flooding-interval*: Specifies the delay of the flash flooding, in the range of 10 to 50000 milliseconds. The default is 10.

level-1: Enables flash flooding for Level-1.

level-2: Enables flash flooding for Level-2.

Usage guidelines

If no level is specified, the command enables IS-IS LSP flash flooding for both Level-1 and Level-2.

Examples

Enable fast flooding, and set the maximum LSPs to be sent to 10 and the delay time to 100 milliseconds.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] flash-flood flood-count 10 max-timer-interval 100
```

graceful-restart

Use **graceful-restart** to enable IS-IS GR.

Use **undo graceful-restart** to disable IS-IS GR.

Syntax

graceful-restart

undo graceful-restart

Default

IS-IS GR is disabled.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Usage guidelines

IS-IS GR and IS-IS NSR are mutually exclusive. Therefore, do not configure the **graceful-restart** command and the **non-stop-routing** command at the same time.

Examples

Enable GR for IS-IS process 1.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] graceful-restart
```

Related commands

graceful-restart suppress-sa

graceful-restart suppress-sa

Use **graceful-restart suppress-sa** to suppress the Suppress-Advertisement (SA) bit during restart.

Use **undo graceful-restart suppress-sa** to restore the default.

Syntax

graceful-restart suppress-sa

undo graceful-restart suppress-sa

Default

The SA bit is set during restart.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Usage guidelines

Suppressing the SA bit is mainly for avoiding black hole route. If a router starts or reboots without keeping the local forwarding table, sending packets to the router might result in severe packet loss. To avoid this, you can set the SA bit of the hello packet sent by the GR restarter to 1. Upon receiving such hello packets, the GR helpers will not advertise the GR restarter through LSP.

Examples

Suppress the SA bit during graceful restart.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] graceful-restart suppress-sa
```

Related commands

graceful-restart

graceful-restart t1

Use **graceful-restart t1** to set the T1 timer.

Use **undo graceful-restart t1** to restore the default.

Syntax

graceful-restart t1 *seconds* **count** *count*

undo graceful-restart t1

Default

The T1 timer is 3 seconds and can expire 10 times.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the T1 timer in the range of 3 to 10 seconds.

count: Specifies the number of times that the T1 timer can expire, in the range of 1 to 20.

Usage guidelines

The T1 timer specifies the number of times that GR restarter can send a Restart TLV with the RR bit set. After restart, the GR restarter sends a Restart TLV with the RR bit set to its neighbor. If the restarting router receives a Restart TLV with the RA set from its neighbor before the T1 timer expires, the GR process starts. Otherwise, the GR process fails.

To avoid configuration failure, follow these guidelines when you set the GR timers:

- The product of the T1 timer and the number of times that the T1 timer can expire must be smaller than the T2 timer.
- The T2 timer must be smaller than the T3 timer.

Examples

Set the T1 timer of IS-IS process 1 to 5 seconds, and the expiration times to 5.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] graceful-restart t1 5 count 5
```

Related commands

graceful-restart

graceful-restart t2

graceful-restart t3

graceful-restart t2

Use **graceful-restart t2** to set the T2 timer.

Use **undo graceful-restart t2** to restore the default.

Syntax

graceful-restart t2 *seconds*

undo graceful-restart t2

Default

The T2 timer is 60 seconds.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the T2 timer in the range of 30 to 65535 seconds.

Usage guidelines

The T2 timer specifies the LSDB synchronization interval. Each LSDB has a T2 timer. The Level-1-2 router has two T2 timers: a Level-1 timer and a Level-2 timer. If the LSDBs have not achieved synchronization before the two timers expire, the GR process fails.

To avoid configuration failure, follow these guidelines when you set the GR timers:

- The product of the T1 timer and the number of times that the T1 timer can expire must be smaller than the T2 timer.
- The T2 timer must be smaller than the T3 timer.

Examples

Set the T2 timer of IS-IS process 1 to 50 seconds.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] graceful-restart t2 50
```

Related commands

graceful-restart

graceful-restart t1

graceful-restart t3

graceful-restart t3

Use **graceful-restart t3** to set the T3 timer.

Use **undo graceful-restart t3** to restore the default.

Syntax

graceful-restart t3 *seconds*

undo graceful-restart t3

Default

The T3 timer is 300 seconds.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the T3 timer in the range of 300 to 65535 seconds.

Usage guidelines

The T3 timer specifies the GR interval. The GR interval is set as the holdtime in hello PDUs. Within the interval, the neighbors maintain their adjacency with the GR restarter. If the GR process has not completed within the holdtime, the neighbors tear down the neighbor relationship and the GR process fails.

To avoid configuration failure, follow these guidelines when you set the GR timers:

- The product of the T1 timer and the number of times that the T1 timer can expire must be smaller than the T2 timer.

- The T2 timer must be smaller than the T3 timer.

Examples

Set the T3 timer of IS-IS process 1 to 500 seconds.

```
<Sysname> system-view

```

import-route

Use **import-route** to redistribute routes from another routing protocol or another IS-IS process.

Use **undo import-route** to disable route redistribution.

Syntax

In IS-IS IPv4 unicast address family view:

import-route bgp [*as-number*] [**allow-ibgp**] [**cost** *cost-value* | **cost-type** { **external** | **internal** } | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

import-route { **direct** | **static** } [**cost** *cost-value* | **cost-type** { **external** | **internal** } | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

import-route { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] [**allow-direct** | **cost** *cost-value* | **cost-type** { **external** | **internal** } | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

undo import-route { **bgp** | **direct** | { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] | **static** }

In IS-IS IPv6 unicast address family view:

Default

IS-IS does not redistribute routes from other routing protocols or processes.

Views

IS-IS IPv4 unicast address family view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

bgp: Redistributes BGP routes.

direct: Redistributes direct routes.

isis: Redistributes IS-IS routes.

ospf: Redistributes OSPF routes.

rip: Redistributes RIP routes.

static: Redistributes static routes.

bgp4+: Redistributes IPv6 BGP routes.

isisv6: Redistributes IPv6 IS-IS routes.

ospfv3: Redistributes OSPFv3 routes.

ripng: Redistributes RIPng routes.

as-number: Specifies an AS by its number in the range of 1 to 4294967295. If you do not specify this argument for the BGP or BGP4+ protocol, the command redistributes all IPv4 or IPv6 EBGP routes. As a best practice, specify an AS to prevent the system from redistributing excessive routes.

process-id: Specifies a process by its ID in the range of 1 to 65535.

all-processes: Redistributes routes from all the processes of the specified routing protocol.

allow-ibgp: Allows redistribution of IBGP routes.

allow-direct: Redistributes the networks of the local interfaces enabled with the specified routing protocol. By default, the networks of the local interfaces are not redistributed. If you specify both the **allow-direct** keyword and the **route-policy** *route-policy-name* option, make sure the **if-match** rule defined in the routing policy does not conflict with the **allow-direct** keyword. For example, if you specify the **allow-direct** keyword, do not configure the **if-match route-type** rule for the routing policy. Otherwise, the **allow-direct** keyword does not take effect.

cost *cost-value*: Specifies a cost for redistributed routes, which is in the range of 0 to 4261412864.

- For the styles of **narrow**, **narrow-compatible**, and **compatible**, the cost is in the range of 0 to 63.
- For the styles of **wide** and **wide-compatible**, the cost is in the range of 0 to 4261412864.

cost-type { **external** | **internal** }: Specifies the cost type. The **internal** type indicates internal routes, and the **external** type indicates external routes. If **external** is specified, the cost of a redistributed route is added by 64 to make internal routes take priority over external routes. The type is **external** by default. The keywords are available only when the cost type is **narrow, narrow-compatible**, or **compatible**.

level-1: Redistributes routes into the Level-1 routing table.

level-1-2: Redistributes routes into both Level-1 and Level-2 routing tables.

level-2: Redistributes routes into the Level-2 routing table. If no level is specified, the routes are redistributed into the Level-2 routing table by default.

route-policy *route-policy-name*: Redistributes only routes matching the specified routing policy. The *route-policy-name* argument is a case-sensitive string of 1 to 63 characters.

tag *tag*: Specifies a tag value for marking redistributed routes, in the range of 1 to 4294967295.

Usage guidelines

IS-IS takes all the redistributed routes as external routes to destinations outside the IS-IS routing domain.

The effective cost varies by cost style. For the styles of **narrow**, **narrow-compatible**, and **compatible**, the cost is in the range of 0 to 63. If the cost is more than 63, 63 is used. For the style of wide or wide-compatible, the configured value is the effective value.

This **import-route** command cannot redistribute default routes. The command redistributes only active routes. To display route state information, use the **display ip routing-table protocol** command.

The **import-route bgp** or **import-route bgp4+** command redistributes only EBGP routes.

The **import-route bgp allow-ibgp** or **import-route bgp4+ allow-ibgp** command redistributes both EBGP and IBGP routes. Because this command might cause routing loops, use it with caution.

The **undo import-route** { **isis** | **ospf** | **rip** } **all-processes** or **undo import-route** { **isisv6** | **ospfv3** | **ripng** } **all-processes** command removes only the configuration made by the **import-route** { **isis** | **ospf** | **rip** } **all-processes** or **import-route** { **isisv6** | **ospfv3** | **ripng** } **all-processes** command, instead of the configuration made by the **import-route** { **isis** | **ospf** | **rip** } *process-id* or **import-route** { **isisv6** | **ospfv3** | **ripng** } *process-id* command.

Examples

Redistribute static routes into IS-IS, and set the cost for redistributed routes to 15.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
[Sysname-isis-1-ipv4] import-route static cost 15
```

Related commands

import-route limit

import-route isis level-1 into level-2

Use **import-route isis level-1 into level-2** to enable route advertisement from Level-1 to Level-2.

Use **undo import-route isis level-1 into level-2** to disable route advertisement from Level-1 to Level-2.

Syntax

import-route isis level-1 into level-2 [**filter-policy** { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } | **tag** *tag*] *

undo import-route isis level-1 into level-2

Default

Route advertisement from Level-1 to Level-2 is enabled.

Views

IS-IS IPv4 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

filter-policy: Specifies a filtering policy.

ipv4-acl-number: Specifies an ACL by its number in the range of 2000 to 3999 to filter routes from Level-1 to Level-2.

prefix-list *prefix-list-name*: Specifies an IPv4 prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter routes from Level-1 to Level-2 by destination address.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter routes from Level-1 to Level-2.

tag *tag*: Specifies a tag for marking redistributed routes, in the range of 1 to 4294967295.

Usage guidelines

If a routing policy is used, the routing policy must be specified in the **import-route isis level-1 into level-2** command to filter routes from Level-1 to Level-2. Other routing policies specified for route reception and redistribution do not affect the route leaking.

If a filtering policy is configured, only Level-1 routes not filtered out can be advertised into the Level-2 area.

When you specify an IPv4 ACL, follow these guidelines:

- If the ACL does not exist or has no rules, IS-IS does not filter routes advertised from Level-1 to Level-2.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all routes advertised from Level-1 to Level-2.

Examples

Enable route advertisement from Level-1 to Level-2.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
```

```
[Sysname-isis-1-ipv4] import-route isis level-1 into level-2
```

Parameters

filter-policy: Specifies a filtering policy.

ipv4-acl-number: Specifies an ACL by its number in the range of 2000 to 3999 to filter routes from Level-2 to Level-1.

prefix-list *prefix-list-name*: Specifies an IPv4 prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter routes from Level-2 to Level-1 by destination address.

route-policy *route-policy-name*: Uses the specified routing policy to filter routes from Level-2 to Level-1. The *route-policy-name* argument is a case-sensitive string of 1 to 63 characters.

tag *tag*: Specifies a tag for marking redistributed routes, in the range of 1 to 4294967295.

Usage guidelines

If a routing policy is used, the routing policy must be specified in the **import-route isis level-2 into level-1** command to filter routes from Level-2 to Level-1. Other routing policies specified for route reception and redistribution does not affect the route leaking.

If a filtering policy is configured, only Level-2 routes not filtered out can be advertised into the Level-1 area.

When you specify an IPv4 ACL, follow these guidelines:

- If the ACL does not exist or has no rules, IS-IS does not filter routes advertised from Level-2 to Level-1.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all routes advertised from Level-2 to Level-1.

Examples

Enable route advertisement from Level-2 to Level-1.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
[Sysname-isis-1-ipv4] import-route isis level-2 into level-1
```

Parameters

filter-policy: Specifies a filtering policy.

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

tag *tag*: Specifies an administrative tag for marking redistributed routes, in the range of 1 to 4294967295.

Usage guidelines

This command enables a Level-1-2 router to redistribute Level-1 routes to Level-2 routers and Level-1-2 routers in the local area.

When you specify an IPv6 ACL, follow these guidelines:

- If the ACL does not exist or has no rules, IS-IS does not filter routes advertised from Level-1 to Level-2.

- If a rule in the ACL is applied to a VPN instance, the rule will deny all routes advertised from Level-1 to Level-2.

Examples

Enable route advertisement from Level-1 to Level-2.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv6
[Sysname-isis-1-ipv6] import-route isisv6 level-1 into level-2
```

import-route isisv6 level-2 into level-1

Use **import-route isisv6 level-2 into level-1** to enable IPv6 IS-IS route advertisement from Level-2 to Level-1.

Use **undo import-route isisv6 level-2 into level-1** to restore the default.

Syntax

import-route isisv6 level-2 into level-1 [**filter-policy** { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } | **tag** *tag*] *

undo import-route isisv6 level-2 into level-1

Default

Route advertisement from Level-2 to Level-1 is disabled.

Parameters

filter-policy: Specifies a filtering policy.

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

tag: Specifies an administrative tag for marking redistributed routes, in the range of 1 to 4294967295.

Usage guidelines

This command enables a Level-1-2 router to redistribute Level-2 routes to the Level-1 and Level-1-2 routers in the local area.

When you specify an IPv6 ACL, follow these guidelines:

- If the ACL does not exist or has no rules, IS-IS does not filter routes advertised from Level-2 to Level-1.
- If a rule in the ACL is applied to a VPN instance, the rule will deny all routes advertised from Level-2 to Level-1.

Examples

Enable IPv6 IS-IS route advertisement from Level-2 to Level-1.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv6
[Sysname-isis-1-ipv6] import-route isisv6 level-2 into level-1
```

import-route limit

Use **import-route limit** to configure the maximum number of redistributed Level 1/Level 2 routes.

Use **undo import-route limit** to restore the default.

Syntax

import-route limit *number*

undo import-route limit

Default

The maximum number of redistributed Level 1/Level 2 routes is 1000000.

network-entity

isis authentication send-only

Use **isis authentication send-only** to configure an IS-IS interface not to check the authentication information in the received hello packets.

Use **undo isis authentication send-only** to remove the configuration.

Syntax

isis authentication send-only [**level-1** | **level-2**]

undo isis authentication send-only [**level-1** | **level-2**]

Default

When interface authentication mode and key are configured, an IS-IS interface checks the authentication information in the received packets.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

level-1: Configures IS-IS not to check the authentication information in the received Level-1 hello packets.

level-2: Configures IS-IS not to check the authentication information in the received Level-2 hello packets.

Usage guidelines

When peer authentication mode and key are configured, an IS-IS interface adds the key in the specified mode into transmitted hello packets. It also checks the key in the received hello packets.

To prevent packet exchange failure in case of an authentication key change, configure the IS-IS interface not to check the authentication information in the received packets.

Examples

Configure GigabitEthernet 1/0/1 not to check the authentication information in the received Level-1 hello packets.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis authentication send-only level-1
```

isis authentication-mode

Use **isis authentication-mode** to specify the neighbor relationship authentication mode and a key.

Use **undo isis authentication-mode** to remove the configuration.

Syntax

isis authentication-mode { { **gca** *key-id* { **hmac-sha-1** | **hmac-sha-224** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** } [**nonstandard**] | **md5** | **simple** } { **cipher** | **plain** } *string* | **keychain** *keychain-name* } [**level-1** | **level-2**] [**ip** | **osi**]

undo isis authentication-mode [**level-1** | **level-2**]

Default

No neighbor relationship authentication mode or key is configured.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

gca: Specifies the GCA mode.

key-id: Uniquely identifies an SA in the range of 1 to 65535. The sender inserts the Key ID into the authentication TLV, and the receiver authenticates the packet by using the SA that is selected based on the Key ID.

hmac-sha-1: Specifies the HMAC-SHA-1 algorithm.

hmac-sha-224: Specifies the HMAC-SHA-224 algorithm.

hmac-sha-256: Specifies the HMAC-SHA-256 algorithm.

hmac-sha-384: Specifies the HMAC-SHA-384 algorithm.

hmac-sha-512: Specifies the HMAC-SHA-512 algorithm.

nonstandard: Specifies the nonstandard GCA mode.

md5: Specifies the MD5 authentication mode.

simple: Specifies the simple authentication mode.

cipher: Specifies a key in encrypted form.

plain: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. Its plaintext form is a case-sensitive string of 1 to 16 characters. Its encrypted form is a case-sensitive string of 33 to 53 characters.

keychain: Specifies the keychain authentication mode.

keychain-name: Specifies a keychain by its name, a case-sensitive string of 1 to 63 characters.

level-1: Configures the key for Level-1.

level-2: Configures the key for Level-2.

ip: Checks IP-related fields in LSPs and SNPs.

osi: Checks OSI-related fields in LSPs and SNPs.

Usage guidelines

The key in the specified mode is inserted into all outbound hello packets and is used for authenticating inbound hello packets. Only if the authentication succeeds can the neighbor relationship be formed.

IS-IS keychain authentication supports the HMAC-MD5 and HMAC-SM3 authentication algorithms. For the HMAC-SM3 authentication algorithm, only key IDs in the range of 0 to 65535 are supported. When keychain authentication is used, IS-IS receives and sends packets as follows:

- Before IS-IS sends a Hello packet, it uses the valid send key obtained from the keychain to authenticate the packet. If no valid send key exists or the valid send key does not use the HMAC-MD5 or HMAC-SM3 algorithm, the authentication fails and the packet does not contain the authentication information.
- After IS-IS receives a Hello packet, it processes the packet as follows:
  - If the authentication algorithm of the packet is HMAC-MD5, IS-IS uses a valid accept key obtained from the keychain to authenticate the packet. If no valid accept key exists or all valid accept keys fail to authenticate the packet, the authentication fails and the packet is discarded.
  - If the authentication algorithm of the packet is HMAC-SM3, IS-IS uses the key ID of the received packet to obtain the corresponding valid accept key from the keychain. Then, IS-IS uses the accept key to authenticate the packet. If IS-IS cannot find a valid accept key based on the key ID of the received packet or the packet fails the authentication, the packet is discarded.

The **level-1** and **level-2** keywords are configurable on an interface that has had IS-IS enabled with the **isis enable** command.

If you configure a key without specifying a level, the key applies to both Level-1 and Level-2.

For two routers to become neighbors, the authentication mode and key at both ends must be identical.

If neither **ip** nor **osi** is specified, the OSI-related fields in LSPs are checked.

When you specify the GCA mode, follow these guidelines:

- If you do not specify the **nonstandard** keyword, the device can communicate only with devices that use the GCA mode.
- If you specify the **nonstandard** keyword, the device can communicate only with devices that use the nonstandard GCA mode.

Examples

On GigabitEthernet 1/0/1, set the authentication mode to **simple**, and set the plaintext key to **123456**.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis authentication-mode simple plain 123456
```

[Sysname-GigabitEthernet1/0/1] isis enable
[Sysname-GigabitEthernet1/0/1] isis bfd enable
```

isis bfd session-restrict-adj

Use **isis bfd session-restrict-adj** to enable IPv4 adjacency establishment and maintenance control based on BFD session state.

Use **undo isis bfd session-restrict-adj** to disable IPv4 adjacency establishment and maintenance control based on BFD session state.

Syntax

isis bfd session-restrict-adj

undo isis bfd session-restrict-adj

Default

IPv4 adjacency establishment and maintenance control based on BFD session state is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

When BFD detects a Layer 3 forwarding failure between two routers, the BFD session goes down, which causes the IPv4 IS-IS adjacency to go down. If Layer 2 forwarding is still available, the routers can exchange IS-IS packets and re-establish the adjacency, which might cause traffic loss.

To avoid the issue, execute this command on the BFD-enabled interfaces of the local and remote routers, enabling the interfaces to carry BFD-enabled TLVs in hello packets. After the BFD session goes down, the routers do not establish an adjacency if the exchanged BFD-enabled TLVs are identical.

If you configure this command for an existing adjacency, the BFD session state does not affect the adjacency relationship within the hold time. This mechanism avoids adjacency flaps during the BFD session establishment.

Before configuring this command, enable IPv4 IS-IS BFD by using the **isis bfd enable** command.

Examples

Enable IPv4 adjacency establishment and maintenance control based on BFD session state on interface GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis enable
[Sysname-GigabitEthernet1/0/1] isis bfd enable
[Sysname-GigabitEthernet1/0/1] isis bfd session-restrict-adj
```

Enable IPv4 adjacency establishment and maintenance control based on BFD session state on interface VLAN-interface 11.

```
<Sysname> system-view
[Sysname] interface vlan-interface 11

isis bfd enable

isis circuit-level

Use **isis circuit-level** to set the circuit level for the interface.

Use **undo isis circuit-level** to restore the default.

Syntax

isis circuit-level [**level-1** | **level-1-2** | **level-2**]

undo isis circuit-level

Default

An interface can establish either the Level-1 or Level-2 adjacency.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

level-1: Sets the circuit level to Level-1.

level-1-2: Sets the circuit level to Level-1-2.

level-2: Sets the circuit level to Level-2.

Usage guidelines

For a Level-1 (Level-2) router, the circuit level can only be Level-1 (Level-2). For a Level-1-2 router, you must specify a circuit level for a specific interface to form only the specified level neighbor relationship.

Examples

GigabitEthernet 1/0/1 is connected to a non-backbone router in the same area. Set the circuit level of Ethernet 1/1 to Level-1 to prevent sending and receiving Level-2 Hello packets.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis enable
[Sysname-GigabitEthernet1/0/1] isis circuit-level level-1
```

Related commands

is-level

isis circuit-type p2p

Use **isis circuit-type p2p** to set the network type of an interface to P2P.

Use **undo isis circuit-type** to restore the default.

Syntax

isis circuit-type p2p

undo isis circuit-type

Default

The network type of an interface varies by physical media. (The network type of a VLAN interface is broadcast.)

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this command only on a broadcast network with two attached routers.

Interfaces with different network types operate differently. For example, broadcast interfaces must elect a DIS and flood CSNP packets to synchronize the LSDBs. P2P interfaces do not need to elect a DIS, and use a different LSDB synchronization mechanism.

If only two routers exist on a broadcast network, set the network type of attached interfaces to P2P to avoid DIS election and CSNP flooding. This saves network bandwidth and speeds up network convergence.

Examples

Set the network type of GigabitEthernet 1/0/1 to P2P.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis enable
[Sysname-GigabitEthernet1/0/1] isis circuit-type p2p
```

isis cost

Use **isis cost** to set the IS-IS cost for an interface.

Use **undo isis cost** to remove the configuration.

Syntax

isis cost *cost-value* [**level-1** | **level-2**]

undo isis cost [**level-1** | **level-2**]

Default

No IS-IS cost is configured for an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

cost-value: Specifies an IS-IS cost in the range of 1 to 16777215.

level-1: Applies the cost to Level-1.

level-2: Applies the cost to Level-2.

Usage guidelines

If neither **level-1** nor **level-2** is included, the cost applies to both Level-1 and Level-2.

Examples

Set the Level-2 IS-IS cost to 5 for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
```

```
[Sysname-GigabitEthernet1/0/1] isis cost 5 level-2
```

Related commands

auto-cost enable

bandwidth-reference

isis dis-name

Use **isis dis-name** to configure a name for a DIS to represent the pseudo node on a broadcast network.

Use **undo isis dis-name** to restore the default.

Syntax

isis dis-name *symbolic-name*

undo isis dis-name

Default

No name is configured for the DIS.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

symbolic-name: Specifies a DIS name, a case-insensitive string of 1 to 64 characters.

Usage guidelines

This command takes effect only on routers that have dynamic system ID to host name mapping enabled. This command does not take effect on Point-to-Point interfaces.

Examples

Set the DIS name to **LOCALAREA**.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis dis-name LOCALAREA
```

Related commands

display isis name-table

is-name

isis dis-priority

Use **isis dis-priority** to specify a DIS priority at a specified level for an interface.

Use **undo isis dis-priority** to remove the configuration.

Syntax

isis dis-priority *priority* [**level-1** | **level-2**]

undo isis dis-priority [**level-1** | **level-2**]

Default

The priority of Level-1 and Level-2 is 64.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

priority: Specifies a DIS priority in the range of 0 to 127.

level-1: Applies the DIS priority to Level-1.

level-2: Applies the DIS priority to Level-2.

Usage guidelines

On an IS-IS broadcast network, a router must be elected as the DIS at each routing level. Specify a DIS priority at a level for an interface. The greater the interface's priority is, the more likelihood it becomes the DIS. If multiple routers in the broadcast network have the same highest DIS priority, the router with the highest Subnetwork Point of Attachment (SNPA) address becomes the DIS. SNPA addresses are MAC addresses on a broadcast network.

IS-IS has no backup DIS. The router with a priority of 0 can also participate in DIS election.

If neither **level-1** nor **level-2** is specified, the DIS priority applies to both Level-1 and Level-2.

Examples

Set the Level-2 DIS priority to 127 for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis dis-priority 127 level-2
```

isis enable

Use **isis enable** to enable an IS-IS process on an interface.

Use **undo isis enable** to disable IS-IS.

Syntax

isis enable [*process-id*]

undo isis enable

Default

No IS-IS process is enabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an IS-IS process by its ID in the range of 1 to 65535. The default is 1.

Examples

Enable IS-IS process 1 globally and enable it on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] network-entity 10.0001.1010.1020.1030.00
[Sysname-isis-1] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis enable 1
```

Related commands

network-entity

isis fast-reroute lfa-backup exclude

Use **isis fast-reroute lfa-backup exclude** to disable LFA calculation on an interface.

Use **undo isis fast-reroute lfa-backup exclude** to restore the default.

Syntax

isis fast-reroute lfa-backup exclude [**level-1** | **level-2**]

undo isis fast-reroute lfa-backup exclude [**level-1** | **level-2**]

Default

LFA calculation is enabled on an interface, and the interface can be elected as a backup interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

level-1: Disables LFA calculation on the interface whose circuit level is Level-1.

level-2: Disables LFA calculation on the interface whose circuit level is Level-2.

Usage guidelines

When this command is configured, the interface does not participate in the LFA calculation, and cannot be elected as a backup interface.

If you do not specify the **level-1** or **level-2** keyword, LFA calculation is disabled on the interface regardless of its circuit level.

Examples

Disable LFA calculation on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] network-entity 10.0001.1010.1020.1030.00
[Sysname-isis-1] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis enable 1
```

```
[Sysname-GigabitEthernet1/0/1] isis fast-reroute lfa-backup exclude
```

[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis ipv6 bfd enable
```

isis ipv6 bfd session-restrict-adj

Use **isis ipv6 bfd session-restrict-adj** to enable IPv6 adjacency establishment and maintenance control based on BFD session state.

Use **undo isis ipv6 bfd session-restrict-adj** to disable IPv6 adjacency establishment and maintenance control based on BFD session state.

Syntax

isis ipv6 bfd session-restrict-adj

undo isis ipv6 bfd session-restrict-adj

Default

IPv6 adjacency establishment and maintenance control based on BFD session state is disabled.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

When BFD detects a Layer 3 forwarding failure between two routers, the BFD session goes down, which causes the IPv6 IS-IS adjacency to go down. If Layer 2 forwarding is still available, the routers can exchange IS-IS packets and re-establish the adjacency, which might cause traffic loss.

To avoid the issue, execute this command on the BFD-enabled interfaces of the local and remote routers, enabling the interfaces to carry BFD-enabled TLVs in hello packets. After the BFD session goes down, the routers do not establish an adjacency if the exchanged BFD-enabled TLVs are identical.

If you configure this command for an existing adjacency, the BFD session state does not affect the adjacency relationship within the hold time. This mechanism avoids adjacency flaps during the BFD session establishment.

Before configuring this command, enable IPv6 IS-IS BFD by using the **isis ipv6 bfd enable** command.

Examples

Enable IPv6 adjacency establishment and maintenance control based on BFD session state on interface GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis ipv6 enable
[Sysname-GigabitEthernet1/0/1] isis ipv6 bfd enable
[Sysname-GigabitEthernet1/0/1] isis ipv6 bfd session-restrict-adj
```

Enable IPv6 adjacency establishment and maintenance control based on BFD session state on interface VLAN-interface 11.

```
<Sysname> system-view
[Sysname] interface vlan-interface 11
[Sysname-Vlan-interface11] isis ipv6 enable
[Sysname-Vlan-interface11] isis ipv6 bfd enable
[Sysname-Vlan-interface11] isis ipv6 bfd session-restrict-adj
```

Related commands

isis ipv6 bfd enable

isis ipv6 cost

Use **isis ipv6 cost** to set the IPv6 IS-IS cost for an interface.

Use **undo isis ipv6 cost** to remove the configuration.

Syntax

isis ipv6 cost *cost-value* [**level-1** | **level-2**]

undo isis ipv6 cost [**level-1** | **level-2**]

Default

No IPv6 IS-IS cost is configured for an interface.

Views

Interface view

Predefined user roles

network-admin

isis ipv6 prefix-suppression

Use **isis ipv6 prefix-suppression** to enable prefix suppression on an interface.

Use **undo isis ipv6 prefix-suppression** to disable prefix suppression on an interface.

Syntax

isis ipv6 prefix-suppression

undo isis ipv6 prefix-suppression

Default

Prefix suppression is disabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

By default, IS-IS interfaces advertise their IPv6 prefixes in LSPs. Use this command to disable an interface from advertising its IPv6 prefix in LSPs. This enhances network security by preventing IP routing to the internal nodes and speeds up network convergence.

Examples

Enable prefix suppression on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis ipv6 prefix-suppression
```

isis ipv6 primary-path-detect bfd

Use **isis ipv6 primary-path-detect bfd** to enable BFD for IPv6 IS-IS.

Use **undo isis ipv6 primary-path-detect bfd** to disable BFD for IPv6 IS-IS.

Syntax

isis ipv6 primary-path-detect bfd { **ctrl** | **echo** }

undo isis ipv6 primary-path-detect bfd

Default

BFD is disabled for IPv6 IS-IS.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ctrl: Enables BFD control packet mode.

echo: Enables BFD echo packet mode.

Usage guidelines

This command enables IPv6 IS-IS FRR or IPv6 IS-IS PIC to use BFD to detect primary link failures.

For an interface to run the BFD session in echo packet mode correctly, make sure the interface has an IPv6 global unicast address. For more information about IPv6 global unicast addresses, see IPv6 basics configuration in *Layer 3—IP Services Configuration Guide*.

Examples

Enable BFD control packet mode for IPv6 IS-IS FRR on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv6
[Sysname-isis-1-ipv6] fast-reroute lfa
[Sysname-isis-1-ipv6] quit
[Sysname-isis-1] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis ipv6 primary-path-detect bfd ctrl
```

Enable BFD echo packet mode for IPv6 IS-IS PIC on GigabitEthernet 1/0/2.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] pic additional-path-always
[Sysname-isis-1] quit
[Sysname] bfd echo-source-ipv6 1::1
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] isis ipv6 primary-path-detect bfd echo
```

isis ipv6 tag

Use **isis ipv6 tag** to configure the tag value on an interface.

Use **undo isis ipv6 tag** to restore the default.

Syntax

isis ipv6 tag *tag*

undo isis ipv6 tag

Default

No tag value is configured on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

tag: Specifies a tag value in the range of 1 to 4294967295.

Usage guidelines

When IS-IS advertises an IPv6 prefix with a tag value, it adds the tag to the IPv6 reachability information TLV, regardless of the link cost style.

Examples

Set the tag value on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis ipv6 tag 4294967295
```

isis mib-binding

Use **isis mib-binding** to bind an IS-IS process to MIB.

Use **undo isis mib-binding** to restore the default.

Syntax

isis mib-binding *process-id*

undo isis mib-binding

Default

MIB operation is bound to the IS-IS process with the smallest process ID.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an IS-IS process by its ID in the range of 1 to 65535.

Usage guidelines

If the specified the process ID does not exist, the MIB binding configuration fails.

Deleting an IS-IS process bound to MIB operation deletes the MIB binding configuration. MIB operation is bound to the IS-IS process with the smallest process ID.

Examples

Bind IS-IS process 100 to MIB.

```
<Sysname> system-view
[Sysname] isis mib-binding 100
```

isis peer-ip-check

Use **isis peer-ip-check** to enable source address check for hello packets on an IS-IS P2P interface. An IS-IS P2P interface can establish a neighbor relationship only with a peer on the same network.

Use **undo isis peer-ip-check** to restore the default.

Syntax

isis peer-ip-check

undo isis peer-ip-check

Default

An IS-IS P2P interface can have a peer on a different network.

Views

Interface view

Predefined user roles

network-admin

context-admin

Examples

Enable source address check for hello packets on interface GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis peer-ip-check
```

Related commands

isis circuit-type p2p

Use **isis prefix-suppression** to enable prefix suppression on an interface.

Use **undo isis prefix-suppression** to disable prefix suppression on an interface.

Syntax

isis prefix-suppression

undo isis prefix-suppression

Default

Prefix suppression is disabled on an interface.

Views

Interface view

Predefined user roles

network-admin

context-admin

Usage guidelines

Use this command to disable an interface from advertising its prefix in LSPs. This enhances network security by preventing IP routing to the interval nodes and speeds up network convergence.

This command is also applicable to the secondary IP address of the interface.

Examples

Enable prefix suppression on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis prefix-suppression
```

isis primary-path-detect bfd

Use **isis primary-path-detect bfd** to enable BFD for IS-IS FRR or IS-IS PIC.

Use **undo isis primary-path-detect bfd** to disable BFD for IS-IS FRR or IS-IS PIC.

Syntax

isis primary-path-detect bfd { **ctrl** | **echo** }

undo isis primary-path-detect bfd

Default

BFD is disabled for IS-IS FRR or IS-IS PIC.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

ctrl: Specifies the BFD control packet mode.

echo: Specifies the BFD echo packet mode.

Usage guidelines

This command enables IS-IS FRR or IS-IS PIC to use BFD to detect primary link failures.

Examples

Enable BFD control packet mode for IS-IS FRR on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
[Sysname-isis-1-ipv4] fast-reroute lfa
[Sysname-isis-1-ipv4] quit

context-admin

Usage guidelines

This command is not available in loopback interface view.

Examples

Configure GigabitEthernet 1/0/1 to send small Hello packets.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis small-hello
```

isis tag

Use **isis tag** to configure the tag value for an interface.

Use **undo isis tag** to restore the default.

Syntax

isis tag *tag*

undo isis tag

Default

The interface is not configured with a tag value.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

tag: Specifies the tag value in the range of 1 to 4294967295.

Usage guidelines

When IS-IS advertises an IP prefix with a tag value, it adds the tag to the IP reachability information TLV if the link cost style is **wide**, **wide-compatible**, or **compatible**.

Examples

Configure the tag value for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis tag 4294967295
```

isis timer csnp

Use **isis timer csnp** to set on the DIS of a broadcast network the interval for sending CSNP packets.

Use **undo isis timer csnp** to remove the configuration.

Syntax

isis timer csnp *seconds* [**level-1** | **level-2**]

undo isis timer csnp [**level-1** | **level-2**]

Default

The default CSNP interval is 10 seconds.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies on the DIS of a broadcast network the interval for sending CSNP packets. The value range is 1 to 600 seconds.

level-1: Applies the interval to Level-1.

level-2: Applies the interval to Level-2.

Usage guidelines

On a broadcast network, this command only applies to the DIS, because the DIS sends CSNP packets periodically for LSDB synchronization.

If no level is specified, the CSNP interval applies to both Level-1 and Level-2.

Examples

Configure Level-2 CSNP packets to be sent every 15 seconds over GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis timer csnp 15 level-2
```

isis timer hello

Use **isis timer hello** to set the interval for sending hello packets.

Use **undo isis timer hello** to remove the configuration.

Syntax

isis timer hello *seconds* [**level-1** | **level-2**]

undo isis timer hello [**level-1** | **level-2**]

Default

The hello interval is 10 seconds.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the interval for sending hello packets, in the range of 1 to 255 seconds.

level-1: Specifies the interval for sending Level-1 hello packets.

level-2: Specifies the interval for sending Level-2 hello packets.

Usage guidelines

If a neighbor does not receive any hello packets from the router within the advertised hold time, it considers the router down and recalculates the routes. The hold time is the hello multiplier multiplied by the hello interval.

Level-1 and Level-2 hello packets are sent independently on a broadcast network, so you need to specify an interval for each level. On a P2P link, Level-1 and Level-2 packets are both sent in P2P hello packets, and you need not specify an interval for each level.

You can configure the **level-1** and **level-2** keywords only on broadcast interfaces. Before you configure the **level-1** or **level-2** keyword, enable IS-IS on the interface.

The shorter the interval, the more system resources will be occupied.

If no level is specified, the hello interval applies to both Level-1 and Level-2.

Examples

Configure Level-2 hello packets to be sent every 20 seconds over GigabitEthernet 1/0/1.

```
<Sysname> system-view
```

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis timer hello 20 level-2
```

Related commands

isis timer holding-multiplier

isis timer holding-multiplier

Use **isis timer holding-multiplier** to set the IS-IS hello multiplier.

Use **undo isis timer holding-multiplier** to remove the configuration.

Syntax

isis timer holding-multiplier *value* [**level-1** | **level-2**]

undo isis timer holding-multiplier [**level-1** | **level-2**]

Default

The default IS-IS hello multiplier is 3.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies the number of hello intervals, in the range of 3 to 1000.

level-1: Applies the number to the Level-1 IS-IS neighbor.

level-2: Applies the number to the Level-2 IS-IS neighbor.

Usage guidelines

The hello multiplier is the number of hello packets a neighbor must miss before declaring the router is down.

If a neighbor does not receive any hello packets from the router within the advertised hold time, it considers the router down and recalculates the routes. The hold time is the hello multiplier multiplied by the hello interval.

Level-1 and Level-2 hello packets are sent independently on a broadcast network, so you need to specify a hello multiplier for each level. On a P2P link, Level-1 and Level-2 packets are both sent in P2P hello packets, and you need not specify Level-1 or Level-2.

You can configure the **level-1** and **level-2** keywords only on broadcast interfaces. Before you configure the **level-1** or **level-2** keyword, enable IS-IS on the interface.

If no level is specified, the hello multiplier applies to both Level-1 and Level-2.

The value of hello multiplier multiplied by hello interval cannot be more than 65535.

Examples

Set the hello multiplier to 6 for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis timer holding-multiplier 6 level-2
```

Related commands

isis timer hello

isis timer lsp

Use **isis timer lsp** to set the minimum interval for sending LSPs on the interface and specify the maximum number of LSPs that can be sent per time.

Use **undo isis timer lsp** to restore the default.

Syntax

isis timer lsp *time* [**count** *count*]

undo isis timer lsp

Default

The minimum interval for sending LSPs on the interface is 33 milliseconds, and the maximum number of LSPs that can be sent at a time is 5.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

time: Specifies the minimum interval for sending link-state packets, in the range of 1 to 1000 milliseconds.

count: Specifies the maximum number of link-state packets to be sent at one time, in the range of 1 to 1000.

Usage guidelines

If a change occurs in the LSDB, IS-IS advertises the changed LSP to neighbors. You can specify the minimum interval for sending these LSPs to control the amount of LSPs on the network.

Examples

Set the interval to 500 milliseconds for sending LSPs on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis timer lsp 500
```

isis timer retransmit

isis timer retransmit

Use **isis timer retransmit** to configure the interval for retransmitting LSP packets over a point-to-point link.

Use **undo isis timer retransmit** to restore the default.

Syntax

isis timer retransmit *seconds*

undo isis timer retransmit

Default

The retransmission interval on a P2P link is 5 seconds.

Views

Interface view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the interval for retransmitting LSP packets, in the range of 1 to 300 seconds.

Usage guidelines

On a P2P link, IS-IS requires an advertised LSP be acknowledged. If no acknowledgment is received within a configurable interval, IS-IS will retransmit the LSP.

You do not need to use this command over a broadcast link where CSNPs are periodically broadcast to implement LSDB synchronization.

Examples

Set the LSP retransmission interval on a P2P link to 50 seconds for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] isis circuit-type p2p
[Sysname-GigabitEthernet1/0/1] isis timer retransmit 50
```

Related commands

isis circuit-type p2p

isis timer lsp

is-level

Use **is-level** to specify the IS level.

Use **undo is-level** to restore the default.

Syntax

is-level { **level-1** | **level-1-2** | **level-2** }

undo is-level

Default

The IS level is **level-1-2**.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

level-1: Specifies Level-1, which means IS-IS only calculates intra-area routes and maintains the Level-1 LSDB.

level-1-2: Specifies Level-1-2, which means IS-IS calculates routes and maintains the LSDBs for both Level-1 and Level-2.

level-2: Specifies Level-2, which means IS-IS calculates routes and maintains the LSDB for Level-2 only.

Usage guidelines

If only one area exists, configure all the routers as either Level-1 or Level-2, because the routers do not need to maintain two identical LSDBs at the same time.

If the only area is an IP network, configure all the routers as Level-2 for scalability.

Examples

Set the IS level to Level-1 for IS-IS process 1.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] is-level level-1
```

is-name

Use **is-name** to specify a host name for the IS and enable dynamic system ID to hostname mapping.

Use **undo is-name** to disable dynamic system ID to hostname mapping.

Syntax

is-name *sys-name*

undo is-name

Default

Dynamic system ID to hostname mapping is disabled, and no host name is configured for the IS.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

sys-name: Specifies a host name for the local IS, a case-insensitive string of 1 to 64 characters.

Usage guidelines

To display the host name rather than the system ID of an IS by using the **display isis lsdb** command, first enable dynamic system ID to hostname mapping.

Examples

Configure a host name for the local IS.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] is-name RUTA
```

Related commands

display isis name-table

is-name map

Use **is-name map** to configure a system ID to host name mapping for a remote IS.

Use **undo is-name map** to remove the mapping.

Syntax

is-name map *sys-id map-sys-name*

undo is-name map *sys-id*

Default

No system ID to host name mapping is configured for a remote IS.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

sys-id: Specifies the system ID or pseudonode ID of a remote IS.

map-sys-name: Specifies a host name for the remote IS, a case-insensitive string of 1 to 64 characters.

Usage guidelines

Each remote IS system ID corresponds to only one name.

Examples

Map the host name **RUTB** to the system ID 0000.0000.0041 of the remote IS.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] is-name map 0000.0000.0041 RUTB
```

Related commands

display isis name-table

ispf enable

Use **ispf enable** to enable incremental SPF (ISPF).

Use **undo ispf enable** to disable ISPF.

Syntax

ispf enable

undo ispf enable

Default

IS-IS ISPF is enabled.

Views

IS-IS view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Usage guidelines

When a network topology is changed, ISPF recomputes only the affected part of the SPT, instead of the entire SPT.

Examples

Enable ISPF.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] ispf enable
```

log-peer-change

Use **log-peer-change** to enable the logging of neighbor state changes.

Use **undo log-peer-change** to disable the logging.

Syntax

log-peer-change

undo log-peer-change

Default

The logging of IS-IS neighbor state changes is enabled.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command enables sending logs about IS-IS neighbor state changes to the information center. For IS-IS neighbor state change logs to be sent correctly, you must also configure the information center parameters on the device. For more information about information center, see the network management and monitoring configuration guide for the device.

Examples

Disable the logging of IS-IS neighbor state changes.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] undo log-peer-change
```

lsp-fragments-extend

Use **lsp-fragments–extend** to enable LSP fragment extension for a level.

Use **undo lsp-fragments–extend** to restore the default.

Syntax

lsp-fragments-extend [**level-1** | **level-1-2** | **level-2**]

undo lsp-fragments-extend

Default

LSP fragment extension is disabled.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

level-1: Applies the fragment extension to Level-1 LSPs.

level-1-2: Applies the fragment extension to both Level-1 and Level-2 LSPs.

level-2: Applies the fragment extension to Level-2 LSPs.

Usage guidelines

If no level is specified, the command enables LSP fragment extension for both Level-1 and Level-2.

Examples

Enable LSP fragment extension for Level-2.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] lsp-fragments-extend level-2
```

lsp-length originate

Use **lsp-length originate** to configure the maximum size of generated Level-1 or Level-2 LSPs.

Use **undo lsp-length originate** to remove the configuration.

Syntax

lsp-length originate *size* [**level-1** | **level-2**]

undo lsp-length originate [**level-1** | **level-2**]

Default

The maximum size of generated Level-1 and Level-2 LSPs is 1497 bytes.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

size: Specifies the maximum size of LSP packets, in the range of 512 to 16384 bytes.

level-1: Applies the size to Level-1 LSP packets.

level-2: Applies the size to Level-2 LSP packets.

Usage guidelines

If neither Level-1 nor Level-2 is specified in the command, the configured maximum size applies to the current IS-IS level.

Examples

Set the maximum size of the generated Level-2 LSPs to 1024 bytes.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] lsp-length originate 1024 level-2
```

lsp-length receive

Use **lsp-length receive** to configure the maximum size of received LSPs.

Use **undo lsp-length receive** to restore the default.

Syntax

lsp-length receive *size*

undo lsp-length receive

Default

The maximum size of received LSPs is 1497 bytes.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

size: Specifies the maximum size of received LSPs, in the range of 512 to 16384 bytes.

Examples

Configure the maximum size of received LSPs to 1024 bytes.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] lsp-length receive 1024
```

maximum load-balancing

Use **maximum load-balancing** to configure the maximum number of ECMP routes for load balancing.

Use **undo maximum load-balancing** to restore the default.

Syntax

maximum load-balancing *number*

undo maximum load-balancing

Default

The maximum number of IS-IS ECMP routes equals the maximum number of ECMP routes supported by the system.

Views

IS-IS IPv4 unicast address family view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

number: Specifies the maximum number of ECMP routes. The value of 1 indicates that IS-IS does not perform load balancing.

The following compatibility matrixes show the value ranges for the maximum number of ECMP routes:

Models	Value range
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280	1 to 16
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	1 to 32

Usage guidelines

If you use the **max-ecmp-num** command to configure the maximum number of ECMP routes supported by the system as *m*:

- The default setting for the **maximum load-balancing** command is *m*.
- The value range for the *number* argument of the **maximum load-balancing** command is 1 to *m*.

Examples

Set the maximum number of ECMP routes to 2.

```
<Sysname> system-view
[Sysname] isis 100
[Sysname-isis-100] address-family ipv4
[Sysname-isis-100-ipv4] maximum load-balancing 2
```

Related commands

max-ecmp-num

multi-topology

Use **multi-topology** to enable IPv6 IS-IS MTR.

Use **undo multiple-topology** to disable IPv6 IS-IS MTR.

Syntax

multi-topology [**compatible**]

undo multi-topology

Default

IPv6 IS-IS MTR is disabled.

Views

IS-IS IPv6 address family view

Predefined user roles

network-admin

context-admin

Parameters

compatible: Specifies the compatible mode to advertise IPv6 prefixes to both IPv4 and IPv6 topologies. If you do not specify this keyword, the command advertises IPv6 prefixes only to the IPv6 topology.

Usage guidelines

This command enables separate route calculation in IPv4 and IPv6 topologies.

This command is available when the link cost style is **wide**, **compatible**, or **wide-compatible**.

Examples

Enable IPv6 IS-IS MTR.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv6
[Sysname-isis-1-ipv6] multi-topology
```

Related commands

cost-style

network-entity

Use **network-entity** to configure the Network Entity Title (NET) for an IS-IS process.

Use **undo network-entity** to delete a NET.

Syntax

network-entity *net*

undo network-entity *net*

Default

No NET is configured.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

net: Specifies a NET as a dotted hexadecimal string in the X…X.XXXX....XXXX.00 format. The X…X segment represents the area address, the XXXX....XXXX segment represents the system ID, and the 00 segment is the SEL.

Usage guidelines

CAUTION:

When you execute the **network-entity** command together with the **cost-style** and **is-level** commands for the same IS-IS process, execute the **network-entity** command at last. Incorrect configuration order might cause data loss because the IS-IS process will restart.

A NET is a special NSAP address with the SEL being 0. The length of the NET is in the range of 8 to 20 bytes.

A NET comprises the following parts:

- **Area ID**—With a length of 1 to 13 bytes.
- **System ID**—A system ID uniquely identifies a host or router in the area and has a fixed 6-byte length.
- **SEL**—It has a value of 0 and a fixed 1-byte length.

For example, a NET of ab.cdef.1234.5678.9abc.00 specifies the area ID ab.cdef, the system ID 1234.5678.9abc, and the SEL 00.

Examples

Set the NET to 10.0001.1010.1020.1030.00, of which 10.0001 is the area ID and 1010.1020.1030 is the system ID.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] network-entity 10.0001.1010.1020.1030.00
```

Related commands

cost-style

isis

isis enable

is-level

non-stop-routing

Use **non-stop-routing** to enable IS-IS NSR.

Use **undo non-stop-routing** to disable IS-IS NSR.

Syntax

non-stop-routing

undo non-stop-routing

Default

IS-IS NSR is disabled.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Usage guidelines

IS-IS NSR takes effect on a per-process basis. As a best practice, enable NSR for each IS-IS process.

IS-IS NSR and IS-IS GR are mutually exclusive. Therefore, do not configure the **non-stop-routing** command and the **graceful-restart** command at the same time.

Examples

Enable NSR for IS-IS process 1.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] non-stop-routing
```

pic

Use **pic** to enable IS-IS PIC.

Use **undo pic** to disable IS-IS PIC.

Syntax

pic [**additional-path-always**]

undo pic

Default

IS-IS PIC is disabled.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

additional-path-always: Allows the indirect suboptimal route as the backup route.

Usage guidelines

Prefix Independent Convergence (PIC) enables the device to speed up network convergence by ignoring the number of prefixes. PIC applies only to indirect routes.

When both IS-IS PIC and IS-IS FRR are configured, only IS-IS FRR takes effect.

Examples

Configure IS-IS PIC to support the indirect suboptimal route as the backup route.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] pic additional-path-always
```

preference

Use **preference** to configure the preference for IS-IS.

Use **undo preference** to restore the default.

Syntax

preference { *preference* | **route-policy** *route-policy-name* } *

undo preference

Default

IS-IS preference is 15.

Views

IS-IS IPv4 unicast address family view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

preference: Specifies an IS-IS protocol preference in the range of 1 to 255.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to assign a priority to the matching routes.

Usage guidelines

If multiple routing protocols find routes to the same destination, the route found by the routing protocol with the highest preference is selected as the optimal route.

If a routing policy is specified in this command, the preference set by the routing policy applies to the matching routes. Other routes use the preference set by the **preference** command.

Examples

Set the preference for IS-IS to 25.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
[Sysname-isis-1-ipv4] preference 25
```

prefix-priority

Use **prefix-priority** to assign convergence priorities to specific IS-IS routes.

Use **undo prefix-priority** to remove the configuration.

Syntax

prefix-priority { **critical** | **high** | **medium** } { **prefix-list** *prefix-list-name* | **tag** *tag-value* }

prefix-priority route-policy *route-policy-name*

undo prefix-priority { **critical** | **high** | **medium** } [**prefix-list** | **tag**]

undo prefix-priority route-policy

Default

IS-IS routes have the lowest convergence priority.

Views

IS-IS IPv4 unicast address family view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

critical: Specifies the highest convergence priority.

high: Specifies the high convergence priority.

medium: Specifies the medium convergence priority.

prefix-list *prefix-list-name*: Specifies a prefix list by its name, a case-sensitive string of 1 to 63 characters.

tag *tag-value*: Specifies a tag value in the range of 1 to 4294967295.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

The higher the convergence priority, the faster the convergence speed.

IS-IS host routes have a medium convergence priority.

Examples

Assign the high convergence priority to IS-IS routes permitted by IP prefix list **standtest**.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
[Sysname-isis-1-ipv4] prefix-priority high prefix-list standtest
```

reset isis all

Use **reset isis all** to clear all IS-IS data structure information.

Syntax

reset isis all [*process-id*] [**graceful-restart**]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

process-id: Specifies an IS-IS process by its ID in the range of 1 to 65535 to clear the data structure information for an IS-IS process.

graceful-restart: Recovers the data through graceful restart after the data is cleared.

Usage guidelines

If no IS-IS process is specified, the command clears data structure information for all IS-IS processes.

Use this command when LSPs must be updated immediately.

Examples

Clear all IS-IS data structure information.

```
<Sysname> reset isis all
```

reset isis event-log lsp

Use **reset isis event-log lsp** to clear IS-IS LSP log information.

Syntax

reset isis event-log lsp { **purged** | **refreshed** } [*process-id*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

purged: Clears log information about purged LSPs.

refreshed: Clears log information about refreshed LSPs.

process-id: Specifies an IS-IS process by its ID in the range of 1 to 65535. If you do not specify this argument, the command clears LSP log information for all IS-IS processes.

Examples

Clear log information about refreshed LSPs for IS-IS process 1.

```
<Sysname> reset isis event-log lsp refreshed 1
```

Related commands

display isis event-log lsp

reset isis graceful-restart event-log

Use **reset isis graceful-restart event-log** to clear IS-IS GR log information.

Syntax

reset isis graceful-restart event-log slot *slot-number*

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its ID.

Examples

Clear IS-IS GR log information for the specified slot.

```
<Sysname> reset isis graceful-restart event-log slot 1
```

reset isis non-stop-routing event-log

Use **reset isis non-stop-routing event-log** to clear IS-IS NSR log information.

Syntax

reset isis non-stop-routing event-log slot *slot-number*

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

slot *slot-number*: Specifies an IRF member device by its ID.

Examples

Clear IS-IS NSR log information for the specified slot.

```
<Sysname> reset isis non-stop-routing event-log slot 1
```

reset isis peer

Use **reset isis peer** to clear data structure information for a specified IS-IS neighbor.

Syntax

reset isis peer *system-id* [*process-id*]

Views

User view

Predefined user roles

network-admin

context-admin

Parameters

system-id: Specifies an IS-IS neighbor by its system ID.

process-id: Specifies an IS-IS process by its ID in the range of 1 to 65535 to clear data structure information for the neighbor in the specified IS-IS process.

Usage guidelines

Use this command when you re-establish an IS-IS neighbor relationship.

Examples

Clear the data structure information of the neighbor with the system ID 0000.0c11.1111.

```
<Sysname> reset isis peer 0000.0c11.1111
```

reset osi statistics

Use **reset osi statistics** to clear OSI packet statistics.

Syntax

reset osi statistics

Views

User view

Predefined user roles

network-admin

context-admin

Usage guidelines

To obtain OSI packet statistics from the specified time point, first clear the existing statistics.

Examples

Clear OSI packet statistics.

```
<Sysname> reset osi statistics
```

Related commands

display osi statistics

set-att

Use **set-att** to set the ATT bit of Level-1 LSPs.

Use **undo set-att** to restore the default.

Syntax

set-att { **always** | **never** }

undo set-att

Default

The Level-1-2 router sets the ATT bit for Level-1 LSPs in accordance with the default ATT bit setting rule.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

always: Sets the ATT bit of Level-1 LSPs.

never: Keeps the ATT bit of Level-1 LSPs not set.

Usage guidelines

The ATT bit is used to identify the connection status between a Level-1 area and other areas. By default, a Level-1-2 router sets the ATT bit for Level-1 LSPs as follows:

- The Level-1-2 router sets the ATT bit in Level-1 LSPs to inform the Level-1 routers that it can reach other areas. After a Level-1 router receives a Level-1 LSP with the ATT bit set, it generates a default route destined for the Level-1-2 router.
- The Level-1-2 router does not set the ATT bit in Level-1 LSPs if it can reach only one area.

To edit the default ATT bit setting rule for a Level-1-2 router, perform the following tasks as needed:

- To enable ATT bit setting for all Level-1 LSPs, execute the **set-att always** command on the Level-1-2 router.
- To disable a Level-1 router from generating a default route upon receiving an ATT-bit-set Level-1 LSP from the Level-1-2 router, you can perform one of the following tasks:
  - Execute the **ignore-att** command on the Level-1 router.

- Execute the **set-att never** command on the Level-1-2 router.

The **set-att** command is applicable to only Level-1-2 routers.

Examples

Set the ATT bit of Level-1 LSPs.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] set-att always
```

set-overload

Use **set-overload** to set the overload bit.

Use **undo set-overload** to restore the default.

Syntax

In IS-IS view:

set-overload [**on-startup** [[**start-from-nbr** *system-id* [*timeout1* [*nbr-timeout*]]] | *timeout2* | **wait-for-bgp** [*timeout3*]]] [**allow** { **external** | **interlevel** } *]

undo set-overload

In IS-IS IPv6 unicast address family view:

set-overload [**on-startup** [[**start-from-nbr** *system-id* [*timeout1* [*nbr-timeout*]]] | *timeout2* | **wait-for-bgp4+** [*timeout3*]]] [**allow** { **external** | **interlevel** } *]

undo set-overload

Default

The overload bit is not set.

Views

IS-IS view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

on-startup: Sets the overload bit upon system startup.

start-from-nbr *system-id* [*timeout1* [*nbr-timeout*]]: Starts the *nbr-timeout* timer when the router begins to establish the neighbor relationship with the neighbor after system startup. If the neighbor relationship is formed within the *nbr-timeout* interval, IS-IS keeps the overload bit set. If not, the bit is cleared. IS-IS keeps the overload bit set within the *timeout1* interval after the neighbor relationship is formed within the *nbr-timeout* interval.

- *system-id*—Specifies the neighbor.
- *timeout1*—The *timeout1* interval is in the range of 5 to 86400 seconds, and the default is 600 seconds.
- *nbr-timeout*—The timer has an interval from 5 to 86400 seconds. The default is 1200 seconds.

timeout2: Sets the overload bit within the *timeout2* interval after system startup. The interval is in the range of 5 to 86400 seconds, and the default is 600 seconds.

wait-for-bgp [*timeout3*]: Starts the *timeout3* timer for BGP convergence after system startup. If BGP is not converged within the *timeout3* interval, IS-IS clears the overload bit. The value range for the *timeout3* argument is 5 to 86400 seconds, and the default is 600 seconds.

wait-for-bgp4+ [*timeout3*]: Starts the *timeout3* timer for IPv6 BGP convergence after system startup. If IPv6 BGP is not converged within the *timeout3* interval, IPv6 IS-IS clears the overload bit. The value range for the *timeout3* argument is 5 to 86400 seconds, and the default is 600 seconds.

allow: Allows advertising address prefixes. By default, no address prefixes are allowed to be advertised when the overload bit is set.

external: Allows advertising IP address prefixes redistributed from other routing protocols with the **allow** keyword specified.

interlevel: Allows advertising IP address prefixes learned from different IS-IS levels with the **allow** keyword specified.

Usage guidelines

If the **on-startup** keyword is not specified, the command sets the overload bit immediately until the **undo set-overload** command is executed.

If the **on-startup** keyword is specified, IS-IS sets the overload bit upon system startup and keeps it set within the *timeout2* interval.

Examples

Set overload flag on the current router.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] set-overload
```

snmp context-name

Use **snmp context-name** to set the context name for the SNMP object for managing IS-IS.

Use **undo snmp context-name** to restore the default.

Syntax

snmp context-name *context-name*

undo snmp context-name

Default

No context name is set for the SNMP object for managing IS-IS.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

context-name: Specifies a context name, a case-sensitive string of 1 to 32 characters.

Examples

Configure the context name as **isis** for the SNMP object for managing IS-IS process 1.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] snmp context-name isis
```

snmp-agent trap enable isis

Use **snmp-agent trap enable isis** to enable IS-IS SNMP notifications.

Use **undo snmp-agent trap enable isis** to disable IS-IS SNMP notifications.

Syntax

snmp-agent trap enable isis [**adjacency-state-change** | **area-mismatch** | **authentication** | **authentication-type** | **buffsize-mismatch** | **id-length-mismatch** | **lsdboverload-state-change** | **lsp-corrupt** | **lsp-parse-error** | **lsp-size-exceeded** | **manual-address-drop** | **max-seq-exceeded** | **maxarea-mismatch** | **own-lsp-purge** | **protocol-support** | **rejected-adjacency** | **skip-sequence-number** | **version-skew**] *

undo snmp-agent trap enable isis [**adjacency-state-change** | **area-mismatch** | **authentication** | **authentication-type** | **buffsize-mismatch** | **id-length-mismatch** | **lsdboverload-state-change** | **lsp-corrupt** | **lsp-parse-error** | **lsp-size-exceeded** | **manual-address-drop** | **max-seq-exceeded** | **maxarea-mismatch** | **own-lsp-purge** | **protocol-support** | **rejected-adjacency** | **skip-sequence-number** | **version-skew**] *

Default

IS-IS SNMP notifications are enabled.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

adjacency-state-change: Specifies notifications about IS-IS adjacency status changes.

area-mismatch: Specifies notifications about area address mismatches between hello packets.

authentication: Specifies notifications about authentication failures of IS-IS packets.

authentication-type: Specifies notifications about authentication type errors of IS-IS packets.

buffsize-mismatch: Specifies notifications about buffer size mismatches for LSPs.

id-length-mismatch: Specifies notifications about system ID length mismatches of IS-IS packets.

lsdboverload-state-change: Specifies notifications about LSDB overload state changes.

lsp-corrupt: Specifies notifications about LSP checksum errors in the LSDB.

lsp-parse-error: Specifies notifications about LSP packet parse failures.

lsp-size-exceeded: Specifies notifications about propagation failures caused by oversized LSPs.

manual-address-drop: Specifies notifications about manually configured area addresses that have been dropped.

max-seq-exceeded: Specifies notifications about attempts to exceed the maximum LSP sequence number.

maxarea-mismatch: Specifies notifications about maximum area address mismatches of hello packets.

own-lsp-purge: Specifies notifications about attempts to remove the local LSP.

protocol-support: Specifies notifications about supported-protocol mismatches.

rejected-adjacency: Specifies notifications about adjacency creation failures.

skip-sequence-number: Specifies notifications about LSP sequence number duplications.

version-skew: Specifies notifications about hello packet version mismatches.

Usage guidelines

If you do not specify a notification, this command enables all IS-IS SNMP notifications.

If no IS-IS process exists, the configuration is not allowed.

This function does not take effect if all configured IS-IS processes are deleted.

Examples

Disable IS-IS SNMP notifications.

```
<Sysname> system-view
[Sysname] undo snmp-agent trap enable isis
```

summary

Use **summary** to configure a summary route.

Use **undo summary** to remove a summary route.

Syntax

In IS-IS IPv4 unicast address family view:

summary *ip-address* { *mask-length* | *mask* } [**avoid-feedback** | **generate_null0_route** | [**level-1** | **level-1-2** | **level-2**] | **tag** *tag*] *

undo summary *ip-address* { *mask-length* | *mask* } [**level-1** | **level-1-2** | **level-2**]

In IS-IS IPv6 unicast address family view:

summary *ipv6-prefix prefix-length* [**avoid-feedback** | **generate_null0_route** | [**level-1** | **level-1-2** | **level-2**] | **tag** *tag*] *

undo summary *ipv6-prefix prefix-length* [**level-1** | **level-1-2** | **level-2**]

Default

No summary route is configured.

Views

IS-IS IPv4 unicast address family view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

ip-address: Specifies the destination IP address of the summary route.

mask-length: Specifies the mask length of the summary route, in the range of 0 to 32.

mask: Specifies the mask of the destination IP address, in dotted decimal notation.

ipv6-prefix: Specifies an IPv6 prefix for the summary route.

prefix-length: Specifies the length of the IPv6 prefix, in the range of 0 to 128.

avoid-feedback: Avoids learning summary routes by route calculation.

generate_null0_route: Generates the Null 0 route to avoid routing loops.

level-1: Summarizes only the routes redistributed to Level-1.

level-1-2: Summarizes the routes redistributed to both Level-1 and Level-2.

level-2: Summarizes only the routes redistributed to Level-2.

tag *tag*: Specifies a management tag in the range of 1 to 4294967295.

Usage guidelines

To reduce the size of the routing table, as well as the size of LSP and LSDB generated by the router, summarize multiple contiguous networks into a single network. You can summarize native IS-IS routes and redistributed routes. After summarization, the cost of the summary route is the smallest cost of the summarized routes.

If no level is specified, only **level-2** routes are summarized.

The router summarizes only routes generated from local LSPs.

Examples

Configure a summary route of 202.0.0.0/8.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] address-family ipv4
[Sysname-isis-1-ipv4] summary 202.0.0.0 255.0.0.0
```

timer lsp-generation

Use **timer lsp-generation** to set the LSP generation interval.

Use **undo timer lsp-generation** to remove the configuration.

Syntax

timer lsp-generation *maximum-interval* [*minimum-interval* [*incremental-interval*]] [**level-1** | **level-2**]

undo timer lsp-generation [**level-1** | **level-2**]

Default

The maximum interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

maximum-interval: Specifies the maximum interval in the range of 1 to 120 seconds.

minimum-interval: Specifies the minimum interval in the range of 10 to 60000 milliseconds.

incremental-interval: Specifies the incremental interval in the range of 10 to 60000 milliseconds.

level-1: Applies the intervals to Level-1.

level-2: Applies the intervals to Level-2. If no level is specified, the specified intervals apply to both Level-1 and Level-2.

Usage guidelines

By adjusting the LSP generation interval, you can prevent bandwidth and router resources from being over consumed due to frequent topology changes.

If you specify only the *maximum-interval* argument, the LSP generation interval is *maximum-interval*.

If you do not specify the *incremental-interval* argument, the LSP generation interval is in the range of *minimum-interval* to *maximum-interval*.

If you specify the *incremental-interval* argument, the LSP generation interval is as follows:

- When network changes are not frequent, the *minimum-interval* is adopted.
- If network changes are frequent, the LSP generation interval increases by *incremental-interval* × 2^{n-2} (n is the number of calculation times) each time a generation occurs until the *maximum-interval* is reached.

The minimum interval and the incremental interval cannot be greater than the maximum interval.

Examples

Set the maximum interval, minimum interval, and incremental interval to 10 seconds, 100 milliseconds, and 200 milliseconds, respectively.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1]timer lsp-generation 10 100 200
```

timer lsp-max-age

Use **timer lsp-max-age** to set the LSP maximum age in the LSDB.

Use **undo timer lsp-max-age** to restore the default.

Syntax

timer lsp-max-age *seconds*

undo timer lsp-max-age

Default

The LSP maximum age is 1200 seconds.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the LSP maximum aging time in the range of 1 to 65535 seconds.

Usage guidelines

Each LSP has an age that decreases in the LSDB. Any LSP with an age of 0 is deleted from the LSDB. You can adjust the age value based on the scale of a network.

Examples

Set the maximum LSP age to 1500 seconds.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] timer lsp-max-age 1500
```

Related commands

timer lsp-refresh

timer lsp-refresh

Use **timer lsp-refresh** to set the LSP refresh interval.

Use **undo timer lsp-refresh** to restore the default.

Syntax

timer lsp-refresh *second*s

undo timer lsp-refresh

Default

The default LSP refresh interval is 900 seconds.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

*second*s: Specifies the LSP refresh interval in the range of 1 to 65534 seconds.

Usage guidelines

Each router refreshes its LSPs at a configurable interval and sends them to other routers to achieve the following purposes:

- Prevent valid routes from aging out.
- Synchronize LSPs in the network.

A smaller refresh interval speeds up network convergence but consumes more bandwidth.

To refresh LSPs before they are aged out, the interval configured by the **timer lsp-refresh** command must be smaller than that configured by the **timer lsp-max-age** command.

Examples

Set the LSP refresh interval to 1500 seconds.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] timer lsp-refresh 1500
```

Related commands

timer lsp-max-age

timer spf

Use **timer spf** to set the SPF calculation interval.

Use **undo timer spf** to restore the default.

Syntax

timer spf *maximum-interval* [*minimum-interval* [*incremental-interval*]]

undo timer spf

Default

The maximum interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Views

IS-IS view

IS-IS IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

maximum-interval: Specifies the maximum SPF calculation interval in the range of 1 to 120 seconds.

minimum-interval: Specifies the minimum SPF calculation interval in the range of 10 to 60000 milliseconds.

incremental-interval: Specifies the incremental SPF calculation interval in the range of 10 to 60000 milliseconds.

Usage guidelines

Based on the LSDB, an IS-IS router uses the SPF algorithm to calculate a shortest path tree with itself being the root, and uses the shortest path tree to determine the next hop to a destination network. By adjusting the SPF calculation interval, you can prevent bandwidth and router resources from being overused due to frequent topology changes.

When network changes are not frequent, the *minimum-interval is* adopted. If network changes become frequent, the SPF calculation interval increases by the *incremental-interval* each time a generation happens until the *maximum-interval* is reached.

The minimum interval and the incremental interval cannot be greater than the maximum interval.

Examples

Set the maximum interval to 10 seconds, the minimum interval to 100 milliseconds, and the incremental interval to 300 milliseconds, respectively.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] timer spf 10 100 300
```

virtual-system

Use **virtual-system** to configure a virtual system ID for the IS-IS process.

Use **undo virtual-system** to remove a virtual system ID.

Syntax

virtual-system *virtual-system-id*

undo virtual-system *virtual-system-id*

Default

No virtual system ID is configured.

Views

IS-IS view

Predefined user roles

network-admin

context-admin

Parameters

virtual-system-id: Specifies a virtual system ID for the IS-IS process.

Examples

Set a virtual system ID of 2222.2222.2222 for IS-IS process 1.

```
<Sysname> system-view
[Sysname] isis 1
[Sysname-isis-1] virtual-system 2222.2222.2222
```

Contents

BGP commands

address-family ipv4

Use **address-family ipv4** to create the BGP IPv4 unicast address family, BGP-VPN IPv4 unicast address family, BGP IPv4 RT filter address family, or BGP IPv4 multicast address family, and enter its view, or enter the view of the existing address family.

Use **undo address-family ipv4** to remove the BGP IPv4 unicast address family, BGP-VPN IPv4 unicast address family, BGP IPv4 RT filter address family, or BGP IPv4 multicast address family, and all its configurations.

Syntax

In BGP instance view:

address-family ipv4 [**multicast** | **rtfilter** | **unicast**]

undo address-family ipv4 [**multicast** | **rtfilter** | **unicast**]

In BGP-VPN instance view:

address-family ipv4 [**unicast**]

undo address-family ipv4 [**unicast**]

Default

No BGP IPv4 unicast address family, BGP-VPN IPv4 unicast address family, BGP IPv4 RT filter address family, or BGP IPv4 multicast address family exists.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

multicast: Specifies the IPv4 multicast address family.

rtfilter: Specifies the BGP IPv4 RT filter address family.

The following compatibility matrixes show the support of hardware platforms for the **rtfilter** keyword:

Models	Parameter compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No

unicast: Specifies the IPv4 unicast address family. If this command is executed with the **unicast** keyword in BGP instance view, it places you into BGP IPv4 unicast address family view. If this command is executed with the **unicast** keyword in BGP-VPN instance view, it places you into BGP-VPN IPv4 unicast address family view.

Usage guidelines

Configurations made in BGP IPv4 unicast address family view apply only to the BGP IPv4 unicast routes and peers of the public network.

Configurations made in BGP-VPN IPv4 unicast address family view apply only to the BGP IPv4 unicast routes and peers of the specified VPN instance.

Configurations made in BGP IPv4 multicast address family view apply only to the BGP IPv4 multicast routes and peers.

Configurations made in BGP IPv4 RT filter address family view apply only to the BGP IPv4 RT filter routes and peers.

By default, the **unicast** keyword is used if you do not specify the **multicast**, **rtfilter**, or **unicast** keyword.

Examples

In BGP instance view, create the BGP IPv4 unicast address family and enter its view.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4]
```

address-family ipv6

Use **address-family ipv6** to create the BGP IPv6 unicast address family, BGP-VPN IPv6 unicast address family, or BGP IPv6 multicast address family, and enter its view, or enter the view of the existing address family.

Use **undo address-family ipv6** to remove the BGP IPv6 unicast address family, BGP-VPN IPv6 unicast address family, or BGP IPv6 multicast address family, and all its configurations.

Syntax

In BGP instance view:

address-family ipv6 [**multicast** | **unicast**]

undo address-family ipv6 [**multicast** | **unicast**]

In BGP-VPN instance view:

address-family ipv6 [**unicast**]

undo address-family ipv6 [**unicast**]

Default

No BGP IPv6 unicast address family, BGP-VPN IPv6 unicast address family, or BGP IPv6 multicast address family exists.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

unicast: Specifies the IPv6 unicast address family. If this command is executed with the **unicast** keyword in BGP instance view, it places you into BGP IPv6 unicast address family view. If this command is executed with the **unicast** keyword in BGP-VPN instance view, it places you into BGP-VPN IPv6 unicast address family view.

multicast: Specifies the IPv6 multicast address family.

Usage guidelines

Configurations made in BGP IPv6 unicast address family view apply only to the BGP IPv6 unicast routes and peers of the public network.

Configurations made in BGP-VPN IPv6 unicast address family view apply only to the BGP IPv6 unicast routes and peers of the specified VPN instance.

Configurations made in BGP IPv6 multicast address family view apply only to the BGP IPv6 multicast routes and peers.

By default, the **unicast** keyword is used if neither the **multicast** keyword nor the **unicast** keyword is specified.

Examples

In BGP instance view, create the BGP IPv6 unicast address family and enter its view.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv6 unicast
[Sysname-bgp-default-ipv6]
```

address-family link-state

Use **address-family link-state** to create the BGP LS address family and enter its view, or enter the view of the existing address family.

Use **undo address-family link-state** to remove the BGP LS address family and all its configurations.

Syntax

address-family link-state

undo address-family link-state

Default

No BGP LS address family exists.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Usage guidelines

Configurations made in BGP LS address family view apply only to the BGP LS routes and peers of the public network.

Examples

In BGP instance view, create the BGP LS address family and enter its view.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family link-state
[Sysname-bgp-default-ls]
```

advertise-rib-active

Use **advertise-rib-active** to enable BGP to advertise only the optimal BGP routes in the IP routing table.

Use **undo advertise-rib-active** to restore the default.

Syntax

advertise-rib-active

undo advertise-rib-active

Default

In BGP instance view, BGP advertises optimal routes in the BGP routing table, regardless of whether they are optimal in the IP routing table. In other views, the setting is the same as that in BGP instance view.

Views

BGP instance view

BGP IPv4 unicast address family view

BGP-VPN IPv4 unicast address family view

BGP IPv6 unicast address family view

BGP-VPN IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Usage guidelines

The **advertise-rib-active** command does not apply to the following routes:

- Routes redistributed by the **import-route** command.
- Routes advertised by the **network** command.
- Default routes redistributed by the **default-route imported** command.
- VPNv4 routes.
- VPNv6 routes.

This command takes effect only on the routes generated after you execute this command. To apply this command to existing routes, use the **reset bgp** command to reset BGP sessions.

The setting in BGP unicast address family view applies when it is different from that in BGP instance view.

Examples

In BGP instance view, enable BGP to advertise optimal routes in the IP routing table.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] advertise-rib-active
```

aggregate

Use **aggregate** to create a summary route in the BGP routing table.

Use **undo aggregate** to remove a summary route.

Syntax

In BGP IPv4 unicast address family view/BGP-VPN IPv4 unicast address family view/BGP IPv4 multicast address family view:

aggregate *ipv4-address* { *mask-length* | *mask* } [**as-set** | **attribute-policy** *route-policy-name* | **detail-suppressed** | **origin-policy** *route-policy-name* | **suppress-policy** *route-policy-name*] *

undo aggregate ipv4-address { *mask-length* | *mask* }

Default

No summary routes are configured.

Views

BGP IPv4 unicast address family view

BGP-VPN IPv4 unicast address family view

BGP IPv6 unicast address family view

BGP-VPN IPv6 unicast address family view

BGP IPv4 multicast address family view

BGP IPv6 multicast address family view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies an IPv4 summary address.

mask-length: Specifies a mask length for the IPv4 summary address, in the range of 0 to 32.

mask: Specifies a mask for the IPv4 summary address, in dotted decimal notation.

ipv6-address: Specifies an IPv6 summary address.

prefix-length: Specifies a prefix length for the IPv6 summary address, in the range of 0 to 128.

as-set: Enables the AS_PATH attribute of the summary route to contain the AS path information for all summarized routes. The AS_PATH attribute is of the AS_SET type that requires no sequence when arranging AS numbers. If you do not specify this keyword, the AS_PATH attribute of the summary route contains only the AS number of the local router.

attribute-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to set attributes for the summary route.

detail-suppressed: Advertises only the summary route. If you do not specify this keyword, BGP advertises both the summary route and the more specific routes.

origin-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to select routes to be summarized.

suppress-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter more specific routes to be advertised. Routes

permitted by the specified routing policy are not advertised. Routes denied by the specified routing policy are advertised.

Usage guidelines

This command creates a summary route. If the BGP routing table has routes whose destination addresses fall within the specified network, the summary route is added to the BGP routing table. For example, if two routes 10.1.1.0/24 and 10.1.2.0/24 exist in the BGP routing table, configuring the **aggregate 10.1.0.0 16** command creates a summary route 10.1.0.0/16.

If the summarized routes have different ORIGIN attributes, the summary route selects the ORIGIN attribute in the sequence of INCOMPLETE, EGP, and IGP. For example, if the ORIGIN attributes of the summarized routes include INCOMPLETE and IGP, the ORIGIN attribute of the summary route is INCOMPLETE.

The COMMUNITY attribute of the summary route includes all the COMMUNITY (or extended community) attribute values if the routes have the following details:

- Summarized routes have different COMMUNITY (or extended community) attribute values.
- The summary route does not have the ATOMIC_AGGREGATE attribute.

Table 1 Functions of the keywords

Keywords	Function
as-set	Enables the summary route to carry the AS path information for all summarized routes. This feature can help avoid routing loops. However, if many routes are summarized and are changed frequently, do not specify this keyword. This configuration causes the summary route to flap with the more specific routes.
attribute-policy	Sets attributes except the AS-PATH attribute for the summary route. The **peer route-policy** command can achieve the same purpose.
detail-suppressed	Disables advertisement of all more specific routes. To disable advertisement of some more specific routes, use the **suppress-policy** keyword or the **peer filter-policy** command.
origin-policy	Summarizes only routes matching a routing policy. If the destination address of a route falls within the summary network but does not match the routing policy, the route is not summarized. It is not controlled by the **detail-suppressed** and **suppress-policy** keywords. There is no need to configure **apply** clauses for the routing policy applied by the **origin-policy** keyword because they do not take effect.
suppress-policy	Disables advertisement of some more specific routes filtered by a routing policy. The routing policy uses **if-match** clauses to filter routes. There is no need to configure **apply** clauses for the routing policy applied by the **suppress-policy** keyword because they do not take effect.

Examples

In BGP IPv4 unicast address family view, create summary route 1.1.0.0/16 in the BGP routing table.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] aggregate 1.1.0.0 255.255.0.0
```

balance

Use **balance** to enable load balancing and set the maximum number of BGP ECMP routes for load balancing.

Use **undo balance** to disable load balancing.

Syntax

balance [**ebgp** | **eibgp** | **ibgp**] *number*

undo balance [**ebgp** | **eibgp** | **ibgp**]

Default

Load balancing is disabled.

Views

BGP IPv4 unicast address family view

BGP-VPN IPv4 unicast address family view

BGP IPv6 unicast address family view

BGP-VPN IPv6 unicast address family view

BGP IPv4 multicast address family view

BGP IPv6 multicast address family view

Predefined user roles

network-admin

context-admin

Parameters

ebgp: Enables load balancing over EBGP routes.

eibgp: Enables load balancing between EBGP and IBGP routes.

ibgp: Enables load balancing over IBGP routes.

number: Specifies the maximum number of BGP ECMP routes for load balancing. When it is set to 1, load balancing is disabled.

Usage guidelines

Unlike IGP, BGP has no explicit metric for making load balancing decision. Instead, it implements load balancing by modifying route selection rules.

If multiple BGP routes destined for a network meet the following conditions, the device selects the specified number of routes for load balancing:

BGP uses the following load balancing criteria to determine load balanced routes:

- The routes have the same ORIGIN, LOCAL_PREF, and MED attributes.
- The routes meet the following requirements on the AS_PATH attribute:
  - If the **balance as-path-neglect** command is configured, the routes can have different AS_PATH attributes.

- If only the **balance as-path-relax** command is configured, the routes can have different AS_PATH attributes, but the length of the AS_PATH attributes must be the same.
- If neither the **balance as-path-neglect** nor the **balance as-path-relax** command is configured, the routes must have the same AS_PATH attribute.

- The next hops of the routes meet the following requirements on IGP metrics:
  - If the **bestroute igp-metric-ignore** command is not configured, the next hops of the routes must have the same IGP metric value.
  - If the **bestroute igp-metric-ignore** command is configured, the next hops of the routes can have different IGP metric values.

If you do not specify the **ibgp**, **eibgp**, or **ebgp** keyword, this command enables load balancing over EBGP routes and IBGP routes, but not between EBGP and IBGP routes.

You can remove the configuration of the **balance eibgp** *number* command only by executing the **undo balance eibgp** command.

After you execute the **balance eibgp** *number* command, the **balance** [**ebgp** | **ibgp**] *number* command cannot be executed; and vice versa.

Examples

In BGP IPv4 unicast address family view, enable load balancing and set the maximum number of BGP ECMP routes used for load balancing to 2.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] balance 2
```

Predefined user roles

network-admin

context-admin

Usage guidelines

For BGP to implement load balancing over routes with different AS_PATH attributes, you must use this command together with the **balance** command.

After this command is executed, BGP ignores the AS_PATH attributes in the routes for load balancing and changes the attributes of the advertised routes to those of the optimal route. The operations might cause routing loops. In addition, this command might also affect the NetStream data. Therefore, use this command with caution.

Examples

In BGP IPv4 unicast address family view, enable BGP to ignore the AS_PATH attribute when it implements load balancing.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] balance as-path-neglect
```

Related commands

balance

balance as-path-relax

Use **balance as-path-relax** to enable load balancing for routes that have different AS_PATH attributes of the same length.

Use **undo balance as-path-relax** to restore the default.

Syntax

balance as-path-relax

undo balance as-path-relax

Default

BGP cannot perform load balancing for routes that have different AS_PATH attributes of the same length.

Views

Predefined user roles

network-admin

context-admin

Usage guidelines

For BGP to perform load balancing for routes with different AS_PATH attributes of the same length, you must use this command together with the **balance** command.

If you configure both the **balance as-path-relax** and **balance as-path-neglect** commands, the **balance as-path-neglect** command takes effect.

After this command is executed, BGP ignores the AS_PATH attributes in the routes for load balancing and changes the attributes of the advertised routes to those of the optimal route. This might cause routing loops and affect NetStream statistics. Therefore, use this command with caution.

Examples

In BGP IPv4 unicast address family view, enable load balancing for routes that have different AS_PATH attributes of the same length.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] balance as-path-relax
```

bestroute as-path-neglect

Use **bestroute as-path-neglect** to configure BGP to ignore the AS_PATH attribute during optimal route selection.

Use **undo bestroute as-path-neglect** to restore the default.

Syntax

In BGP instance view:

bestroute as-path-neglect [**all-instance**]

undo bestroute as-path-neglect [**all-instance**]

In BGP-VPN instance view:

bestroute as-path-neglect

undo bestroute as-path-neglect

Default

BGP considers the AS_PATH attribute during optimal route selection.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

all-instance: Enables this feature for the BGP instance and all BGP-VPN instances created in the BGP instance. If you do not specify this keyword, the command enables this feature for only the BGP instance or BGP-VPN instance.

Usage guidelines

If you do not specify the **all-instance** keyword for this command, this feature is enabled for only the current BGP instance or BGP-VPN instance.

After executing the **bestroute as-path-neglect all-instance** command in BGP instance view, you enable this feature for the BGP instance and all BGP-VPN instances in the BGP instance. Executing the **undo bestroute as-path-neglect** command in BGP instance view or BGP-VPN instance view cannot disable this feature. To enable this feature for a specific instance, execute the **bestroute as-path-neglect** command in BGP instance or BGP-VPN instance view and make sure the **bestroute as-path-neglect all-instance** command is not executed in BGP instance view.

Examples

In BGP instance view, ignore AS_PATH during optimal route selection.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] bestroute as-path-neglect
```

bestroute compare-med

Use **bestroute compare-med** to enable MED comparison for routes on a per-AS basis.

Use **undo bestroute compare-med** to restore the default.

Syntax

In BGP instance view:

bestroute compare-med [**all-instance**]

undo bestroute compare-med [**all-instance**]

In BGP-VPN instance view:

bestroute compare-med

undo bestroute compare-med

Default

MED comparison for routes on a per-AS basis is disabled.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

all-instance: Enables this feature for the BGP instance and all BGP-VPN instances created in the BGP instance. If you do not specify this keyword, the command enables this feature for only the BGP instance or BGP-VPN instance.

Usage guidelines

By default, BGP does not compare MEDs for routes from the same AS. When a router learns a new route, it compares the route with the optimal route in its BGP routing table. If the new route is more optimal, it becomes the optimal route in the BGP routing table. In this way, route learning sequence might affect optimal route selection.

To solve the selection problem, the router puts routes received from the same AS into a group when the **bestroute compare-med** command is configured. The router then selects the route with the lowest MED from the same group, and compares routes from different groups.

If you do not specify the **all-instance** keyword for this command, this feature is enabled for only the current BGP instance or BGP-VPN instance.

After executing the **bestroute compare-med all-instance** command in BGP instance view, you enable this feature for the BGP instance and all BGP-VPN instances in the BGP instance. Executing the **undo bestroute compare-med** command in BGP instance view or BGP-VPN instance view cannot disable this feature. To enable this feature for a specific instance, execute the **bestroute compare-med** command in BGP instance or BGP-VPN instance view and make sure the **bestroute compare-med all-instance** command is not executed in BGP instance view.

Examples

In BGP instance view, enable MED comparison for routes on a per-AS basis.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] bestroute compare-med
```

bestroute igp-metric-ignore

Use **bestroute igp-metric-ignore** to configure BGP to ignore IGP metrics during optimal route selection.

Use **undo bestroute igp-metric-ignore** to restore the default.

Syntax

In BGP instance view:

bestroute igp-metric-ignore [**all-instance**]

undo bestroute igp-metric-ignore [**all-instance**]

In BGP-VPN instance view:

bestroute igp-metric-ignore

undo bestroute igp-metric-ignore

Default

BGP considers IGP metrics during optimal route selection, and selects the route with the smallest IGP metric as the optimal route.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

all-instance: Enables this feature for the BGP instance and all BGP-VPN instances created in the BGP instance. If you do not specify this keyword, the command enables this feature for only the BGP instance or BGP-VPN instance.

Usage guidelines

After executing the **bestroute igp-metric-ignore all-instance** command in BGP instance view, you enable this feature for the BGP instance and all BGP-VPN instances in the BGP instance. Executing the **undo bestroute igp-metric-ignore** command in BGP instance view or BGP-VPN instance view cannot disable this feature. To enable this feature for a specific instance, execute the **bestroute igp-metric-ignore** command in BGP instance or BGP-VPN instance view and make sure the **bestroute igp-metric-ignore all-instance** command is not executed in BGP instance view.

Examples

In BGP instance view, ignore IGP metrics during optimal route selection.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] bestroute igp-metric-ignore
```

bestroute med-confederation

Use **bestroute med-confederation** to enable MED comparison for routes received from confederation peers.

Use **undo bestroute med-confederation** to restore the default.

Syntax

In BGP instance view:

bestroute med-confederation [**all-instance**]

undo bestroute med-confederation [**all-instance**]

In BGP-VPN instance view:

bestroute med-confederation

undo bestroute med-confederation

Default

MED comparison is disabled for routes received from confederation peers.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

all-instance: Enables this feature for the BGP instance and all BGP-VPN instances created in the BGP instance. If you do not specify this keyword, the command enables this feature for only the BGP instance or BGP-VPN instance.

Usage guidelines

This command enables BGP to compare the MEDs of routes received from confederation peers. However, if a route from a confederation peer has an AS number that does not belong to the confederation, BGP does not compare the route with other routes. For example, a confederation has three AS numbers 65006, 65007, and 65009. BGP receives three routes from different confederation peers. The AS_PATH attributes of these routes are 65006 65009, 65007 65009, and 65008 65009,

and the MED values of them are 2, 3, and 1. Because the third route's AS_PATH attribute contains AS number 65008, which does not belong to the confederation, BGP does not compare it with other routes. As a result, the first route becomes the optimal route.

After executing the **bestroute med-confederation all-instance** command in BGP instance view, you enable this feature for the BGP instance and all BGP-VPN instances in the BGP instance. Executing the **undo bestroute med-confederation** command in BGP instance view or BGP-VPN instance view cannot disable this feature. To enable this feature for a specific instance, execute the **bestroute med-confederation** command in BGP instance or BGP-VPN instance view and make sure the **bestroute med-confederation all-instance** command is not executed in BGP instance view.

Examples

In BGP instance view, enable MED comparison for routes received from confederation peers.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] bestroute med-confederation
```

bestroute router-id-ignore

Use **bestroute router-id-ignore** to enable BGP to ignore router IDs during optimal route selection.

Use **undo bestroute router-id-ignore** to restore the default.

Syntax

In BGP instance view:

bestroute router-id-ignore [**all-instance**]

undo bestroute router-id-ignore [**all-instance**]

In BGP-VPN instance view:

bestroute router-id-ignore

undo bestroute router-id-ignore

Default

BGP compares router IDs during optimal route selection. If multiple routes to the same destination are available, BGP selects the route with the smallest router ID as the optimal route.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

all-instance: Enables this feature for the BGP instance and all BGP-VPN instances created in the BGP instance. If you do not specify this keyword, the command enables this feature for only the BGP instance or BGP-VPN instance.

Usage guidelines

After executing the **bestroute router-id-ignore all-instance** command in BGP instance view, you enable this feature for the BGP instance and all BGP-VPN instances in the BGP

instance. Executing the **undo bestroute router-id-ignore** command in BGP instance view or BGP-VPN instance view cannot disable this feature. To enable this feature for a specific instance, execute the **bestroute router-id-ignore** command in BGP instance or BGP-VPN instance view and make sure the **bestroute router-id-ignore all-instance** command is not executed in BGP instance view.

Examples

In BGP instance view, enable BGP to ignore router IDs during optimal route selection.

```
<Sysname> system-view
[Sysname] bgp 1
[Sysname-bgp-default] bestroute router-id-ignore
```

bgp

Use **bgp** to enable a BGP instance and enter its view.

Use **undo bgp** to disable a BGP instance.

Syntax

bgp *as-number* [**instance** *instance-name*]

undo bgp [*as-number* [**instance** *instance-name*]]

Default

BGP is disabled and no BGP instances exist.

Views

System view

Predefined user roles

network-admin

context-admin

Parameters

as-number: Specifies a local AS by its number in the range of 1 to 4294967295.

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command enables the BGP instance **default**.

Usage guidelines

A router supports 4-byte AS number.

A BGP router can run multiple BGP processes. Each BGP process corresponds to a BGP instance. BGP maintains an independent routing table for each BGP instance.

You can create multiple public address families for a BGP instance. However, each public address family (except for public VPNv4 address family and public VPNv6 address family) can belong to only one BGP instance.

You can create multiple VPN instances for a BGP instance, and each VPN instance can have multiple address families. A VPN instance can belong to only one BGP instance.

You cannot specify the same peer for the same address family of different BGP instances.

The IPv4 and IPv6 multicast address families must belong to the same BGP instance.

Different BGP instances can have the same AS number but cannot have the same name.

Examples

Enable BGP instance **default**, set the local AS number to 100, and enter BGP instance view.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default]
```

bgp update-delay on-startup

Use **bgp update-delay on-startup** to configure BGP to delay sending route updates when it restores after a device reboot.

Use **undo bgp update-delay on-startup** to restore the default.

Syntax

bgp update-delay on-startup *seconds*

undo bgp update-delay on-startup

Default

BGP sends route updates immediately to BGP peers in established state when it restores after a device reboot.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Parameters

seconds: Specifies the delay time in the range of 0 to 3600 seconds. The value of 0 indicates that BGP sends route updates immediately when it restores after a device reboot.

Usage guidelines

With this feature enabled, BGP delays sending route updates when it restores after a device reboot. During the delay time, BGP learns all routes from other neighbors, and then selects the optimal route. After the delay time elapses, BGP will advertise the optimal route. Using this feature can reduce traffic loss caused by device reboot.

Examples

In BGP instance view, configure BGP to delay sending route updates when it restores after a device reboot, and set the delay time to 100 seconds.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] bgp update-delay on-startup 100
```

Related commands

bgp update-delay on-startup prefix-list

bgp update-delay on-startup prefix-list

Use **bgp update-delay on-startup prefix-list** to configure BGP to immediately send route updates for routes that match a prefix list.

Use **undo bgp update-delay on-startup prefix-list** to restore the default.

Syntax

bgp update-delay on-startup prefix-list *ipv4-prefix-list-name*

undo bgp update-delay on-startup prefix-list

Default

No prefix list is specified to filter routes.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-prefix-list-name: Specifies an IPv4 prefix list by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

After the **bgp update-delay on-startup** command is configured, BGP delays sending updates for all routes when it restores after a device reboot. For BGP to immediately send updates for the specified routes, execute the **bgp update-delay on-startup prefix-list** command.

This command is available only to IPv4 prefix lists.

Examples

In BGP instance view, configure BGP to send updates 100 seconds after it restores from a device reboot, and immediately send updates for routes that match prefix list **aaa**.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] bgp update-delay on-startup 100
[Sysname-bgp-default] bgp update-delay on-startup prefix-list aaa
```

Related commands

bgp update-delay on-startup

compare-different-as-med

Use **compare-different-as-med** to enable MED comparison for routes from peers in different ASs.

Use **undo compare-different-as-med** to restore the default.

Syntax

compare-different-as-med

undo compare-different-as-med

Default

MED comparison is disabled for routes from peers in different ASs.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Usage guidelines

If multiple routes to a destination exist, the route with the smallest MED is selected.

Generally BGP only compares MEDs of routes received from the same AS. You can use the **compare-different-as-med** command to force BGP to compare MED values of routes received from different ASs.

Do not use this command unless relevant ASs adopt the same IGP protocol and routing selection method.

Examples

In BGP instance view, enable MED comparison for routes from peers in different ASs.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] compare-different-as-med
```

confederation id

Use **confederation id** to configure a confederation ID.

Use **undo confederation id** to restore the default.

Syntax

confederation id *as-number*

undo confederation id

Default

No confederation ID is configured.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Parameters

as-number: Specifies an AS number that identifies the confederation, in the range of 1 to 4294967295.

Usage guidelines

You can split an AS into several sub-ASs, and each sub-AS remains fully meshed. These sub-ASs form a confederation. Key path attributes of a route, such as the Next_HOP, MED, and LOCAL_PREF, are not discarded when crossing each sub-AS. The sub-ASs still look like one AS from the perspective of other ASs. The AS number is the confederation ID.

Confederation can ensure the integrity of the former AS, and solve the problem of too many IBGP connections in the AS.

Configure the same confederation ID for all routers in one confederation.

For a non-confederation BGP router that establishes a BGP connection to a router in a confederation, the confederation ID is the AS number of the router.

Examples

Confederation 9 consists of four sub-ASs numbered 38, 39, 40 and 41. Peer 10.1.1.1 is a member of sub-AS 38. Peer 200.1.1.1 is a member outside of confederation 9, which belongs to AS 98. Confederation 9 looks like one AS (with AS number 9) from the perspective of peer 200.1.1.1. This example uses a router in sub-AS 41.

```
<Sysname> system-view
[Sysname] bgp 41
[Sysname-bgp-default] confederation id 9
[Sysname-bgp-default] confederation peer-as 38 39 40
[Sysname-bgp-default] group Confed38 external
[Sysname-bgp-default] peer Confed38 as-number 38
[Sysname-bgp-default] peer 10.1.1.1 group Confed38
[Sysname-bgp-default] group Remote98 external
[Sysname-bgp-default] peer Remote98 as-number 98
[Sysname-bgp-default] peer 200.1.1.1 group Remote98
```

Related commands

confederation nonstandard

confederation peer-as

confederation nonstandard

Use **confederation nonstandard** to enable compatibility with routers not compliant with RFC 3065 in the confederation.

Use **undo confederation nonstandard** to restore the default.

Syntax

confederation nonstandard

undo confederation nonstandard

Default

The device is compatible with only routers compliant with RFC 3065 in the confederation.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Usage guidelines

Configure this command on all routers compliant with RFC 3065 to interact with those routers not compliant with RFC 3065 in the confederation.

Examples

Confederation 100 consists of two sub-ASs, 64000 and 65000, and contains routers not compliant with RFC 3065. Enable compatibility with routers not compliant with RFC 3065 in the confederation.

```
<Sysname> system-view
[Sysname] bgp 64000
[Sysname-bgp-default] confederation id 100
[Sysname-bgp-default] confederation peer-as 65000
```

```
[Sysname-bgp-default] confederation nonstandard
```

Related commands

confederation id

confederation peer-as

confederation peer-as

Use **confederation peer-as** to specify confederation peer sub-ASs.

Use **undo confederation peer-as** to remove the specified confederation peer sub-ASs.

Syntax

confederation peer-as *as-number-list*

undo confederation peer-as [*as-number-list*]

Default

No confederation peer sub-ASs are specified.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Parameters

as-number-list: Specifies a sub-AS number list. A maximum of 32 sub-ASs can be configured in one command line. The expression is *as-number-list = as-number* &<1-32>. The *as-number* argument specifies a sub-AS number in the range of 1 to 4294967295, and &<1-32> indicates that a maximum of 32 numbers can be specified.

Usage guidelines

Before this configuration, use the **confederation id** command to specify the confederation ID for the sub-ASs.

If the **undo confederation peer-as** command is executed without the *as-number-list* argument, all confederation peer sub-ASs are removed.

Examples

In BGP instance view, specify confederation peer sub-ASs 2000 and 2001.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] confederation id 10
[Sysname-bgp-default] confederation peer-as 2000 2001
```

Related commands

confederation id

confederation nonstandard

dampening

Use **dampening** to enable BGP route dampening.

Use **undo dampening** to restore the default.

Syntax

dampening [*half-life-reachable half-life-unreachable reuse suppress ceiling* | **route-policy** *route-policy-name*] *

undo dampening

Default

Route dampening is disabled.

Views

Predefined user roles

network-admin

context-admin

Parameters

half-life-reachable: Specifies a half-life for active routes, in the range of 1 to 45 minutes. By default, the value is 15 minutes.

half-life-unreachable: Specifies a half-life for suppressed routes, in the range of 1 to 45 minutes. By default, the value is 15 minutes.

reuse: Specifies a reuse threshold value for suppressed routes, in the range of 1 to 20000. A suppressed route whose penalty value decreases under the value is reused. By default, the reuse value is 750. The reuse threshold must be less than the suppression threshold.

suppress: Specifies a suppression threshold in the range of 1 to 20000. The route with a penalty value greater than the threshold is suppressed. The default value is 2000.

ceiling: Specifies a ceiling penalty value in the range of 1001 to 20000. The value must be greater than the *suppress* value. By default, the value is 16000.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

This command dampens only EBGP routes.

If an EBGP peer goes down after you configure this command, routes coming from the peer are dampened but not deleted.

Examples

In BGP IPv4 unicast address family view, configure BGP route dampening. Set the half-life for both active and suppressed routes to 10 minutes, the reuse threshold to 1000, the suppression threshold to 2000, and the ceiling penalty to 10000.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] dampening 10 10 1000 2000 10000
```

Related commands

BGP-VPN IPv6 unicast address family view

BGP IPv4 multicast address family view

BGP IPv6 multicast address family view

Predefined user roles

network-admin

context-admin

Parameters

value: Specifies a default local preference in the range of 0 to 4294967295. A larger value represents a higher preference.

Usage guidelines

You can also use the **apply local-preference** command in a routing policy to configure the local preference for BGP routes. If no routing policy is configured, all BGP routes use the local preference set by the **default local-preference** command. If a routing policy is configured, BGP routes matching the routing policy use the local preference set by the **apply local-preference** command. Other BGP routes use the local preference set by the **default local-preference** command.

Examples

In BGP IPv4 unicast address family view, set the default local preference to 180.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] default local-preference 180
```

Related commands

apply local-preference

BGP IPv6 multicast address family view

Predefined user roles

network-admin

context-admin

Parameters

med-value: Specifies the default MED value in the range of 0 to 4294967295.

Usage guidelines

BGP selects a MED value in the following order:

1. MED set by the **apply cost** command.
2. MED set by the **med** keyword in the **import-route** command.
3. MED set by the **default med** command.
4. Original MED of a BGP route, or MED changed from the metric of a redistributed IGP route.

Examples

In BGP IPv4 unicast address family view, set the default MED to 25.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] default med 25
```

display bgp [**instance** *instance-name*] **dampening parameter vpnv4**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP route dampening parameters for the default BGP instance.

ipv4: Displays BGP IPv4 route dampening parameters.

ipv6: Displays BGP IPv6 route dampening parameters.

multicast: Displays BGP multicast route dampening parameters.

unicast: Displays BGP unicast route dampening parameters.

vpnv4: Displays IBGP VPNv4 route dampening parameters.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays BGP route dampening parameters for the public network.

Usage guidelines

By default, the **unicast** keyword is used if neither the **multicast** keyword nor the **unicast** keyword is specified.

Examples

Display BGP IPv4 unicast route dampening parameters.

```
<Sysname> display bgp dampening parameter ipv4
Maximum suppression time (in seconds)              : 3973
Ceiling value                                      : 16000
Reuse value                                        : 750
Half-life time for reachable routes (in seconds)   : 900
Half-life time for unreachable routes (in seconds) : 900
Suppression threshold                              : 2000
```

Table 2 Command output

Field	Description
Maximum suppression time	Maximum time (in seconds) for the penalty value to decrease from the ceiling value to the reuse value.
Ceiling value	Penalty ceiling value.
Reuse value	Reuse threshold.

network-operator

context-admin

context-operator

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP peer group information for the default BGP instance.

ipv4: Displays IPv4 BGP peer group information.

ipv6: Displays IPv6 BGP peer group information.

link-state: Displays BGP LS peer group information.

mdt: Displays BGP MDT peer group information.

multicast: Displays BGP multicast peer group information.

mvpn: Displays BGP IPv4 MVPN peer group information.

rtfilter: Displays BGP IPv4 RT filter peer group information.

The following compatibility matrixes show the support of hardware platforms for the **rtfilter** keyword:

Models	Parameter compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No

flowspec: Displays BGP flowspec peer group information.

unicast: Displays BGP unicast peer group information.

vpnv4: Displays BGP VPNv4 peer group information.

vpnv6: Displays BGP VPNv6 peer group information.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays BGP peer group information for the public network.

group-name *group-name*: Specifies a BGP peer group by its name, a case-sensitive string of 1 to 47 characters. If you do not specify a group, this command displays brief information about all BGP peer groups for the specified address family.

Usage guidelines

By default, the **unicast** keyword is used if the **unicast**, **mdt**, **mvpn**, **rtfilter**, and **multicast** keywords are not specified.

Examples

Display brief information about all BGP IPv4 unicast peer groups.

```
<Sysname> display bgp group ipv4
 BGP peer group: group1
 Remote AS: 600
 Type: external
 Members:
  1.1.1.10

 BGP peer group: group2
 Remote AS number: not specified
 Type: external
 Members:
  2.2.2.2
```

Display detailed information about BGP IPv4 unicast peer group **group1**.

```
<Sysname> display bgp group ipv4 group-name group1
 BGP peer group: group1
 Remote AS: 600
 Type: external
 Maximum number of prefixes allowed: 4294967295
 Threshold: 75%
 Configured hold time: 180 seconds
 Keepalive time: 60 seconds
 Minimum time between advertisements: 30 seconds
 Peer preferred value: 0
 Site-of-Origin: Not specified

 Routing policy configured:
 No routing policy is configured

 Members:
* - Dynamically created peer
  Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

  1.1.1.10               600        0        0    0       0 00:00:55 Established
```

Display detailed information about BGP IPv6 unicast peer group **group2**.

```
<Sysname> display bgp group ipv6 group-name group2
 BGP peer group: group2
 Remote AS: 600
 Type: external
 Maximum number of prefixes allowed: 4294967295
 Threshold: 75%
 Configured hold time: 180 seconds
 Keepalive time: 60 seconds
 Minimum time between advertisements: 30 seconds
 Peer preferred value: 0
 IPsec profile name: profile001
 Site-of-Origin: Not specified

 Routing policy configured:
 No routing policy is configured

 Members:
* - Dynamically created peer
  Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

  2::2                   600        0        0    0       0 00:00:45 Established
  3::3                   600        0        0    0       0 00:00:40 Established
```

Table 3 Command output

Field	Description
BGP peer group	Name of the BGP peer group.
Remote AS	AS number of the peer group.
Type	Type of the peer groups: • **external**—EBGP peer group. • **internal**—IBGP peer group.
Maximum number of prefixes allowed	Maximum number of routes allowed to learn from the peer.
Threshold	Percentage of received routes from the peer to maximum routes allowed to learn from the peer. If the percentage is reached, the system generates a log message.
Configured hold time	Configured hold interval in seconds.
Keepalive time	Keepalive interval in seconds.
Minimum time between advertisements	Minimum route advertisement interval in seconds.
Peer preferred value	Preferred value specified for routes from the peer.
Site-of-Origin	SoO for the peer group.
Routing policy configured	Routing policy configured for the peer group. If you do not specify a routing policy, this field displays **No routing policy is configured**.
Members	Information about peers included in the peer group.

Field	Description
* - Dynamically created peer	An asterisk (*) before a peer address indicates that the peer is a dynamic peer.
Peer	IPv4 or IPv6 address of the peer.
AS	AS number of the peer.
MsgRcvd	Number of messages received.
MsgSent	Number of messages sent.
OutQ	Number of messages to be sent.
PrefRcv	For the IPv4, IPv6, VPNv4, and VPNv6 address families, this field displays the number of prefixes received from the peer. For the IPv4 flowspec address family, this field displays the number of IPv4 flowspec messages received from the peer. For the IPv4 MDT address family, this field displays the number of MDT messages received from the peer.
Up/Down	Lasting time of the current BGP session state.
State	Current state of the BGP session between the local router and the peer.
IPsec profile name	IPsec profile applied to the IPv6 BGP peer group.

display bgp instance-info

Use **display bgp instance-info** to display information about all BGP instances.

Syntax

display bgp instance-info

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Examples

Display information about all BGP instances.

```
<Sysname> display bgp instance-info
Total BGP instances: 3
  BGP instance name               AS
  BGP1                            100
  BGP2                            200
  BGP3                            300
```

Table 4 Command output

Field	Description
Total BGP instances	Number of BGP instances.
BGP instance name	BGP instance name.
AS	AS number of the BGP instance.

display bgp link-state

Use **display bgp link-state** to display BGP LS information.

Syntax

display bgp [**instance** *instance-name*] **link-state** [*ls-prefix* [**advertise-info**] | **peer** { *ipv4-address* | *ipv6-address* } { **advertised** | **received** } [**statistics**] | **statistics**]

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP LS information for the default BGP instance.

ls-prefix: Specifies an LS prefix. If you do not specify this argument, the command displays all BGP LS information.

advertise-info: Displays advertisement information for the specified LS prefix.

ipv4-address: Specifies a peer by its IPv4 address.

ipv6-address: Specifies a peer by its IPv6 address.

advertised: Displays advertised LS information.

received: Displays received LS information.

statistics: Displays statistics about LS messages.

Usage guidelines

If you do not specify any parameters, this command displays brief BGP LS information.

Examples

Display brief BGP LS information for the public network.

```
<Sysname> display bgp link-state

 Total number of routes: 2

 BGP local router ID is 1.1.2.1
```

```
 Status codes: * - valid, > - best, d – dampened, h – history
               s – suppressed, S – stale, i - internal, e - external
       Origin: i - IGP, e - EGP, ? - incomplete
 Prefix codes: E link, V node, T IP reachable route, u/U unknown,
               I Identifier, N local node, R remote node, L link, P prefix,
               L1/L2 ISIS level-1/level-2, O OSPF, D direct, S static,
               a area-ID, , l link-ID, t topology-ID, s ISO-ID,
               c confed-ID/ASN, b bgp-identifier, r router-ID,
               i if-address, n peer-address, o OSPF Route-type, p IP-prefix
               d designated router address
* >e Network : [V][O][I0x0][N[c20][b1.1.1.2][a0.0.0.0][r1.1.1.2]]/376

     PrefVal : 0                                        OutLabel  : NULL
     MED     :
     Path/Ogn: 20i

* >e Network :
[T][O][I0x0][N[c20][b1.1.1.2][a0.0.0.0][r1.1.1.2]][P[o0x1][p1.1.1.0/24]]/480
     NextHop : 1.1.1.2                                  LocPrf    :
     PrefVal : 0                                        OutLabel  : NULL
     MED     :
     Path/Ogn: 20i
```

Table 5 Command output

Field	Description
Status codes	Status codes: • *** – valid**—Valid route. • **> – best**—Optimal route. • **d - dampened**—Dampened route. • **h – history**—History route. • **s – suppressed**—Suppressed route. • **S – stale**—Stale route. • **i – internal**—Internal route. • **e – external**—External route.

Field	Description
Prefix codes	Route status codes: • E – link. • V – node. • T – IP reachable route. • u/U – unknown. • I – Identifier. • N – local node. • R – remote node. • L – link. • P – prefix. • L1/L2 – ISIS level-1/level-2. • O – OSPF. • D – direct. • S – static. • a – area-ID. • l – link-ID. • t – topology-ID. • s – ISO-ID. • c – confed-ID/ASN. • b – bgp-identifier. • r – router-ID. • i – if-address. • n – peer-address. • o – OSPF Route-type. • p – IP-prefix. • d – designated router address.
Origin	Origin of the route: • **i – IGP**—Originated in the AS. The origin of routes advertised with the **network** command is IGP. • **e – EGP**—Learned through EGP. • **? – incomplete**—Unknown origin. The origin of routes redistributed from IGP protocols is INCOMPLETE.
Network	NLRI for the LS.
NextHop	Next hop IP address.
LocPrf	Local preference.
OutLabel	Outgoing label of the route.
MED	MED attribute.
Path/Ogn	AS_PATH and ORIGIN attributes of the route: • **AS_PATH**—Records the ASs the route has passed, which avoids routing loops. • **ORIGIN**—Identifies the origin of the route.

Display detailed BGP LS information with the specified LS prefix.

```
<Sysname> display bgp link-state [V][O][I0x0][N[c20][b1.1.1.2][a0.0.0.0][r1.1.1.2]]/376

 BGP local router ID: 1.1.1.2
 Local AS number: 20
```

```
Paths:   1 available, 1 best

BGP LS information of [V][O][I0x0][N[c20][b1.1.1.2][a0.0.0.0][r1.1.1.2]]/376:
Imported route.
Original nexthop: 0.0.0.0
OutLabel        : NULL
LS              : Node flag bits: 30[EA]
AS-path         : (null)
Origin          : igp
Attribute value : pref-val 32768
State           : valid, local, best
IP precedence   : N/A
QoS local ID    : N/A
Traffic index   : N/A
```

Table 6 Command output

Field	Description
Paths	Number of routes: • **available**—Number of valid routes. • **best**—Number of optimal routes.
BGP LS information of	NLRI prefix.
Original nexthop	Original next hop of the route. If the route was obtained from a BGP update message, the original next hop is the next hop IP address in the message.

LS	LS attribute:
	• **Node flag bits**—Node attribute in hexadecimal format:
	  ○ **10[A]**—OSPF ABR bit.
	  ○ **30[E]**—OSPF External bit.
	• **Metric**—Link or prefix cost.

AS-path	AS_PATH attribute of the route, which records the ASs the route has passed and avoids routing loops.
Attribute value	BGP path attributes: • **MED**—MED value. • **localpref**—Local preference value. • **pref-val**—Preferred value. • **pre**—Route preference.
State	Current state of the route: • valid. • internal. • external. • local. • synchronize. • best.
IP precedence	IP precedence in the range of 0 to 7. **N/A** indicates that the route does not support this field.
QoS local ID	QoS local ID in the range of 1 to 4095. **N/A** indicates that the route does not support this field.

Field	Description
Traffic index	Traffic index in the range of 1 to 64. **N/A** indicates that the route does not support this field.

Display advertisement information for the specified LS prefix.

```
<Sysname> display bgp link-state
[E][B][I0x0][N[r1.1.1.2]][c65008][R[r44.33.22.11]][c65009]][L[i2.1.1.3][n1.1.1.3]]/53

 Local AS number: 65008

 Paths:  1 best

 BGP LS information of
[E][B][I0x0][N[r1.1.1.2]][c65008][R[r44.33.22.11]][c65009]][L[i2.1.1.3][n1.1.1.3]]/53
6
(TxPathID:0):

 Advertised to peers (1 in total):
10.1.1.2
 LS attribute :
   Peer node segment identifier : Flag c0[VL], Metric 0, Label 23001
```

Table 7 Command output

Field	Description
Paths	Number of routes: • **available**—Number of valid routes. • **best**—Number of optimal routes.
BGP LS information of	NLRI prefix.
Advertised to peers (1 in total)	Peers to which the information has been advertised, and the total number of such peers.

Peer node segment identifier	Peer node SID:
	• **Flag c0[VL]**:
	  ◦ **V**—Value flag. If set, the SID carries a label value.
	  ◦ **L**—Local flag. If set, the SID has local significance.
	• **Metric**—Link cost.
	• **Label**—Label value.

TxPathID	Add-path ID of advertised routes.

display bgp network

Use **display bgp network** to display information about routes advertised by the **network** command and shortcut routes configured by the **network short-cut** command.

Syntax

display bgp [**instance** *instance-name*] **network** { **ipv4** | **ipv6** } [**multicast** | [**unicast**] [**vpn-instance** *vpn-instance-name*]]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays information for the default BGP instance.

ipv4: Displays IPv4 address family information.

ipv6: Displays IPv6 address family information.

multicast: Displays BGP multicast address family information.

unicast: Displays BGP unicast address family information.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays routing information for the public network.

Usage guidelines

By default, the **unicast** keyword is used if neither the **multicast** keyword nor the **unicast** keyword is specified.

Examples

Display information about routes advertised by the **network** command and shortcut routes configured by the **network short-cut** command in the IPv4 unicast address family.

```
<Sysname> display bgp network ipv4

  BGP local router ID: 192.168.1.135
  Local AS number: 100

  Network           Mask            Route-policy        Short-cut
  20.1.1.0          255.255.255.0                       No
  40.1.1.0          255.255.255.0   abc                 No
  30.1.1.0          255.255.255.0                       Yes
```

Display information about routes advertised by the **network** command and shortcut routes configured by the **network short-cut** command in the IPv6 unicast address family.

```
<Sysname> display bgp network ipv6

  BGP local router ID: 192.168.1.135
  Local AS number: 100

  Network           PrefixLen       Route-policy        Short-cut
  1::               24                                  No
  2::               24                                  No
  3::               64              policy1             No
```

```
2::                24                                      Yes
```

Table 8 Command output

Field	Description
Network	Destination network address of the routes advertised by the **network** command and the shortcut routes.
Mask	Mask of the destination network address.
PrefixLen	Prefix length of the destination network address.
Route-policy	Routing policy that is applied to the route.
Short-cut	Whether the route is a shortcut route: • Yes. • No.

display bgp non-stop-routing status

Use **display bgp non-stop-routing status** to display BGP NSR status information.

Syntax

display bgp [**instance** *instance-name*] **non-stop-routing status**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP NSR status information for the default BGP instance.

Examples

Display BGP NSR status information.

```
<Sysname> display bgp non-stop-routing status

BGP NSR status: Not ready
 Location of preferred standby process: -
 TCP NSR status: Not ready
```

Table 9 Command output

Field	Description
BGP NSR status	BGP NSR status: • **Ready**—BGP NSR has backed up BGP neighbor and routing information from the active process to the standby process. In this state, BGP NSR can ensure continuous routing when an active/standby process switchover occurs. • **Not ready**—BGP NSR is backing up BGP neighbor and routing information from the active process to the standby process. If an active/standby process switchover occurs in this state, traffic is interrupted and the BGP session will be re-established. • **Not configured**—BGP NSR is disabled.
Location of preferred standby process	ID of the IRF member device where the preferred standby process resides. This field displays **-** if no standby processes exist.
TCP NSR status	TCP NSR status: • **Ready**—TCP NSR has backed up TCP connection information from the active process to the standby process. • **Not ready**—TCP NSR is backing up TCP connection information from the active process to the standby process.

display bgp paths

Use **`display bgp paths`** to display BGP path attribute information.

Syntax

`display bgp` [**`instance`** *`instance-name`*] **`paths`** [*`as-regular-expression`*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

`instance` *`instance-name`*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP path attribute information for the default BGP instance.

`as-regular-expression`: Displays information about BGP path attributes whose AS_PATH attribute matches the specified regular expression. The *`as-regular-expression`* argument is a string of 1 to 256 characters. If you do not specify this argument, the command displays information about all BGP path attributes.

Examples

Display information about all BGP path attributes.

```
<Sysname> display bgp paths

  RefCount    MED         Path/Origin
  3           0           ?
  2           0           100i
  3           0           100i
  1           0           ?
  1           0           ?
  1           0           ?
```

Table 10 Command output

Field	Description
RefCount	Number of BGP routes with these path attributes.
MED	MULTI_EXIT_DISC attribute.

Path/Origin	AS_PATH and ORIGIN attributes of the route:
	• **AS_PATH attribute**—Records the ASs the route has passed, which avoids routing loops.
	• **ORIGIN attribute**—Identifies the origin of the route:
	  ○ **i**—Originated in the AS. The origin of routes advertised with the **network** command is IGP.
	  ○ **e**—Learned through EGP.
	  ○ **?**—Unknown origin. The origin of routes redistributed from IGP protocols is INCOMPLETE.

display bgp peer

Use **display bgp peer** to display BGP peer or peer group information.

Syntax

display bgp [**instance** *instance-name*] **peer ipv4** [**mdt** | **multicast** | **mvpn** | **rtfilter** | [**flowspec** | **unicast**] [**vpn-instance** *vpn-instance-name*]] [*ipv4-address mask-length* | { *ipv4-address* | **group-name** *group-name* } **log-info** | [*ipv4-address*] **verbose**]

display bgp [**instance** *instance-name*] **peer ipv6** [**multicast** | [**unicast**] [**vpn-instance** *vpn-instance-name*]] [*ipv6-address prefix-length* | { *ipv6-address* | **group-name** *group-name* } **log-info** | [*ipv6-address*] **verbose**]

display bgp [**instance** *instance-name*] **peer ipv6** [**unicast**] [*ipv4-address mask-length* | *ipv4-address* **log-info** | [*ipv4-address*] **verbose**]

display bgp [**instance** *instance-name*] **peer link-state** [*ipv4-address mask-length* | *ipv6-address prefix-length* | { *ipv4-address* | *ipv6-address* | **group-name** *group-name* } **log-info** | [*ipv4-address* | *ipv6-address*] **verbose**]

display bgp [**instance** *instance-name*] **peer vpnv4** [**flowspec** | **vpn-instance** *vpn-instance-name*] [*ipv4-address mask-length* | { *ipv4-address* | **group-name** *group-name* } **log-info** | [*ipv4-address*] **verbose**]

display bgp [**instance** *instance-name*] **peer vpnv6** [*ipv4-address mask-length* | { *ipv4-address* | **group-name** *group-name* } **log-info** | [*ipv4-address*] **verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP peer or peer group information for the default BGP instance.

flowspec: Displays BGP flowspec peer or peer group information.

ipv4: Displays IPv4 BGP peer or peer group information.

ipv6: Displays IPv6 BGP peer or peer group information.

link-state: Displays BGP LS peer or peer group information.

vpnv4: Displays BGP VPNv4 peer or peer group information.

vpnv6: Displays BGP VPNv6 peer or peer group information.

mdt: Displays BGP MDT peer or peer group information.

multicast: Displays BGP multicast peer or peer group information.

mvpn: Displays BGP IPv4 MVPN peer or peer group information.

rtfilter: Displays BGP IPv4 RT filter peer or peer group information.

The following compatibility matrixes show the support of hardware platforms for the **rtfilter** keyword:

Models	Parameter compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No

unicast: Displays BGP unicast peer or peer group information.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays BGP peer or peer group information for the public network.

ipv4-address mask-length: Specifies a subnet. The value range for the mask length is 0 to 32. If you specify a subnet, this command displays information about all dynamic peers in the subnet.

ipv4-address: Specifies a peer by its IPv4 address.

ipv6-address prefix-length: Specifies a subnet. The value range for the prefix length is 0 to 128. If you specify a subnet, this command displays information about all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address.

group-name *group-name*: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters.

log-info: Displays log information.

verbose: Displays detailed information. If you do not specify this keyword, the command displays brief BGP peer or peer group information.

Usage guidelines

If you do not specify any parameters, this command displays brief information about all BGP peers for the specified address family.

By default, the **unicast** keyword is used if the **unicast**, **mdt**, **mvpn**, **rtfilter**, **flowspec**, and **multicast** keywords are not specified.

Examples

Display brief information about all BGP IPv4 unicast peers.

```
<Sysname> display bgp peer ipv4

 BGP local router ID: 192.168.100.1
 Local AS number: 100
 Total number of peers: 1                 Peers in established state: 1

  * - Dynamically created peer
  Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

  10.2.1.2               200       13       16    0       0 00:10:34 Established
```

Table 11 Command output

Field	Description
* - Dynamically created peer	An asterisk (*) before a peer address indicates that the peer is a dynamic peer.
Peer	IPv4 or IPv6 address of the peer.
AS	AS number of the peer.
MsgRcvd	Number of messages received.
MsgSent	Number of messages sent.
OutQ	Number of messages to be sent.
PrefRcv	For the IPv4, IPv6, VPNv4, and VPNv6 address families, this field displays the number of prefixes that have been received from the peer and added into the local BGP routing table. For the IPv4 flowspec address family, this field displays the number of IPv4 flowspec messages received from the peer. For the VPNv4 flowspec address family, this field displays the number of VPNv4 flowspec messages received from the peer. For the IPv4 MDT address family, this field displays the number of MDT messages received from the peer. For IPv4 RT filter address family, this field displays the number of route targets received from the peer.
Up/Down	Lasting time of the current BGP session state.
State	Current state of the BGP session between the local router and the peer.

Display brief information about all dynamic peers in network 1.1.1.0/24.

```
<Sysname> display bgp peer ipv4 1.1.1.0 24

 Type: EBGP link
 Dynamic address range: 1.1.1.0 24
 Configured: Active Hold Time: 3 sec     Keepalive Time: 1 sec
 Address family IPv4 Unicast: Configured
 Address family IPv4 Multicast: Configured
 Address family IPv4 Label: Configured
 Address family VPNv4: Configured
 Address family IPv4 RT-Filter: Configured
 Address family IPv6 Unicast: Configured
 Address family VPNv6: Configured

 Maximum allowed prefix number: 100
 Threshold: 75%
 Minimum time between advertisements is 100 seconds
 Optional capabilities:
  Multi-protocol extended capability has been enabled
  Route refresh capability has been enabled
 Nexthop self has been configured
 Keep-all-routes has been configured
 Send community has been configured
 Send extend community has been configured
 Default route originating has been configured
 Multi-hop ebgp has been enabled
 Peer preferred value: 100
 BFD: Enabled
 Site-of-Origin: 1:1
 Routing policy configured:
 No import as-path-acl list
 Export as-path-acl list is: 22
 No import prefix list
 Export prefix list is: p1
 No import route policy
 Export route policy is: p1
 No import filter-policy
 No export filter-policy

 Dynamic peers:
  1.1.1.3
```

Display brief information about all dynamic peers in network 1::/64.

```
<Sysname> display bgp peer ipv6 1:: 64

 Type: IBGP link
 Dynamic address range: 1:: 64
 Configured: Active Hold Time: 180 sec   Keepalive Time: 60 sec
 Address family IPv6 Unicast: Configured
```

```
Maximum allowed prefix number: 4294967295
Threshold: 75%
Minimum time between advertisements is 15 seconds
Optional capabilities:
 Multi-protocol extended capability has been enabled
 Route refresh capability has been enabled
Send community has been configured
Peer preferred value: 0
Site-of-Origin: Not specified
Routing policy configured:
No routing policy is configured

Dynamic peers:
 1::1
```

Table 12 Command output

Field	Description
Type	BGP connection type between the local router and the dynamic peer: • **IBGP link**—IBGP connection. • **EBGP link**—EBGP connection.
Configured	Timers configured on the local router in seconds, including the hold time (Active Hold Time) and keepalive interval (Keepalive Time).
Address family IPv4 Unicast	IPv4 unicast address family capability.
Address family IPv4 Flowspec	IPv4 flowspec address family capability.
Address family link-state	LS address family capability.
Address family IPv6 Unicast	IPv6 unicast address family capability.
Address family IPv4 Multicast	IPv4 multicast address family capability.
Address family IPv6 Multicast	IPv6 multicast address family capability.
Address family MDT	IPv4 MDT address family capability.
Address family IPv4 RT-Filter	IPv4 RT filter address family capability.
Maximum allowed prefix number	Maximum number of routes allowed to learn from the peer.
Threshold	Percentage of received routes from the peer to maximum routes allowed to learn from the peer. If the percentage is reached, the system generates alarm messages.
Minimum time between advertisements	Minimum route advertisement interval in seconds.
Optional capabilities	Optional capabilities supported by the local end.
Peer Preferred Value	Preferred value specified for the routes from the peer.
BFD	Whether BFD is enabled to detect the link to the BGP peers.
IPsec profile name	IPsec profile applied to the IPv6 BGP peer. This field is available only for the IPv6 unicast and IPv6 multicast address families.

Field	Description
Routing policy configured	Routing policy configured for the peer. If you do not specify a routing policy, this field displays **No routing policy is configured**.
Dynamic peers	IP addresses of dynamic peers.

Display detailed information about BGP IPv4 unicast peer 10.2.1.2.

```
<Sysname> display bgp peer ipv4 10.2.1.2 verbose

Table 13 Command output

Field	Description
Peer	IPv4 or IPv6 address of the peer.
Local	Local router ID.
Type	BGP connection type between the local router and the peer: • **IBGP link**—IBGP connection. • **EBGP link**—EBGP connection.
remote router ID	Router ID of the peer.
BGP current state	Current state of the BGP session between the local router and the peer.
Up for	Lasting time of the BGP session.
BGP current event	Current event of the BGP session between the local router and the peer.
BGP last state	Previous state of the BGP session.
Port	TCP port numbers of the local router and its peer.
Configured	Timers configured on the local router in seconds, including the hold time (Active Hold Time) and keepalive interval (Keepalive Time).
Received	Received timer (configured on the peer) in seconds, including the hold time (Active Hold Time).
Negotiated	Negotiated timers in seconds, including the hold time (Active Hold Time) and keepalive interval (Keepalive Time).
Peer optional capabilities	Optional capabilities supported by the peer.
Peer supports BGP route AS4 capability	The peer supports 4-byte AS number.
Address family IPv4 Unicast	IPv4 unicast address family capability: routes of the address family can be advertised and received.
Address family IPv4 Flowspec	IPv4 flowspec address family capability: routes of the address family can be advertised and received.

Field	Description
Address family LS	LS address family capability: routes of the address family can be advertised and received.
Address family IPv6 Unicast	IPv6 unicast address family capability: routes of the address family can be advertised and received.
Address family IPv4 Multicast	IPv4 multicast address family capability: routes of the address family can be advertised and received.
Address family IPv6 Multicast	IPv6 multicast address family capability: routes of the address family can be advertised and received.
Address family MDT	IPv4 MDT address family capability: routes of the address family can be advertised and received.
Address family IPv4 RT-Filter	IPv4 RT filter address family capability: route target filter information can be advertised and received.
InQ updates	Number of received updates to be processed.
OutQ updates	Number of updates to be sent to the peer.
NLRI statistics	Number of the reachable and unreachable routes received from and sent to the peer after the BGP session is established.
Message statistics	BGP message statistics.
Msg type	BGP message type.
Last rcvd time/Last sent time	Time when the most recent BGP message was received from or sent to the peer.
Current rcvd count/Current sent count	Number of BGP messages received from or sent to the peer on the current BGP session.
History rcvd count/History sent count	Number of BGP messages received from or sent to the peer since the BGP peer relationship was established.
Total	Total number of received and sent messages.
Maximum allowed prefix number	Maximum number of routes allowed to learn from the peer.
Threshold	Percentage of received routes from the peer to maximum routes allowed to learn from the peer. If the percentage is reached, the system generates alarm messages.
Minimum time between advertisements	Minimum route advertisement interval in seconds.
Optional capabilities	Optional capabilities supported by the local end.
Peer Preferred Value	Preferred value specified for the routes from the peer.
GTSM has been enabled	GTSM is supported.
the maximum number of hops	Maximum number of hops to the specified peer.
BFD	Whether BFD is enabled to detect the link to the BGP peer.
IPsec profile name	IPsec profile applied to the IPv6 BGP peer. This field is available only for the IPv6 unicast address families.
Routing policy configured	Routing policy configured for the peer. If you do not specify a routing policy, this field displays **No routing policy is configured**.

Display log information for BGP IPv4 unicast peer 1.1.1.1.

```
<Sysname> display bgp peer ipv4 1.1.1.1 log-info
```

```
Peer : 1.1.1.1

    Date      Time    State Notification
                            Error/SubError

 06-Feb-2013 22:54:42 Down  Send notification with error 6/4
                            Cease/Administrative Reset
                            <administrative reset>
```

Table 14 Command output

Field	Description
Peer	IPv4 or IPv6 address of the peer.
Date	Date on which the Notification was sent or received.
Time	Time at which the Notification was sent or received.
State	BGP session state: • **Up**—The BGP session is in Established state. • **Down**—The BGP session is down.
Notification Error/SubError	Error code of the Notification, indicating the cause of why the BGP session was down. • **Error**—Refers to the error code, which identifies the type of the Notification. • **SubError**—Refers to the error subcode of the Notification, which identifies the specific information about the reported error.

display bgp routing-table dampened

Use **display bgp routing-table dampened** to display dampened BGP routes.

Syntax

display bgp [**instance** *instance-name*] **routing-table dampened** { **ipv4** | **ipv6** } [**multicast** | [**unicast**] [**vpn-instance** *vpn-instance-name*]]

display bgp [**instance** *instance-name*] **routing-table dampened vpnv4**

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays dampened BGP routes for the default BGP instance.

ipv4: Displays dampened BGP IPv4 routes.

ipv6: Displays dampened BGP IPv6 routes.

vpnv4: Displays dampened IBGP VPNv4 routes.

multicast: Displays dampened BGP multicast routes.

unicast: Displays dampened BGP unicast routes.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays dampened BGP routes for the public network.

Usage guidelines

By default, the **unicast** keyword is used if neither the **multicast** keyword nor the **unicast** keyword is specified.

Examples

Display dampened BGP IPv4 unicast routes.

```
<Sysname> display bgp routing-table dampened ipv4

 Total number of routes: 1

 BGP local router ID is 192.168.1.135
 Status codes: * - valid, > - best, d - dampened, h - history
               s - suppressed, S - stale, i - internal, e - external
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            From            Reuse                         Path/Ogn

  de 20.1.1.0/24        10.1.1.2        00:56:27                      100i
```

Display dampened BGP IPv6 unicast routes.

```
<Sysname> display bgp routing-table dampened ipv6

 Total number of routes: 2

 BGP local router ID is 192.168.1.135
 Status codes: * - valid, > - best, d - dampened, h - history
               s - suppressed, S - stale, i - internal, e - external
       Origin: i - IGP, e - EGP, ? - incomplete

  de Network : 2::                                  PrefixLen : 64
     From    : 10.1.1.1                             Reuse     : 00:39:49
     Path/Ogn: 100i

  de Network : 2::                                  PrefixLen : 64
     From    : 1::1                                 Reuse     : 00:39:49
     Path/Ogn: 100i
```

Table 15 Command output

Field	Description
Status codes	Status codes: • *** – valid**—Valid route. • **> – best**—Optimal route. • **d – dampened**—Dampened route. • **h – history**—History route. • **s – suppressed**—Suppressed route. • **S – stale**—Stale route. • **i – internal**—Internal route. • **e – external**—External route.
Origin	Origin of the route: • **i – IGP**—Originated in the AS. The origin of routes advertised with the **network** command is IGP. • **e – EGP**—Learned through EGP. • **?– incomplete**—Unknown origin. The origin of routes redistributed from IGP protocols is INCOMPLETE.
Network	Destination network address.
From	IP address from which the route was received.
Reuse	Reuse time of the route.
Path/Ogn	AS_PATH and ORIGIN attributes of the route: • **AS_PATH attribute**—Records the ASs the route has passed, which avoids routing loops. • **ORIGIN attribute**—Identifies the origin of the route.

Related commands

dampening

reset bgp dampening

display bgp routing-table flap-info

Use **display bgp routing-table flap-info** to display BGP route flap statistics.

Syntax

display bgp [**instance** *instance-name*] **routing-table flap-info ipv4** [**multicast** | [**unicast**] [**vpn-instance** *vpn-instance-name*]] [*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | **as-path-acl** *as-path-acl-number*]

display bgp [**instance** *instance-name*] **routing-table flap-info ipv6** [**multicast** | [**unicast**] [**vpn-instance** *vpn-instance-name*]] [*ipv6-address prefix-length* | **as-path-acl** *as-path-acl-number*]

display bgp [**instance** *instance-name*] **routing-table flap-info vpnv4** [*ipv4-address* [{ *mask* | *mask-length* } [**longest-match**]] | **as-path-acl** *as-path-acl-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP route flap statistics for the default BGP instance.

ipv4: Displays BGP IPv4 route flap statistics.

ipv6: Displays BGP IPv6 route flap statistics.

vpnv4: Displays IBGP VPNv4 route flap statistics.

multicast: Displays BGP multicast route flap statistics.

unicast: Displays BGP unicast route flap statistics.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays BGP route flap statistics for the public network.

ipv4-address: Specifies a destination network address.

mask-length: Specifies a mask length in the range of 0 to 32.

mask: Specifies a network mask in dotted decimal notation.

longest-match: Specifies longest match mode, which selects the longest matching route through the following steps:

1. ANDs the specified network address with the mask of each route.
2. Matches a route if the AND result is the same as the network address of the route and the mask of the route is shorter than or equal to the specified mask.
3. Selects the route with the longest mask among the matching routes.

ipv6-address prefix-length: Displays route flap statistics for BGP IPv6 routes that match the specified network address, and match the prefix length in the range of 0 to 128.

as-path-acl *as-path-acl-number*: Displays route flap statistics for BGP routes that match the AS path list specified by its number in the range of 1 to 256.

Usage guidelines

If you specify only the *ipv4-address* argument, the system ANDs the network address with the mask of a route. If the result matches the network address of the route, the command displays flap statistics of the route.

If you specify the *ipv4-address mask* or *ipv4-address mask-length* argument, and do not specify the **longest-match** keyword, the command displays flap statistics of the BGP IPv4 unicast or multicast route that matches both the specified destination network address and the mask (or mask length).

By default, the **unicast** keyword is used if neither the **multicast** keyword nor the **unicast** keyword is specified.

Examples

Display BGP IPv4 unicast route flap statistics.

```
<Sysname> display bgp routing-table flap-info ipv4
```

```

Table 16 Command output

Field	Description
Status codes	Status codes: • *** – valid**—Valid route. • **> – best**—Optimal route. • **d – dampened**—Dampened route. • **h – history**—History route. • **s – suppressed**—Suppressed route. • **S – stale**—Stale route. • **i – internal**—Internal route. • **e – external**—External route.
Origin	Origin of the route: • **i – IGP**—Originated in the AS. The origin of routes advertised with the **network** command is IGP. • **e – EGP**—Learned through EGP. • **?– incomplete**—Unknown origin. The origin of routes redistributed from IGP protocols is INCOMPLETE.

Field	Description
Network	Destination network address.
From	Source IP address of the route.
Flaps	Number of routing flaps.
Duration	Duration time of the flap route.
Reuse	Reuse time of the route.
Path/Ogn	AS_PATH and ORIGIN attributes of the route: • **AS_PATH attribute**—Records the ASs the route has passed, which avoids routing loops. • **ORIGIN attribute**—Identifies the origin of the route.

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP IPv4 multicast routing information for the default BGP instance.

ipv4-address: Specifies a destination network address.

mask-length: Specifies a mask length in the range of 0 to 32.

mask: Specifies a network mask in dotted decimal notation.

longest-match: Specifies longest match mode, which selects the longest matching route through the following steps:

1. ANDs the specified network address with the mask of each route.
2. Matches a route if the AND result is the same as the network address of the route and the mask of the route is shorter than or equal to the specified mask.
3. Selects the route with the longest mask among the matching routes.

advertise-info: Displays advertisement information for BGP IPv4 multicast routes.

as-path-acl *as-path-acl-number*: Displays BGP IPv4 multicast routes that match the AS path list specified by its number in the range of 1 to 256.

community-list: Displays BGP IPv4 multicast routes that match a community list.

basic-community-list-number: Specifies a basic community list by its number in the range of 1 to 99.

comm-list-name: Specifies a community list by its name, a case-sensitive string of 1 to 63 characters.

whole-match: Displays BGP IPv4 multicast routes exactly matching the specified community list. If you do not specify this keyword, the command displays BGP IPv4 multicast routes whose COMMUNITY attributes include the specified community list.

adv-community-list-number: Specifies an advanced community list by its number in the range of 100 to 199.

peer *ipv4-address*: Displays BGP IPv4 multicast routing information advertised to or received from the specified peer.

advertised-routes: Displays BGP IPv4 multicast routing information advertised to the specified peer.

received-routes: Displays BGP IPv4 multicast routing information received from the specified peer.

statistics: Displays routing statistics.

Usage guidelines

If you do not specify any parameters, this command displays brief information about all BGP IPv4 multicast routes.

If you specify only the *ipv4-address* argument, the system ANDs the network address with the mask of a route. If the result matches the network address of the route, the command displays information about the route.

If you specify the *ipv4-address mask* or *ipv4-address mask-length* argument and do not specify the **longest-match** keyword, this command displays information about the BGP IPv4 multicast route that matches both the specified destination network address and the mask (or mask length).

Examples

Display brief information about all BGP IPv4 multicast routes.

```
<Sysname> display bgp routing-table ipv4 multicast

Table 18 Command output

Field	Description
Paths	Number of routes: • **available**—Number of valid routes. • **best**—Number of optimal routes.
From	IP address of BGP peer that advertised the route.
Rely Nexthop	Next hop found by route recursion. If no next hop is found, this field displays **not resolved**.
Original nexthop	Original next hop of the route. If the route was obtained from a BGP update message, the original next hop is the next hop IP address in the message.
OutLabel	Outgoing label of the route.
AS-path	AS_PATH attribute of the route.
Origin	Origin of the route: • **igp**—Originated in the AS. The origin of routes advertised with the **network** command is IGP. • **egp**—Learned through EGP. • **incomplete**—Unknown origin. The origin of routes redistributed from IGP protocols is INCOMPLETE.
Attribute value	BGP path attributes: • **MED**—MED value. • **localpref**—Local preference value. • **pref-val**—Preferred value. • **pre**—Route preference.

Field	Description
State	Current state of the route: • valid. • internal. • external. • local. • synchronize. • best.
Originator	Router ID of the peer that advertised the route to the reflector.
IP precedence	IP precedence in the range of 0 to 7. **N/A** indicates that the route does not support this field.
QoS local ID	QoS local ID in the range of 1 to 4095. **N/A** indicates that the route does not support this field.
Traffic index	Traffic index in the range of 1 to 64. **N/A** indicates that the route does not support this field.
VPN-Peer UserID	VPN peer ID in the range of 1 to 134217727. **N/A** indicates that the route does not support this field.
DSCP	DSCP value in the range of 0 to 63. **N/A** indicates that the route does not support this field.
EXP	MPLS EXP value of the route. **N/A** indicates that the route does not support this field.

Display statistics for BGP IPv4 multicast routes advertised to peer 192.168.1.62.

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP IPv4 RT filter routing information for the default BGP instance.

default-rt: Displays BGP IPv4 RT filter routing information for an all-zero RT.

origin-as *as-number*: Specifies an origin AS by its number.

route-target: Specifies an RT, a string of 3 to 21 characters.

An RT has the following formats:

- *16-bit AS number:32-bit user-defined number*. For example, 101:3.
- *32-bit IP address:16-bit user-defined number*. For example, 192.168.122.15:1.
- *32-bit AS number:16-bit user-defined number*, where the minimum value of the AS number is 65536. For example, 65536:1.

advertise-info: Displays advertisement information for BGP IPv4 RT filter routes.

peer *ipv4-address*: Displays BGP IPv4 RT filter routing information advertised to or received from the specified peer.

advertised-routes: Displays BGP IPv4 RT filter routing information advertised to the specified peer.

received-routes: Displays BGP IPv4 RT filter routing information received from the specified peer.

statistics: Displays routing statistics.

Usage guidelines

If you do not specify any parameters, this command displays brief information about all BGP IPv4 RT filter routes.

Examples

Display brief information about all BGP IPv4 RT filter routes.

```
<Sysname> display bgp routing-table ipv4 rtfilter

```

Table 23 Command output

Field	Description
Paths	Number of routes: • **available**—Number of valid routes. • **best**—Number of optimal routes.
Imported route	The BGP RT filter route is locally generated.
Original nexthop	Original next hop of the route. If the route was obtained from a BGP update message, the original next hop is the next hop IP address in the message.
OutLabel	Outgoing label of the route.
AS-path	AS_PATH attribute of the route.
Origin	Origin of the route: • **igp**—Originated in the AS. The origin of routes advertised with the **network** command is IGP. • **egp**—Learned through EGP. • **incomplete**—Unknown origin. The origin of routes redistributed from IGP protocols is INCOMPLETE.
Attribute value	BGP path attributes: • **MED**—MED value. • **localpref**—Local preference value. • **pref-val**—Preferred value. • **pre**—Route preference.
State	Current state of the route: • valid. • internal.

	• external. • local. • synchronize. • best.
From	IP address of BGP peer that advertised the route.
Rely Nexthop	Next hop found by route recursion. If no next hop is found, this field displays **not resolved**.
IP precedence	IP precedence in the range of 0 to 7. **N/A** indicates that the route does not support this field.
QoS local ID	QoS local ID in the range of 1 to 4095. **N/A** indicates that the route does not support this field.
Traffic index	Traffic index in the range of 1 to 64. **N/A** indicates that the route does not support this field.
VPN-Peer UserID	VPN peer ID in the range of 1 to 134217727. **N/A** indicates that the route does not support this field.
DSCP	DSCP value in the range of 0 to 63. **N/A** indicates that the route does not support this field.
Backup route	The route is a backup route.

Display statistics for BGP IPv4 RT filter routes advertised to peer 10.2.1.2.

```
<Sysname> display bgp routing-table ipv4 rtfilter peer 10.2.1.2 advertised-routes
statistics

 Advertised routes total: 2
```

Display statistics for BGP IPv4 RT filter routes received from peer 10.2.1.2.

```
<Sysname> display bgp routing-table ipv4 rtfilter peer 10.2.1.2 received-routes statistics

 Received routes total: 2
```

Table 24 Command output

Field	Description
Advertised routes total	Total number of advertised routes.
Received routes total	Total number of received routes.

Display BGP IPv4 RT filter route statistics.

Table 25 Command output

Field	Description
Paths	Number of optimal routes to the destination.
BGP route-target filter information of <1.1.1.1:1>/96	Information about BGP IPv4 RT filter route 1.1.1.1:1/96.
Advertised to VPN peers (1 in total)	Peers to which the network has been advertised.

display bgp routing-table ipv4 unicast

Use **display bgp routing-table ipv4 unicast** to display BGP IPv4 unicast routing information.

Syntax

display bgp [**instance** *instance-name*] **routing-table ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | *ipv4-address* [*mask-length* | *mask*] **advertise-info** | **as-path-acl** *as-path-acl-number* | **community-list** { { *basic-community-list-number* | *comm-list-name* } [**whole-match**] | *adv-community-list-number* } | **peer** *ipv4-address* { **advertised-routes** | **received-routes** } [*ipv4-address* [*mask-length* | *mask*] | **statistics**] | **statistics**]

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP IPv4 unicast routing information for the default BGP instance.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays the BGP IPv4 unicast routing information for the public network.

ipv4-address: Specifies a destination network address.

mask-length: Specifies a mask length in the range of 0 to 32.

mask: Specifies a network mask in dotted decimal notation.

longest-match: Specifies longest match mode, which selects the longest matching route through the following steps:

1. ANDs the specified network address with the mask of each route.
2. Matches a route if the AND result is the same as the network address of the route and the mask of the route is shorter than or equal to the specified mask.
3. Selects the route with the longest mask among the matching routes.

advertise-info: Displays advertisement information for BGP IPv4 unicast routes.

as-path-acl *as-path-acl-number*: Displays BGP IPv4 unicast routes that match the AS path list specified by its number in the range of 1 to 256.

community-list: Displays BGP IPv4 unicast routes that match a community list.

basic-community-list-number: Specifies a basic community list by its number in the range of 1 to 99.

comm-list-name: Specifies a community list by its name, a case-sensitive string of 1 to 63 characters.

whole-match: Displays routes exactly matching the specified community list. If you do not specify this keyword, the command displays routes whose COMMUNITY attributes include the specified community list.

adv-community-list-number: Specifies an advanced community list by its number in the range of 100 to 199.

peer *ipv4-address*: Displays BGP IPv4 unicast routing information advertised to or received from the specified peer.

advertised-routes: Displays routing information advertised to the specified peer.

received-routes: Displays routing information received from the specified peer.

statistics: Displays routing statistics.

Usage guidelines

If you do not specify any parameters, this command displays brief information about all BGP IPv4 unicast routes.

If you specify only the *ipv4-address* argument, the system ANDs the network address with the mask of a route. If the result matches the network address of the route, the command displays information about the route.

If you specify the *ipv4-address mask* or *ipv4-address mask-length* argument and do not specify the **longest-match** keyword, this command displays information about the BGP IPv4

unicast route that matches both the specified destination network address and the mask (or mask length).

This command displays BGP IPv4 unicast routing information regardless of whether the **unicast** keyword is specified.

Examples

Display brief information about all BGP IPv4 unicast routes.

```
<Sysname> display bgp routing-table ipv4

 Total number of routes: 4

Table 26 Command output

Field	Description
Status codes	Status codes: • *** – valid**—Valid route. • **> – best**—Optimal route. • **d – dampened**—Dampened route. • **h – history**—History route. • **s – suppressed**—Suppressed route. • **S – stale**—Stale route. • **i – internal**—Internal route. • **e – external**—External route.
Origin	Origin of the route: • **i – IGP**—Originated in the AS. The origin of routes advertised with the **network** command is IGP. • **e – EGP**—Learned through EGP. • **?– incomplete**—Unknown origin. The origin of routes redistributed from IGP protocols is INCOMPLETE.
Network	Destination network address.
NextHop	Next hop IP address.
MED	MULTI_EXIT_DISC attribute.
LocPrf	Local preference value.
PrefVal	Preferred value of the route.
Path/Ogn	AS_PATH and ORIGIN attributes of the route: • **AS_PATH**—Records the ASs the route has passed, which avoids routing loops. This field can display a maximum of 16 AS numbers. More AS numbers are omitted and can be viewed in the detailed route information. • **ORIGIN**—Identifies the origin of the route.

Table 27 Command output

Field	Description
Paths	Number of routes: • **available**—Number of valid routes. • **best**—Number of optimal routes.
Original nexthop	Original next hop of the route. If the route was obtained from a BGP update message, the original next hop is the next hop IP address in the message.
OutLabel	Outgoing label of the route.
AS-path	AS_PATH attribute of the route, which records the ASs the route has passed and avoids routing loops.
Origin	Origin of the route: • **igp**—Originated in the AS. The origin of routes advertised with the **network** command is IGP. • **egp**—Learned through EGP. • **incomplete**—Unknown origin. The origin of routes redistributed from IGP protocols is INCOMPLETE.
PrefixSID	Prefix SID: • **Label index**—Label index. • **SRGB**—SRGB range.

Field	Description
Attribute value	BGP path attributes: • **MED**—MED value. • **localpref**—Local preference value. • **pref-val**—Preferred value. • **pre**—Route preference.
State	Current state of the route: • valid. • internal. • external. • local. • synchronize. • best.
Originator	Router ID of the peer that advertised the route to the reflector.
From	IP address of the BGP peer that advertised the route.
Rely Nexthop	Next hop found by route recursion. If no next hop is found, this field displays **not resolved**.
IP precedence	IP precedence in the range of 0 to 7. **N/A** indicates that the route does not support this field.
QoS local ID	QoS local ID in the range of 1 to 4095. **N/A** indicates that the route does not support this field.
Traffic index	Traffic index in the range of 1 to 64. **N/A** indicates that the route does not support this field.
VPN-Peer UserID	VPN peer ID in the range of 1 to 134217727. **N/A** indicates that the route does not support this field.
DSCP	DSCP value in the range of 0 to 63. **N/A** indicates that the route does not support this field.
Backup route	The route is a backup route.
EXP	MPLS EXP value of the route. **N/A** indicates that the route does not support this field.
Tunnel policy	Tunnel policy that takes effect. **NULL** indicates that no tunnel policy takes effect.
Rely Tunnel IDs	Tunnel index IDs after route recursion. This field displays multiple tunnel index IDs if ECMP tunnels exist and displays **N/A** if no tunnels are found by route recursion.

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP IPv6 multicast routing information for the default BGP instance.

ipv6-address prefix-length: Specifies the destination network address and prefix length. The value range for the *prefix-length* argument is 0 to 128. If you do not specify this argument, the command displays brief information about all BGP IPv6 multicast routing information.

advertise-info: Displays advertisement information for BGP IPv6 multicast routes. If you do not specify this keyword, the command displays the BGP IPv6 multicast routing table.

as-path-acl *as-path-acl-number*: Displays BGP IPv6 multicast routes that match the AS path list specified by its number in the range of 1 to 256.

community-list: Displays BGP IPv6 multicast routes that match a community list.

basic-community-list-number: Specifies a basic community list by its number in the range of 1 to 99.

comm-list-name: Specifies a community list by its name, a case-sensitive string of 1 to 63 characters.

whole-match: Displays BGP IPv6 multicast routes exactly matching the specified community list. If you do not specify this keyword, the command displays BGP IPv6 multicast routes whose COMMUNITY attributes include the specified community list.

adv-community-list-number: Specifies an advanced community list by its number in the range of 100 to 199.

peer: Displays BGP IPv6 multicast routing information advertised to or received from the specified peer.

ipv6-address: Specifies the peer IPv6 address.

advertised-routes: Displays BGP IPv6 multicast routing information advertised to the specified peer.

received-routes: Displays BGP IPv6 multicast routing information received from the specified peer.

statistics: Displays routing statistics.

Examples

Display brief information about all BGP IPv6 multicast routes.

```
<Sysname> display bgp routing-table ipv6 multicast

Table 31 Command output

Field	Description
Status codes	Status codes: • *** – valid**—Valid route. • **> – best**—Optimal route. • **d – dampened**—Dampened route. • **h – history**—History route. • **s – suppressed**—Suppressed route. • **S – stale**—Stale route. • **i – internal**—Internal route. • **e – external**—External route.
Origin	Origin of the route: • **i – IGP**—Originated in the AS. The origin of routes advertised with the **`network`** command is IGP. • **e – EGP**—Learned through EGP. • **?– incomplete**—Unknown origin. The origin of routes redistributed from IGP protocols is INCOMPLETE.
Network	Destination network address.
PrefixLen	Prefix length of the destination network address.
NextHop	Next hop IP address.
LocPrf	Local preference value.
PrefVal	Preferred value of the route.
OutLabel	Outgoing label of the route.
MED	MULTI_EXIT_DISC attribute.
Path/Ogn	AS_PATH and ORIGIN attributes of the route: • **AS_PATH**—Records the ASs the route has passed, which avoids routing loops. • **ORIGIN**—Identifies the origin of the route.

Display detailed information about BGP IPv6 multicast routes destined to network 2::2/128.

```
<Sysname> display bgp routing-table ipv6 multicast 2::2 128
```

```
BGP local router ID: 192.168.1.139
Local AS number: 100

Paths:   1 available, 1 best

BGP routing table information of 2::2/128:
Imported route.
Original nexthop: ::1
OutLabel        : NULL
AS-path         : (null)

Attribute value : MED 0, pref-val 32768
State           : valid, local, best
Originator      : 176.1.1.2
Cluster list    : 80
IP precedence   : N/A
QoS local ID    : N/A
Traffic index   : N/A
VPN-Peer UserID : N/A
DSCP            : N/A
EXP             : N/A
```

Table 32 Command output

Field	Description
Paths	Number of routes: • **available**—Number of valid routes. • **best**—Number of optimal routes.
Original nexthop	Original next hop of the route. If the route was obtained from a BGP update message, the original next hop is the next hop IP address in the message.
OutLabel	Outgoing label of the route.
AS-path	AS_PATH attribute of the route, which records the ASs the route has passed and avoids routing loops.
Origin	Origin of the route: • **igp**—Originated in the AS. The origin of routes advertised with the **network** command is IGP. • **egp**—Learned through EGP. • **incomplete**—Unknown origin. The origin of routes redistributed from IGP protocols is INCOMPLETE.
Attribute value	BGP path attributes: • **MED**—MED value. • **localpref**—Local preference value. • **pref-val**—Preferred value. • **pre**—Route preference.

Field	Description
State	Current state of the route: • valid. • internal. • external. • local. • synchronize. • best.
Originator	Router ID of the peer that advertised the route to the reflector.
From	IP address of the BGP peer that advertised the route.
Rely Nexthop	Next hop found by route recursion. If no next hop is found, this field displays **not resolved**.
IP precedence	IP precedence in the range of 0 to 7. **N/A** indicates that the route does not support this field.
QoS local ID	QoS local ID in the range of 1 to 4095. **N/A** indicates that the route does not support this field.
Traffic index	Traffic index in the range of 1 to 64. **N/A** indicates that the route does not support this field.
VPN-Peer UserID	VPN peer ID in the range of 1 to 134217727. **N/A** indicates that the route does not support this field.
DSCP	DSCP value in the range of 0 to 63. **N/A** indicates that the route does not support this field.
EXP	MPLS EXP value of the route. **N/A** indicates that the route does not support this field.

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP IPv6 unicast routing information for the default BGP instance.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays the BGP IPv6 unicast routing information for the public network.

ipv6-address prefix-length: Specifies the destination network address and prefix length. The value range for the *prefix-length* argument is 0 to 128. If you do not specify this argument, the command displays brief information about all BGP IPv6 unicast routing information.

advertise-info: Displays advertisement information for BGP IPv6 unicast routes. If you do not specify this keyword, the command displays the BGP IPv6 unicast routing table.

as-path-acl *as-path-acl-number*: Displays BGP IPv6 unicast routes that match the AS path list specified by its number in the range of 1 to 256.

community-list: Displays BGP IPv6 unicast routes that match a community list.

basic-community-list-number: Specifies a basic community list by its number in the range of 1 to 99.

comm-list-name: Specifies a community list by its name, a case-sensitive string of 1 to 63 characters.

whole-match: Displays routes exactly matching the specified community list. If you do not specify this keyword, the command displays routes whose COMMUNITY attributes include the specified community list.

adv-community-list-number: Specifies an advanced community list by its number in the range of 100 to 199.

peer: Displays BGP IPv6 unicast routing information advertised to or received from the specified peer.

ipv4-address: Specifies the peer IPv4 address.

ipv6-address: Specifies the peer IPv6 address.

advertised-routes: Displays routing information advertised to the specified peer.

received-routes: Displays routing information received from the specified peer.

statistics: Displays routing statistics.

Usage guidelines

This command displays BGP IPv6 unicast routing information regardless of whether the **unicast** keyword is specified.

Examples

Display brief information about all BGP IPv6 unicast routes.

```
<Sysname> display bgp routing-table ipv6

     Path/Ogn: 100i
```

Table 36 Command output

Field	Description
Status codes	Status codes: • *** – valid**—Valid route. • **> – best**—Optimal route. • **d – dampened**—Dampened route. • **h – history**—History route. • **s – suppressed**—Suppressed route. • **S – stale**—Stale route. • **i – internal**—Internal route. • **e – external**—External route.

Field	Description
Origin	Origin of the route: • **i – IGP**—Originated in the AS. The origin of routes advertised with the **network** command is IGP. • **e – EGP**—Learned through EGP. • **?– incomplete**—Unknown origin. The origin of routes redistributed from IGP protocols is INCOMPLETE.
Network	Destination network address.
PrefixLen	Prefix length of the destination network address.
NextHop	Next hop IPv6 address.
LocPrf	Local preference value.
PrefVal	Preferred value of the route.
OutLabel	Outgoing label of the route.
MED	MULTI_EXIT_DISC attribute.
Path/Ogn	AS_PATH and ORIGIN attributes of the route: • **AS_PATH attribute**—Records the ASs the route has passed, which avoids routing loops. This field can display a maximum of 16 AS numbers. More AS numbers are omitted and can be viewed in the detailed route information. • **ORIGIN attribute**—Identifies the origin of the route.

Display detailed information about BGP IPv6 unicast routes destined to network 2::/64.

```
<Sysname> display bgp routing-table ipv6 2:: 64

 BGP local router ID: 192.168.1.135

Table 37 Command output

Field	Description
Paths	Number of routes: • **available**—Number of valid routes. • **best**—Number of optimal routes.
Original nexthop	Original next hop of the route. If the route was obtained from a BGP update message, the original next hop is the next hop IP address in the message.
OutLabel	Outgoing label of the route.
AS-path	AS_PATH attribute of the route, which records the ASs the route has passed and avoids routing loops.
Origin	Origin of the route: • **igp**—Originated in the AS. The origin of routes advertised with the **network** command is IGP. • **egp**—Learned through EGP. • **incomplete**—Unknown origin. The origin of routes redistributed from IGP protocols is INCOMPLETE.
Attribute value	BGP path attributes: • **MED**—MED value. • **localpref**—Local preference value. • **pref-val**—Preferred value. • **pre**—Route preference.
State	Current state of the route: • valid. • internal. • external. • local. • best.
Originator	Router ID of the peer that advertised the route to the reflector.
From	IP address of the BGP peer that advertised the route.
Relay Nexthop	Next hop found by route recursion. If no next hop is found, this field displays **not resolved**.

Field	Description
IP precedence	IP precedence in the range of 0 to 7. **N/A** indicates that the route does not support this field.
QoS local ID	QoS local ID in the range of 1 to 4095. **N/A** indicates that the route does not support this field.
Traffic index	Traffic index in the range of 1 to 64. **N/A** indicates that the route does not support this field.
VPN-Peer UserID	VPN peer ID in the range of 1 to 134217727. **N/A** indicates that the route does not support this field.
DSCP	DSCP value in the range of 0 to 63. **N/A** indicates that the route does not support this field.
Backup route	The route is a backup route.
EXP	MPLS EXP value of the route. **N/A** indicates that the route does not support this field.
Tunnel policy	Tunnel policy that takes effect. **NULL** indicates that no tunnel policy takes effect.
Rely Tunnel IDs	Tunnel index IDs after route recursion. This field displays multiple tunnel index IDs if ECMP tunnels exist and displays **N/A** if no tunnels are found by route recursion.

Display advertisement information for BGP IPv6 unicast routes destined to network 2::/64.

```
<Sysname> display bgp routing-table ipv6 2:: 64 advertise-info

context-operator

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays incoming labels of BGP IPv6 unicast routes in the default BGP instance.

Usage guidelines

This command displays incoming labels for BGP IPv6 unicast routes regardless of whether the **unicast** keyword is specified.

Examples

Display incoming labels for all BGP IPv6 unicast routes.

```
<Sysname> display bgp routing-table ipv6 inlabel

 Total number of routes: 2

 BGP local router ID is 2.2.2.2
 Status codes: * - valid, > - best, d - dampened, h - history

Predefined user roles

network-admin

network-operator

context-admin

context-operator

Parameters

instance *instance-name*: Specifies a BGP instance by its name, a case-sensitive string of 1 to 31 characters. If you do not specify this option, the command displays BGP update group information for the default BGP instance.

flowspec: Displays BGP update group information for flowspec address family.

ipv4: Displays BGP update group information for IPv4 address family.

ipv6: Displays BGP update group information for IPv6 address family.

link-state: Displays BGP update group information for LS address family.

vpnv4: Displays BGP update group information for VPNv4 address family.

vpnv6: Displays BGP update group information for VPNv6 address family.

mdt: Displays BGP update group information for MDT address family.

multicast: Displays BGP update group information for multicast address family.

mvpn: Displays BGP update group information for IPv4 MVPN address family.

rtfilter: Displays BGP update group information for BGP IPv4 RT filter address family.

The following compatibility matrixes show the support of hardware platforms for the **rtfilter** keyword:

Models	Parameter compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No

unicast: Displays BGP update group information for unicast address family.

vpn-instance *vpn-instance-name*: Displays BGP update group information for the MPLS L3VPN instance specified by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a VPN instance, this command displays update group information for the public network.

ipv4-address: Displays BGP update group information for the specified BGP peer.

ipv6-address: Displays BGP update group information for the specified IPv6 BGP peer.

Usage guidelines

The update group feature classifies BGP peers that have the same export policy into an update group. When BGP advertises routes to the peers in the update group, it uses the export policy to filter the routes and generates route updates for all the peers only once.

With this feature, BGP performs one-time policy filtering and encapsulation for a prefix before advertising the prefix to all the peers in the update group. For example, BGP advertises 1000 prefixes to 1000 peers that have the same export policy (in data centers for example). Without the update group feature, BGP matches the export policy 1000 × 1000 times. With the update group feature, BGP matches the export policy only 1000 × 1 times, improving encapsulation efficiency 1000 times.

If you do not specify any parameters, this command displays all update groups for the specified address family on the public network.

By default, the **unicast** keyword is used if the **unicast**, **mdt**, **mvpn**, **rtfilter**, **multicast**, and **flowspec** keywords are not specified.

Examples

Display information about all BGP update groups for the IPv4 unicast address family.

```
<Sysname> display bgp update-group ipv4

  Update-group ID: 0
  Type: EBGP link
  4-byte AS number: Supported
  Site-of-Origin: Not specified
  Minimum time between advertisements: 30 seconds
  OutQ: 0
  Members: 1
    99.1.1.1
```

Table 43 Command output

Field	Description
Update-group ID	ID of the update group.
Type	BGP link type: • **IBGP link**. • **EBGP link**. • **Confed IBGP link**—Confederation IBGP link. • **Confed EBGP link**—Confederation EBGP link.
Label capability: Supported	This field is not supported in the current software version. The peers in the update group support labeled routes.
4-byte AS number: Supported	4-byte AS number suppression is disabled for the peers in the update group. The peers in the update group support 4-byte AS numbers.
4-byte AS number: Suppressed	4-byte AS number suppression is enabled for the peers in the update group.
Fake AS	A fake local AS number is configured for the peers in the update group.

Field	Description
Public-AS-Only: Yes	BGP route updates advertised to the peers in the update group only carry the public AS number without the private AS number. • **Yes**—If a peer uses a private AS number, the AS number is used as an update group classification criterion. If a peer uses a public AS number, the AS number is not used as an update group classification criterion. • **No**—The AS number is not used as an update group classification criterion.
Substitute-AS: Yes	AS number substitution is enabled.
Minimum time between advertisements: number seconds	Minimum time between advertisements.
Advertising community: Yes	Community advertisement to peers in the update group is enabled.
Route-reflect client: Yes	The peer is a client of the route reflector.
Advertising extended community: Yes	Extended community advertisement to peers in the update group is enabled.
Export AS-path-ACL	AS path ACL used to filter BGP routes advertised to peers in the update group.
Export prefix list	Prefix list used to filter BGP routes advertised to peers in the update group.
Export route policy	Routing policy used to filter BGP routes advertised to peers in the update group.
Export filter-policy	ACL used to filter BGP routes advertised to peers in the update group.
OutQ	Number of prefixes to be advertised to peers in the update group.
Members	Number and IP addresses of peers in the update group.
Nesting VPN	Peers in the update group support nesting VPN.
UPE: Yes	Peers in the update group are UPE devices.
UPE export route policy	An outgoing routing policy is applied to peers in the update group.

domain-distinguisher

Use **domain-distinguisher** to specify an AS number and a router ID for BGP LS messages.

Use **undo domain-distinguisher** to restore the default.

Syntax

domain-distinguisher *as-number:router-id*

undo domain-distinguisher

Default

The AS number and router ID of the current BGP process are used.

Views

BGP LS address family view

Predefined user roles

network-admin

context-admin

Parameters

as-number:router-id: Specifies the AS number and router ID. The value range for the *as-number* argument is 1 to 4294967295, and the router ID is in IP address format.

Examples

Set the AS number and router ID for BGP LS messages to 65009 and 1.1.1.1, respectively.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family link-state
[Sysname-bgp-default-ls] domain-distinguisher 65009:1.1.1.1
```

ebgp-interface-sensitive

Use **ebgp-interface-sensitive** to enable immediate re-establishment of direct EBGP sessions.

Use **undo ebgp-interface-sensitive** to disable immediate re-establishment of direct EBGP sessions.

Syntax

ebgp-interface-sensitive

undo ebgp-interface-sensitive

Default

Immediate re-establishment of direct EBGP sessions is enabled.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Usage guidelines

When a direct link to an EBGP peer fails, BGP tears down the session and re-establishes a session to the peer immediately. If the feature is not enabled, the router does not tear down the session until the hold time expires. However, disabling this feature can prevent routing flaps from affecting EBGP session state.

This command applies only to direct EBGP sessions.

Examples

Enable immediate re-establishment of direct EBGP sessions.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] ebgp-interface-sensitive
```

fast-reroute route-policy

Use **fast-reroute route-policy** to apply a routing policy to fast reroute (FRR) for a BGP address family.

Use **undo fast-reroute route-policy** to restore the default.

Syntax

fast-reroute route-policy *route-policy-name*

undo fast-reroute route-policy

Default

No routing policy is applied to FRR.

Views

BGP IPv4 unicast address family view

BGP-VPN IPv4 unicast address family view

BGP IPv6 unicast address family view

BGP-VPN IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

route-policy-name: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

You can use the following methods to configure BGP FRR:

- **Method 1**—Execute the **pic** command in BGP address family view. BGP calculates a backup next hop for a BGP route in the address family if there are two or more unequal-cost routes to reach the destination.
- **Method 2**—Execute the **fast-reroute route-policy** command to use a routing policy in which a backup next hop is specified by using the command **apply** [**ipv6**] **fast-reroute backup-nexthop**. For BGP to generate a backup next hop for the primary route, the backup next hop calculated by BGP must be the same as the specified backup next hop. You can also configure **if-match** clauses in the routing policy to identify the routes protected by FRR.

If both methods are configured, Method 2 takes precedence over Method 1.

Examples

Apply routing policy **frr-policy** to FRR in BGP IPv4 unicast address family view.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4
[Sysname-bgp-default-ipv4] fast-reroute route-policy frr-policy
```

Predefined user roles

network-admin

context-admin

Parameters

ipv4-acl-number: Specifies an IPv4 ACL by its number in the range of 2000 to 3999, to match routes by destination.

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999, to match routes by destination.

prefix-list *ipv4-prefix-list-name*: Specifies an IPv4 prefix list by its name, a case-sensitive string of 1 to 63 characters, to match routes by destination.

prefix-list *ipv6-prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters, to match routes by destination.

direct: Filters direct routes.

isis: Filters IS-IS routes.

isisv6: Filters IPv6 IS-IS routes.

ospf: Filters OSPF routes.

ospfv3: Filters OSPFv3 routes.

rip: Filters RIP routes.

ripng: Filters RIPng routes.

static: Filters static routes.

process-id: Specifies a routing protocol by its ID in the range of 1 to 65535.

Usage guidelines

If you specify a protocol (such as **direct** and **isis**), this command filters only routes redistributed from the specified protocol. If you do not specify a protocol, this command filters all advertised routes, including the following routes:

- Redistributed from IGP.
- Injected by the **network** command.
- Learned from BGP peers.

If you use a basic ACL (with a number from 2000 to 2999) configured with the **rule** [*rule-id*] { **deny** | **permit** } **source** *source-address source-wildcard* command, the command matches routes whose destination network addresses match the *source-address source-wildcard* argument. However, it does not match the masks of the destination addresses.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following steps:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.
- To deny/permit a route with the specified destination and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the subnet mask of the destination address. For the mask configuration to take effect, specify a contiguous subnet mask.

Examples

In BGP IPv4 unicast address family view, use IPv4 basic ACL 2000 to filter advertised BGP IPv4 routes.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] filter-policy 2000 export
```

ipv4-acl-number: Specifies an IPv4 ACL by its number in the range of 2000 to 3999, to match routes by destination.

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999, to match routes by destination.

prefix-list *ipv4-prefix-list-name*: Specifies an IPv4 prefix list by its name, a case-sensitive string of 1 to 63 characters, to match routes by destination.

prefix-list *ipv6-prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters, to match routes by destination.

Usage guidelines

If you use a basic ACL (with a number from 2000 to 2999) configured with the **rule** [*rule-id*] { **deny** | **permit** } **source** *source-address source-wildcard* command, the command matches routes whose destination network addresses match the *source-address source-wildcard* argument. However, it does not match the masks of the destination addresses.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following steps:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.
- To deny/permit a route with the specified destination and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the subnet mask of the destination address. For the mask configuration to take effect, specify a contiguous subnet mask.

Examples

In BGP IPv4 unicast address family view, use IPv4 basic ACL 2000 to filter received BGP routes.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] filter-policy 2000 import
```

flush suboptimal-route

Use **flush suboptimal-route** to enable BGP to flush the suboptimal BGP route to the RIB.

Use **undo flush suboptimal-route** to disable BGP from flushing the suboptimal BGP route to the RIB.

Syntax

flush suboptimal-route

undo flush suboptimal-route

Default

BGP is disabled from flushing the suboptimal BGP route to the RIB. Only the optimal route is flushed to the RIB.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Usage guidelines

This command flushes the suboptimal BGP route to the RIB when the following conditions are met:

- The optimal route is generated by the **network** command or is redistributed by the **import-route** command.
- The suboptimal route is received from a BGP peer.

After the suboptimal route is flushed to the RIB on a network, BGP immediately switches traffic to the suboptimal route when the optimal route fails.

For example, the device has a static route to the subnet 1.1.1.0/24 that has a higher priority than a BGP route. BGP redistributes the static route and receives a route to 1.1.1.0/24 from a peer. After the **flush suboptimal-route** command is executed, BGP flushes the received BGP route to the RIB as the suboptimal route. When the static route fails, BGP immediately switches traffic to the suboptimal route if inter-protocol FRR is enabled. For more information about inter-protocol FRR, see *Layer 3—IP Routing Configuration Guide*.

Examples

Enable BGP to flush the suboptimal BGP route to the RIB.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] flush suboptimal-route
```

graceful-restart

Use **graceful-restart** to enable BGP Graceful Restart (GR) capability.

Use **undo graceful-restart** to disable BGP GR capability.

Syntax

graceful-restart

undo graceful-restart

Default

BGP GR capability is disabled.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Usage guidelines

GR ensures continuous forwarding when BGP restarts or an active/standby switchover occurs.

BGP peers exchange Open messages containing GR information. If both parties have GR capability, they establish a GR-capable session.

After you execute this command, the device re-establishes BGP sessions.

Examples

Enable GR capability for BGP process 100.

```
<Sysname> system-view
[Sysname] bgp 100
```

```
[Sysname-bgp-default] graceful-restart
```

graceful-restart timer wait-for-rib

graceful-restart timer purge-time

Use **graceful-restart timer purge-time** to set the Routing Information Base (RIB) purge timer.

Use **undo graceful-restart timer purge-time** to restore the default.

Syntax

graceful-restart timer purge-time *timer*

undo graceful-restart timer purge-time

Default

The RIB purge timer is 480 seconds.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Parameters

timer: Sets the RIB purge timer in the range of 1 to 6000 seconds.

Usage guidelines

BGP starts the RIB purge timer when an active/standby switchover occurs or BGP restarts. If BGP route exchange is not completed within the RIB purge timer, the GR restarter quits the GR process. It updates the RIB with the BGP routes already learned, and removes the stale routes from RIB.

Enable BGP GR before you execute this command.

Set the RIB purge timer to be long enough to complete GR, especially when large numbers of BGP routes exist.

As a best practice, set the RIB purge timer in the following way:

- Set the timer to be greater than the timer set by the **graceful-restart timer wait-for-rib** command
- Set the timer to be less than the timer set by the **protocol lifetime** command.

Examples

Set the RIB purge timer to 300 seconds.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] graceful-restart
[Sysname-bgp-default] graceful-restart timer purge-time 300
```

Related commands

protocol lifetime (*Layer 3—IP Routing Command Reference*)

graceful-restart timer restart

Use **graceful-restart timer restart** to configure the GR timer.

Use **undo graceful-restart timer restart** to restore the default.

Syntax

graceful-restart timer restart *timer*

undo graceful-restart timer restart

Default

The GR timer is 150 seconds.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Parameters

timer: Specifies the GR timer in the range of 3 to 600 seconds.

Usage guidelines

The GR restarter sends the GR timer to the GR helper in an Open message. When the GR helper detects that an active/standby switchover or a BGP restart occurred on the GR restarter, the GR helper performs the following operations:

1. Marks all routes learned from the GR restarter as stale.
2. Starts the GR timer.
3. If no BGP session is established before the GR timer expires, the GR helper removes the stale routes.

Before you configure this command, enable the BGP GR capability.

To apply a new GR timer, you must re-establish BGP sessions.

Examples

Set the GR timer to 300 seconds.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] graceful-restart
[Sysname-bgp-default] graceful-restart timer restart 300
```

Related commands

graceful-restart timer wait-for-rib

graceful-restart timer wait-for-rib

Use **graceful-restart timer wait-for-rib** to configure the time to wait for the End-of-RIB marker.

Use **undo graceful-restart timer wait-for-rib** to restore the default.

Syntax

graceful-restart timer wait-for-rib *timer*

undo graceful-restart timer wait-for-rib

Default

The time to wait for the End-of-RIB marker is 180 seconds.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Parameters

timer: Specifies the time to wait for the End-of-RIB marker, in the range of 3 to 3600 seconds.

Usage guidelines

BGP uses this timer to control the time to receive updates from the peer. The timer is not advertised to the peer.

After the GR restarter and GR helper re-establish a BGP session, they start this timer. If they do not complete route exchange within the time period, the GR restarter does not receive new routes. It updates its routing table and forwarding table with learned BGP routes, and the GR helper removes the stale routes. Set a large value for the maximum time to wait for the End-of-RIB marker when a large number of routes exist.

This command controls the routing convergence speed. A smaller timer value means faster routing convergence but possibly results in incomplete routing information.

Before configuring this command, you must enable the BGP GR capability.

Examples

Set the time to wait for the End-of-RIB marker on the local end to 100 seconds.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] graceful-restart
[Sysname-bgp-default] graceful-restart timer wait-for-rib 100
```

Related commands

graceful-restart

graceful-restart timer restart

group

Use **group** to create a peer group.

Use **undo group** to delete a peer group.

Syntax

group *group-name* [**external** | **internal**]

undo group *group-name*

Default

No peer groups exist.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a name for the peer group, a case-sensitive string of 1 to 47 characters.

external: Creates an EBGP peer group.

internal: Creates an IBGP peer group.

Usage guidelines

In a large-scale network, many peers can use the same route selection policy. You can configure a peer group and add these peers into this group. In this way, peers can share the same policy as the peer group. When the policy of the group is modified, the modification also applies to peers in it.

If you do not specify the **internal** or **external** keyword, this command creates an IBGP peer group.

If you perform configurations on a peer group and peers of the peer group, the most recent configuration takes effect.

After you create a peer group, you must use the **peer enable** command to enable BGP to exchange routing information with the specified peer group.

Examples

In BGP instance view, create EBGP peer group **test** with AS number 200, and add EBGP peers 10.1.1.1 and 10.1.2.1 into the group.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] group test external
[Sysname-bgp-default] peer test as-number 200
[Sysname-bgp-default] peer 10.1.1.1 group test
[Sysname-bgp-default] peer 10.1.2.1 group test
```

Related commands

display bgp group

peer enable

ignore-first-as

Use **ignore-first-as** to configure BGP to ignore the first AS number of EBGP route updates.

Use **undo ignore-first-as** to restore the default.

Syntax

ignore-first-as

undo ignore-first-as

Default

BGP checks the first AS number of a received EBGP route update. If the first AS number is neither that of the BGP peer nor a private AS number, the BGP router disconnects the BGP session to the peer.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Examples

Configure BGP to ignore the first AS number of EBGP route updates.

```

[Sysname] bgp 100
[Sysname-bgp-default] ignore-first-as
```

Related commands

peer ignore-first-as

import-route

Use **import-route** to enable BGP to redistribute routes from an IGP protocol.

Use **undo import-route** to disable route redistribution from an IGP protocol.

Syntax

In BGP IPv4 unicast address family view/BGP-VPN IPv4 unicast address family view/BGP IPv4 multicast address family view:

import-route { **isis** | **ospf** | **rip** } [{ *process-id* | **all-processes** } [**allow-direct** | **med** *med-value* | **route-policy** *route-policy-name*] *]

import-route { **direct** | **static** } [**med** *med-value* | **route-policy** *route-policy-name*] *

undo import-route { **direct** | { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] | **static** }

In BGP IPv6 unicast address family view/BGP-VPN IPv6 unicast address family view/BGP IPv6 multicast address family view:

import-route { **isisv6** | **ospfv3** | **ripng** } [{ *process-id* | **all-processes** } [**allow-direct** | **med** *med-value* | **route-policy** *route-policy-name*] *]

import-route { **direct** | **static** } [**med** *med-value* | **route-policy** *route-policy-name*] *

undo import-route { **direct** | { **isisv6** | **ospfv3** | **ripng** } [*process-id* | **all-processes**] | **static** }

Default

BGP does not redistribute IGP routes.

Views

BGP IPv4 unicast address family view

BGP-VPN IPv4 unicast address family view

BGP IPv6 unicast address family view

BGP-VPN IPv6 unicast address family view

BGP IPv4 multicast address family view

BGP IPv6 multicast address family view

Predefined user roles

network-admin

context-admin

Parameters

direct: Redistributes direct routes.

isis: Redistributes IS-IS routes.

ospf: Redistributes OSPF routes.

rip: Redistributes RIP routes.

static: Redistributes static routes.

process-id: Specifies a process by its ID in the range of 1 to 65535.

all-processes: Redistributes routes from all the processes of the specified IGP protocol.

allow-direct: Redistributes the networks of the local interfaces enabled with the specified routing protocol. By default, the networks of the local interfaces are not redistributed. If you specify both the **allow-direct** keyword and the **route-policy** *route-policy-name* option, make sure the **if-match** rule defined in the routing policy does not conflict with the **allow-direct** keyword. For example, if you specify the **allow-direct** keyword, do not configure the **if-match route-type** rule for the routing policy. Otherwise, the **allow-direct** keyword does not take effect.

med *med-value*: Specifies a MED value for redistributed routes, in the range of 0 to 4294967295. If you do not specify an MED, the metric of a redistributed route is used as its MED.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter redistributed routes or set route attributes for redistributed routes.

Usage guidelines

The **import-route** command cannot redistribute default IGP routes. To redistribute default IGP routes, use the **default-route imported** command together with the **import-route** command.

Only active routes can be redistributed. You can use the **display ip routing-table protocol** or **display ipv6 routing-table protocol** command to view route state information.

If you do not specify any parameters when redistributing IS-IS, IPv6 IS-IS, OSPF, OSPFv3, RIP, or RIPng routes, the command redistributes routes from process 1.

The ORIGIN attribute of routes redistributed by the **import-route** command is INCOMPLETE.

After you redistribute routes from all processes of a routing protocol by using the **all-processes** keyword, this command does not take effect on any processes of the protocol.

Examples

In BGP IPv4 unicast address family view, redistribute routes from RIP process 1, and set the MED value for redistributed routes to 100.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] import-route rip 1 med 100
```

Related commands

display ip routing-table protocol

display ipv6 routing-table protocol

import-route-append

import-route-append

Use **import-route-append** to redistribute routes from an IGP without overwriting the routes redistributed by the **import-route** command.

Use **undo import-route-append** to remove the redistributed routes.

Syntax

In BGP IPv4 unicast address family view/BGP-VPN IPv4 unicast address family view/BGP IPv4 multicast address family view:

import-route-append { **isis** | **ospf** | **rip** } [{ *process-id* | **all-processes** } [**allow-direct** | **med** *med-value* | **route-policy** *route-policy-name*] *]

import-route-append { **direct** | **static** } [**med** *med-value* | **route-policy** *route-policy-name*] *

undo import-route-append { **direct** | { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] | **static** }

In BGP IPv6 unicast address family view/BGP-VPN IPv6 unicast address family view/BGP IPv6 multicast address family view:

import-route-append { **isisv6** | **ospfv3** | **ripng** } [{ *process-id* | **all-processes** } [**allow-direct** | **med** *med-value* | **route-policy** *route-policy-name*] *]

import-route-append { **direct** | **static** } [**med** *med-value* | **route-policy** *route-policy-name*] *

undo import-route-append { **direct** | { **isisv6** | **ospfv3** | **ripng** } [*process-id* | **all-processes**] | **static** }

Default

BGP does not redistribute IGP routes.

Views

BGP IPv4 unicast address family view

BGP-VPN IPv4 unicast address family view

BGP IPv6 unicast address family view

BGP-VPN IPv6 unicast address family view

BGP IPv4 multicast address family view

BGP IPv6 multicast address family view

Predefined user roles

network-admin

context-admin

Parameters

direct: Redistributes direct routes.

isis: Redistributes IS-IS routes.

isisv6: Redistributes IPv6 IS-IS routes.

ospf: Redistributes OSPF routes.

ospfv3: Redistributes OSPFv3 routes.

rip: Redistributes RIP routes.

ripng: Redistributes RIPng routes.

static: Redistributes static routes.

process-id: Specifies a process by its number in the range of 1 to 65535.

all-processes: Redistributes routes from all processes of the specified routing protocol.

allow-direct: Redistributes the networks of the local interfaces enabled with the specified routing protocol. By default, the networks of the local interfaces are not redistributed. If you specify both the **allow-direct** keyword and the **route-policy** *route-policy-name* option, make sure the **if-match** rule defined in the routing policy does not conflict with the **allow-direct** keyword. For example, if you specify the **allow-direct** keyword, do not configure the **if-match route-type** rule for the routing policy. Otherwise, the **allow-direct** keyword does not take effect.

med *med-value*: Specifies a MED value for redistributed routes, in the range of 0 to 4294967295. If you do not specify an MED, the metric of a redistributed route is used as its MED.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter redistributed routes or set route attributes for redistributed routes.

Usage guidelines

If you execute the **import-route-append** command without executing the **import-route** command, the **import-route-append** command has the same effect as the **import-route** command.

If you execute both the **import-route** and **import-route-append** commands for an IGP process, the commands take effect as follows:

- A route is redistributed as long as it matches the criteria of either command.
- If a route matches the criteria of both commands, the route is redistributed, and the apply clauses in the routing policies specified in the two commands take effect as follows:
  - If the apply clauses do not conflict, all apply clauses take effect.
  - If conflicts occur between the apply clauses, only the apply clauses in the **import-route-append** command take effect.
- The MED value specified by the **import-route-append** command takes precedence over that specified by the **import-route** command.

If you execute the **import-route-append** command multiple times for an IGP process, the most recent configuration takes effect.

After you redistribute routes from all processes of a routing protocol by using the **all-processes** keyword, this command does not take effect on any processes of the protocol.

Examples

In BGP IPv4 unicast address family view, redistribute routes matching routing policy **policy1** from IS-IS process 1 without overwriting the routes redistributed by the **import-route** command.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] import-route isis 1
[Sysname-bgp-default-ipv4] import-route-append isis 1 route-policy policy1
```

import-route

ip vpn-instance (BGP instance view)

Use **ip vpn-instance** to create a BGP-VPN instance and enter its view, or enter the view of an existing BGP-VPN instance.

Use **undo ip vpn-instance** to remove a BGP-VPN instance and all its configurations.

Syntax

ip vpn-instance *vpn-instance-name*

undo ip vpn-instance *vpn-instance-name*

Default

No BGP-VPN instances exist.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Parameters

vpn-instance-name: Specifies a VPN instance by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

After you create a BGP peer in BGP-VPN instance view, the BGP routes learned from the peer are added into the routing table of the specified VPN instance.

After entering BGP-VPN instance view, you can execute related commands to add routes learned from different sites into different VPN instances.

Before you execute this command, you must perform the following tasks:

- Use the **ip vpn-instance** command to create the VPN instance in system view.
- Use the **route-distinguisher** command to configure a route distinguisher (RD) for the VPN instance.

Examples

Create a BGP-VPN instance and enter its view.

```
<Sysname> system-view
[Sysname] ip vpn-instance vpn1
[Sysname-vpn-instance-vpn1] route-distinguisher 100:1
[Sysname-vpn-instance-vpn1] quit
[Sysname] bgp 100
[Sysname-bgp-default] ip vpn-instance vpn1
[Sysname-bgp-default-vpn1]
```

Related commands

ip vpn-instance (system view)(*VPN Instance Command Reference*)

route-distinguisher(*VPN Instance Command Reference*)

label-allocation-mode

Use **label-allocation-mode** to specify a label allocation mode.

Use **undo label-allocation-mode** to restore the default.

Syntax

label-allocation-mode { **per-prefix** | **per-vrf** }

undo label-allocation-mode

Default

BGP allocates labels on a per-next-hop basis.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Parameters

per-prefix: Allocates a label to each route prefix.

per-vrf: Allocates a label to each VPN instance.

Usage guidelines

CAUTION:

A change to the label allocation mode enables BGP to re-advertise all routes, which will cause temporary service interruption. Use this command with caution.

BGP supports the following label allocation modes:

- **Per-prefix**—Allocates a label to each route prefix.
- **Per-next-hop**—Allocates a label to each next hop. This mode is applicable when the number of labels required by the per-prefix mode exceeds the maximum number of labels supported by the device.
- **Per-VPN-instance**—Allocates a label to each VPN instance. This mode is applicable when the number of labels required by the per-next-hop mode exceeds the maximum number of labels supported by the device.

When you specify the per-prefix or per-next-hop label allocation mode, you can execute the **vpn popgo** command to specify the POPGO forwarding mode on an egress PE. The egress PE will pop the label for each packet and forward the packet out of the interface corresponding to the label.

When you specify the per-VPN instance label allocation mode, do not execute the **vpn popgo** command because it is mutually exclusive with the **label-allocation-mode per-vrf** command. The egress PE will pop the label for each packet and forward the packet through the FIB table.

Examples

Specify the per-prefix label allocation mode.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] label-allocation-mode per-prefix
```

Related commands

vpn popgo

log-peer-change

Use **log-peer-change** to enable logging for BGP session state changes globally.

Use **undo log-peer-change** to disable logging for BGP session state changes globally.

Syntax

log-peer-change

undo log-peer-change

Default

Logging for BGP session state changes is enabled globally.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Usage guidelines

After you execute both the **log-peer-change** and **peer log-change** commands, BGP logs session establishment and disconnection events for the peer or peer group. To display the log information, use the **display bgp peer ipv4 unicast log-info** command or the **display bgp peer ipv6 unicast log-info** command. The logs are sent to the information center of the device. The output rules of the logs (whether to output the logs and where to output) are determined by the information center configuration. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

If you disable logging for BGP session state changes globally or disable logging for a peer or peer group, BGP does not generate logs for session establishments and disconnections.

Examples

Enable logging for session state changes globally.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] log-peer-change
```

Related commands

display bgp peer

peer log-change

network

Use **network** to inject a network to the BGP routing table and configure BGP to advertise the network.

Use **undo network** to remove a local network.

Syntax

In BGP IPv4 unicast address family view/BGP-VPN IPv4 unicast address family view/BGP IPv4 multicast address family view:

network *ipv4-address* [*mask-length* | *mask*] [**route-policy** *route-policy-name*]

undo network *ipv4-address* [*mask-length* | *mask*]

In BGP IPv6 unicast address family view/BGP-VPN IPv6 unicast address family view/BGP IPv6 multicast address family view:

network *ipv6-address prefix-length* [**route-policy** *route-policy-name*]

undo network *ipv6-address prefix-length*

Default

BGP does not advertise local networks.

Views

BGP IPv6 unicast address family view

BGP-VPN IPv6 unicast address family view

BGP IPv4 multicast address family view

BGP IPv6 multicast address family view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies an IPv4 network address. If you do not specify the *mask* or *mask-length* argument, natural mask is used.

mask-length: Specifies a mask length in the range of 0 to 32.

mask: Specifies a mask in dotted decimal notation.

ipv6-address: Specifies an IPv6 network address.

prefix-length: Specifies a prefix length in the range of 0 to 128.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter routes or set the route attributes.

Usage guidelines

The network to be injected must be available and active in the local IP routing table.

The ORIGIN attribute of the route injected with the **network** command is IGP.

When you execute the **undo network** command, you must specify the same mask or mask length/prefix length that you specified for the **network** command. Otherwise, the configuration cannot be removed.

Examples

In BGP IPv4 unicast address family view, inject local network 10.0.0.0/16 to the BGP routing table.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] network 10.0.0.0 255.255.0.0
```

network short-cut

Use **network short-cut** to increase the preference for a received EBGP route. This EBGP route is called a shortcut route.

Use **undo network short-cut** to remove the configuration.

Syntax

In BGP IPv4 unicast address family view/BGP-VPN IPv4 unicast address family view/BGP IPv4 multicast address family view:

network *ipv4-address* [*mask-length* | *mask*] **short-cut**

undo network *ipv4-address* [*mask-length* | *mask*] **short-cut**

In BGP IPv6 unicast address family view/BGP-VPN IPv6 unicast address family view/BGP IPv6 multicast address family view:

network *ipv6-address prefix-length* **short-cut**

undo network *ipv6-address prefix-length* **short-cut**

Default

A received EBGP route has a preference of 255.

Views

BGP IPv6 unicast address family view

BGP-VPN IPv6 unicast address family view

BGP IPv4 multicast address family view

BGP IPv6 multicast address family view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies an IPv4 network address. If you do not specify the *mask* or *mask-length* argument, natural mask is used.

mask-length: Specifies a mask length in the range of 0 to 32.

mask: Specifies a mask for the network address, in dotted decimal notation.

ipv6-address: Specifies an IPv6 network address.

prefix-length: Specifies a prefix length in the range of 0 to 128.

Usage guidelines

Different routing protocols might find different routes to the same destination. However, not all of those routes are optimal. For route selection, routing protocols, direct routes, and static routes are assigned different preferences. The route with the highest preference is preferred.

By default, the preference of an EBGP route is lower than a local route. If a device has an EBGP route and a local route to reach the same destination, the device does not select the EBGP route. You can use the **network shortcut** command to configure the EBGP route to have the same preference as the local route so the EBGP route is more likely to become the optimal route.

You can use the **preference** command to modify the preferences for external and local BGP routes.

Examples

In BGP IPv4 unicast address family view, increase the preference of EBGP route 10.0.0.0/16.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] network 10.0.0.0 255.255.0.0 short-cut
```

Related commands

preference

non-stop-routing

Use **non-stop-routing** to enable BGP nonstop routing (NSR).

Use **undo non-stop-routing** to disable BGP NSR.

Syntax

non-stop-routing

undo non-stop-routing

Default

BGP NSR is disabled.

Views

BGP instance view

Predefined user roles

network-admin

context-admin

Usage guidelines

BGP NSR ensures continuous routing by synchronizing BGP state and data information from the active BGP process to the standby BGP process. The standby BGP process can seamlessly take over all services when the active process fails.

Examples

Enable BGP NSR.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] non-stop-routing
```

Related commands

display bgp non-stop-routing status

peer advertise-community

Use **peer advertise-community** to advertise the COMMUNITY attribute to a peer or peer group.

Use **undo peer advertise-community** to disable the COMMUNITY attribute advertisement to a peer or peer group.

Syntax

In BGP IPv4 unicast address family view/BGP-VPN IPv4 unicast address family view/BGP VPNv4 address family view/BGP VPNv6 address family view/BGP IPv4 multicast address family view/BGP IPv4 MVPN address family view:

peer { *group-name* | *ipv4-address* [*mask-length*] } **advertise-community**

undo peer { *group-name* | *ipv4-address* [*mask-length*] } **advertise-community**

In BGP IPv6 unicast address family view:

peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise-community**

undo peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise-community**

In BGP IPv6 multicast address family view/BGP-VPN IPv6 unicast address family view:

peer { *group-name* | *ipv6-address* [*prefix-length*] } **advertise-community**

undo peer { *group-name* | *ipv6-address* [*prefix-length*] } **advertise-community**

Default

No COMMUNITY attribute is advertised to any peers or peer groups.

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command advertises the COMMUNITY attribute to all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command advertises the COMMUNITY attribute to all dynamic peers in the subnet.

Usage guidelines

The COMMUNITY attribute is a group of specific data carried in update messages. A route can carry one or more COMMUNITY attribute values (each is represented by a 4-byte integer). The receiving router processes the route (for example, determining whether to advertise the route and the scope for advertising the route) based on the COMMUNITY attribute values.

After you execute the **peer advertise-community** command, routing updates advertised to the peer carry the COMMUNITY attribute.

After you execute the **undo peer advertise-community** command, BGP, upon receiving a route with the COMMUNITY attribute, removes the COMMUNITY attribute before sending the route to the peer or peer group.

Examples

In BGP IPv4 unicast address family view, advertise the COMMUNITY attribute to peer group **test**.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] peer test advertise-community
```

Related commands

BGP IPv6 multicast address family view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command advertises the extended community attribute to all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command advertises the extended community attribute to all dynamic peers in the subnet.

Usage guidelines

To meet increasing user demands, BGP defines a new attribute—extended community attribute. The extended community attribute has the following advantages over the COMMUNITY attribute:

- The extended community attribute has an 8-byte length.
- The extended community attribute supports various types. You can select an extended community attribute type as needed to implement route filtering and control. This simplifies configuration and management.

After you execute the **peer advertise-ext-community** command, route updates sent to the peer or peer group carry the extended community attribute.

After you execute the **undo peer advertise-ext-community** command, BGP, upon receiving a route with the extended community attribute, removes the extended community attribute before sending the route to the peer or peer group.

Examples

In BGP IPv4 unicast address family view, advertise the extended community attribute to peer group **test**.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] peer test advertise-ext-community
```

Related commands

peer advertise-policy exist-policy

Use **peer advertise-policy exist-policy** to specify an existent policy to control route advertisement.

Use **undo peer advertise-policy exist-policy** to remove the configuration.

Syntax

In BGP IPv4 unicast address family view:

peer { *group-name* | *ipv4-address* [*mask-length*] } **advertise-policy** *advertise-policy-name* **exist-policy** *exist-policy-name*

undo peer { *group-name* | *ipv4-address* [*mask-length*] } **advertise-policy exist-policy**

In BGP IPv6 unicast address family view:

peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise-policy** *advertise-policy-name* **exist-policy** *exist-policy-name*

undo peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise-policy exist-policy**

Default

No existent policy is specified to control route advertisement.

Views

BGP IPv4 unicast address family view

BGP IPv6 unicast address family view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command specifies all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command specifies all dynamic peers in the subnet.

advertise-policy-name: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. The routing policy is used as the route advertisement policy.

exist-policy *exist-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. The routing policy is used as the existent policy.

Usage guidelines

After you configure this command, routes that match the route advertisement policy can be advertised only when the BGP routing table contains prefixes that match the existent policy.

The existent policy does not apply to routes that do not match the route advertisement policy.

Examples

In BGP IPv4 unicast address family view, configure BGP to advertise routes matching routing policy **adv-policy** to peer 1.1.1.1 only when the BGP routing table contains prefixes matching routing policy **ex-policy**.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] peer 1.1.1.1 advertise-policy adv-policy exist-policy
ex-policy
```

network-admin

context-admin

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command specifies all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command specifies all dynamic peers in the subnet.

advertise-policy-name: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. The routing policy is used as the route advertisement policy.

non-exist-policy *non-exist-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. The routing policy is used as the nonexistent policy.

Usage guidelines

After you configure this command, routes that match the route advertisement policy can be advertised only when the BGP routing table does not contain any prefixes that match the nonexistent policy.

The nonexistent policy does not apply to routes that do not match the route advertisement policy.

Examples

In BGP IPv4 unicast address family view, configure BGP to advertise routes matching routing policy **adv-policy** to peer 1.1.1.1 only when the BGP routing table does not contain any prefixes matching routing policy **n-ex-policy**.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] peer 1.1.1.1 advertise-policy adv-policy non-exist-policy
n-ex-policy
```

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet in this command, BGP allows a local AS number to exist in the AS_PATH attribute of routes from all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet in this command, BGP allows a local AS number to exist in the AS_PATH attribute of routes from all dynamic peers in the subnet.

number: Specifies the number of times for which the local AS number can appear, in the range of 1 to 10. The default number is 1. If the number of times for which the local AS number appears in a route is more than the specified number, BGP considers that a routing loop occurs and discards the route.

Usage guidelines

By default, BGP does not receive routes that contain the local AS number in the AS_PATH attribute to avoid routing loops. However, in some network environments, the AS_PATH attribute of a route from a peer must be allowed to contain the local AS number. Otherwise, the route cannot be advertised correctly.

Examples

In BGP IPv4 unicast address family view, set the number of times the local AS number can appear in AS_PATH attribute of routes from peer group **test** to 2.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] peer test allow-as-loop 2
```

peer as-number (for a BGP peer group)

Use **peer as-number** to specify an AS number for a peer group.

Use **undo peer as-number** to delete the AS number of a peer group.

Syntax

peer *group-name* **as-number** *as-number*

undo peer *group-name* **as-number**

Default

No AS number is specified for a peer group.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a name for a peer group, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

as-number: Specifies an AS number for a peer group, in the range of 1 to 4294967295.

Usage guidelines

This command applies only to a peer group with no peers in it.

When you specify an AS number for a peer group and want to add peers to it, make sure the AS number of the peers is the same as the peer group.

If you do not specify an AS number for a peer group, peers added to it can use their own AS numbers.

Examples

In BGP instance view, set the AS number for peer group **test** to 100.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] peer test as-number 100
```

Related commands

peer group

peer as-number (for a BGP peer)

Use **peer as-number** to create a BGP peer and specify its AS number.

Use **undo peer** to delete a BGP peer.

Syntax

peer { *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **as-number** *as-number*

undo peer { *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] }

Default

No BGP peers exist.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

ipv4-address: Specifies the IPv4 address of a peer.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command enables BGP to establish dynamic peer relationships with all devices in the subnet.

ipv6-address: Specifies the IPv6 address of a peer.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command enables BGP to establish dynamic peer relationships with all devices in the subnet.

as-number: Specifies an AS number for the peer, in the range of 1 to 4294967295. If the AS numbers of the peer and the local router are the same, the peer is an IBGP peer. If they are different, the peer is an EBGP peer.

Usage guidelines

You can also create a peer and add it to a peer group by using the **peer group** command.

To modify the AS number of a peer, do not execute the **peer as-number** command repeatedly. Instead, you must first delete the peer and configure it again.

After you create a peer, you must use the **peer enable** command to enable BGP to exchange routing information with the specified peer.

For a remote device to establish a peer relationship with the local device, you must specify the IP address of the local device on the remote device.

Examples

In BGP instance view, create BGP peer 1.1.1.1 and set its AS number to 100.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] peer 1.1.1.1 as-number 100
```

Related commands

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command specifies an AS path list to filter routes incoming from or outgoing to all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command specifies an AS path list to filter routes incoming from or outgoing to all dynamic peers in the subnet.

as-path-acl-number: Specifies an AS path list by its number in the range of 1 to 256.

export: Filters outgoing routes.

import: Filters incoming routes.

Usage guidelines

The specified AS path list must have been created with the **ip as-path** command in system view. If you specify a nonexistent AS path list, all routes can pass the AS path list.

Examples

In BGP IPv4 unicast address family view, specify AS path list 1 to filter routes outgoing to peer group **test**.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] peer test as-path-acl 1 export
```

peer bfd

Use **peer bfd** to enable BFD for the link to a BGP peer or peer group.

Use **undo peer bfd** to remove the configuration.

Syntax

peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **bfd** [**multi-hop** | **single-hop**]

undo peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **bfd**

Default

BFD is disabled for the link to a BGP peer or peer group.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command enables BFD for links to all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command enables BFD for links to all dynamic peers in the subnet.

multi-hop: Enables multi-hop BFD.

single-hop: Enables single-hop BFD.

Usage guidelines

When you do not specify the **multi-hop** keyword or the **single-hop** keyword:

- If an IBGP peer or peer group is specified, this command enables multi-hop BFD for the IBGP peer or peer group.
- If a directly connected EBGP peer or peer group is specified and the **peer ebgp-max-hop** command is not configured, this command enables single-hop BFD for the EBGP peer or peer group. If the EBGP peer or peer group is not directly connected or the **peer ebgp-max-hop** command is configured, this command enables multi-hop BFD for the EBGP peer or peer group.

For more information about multi-hop and single-hop BFD, see BFD configuration in *Network Management and Monitoring Configuration Guide*.

BFD helps speed up BGP routing convergence upon link failures. However, if you have enabled GR, use BFD with caution. BFD might detect a failure before the system performs GR, resulting in GR failure. If you have enabled both BFD and GR for BGP, do not disable BFD during a GR process to avoid GR failure.

For BGP sessions established with link-local addresses, you can use only single-hop BFD to detect the link between BGP peers.

To establish a BFD session to a BGP peer, you must configure the same BFD detection mode (multi-hop or single-hop) on the local router and the BGP peer.

Examples

In BGP instance view, enable BFD for the link to BGP peer group **test**.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] peer test bfd
```

context-admin

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command disables BGP multi-protocol extension and route refresh for all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command disables BGP multi-protocol extension and route refresh for all dynamic peers in the subnet.

Usage guidelines

The route refresh feature enables BGP to send and receive Route-refresh messages and implement BGP session soft-reset.

The multi-protocol extension feature enables BGP to advertise and receive routing information for various protocols (for example, IPv6 routing information).

The 4-byte AS number feature enables BGP to use 4-byte AS numbers in the range of 1 to 4294967295.

If both the **peer capability-advertise conventional** and **peer capability-advertise route-refresh** commands are executed, the most recent configuration takes effect.

Examples

In BGP instance view, disable the multi-protocol extension, route refresh, and 4-byte AS number features for peer 1.1.1.1.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] peer 1.1.1.1 as-number 100
[Sysname-bgp-default] peer 1.1.1.1 capability-advertise conventional
```

Related commands

display bgp peer

peer capability-advertise route-refresh

peer capability-advertise route-refresh

Use **peer capability-advertise route-refresh** to enable BGP route refresh for a peer or peer group.

Use **undo peer capability-advertise route-refresh** to disable BGP route refresh for a peer or peer group.

Syntax

peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **capability-advertise route-refresh**

undo peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **capability-advertise route-refresh**

Default

BGP route refresh is enabled.

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command enables BGP route refresh for all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command enables BGP route refresh for all dynamic peers in the subnet.

Usage guidelines

The route refresh feature enables BGP to send and receive Route-refresh messages.

BGP uses the route refresh feature to implement BGP session soft-reset. After a policy is modified, the router advertises a Route-refresh message to the peers. The peers resend their routing information to the router. After receiving the routing information, the router filters the routing information by using the new policy. This method allows you to refresh the BGP routing table and apply the new route selection policy without tearing down BGP sessions.

BGP route refresh requires that both the local router and the peer support route refresh.

If both the **peer capability-advertise route-refresh** and **peer capability-advertise conventional** commands are executed, the most recent configuration takes effect.

Examples

In BGP instance view, enable BGP route refresh for peer 1.1.1.1.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] peer 1.1.1.1 as-number 100
[Sysname-bgp-default] peer 1.1.1.1 capability-advertise route-refresh
```

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command enables 4-byte AS number suppression for all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command enables 4-byte AS number suppression for all dynamic peers in the subnet.

Usage guidelines

BGP supports 4-byte AS numbers. The 4-byte AS number occupies four bytes, in the range of 1 to 4294967295. By default, a device sends an Open message to the peer device for session

establishment. The Open message indicates that the device supports 4-byte AS numbers. If the peer device supports 2-byte AS numbers instead of 4-byte AS numbers, the session cannot be established. To resolve this issue, enable the 4-byte AS number suppression feature. The device then sends an Open message to inform the peer that it does not support 4-byte AS numbers, so the BGP session can be established.

If the peer device supports 4-byte AS numbers, do not enable the 4-byte AS number suppression feature. If this feature is enabled, the BGP session cannot be established.

Examples

In BGP instance view, enable 4-byte AS number suppression for peer 1.1.1.1.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] peer 1.1.1.1 as-number 100
[Sysname-bgp-default] peer 1.1.1.1 capability-advertise suppress-4-byte-as
```

Related commands

display bgp peer

peer connect-interface

Use **peer connect-interface** to specify a source interface (IPv4 address/IPv6 address) for establishing TCP connections to a peer or peer group.

Use **undo peer connect-interface** to remove the configuration.

Syntax

peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **connect-interface** *interface-type interface-number*

undo peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **connect-interface**

Default

BGP uses the primary IPv4 or IPv6 address of the output interface in the optimal route destined for the BGP peer or peer group as the source address.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command specifies a source interface for establishing TCP connections to all dynamic peers in the network.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command specifies a source interface for establishing TCP connections to all dynamic peers in the subnet.

interface-type interface-number: Specifies an interface by its type and number.

Usage guidelines

The **peer connect-interface** command and the **peer source-address** command can both change the source address for establishing TCP connections. If you execute both commands, the most recent configuration takes effect.

The **peer source-address** and **peer connect-interface** commands are applicable to the following scenarios:

- The peer's IPv4/IPv6 address does not belong to the interface directly connected to the local router. To ensure successful TCP connection establishment, use one of the following methods:
  - Specify the interface to which the IPv4/IPv6 address belongs as the source interface on the peer.
  - Specify the IPv4/IPv6 address of the interface directly connected to the local router as the source address on the peer.
- A BGP peer at an IPv6 link-local address must be directly connected to the local router. On the local router, you must use the **peer connect-interface** command to specify the interface directly connected to the BGP peer as the source interface of TCP connections.
- On a BGP router that has multiple links to a peer, the source interface for TCP connection changes because the primary source interface fails. To avoid this problem, specify a loopback interface as the source interface or specify the IP address of a loopback interface as the source address.
- You want to establish multiple BGP sessions to a router. In this case, BGP might fail to determine the source address for each TCP connection based on the optimal route to the peer. To prevent this problem, use one of the following methods:
  - If the BGP sessions use IP addresses of different interfaces, specify a source interface or source address for each session.
  - If the BGP sessions use different IP addresses of the same interface, specify a source address for each session.

The source interfaces on the local router and the peer must be reachable to each other.

To specify an indirectly connected interface on an EBGP peer as the source interface, use the **peer ebgp-max-hop** command. The command allows the establishment of an EBGP session to the indirectly connected peer.

If an interface has multiple IPv4 addresses, BGP uses the primary IPv4 address to establish TCP connections. If an interface has multiple IPv6 addresses, BGP selects a source IPv6 address. To use an IPv6 address as the source address, specify that IPv6 address by using the **peer source-address** command.

You cannot specify a virtual template (VT) interface as the source interface for establishing TCP connections because a VT interface cannot process services.

Examples

In BGP instance view, specify loopback 0 as the source interface for TCP connections to peer group **test**.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] peer test connect-interface loopback 0
```

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command advertises a default route to all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command advertises a default route to all dynamic peers in the subnet.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to modify the route attribute.

vpn-instance *vpn-instance-name*: Specifies an MPLS L3VPN instance by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

This command enables the router to send a default route with the next hop being itself to the peer or peer group regardless of whether the default route exists in the routing table.

Examples

In BGP IPv4 unicast address family view, advertise a default route to peer group **test**.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] peer test default-route-advertise
```

peer description

Use **peer description** to configure a description for a peer or peer group.

Use **undo peer description** to remove the description for a peer or peer group.

Syntax

peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **description** *text*

undo peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **description**

Default

No description information is configured for a peer or peer group.

Views

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet, this command configures a description for all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet, this command configures a description for all dynamic peers in the subnet.

text: Specifies a description for a peer or peer group, a case-sensitive string of 1 to 79 characters.

Examples

In BGP instance view, set the description for peer group **test** to **ISP1**.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] peer test description ISP1
```

peer ebgp-max-hop

Use **peer ebgp-max-hop** to enable BGP to establish an EBGP session to an indirectly connected peer or peer group and specify the maximum hop count.

Use **undo peer ebgp-max-hop** to disable BGP from establishing an EBGP session to an indirectly connected peer or peer group.

Syntax

peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **ebgp-max-hop** [*hop-count*]

undo peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **ebgp-max-hop**

Default

BGP does not establish an EBGP session to an indirectly connected peer or peer group.

Views

BGP instance view

BGP-VPN instance view

Predefined user roles

network-admin

context-admin

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet in this command, BGP establishes EBGP sessions to all indirectly connected dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet in this command, BGP establishes EBGP sessions to all indirectly connected dynamic peers in the subnet.

hop-count: Specifies the maximum number of hop counts, in the range of 1 to 255. The default is 64.

Usage guidelines

To become EBGP peers, two routers must be directly connected and use directly connected interfaces to establish an EBGP session. If they are not directly connected, use the **peer ebgp-max-hop** command to establish an EBGP session over multiple hops between two peers.

This command takes effect only on routes received after you execute this command. To apply this command to existing routes, use the **refresh bgp** command to soft-reset BGP sessions.

When the BGP GTSM feature is enabled, two peers can establish an EBGP session after passing GTSM check, regardless of whether the maximum number of hops is reached.

Examples

In BGP instance view, enable BGP to establish EBGP sessions to indirectly connected EBGP peer group **test**, and set the maximum hop count to 64 (default).

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] peer test ebgp-max-hop
```

network-admin

context-admin

Parameters

group-name: Specifies a peer group by its name, a case-sensitive string of 1 to 47 characters. The peer group must have been created.

ipv4-address: Specifies a peer by its IPv4 address. The peer must have been created.

mask-length: Specifies a mask length in the range of 0 to 32. You can use the *ipv4-address* and *mask-length* arguments together to specify a subnet. If you specify a subnet in this command, BGP exchanges routing information for an address family with all dynamic peers in the subnet.

ipv6-address: Specifies a peer by its IPv6 address. The peer must have been created.

prefix-length: Specifies a prefix length in the range of 0 to 128. You can use the *ipv6-address* and *prefix-length* arguments together to specify a subnet. If you specify a subnet in this command, BGP exchanges routing information for an address family with all dynamic peers in the subnet.

Usage guidelines

Executing the **peer enable** command in different views enables BGP to exchange routing information for the corresponding address families with the specified peer.

- In BGP IPv4 unicast address family view, the command enables the capability to exchange IPv4 unicast routing information. It also adds the learned routes to the BGP routing table of the public network.
- In BGP-VPN IPv4 unicast address family view, the command enables the capability to exchange IPv4 unicast routing information. It also adds the learned routes to the BGP routing table of the specified VPN instance.
- In BGP VPNv4 address family view, the command enables the capability to exchange VPNv4 routing information.
- In BGP IPv6 unicast address family view, the command enables the capability to exchange IPv6 unicast routing information. It also adds the learned routes to the IPv6 BGP routing table of the public network.
- In BGP-VPN IPv6 unicast address family view, the command enables the capability to exchange IPv6 unicast routing information. It also adds the learned routes to the IPv6 BGP routing table of the specified VPN instance.
- In BGP VPNv6 address family view, the command enables the capability to exchange VPNv6 routing information.
- In BGP IPv4 multicast address family view, the command enables the capability to exchange IPv4 unicast routes used for RPF check. For information about RPF check, see *IP Multicast Configuration Guide*.
- In BGP IPv6 multicast address family view, the command enables the capability to exchange IPv6 unicast routes used for RPF check.
- In BGP IPv4 flowspec address family view, the command enables the capability to exchange IPv4 flowspec routing information. It also adds the learned routes to the BGP IPv4 flowspec routing table.
- In BGP-VPN IPv4 flowspec address family view, the command enables the capability to exchange IPv4 flowspec routing information. It also adds the learned routes to the BGP IPv4 flowspec routing table of the VPN instance.
- In BGP VPNv4 flowspec address family view, the command enables the capability to exchange VPNv4 flowspec routing information. It also adds the learned routes to the BGP VPNv4 flowspec routing table of the VPN instance.
- In BGP IPv4 RT filter address family view, the command enables the capability to exchange IPv4 RT filter routing information.

The **undo peer enable** command disables BGP to exchange routing information for the corresponding address family with the peer.

Examples

In BGP IPv4 unicast address family view, enable BGP to exchange IPv4 unicast routing information with peer 1.1.1.1.

```
<Sysname> system-view
[Sysname] bgp 100
[Sysname-bgp-default] address-family ipv4 unicast
[Sysname-bgp-default-ipv4] peer 1.1.1.1 enable
```
