   b. Associate the traffic class with the traffic behavior in the QoS policy.

      classifier *classifier-name* **behavior** *behavior-name*

      By default, a traffic class is not associated with a traffic behavior.

    c. Return to system view.

       quit

5. Apply the QoS policy.

   For more information, see "Applying the QoS policy."

   By default, no QoS policy is applied.

6. (Optional.) Display the traffic filtering configuration.

   display traffic behavior user-defined [*behavior-name*] [**slot** *slot-number*]

   This command is available in any view.

Configuring priority marking

About priority marking

Priority marking sets the priority fields or flag bits of packets to modify the priority of packets. For example, you can use priority marking to set IP precedence or DSCP for a class of IP packets to control the forwarding of these packets.

To configure priority marking to set the priority fields or flag bits for a class of packets, perform the following tasks:

1. Configure a traffic behavior with a priority marking action.
2. Associate the traffic class with the traffic behavior.

Configuring priority marking

Restrictions and guidelines

The device supports applying priority marking to an interface or control plane.

Procedure

1. Enter system view.

   system-view

2. Define a traffic class.

   a. Create a traffic class and enter traffic class view.

      traffic classifier *classifier-name* [**operator** { **and** | **or** }]

   b. Configure a match criterion.

      if-match [**not**] *match-criteria*

      By default, no match criterion is configured.

      For more information about the **if-match** command, see *ACL and QoS Command Reference*.

   c. Return to system view.

      quit

3. Define a traffic behavior.

   a. Create a traffic behavior and enter traffic behavior view.

      traffic behavior *behavior-name*

   b. Configure a priority marking action.

      For configurable priority marking actions, see the **remark** commands in *ACL and QoS Command Reference*.

   c. Return to system view.

      quit

4. Define a QoS policy.

   a. Create a QoS policy and enter QoS policy view.

      qos policy *policy-name*

   b. Associate the traffic class with the traffic behavior in the QoS policy.

      classifier *classifier-name* **behavior** *behavior-name*

      By default, a traffic class is not associated with a traffic behavior.

c. Return to system view.

   quit

5. Apply the QoS policy.

   For more information, see "Applying the QoS policy."

   By default, no QoS policy is applied.

6. (Optional.) Display the priority marking configuration.

   display traffic behavior user-defined [*behavior-name*] [**slot** *slot-number*]

   This command is available in any view.

Appendixes

Appendix A Acronyms

Table 1 Appendix A Acronyms

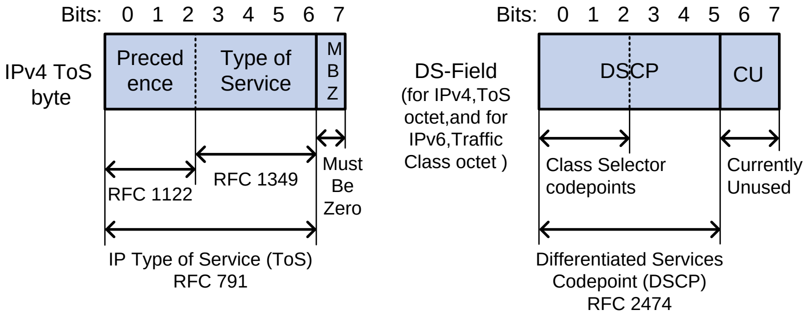
Acronym	Full spelling
AF	Assured Forwarding
BE	Best Effort
BQ	Bandwidth Queuing
CAR	Committed Access Rate
CBS	Committed Burst Size
CBQ	Class Based Queuing
CE	Congestion Experienced
CIR	Committed Information Rate
CQ	Custom Queuing
DiffServ	Differentiated Service
DSCP	Differentiated Services Code Point
EBS	Excess Burst Size
ECN	Explicit Congestion Notification
EF	Expedited Forwarding
FIFO	First in First out
FQ	Fair Queuing
GMB	Guaranteed Minimum Bandwidth
GTS	Generic Traffic Shaping
IntServ	Integrated Service
ISP	Internet Service Provider
LLQ	Low Latency Queuing
LSP	Label Switched Path
MPLS	Multiprotocol Label Switching
PE	Provider Edge
PIR	Peak Information Rate
PQ	Priority Queuing
PW	Pseudowire
QoS	Quality of Service
QPPB	QoS Policy Propagation Through the Border Gateway Protocol
RED	Random Early Detection
RSVP	Resource Reservation Protocol

Acronym	Full spelling
RTP	Real-Time Transport Protocol
SP	Strict Priority
ToS	Type of Service
VPN	Virtual Private Network
WFQ	Weighted Fair Queuing
WRED	Weighted Random Early Detection
WRR	Weighted Round Robin

Appendix B Introduction to packet precedence

IP precedence and DSCP values

Figure 7 ToS and DS fields



Bits: 0 1 2 3 4 5 6 7
IPv4 ToS byte
Preced ence
Type of Service
M B Z
RFC 1122
RFC 1349
Must Be Zero
IP Type of Service (ToS) RFC 791
Bits: 0 1 2 3 4 5 6 7
DS-Field (for IPv4,ToS octet,and for IPv6,Traffic Class octet)
DSCP
CU
Class Selector codepoints
Currently Unused
Differentiated Services Codepoint (DSCP) RFC 2474

As shown in Figure 7, the ToS field in the IP header contains 8 bits. The first 3 bits (0 to 2) represent IP precedence from 0 to 7. According to RFC 2474, the ToS field is redefined as the differentiated services (DS) field. A DSCP value is represented by the first 6 bits (0 to 5) of the DS field and is in the range 0 to 63. The remaining 2 bits (6 and 7) are reserved.

Table 2 IP precedence

IP precedence (decimal)	IP precedence (binary)	Description
0	000	Routine
1	001	priority
2	010	immediate
3	011	flash
4	100	flash-override
5	101	critical
6	110	internet
7	111	network

Table 3 DSCP values

DSCP value (decimal)	DSCP value (binary)	Description
46	101110	ef
10	001010	af11
12	001100	af12

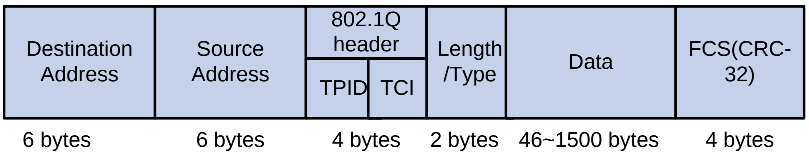
32	100000	cs4
40	101000	cs5
48	110000	cs6
56	111000	cs7
0	000000	be (default)

802.1p priority

802.1p priority lies in the Layer 2 header. It applies to occasions where Layer 3 header analysis is not needed and QoS must be assured at Layer 2.

Figure 8 An Ethernet frame with an 802.1Q tag header



As shown in Figure 8, the 4-byte 802.1Q tag header contains the 2-byte tag protocol identifier (TPID) and the 2-byte tag control information (TCI). The value of the TPID is 0x8100. Figure 9 shows the format of the 802.1Q tag header. The Priority field in the 802.1Q tag header is called 802.1p priority, because its use is defined in IEEE 802.1p. Table 4 shows the values for 802.1p priority.

Figure 9 802.1Q tag header

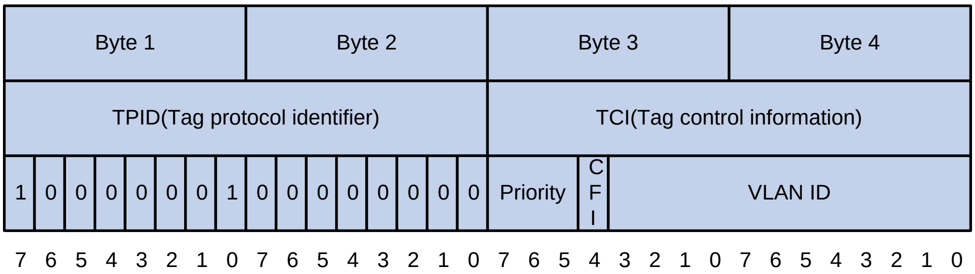


Table 4 Description on 802.1p priority

802.1p priority (decimal)	802.1p priority (binary)	Description
0	000	best-effort
1	001	background
2	010	spare

Configuring time ranges

About time ranges

You can implement a service based on the time of the day by applying a time range to it. A time-based service takes effect only in time periods specified by the time range. For example, you can implement time-based ACL rules by applying a time range to them.

The following basic types of time ranges are available:

- **Periodic time range**—Recurs periodically on a day or days of the week.
- **Absolute time range**—Represents only a period of time and does not recur.

The active period of a time range is calculated as follows:

1. Combining all periodic statements.
2. Combining all absolute statements.
3. Taking the intersection of the two statement sets as the active period of the time range.

Restrictions and guidelines: Time range configuration

When you configure the ACL hardware mode, follow these restrictions and guidelines:

- If a time range does not exist, the service based on the time range does not take effect.
- You can create a maximum of 1024 time ranges, each with a maximum of 32 periodic statements and 12 absolute statements.

Procedure

1. Enter system view.

   `system-view`

2. Create or edit a time range.

   `time-range` *`time-range-name`* { *`start-time`* **`to`** *`end-time`* *`days`* [**`from`** *`time1 date1`*] [**`to`** *`time2 date2`*] | **`from`** *`time1 date1`* [**`to`** *`time2 date2`*] | **`to`** *`time2 date2`* }

   If an existing time range name is provided, this command adds a statement to the time range.

Display and maintenance commands for time ranges

Execute the **`display`** command in any view.

Task	Command

Display time range configuration and status.	**`display time-range`**
	{ *`time-range-name`* | **`all`** }

NSFOCUS Firewall Series

NF IP Multicast Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for IP multicast features, including multicast overview, multicast routing and forwarding, PIM, IPv6 multicast routing, MLD and forwardingand IGMP.
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
ⓘ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Multicast overview

Introduction to multicast

As a technique that coexists with unicast and broadcast, the multicast technique effectively addresses the issue of point-to-multipoint data transmission. By enabling high-efficiency point-to-multipoint data transmission over a network, multicast greatly saves network bandwidth and reduces network load.

By using multicast technology, a network operator can easily provide bandwidth-critical and time-critical information services. These services include live webcasting, Web TV, distance learning, telemedicine, Web radio, and real-time video conferencing.

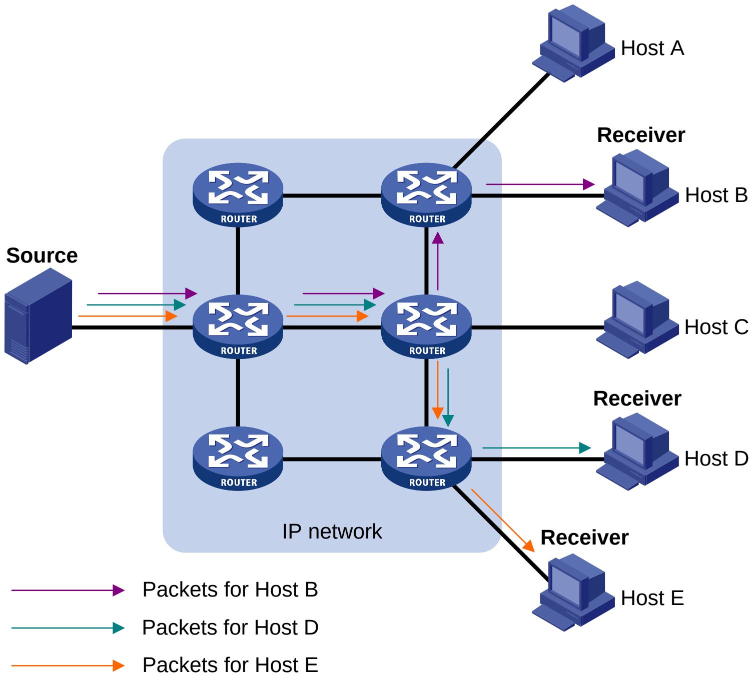
Information transmission techniques

The information transmission techniques include unicast, broadcast, and multicast.

Unicast

In unicast transmission, the information source must send a separate copy of information to each host that needs the information.

Figure 1 Unicast transmission



In Figure 1, Host B, Host D, and Host E need the information. A separate transmission channel must be established from the information source to each of these hosts.

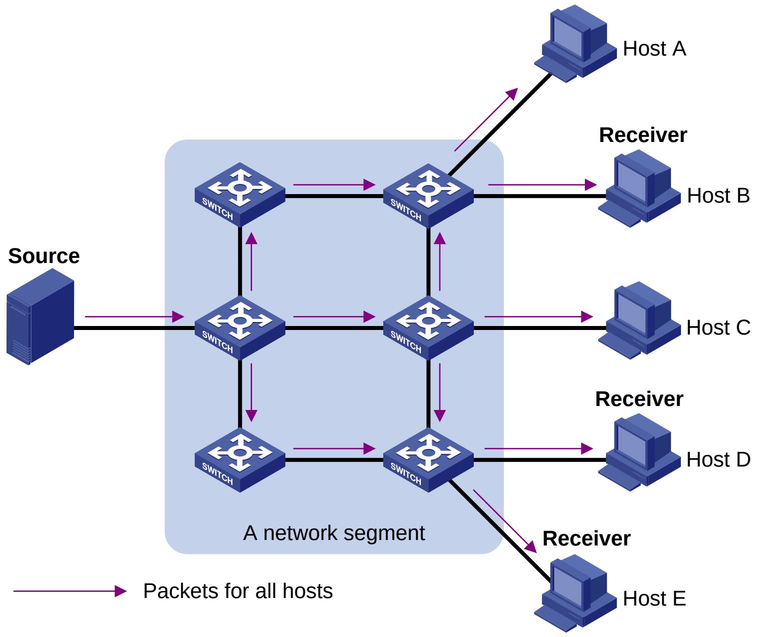
In unicast transmission, the traffic transmitted over the network is proportional to the number of hosts that need the information. If a large number of hosts need the information, the information source must send a separate copy of the same information to each of these hosts. Sending many copies can place a tremendous pressure on the information source and the network bandwidth.

Unicast is not suitable for batch transmission of information.

Broadcast

In broadcast transmission, the information source sends information to all hosts on the subnet, even if some hosts do not need the information.

Figure 2 Broadcast transmission



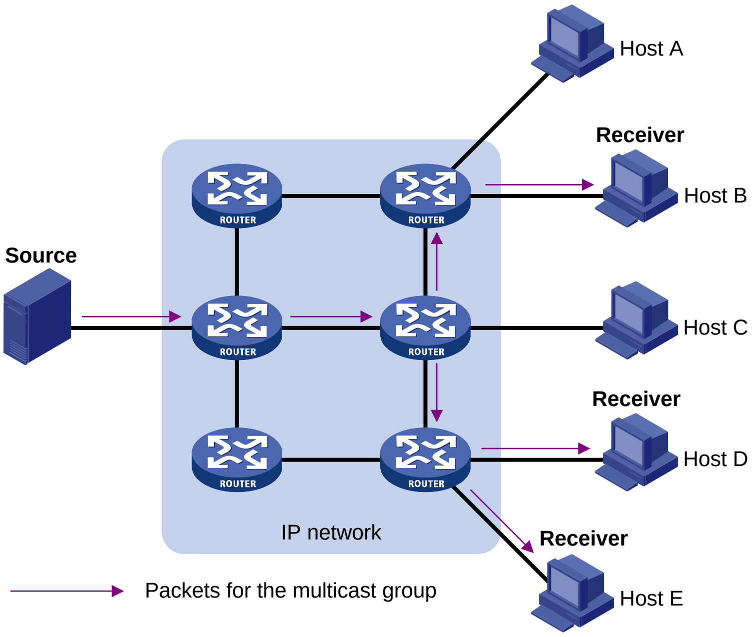
In Figure 2, only Host B, Host D, and Host E need the information. If the information is broadcast to the subnet, Host A and Host C also receive it. In addition to information security issues, broadcasting to hosts that do not need the information also causes traffic flooding on the same subnet.

Broadcast is disadvantageous in transmitting data to specific hosts. Moreover, broadcast transmission is a significant waste of network resources.

Multicast

Multicast provides point-to-multipoint data transmissions with the minimum network consumption. When some hosts on the network need multicast information, the information sender, or multicast source, sends only one copy of the information. Multicast distribution trees are built through multicast routing protocols, and the packets are replicated only on nodes where the trees branch.

Figure 3 Multicast transmission



In Figure 3, the multicast source sends only one copy of the information to a multicast group. Host B, Host D, and Host E, which are information receivers, must join the multicast group. The routers on the network duplicate and forward the information based on the distribution of the group members. Finally, the information is correctly delivered to Host B, Host D, and Host E.

To summarize, multicast has the following advantages:

- **Advantages over unicast**—Multicast data is replicated and distributed until it flows to the farthest-possible node from the source. The increase of receiver hosts will not remarkably increase the load of the source or the usage of network resources.
- **Advantages over broadcast**—Multicast data is sent only to the receivers that need it. This saves network bandwidth and enhances network security. In addition, multicast data is not confined to the same subnet.

Multicast features

- A multicast group is a multicast receiver set identified by an IP multicast address. Hosts must join a multicast group to become members of the multicast group before they receive the multicast data addressed to that multicast group. Typically, a multicast source does not need to join a multicast group.
- A multicast source is an information sender. It can send data to multiple multicast groups at the same time. Multiple multicast sources can send data to the same multicast group at the same time.
- The group memberships are dynamic. Hosts can join or leave multicast groups at any time. Multicast groups are not subject to geographic restrictions.
- Multicast routers or Layer 3 multicast devices are routers or Layer 3 switches that support Layer 3 multicast. They provide multicast routing and manage multicast group memberships on stub subnets with attached group members. A multicast router itself can be a multicast group member.

For a better understanding of the multicast concept, you can compare multicast transmission to the transmission of TV programs.

Table 1 Comparing TV program transmission and multicast transmission

TV program transmission	Multicast transmission
A TV station transmits a TV program through a channel.	A multicast source sends multicast data to a multicast group.
A user tunes the TV set to the channel.	A receiver joins the multicast group.
The user starts to watch the TV program transmitted by the TV station on the channel.	The receiver starts to receive the multicast data sent by the source to the multicast group.
The user turns off the TV set or tunes to another channel.	The receiver leaves the multicast group or joins another group.

Multicast benefits and applications

Multicast benefits

- **Enhanced efficiency**—Reduces the processor load of information source servers and network devices.
- **Optimal performance**—Reduces redundant traffic.
- **Distributed application**—Enables point-to-multipoint applications at the price of minimum network resources.

Multicast applications

- Multimedia and streaming applications, such as Web TV, Web radio, and real-time video/audio conferencing
- Communication for training and cooperative operations, such as distance learning and telemedicine
- Data warehouse and financial applications (stock quotes)
- Any other point-to-multipoint application for data distribution

Multicast models

Based on how the receivers treat the multicast sources, the multicast models include any-source multicast (ASM), source-filtered multicast (SFM), and source-specific multicast (SSM).

ASM model

In the ASM model, any multicast sources can send information to a multicast group. Receivers can join a multicast group and get multicast information addressed to that multicast group from any multicast sources. In this model, receivers do not know the positions of the multicast sources in advance.

SFM model

The SFM model is derived from the ASM model. To a multicast source, the two models appear to have the same multicast membership architecture.

The SFM model functionally extends the ASM model. The upper-layer software checks the source address of received multicast packets and permits or denies multicast traffic from specific sources.

The receivers obtain the multicast data from only part of the multicast sources. To a receiver, multicast sources are not all valid, but are filtered.

SSM model

The SSM model provides a transmission service that enables multicast receivers to specify the multicast sources in which they are interested.

In the SSM model, receivers have already determined the locations of the multicast sources. This is the main difference between the SSM model and the ASM model. In addition, the SSM model uses a different multicast address range than the ASM/SFM model. Dedicated multicast forwarding paths are established between receivers and the specified multicast sources.

Multicast addresses

IP multicast addresses

IPv4 multicast addresses

IANA assigned the Class D address block (224.0.0.0 to 239.255.255.255) to IPv4 multicast.

Table 2 Class D IP address blocks and description

Address block	Description
224.0.0.0 to 224.0.0.255	Reserved permanent group addresses. The IP address 224.0.0.0 is reserved. Other IP addresses can be used by routing protocols and for topology searching, protocol maintenance, and so on. Table 3 lists common permanent group addresses. A packet destined for an address in this block will not be forwarded beyond the local subnet regardless of the TTL value in the IP header.
224.0.1.0 to 238.255.255.255	Globally scoped group addresses. This block includes the following types of designated group addresses: • **232.0.0.0/8**—SSM group addresses. • **233.0.0.0/8**—Glop group addresses.
239.0.0.0 to 239.255.255.255	Administratively scoped multicast addresses. These addresses are considered locally unique rather than globally unique. You can reuse them in domains administered by different organizations without causing conflicts. For more information, see RFC 2365.

NOTE:

Glop is a mechanism for assigning multicast addresses between different ASs. By filling an AS number into the middle two bytes of 233.0.0.0, you get 255 multicast addresses for that AS. For more information, see RFC 2770.

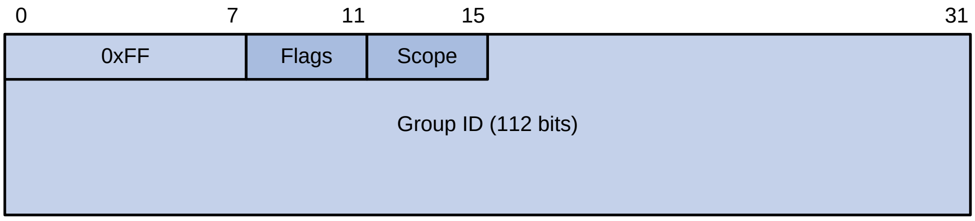
Table 3 Common permanent multicast group addresses

Address	Description
224.0.0.1	All systems on this subnet, including hosts and routers.
224.0.0.2	All multicast routers on this subnet.
224.0.0.3	Unassigned.
224.0.0.4	DVMRP routers.
224.0.0.5	OSPF routers.

Address	Description
224.0.0.6	OSPF designated routers and backup designated routers.
224.0.0.7	Shared Tree (ST) routers.
224.0.0.8	ST hosts.
224.0.0.9	RIPv2 routers.
224.0.0.11	Mobile agents.
224.0.0.12	DHCP server/relay agent.
224.0.0.13	All Protocol Independent Multicast (PIM) routers.
224.0.0.14	RSVP encapsulation.
224.0.0.15	All Core-Based Tree (CBT) routers.
224.0.0.16	Designated SBM.
224.0.0.17	All SBMs.
224.0.0.18	VRRP.

IPv6 multicast addresses

Figure 4 IPv6 multicast format



The following describes the fields of an IPv6 multicast address:

- **0xFF**—The most significant eight bits are 11111111.
- **Flags**—The Flags field contains four bits.

  Figure 5 Flags field format

  
  Table 4 Flags field description

Bit	Description
0	Reserved, set to 0.
R	• When set to 0, this address is an IPv6 multicast address without an embedded RP address. • When set to 1, this address is an IPv6 multicast address with an embedded RP address. (The P and T bits must also be set to 1.)
P	• When set to 0, this address is an IPv6 multicast address not based on a unicast prefix. • When set to 1, this address is an IPv6 multicast address based on a unicast prefix. (The T bit must also be set to 1.)

Bit	Description
T	• When set to 0, this address is an IPv6 multicast address permanently-assigned by IANA. • When set to 1, this address is a transient or dynamically assigned IPv6 multicast address.

- **Scope**—The Scope field contains four bits, which represent the scope of the IPv6 internetwork for which the multicast traffic is intended.

Table 5 Values of the Scope field

Value	Meaning
0, F	Reserved.
1	Interface-local scope.
2	Link-local scope.
3	Subnet-local scope.
4	Admin-local scope.
5	Site-local scope.
6, 7, 9 through D	Unassigned.
8	Organization-local scope.
E	Global scope.

- **Group ID**—The Group ID field contains 112 bits. It uniquely identifies an IPv6 multicast group in the scope that the Scope field defines.

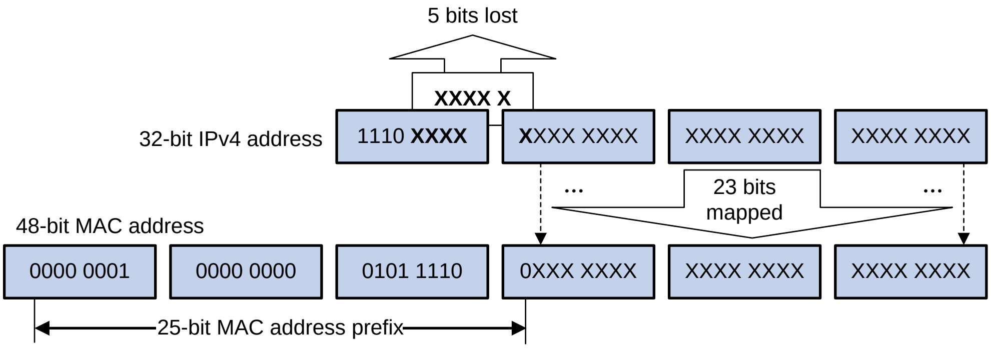
Ethernet multicast MAC addresses

An Ethernet multicast MAC address identifies receivers that belong to the same multicast group at the data link layer.

IPv4 multicast MAC addresses

As defined by IANA, the most significant 24 bits of an IPv4 multicast MAC address are 0x01005E. Bit 25 is 0, and the other 23 bits are the least significant 23 bits of an IPv4 multicast address.

Figure 6 IPv4-to-MAC address mapping

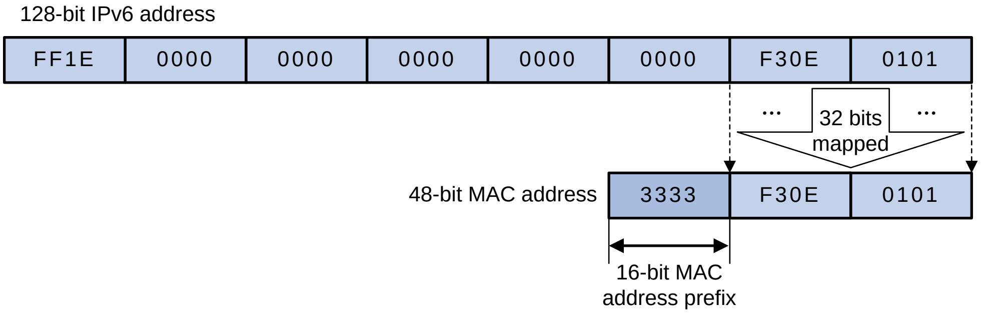


The most significant four bits of an IPv4 multicast address are fixed at 1110. In an IPv4-to-MAC address mapping, five bits of the IPv4 multicast address are lost. As a result, 32 IPv4 multicast addresses are mapped to the same IPv4 multicast MAC address. A device might receive unwanted multicast data at Layer 2 processing, which needs to be filtered by the upper layer.

IPv6 multicast MAC addresses

As defined by IANA, the most significant 16 bits of an IPv6 multicast MAC address are 0x3333. The least significant 32 bits are mapped from the least significant 32 bits of an IPv6 multicast address. Therefore, the problem of duplicate IPv6-to-MAC address mapping also arises like IPv4-to-MAC address mapping.

Figure 7 IPv6-to-MAC address mapping



Multicast protocols

Multicast protocols include the following categories:

- Layer 3 and Layer 2 multicast protocols:
  - Layer 3 multicast refers to IP multicast operating at the network layer.

    Layer 3 multicast protocols—IGMP, MLD, PIM, IPv6 PIM, MSDP, MBGP, and IPv6 MBGP.
  - Layer 2 multicast refers to IP multicast operating at the data link layer.

    Layer 2 multicast protocols—IGMP snooping, MLD snooping, PIM snooping, IPv6 PIM snooping, multicast VLAN, and IPv6 multicast VLAN.
- IPv4 and IPv6 multicast protocols:
  - **For IPv4 networks**—IGMP snooping, PIM snooping, multicast VLAN, IGMP, PIM, MSDP, and MBGP.
  - **For IPv6 networks**—MLD snooping, IPv6 PIM snooping, IPv6 multicast VLAN, MLD, IPv6 PIM, and IPv6 MBGP.

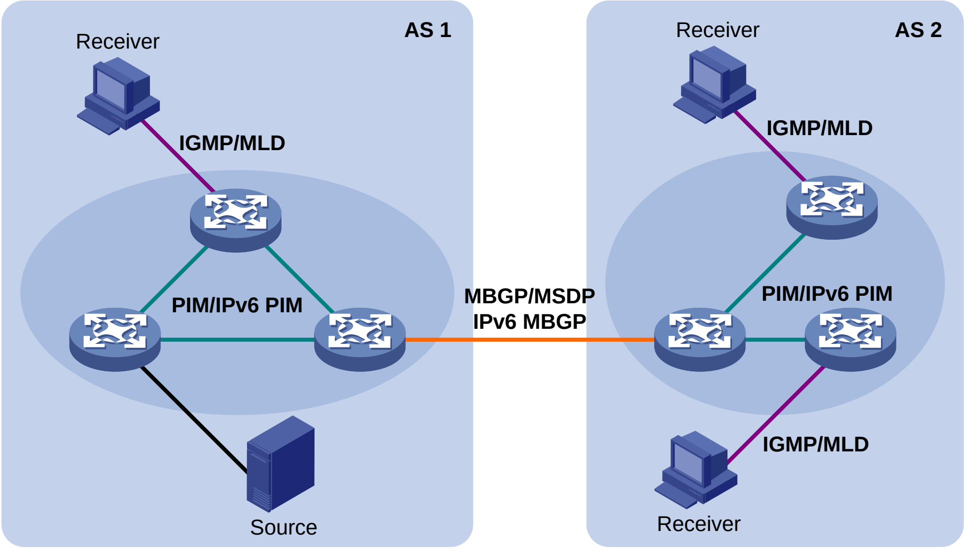
This section provides only general descriptions about applications and functions of the Layer 2 and Layer 3 multicast protocols in a network. For more information about these protocols, see the related chapters.

The device supports only the following Layer 3 multicast prototols: IGMP, MLD, and PIM.

Layer 3 multicast protocols

In Figure 8, Layer 3 multicast protocols include multicast group management protocols and multicast routing protocols.

Figure 8 Positions of Layer 3 multicast protocols



- Multicast group management protocols:

  Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) protocol are multicast group management protocols. Typically, they run between hosts and Layer 3 multicast devices that directly connect to the hosts to establish and maintain multicast group memberships.

- Multicast routing protocols:

  A multicast routing protocol runs on Layer 3 multicast devices to establish and maintain multicast routes and correctly and efficiently forward multicast packets. Multicast routes constitute loop-free data transmission paths (also known as multicast distribution trees) from a data source to multiple receivers.

  In the ASM model, multicast routes include intra-domain routes and inter-domain routes.

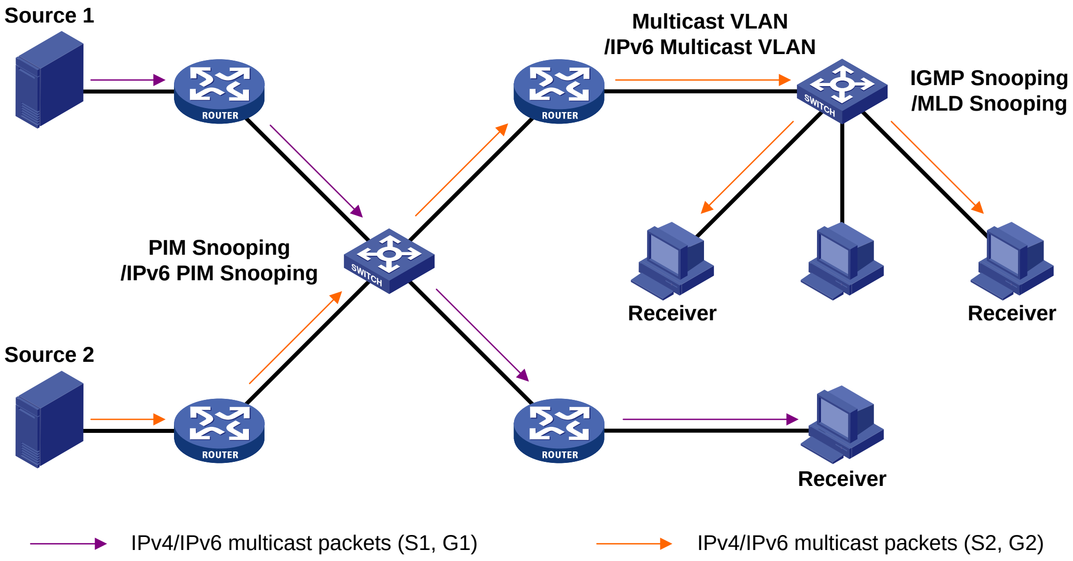
  - An intra-domain multicast routing protocol discovers multicast sources and builds multicast distribution trees within an AS to deliver multicast data to receivers. Among a variety of mature intra-domain multicast routing protocols, PIM is most widely used. Based on the forwarding mechanism, PIM has dense mode (often referred to as PIM-DM) and sparse mode (often referred to as PIM-SM).
  - An inter-domain multicast routing protocol is used for delivering multicast information between two ASs. So far, mature solutions include Multicast Source Discovery Protocol (MSDP) and MBGP. MSDP propagates multicast source information among different ASs. MBGP is an extension of the MP-BGP for exchanging multicast routing information among different ASs.

  For the SSM model, multicast routes are not divided into intra-domain routes and inter-domain routes. Because receivers know the positions of the multicast sources, channels established through PIM-SM are sufficient for the transport of multicast information.

Layer 2 multicast protocols

In Figure 9, Layer 2 multicast protocols include IGMP snooping, MLD snooping, PIM snooping, IPv6 PIM snooping, multicast VLAN, and IPv6 multicast VLAN.

Figure 9 Positions of Layer 2 multicast protocols



- IGMP snooping and MLD snooping:

  IGMP snooping and MLD snooping are multicast constraining mechanisms that run on Layer 2 devices. They manage and control multicast groups by monitoring and analyzing IGMP or MLD messages exchanged between the hosts and Layer 3 multicast devices. This effectively controls the flooding of multicast data in Layer 2 networks.

- PIM snooping and IPv6 PIM snooping:

  PIM snooping and IPv6 PIM snooping run on Layer 2 devices. They work with IGMP snooping or MLD snooping to analyze received PIM messages. Then, they add the ports that are interested in specific multicast data to a PIM snooping routing entry or IPv6 PIM snooping routing entry. In this way, multicast data can be forwarded to only the ports that are interested in the data.

- Multicast VLAN and IPv6 multicast VLAN:

  Multicast VLAN or IPv6 multicast VLAN runs on a Layer 2 device in a multicast network where multicast receivers for the same group exist in different VLANs. With these protocols, the Layer 3 multicast device sends only one copy of multicast to the multicast VLAN or IPv6 multicast VLAN on the Layer 2 device. This method avoids waste of network bandwidth and extra burden on the Layer 3 device.

Multicast packet forwarding mechanism

In a multicast model, receiver hosts of a multicast group are usually located at different areas on the network. They are identified by the same multicast group address. To deliver multicast packets to these receivers, a multicast source encapsulates the multicast data in an IP packet with the multicast group address as the destination address. Multicast routers on the forwarding paths forward multicast packets that an incoming interface receives through multiple outgoing interfaces. Compared to a unicast model, a multicast model is more complex in the following aspects:

- To ensure multicast packet transmission on the network, different routing tables are used to guide multicast forwarding. These routing tables include unicast routing tables, routing tables for multicast (for example, the MBGP routing table), and static multicast routing tables.
- To process the same multicast information from different peers received on different interfaces, the multicast device performs an RPF check on each multicast packet. The RPF check result determines whether the packet will be forwarded or discarded. The RPF check mechanism is the basis for most multicast routing protocols to implement multicast forwarding.

For more information about the RPF mechanism, see "Configuring multicast routing and forwarding" and "Configuring IPv6 multicast routing and forwarding."

IP multicast architecture

IP multicast addresses the following issues:

- Where should the multicast source transmit information to? (Multicast addressing.)
- What receivers exist on the network? (Host registration.)
- Where is the multicast source that will provide data to the receivers? (Multicast source discovery.)
- How is the information transmitted to the receivers? (Multicast routing.)

IP multicast is an end-to-end service. The multicast architecture involves the following parts:

- **Addressing mechanism**—A multicast source sends information to a group of receivers through a multicast address.
- **Host registration**—Receiver hosts can join and leave multicast groups dynamically. This mechanism is the basis for management of group memberships.
- **Multicast routing**—A multicast distribution tree (a forwarding path tree for multicast data on the network) is constructed for delivering multicast data from a multicast source to receivers.
- **Multicast applications**—A software system that supports multicast applications, such as video conferencing, must be installed on multicast sources and receiver hosts. The TCP/IP stack must support reception and transmission of multicast data.

Common notations in multicast

The following notations are commonly used in multicast transmission:

- **(*, G)**—Rendezvous point tree (RPT), or a multicast packet that any multicast source sends to multicast group G. The asterisk (*) represents any multicast source, and "G" represents a specific multicast group.
- **(S, G)**—Shortest path tree (SPT), or a multicast packet that multicast source "S" sends to multicast group "G." "S" represents a specific multicast source, and "G" represents a specific multicast group.

For more information about the concepts RPT and SPT, see "Configuring PIM."

Contents

Configuring multicast routing and forwarding

About multicast routing and forwarding

Each multicast routing protocol has its own routing table. Multicast routing information in routing entries generated by the multicast routing protocols and statically configured multicast routing entries are summarized in a set of (S, G) and (*, G) entries. All the (S, G) and (*, G) entries form a general multicast routing table. The optimal multicast routing entries in the general multicast routing table are added to the multicast forwarding table to guide multicast data forwarding.

RPF check mechanism

A multicast routing protocol uses reverse path forwarding (RPF) check to ensure the multicast data delivery along the correct path and to avoid data loops.

RPF check process

A multicast device performs the RPF check on a multicast packet as follows:

1. Chooses an optimal route back to the packet source separately from the unicast, MBGP, and static multicast routing tables.

   The term "packet source" means different things in different situations:

   - For a packet that travels along the SPT, the packet source is the multicast source.
   - For a packet that travels along the RPT, the packet source is the RP.
   - For a bootstrap message originated from the BSR, the packet source is the BSR.

   For more information about the concepts of SPT, RPT, source-side RPT, RP, and BSR, see "Configuring PIM."
2. Selects one of the three optimal routes as the RPF route as follows:
   - If the device uses the longest prefix match principle, the route with the highest subnet mask becomes the RPF route. If the routes have the same mask, the route with the highest route preference becomes the RPF route. If the routes have the same route preference, the unicast route becomes the RPF route. If equal cost routes exist, the route with the highest next hop IP address becomes the RPF route.

     For more information about the route preference, see *Layer 3—IP Routing Configuration Guide*.
   - If the device does not use the longest prefix match principle, the route with the highest route preference becomes the RPF route. If the routes have the same preference, the unicast route becomes the RPF route. If equal cost routes exist, the route with the highest next hop IP address becomes the RPF route.

   The RPF route contains the RPF interface and RPF neighbor information.

   - If the RPF route is a unicast route or MBGP route, the outgoing interface is the RPF interface and the next hop is the RPF neighbor.
   - If the RPF route is a static multicast route, the RPF interface and RPF neighbor are specified in the route.
3. Determines whether the packet arrived at the RPF interface.
   - If the packet arrived at the RPF interface, the RPF check succeeds and the packet is forwarded.

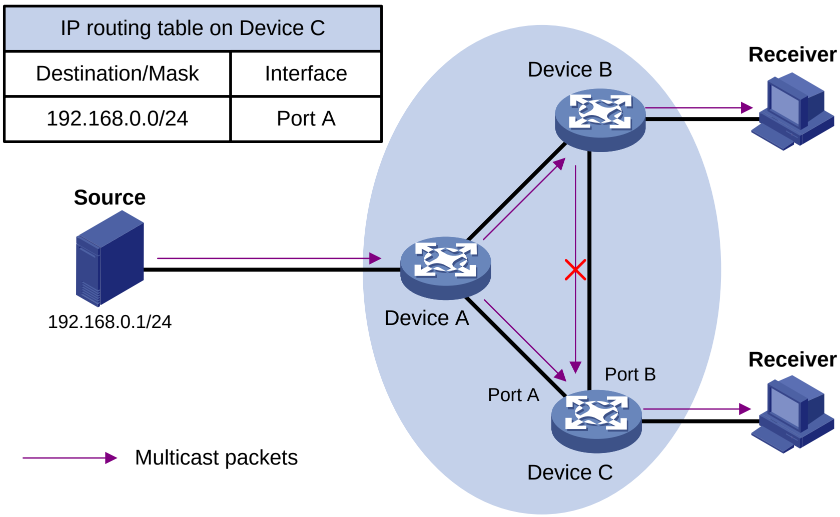
  - If the packet arrived at the non-RPF interface, the RPF check fails and the packet is discarded.

RPF check implementation in multicast

Implementing an RPF check on each received multicast packet brings a big burden to the device. The use of a multicast forwarding table is the solution to this issue. When the device creates a multicast forwarding entry for an (S, G) packet, it sets the RPF interface of the packet as the incoming interface of the (S, G) entry. After the device receives another (S, G) packet, it looks up the multicast forwarding table for a matching (S, G) entry.

- If no match is found, the device first determines the RPF route back to the packet source and the RPF interface. Then, it creates a forwarding entry with the RPF interface as the incoming interface and makes the following judgments:
  - If the receiving interface is the RPF interface, the RPF check succeeds and the device forwards the packet out of all the outgoing interfaces.
  - If the receiving interface is not the RPF interface, the RPF check fails and the device discards the packet.
- If a match is found and the matching forwarding entry contains the receiving interface, the device forwards the packet out of all the outgoing interfaces.
- If a match is found but the matching forwarding entry does not contain the receiving interface, the device determines the RPF route back to the packet source. Then, the device performs one of the following actions:
  - If the RPF interface is the incoming interface, it means that the forwarding entry is correct but the packet traveled along a wrong path. The packet fails the RPF check, and the device discards the packet.
  - If the RPF interface is not the incoming interface, it means that the forwarding entry has expired. The device replaces the incoming interface with the RPF interface and matches the receiving interface against the RPF interface. If the receiving interface is the RPF interface, the device forwards the packet out of all outgoing interfaces. Otherwise, it discards the packet.

Figure 1 RPF check process



IP routing table on Device C	
Destination/Mask	Interface
192.168.0.0/24	Port A

As shown in Figure 1, assume that unicast routes are available on the network, MBGP is not configured, and no static multicast routes have been configured on Device C. Multicast packets travel along the SPT from the multicast source to the receivers. The multicast forwarding table on Device C contains the (S, G) entry, with Port A as the incoming interface.

- If a multicast packet arrives at Device C on Port A, the receiving interface is the incoming interface of the (S, G) entry. Device C forwards the packet out of all outgoing interfaces.

- If a multicast packet arrives at Device C on Port B, the receiving interface is not the incoming interface of the (S, G) entry. Device C searches its unicast routing table and finds that the outgoing interface to the source (the RPF interface) is Port A. In this case, the (S, G) entry is correct, but the packet traveled along a wrong path. The packet fails the RPF check and Device C discards the packet.

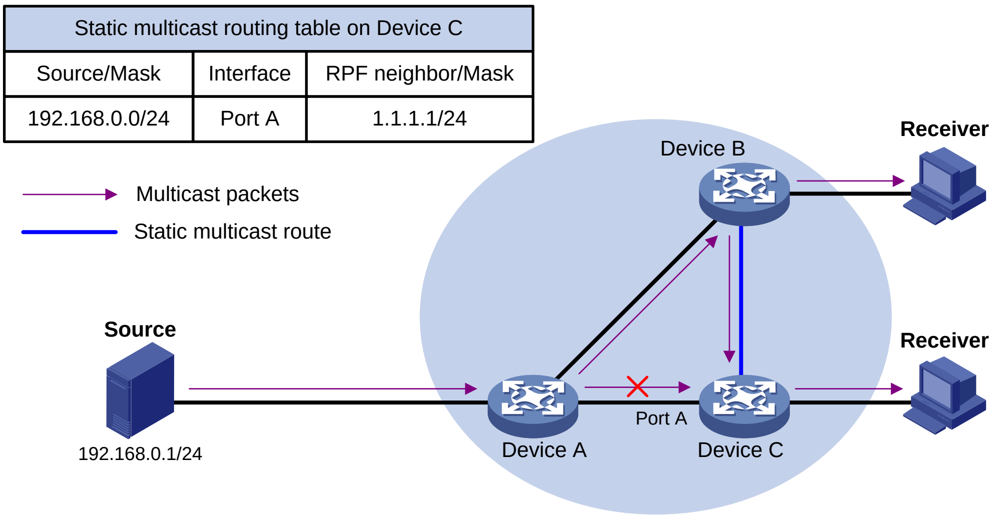
Usages of static multicast routes

A static multicast route can change an RPF route or create an RPF route.

Changing an RPF route

Typically, the topology structure of a multicast network is the same as that of a unicast network, and multicast traffic follows the same transmission path as unicast traffic does. You can configure a static multicast route for a multicast source to change the RPF route. As a result, the device creates a transmission path for multicast traffic that is different from the transmission path for unicast traffic.

Figure 2 Changing an RPF route



Static multicast routing table on Device C

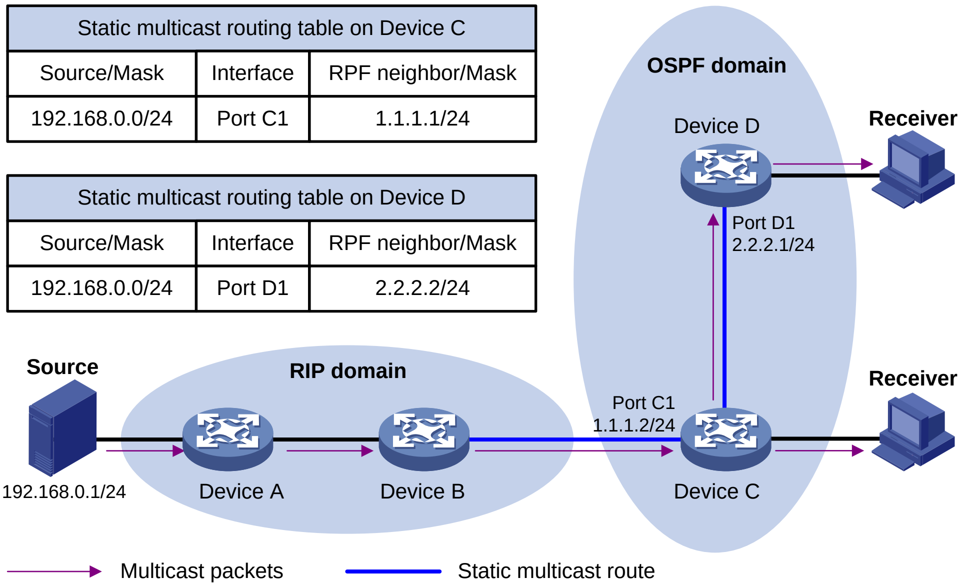
Source/Mask	Interface	RPF neighbor/Mask
192.168.0.0/24	Port A	1.1.1.1/24

As shown in Figure 2, when no static multicast route is configured, Device C's RPF neighbor on the path back to the source is Device A. The multicast data from the source travels through Device A to Device C. You can configure a static multicast route on Device C and specify Device B as Device C's RPF neighbor on the path back to the source. The multicast data from the source travels along the path: Device A to Device B and then to Device C.

Creating an RPF route

When a unicast route is blocked, multicast forwarding might be stopped due to lack of an RPF route. You can configure a static multicast route to create an RPF route. In this way, a multicast routing entry is created to guide multicast forwarding.

Figure 3 Creating an RPF route



Static multicast routing table on Device C		
Source/Mask	Interface	RPF neighbor/Mask
192.168.0.0/24	Port C1	1.1.1.1/24

Static multicast routing table on Device D		
Source/Mask	Interface	RPF neighbor/Mask
192.168.0.0/24	Port D1	2.2.2.2/24

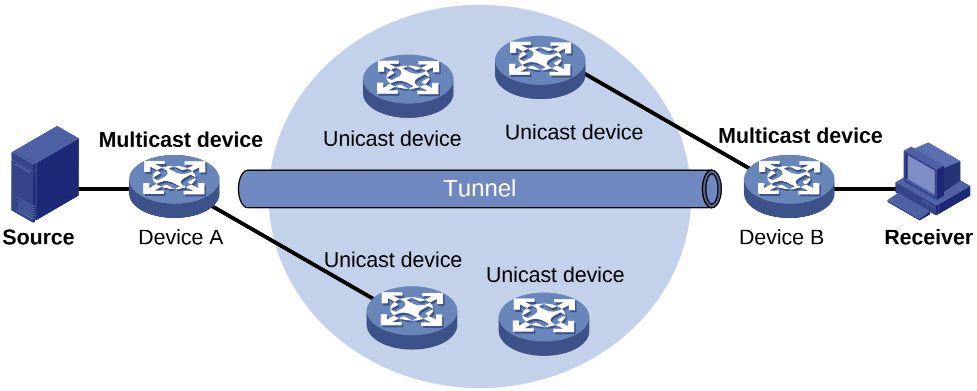
As shown in Figure 3, the RIP domain and the OSPF domain are unicast isolated from each other. For the receiver hosts in the OSPF domain to receive multicast packets from the multicast source in the RIP domain, you must configure Device C and Device D as follows:

- On Device C, configure a static multicast route for the multicast source and specify Device B as the RPF neighbor.
- On Device D, configure a static multicast route for the multicast source and specify Device C as the RPF neighbor.

Multicast forwarding across unicast subnets

Devices forward the multicast data from a multicast source hop by hop along the forwarding tree, but some devices might not support multicast protocols in a network. When the multicast data is forwarded to a device that does not support IP multicast, the forwarding path is blocked. In this case, you can enable multicast forwarding across two unicast subnets by establishing a tunnel between the devices at the edges of the two unicast subnets.

Figure 4 Multicast data transmission through a tunnel



As shown in Figure 4, a tunnel is established between Device A and Device B. Device A encapsulates the multicast data in unicast IP packets, and forwards them to Device B across the tunnel through unicast devices. Then, Device B strips off the unicast IP header and continues to forward the multicast data to the receiver.

To use this tunnel only for multicast traffic, configure the tunnel as the outgoing interface only for multicast routes.

Restrictions and guidelines: Multicast routing and forwarding configuration

The device can route and forward multicast data only through the primary IP addresses of interfaces, rather than their secondary addresses or unnumbered IP addresses. For more information about primary and secondary IP addresses, and IP unnumbered, see *Layer 3—IP Services Configuration Guide.*

Multicast routing and forwarding tasks at a glance

To configure multicast routing and forwarding, perform the following tasks:

1. Enabling IP multicast routing
2. (Optional.) Configuring static multicast routes
3. (Optional.) Specifying the longest prefix match principle
4. (Optional.) Configuring multicast load splitting
5. (Optional.) Configuring a multicast forwarding boundary
6. (Optional.) Setting the maximum number of cached unknown multicast packets
7. (Optional.) Configuring an IPv4 MVPN extranet RPF selection policy

Prerequisites for multicast routing and forwarding

Before you configure multicast routing and forwarding, configure a unicast routing protocol so that all devices in the domain can interoperate at the network layer.

Enabling IP multicast routing

About this task

Enable IP multicast routing before you configure any Layer 3 multicast functionality on the public network or VPN instance.

Procedure

1. Enter system view.

   system-view

2. Enable IP multicast routing and enter MRIB view.

   multicast routing [**vpn-instance** *vpn-instance-name*]

   By default, IP multicast routing is disabled.

Configuring static multicast routes

About this task

To configure a static multicast route for a multicast source, you can specify an RPF interface or an RPF neighbor for the multicast traffic from that source.

Restrictions and guidelines

Static multicast routes take effect only on the multicast devices on which they are configured, and will not be advertised throughout the network or redistributed to other devices.

Procedure

1. Enter system view.

   system-view

2. Configure a static multicast route.

   ip rpf-route-static [**vpn-instance** *vpn-instance-name*] *source-address* { *mask-length* | *mask* } { *rpf-nbr-address* | *interface-type interface-number* } [**preference** *preference*]

3. (Optional.) Delete all static multicast routes.

   delete ip rpf-route-static [**vpn-instance** *vpn-instance-name*]

   You can use the **undo ip rpf-route-static** command to delete a specific static multicast route or use the **delete ip rpf-route-static** command to delete all static multicast routes.

Specifying the longest prefix match principle

About this task

You can enable the device to use the longest prefix match principle for RPF route selection. For more information about RPF route selection, see "RPF check process."

Procedure

1. Enter system view.

   system-view

2. Enter MRIB view.

   multicast routing [**vpn-instance** *vpn-instance-name*]

3. Specify the longest prefix match principle.

   longest-match

   By default, the route preference principle is used.

Configuring multicast load splitting

About this task

You can enable the device to split multiple data flows on a per-source basis or on a per-source-and-group basis. This optimizes the traffic delivery.

Restrictions and guidelines

This feature does not take effect on BIDIR-PIM.

Procedure

1. Enter system view.

   system-view

2. Enter MRIB view.

   multicast routing [**vpn-instance** *vpn-instance-name*]

3. Configure multicast load splitting.

load-splitting { **source** | **source-group** }

By default, multicast load splitting is disabled.

Configuring a multicast forwarding boundary

About this task

You can configure an interface as a multicast forwarding boundary for a multicast group range. The interface cannot receive or forward multicast packets for the group range.

Restrictions and guidelines

You do not need to enable IP multicast before this configuration.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the interface as a multicast forwarding boundary for a multicast group range.

   multicast boundary *group-address* { *mask-length* | *mask* }

   By default, an interface is not a multicast forwarding boundary.

Setting the maximum number of cached unknown multicast packets

About this task

The device caches a multicast packet for a period of time if no matching multicast forwarding entry is found for the packet. If a multicast forwarding entry is established for the packet within the time period, the device forwards the packet. This mechanism prevents the device from mistakenly dropping multicast packets when the multicast forwarding entries for these packets are to be created.

You can set the maximum number of unknown multicast packets that can be cached for an (S, G) entry, in total, or both.

Restrictions and guidelines

As a best practice, set the value in the **multicast forwarding-table cache-unknown total** command to be far greater than the value in the **multicast forwarding-table cache-unknown per-entry** command.

Procedure

1. Enter system view.

   system-view

2. Set the maximum number of unknown multicast packets that can be cached for an (S, G) entry.

   multicast forwarding-table cache-unknown per-entry *per-entry-limit*

   By default, the device can cache only one unknown multicast packet for an (S, G) entry.

3. Set the maximum number of unknown multicast packets that can be cached in total.

   multicast forwarding-table cache-unknown total *total-limit*

   By default, the device can cache 1024 unknown multicast packets in total.

Configuring an IPv4 MVPN extranet RPF selection policy

About this task

IPv4 MVPN extranet RPF routing policies are used for IPv4 multicast transmission when multicast sources and receivers are located in different VPNs.

Restrictions and guidelines

The PIM modes in the source VPN instance and the receiver VPN instance must be the same. Only PIM-SM and PIM-SSM are supported.

Multicast packets can only be forwarded between two VPNs. The receiver VPN instance cannot also be the source VPN instance.

In PIM-SM mode, you can configure only one RPF selection policy for a multicast group in a VPN instance.

If an IPv4 MVPN extranet RPF selection policy with only the multicast group address specified is configured in the receiver VPN instance, the multicast traffic for the intra-VPN transmission will be interrupted.

To implement source-specific RPF selection in MVPN extranet, you must configure two MVPN extranet RPF routing policies as follows:

- In one policy, specify the address of the RP designated to the multicast group that requires inter-VPN multicast communication as the source address.
- In the other policy, specify the multicast source in the source VPN instance as the source address.

To implement source-and-group-specific RPF selection in MVPN extranet, you must configure two MVPN extranet RPF routing policies as follows:

- In one policy, specify the address of the RP designated to the multicast group as the source address, and specify the multicast group.
- In the other policy, specify the multicast source in the source VPN instance as the source address, and specify the multicast group.
- Make sure the multicast groups in the two policies are the same to avoid inter-VPN multicast transmission failure.

Common Layer 3 multicast supports both the source-PE-based MVPN extranet option and receiver-PE-based MVPN extranet option.

For the source-PE-based MVPN extranet option, if PIM-SM mode is used, the RP of the receiver VPN instance must be configured on the multicast source-side device.

Procedure

1. Enter system view.

   system-view

2. Enter MRIB view.

   multicast routing [**vpn-instance** *vpn-instance-name*]

3. Configure an IPv4 MVPN extranet RPF selection policy.

   multicast extranet select-rpf [**vpn-instance** *vpn-instance-name*] { **source** *source-address* { *mask* | *mask-length* } | **group** *group-address* { *mask* | *mask-length* } } *

   By default, no IPv4 MVPN extranet RPF selection policies are configured.

Display and maintenance commands for multicast routing and forwarding

CAUTION:

The **reset** commands might cause multicast data transmission failures.

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about the interfaces maintained by the MRIB.	**display mrib** [**vpn-instance** *vpn-instance-name*] **interface** [*interface-type interface-number*]
Display multicast boundary information.	**display multicast** [**vpn-instance** *vpn-instance-name*] **boundary** [*group-address* [*mask-length* | *mask*]] [**interface** *interface-type interface-number*]
Display multicast fast forwarding entries.	**display multicast** [**vpn-instance** *vpn-instance-name*] **fast-forwarding cache** [*source-address* | *group-address*] * [**slot** *slot-number*]
Display DF information.	**display multicast** [**vpn-instance** *vpn-instance-name*] **forwarding df-info** [*rp-address*] [**verbose**] [**slot** *slot-number*]
Display statistics for multicast forwarding events.	**display multicast** [**vpn-instance** *vpn-instance-name*] **forwarding event** [**slot** *slot-number*]
Display multicast forwarding entries.	**display multicast** [**vpn-instance** *vpn-instance-name*] **forwarding-table** [*source-address* [**mask** { *mask-length* | *mask* }] | *group-address* [**mask** { *mask-length* | *mask* }] | **incoming-interface** *interface-type interface-number* | **outgoing-interface** { **exclude** | **include** | **match** } *interface-type interface-number* | **slot** *slot-number* | **statistics**] *
Display information about the DF list in the multicast forwarding table.	**display multicast** [**vpn-instance** *vpn-instance-name*] **forwarding-table df-list** [*group-address*] [**verbose**] [**slot** *slot-number*]
Display multicast routing entries.	**display multicast** [**vpn-instance** *vpn-instance-name*] **routing-table** [*source-address* [**mask** { *mask-length* | *mask* }] | *group-address* [**mask** { *mask-length* | *mask* }] | **incoming-interface** *interface-type interface-number* | **outgoing-interface** { **exclude** | **include** |

Task	Command
	match } *interface-type interface-number*] *
Display static multicast routing entries.	**display multicast** [**vpn-instance** *vpn-instance-name*] **routing-table static** [*source-address* { *mask-length* | *mask* }]
Display RPF information for a multicast source.	**display multicast** [**vpn-instance** *vpn-instance-name*] **rpf-info** *source-address* [*group-address*]
Clear multicast fast forwarding entries.	**reset multicast** [**vpn-instance** *vpn-instance-name*] **fast-forwarding cache** { { *source-address* | *group-address* } * | **all** } [**slot** *slot-number*]
Clear statistics for multicast forwarding events.	**reset multicast** [**vpn-instance** *vpn-instance-name*] **forwarding event**
Clear multicast forwarding entries.	**reset multicast** [**vpn-instance** *vpn-instance-name*] **forwarding-table** { { *source-address* [**mask** { *mask-length* | *mask* }] | *group-address* [**mask** { *mask-length* | *mask* }] | **incoming-interface** { *interface-type interface-number* } } * | **all** }
Clear multicast routing entries.	**reset multicast** [**vpn-instance** *vpn-instance-name*] **routing-table** { { *source-address* [**mask** { *mask-length* | *mask* }] | *group-address* [**mask** { *mask-length* | *mask* }] | **incoming-interface** *interface-type interface-number* } * | **all** }

NOTE:

- When you clear a multicast routing entry, the associated multicast forwarding entry is also cleared.
- When you clear a multicast forwarding entry, the associated multicast routing entry is also cleared.

Troubleshooting multicast routing and forwarding

Static multicast route failure

Symptom

No dynamic routing protocol is enabled on the routers, and the physical status and link layer status of interfaces are both up, but the static multicast route fails.

Solution

To resolve the problem:

1. Use the **display multicast routing-table static** command to display information about static multicast routes. Verify that the static multicast route has been correctly configured and that the route entry exists in the static multicast routing table.
2. Check the type of interface that connects the static multicast route to the RPF neighbor. If the interface is not a point-to-point interface, be sure to specify the address for the RPF neighbor.

3. If the problem persists, contact NSFOCUS Support.

Contents

Configuring IGMP

About IGMP

Internet Group Management Protocol (IGMP) establishes and maintains the multicast group memberships between a Layer 3 multicast device and the hosts on the directly connected subnet.

IGMP versions

IGMP has the following versions:

- IGMPv1 (defined by RFC 1112).
- IGMPv2 (defined by RFC 2236).
- IGMPv3 (defined by RFC 3376).

All IGMP versions support the ASM model. IGMPv3 can directly implement the SSM model. IGMPv1 and IGMPv2 must work with the IGMP SSM mapping feature to implement the SSM model. For more information about the ASM and SSM models, see "Multicast overview."

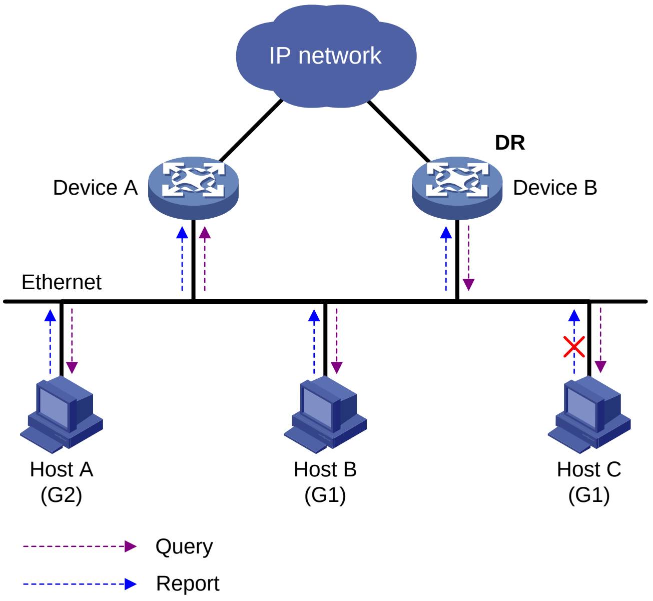
IGMPv1 overview

IGMPv1 manages multicast group memberships based on the query and response mechanism.

All devices that run IGMP on the same subnet can get IGMP membership report messages (called reports) from hosts. However, only one device can act as the IGMP querier to send IGMP query messages (called queries). The querier election mechanism determines which device acts as the IGMP querier on the subnet.

In IGMPv1, the DR elected by the multicast routing protocol (such as PIM) acts as the IGMP querier. For more information about DR, see "Configuring PIM."

Figure 1 IGMP queries and reports



As shown in Figure 1, Host B and Host C are interested in the multicast data addressed to the multicast group G1. Host A is interested in the multicast data addressed to G2. The following process describes how the hosts join the multicast groups and how the IGMP querier (Device B in Figure 1) maintains the multicast group memberships:

1. The hosts send unsolicited IGMP reports to the multicast groups they want to join without having to wait for the IGMP queries.
2. The IGMP querier periodically multicasts IGMP queries (with the destination address of 224.0.0.1) to all hosts and devices on the local subnet.
3. After receiving a query message, the host whose report delay timer expires first sends an IGMP report to multicast group G1 to announce its membership for G1. In this example, Host B sends the report message. After receiving the report from Host B, Host C suppresses its own report for G1.

   Because IGMP devices already know that G1 has a minimum of one member, other members do not need to report their memberships. This mechanism, known as the host IGMP report suppression, helps reduce traffic on the local subnet.
4. At the same time, Host A sends a report to the multicast group G2 after receiving a query.
5. Through the query and response process, the IGMP devices (Device A and Device B) determine that the local subnet has members of G1 and G2. The multicast routing protocol (PIM, for example) on the devices generates (*, G1) and (*, G2) multicast forwarding entries, where asterisk (*) represents any multicast source. These entries are the basis for subsequent multicast forwarding.
6. When the multicast data addressed to G1 or G2 reaches an IGMP device, the device looks up the multicast forwarding table. Based on the (*, G1) or (*, G2) entries, the device forwards the multicast data to the local subnet. Then, the receivers on the subnet can receive the data.

IGMPv1 does not define a leave group message (often called a leave message). When an IGMPv1 host is leaving a multicast group, it stops sending reports to that multicast group. If the subnet has no members for a multicast group, the IGMP devices will not receive any report addressed to that multicast group. In this case, the devices clear the information for that multicast group after a period of time.

IGMPv2 enhancements

Backwards-compatible with IGMPv1, IGMPv2 has introduced a querier election mechanism and a leave-group mechanism.

Querier election mechanism

In IGMPv1, the DR elected by the Layer 3 multicast routing protocol (such as PIM) acts as the querier.

IGMPv2 introduced an independent querier election mechanism. The querier election process is as follows:

1. Initially, every IGMPv2 device assumes itself to be the querier. Each device sends IGMP general query messages (called general queries) to all hosts and devices on the local subnet. The destination address is 224.0.0.1.
2. After receiving a general query, every IGMPv2 device compares the source IP address of the query with its own interface address. The device with the lowest IP address becomes the querier. All the other IGMPv2 devices become non-queriers.
3. All the non-queriers start the other querier present timer. If a device receives an IGMP query from the querier before the timer expires, it resets this timer. Otherwise, the device considers that the querier has timed out. In this case, the device initiates a new querier election process.

"Leave group" mechanism

In IGMPv1, when a host leaves a multicast group, it does not send any notification to the multicast devices. The multicast devices determine whether a group has members by using the maximum response time. This adds to the leave latency.

In IGMPv2, when a host is leaving a multicast group, the following process occurs:

1. The host sends a leave message to all devices on the local subnet. The destination address of leave messages is 224.0.0.2.
2. After receiving the leave message, the querier sends a configurable number of IGMP group-specific queries to the group that the host is leaving. Both the destination address field and the group address field of the message are the address of the multicast group that is being queried.
3. One of the remaining members (if any on the subnet) in the group should send a report within the maximum response time advertised in the group-specific queries.
4. If the querier receives a report for the group before the maximum response timer expires, it maintains the memberships for the group. Otherwise, the querier assumes that the local subnet has no member hosts for the group and stops maintaining the memberships for the group.

IGMPv3 enhancements

IGMPv3 is based on and is compatible with IGMPv1 and IGMPv2. It enhances the control capabilities of hosts and the query and report capabilities of IGMP devices.

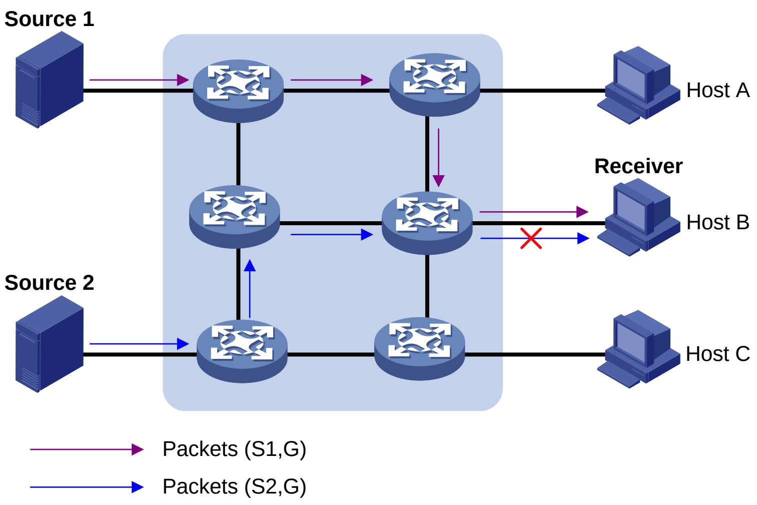
Enhancements in control capability of hosts

IGMPv3 introduced two source filtering modes (Include and Exclude). These modes allow a host to receive or reject multicast data from the specified multicast sources. When a host joins a multicast group, one of the following occurs:

- If the host expects to receive multicast data from specific sources like S1, S2, …, it sends a report with the Filter-Mode denoted as "Include Sources (S1, S2, …)."
- If the host expects to reject multicast data from specific sources like S1, S2, …, it sends a report with the Filter-Mode denoted as "Exclude Sources (S1, S2, …)."

As shown in Figure 2, the network has two multicast sources: Source 1 (S1) and Source 2 (S2). Both of these sources can send multicast data to the multicast group G. Host B wants to receive the multicast data addressed to G from Source 1 but not from Source 2.

Figure 2 Flow paths of source-and-group-specific multicast traffic



In IGMPv1 or IGMPv2, Host B cannot select multicast sources when it joins the multicast group G. The multicast streams from both Source 1 and Source 2 flow to Host B whether or not it needs them.

In IGMPv3, Host B can explicitly express that it needs to receive multicast data destined to the multicast group G from Source 1 but not from Source 2.

Enhancements in query and report capabilities

IGMPv3 introduces IGMP group-and-source queries and IGMP reports carrying group records.

- Query message carrying the source addresses

  IGMPv3 is compatible with IGMPv1 and IGMPv2 and supports IGMP general queries and IGMP group-specific queries. It also introduces IGMP group-and-source-specific queries.

  - A general query does not carry a group address or a source address.
  - A group-specific query carries a group address, but no source address.
  - A group-and-source-specific query carries a group address and one or more source addresses.

- Reports containing multiple group records

  Unlike an IGMPv1 or IGMPv2 report, an IGMPv3 report is destined to 224.0.0.22 and contains one or more group records. Each group record contains a multicast group address and a multicast source address list.

  Group records include the following categories:

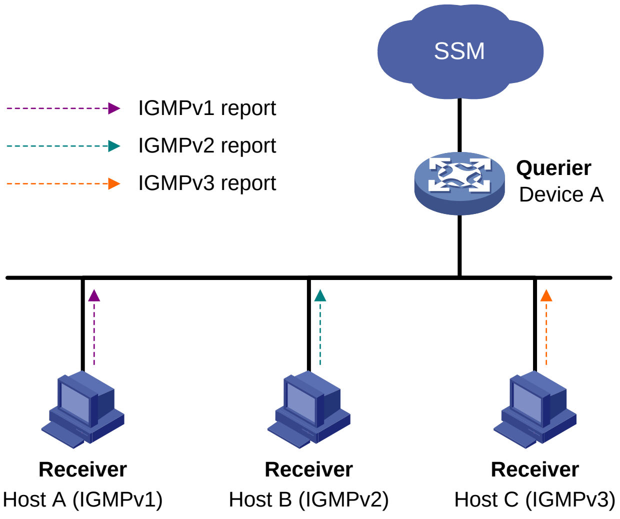
  - **IS_IN**—The current filtering mode is Include. The report sender requests the multicast data only from the sources specified in the Source Address field.
  - **IS_EX**—The current filtering mode is Exclude. The report sender requests the multicast data from any sources except those specified in the Source Address field.
  - **TO_IN**—The filtering mode has changed from Exclude to Include.
  - **TO_EX**—The filtering mode has changed from Include to Exclude.
  - **ALLOW**—The Source Address field contains a list of additional sources from which the receiver wants to obtain data. If the current filtering mode is Include, these sources are added to the multicast source list. If the current filtering mode is Exclude, these sources are deleted from the multicast source list.
  - **BLOCK**—The Source Address field contains a list of the sources from which the receiver no longer wants to obtain data. If the current filtering mode is Include, these sources are deleted from the multicast source list. If the current filtering mode is Exclude, these sources are added to the multicast source list.

IGMP SSM mapping

An IGMPv3 host can explicitly specify multicast sources in its IGMPv3 reports. From the reports, the IGMP device can obtain the multicast source addresses and directly provide the SSM service. However, an IGMPv1 or IGMPv2 host cannot specify multicast sources in its IGMPv1 or IGMPv2 reports.

The IGMP SSM mapping feature enables the IGMP device to provide SSM support for IGMPv1 or IGMPv2 hosts. The device translates (*, G) in IGMPv1 or IGMPv2 reports into (G, INCLUDE, (S1, S2...)) based on the configured IGMP SSM mappings.

Figure 3 IGMP SSM mapping



As shown in Figure 3, on an SSM network, Host A, Host B, and Host C run IGMPv1, IGMPv2, and IGMPv3, respectively. To provide the SSM service for Host A and Host B, you must configure the IGMP SSM mapping feature on Device A.

After IGMP SSM mappings are configured, Device A checks the multicast group address G in the received IGMPv1 or IGMPv2 report, and performs the following operations:

- If G is not in the SSM group range, Device A provides the ASM service.
- If G is in the SSM group range but does not match any IGMP SSM mapping, Device A drops the report.
- If G is in the SSM group range and matches IGMP SSM mappings, Device A translates (*, G) in the report into (G, INCLUDE, (S1, S2...)) to provide SSM services.

NOTE:

The IGMP SSM mapping feature does not process IGMPv3 reports.

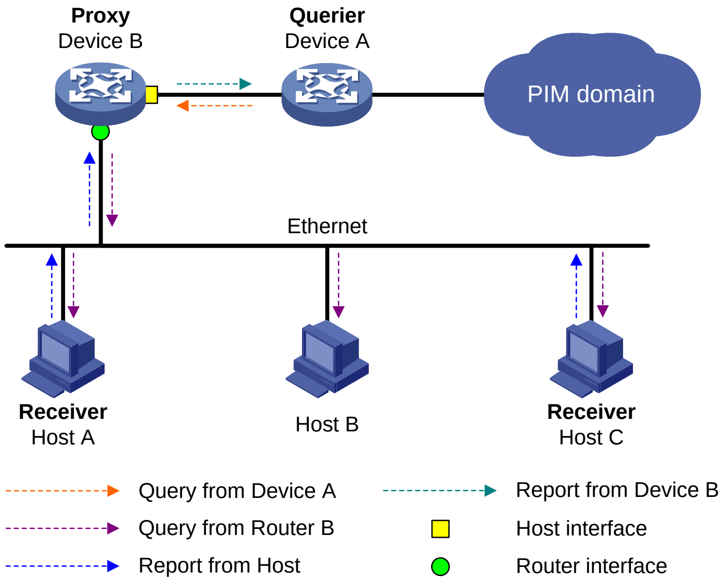
For more information about SSM group ranges, see "Configuring PIM."

IGMP proxying

As shown in Figure 4, in a simple tree-shaped topology, it is not necessary to run multicast routing protocols, such as PIM, on edge devices. Instead, you can configure IGMP proxying on these devices. With IGMP proxying configured, the edge device acts as an IGMP proxy:

- For the upstream IGMP querier, the IGMP proxy device acts as a host.
- For the downstream receiver hosts, the IGMP proxy device acts as an IGMP querier.

Figure 4 IGMP proxying



The following types of interfaces are defined in IGMP proxying:

- **Host interface**—An interface that is in the direction toward the root of the multicast forwarding tree. A host interface acts as a receiver host that is running IGMP. IGMP proxying must be enabled on this interface. This interface is also called the "proxy interface."
- **Router interface**—An interface that is in the direction toward the leaf of the multicast forwarding tree. A router interface acts as a router that is running IGMP. IGMP must be configured on this interface.

An IGMP proxy device maintains a group membership database, which stores the group memberships on all the router interfaces. The host interfaces and router interfaces perform actions based on this membership database.

- The host interfaces respond to queries according to the membership database or send join/leave messages when the database changes.
- The router interfaces participate in the querier election, send queries, and maintain memberships based on received IGMP reports.

IGMP support for VPNs

IGMP maintains group memberships on a per-interface basis. After receiving an IGMP message on an interface, IGMP processes the packet within the VPN to which the interface belongs. IGMP only communicates with other multicast protocols within the same VPN instance.

Protocols and standards

- RFC 1112, *Host Extensions for IP Multicasting*
- RFC 2236, *Internet Group Management Protocol, Version 2*
- RFC 3376, *Internet Group Management Protocol, Version 3*

IGMP tasks at a glance

To configure IGMP, perform the following tasks:

1. Enabling IGMP
2. (Optional.) Configuring basic IGMP features
   - Specifying an IGMP version
   - Configuring a static group member
   - Configuring a multicast group policy
3. (Optional.) Adjusting IGMP performance
   - Configuring IGMP query and response parameters
   - Enabling fast-leave processing
4. (Optional.) Configuring IGMP SSM mappings
5. (Optional.) Configuring IGMP proxying
   - Enabling IGMP proxying
   - Enabling multicast forwarding on a non-querier interface
   - Configuring multicast load splitting for IGMP proxy interfaces
6. (Optional.) Enabling IGMP NSR

Prerequisites for IGMP

Before you configure IGMP, you must configure any unicast routing protocol so that all devices can interoperate at the network layer.

Enabling IGMP

Restrictions and guidelines

Enable IGMP on interfaces where the multicast group memberships are established and maintained.

Procedure

1. Enter system view.
   system-view
2. Enable IP multicast routing and enter MRIB view.
   multicast routing [**vpn-instance** *vpn-instance-name*]
   By default, IP multicast routing is disabled.
   For more information about this command, see *IP Multicast Command Reference*.
3. Return to system view.
   quit
4. Enter interface view.
   interface *interface-type interface-number*
5. Enable IGMP.
   igmp enable
   By default, IGMP is disabled.

Configuring basic IGMP features

Specifying an IGMP version

1. Enter system view.

```
system-view
```

2. Enter interface view.

```
interface interface-type interface-number
```

3. Specify an IGMP version on the interface.

```
igmp version version-number
```

By default, the IGMP version on an interface is IGMPv2.

CAUTION:

For IGMP to operate correctly, specify the same IGMP version for all devices on the same subnet.

Configuring a static group member

About this task

You can configure an interface as a static group member of a multicast group. Then, the interface can always receive multicast data addressed to the specified multicast group.

A static group member does not respond to IGMP queries. When you complete or cancel this configuration on an interface, the interface does not send an unsolicited IGMP report or leave message.

Restrictions and guidelines

The interface to be configured as a static group member has the following restrictions:

- If the interface is IGMP and PIM-SM enabled, it must be a PIM-SM DR.
- If the interface is IGMP enabled but not PIM-SM enabled, it must be an IGMP querier.

For more information about PIM-SM and DR, see "Configuring PIM."

Procedure

1. Enter system view.

```
system-view
```

2. Enter interface view.

```
interface interface-type interface-number
```

3. Configure the interface as a static group member.

```
igmp static-group group-address [ source source-address ]
```

Configuring a multicast group policy

About this task

This feature enables an interface to filter IGMP reports by using an ACL that specifies multicast groups and the optional sources. It is used to control the multicast groups that the hosts attached to an interface can join.

Restrictions and guidelines

This configuration does not take effect on static group members, because static group members do not send IGMP reports.

Procedure

1. Enter system view.

```
system-view
```

2. Enter interface view.
   interface *interface-type interface-number*
3. Configure a multicast group policy.
   igmp group-policy *ipv4-acl-number* [*version-number*]

Adjusting IGMP performance

Configuring IGMP query and response parameters

About this task

The following are IGMP query and response parameters:

- **IGMP querier's robustness variable**—Number of times for retransmitting IGMP queries in case of packet loss. A higher robustness variable makes the IGMP querier more robust, but increases the timeout time for multicast groups.
- **IGMP startup query interval**—Interval at which an IGMP querier sends IGMP general queries at startup.
- **IGMP startup query count**—Number of IGMP general queries that an IGMP querier sends at startup.
- **IGMP general query interval**—Interval at which an IGMP querier sends IGMP general queries to check for multicast group members on the network.
- **IGMP last member query interval**—In IGMPv2, it sets the interval at which a querier sends group-specific queries after receiving a leave message. In IGMPv3, it sets the interval at which a querier sends group-and-source-specific queries after receiving a report that changes multicast source and group mappings.
- **IGMP last member query count**—In IGMPv2, it sets the number of group-specific queries that a querier sends after receiving a leave message. In IGMPv3, it sets the number of group-and-source-specific queries that a querier sends after receiving a report that changes multicast source and group mappings.
- **IGMP maximum response time**—Maximum time before a receiver responds with a report to an IGMP general query. This per-group timer is initialized to a random value in the range of 0 to the maximum response time specified in the IGMP query. When the timer value for a group decreases to 0, the receiver sends an IGMP report to the group.
- **IGMP other querier present timer**—Lifetime for an IGMP querier after a non-querier receives an IGMP general query. If the non-querier does not receive a new query when this timer expires, the non-querier considers that the querier has failed and starts a new querier election.

Restrictions and guidelines

To avoid frequent IGMP querier changes, set the IGMP other querier present timer greater than the IGMP general query interval. In addition, configure the same IGMP other querier present timer for all IGMP devices on the same subnet.

To avoid mistakenly deleting multicast receivers, set the IGMP general query interval greater than the maximum response time for IGMP general queries.

To speed up the response to IGMP queries and avoid simultaneous timer expirations that cause IGMP report traffic bursts, set an appropriate maximum response time.

- For IGMP general queries, the maximum response time is set by the **max-response-time** command.
- For IGMP group-specific queries and IGMP group-and-source-specific queries, the maximum response time equals the IGMP last member query interval.

The following configurations take effect only on the devices that run IGMPv2 and IGMPv3:

- Maximum response time for IGMP general queries.
- IGMP last member query interval.
- IGMP last member query count.
- IGMP other querier present interval.

You can configure the IGMP query and response parameters globally for all interfaces in IGMP view or for an interface in interface view. The interface-specific configuration takes priority over the global configuration.

Configuring the IGMP query and response parameters globally

1. Enter system view.

   system-view

2. Enter IGMP view.

   igmp [**vpn-instance** *vpn-instance-name*]

3. Set the IGMP querier's robustness variable.

   robust-count *count*

   By default, the IGMP querier's robustness variable is 2.

4. Set the IGMP startup query interval.

   startup-query-interval *interval*

   By default, the IGMP startup query interval is equal to one quarter of the IGMP general query interval.

5. Set the IGMP startup query count.

   startup-query-count *count*

   By default, the IGMP startup query count is equal to the IGMP querier's robustness variable.

6. Set the IGMP general query interval.

   query-interval *interval*

   By default, the IGMP general query interval is 125 seconds.

7. Set the IGMP last member query interval.

   last-member-query-interval *interval*

   By default, the IGMP last member query interval is 1 second.

8. Set the IGMP last member query count.

   last-member-query-count *count*

   By default, the IGMP last member query count is equal to the IGMP querier's robustness variable.

9. Set the maximum response time for IGMP general queries.

   max-response-time *time*

   By default, the maximum response time for IGMP general queries is 10 seconds.

10. Set the IGMP other querier present timer.

    other-querier-present-interval *interval*

    By default, the IGMP other querier present timer is calculated by using the following formula:
    [IGMP general query interval] × [IGMP robustness variable] + [maximum response time for IGMP general queries] / 2.

Configuring the IGMP query and response parameters on an interface

1. Enter system view.

   system-view

2. Enter interface view.

interface *interface-type interface-number*

3. Set the IGMP querier's robustness variable.

   igmp robust-count *count*

   By default, the IGMP querier's robustness variable is 2.

4. Set the IGMP startup query interval.

   igmp startup-query-interval *interval*

   By default, the IGMP startup query interval is equal to one quarter of the IGMP general query interval.

5. Set the IGMP startup query count.

   igmp startup-query-count *count*

   By default, the IGMP startup query count is equal to the IGMP querier's robustness variable.

6. Set the IGMP general query interval.

   igmp query-interval *interval*

   By default, the IGMP general query interval is 125 seconds.

7. Set the IGMP last member query interval.

   igmp last-member-query-interval *interval*

   By default, the IGMP last member query interval is 1 second.

8. Set the IGMP last member query count.

   igmp last-member-query-count *count*

   By default, the IGMP last member query count is equal to the IGMP querier's robustness variable.

9. Set the maximum response time for IGMP general queries.

   igmp max-response-time *time*

   By default, the maximum response time for IGMP general queries is 10 seconds.

10. Set the IGMP other querier present timer.

    igmp other-querier-present-interval *interval*

    By default, the IGMP other querier present timer is calculated by using the following formula:
    [IGMP general query interval] × [IGMP robustness variable] + [maximum response time for IGMP general queries] / 2.

Enabling fast-leave processing

About this task

This feature enables an IGMP querier to send leave notifications to the upstream without sending group-specific or group-and-source-specific queries after receiving a leave message. Use this feature to reduce leave latency and to preserve the network bandwidth.

Restrictions and guidelines

The fast-leave processing configuration takes effect only when the device runs IGMPv2 or IGMPv3.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable fast-leave processing.

   igmp fast-leave [**group-policy** *ipv4-acl-number*]

By default, fast-leave processing is disabled.

Configuring IGMP SSM mappings

About this task

This feature enables the device to provide SSM services for IGMPv1 or IGMPv2 hosts.

Restrictions and guidelines

This feature does not process IGMPv3 messages. Enable IGMPv3 on the receiver-side interface to ensure that IGMPv3 reports can be processed..

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter IGMP view.

   ```
   igmp [ vpn-instance vpn-instance-name ]
   ```

3. Configure an IGMP SSM mapping.

   ```
   ssm-mapping source-address ipv4-acl-number
   ```

Configuring IGMP proxying

Prerequisites for configuring IGMP proxying

Before you configure IGMP proxying, determine the router interfaces and host interfaces based on the network topology, and enable IGMP on the router interfaces.

Enabling IGMP proxying

Restrictions and guidelines

Enable IGMP proxying on the receiver-side interfaces.

On an interface enabled with IGMP proxying, only the **igmp version** command takes effect and other IGMP commands do not take effect.

If you enable both IGMP proxying and a multicast routing protocol (such as PIM) on the same device, the multicast routing protocol does not take effect.

In IGMPv1, the DR is elected by PIM and acts as the IGMP querier. Because PIM does not take effect on a proxy device, a router interface running IGMPv1 cannot be elected as the DR. To ensure that the downstream receiver hosts on the router interface can receive multicast data, you must enable multicast forwarding on the interface. For more information, see "Enabling multicast forwarding on a non-querier interface."

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Enable IGMP proxying.

   ```
   igmp proxying enable
   ```

By default, IGMP proxying is disabled.

Enabling multicast forwarding on a non-querier interface

About this task

Typically, only IGMP queriers can forward multicast traffic and non-queriers cannot. This prevents multicast data from being repeatedly forwarded. If a router interface on an IGMP proxy device failed in the querier election, enable multicast forwarding on the interface to forward multicast data to attached receiver hosts.

Restrictions and guidelines

A shared-media network might have multiple IGMP proxies, including one proxy acting as a querier. To avoid duplicate multicast traffic, do not enable multicast forwarding on any of the non-querier IGMP proxies for the network.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Enable multicast forwarding on the interface.

   `igmp proxy forwarding`

   By default, multicast forwarding is disabled on a non-querier interface.

Configuring multicast load splitting for IGMP proxy interfaces

About this task

If multiple IGMP proxy interfaces exist on the device, only the proxy interface with the highest IP address forwards multicast traffic. You can enable multicast load splitting for IGMP proxy interfaces so that all the proxy interfaces can share multicast traffic.

Procedure

1. Enter system view.

   `system-view`

2. Enter IGMP view.

   `igmp` [**`vpn-instance`** *`vpn-instance-name`*]

3. Enable multicast load splitting for IGMP proxy interfaces.

   `proxy multipath`

   By default, multicast load splitting is disabled for IGMP proxy interfaces.

Enabling IGMP NSR

About this task

This feature backs up information about IGMP interfaces and IGMP multicast groups to the standby process. The device recovers the information without cooperation of other devices when an active/standby switchover occurs. Use this feature to prevent an active/standby switchover from affecting the multicast service.

Procedure

1. Enter system view.
   system-view
2. Enable IGMP NSR.
   igmp non-stop-routing
   By default, IGMP NSR is disabled.

Display and maintenance commands for IGMP

△ **CAUTION:**

The **reset igmp group** command might cause multicast data transmission failures.

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about IGMP multicast groups.	**display igmp** [**vpn-instance** *vpn-instance-name*] **group** [*group-address* | **interface** *interface-type interface-number*] [**static** | **verbose**]
Display IGMP information for interfaces.	**display igmp** [**vpn-instance** *vpn-instance-name*] **interface** [*interface-type interface-number*] [**proxy**] [**verbose**]
Display multicast group membership information maintained by the IGMP proxy.	**display igmp** [**vpn-instance** *vpn-instance-name*] **proxy group** [*group-address* | **interface** *interface-type interface-number*] [**verbose**]
Display multicast routing entries maintained by the IGMP proxy.	**display igmp** [**vpn-instance** *vpn-instance-name*] **proxy routing-table** [*source-address* [**mask** { *mask-length* | *mask* }] | *group-address* [**mask** { *mask-length* | *mask* }]] * [**verbose**]
Display IGMP SSM mappings.	**display igmp** [**vpn-instance** *vpn-instance-name*] **ssm-mapping** *group-address*
Clear dynamic IGMP multicast group entries.	**reset igmp** [**vpn-instance** *vpn-instance-name*] **group** { **all** | **interface** *interface-type interface-number* { **all** | *group-address* [**mask** { *mask* | *mask-length* }] [*source-address* [**mask** { *mask* | *mask-length* }]] } }

Troubleshooting IGMP

No membership information on the receiver-side device

Symptom

When a host sends a report for joining multicast group G, no membership information of multicast group G exists on the device closest to that host.

Solution

To resolve the problem:

1. Use the **`display igmp interface`** command to verify that the networking, interface connection, and IP address configuration are correct.
2. Use the **`display current-configuration`** command to verify that multicast routing is enabled. If it is not enabled, use the **`multicast routing`** command in system view to enable IP multicast routing. In addition, verify that IGMP is enabled on the associated interfaces.
3. Use the **`display igmp interface`** command to verify that the IGMP version on the interface is lower than that on the host.
4. Use the **`display current-configuration interface`** command to verify that no multicast group policies have been configured to filter IGMP reports for multicast group G.
5. If the problem persists, contact NSFOCUS Support.

Inconsistent membership information on the devices on the same subnet

Symptom

Different memberships are maintained on different IGMP devices on the same subnet.

Solution

To resolve the problem:

1. Use the **`display current-configuration`** command to verify the IGMP information on the interfaces. Make sure the devices on the subnet have the same IGMP settings on their interfaces.
2. Use the **`display igmp interface`** command on all devices on the same subnet to verify the IGMP-related timer settings. Make sure the settings are consistent on all the devices.
3. Use the **`display igmp interface`** command to verify that all devices on the same subnet are running the same IGMP version.
4. If the problem persists, contact NSFOCUS Support.

Contents

PIM overview

Protocol Independent Multicast (PIM) provides IP multicast forwarding by leveraging unicast static routes or unicast routing tables generated by any unicast routing protocol. PIM uses the underlying unicast routing to generate a multicast routing table without relying on any particular unicast routing protocol. PIM uses the RPF mechanism to implement multicast forwarding. For more information about RPF, see "Configuring multicast routing and forwarding."

PIM modes

Based on the implementation mechanism, PIM includes the following modes:

- Protocol Independent Multicast–Dense Mode (PIM-DM).
- Protocol Independent Multicast–Sparse Mode (PIM-SM).
- Bidirectional Protocol Independent Multicast (BIDIR-PIM).
- Protocol Independent Multicast Source-Specific Multicast (PIM-SSM).

In this document, a PIM domain refers to a network that contains PIM devices.

PIM-DM

PIM-DM uses the push mode for multicast forwarding, and is suitable for small-sized networks with densely distributed multicast members.

PIM-DM assumes that all downstream nodes want to receive multicast data from a source, so multicast data is flooded to all downstream nodes on the network. Branches without downstream receivers are pruned from the forwarding trees. When a pruned branch has new receivers, the graft mechanism turns the pruned branch into a forwarding branch.

In PIM-DM, the multicast forwarding paths for a multicast group constitutes a forwarding tree. The forwarding tree is rooted at the multicast source and has multicast group members as its "leaves." Because the forwarding tree consists of the shortest paths from the multicast source to the receivers, it is also called a "shortest path tree (SPT)."

PIM-DM mechanisms include neighbor discovery, SPT building, graft, and assert.

Neighbor discovery

In a PIM domain, each PIM interface on a device periodically multicasts PIM hello messages to all other PIM devices (identified by the address 224.0.0.13) on the local subnet. Through the exchanging of hello messages, all PIM devices on the subnet determine their PIM neighbors, maintain PIM neighboring relationship with other devices, and build and maintain SPTs.

SPT building

The process of building an SPT is the flood-and-prune process:

1. In a PIM-DM domain, the multicast data from the multicast source S to the multicast group G is flooded throughout the domain. A device performs an RPF check on the multicast data. If the RPF check succeeds, the device creates an (S, G) entry and forwards the data to all downstream nodes on the network. In the flooding process, all the devices in the PIM-DM domain create the (S, G) entry.
2. The nodes without downstream receivers are pruned. A device that has no downstream receivers multicasts a prune message to all PIM devices on the subnet. When an upstream

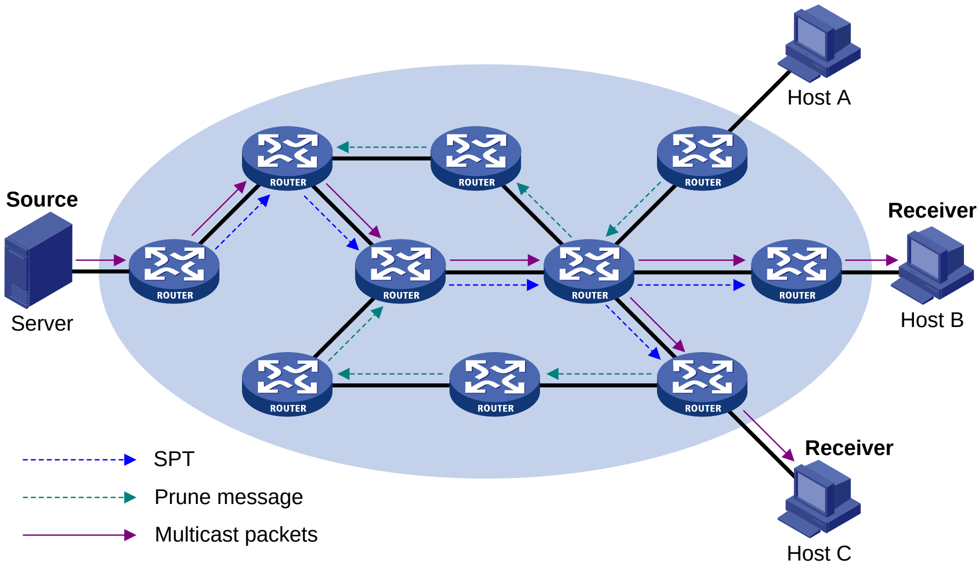
node receives the prune message, it removes the receiving interface from the (S, G) entry. In this way, the upstream stream node stops forwarding subsequent packets addressed to that multicast group down to this node.

NOTE:

An (S, G) entry contains a multicast source address S, a multicast group address G, an outgoing interface list, and an incoming interface.

A prune process is initiated by a leaf device. As shown in Figure 1, the device interface that does not have any downstream receivers initiates a prune process by sending a prune message toward the multicast source. This prune process goes on until only necessary branches are left in the PIM-DM domain, and these necessary branches constitute an SPT.

Figure 1 SPT building



The pruned state of a branch has a finite holdtime timer. When the timer expires, multicast data is again forwarded to the pruned branch. The flood-and-prune cycle takes place periodically to maintain the forwarding branches.

Graft

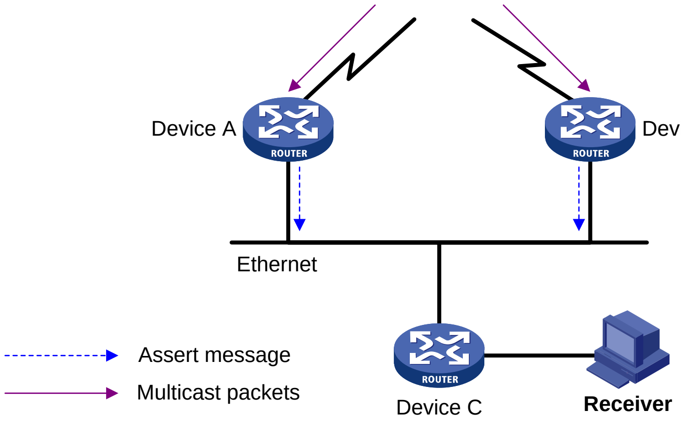
A previously pruned branch might have new downstream receivers. To reduce the latency for resuming the forwarding capability of this branch, a graft mechanism is used as follows:

1. The node that needs to receive the multicast data sends a graft message to its upstream node, telling it to rejoin the SPT.
2. After receiving this graft message on an interface, the upstream node adds the receiving interface to the outgoing interface list of the (S, G) entry. It also sends a graft-ack message to the graft sender.
3. If the graft sender receives a graft-ack message, the graft process finishes. Otherwise, the graft sender continues to send graft messages at a graft retry interval until it receives an acknowledgment from its upstream node.

Assert

On a subnet with more than one multicast device, the assert mechanism shuts off duplicate multicast flows to the network. It does this by electing a unique multicast forwarder for the subnet.

Figure 2 Assert mechanism



As shown in Figure 2, after Device A and Device B receive an (S, G) packet from the upstream node, they both forward the packet to the local subnet. As a result, the downstream node Device C receives two identical multicast packets. In addition, both Device A and Device B, on their downstream interfaces, receive a duplicate packet forwarded by the other. After detecting this condition, both devices send an assert message to all PIM devices (224.0.0.13) on the local subnet through the interface that received the packet. The assert message contains the multicast source address (S), the multicast group address (G), and the metric preference and metric of the unicast route/MBGP route/static multicast route to the multicast source. By comparing these parameters, either Device A or Device B becomes the unique forwarder of the subsequent (S, G) packets on the shared-media LAN. The comparison process is as follows:

1. The device with a higher metric preference to the multicast source wins.
2. If both devices have the same metric preference, the device with a smaller metric wins.
3. If both devices have the same metric, the device with a higher IP address on the downstream interface wins.

PIM-SM

PIM-DM uses the flood-and-prune cycles to build SPTs for multicast data forwarding. Although an SPT has the shortest paths from the multicast source to the receivers, it is built with a low efficiency. Therefore, PIM-DM is not suitable for large and medium-sized networks. PIM-SM uses the pull mode for multicast forwarding, and it is suitable for large- and medium-sized networks with sparsely and widely distributed multicast group members.

PIM-SM assumes that no hosts need multicast data. A multicast receiver must express its interest in the multicast data for a multicast group before the data is forwarded to it. A rendezvous point (RP) is the core of a PIM-SM domain. Relying on the RP, SPTs and rendezvous point trees (RPTs) are established and maintained to implement multicast data forwarding. An SPT is rooted at the multicast source and has the RPs as its leaves. An RPT is rooted at the RP and has the receiver hosts as its leaves.

PIM-SM mechanisms include neighbor discovery, DR election, RP discovery, Anycast RP, RPT building, multicast source registration, switchover to SPT, and assert.

Neighbor discovery

PIM-SM uses the same neighbor discovery mechanism as PIM-DM does. For more information, see "Neighbor discovery."

DR election

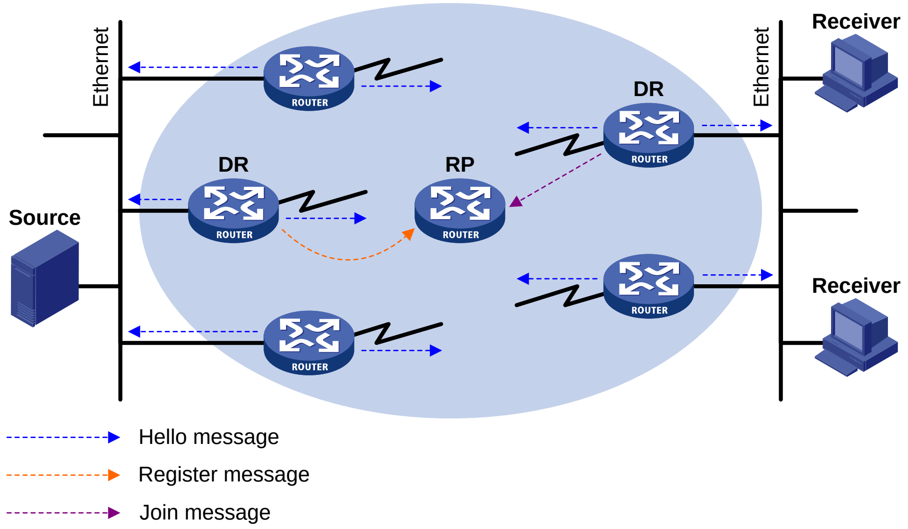
A designated router (DR) is required on both the source-side network and receiver-side network. A source-side DR acts on behalf of the multicast source to send register messages to the RP. The receiver-side DR acts on behalf of the multicast receivers to send join messages to the RP.

PIM-DM does not require a DR. However, if IGMPv1 runs on any shared-media LAN in a PIM-DM domain, a DR must be elected to act as the IGMPv1 querier for the LAN. For more information about IGMP, see "Configuring IGMP."

IMPORTANT:

IGMP must be enabled on the device that acts as the receiver-side DR. Otherwise, the receiver hosts attached to the DR cannot join any multicast groups.

Figure 3 DR election



As shown in Figure 3, the DR election process is as follows:

1. The devices on the shared-media LAN send hello messages to one another. The hello messages contain the DR priority for DR election. The device with the highest DR priority is elected as the DR.
2. The device with the highest IP address wins the DR election under one of following conditions:
   - All the devices have the same DR election priority.
   - A device does not support carrying the DR priority in hello messages.

If the DR fails, its PIM neighbor lifetime expires and the other devices will initiate to elect a new DR.

RP discovery

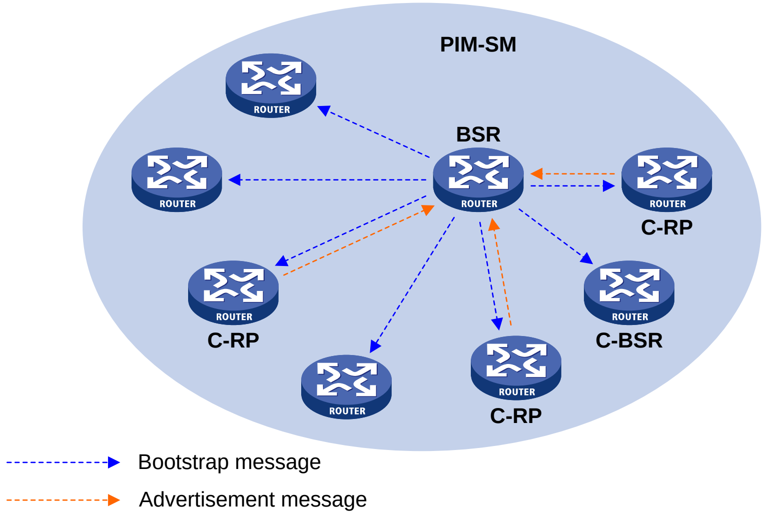
An RP is the core of a PIM-SM domain. A multicast group can have only one RP for multicast forwarding, and an RP can be designated to multiple multicast groups. RPs can be statically configured or dynamically elected through bootstrap router (BSR) mechanism. The BSM mechanism lessens the RP burden and optimizes the topological structure of the RPT.

BSR mechanism includes the following roles:

- **Candidate-RPs (C-RPs)**—An RP is dynamically elected from C-RPs to provide services to a multicast group.

- **BSR**—A BSR is the core of the administrative core of the PIM-SM domain. It is responsible for collecting and advertising RP information in the whole domain. A PIM-SM domain has only one BSR, and the BSR is elected from C-BSRs.
- **Candidate-BSRs (C-BSRs)**—Any devices in the PIM-SM domain can act as C-BSRs and the BSR is elected from the C-BSRs. Once the BSR fails, a new BSR is elected from the C-BSRs to avoid multicast traffic interruption.

Figure 4 Information exchange between C-RPs and BSR



As shown in Figure 4, an RP is elected as follows:

1. Each C-BSR sends a bootstrap message (BSM) to other devices in the PIM-SM domain.
2. When a C-BSR receives a BSM from another C-BSR, it compares its own priority with the priority carried in the message. The C-BSR with a higher priority wins the BSR election. If a tie exists in the priority, the C-BSR with a higher IP address wins. The loser uses the winner's BSR address to replace its own BSR address and no longer regards itself as the BSR. The winner retains its own BSR address and continues to regard itself as the BSR.
3. Each C-RP periodically unicasts an advertisement message to the BSR. An advertisement message contains the address of the advertising C-RP and the multicast group range to which it is designated.
4. The BSR collects these advertisement messages and organizes the C-RP information into an RP-set, which is a database of mappings between multicast groups and RPs. The BSR encapsulates the RP-set information in the bootstrap messages (BSMs) and floods the BSMs to the entire PIM-SM domain.
5. All devices in the PIM-SM domain select an RP for a multicast group based on the following rules:
    a. The C-RP that is designated to the smallest multicast group range wins.
    b. If the C-RPs are designated to the same group ranges, the C-RP with the highest priority wins.
    c. If the C-RPs have the same priority, the C-RP with the largest hash value wins. The hash value is calculated through the hash algorithm.
    d. If the C-RPs have the same hash value, the C-RP with the highest IP address wins.

Anycast RP

PIM-SM requires only one active RP to serve each multicast group. If the active RP fails, the multicast traffic might be interrupted. The Anycast RP mechanism enables redundancy backup among RPs by configuring multiple RPs with the same IP address. A multicast source registers with the closest RP or a receiver joins the closest RP to implement source information synchronization.

Anycast RP has the following benefits:

- **Optimal RP path**—A multicast source registers with the closest RP to build an optimal SPT. A receiver joins the closest RP to build an optimal RPT.
- **Redundancy backup among RPs**—When an RP fails, the RP-related sources will register with the closest available RPs and the receiver-side DRs will join the closest available RPs. This provides redundancy backup among RPs.

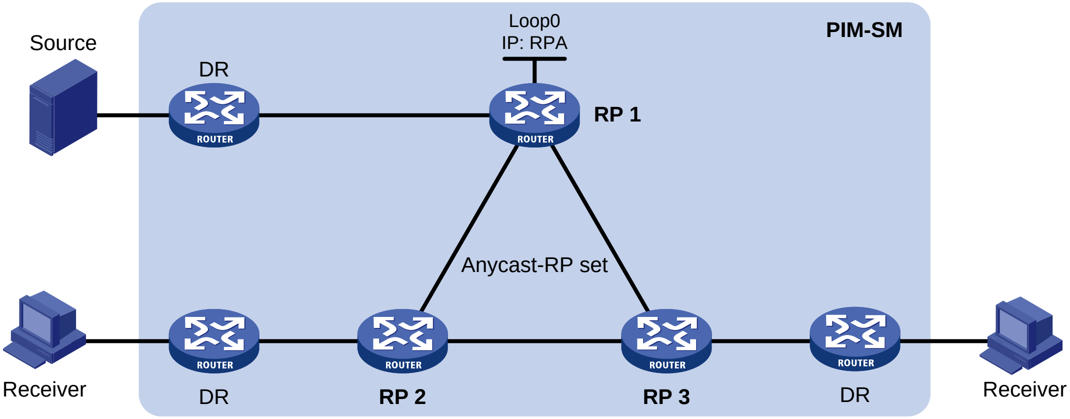
Anycast RP is implemented based on PIM-SM. You can configure multiple RPs for one multicast group and add them to an Anycast RP set.

PIM-SM-based Anycast RP introduces the following concepts:

- **Anycast RP set**—A set of RPs that are designated to the same multicast group.
- **Anycast RP member**—Each RP in the Anycast RP set.
- **Anycast RP member address**—IP address of each Anycast RP member for communication among the RP members.
- **Anycast RP address**—IP address of the Anycast RP set for communication within the PIM-SM domain. It is also known as RPA.

As shown in Figure 5, RP 1, RP 2, and RP 3 are members of an Anycast RP set.

Figure 5 Anycast RP through PIM-SM



The following describes how Anycast RP through PIM-SM is implemented:

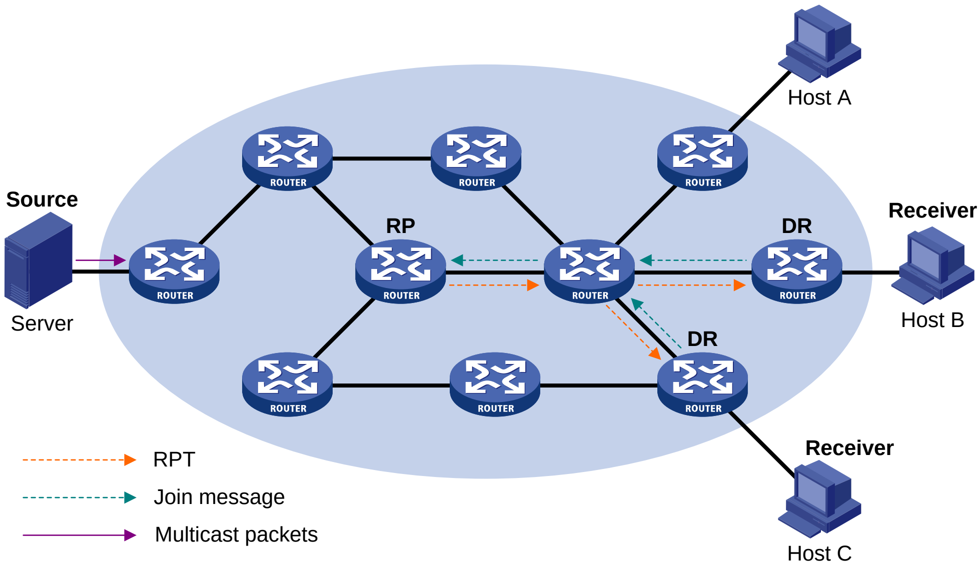
1. RP 1 receives a register message destined to RPA. Because the message is not from other Anycast RP members (RP 2 or RP 3), RP 1 considers that the register message is from the DR. RP 1 changes the source IP address of the register message to its own address and sends the message to the other members (RP 2 and RP 3).

   If a device acts as both a DR and an RP, it creates a register message, and then forwards the message to the other RP members.
2. After receiving the register message, RP 2 and RP 3 find out that the source address of the register message is an Anycast RP member address. They stop forwarding the message to other devices.

In Anycast RP implementation, an RP must forward the register message from the DR to other Anycast RP members to synchronize multicast source information.

RPT building

Figure 6 RPT building in a PIM-SM domain



As shown in Figure 6, the process of building an RPT is as follows:

1. When a receiver wants to join the multicast group G, it uses an IGMP message to inform the receiver-side DR.
2. After getting the receiver information, the DR sends a join message, which travels hop by hop to the RP for the multicast group.
3. The devices along the path from the DR to the RP form an RPT branch. Each device on this branch adds to its forwarding table a (*, G) entry, where the asterisk (*) represents any multicast source. The RP is the root of the RPT, and the DR is a leaf of the RPT.

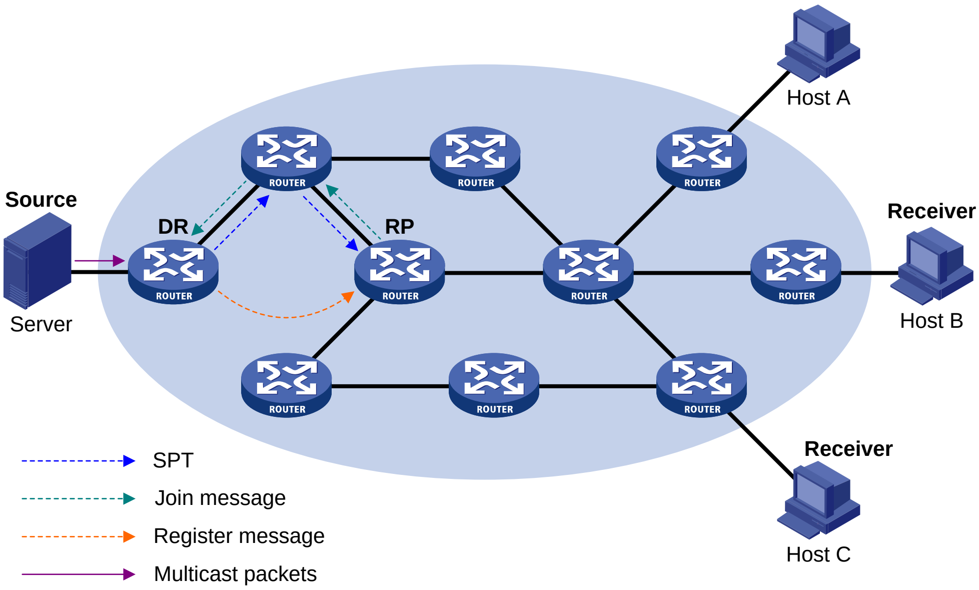
When the multicast data addressed to the multicast group G reaches the RP, the RP forwards the data to the DR along the established RPT, and finally to the receiver.

When a receiver is no longer interested in the multicast data addressed to the multicast group G, the receiver-side DR sends a prune message. The prune message goes hop by hop along the RPT to the RP. After receiving the prune message, the upstream node deletes the interface that connects to this downstream node from the outgoing interface list. At the same time, the upstream device checks for the existence of receivers for that multicast group. If no receivers for the multicast group exist, the device continues to forward the prune message to its upstream device.

Multicast source registration

The multicast source uses the registration process to inform an RP of its presence.

Figure 7 Multicast source registration



As shown in Figure 7, the multicast source registers with the RP as follows:

1. The multicast source S sends the first multicast packet to the multicast group G. When receiving the multicast packet, the source-side DR encapsulates the packet into a PIM register message and unicasts the message to the RP.
2. After the RP receives the register message, it decapsulates the register message and forwards the register message down to the RPT. Meanwhile, it sends an (S, G) source-specific join message toward the multicast source. The devices along the path from the RP to the multicast source constitute an SPT branch. Each device on this branch creates an (S, G) entry in its forwarding table.
3. The subsequent multicast data from the multicast source are forwarded to the RP along the established SPT. When the multicast data reaches the RP along the SPT, the RP forwards the data to the receivers along the RPT. Meanwhile, it unicasts a register-stop message to the source-side DR to prevent the DR from unnecessarily encapsulating the data.

Switchover to SPT

This section takes a router as an example. As compared with the switchover to SPT on a router, switchover to SPT is implemented in a simpler way on a switch.

In a PIM-SM domain, only one RP and one RPT provide services for a specific multicast group. Before the switchover to SPT occurs, the source-side DR encapsulates all multicast data in register messages and sends them to the RP. After receiving these register messages, the RP decapsulates them and forwards them to the receiver-side DR along the RPT.

Multicast forwarding along the RPT has the following weaknesses:

- Encapsulation and decapsulation are complex on the source-side DR and the RP.
- The path for a multicast packet might not be the shortest one.
- The RP might be overloaded by multicast traffic bursts.

To eliminate these weaknesses, PIM-SM allows an RP or the receiver-side DR to initiate the switchover to SPT when the traffic rate exceeds a specific threshold.

- The RP initiates the switchover to SPT:

  The RP periodically checks the multicast packet forwarding rate. If the RP finds that the traffic rate exceeds the specified threshold, it sends an (S, G) source-specific join message toward the multicast source. The routers along the path from the RP to the multicast source constitute an SPT. The subsequent multicast data is forwarded to the RP along the SPT without being encapsulated into register messages.

For more information about the switchover to SPT initiated by the RP, see "Multicast source registration."

- The receiver-side DR initiates the switchover to SPT:

  The receiver-side DR periodically checks the forwarding rate of the multicast packets that the multicast source S sends to the multicast group G. If the forwarding rate exceeds the specified threshold, the DR initiates the switchover to SPT as follows:

  a. The receiver-side DR sends an (S, G) source-specific join message toward the multicast source. The routers along the path create an (S, G) entry in their forwarding table to constitute an SPT branch.

  b. When the multicast packets reach the router where the RPT and the SPT branches, the router drops the multicast packets that travel along the RPT. It then sends a prune message with the RP bit toward the RP.

  c. After receiving the prune message, the RP forwards it toward the multicast source (supposed only one receiver exists). Thus, the switchover to SPT is completed. The subsequent multicast packets travel along the SPT from the multicast source to the receiver hosts.

With the switchover to SPT, PIM-SM builds SPTs more economically than PIM-DM does.

Assert

PIM-SM uses a similar assert mechanism as PIM-DM does. For more information, see "Assert."

BIDIR-PIM

In some many-to-many applications, such as a multi-side video conference, multiple receivers of a multicast group might be interested in the multicast data from multiple multicast sources. With PIM-DM or PIM-SM, each device along the SPT must create an (S, G) entry for each multicast source, consuming a lot of system resources.

BIDIR-PIM addresses the problem. Derived from PIM-SM, BIDIR-PIM builds and maintains a bidirectional RPT, which is rooted at the RP and connects the multicast sources and the receivers. Along the bidirectional RPT, the multicast sources send multicast data to the RP, and the RP forwards the data to the receivers. Each device along the bidirectional RPT needs to maintain only one (*, G) entry, saving system resources.

BIDIR-PIM is suitable for a network with dense multicast sources and receivers.

BIDIR-PIM mechanisms include neighbor discovery, RP discovery, DF election, and bidirectional RPT building.

Neighbor discovery

BIDIR-PIM uses the same neighbor discovery mechanism as PIM-SM does. For more information, see "Neighbor discovery."

RP discovery

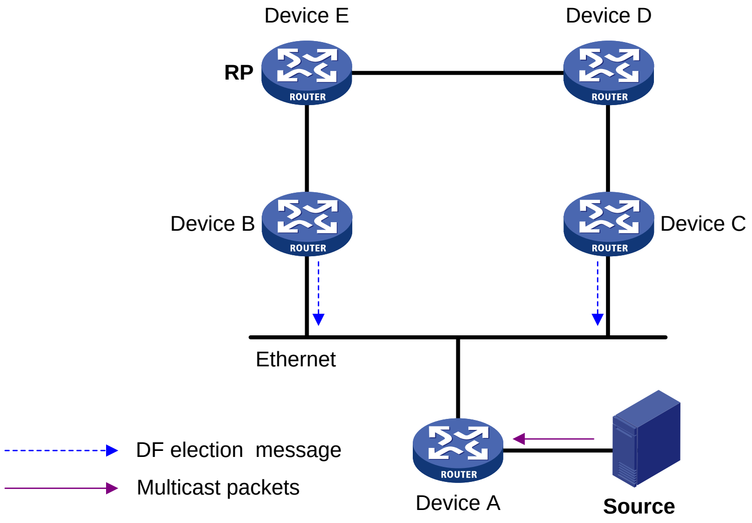
BIDIR-PIM uses the same RP discovery mechanism as PIM-SM does. For more information, see "RP discovery." In BIDIR-PIM, an RPF interface is the interface toward an RP, and an RPF neighbor is the address of the next hop to the RP.

DF election

On a subnet with multiple multicast devices, duplicate multicast packets might be forwarded to the RP. To address this issue, BIDIR-PIM uses a designated forwarder (DF) election mechanism to elect a unique DF for each RP on a subnet. Only the DFs can forward multicast data to the RP.

DF election is not necessary for an RPL.

Figure 8 DF election



As shown in Figure 8, without the DF election mechanism, both Device B and Device C can receive multicast packets from Route A. They also can forward the packets to downstream devices on the local subnet. As a result, the RP (Device E) receives duplicate multicast packets.

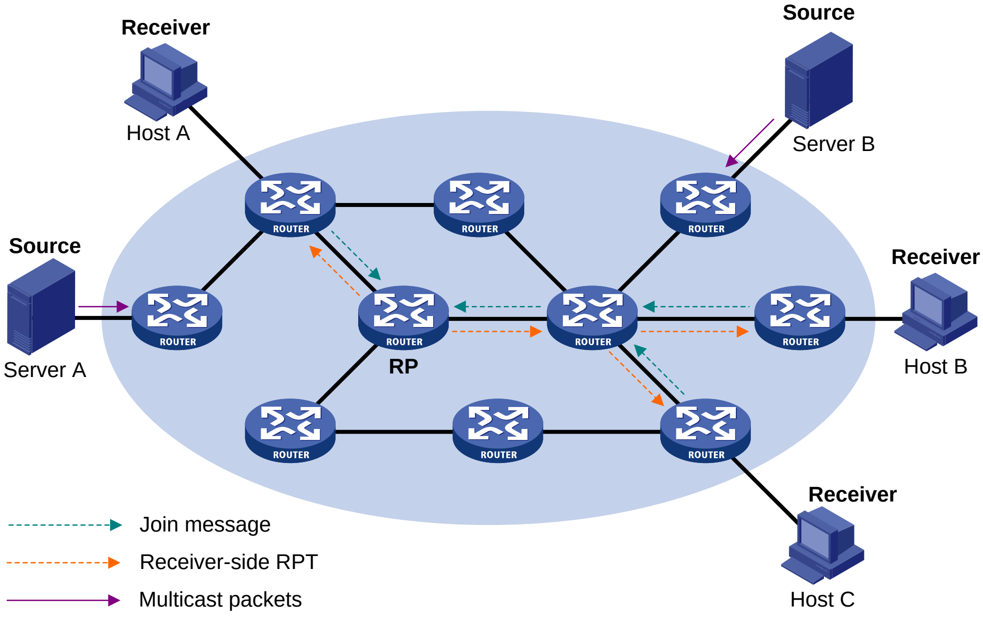
With the DF election mechanism, once receiving the RP information, Device B and Device C multicast a DF election message to all PIM devices (224.0.0.13) to initiate a DF election process. The election message carries the RP's address, and the route preference and the metric of the unicast route or static multicast route to the RP. A DF is elected as follows:

1. The device with a higher route preference becomes the DF.
2. If the devices have the same route preference, the device with a lower metric becomes the DF.
3. If the devices have the same metric, the device with a higher IP address becomes the DF.

Bidirectional RPT building

A bidirectional RPT comprises a receiver-side RPT and a source-side RPT. The receiver-side RPT is rooted at the RP and takes the devices that directly connect to the receivers as leaves. The source-side RPT is also rooted at the RP but takes the devices that directly connect to the sources as leaves. The processes for building these two RPTs are different.

Figure 9 RPT building at the receiver side

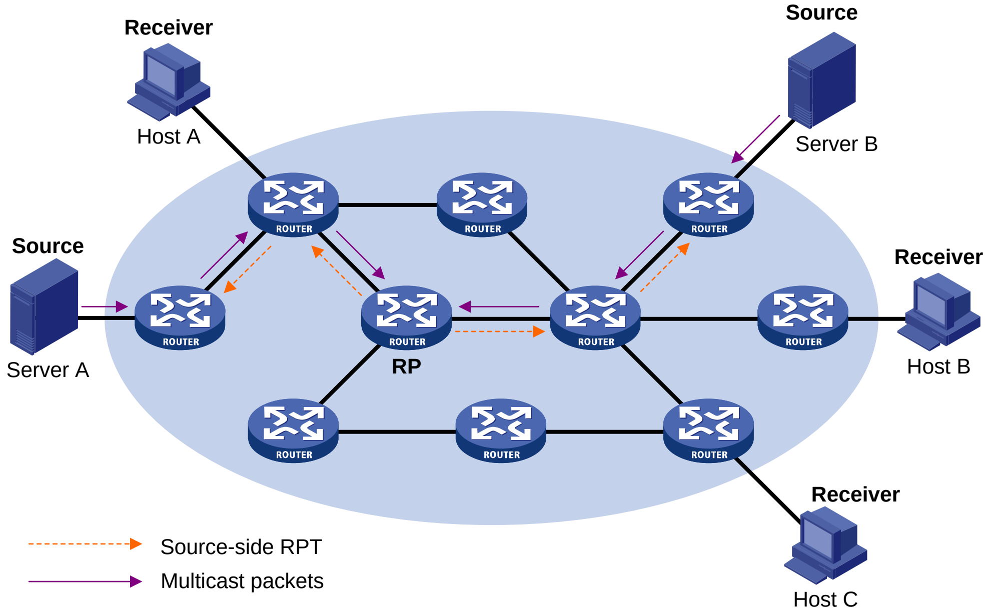


As shown in Figure 9, the process for building a receiver-side RPT is the same as the process for building an RPT in PIM-SM:

1. When a receiver wants to join the multicast group G, it uses an IGMP message to inform the directly connected device.
2. After receiving the message, the device sends a join message, which is forwarded hop by hop to the RP for the multicast group.
3. The devices along the path from the receiver's directly connected device to the RP form an RPT branch. Each device on this branch adds a (*, G) entry to its forwarding table.

After a receiver host leaves the multicast group G, the directly connected device multicasts a prune message to all PIM devices on the subnet. The prune message goes hop by hop along the reverse direction of the RPT to the RP. After receiving the prune message, an upstream node removes the interface that connects to the downstream node from the outgoing interface list. At the same time, the upstream device checks the existence of receivers for that multicast group. If no receivers for the multicast group exist, the device continues to forward the prune message to its upstream device.

Figure 10 RPT building at the multicast source side



As shown in Figure 10, the process for building a source-side RPT is relatively simple:

1. When a multicast source sends multicast packets to the multicast group G, the DF in each subnet unconditionally forwards the packets to the RP.
2. The devices along the path from the source's directly connected device to the RP constitute an RPT branch. Each device on this branch adds to its forwarding table a (*, G) entry.

After a bidirectional RPT is built, the multicast sources send multicast traffic to the RP along the source-side RPT. Then, the RP forwards the traffic to the receivers along the receiver-side RPT.

IMPORTANT:

If a receiver and a multicast source are at the same side of the RP, the source-side RPT and the receiver-side RPT might meet at a node before reaching the RP. In this case, the multicast packets from the multicast source to the receiver are directly forwarded by the node, instead of by the RP.

Administrative scoping

Typically, a PIM-SM domain or a BIDIR-PIM domain contains only one BSR, which is responsible for advertising RP-set information within the entire domain. The information about all multicast groups is forwarded within the network that the BSR administers. This is called the "non-scoped BSR mechanism."

Administrative scoping mechanism

To implement refined management, you can divide a PIM-SM domain or BIDIR-PIM domain into a global-scoped zone and multiple administratively-scoped zones (admin-scoped zones). This is called the "administrative scoping mechanism."

The administrative scoping mechanism effectively releases stress on the management in a single-BSR domain and enables provision of zone-specific services through private group addresses.

Admin-scoped zones are divided for multicast groups. Zone border devices (ZBRs) form the boundary of an admin-scoped zone. Each admin-scoped zone maintains one BSR for multicast groups within a specific range. Multicast protocol packets, such as assert messages and BSMs, for a specific group range cannot cross the boundary of the admin-scoped zone for the group range. Multicast group ranges that are associated with different admin-scoped zones can have intersections. However, the multicast groups in an admin-scoped zone are valid only within the local zone, and theses multicast groups are regarded as private group addresses.

The global-scoped zone maintains a BSR for the multicast groups that do not belong to any admin-scoped zones.

Relationship between admin-scoped zones and the global-scoped zone

The global-scoped zone and each admin-scoped zone have their own C-RPs and BSRs. These devices are effective only on their respective zones, and the BSR election and the RP election are implemented independently. Each admin-scoped zone has its own boundary. The multicast information within a zone cannot cross this boundary in either direction. You can have a better understanding of the global-scoped zone and admin-scoped zones based on geographical locations and multicast group address ranges.

- In view of geographical locations:

  An admin-scoped zone is a logical zone for particular multicast groups. The multicast packets for such multicast groups are confined within the local admin-scoped zone and cannot cross the boundary of the zone.

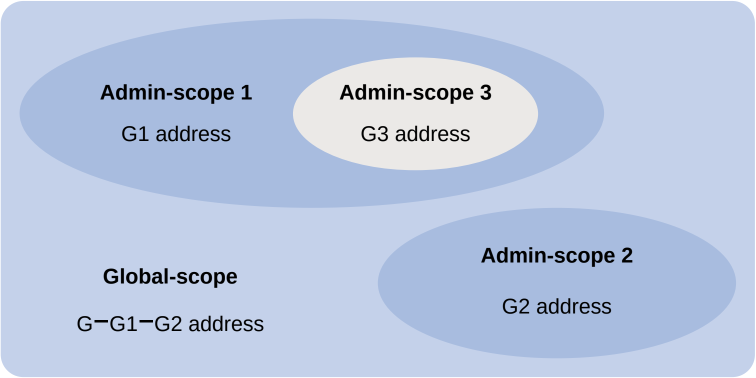
  Figure 11 Relationship in view of geographical locations

  As shown in Figure 11, for the multicast groups in a specific group address range, the admin-scoped zones must be geographically separated and isolated. A device cannot belong to multiple admin-scoped zones. An admin-scoped zone cannot contain a device that belongs to any other admin-scoped zone. However, the global-scoped zone includes all devices in the PIM-SM domain or BIDIR-PIM domain. Multicast packets that do not belong to any admin-scoped zones are forwarded in the entire PIM-SM domain or BIDIR-PIM domain.

- In view of multicast group address ranges:

  Each admin-scoped zone is designated to specific multicast groups, of which the multicast group addresses are valid only within the local zone. The multicast groups of different admin-scoped zones might have intersections. All the multicast groups other than those of the admin-scoped zones use the global-scoped zone.

Figure 12 Relationship in view of multicast group address ranges



As shown in Figure 12, the admin-scoped zones 1 and 2 have no intersection, but the admin-scoped zone 3 is a subset of the admin-scoped zone 1. The global-scoped zone provides services for all the multicast groups that are not covered by the admin-scoped zones 1 and 2, G−G1−G2 in this case.

PIM-SSM

The ASM model includes PIM-DM and PIM-SM. The SSM model can be implemented by leveraging part of the PIM-SM technique. It is also called "PIM-SSM."

The SSM model provides a solution for source-specific multicast. It maintains the relationship between hosts and devices through IGMPv3.

In actual applications, part of IGMPv3 and PIM-SM techniques are adopted to implement the SSM model. In the SSM model, because receivers have located a multicast source, no RP or RPT is required. Multicast sources do not register with the RP.

PIM-SSM mechanisms include neighbor discovery, DR election, and SPT building.

Neighbor discovery

PIM-SSM uses the same neighbor discovery mechanism as PIM-SM. For more information, see "Neighbor discovery."

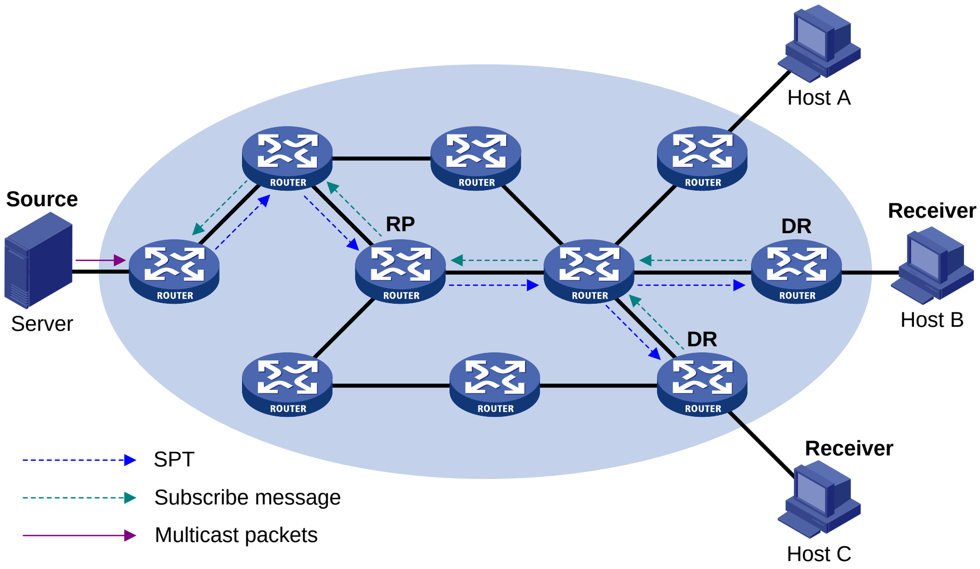
DR election

PIM-SSM uses the same DR election mechanism as PIM-SM. For more information, see "DR election."

SPT building

The decision to build an RPT for PIM-SM or an SPT for PIM-SSM depends on whether the multicast group that the receiver joins is in the SSM group range. The SSM group range reserved by IANA is 232.0.0.0/8.

Figure 13 SPT building in PIM-SSM



As shown in Figure 13, Host B and Host C are receivers. They send IGMPv3 report messages to their DRs to express their interest in the multicast information that the multicast source S sends to the multicast group G.

After receiving a report message, the DR first checks whether the group address in this message is in the SSM group range and does the following:

- If the group address is in the SSM group range, the DR sends a subscribe message hop by hop toward the multicast source S. All devices along the path from the DR to the source create an (S, G) entry to build an SPT. The SPT is rooted at the multicast source S and has the receivers as its leaves. This SPT is the transmission channel in PIM-SSM.
- If the group address is not in the SSM group range, the receiver-side DR sends a (*, G) join message to the RP. The multicast source registers with the source-side DR.

In PIM-SSM, the term "subscribe message" refers to a join message.

Relationship among PIM protocols

In a PIM network, PIM-DM cannot run together with PIM-SM, BIDIR-PIM, or PIM-SSM. However, PIM-SM, BIDIR-PIM, and PIM-SSM can run together. Figure 14 shows how the device selects one protocol from among them for a receiver trying to join a group.

For more information about IGMP SSM mapping, see "Configuring IGMP."

PIM support for VPNs

To support PIM for VPNs, a multicast device that runs PIM maintains an independent set of PIM neighbor table, multicast routing table, BSR information, and RP-set information for each VPN.

After receiving a multicast data packet, the multicast device checks which VPN the data packet belongs to. Then, the device forwards the packet according to the multicast routing table for that VPN or creates a multicast routing entry for that VPN.

Protocols and standards

Configuring PIM

Restrictions and guidelines: PIM configuration

All the interfaces on a device must operate in the same PIM mode on the public network or the same VPN instance.

When both PIM-SM and BIDIR-PIM run on the PIM network, do not use the same RP to provide services for PIM-SM and BIDIR-PIM. Otherwise, exceptions might occur to the PIM routing table.

Configuring PIM-DM

PIM-DM tasks at a glance

To configure PIM-DM, perform the following tasks:

1. Enabling PIM-DM
2. (Optional.) Configuring the state refresh feature
3. (Optional.) Setting the PIM-DM graft retry timer
4. (Optional.) Configuring common PIM timers

Prerequisites for PIM-DM

Before you configure PIM-DM, complete the following tasks:

- Configure a unicast routing protocol so that all devices in the domain can interoperate at the network layer.
- Enable IP multicast routing.

Enabling PIM-DM

About this task

With PIM-DM enabled on interfaces, devices can establish PIM neighbor relationship and process PIM messages from their PIM neighbors.

Restrictions and guidelines

As a best practice, enable PIM-DM on all non-border interfaces of the devices when you deploy a PIM-DM domain.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable IP multicast routing and enter MRIB view.

   ```
   multicast routing [ vpn-instance vpn-instance-name ]
   ```

   By default, IP multicast routing is disabled.

   For more information about this command, see *IP Multicast Command Reference*.

3. Return to system view.

   ```
   quit
   ```

4. Enter interface view.

   interface *interface-type interface-number*

5. Enable PIM-DM.

   pim dm

   By default, PIM-DM is disabled.

Configuring the state refresh feature

About this task

- **State refresh capability**—Enables the PIM device directly connected to the source to periodically send state refresh messages. It also enables other PIM devices to refresh pruned state timers after receiving the state refresh messages. It prevents the pruned interfaces from resuming multicast forwarding.
- **State refresh interval**—Determines the interval at which a device sends state refresh messages.
- **Wait time before accepting a new state refresh message**—A device might receive duplicate state refresh messages within a short time. To prevent this situation, you can configure the time that the device must wait to accept a new state refresh message. If the device receives a new state refresh message before the timer expires, it discards the message. If the device receives a new state refresh message after the timer expires, it accepts the message, refreshes its own PIM-DM state, and resets the waiting timer.
- **TTL value of state refresh messages**—The TTL value of a state refresh message decrements by 1 whenever it passes a device before it is forwarded to the downstream node. The state refresh message is not forwarded when the TTL value comes down to 0. A state refresh message with a large TTL value might cycle on a small network.

  To effectively control the propagation scope of state refresh messages, configure an appropriate TTL value based on the network size on the device directly connected with the multicast source.

Restrictions and guidelines

Perform this task on all devices in the PIM-DM domain.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the state refresh feature.

   pim state-refresh-capable

   By default, the state refresh feature is enabled.

4. Return to system view.

   quit

5. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

6. Set the state refresh interval.

   state-refresh-interval *interval*

   The default setting is 60 seconds.

   Perform this task on the device directly connected to the multicast source.

7. Set the amount of time that the device must wait to accept a new state refresh message.

```
state-refresh-rate-limit time
```

The default setting is 30 seconds.

8. Set the TTL value of state refresh messages.

```
state-refresh-ttl ttl-value
```

The default setting is 255.

Setting the PIM-DM graft retry timer

About this task

Perform this task to adjust the interval at which the device retransmits a graft message if it does not receive a graft-ack message from the upstream device.

Procedure

1. Enter system view.

```
system-view
```

2. Enter interface view.

```
interface interface-type interface-number
```

3. Set the graft retry timer.

```
pim timer graft-retry interval
```

The default setting is 3 seconds.

Configuring PIM-SM

PIM-SM tasks at a glance

To configure PIM-SM, perform the following tasks:

1. Enabling PIM-SM
2. Configuring static RPs

   As a best practice, configure a static RP when only one dynamic RP exists in the network.
3. Configuring dynamic RPs
   - Configuring C-RPs
   - Configuring C-BSRs
   - (Optional.) Configuring a PIM domain border
   - (Optional.) Disabling BSM semantic fragmentation
   - (Optional.) Disabling the device from forwarding BSMs out of their incoming interfaces

   As a best practice, configure dynamic RPs when multiple PIM devices exist in the network.

   You can configure static RPs, dynamic RPs, or both.
4. (Optional.) Enabling Auto-RP listening
5. (Optional.) Configuring Anycast RP
6. (Optional.) Configuring multicast source registration
7. (Optional.) Configuring the switchover to SPT
8. (Optional.) Configuring common PIM features

Prerequisites for PIM-SM

Before you configure PIM-SM, complete the following tasks:

- Configure a unicast routing protocol so that all devices in the domain can interoperate at the network layer.
- Enable IP multicast routing.

Enabling PIM-SM

About this task

With PIM-SM enabled on interfaces, devices can establish PIM neighbor relationship and process PIM messages from their PIM neighbors.

Restrictions and guidelines

As a best practice, enable PIM-SM on all non-border interfaces of devices when you deploy a PIM-SM domain.

Procedure

1. Enter system view.

   `system-view`

2. Enable IP multicast routing and enter MRIB view.

   `multicast routing` [**`vpn-instance`** *`vpn-instance-name`*]

   By default, IP multicast routing is disabled.

   For more information about this command, see *IP Multicast Command Reference*.

3. Return to system view.

   `quit`

4. Enter interface view.

   `interface` *`interface-type interface-number`*

5. Enable PIM-SM.

   `pim sm`

   By default, PIM-SM is disabled.

Configuring static RPs

About this task

If only one dynamic RP exists on a network, you can configure a static RP to avoid communication interruption caused by single-point failures. The static RP can also avoid waste of bandwidth because of frequent message exchanges between C-RPs and the BSR.

Restrictions and guidelines

In a PIM-SM domain, you can configure the same static RP for different multicast groups by using the same RP address but different ACLs.

You do not need to enable PIM for an interface to be configured as a static RP.

If you configure multiple static RPs for a multicast group, only the static RP with the highest IP address takes effect.

The static RP configuration must be the same on all devices in the PIM-SM domain.

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Configure a static RP.

   static-rp *rp-address* [*ipv4-acl-number* | **preferred**] *

Configuring C-RPs

About this task

To avoid C-RP spoofing, configure a C-RP policy to filter C-RP advertisement messages by using an ACL that specifies the packet source address range and multicast group addresses.

Restrictions and guidelines

Configure C-RPs on devices that reside in the backbone network.

Because the RP and other devices exchange a large amount of information in the PIM-SM domain, reserve a large bandwidth between C-RPs and other devices.

You must configure the same C-RP policy on all C-BSRs in the PIM-SM domain because every C-BSR might become the BSR.

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Configure a C-RP.

   c-rp *ip-address* [**advertisement-interval** *adv-interval* | **group-policy** *ipv4-acl-number* | **holdtime** *hold-time* | **priority** *priority*] *

4. (Optional.) Configure a C-RP policy.

   crp-policy *ipv4-acl-number*

   By default, no C-RP policies are configured. All C-RP advertisement messages are regarded as legal.

Configuring C-BSRs

About this task

You must configure C-BSRs when you configure dynamic RP election.

To prevent a legal BSR from being replaced by a malicious host, configure a BSR policy to filter BSR messages by using an ACL that specifies the legal BSR addresses. It is used to prevent the legal BSR from being replaced by a malicious host.

Restrictions and guidelines

Configure C-BSRs on devices that reside in the backbone network.

Because the BSR and other devices exchange a large amount of information in the PIM-SM domain, reserve a large bandwidth between C-BSRs and other devices.

The C-BSR configuration on the devices in the PIM-SM domain must be the same.

For a successful RPF check, configure static multicast routes to ensure that the next hop to a C-BSR is a tunnel interface when C-BSRs connect to other PIM devices through tunnels. For more information about static multicast routes, see "Configuring multicast routing and forwarding."

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Configure a C-BSR.

   c-bsr *ip-address* [**scope** *group-address* { *mask-length* | *mask* }] [**hash-length** *hash-length* | **priority** *priority*] *

4. (Optional.) Configure a BSR policy.

   bsr-policy *ipv4-acl-number*

   By default, no BSR policies are configured. All bootstrap messages are regarded as legal.

Configuring a PIM domain border

About this task

A PIM domain border determines the transmission boundary of bootstrap messages. Bootstrap messages cannot cross the domain border in either direction. A number of PIM domain border interfaces partition a network into different PIM-SM domains.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure a PIM domain border.

   pim bsr-boundary

   By default, an interface is not a PIM domain border.

Disabling BSM semantic fragmentation

About this task

BSM semantic fragmentation enables a BSR to split a BSM into multiple BSM fragments (BSMFs) if the BSM exceeds the MTU. In this way, a non-BSR device can update the RP-set information for a group range after receiving all BSMFs for the range. The loss of one BSMF only affects the RP-set information of the group ranges that the fragment contains.

Restrictions and guidelines

If a device does not support BSM semantic fragmentation, it regards a BSMF as a BSM and updates the RP-set information each time it receives a BSMF. It learns only part of the RP-set information, which further affects the RP election. Therefore, if such a device exists in the PIM-SM domain, you must disable BSM semantic fragmentation on all C-BSRs.

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Disable BSM semantic fragmentation.

   undo bsm-fragment enable

   By default, BSM semantic fragmentation is enabled.

Disabling the device from forwarding BSMs out of their incoming interfaces

About this task

By default, the device forwards BSMs out of their incoming interfaces. This default setting ensures that all devices on the subnet can receive BSMs even when they have inconsistent routing information. However, this default setting results in duplicated multicast traffic. If you are sure that all the devices on the subnet have consistent routing information, you can disable the device from forwarding BSMs out of their incoming interfaces.

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Disable the device from forwarding BSMs out of their incoming interfaces.

   undo bsm-reflection enable

   By default, the device forwards BSMs out of their incoming interfaces.

Enabling Auto-RP listening

About this task

This feature enables the device to receive Auto-RP announcement and discovery messages and learn RP information. The destination IP addresses for Auto-RP announcement and discovery messages are 224.0.1.39 and 224.0.1.40, respectively.

Restrictions and guidelines

After this feature is enabled, the device can receive and forward Auto-RP announcement and discovery messages, but it cannot send these messages unsolicitedly.

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Enable Auto-RP listening.

   auto-rp enable

   By default, Auto-RP listening is disabled.

Configuring Anycast RP

Restrictions and guidelines

To prevent the other Anycast RP member devices from discarding the BSM sent by the BSR, make sure the Anycast RP address is different from the BSR address.

As a best practice to ensure network performance, configure a maximum of 16 Anycast RP members for an Anycast RP set.

As a best practice, configure the IP address of a loopback interface as the RP member address.

If you configure IP addresses of multiple interfaces on the same device as RP member addresses, the lowest IP address takes effect. The rest of the interface addresses become backup RP member addresses.

An Anycast RP address must be a host address with subnet mask 255.255.255.255.

You must add the device where the Anycast RP resides as an RP member to the Anycast RP set.

Prerequisites

You must configure a static RP or C-RPs in the PIM-SM domain before you configure the Anycast RP. Use the address of the static RP or the dynamically elected RP as the Anycast RP address.

Procedure

1. Enter system view.

   `system-view`

2. Enter PIM view.

   `pim` [**`vpn-instance`** *`vpn-instance-name`*]

3. Configure Anycast RP.

   `anycast-rp` *`anycast-rp-address member-rp-address`*

   By default, Anycast RP is not configured.

   You can repeat this command to add multiple RP member addresses to the Anycast RP set.

Configuring multicast source registration

About this task

- **PIM register policy**—A PIM register policy enables an RP to filter register messages by using an ACL that specifies the multicast sources and groups. The policy limits the multicast groups to which the RP is designated. If a register message is denied by the ACL or does not match the ACL, the RP discards the register message and sends a register-stop message to the source-side DR. The registration process stops.
- **Checksum computing method for register messages**—For information integrity of a register message, you can configure the device to calculate the checksum based on the entire register message. If a device cannot calculate the checksum based on the entire register message, you can configure the device to calculate the checksum based on the register message header.
- **Register suppression time—**The source-side DR stops sending register messages encapsulated with multicast data and starts a register-stop timer upon receiving a register-stop message from the RP. Before the register-stop timer expires, the DR sends a null register message (a register message without encapsulated multicast data) to the RP and starts a register probe timer. If the DR receives a register-stop message before the register probe timer expires, it resets its register-stop timer. Otherwise, the DR starts sending register messages with encapsulated data again.

The register-stop timer is set to a random value chosen uniformly from (0.5 × register_suppression_time minus register_probe_time) to (1.5 × register_suppression_time minus register_probe_time). The register_probe_time is fixed to 5 seconds. You can adjust the register suppression time.

Restrictions and guidelines

On all C-RP devices, configure a PIM register policy and the checksum computing method for register messages.

On all devices that might become the source-side DR, set the register suppression time.

Procedure

1. Enter system view.

   `system-view`

2. Enter PIM view.

   `pim` [**`vpn-instance`** *`vpn-instance-name`*]

3. Configure a PIM register policy.

   `register-policy` *`ipv4-acl-number`*

   By default, no PIM register policy is configured. All PIM register messages are regarded as legal.

4. Configure the device to calculate the checksum based on the entire register message.

   `register-whole-checksum`

   By default, the device calculates the checksum based on the header of a register message.

5. Set the register suppression time.

   `register-suppression-timeout` *`interval`*

   The default setting is 60 seconds.

Configuring the switchover to SPT

About this task

Both the receiver-side DR and RP can monitor the traffic rate of passing-by multicast packets and thus trigger a switchover from RPT to SPT. The monitor function is not available on switches.

Restrictions and guidelines

Some devices cannot encapsulate multicast data in register messages destined to the RP. As a best practice to avoid multicast data forwarding failures, do not disable the switchover to SPT on C-RPs that might become the RP.

Procedure

1. Enter system view.

   `system-view`

2. Enter PIM view.

   `pim` [**`vpn-instance`** *`vpn-instance-name`*]

3. Configure RPT to SPT switchover.

   `spt-switch-threshold` { *`traffic-rate`* | **`immediacy`** | **`infinity`** } [**`group-policy`** *`ipv4-acl-number`*]

   By default, the first multicast data packet triggers the RPT to SPT switchover.

   Support for the *`traffic-rate`* argument depends on the device model. For more information, see the command reference.

Configuring BIDIR-PIM

BIDIR-PIM tasks at a glance

To configure BIDIR-PIM, perform the following tasks:

1. Enabling BIDIR-PIM
2. Configuring static RPs

   As a best practice, configure a static RP when only one dynamic RP exists in the network.
3. Configuring dynamic RPs
   - Configuring C-RPs
   - Configuring C-BSRs
   - (Optional.) Configuring a PIM domain border
   - (Optional.) Disabling BSM semantic fragmentation
   - (Optional.) Disabling the device from forwarding BSMs out of their incoming interfaces

   As a best practice, configure dynamic RPs when multiple PIM devices exist in the network.

   You can configure static RPs, dynamic RPs, or both.
4. (Optional.) Setting the maximum number of BIDIR-PIM RPs
5. (Optional.) Enabling Auto-RP listening
6. (Optional.) Configuring common PIM features

Prerequisites for BIDIR-PIM

Before you configure BIDIR-PIM, complete the following tasks:

- Configure a unicast routing protocol so that all devices in the domain can interoperate at the network layer.
- Enable PIM-SM.

Enabling BIDIR-PIM

Restrictions and guidelines

As a best practice, enable PIM-SM on all non-border interfaces of devices when you deploy a BIDIR-PIM domain.

Procedure

1. Enter system view.

   `system-view`
2. Enable IP multicast routing and enter MRIB view.

   `multicast routing` [**`vpn-instance`** *`vpn-instance-name`*]

   By default, IP multicast routing is disabled.

   For more information about this command, see *IP Multicast Command Reference*.
3. Return to system view.

   `quit`
4. Enter interface view.

   `interface` *`interface-type interface-number`*
5. Enable PIM-SM.

```
pim sm
```

By default, PIM-SM is disabled.

6. Return to system view.

   ```
   quit
   ```

7. Enter PIM view.

   ```
   pim [ vpn-instance vpn-instance-name ]
   ```

8. Enable BIDIR-PIM.

   ```
   bidir-pim enable
   ```

   By default, BIDIR-PIM is disabled.

Configuring static RPs

About this task

If only one dynamic RP exists on a network, you can configure a static RP to avoid communication interruption caused by single-point failures. The static RP can also avoid bandwidth waste caused by frequent message exchanges between C-RPs and the BSR.

Restrictions and guidelines

The static RP configuration must be the same on all devices in the BIDIR-PIM domain.

In a BIDIR-PIM domain, you can configure the same static RP for different multicast groups by using the same RP address but different ACLs.

You do not need to enable PIM for an interface to be configured as a static RP.

If you configure multiple static RPs for a multicast group, only the static RP with the highest IP address takes effect.

You can specify an unused IP address for a static RP. This address must be on the same subnet with the link on which the static RP is configured. For example, if the IP addresses of the interfaces at the two ends of a link are 10.1.1.1/24 and 10.1.1.2/24, you can specify the interface with IP address 10.1.1.100/24 as a static RP. As a result, the link becomes an RPL.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter PIM view.

   ```
   pim [ vpn-instance vpn-instance-name ]
   ```

3. Configure a static RP for BIDIR-PIM.

   ```
   static-rp rp-address bidir [ ipv4-acl-number | preferred ] *
   ```

Configuring C-RPs

About this task

To guard against C-RP spoofing, configure a C-RP policy to filter C-RP advertisement messages by using an ACL that specifies the packet source address range and multicast groups.

Restrictions and guidelines

Configure C-RPs on devices that reside in the backbone network.

Because the RP and other devices exchange a large amount of information in the BIDIR-PIM domain, reserve a large bandwidth between C-RPs and other devices.

You must configure the same C-RP policy on all C-BSRs in the BIDIR-PIM domain because every C-BSR might become the BSR.

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Configure a C-RP to provide services for BIDIR-PIM.

   c-rp *ip-address* [**advertisement-interval** *adv-interval* | **group-policy** *ipv4-acl-number* | **holdtime** *hold-time* | **priority** *priority*] * **bidir**

Configuring C-BSRs

About this task

You must configure C-BSRs when you configure dynamic RP election.

To prevent a legal BSR from being replaced by a malicious host, configure a BSR policy to filter BSR messages by using an ACL that specifies the legal BSR addresses.

Restrictions and guidelines

Configure C-BSRs on devices that reside in the backbone device.

Because the BSR and other devices exchange a large amount of information in the BIDIR-PIM domain, reserve a large bandwidth between the C-BSRs and other devices.

The C-BSR configuration on the devices in the BIDIR-PIM domain must be the same.

For C-BSRs interconnected through a GRE tunnel, configure static multicast routes to make sure the next hop to a C-BSR is a tunnel interface. For more information about static multicast routes, see "Configuring multicast routing and forwarding."

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Configure a C-BSR.

   c-bsr *ip-address* [**scope** *group-address* { *mask-length* | *mask* }] [**hash-length** *hash-length* | **priority** *priority*] *

4. (Optional.) Configure a BSR policy.

   bsr-policy *ipv4-acl-number*

   By default, no BSR policy is configured. All bootstrap messages are regarded as legal.

Configuring a PIM domain border

About this task

A PIM domain border determines the transmission boundary of bootstrap messages. Bootstrap messages cannot cross the domain border in either direction. A number of PIM domain border interfaces partition a network into different BIDIR-PIM domains.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure a PIM domain border.

   pim bsr-boundary

   By default, an interface is not a PIM domain border.

Disabling BSM semantic fragmentation

About this task

BSM semantic fragmentation enables a BSR to split a BSM into multiple BSM fragments (BSMFs) if the BSM exceeds the MTU. In this way, a non-BSR device can update the RP-set information for a group range after receiving all BSMFs for the group range. The loss of one BSMF only affects the RP-set information of the group ranges that the fragment contains.

Restrictions and guidelines

If a device does not support BSM semantic fragmentation, it regards a BSMF as a BSM and updates the RP-set information each time it receives a BSMF. It learns only part of the RP-set information, which further affects the RP election. Therefore, if such a device presents in the BIDIR-PIM domain, you must disable BSM semantic fragmentation on all C-BSRs.

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Disable BSM semantic fragmentation.

   undo bsm-fragment enable

   By default, BSM semantic fragmentation is enabled.

Disabling the device from forwarding BSMs out of their incoming interfaces

About this task

By default, the device forwards BSMs out of their incoming interfaces. This default setting ensures that all devices on the subnet can receive BSMs even when they have inconsistent routing information. However, this default setting results in duplicated multicast traffic. If you are sure that all the devices on the subnet have consistent routing information, you can disable the device from forwarding BSMs out of their incoming interfaces.

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Disable the device from forwarding BSMs out of their incoming interfaces.

undo bsm-reflection enable

By default, the device forwards BSMs out of their incoming interfaces.

Setting the maximum number of BIDIR-PIM RPs

About this task

In a BIDIR-PIM domain, one DF election per RP is implemented on all PIM-enabled interfaces. To avoid unnecessary DF elections, do not configure multiple RPs for BIDIR-PIM.

This configuration sets a limit on the number of BIDIR-PIM RPs. If the number of RPs exceeds the limit, excess RPs do not take effect and can be used only for DF election rather than multicast data forwarding. The system does not delete the excess RPs. They must be deleted manually.

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Set the maximum number of BIDIR-PIM RPs.

   bidir-rp-limit *limit*

   By default, the maximum number of BIDIR-PIM RPs is 128.

Enabling Auto-RP listening

About this task

This feature enables the device to receive Auto-RP announcement and discovery messages and learn RP information. The destination IP addresses for Auto-RP announcement and discovery messages are 224.0.1.39 and 224.0.1.40, respectively.

Restrictions and guidelines

After this feature is enabled, the device can receive and forward Auto-RP announcement and discovery messages, but it cannot send these messages unsolicitedly.

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Enable Auto-RP listening.

   auto-rp enable

   By default, Auto-RP listening is disabled.

Configuring PIM-SSM

PIM-SSM tasks at a glance

To configure PIM-SSM, perform the following tasks:

1. Enabling PIM-SM

2. (Optional.) Configuring the SSM group range
3. (Optional.) Configuring common PIM features

Prerequisites for PIM-SSM

Before you configure PIM-SSM, complete the following tasks:

- Configure a unicast routing protocol so that all devices in the domain can interoperate at the network layer.
- Enable PIM-SM.
- Enable IGMPv3 on PIM devices that connect to multicast receivers.

Enabling PIM-SM

Restrictions and guidelines

As a best practice, enable PIM-SM on all non-border interfaces of devices when you deploy a PIM-SSM domain.

Procedure

1. Enter system view.

   `system-view`

2. Enable multicast routing and enter MRIB view.

   `multicast routing` [**`vpn-instance`** *`vpn-instance-name`*]

   By default, multicast routing is disabled.

   For more information about this command, see *IP Multicast Command Reference*.

3. Return to system view.

   `quit`

4. Enter interface view.

   `interface` *`interface-type interface-number`*

5. Enable PIM-SM.

   `pim sm`

   By default, PIM-SM is disabled.

Configuring the SSM group range

About this task

When a PIM-SM enabled interface receives a multicast packet, it checks whether the multicast group address of the packet is in the SSM group range. If the multicast group address is in this range, the PIM mode for this packet is PIM-SSM. If the multicast group address is not in this range, the PIM mode is PIM-SM.

Restrictions and guidelines

Configure the same SSM group range on all devices in the entire PIM-SSM domain. Otherwise, multicast information cannot be delivered through the SSM model.

When a member of a multicast group in the SSM group range sends an IGMPv1 or IGMPv2 report message, the device does not trigger a (*, G) join.

Procedure

1. Enter system view.

system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Configure the SSM group range.

   ssm-policy *ipv4-acl-number*

   By default, the SSM group range is 232.0.0.0/8.

Configuring common PIM features

Common PIM feature tasks at a glance

All the following tasks are optional.

- Configuring a multicast source policy
- Configuring a PIM hello policy
- Configuring PIM hello message options
- Dropping hello messages without the Generation ID option
- Configuring common PIM timers
- Setting the maximum size of a join or prune message
- Enabling PIM prune delay
- Enabling BFD for PIM
- Enabling PIM passive mode
- Enabling PIM NSR
- Enabling NBMA mode for ADVPN tunnel interfaces
- Enabling SNMP notifications for PIM

Configuring a multicast source policy

About this task

This feature enables the device to filter multicast data by using an ACL that specifies the multicast sources and the optional groups. It filters not only data packets but also register messages with multicast data encapsulated. It controls the information available to downstream receivers.

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Configure a multicast source policy.

   source-policy *ipv4-acl-number*

   By default, no multicast source policy is configured. The device does not filter multicast data packets.

Configuring a PIM hello policy

About this task

This feature enables the device to filter PIM hello messages by using an ACL that specifies the packet source addresses. It is used to guard against PIM message attacks and to establish correct PIM neighboring relationships.

If hello messages of an existing PIM neighbor are filtered out by the policy, the neighbor is automatically removed when its aging timer expires.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure a PIM hello policy.

   `pim neighbor-policy` *`ipv4-acl-number`*

   By default, no PIM hello policy is configured on an interface. All PIM hello messages are regarded as legal.

Configuring PIM hello message options

About this task

In either a PIM-DM domain or a PIM-SM domain, hello messages exchanged among devices contain the following configurable options:

- **DR_Priority** (for PIM-SM only)—Priority for DR election. The device with the highest priority wins the DR election. You can configure this option for all the devices in a shared-media LAN that directly connects to the multicast source or the receivers.
- **Holdtime**—PIM neighbor lifetime. If a device does not receive a hello message from a neighbor when the neighbor lifetime expires, it regards the neighbor failed or unreachable.
- **LAN_Prune_Delay**—Delay of pruning a downstream interface on a shared-media LAN. This option has the LAN delay field, the override interval field, and the T bit.

  The LAN delay defines the PIM message propagation delay. The override interval defines a period for a device to override a prune message. The T bit specifies the capability of tracking downstream device status on upstream devices.

  On the shared-media LAN, the propagation delay and override interval are used as follows:

  - If a device receives a prune message on its upstream interface, it means that there are downstream devices on the shared-media LAN. If this device still needs to receive multicast data, it must send a join message to override the prune message within the override interval.
  - When a device receives a prune message from its downstream interface, it does not immediately prune this interface. Instead, it starts a timer (the propagation delay plus the override interval). If interface receives a join message before the timer expires, the device does not prune the interface. Otherwise, the device prunes the interface.
- **Neighbor tracking**—If you enable neighbor tracking on an upstream device, this device can track the states of the downstream nodes for which the joined state holdtime timer has not expired. All join messages from downstream devices are accepted.

Restrictions and guidelines

If the propagation delay or override interval on different PIM devices on a shared-media LAN are different, the largest ones apply.

If you want to enable neighbor tracking, you must enable it on all PIM devices on a shared-media LAN. Otherwise, the upstream device cannot track join messages from every downstream devices.

You can configure hello message options for all interfaces in PIM view or for the current interface in interface view. The configuration made in interface view takes priority over the configuration made in PIM view.

Configuring hello message options globally

1. Enter system view.
   system-view
2. Enter PIM view.
   pim [**vpn-instance** *vpn-instance-name*]
3. Set the DR priority.
   hello-option dr-priority *priority*
   The default setting is 1.
4. Set the neighbor lifetime.
   hello-option holdtime *time*
   The default setting is 105 seconds.
5. Set the PIM message propagation delay for a shared-media LAN.
   hello-option lan-delay *delay*
   The default setting is 500 milliseconds.
6. Set the override interval.
   hello-option override-interval *interval*
   The default setting is 2500 milliseconds.
7. Enable neighbor tracking.
   hello-option neighbor-tracking
   By default, neighbor tracking is disabled.

Configuring hello message options on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the DR priority.
   pim hello-option dr-priority *priority*
   The default setting is 1.
4. Set the neighbor lifetime.
   pim hello-option holdtime *time*
   The default setting is 105 seconds.
5. Set the PIM message propagation delay.
   pim hello-option lan-delay *delay*
   The default setting is 500 milliseconds.
6. Set the override interval.
   pim hello-option override-interval *interval*
   The default setting is 2500 milliseconds.
7. Enable neighbor tracking.

```
pim hello-option neighbor-tracking
```

By default, neighbor tracking is disabled.

Dropping hello messages without the Generation ID option

About this task

A device generates a generation ID for hello messages when an interface is enabled with PIM. The generation ID is a random value, but it changes only when the status of the device changes. If a PIM device finds that the generation ID in a hello message from the upstream device has changed, it assumes that the status of the upstream device has changed. In this case, it sends a join message to the upstream device for status update. You can configure an interface to drop hello messages without the generation ID options to promptly know the status of an upstream device.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Enable the interface to drop hello messages without the Generation ID option.

   ```
   pim require-genid
   ```

   By default, an interface accepts hello messages without the Generation ID option.

Configuring common PIM timers

About this task

The following are common PIM timers:

- **Hello interval**—Interval at which a PIM device sends hello messages to discover PIM neighbors, and maintain PIM neighbor relationship.
- **Triggered hello delay**—Maximum delay for sending a hello message to avoid collisions caused by simultaneous hello messages. After receiving a hello message, a PIM device waits for a random time before sending a hello message. This random time is in the range of 0 to the triggered hello delay.
- **Join/Prune interval**—Interval at which a PIM device sends join/prune messages to its upstream devices for state update.
- **Joined/Pruned state holdtime**—Time for which a PIM device keeps the joined or pruned state for the downstream interfaces. This joined or pruned state holdtime is specified in a join/prune message.
- **Multicast source lifetime**—Lifetime that a PIM device maintains for a multicast source. If a device does not receive subsequent multicast data from the multicast source S when the timer expires, it deletes the (S, G) entry for the multicast source.

Restrictions and guidelines

To prevent upstream neighbors from aging out, set the join/prune interval to be less than the join/pruned state holdtime.

You can configure common PIM timers for all interfaces in PIM view or for the current interface in interface view. The configuration made in interface view takes priority over the configuration made in PIM view.

As a best practice, use the defaults for a network without special requirements.

Configuring common PIM timers globally

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Set the hello interval.

   timer hello *interval*

   The default setting is 30 seconds.

4. Set the join/prune interval.

   timer join-prune *interval*

   The default setting is 60 seconds.

   This configuration takes effect after the current interval ends.

5. Set the joined or pruned state holdtime.

   holdtime join-prune *time*

   The default setting is 210 seconds.

6. Set the multicast source lifetime.

   source-lifetime *time*

   The default setting is 210 seconds.

Configuring common PIM timers on an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the hello interval.

   pim timer hello *interval*

   The default setting is 30 seconds.

4. Set the triggered hello delay.

   pim triggered-hello-delay *delay*

   The default setting is 5 seconds.

5. Set the join/prune interval.

   pim timer join-prune *interval*

   The default setting is 60 seconds.

   This configuration takes effect after the current interval ends.

6. Set the joined or pruned state holdtime.

   pim holdtime join-prune *time*

   The default setting is 210 seconds.

Setting the maximum size of a join or prune message

About this task

The loss of an oversized join or prune message might result in loss of massive information. You can set a small value for the size of a join or prune message to reduce the impact.

Procedure

1. Enter system view.

   system-view

2. Enter PIM view.

   pim [**vpn-instance** *vpn-instance-name*]

3. Set the maximum size of a join or prune message.

   jp-pkt-size *size*

   The default setting is 1200 bytes.

Enabling PIM prune delay

About this task

By default, an interface determines whether to starts the prune delay timer when it receives a prune message based on the number of PIM neighbors it. An interface starts the prune delay timer only when it has more than one PIM neighbor. When the prune delay timer expires, the device remove the receiving interface from the output interface list of the (S, G) entry.

In a DRNI-capable Layer 3 multicast network, the IP addresses of the two DR interfaces on DR devices are the same, the upstream device will consider the DR devices as one PIM neighbor and will not start the prune delay timer. When one DR device sends a prune message to the upstream device, the upstream device immediately remote the DR interface from the output interface list of the (S, G) entry. If the other DR device has receivers connected and the network is complex, the upstream device need to wait a long time to receive prune messages from the DR device. This situation causes multicast traffic interruption for a long time.

This feature allows the device to enable PIM prune delay and start the prune delay timer regardless of the number of PIM neighbors on an interface. The value of the timer is the sum of the override interval (configured by using the **pim hello-option override-interval** command) and the PIM message propagation delay (configured by using the **pim hello-option lan-delay** command).

Restrictions and guidelines

This feature takes effect only if PIM-DM or PIM-SM is enabled.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable BFD for PIM.

   pim prune-pending

   By default, BFD is disabled for PIM.

Enabling BFD for PIM

About this task

If a DR on a shared-media network fails, a new DR election process does not start until the DR ages out. In addition, it might take a long period of time before other devices detect the link failures and trigger a new DR election. To start a new DR election process immediately after the original DR fails, enable BFD for PIM to detect link failures among PIM neighbors.

You must enable BFD for PIM on all PIM devices on a shared-media network. For more information about BFD, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Enable BFD for PIM.

   `pim bfd enable`

   By default, BFD is disabled for PIM.

Enabling PIM passive mode

About this task

To guard against PIM hello spoofing, you can enable PIM passive mode on a receiver-side interface. The PIM passive interface cannot receive or forward PIM protocol messages (excluding register, register-stop, and C-RP-Adv messages), and it acts as the DR on the subnet. In BIDIR-PIM, it also acts as the DF.

Restrictions and guidelines

To avoid duplicate multicast data transmission and flow loop, do not enable this feature on a shared-media LAN with multiple PIM devices.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Enable PIM passive mode on the interface.

   `pim passive`

   By default, PIM passive mode is disabled on an interface.

Enabling PIM NSR

About this task

This feature enables PIM to back up protocol state information and data, including PIM neighbor information and routes, from the active process to the standby process. The standby process immediately takes over when the active process fails. Use this feature to avoid route flapping and forwarding interruption for PIM when an active/standby switchover occurs.

Procedure

1. Enter system view.

   `system-view`

2. Enable PIM NSR.

   `pim non-stop-routing`

   By default, PIM NSR is disabled.

Enabling NBMA mode for ADVPN tunnel interfaces

About this task

This feature allows ADVPN tunnel interfaces to forward multicast data only to target spokes and hubs. For more information about ADVPN, see *VPN Configuration Guide*.

Restrictions and guidelines

This feature is not available for PIM-DM.

This feature takes effect only when PIM-SM is enabled on the ADVPN tunnel interface.

In a BIDIR-PIM domain, make sure RPs do not reside on ADVPN tunnel interfaces or on the subnet where ADVPN tunnel interfaces are located.

Do not configure IGMP features on ADVPN tunnel interfaces that are enabled with NBMA mode.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable NBMA mode.

   pim nbma-mode

   By default, NBMA mode is disabled.

   This command is applicable only to ADVPN tunnel interfaces.

Enabling SNMP notifications for PIM

About this task

To report critical PIM events to an NMS, enable SNMP notifications for PIM. For PIM event notifications to be sent correctly, you must also configure SNMP as described in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for PIM.

   snmp-agent trap enable pim [**candidate-bsr-win-election** | **elected-bsr-lost-election** | **neighbor-loss**] *

   By default, SNMP notifications for PIM are enabled.

Display and maintenance commands for PIM

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display register-tunnel interface information.	**display interface** [**register-tunnel** [*interface-number*]] [**brief** [**description** | **down**]]

Task	Command
Display BSR information in the PIM-SM domain.	**display pim** [**vpn-instance** *vpn-instance-name*] **bsr-info**
Display information about the routes used by PIM.	**display pim** [**vpn-instance** *vpn-instance-name*] **claimed-route** [*source-address*]
Display C-RP information in the PIM-SM domain.	**display pim** [**vpn-instance** *vpn-instance-name*] **c-rp** [**local**]
Display DF information in the BIDIR-PIM domain.	**display pim** [**vpn-instance** *vpn-instance-name*] **df-info** [*rp-address*]
Display PIM information on an interface.	**display pim** [**vpn-instance** *vpn-instance-name*] **interface** [*interface-type interface-number*] [**verbose**]
Display PIM neighbor information.	**display pim** [**vpn-instance** *vpn-instance-name*] **neighbor** [*neighbor-address* | **interface** *interface-type interface-number* | **verbose**] *
Display PIM routing entries.	**display pim** [**vpn-instance** *vpn-instance-name*] **routing-table** [*group-address* [**mask** { *mask-length* | *mask* }] | *source-address* [**mask** { *mask-length* | *mask* }] | **flags** *flag-value* | **fsm** | **incoming-interface** *interface-type interface-number* | **mode** *mode-type* | **outgoing-interface** { **exclude** | **include** | **match** } *interface-type interface-number* | **extranet** { **source-vpn-instance** *source-vpn-instance-name* | **source-public-instance** | **receive-vpn-instance** *receive-vpn-instance-name* | **receive-public-instance** }] *
Display RP information in the PIM-SM domain.	**display pim** [**vpn-instance** *vpn-instance-name*] **rp-info** [*group-address*]
Display statistics for PIM packets.	**display pim statistics**
Display remote end information maintained by PIM for ADVPN tunnel interfaces.	**display pim** [**vpn-instance** *vpn-instance-name*] **nbma-link** [**interface** { *interface-type interface-number* }]

Troubleshooting PIM

A multicast distribution tree cannot be correctly built

Symptom

No multicast forwarding entries are established on the devices (including devices directly connected with multicast sources or receivers) in a PIM network. This means that a multicast distribution tree cannot be built correctly.

Solution

To resolve the problem:

1. Use **display ip routing-table** to verify that a unicast route to the multicast source or the RP is available.
2. Use **display pim interface** to verify PIM information on each interface, especially on the RPF interface. If PIM is not enabled on the interfaces, use **pim dm** or **pim sm** to enable PIM-DM or PIM-SM for the interfaces.
3. Use **display pim neighbor** to verify that the RPF neighbor is a PIM neighbor.
4. Verify that PIM and IGMP are enabled on the interfaces that directly connect to the multicast sources or the receivers.
5. Use **display pim interface verbose** to verify that the same PIM mode is enabled on the RPF interface on a device and the connected interface of the device's RPF neighbor.
6. Use **display current-configuration** to verify that the same PIM mode is enabled on all devices. For PIM-SM, verify that the BSR and C-RPs are correctly configured.
7. If the problem persists, contact NSFOCUS Support.

Multicast data is abnormally terminated on an intermediate device

Symptom

An intermediate device can receive multicast data successfully, but the data cannot reach the last-hop device. An interface on the intermediate device receives multicast data but does not create an (S, G) entry in the PIM routing table.

Solution

To resolve the problem:

1. Use **display current-configuration** to verify the multicast forwarding boundary settings. Use **multicast boundary** to change the multicast forwarding boundary settings to make the multicast packet able to cross the boundary.
2. Use **display current-configuration** to verify the multicast source policy. Change the ACL rule defined in the **source-policy** command so that the source/group address of the multicast data can pass ACL filtering.
3. If the problem persists, contact NSFOCUS Support.

An RP cannot join an SPT in PIM-SM

Symptom

An RPT cannot be correctly built, or an RP cannot join the SPT toward the multicast source.

Solution

To resolve the problem:

1. Use **display ip routing-table** to verify that a unicast route to the RP is available on each device.
2. Use **display pim rp-info** to verify that the dynamic RP information is consistent on all devices.
3. Use **display pim rp-info** to verify that the same static RPs are configured on all devices on the network.
4. If the problem persists, contact NSFOCUS Support.

An RPT cannot be built or multicast source registration fails in PIM-SM

Symptom

The C-RPs cannot unicast advertisement messages to the BSR. The BSR does not advertise BSMs containing C-RP information and has no unicast route to any C-RP. An RPT cannot be correctly established, or the source-side DR cannot register the multicast source with the RP.

Solution

To resolve the problem:

1. Use **display ip routing-table** on each device to view routing table information. Verify that unicast routes to the C-RPs and the BSR are available on each device and that a route is available between each C-RP and the BSR.
2. Use **display pim bsr-info** to verify that the BSR information exists on each device.
3. Use **display pim rp-info** to verify that the RP information is correct on each device.
4. Use **display pim neighbor** to verify that PIM neighboring relationship has been correctly established among the devices.
5. If the problem persists, contact NSFOCUS Support.

Configuring IPv6 multicast routing and forwarding

About IPv6 multicast routing and forwarding

Each IPv6 multicast routing protocol has its own routing table. Multicast routing information in routing entries generated by the IPv6 multicast routing protocols are summarized in a set of (S, G) and (*, G) entries. All the (S, G) and (*, G) entries form a general IPv6 multicast routing table. The optimal IPv6 multicast routing entries in the general IPv6 multicast routing table are added to the IPv6 multicast forwarding table to guide IPv6 multicast data forwarding.

RPF check mechanism

An IPv6 multicast routing protocol uses the reverse path forwarding (RPF) check mechanism to ensure IPv6 multicast data delivery along the correct path and to avoid data loops.

RPF check process

An IPv6 multicast device performs the RPF check on an IPv6 multicast packet as follows:

1. Chooses an optimal route back to the packet source separately from the IPv6 unicast and IPv6 MBGP routing tables.

   In RPF check, the "packet source" means difference things in difference situations:

   - For a packet that travels along the SPT, the packet source is the IPv6 multicast source.
   - For a packet that travels along the RPT, the packet source is the RP.
   - For a bootstrap message originated from the BSR, the packet source is the BSR.

2. Selects one of the optimal routes as the RPF route as follows:

   - If the device uses the longest prefix match principle, the route with a higher prefix length becomes the RPF route. If the routes have the same prefix length, the route with a higher route preference becomes the RPF route. If the routes have the same route preference, the IPv6 MBGP route becomes the RPF route. If equal cost routes exist, the route with the highest next hop IPv6 address becomes the RPF route.

     For more information about the route preference, see *Layer 3—IP Routing Configuration Guide*.

   - If the device does not use the longest prefix match principle, the route with a higher route preference becomes the RPF route. If the routes have the same route preference, the IPv6 MBGP route becomes the RPF route. If equal cost routes exist, the route with the highest next hop IPv6 address becomes the RPF route.

   In the RPF route, the outgoing interface is the RPF interface and the next hop is the RPF neighbor.

3. Determines whether the packet arrived at the RPF interface.

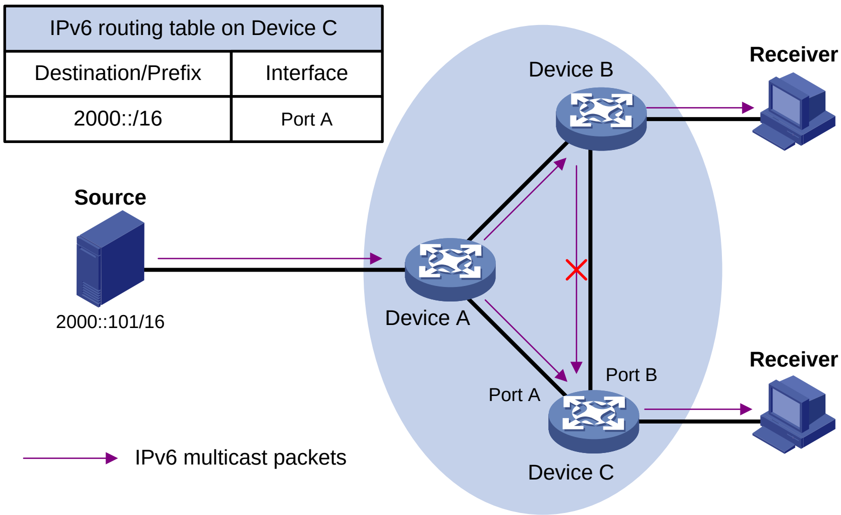
   - If the packet arrived at the RPF interface, the RPF check succeeds and the packet is forwarded.
   - If the packet arrived at the non-RPF interface, the RPF check fails and the packet is discarded.

RPF check implementation in IPv6 multicast

Implementing an RPF check on each received IPv6 multicast packet would heavily burden the device. The use of an IPv6 multicast forwarding table is the solution to this issue. When the device creates an IPv6 multicast forwarding entry for an IPv6 (S, G) packet, it sets the RPF interface of the packet as the incoming interface of the (S, G) entry. After the device receives another (S, G) packet, it looks up its IPv6 multicast forwarding table for a matching (S, G) entry.

- If no match is found, the device first determines the RPF route back to the packet source. Then, it creates a forwarding entry with the RPF interface as the incoming interface and performs one of the following tasks:
    - If the receiving interface is the RPF interface, the RPF check succeeds and the device forwards the packet out of all outgoing interfaces.
    - If the receiving interface is not the RPF interface, the RPF check fails and the device discards the packet.
- If a match is found and the matching forwarding entry contains the receiving interface, the device forwards the packet out of all outgoing interfaces.
- If a match is found but the matching forwarding entry does not contain the receiving interface, the device determines the RPF route back to the packet source. Then, the device performs one of the following tasks:
    - If the RPF interface is the incoming interface, it means that the forwarding entry is correct but the packet traveled along a wrong path. The packet fails the RPF check, and the device discards the packet.
    - If the RPF interface is not the incoming interface, it means that the forwarding entry has expired. The device replaces the incoming interface with the RPF interface and matches the receiving interface against the RPF interface. If the receiving interface is the RPF interface, the device forwards the packet out of all outgoing interfaces. Otherwise, it discards the packet.

Figure 1 RPF check process



IPv6 routing table on Device C	
Destination/Prefix	Interface
2000::/16	Port A

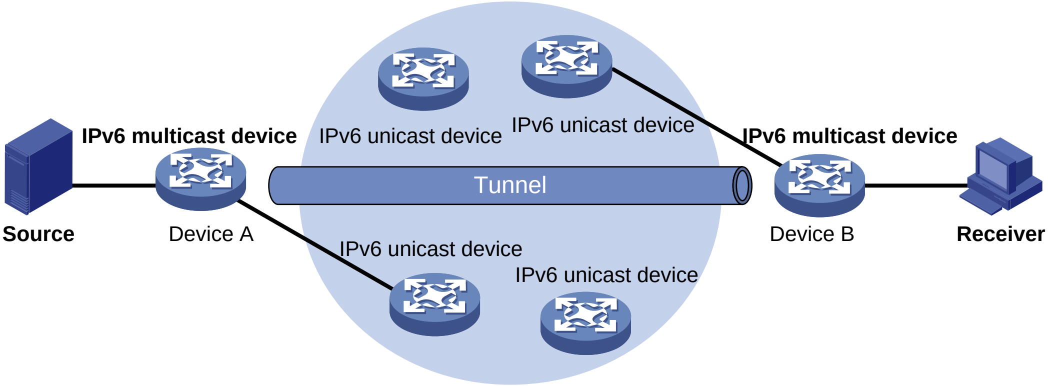
As shown in Figure 1, assume that IPv6 unicast routes are available on the network. IPv6 MBGP is not configured. IPv6 multicast packets travel along the SPT from the multicast source to the receivers. The IPv6 multicast forwarding table on Device C contains the (S, G) entry, with Port A as the RPF interface.

- If an IPv6 multicast packet arrives at Device C on Port A, the receiving interface is the incoming interface of the (S, G) entry. Device C forwards the packet out of all outgoing interfaces.
- If an IPv6 multicast packet arrives at Device C on Port B, the receiving interface is not the incoming interface of the (S, G) entry. Device C searches its IPv6 unicast routing table and finds that the outgoing interface to the source (the RPF interface) is Port A. This means that the (S, G) entry is correct but the packet traveled along a wrong path. The packet fails the RPF check, and Device C discards the packet.

IPv6 multicast forwarding across IPv6 unicast subnets

Devices forward the IPv6 multicast data from an IPv6 multicast source hop by hop along the forwarding tree, but some devices might not support IPv6 multicast protocols in a network. When the IPv6 multicast data is forwarded to a device that does not support IPv6 multicast, the forwarding path is blocked. In this case, you can enable IPv6 multicast data forwarding across the IPv6 unicast subnets by establishing a tunnel between the devices at both ends of the IPv6 unicast subnets.

Figure 2 IPv6 multicast data transmission through a tunnel



As shown in Figure 2, a tunnel is established between Device A and Device B. Device A encapsulates the IPv6 multicast data in unicast IPv6 packets, and forwards them to Device B across the tunnel through unicast devices. Then, Device B strips off the unicast IPv6 header and continues to forward the IPv6 multicast data down toward the receivers.

IPv6 multicast routing and forwarding tasks at a glance

To configure IPv6 multicast routing and forwarding, perform the following tasks:

1. Enabling IPv6 multicast routing
2. (Optional.) Specifying the longest prefix match principle
3. (Optional.) Configuring IPv6 multicast load splitting
4. (Optional.) Configuring an IPv6 multicast forwarding boundary
5. (Optional.) Setting the maximum number of cached unknown IPv6 multicast packets
6. (Optional.) Configuring an IPv6 MVPN extranet RPF selection policy

Prerequisites for IPv6 multicast routing and forwarding

Before you configure multicast routing and forwarding, configure an IPv6 unicast routing protocol so that all devices in the domain can interoperate at the network layer.

Enabling IPv6 multicast routing

About this task

Enable IPv6 multicast routing before you configure any Layer 3 IPv6 multicast functionality in the public network or VPN instance.

Procedure

1. Enter system view.

   system-view

2. Enable IPv6 multicast routing and enter IPv6 MRIB view.

   ipv6 multicast routing [**vpn-instance** *vpn-instance-name*]

   By default, IPv6 multicast routing is disabled.

Specifying the longest prefix match principle

About this task

You can enable the device to use the longest prefix match principle for RPF route selection. For more information about RPF route selection, see "RPF check process."

Procedure

1. Enter system view.

   system-view

2. Enter IPv6 MRIB view.

   ipv6 multicast routing [**vpn-instance** *vpn-instance-name*]

3. Specify the longest prefix match principle for RPF route selection.

   longest-match

   By default, the route preference principle is used.

Configuring IPv6 multicast load splitting

About this task

You can enable the device to split multiple IPv6 multicast data flows on a per-source basis or on a per-source-and-group basis.

Procedure

1. Enter system view.

   system-view

2. Enter IPv6 MRIB view.

   ipv6 multicast routing [**vpn-instance** *vpn-instance-name*]

3. Configure IPv6 multicast load splitting.

   load-splitting { **source** | **source-group** }

   By default, IPv6 multicast load splitting is disabled.

Configuring an IPv6 multicast forwarding boundary

About this task

You can configure an interface as an IPv6 multicast forwarding boundary for an IPv6 multicast group range. The interface cannot receive or forward IPv6 multicast packets for the groups in the range.

Restrictions and guidelines

You do not need to enable IPv6 multicast routing before this configuration.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure an IPv6 multicast forwarding boundary.

   ipv6 multicast boundary { *ipv6-group-address prefix-length* | **scope** { *scope-id* | **admin-local** | **global** | **organization-local** | **site-local** } }

   By default, an interface is not an IPv6 multicast forwarding boundary for any IPv6 multicast groups.

Setting the maximum number of cached unknown IPv6 multicast packets

About this task

The device caches an IPv6 multicast packet for a period of time if no matching multicast forwarding entry is found for the packet. If a multicast forwarding entry is established for the packet within the time period, the device forwards the packet. This mechanism prevents the device from mistakenly dropping IPv6 multicast packets when the multicast forwarding entries for these packets are to be created.

You can set the maximum number of unknown IPv6 multicast packets that can be cached for an (S, G) entry, in total, or both.

Restrictions and guidelines

As a best practice, set the value in the **ipv6 multicast forwarding-table cache-unknown total** command to be far greater than the value in the **ipv6 multicast forwarding-table cache-unknown per-entry** command.

Procedure

1. Enter system view.

   system-view

2. Set the maximum number of unknown IPv6 multicast packets that can be cached for an (S, G) entry.

   ipv6 multicast forwarding-table cache-unknown per-entry *per-entry-limit*

   By default, the device can cache only one unknown IPv6 multicast packet for an (S, G) entry.

3. Set the maximum number of unknown IPv6 multicast packets that can be cached in total.

ipv6 multicast forwarding-table cache-unknown total *total-limit*

By default, the device can cache 1024 unknown IPv6 multicast packets in total.

Configuring an IPv6 MVPN extranet RPF selection policy

About this task

IPv6 MVPN extranet RPF routing policies are used for IPv6 multicast transmission when multicast sources and receivers are located in different VPNs.

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB1780, NFNX3-HDB3080	No

Restrictions and guidelines

The PIM modes in the source VPN instance and the receiver VPN instance must be the same. Only PIM-SM and PIM-SSM are supported.

Multicast packets can only be forwarded between two VPNs. The receiver VPN instance cannot also be the source VPN instance.

In PIM-SM mode, you can configure only one RPF selection policy for a multicast group in a VPN instance.

If an IPv6 MVPN extranet RPF selection policy with only the multicast group address specified is configured in the receiver VPN instance, the multicast traffic for the intra-VPN transmission will be interrupted.

To implement source-specific RPF selection in MVPN extranet, you must configure two MVPN extranet RPF routing policies as follows:

- In one policy, specify the address of the RP designated to the multicast group that requires inter-VPN multicast communication as the source address.
- In the other policy, specify the multicast source in the source VPN instance as the source address.

To implement source-and-group-specific RPF selection in MVPN extranet, you must configure two MVPN extranet RPF routing policies as follows:

- In one policy, specify the address of the RP designated to the multicast group as the source address, and specify the multicast group.
- In the other policy, specify the multicast source in the source VPN instance as the source address, and specify the multicast group.
- Make sure the multicast groups in the two policies are the same to avoid inter-VPN multicast transmission failure.

Common Layer 3 multicast supports both the source-PE-based MVPN extranet option and receiver-PE-based MVPN extranet option.

For the source-PE-based MVPN extranet option, if PIM-SM mode is used, the RP of the receiver VPN instance must be configured on the multicast source-side device.

Procedure

1. Enter system view.
   system-view
2. Enter MRIB view.
   multicast routing [**vpn-instance** *vpn-instance-name*]
3. Configure an IPv6 MVPN extranet RPF selection policy.
   ipv6 multicast extranet select-rpf { **vpn-instance** *vpn-instance-name* } { **source** *ipv6-source-address prefix-length* | **group** *ipv6-group-address prefix-length* }*
   By default, no IPv6 MVPN extranet RPF selection policies are configured.

Display and maintenance commands for IPv6 multicast routing and forwarding

△ **CAUTION:**

The **reset** commands might cause IPv6 multicast data transmission failures.

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about the interfaces maintained by the IPv6 MRIB.	**display ipv6 mrib** [**vpn-instance** *vpn-instance-name*] **interface** [*interface-type interface-number*]
Display IPv6 multicast boundary information.	**display ipv6 multicast** [**vpn-instance** *vpn-instance-name*] **boundary** { **group** [*ipv6-group-address* [*prefix-length*]] | **scope** [*scope-id*] } [**interface** *interface-type interface-number*]
Display IPv6 multicast fast forwarding entries.	**display ipv6 multicast** [**vpn-instance** *vpn-instance-name*] **fast-forwarding cache** [*ipv6-source-address* | *ipv6-group-address*] * [**slot** *slot-number*]
Display DF information.	**display ipv6 multicast** [**vpn-instance** *vpn-instance-name*] **forwarding df-info** [*ipv6-rp-address*] [**verbose**] [**slot** *slot-number*]
Display statistics for IPv6 multicast forwarding events.	**display ipv6 multicast** [**vpn-instance** *vpn-instance-name*] **forwarding event** [**slot** *slot-number*]
Display IPv6 multicast forwarding entries.	**display ipv6 multicast** [**vpn-instance** *vpn-instance-name*] **forwarding-table** [*ipv6-source-address* [*prefix-length*] | *ipv6-group-address* [*prefix-length*] | **incoming-interface** *interface-type interface-number* | **outgoing-interface** { **exclude** | **include** | **match** } *interface-type interface-number* | **slot**

Task	Command
	slot-number | **statistics**] *
Display information about the DF list in the IPv6 multicast forwarding table.	**display ipv6 multicast** [**vpn-instance** *vpn-instance-name*] **forwarding-table df-list** [*ipv6-group-address*] [**verbose**] [**slot** *slot-number*]
Display IPv6 multicast routing entries.	**display ipv6 multicast** [**vpn-instance** *vpn-instance-name*] **routing-table** [*ipv6-source-address* [*prefix-length*] | *ipv6-group-address* [*prefix-length*] | **incoming-interface** *interface-type interface-number* | **outgoing-interface** { **exclude** | **include** | **match** } *interface-type interface-number*] *
Display RPF information for an IPv6 multicast source.	**display ipv6 multicast** [**vpn-instance** *vpn-instance-name*] **rpf-info** *ipv6-source-address* [*ipv6-group-address*]
Clear IPv6 multicast fast forwarding entries.	**reset ipv6 multicast** [**vpn-instance** *vpn-instance-name*] **fast-forwarding cache** { { *ipv6-source-address* | *ipv6-group-address* } * | **all** } [**slot** *slot-number*]
Clear statistics for IPv6 multicast forwarding events.	**reset ipv6 multicast** [**vpn-instance** *vpn-instance-name*] **forwarding event**
Clear IPv6 multicast forwarding entries.	**reset ipv6 multicast** [**vpn-instance** *vpn-instance-name*] **forwarding-table** { { *ipv6-source-address* [*prefix-length*] | *ipv6-group-address* [*prefix-length*] | **incoming-interface** { *interface-type interface-number* } } * | **all** }
Clear IPv6 multicast routing entries.	**reset ipv6 multicast** [**vpn-instance** *vpn-instance-name*] **routing-table** { { *ipv6-source-address* [*prefix-length*] | *ipv6-group-address* [*prefix-length*] | **incoming-interface** *interface-type interface-number* } * | **all** }

NOTE:

- When you clear an IPv6 multicast routing entry, the associated IPv6 multicast forwarding entry is also cleared.
- When you clear an IPv6 multicast forwarding entry, the associated IPv6 multicast routing entry is also cleared.

Contents

Configuring MLD

About MLD

Multicast Listener Discovery (MLD) establishes and maintains IPv6 multicast group memberships between a Layer 3 multicast device and the hosts on the directly connected subnet.

MLD versions

MLD has the following versions:

- MLDv1 (defined by RFC 2710), which is derived from IGMPv2.
- MLDv2 (defined by RFC 3810), which is derived from IGMPv3.

MLDv1 and MLDv2 support the ASM model. MLDv2 can directly implement the SSM model, but MLDv1 must work with the MLD SSM mapping feature to implement the SSM model. For more information about the ASM and SSM models, see "Multicast overview."

How MLDv1 works

MLDv1 implements IPv6 multicast listener management based on the query and response mechanism.

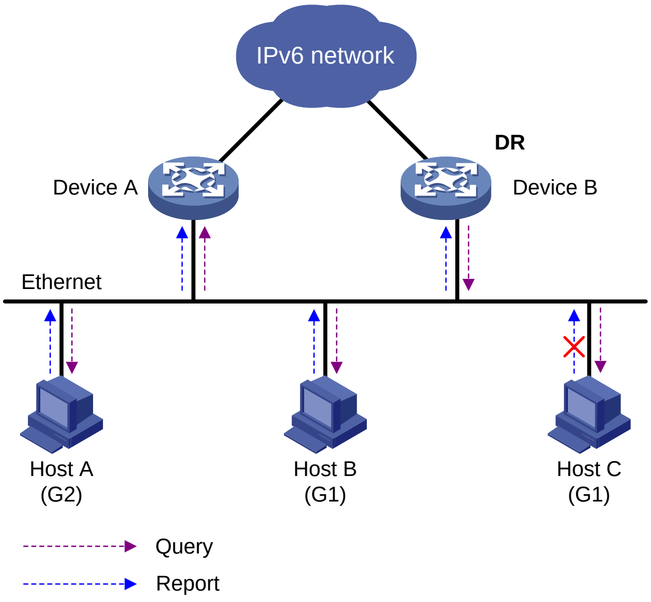
Electing the MLD querier

All IPv6 multicast devices that run MLD on the same subnet can monitor MLD listener report messages (often called reports) from hosts. However, only one device can act as the MLD querier to send MLD query messages (often called queries). A querier election mechanism determines which device acts as the MLD querier on the subnet.

1. Initially, every MLD device assumes itself as the querier. Each device sends MLD general query messages (often called general queries) to all hosts and devices on the local subnet. The destination address of the general queries is FF02::1.
2. After receiving a general query, every MLD device compares the source IPv6 address of the query with its own link-local interface address. The device with the lowest IPv6 address wins the querier election and becomes the querier. All the other devices become non-queriers.
3. All the non-queriers start a timer called the "other querier present timer." If a device receives an MLD query from the querier before the timer expires, it resets this timer. Otherwise, it considers that the querier has timed out. In this case, the device initiates a new querier election process.

Joining an IPv6 multicast group

Figure 1 MLD queries and reports



As shown in Figure 1, Host B and Host C want to receive the IPv6 multicast data addressed to IPv6 multicast group G1. Host A wants to receive the IPv6 multicast data addressed to G2. The following process describes how the hosts join the IPv6 multicast groups and how the MLD querier (Device B in Figure 1) maintains the IPv6 multicast group memberships:

1. The hosts send unsolicited MLD reports to the IPv6 multicast groups they want to join without having to wait for the MLD queries.
2. The MLD querier periodically multicasts MLD queries (with the destination address FF02::1) to all hosts and devices on the local subnet.
3. After receiving a query, the host whose report delay timer expires first sends an MLD report to the IPv6 multicast group G1 to announce its membership for G1. In this example, Host B sends the report. After hearing the report from Host B, Host C, which is on the same subnet as Host B, suppresses its own report for G1.

   Because the MLD devices already know that G1 has a minimum of one member, other members do not need to report their memberships. This mechanism, known as the host MLD report suppression, helps reduce traffic on the local subnet.
4. At the same time, because Host A is interested in G2, it sends a report to the IPv6 multicast group G2.
5. Through the query/report process, the MLD devices determine that G1 and G2 have members on the local subnet. The IPv6 multicast routing protocol (for example, IPv6 PIM) that is running on the devices generates (*, G1) and (*, G2) multicast forwarding entries. These entries are the basis for subsequent IPv6 multicast forwarding. The asterisk (*) represents any IPv6 multicast source.
6. When the IPv6 multicast data addressed to G1 or G2 reaches an MLD device, the device looks up the IPv6 multicast forwarding table. Based on the (*, G1) and (*, G2) entries, the device forwards the IPv6 multicast data to the local subnet. Then, the receivers on the subnet receive the data.

Leaving an IPv6 multicast group

When a host is leaving an IPv6 multicast group, the following process occurs:

1. The host sends an MLD done message to all IPv6 multicast devices on the local subnet. The destination address of done messages is FF02::2.

2. After receiving the MLD done message, the querier sends a configurable number of multicast-address-specific queries to the group that the host is leaving. The IPv6 multicast addresses queried include both the destination address field and the group address field of the message.
3. One of the remaining members (if any on the subnet) in the group sends a report within the time of the maximum response time advertised in the multicast-address-specific queries.
4. If the querier receives a report for the group within the maximum response time, it maintains the memberships of the IPv6 multicast group. Otherwise, the querier assumes that no hosts on the subnet are interested in IPv6 multicast traffic addressed to that group and stops maintaining the memberships of the group.

MLDv2 enhancements

MLDv2 is based on and backwards-compatible with MLDv1. MLDv2 provides hosts with enhanced control capabilities and enhances the MLD state.

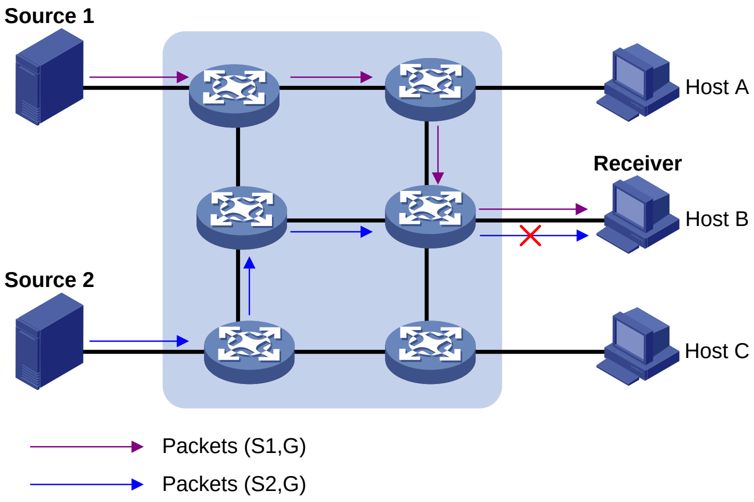
Enhancements in control capability of hosts

MLDv2 has introduced IPv6 multicast source filtering modes (Include and Exclude). These modes allow a host to receive or reject multicast data from the specified IPv6 multicast sources. When a host joins an IPv6 multicast group, one of the following occurs:

- If the host expects IPv6 multicast data from specific IPv6 multicast sources like S1, S2, …, it sends a report with Filter-Mode denoted as "Include Sources (S1, S2, …)."
- If the host does not expect IPv6 multicast data from specific IPv6 multicast sources like S1, S2, …, it sends a report with Filter-Mode denoted as "Exclude Sources (S1, S2, …)."

As shown in Figure 2, the network has two IPv6 multicast sources, Source 1 (S1) and Source 2 (S2). Both of the sources can send IPv6 multicast data to IPv6 multicast group G. Host B wants to receive IPv6 multicast data addressed to G from Source 1 but not from Source 2.

Figure 2 Flow paths of multicast-address-and-source-specific multicast traffic



In MLDv1, Host B cannot select IPv6 multicast sources when it joins IPv6 multicast group G. The IPv6 multicast streams from both Source 1 and Source 2 flow to Host B whether it needs them or not.

In MLDv2, Host B can explicitly express its interest in IPv6 multicast data destined to G from Source 1 but not from Source 2. Then, Host B receives only IPv6 multicast data from Source 1.

Enhancement in MLD state

A multicast device that is running MLDv2 maintains the multicast address state for each multicast address on each attached subnet. The multicast address state consists of the following information:

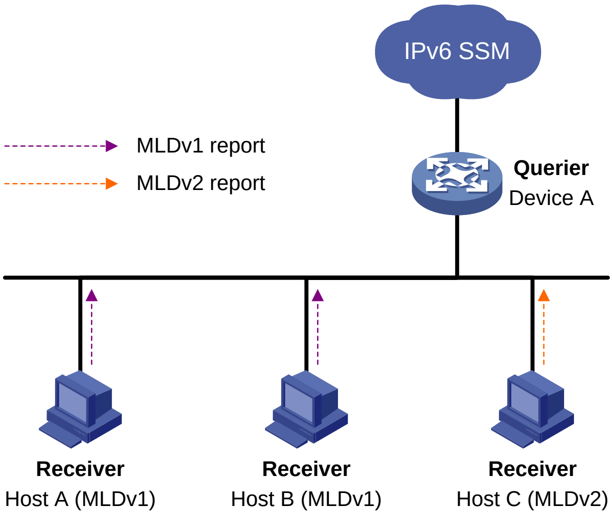
- **Filter mode**—Device keeps tracing the Include or Exclude state.
- **List of sources**—Device keeps tracing the newly added or deleted IPv6 multicast source.
- **Timers**—Filter timers, which include the time that the device waits before switching to the Include mode after an IPv6 multicast address times out, and source timers for source recording.

MLD SSM mapping

An MLDv2 host can explicitly specify multicast sources in its MLDv2 reports. From the reports, the MLD device can obtain the multicast source addresses and directly provide the SSM service. However, an MLDv1 host cannot specify multicast sources in its MLDv1 reports.

The MLD SSM mapping feature enables the MLD device to provide SSM support for MLDv1 receiver host. The device translates (*, G) in MLDv1 reports into (G, INCLUDE, (S1, S2...)) based on the configured MLD SSM mappings.

Figure 3 Network diagram



As shown in Figure 3, Host A and Host B on the IPv6 SSM network run MLDv1, and Host C runs MLDv2. To provide the SSM service for Host A and Host B, you must configure the MLD SSM mapping feature on Device A.

After MLD SSM mappings are configured, Device A checks the IPv6 multicast group address G carried in the message, and performs the following operations:

- If G is not in the IPv6 SSM group range, Device A provides the ASM service.
- If G is in the IPv6 SSM group range but does not match any MLD SSM mapping, Device A drops the report.
- If G is in the IPv6 SSM group range and matches MLD SSM mappings, Device A translates (*, G) in the report to (G, INCLUDE, (S1, S2...)) to provide SSM services.

NOTE:

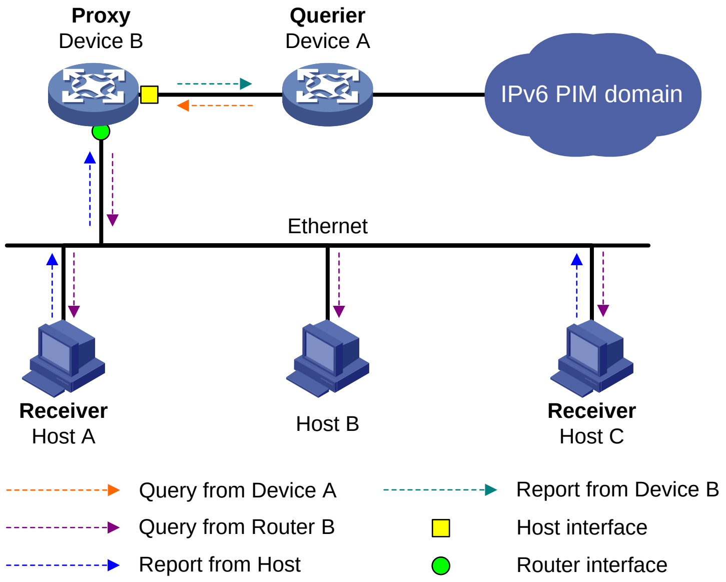
The MLD SSM mapping feature does not process MLDv2 reports.

MLD proxying

As shown in Figure 4, in a simple tree-shaped topology, it is not necessary to configure IPv6 multicast routing protocols, such as IPv6 PIM, on edge devices. Instead, you can configure MLD proxying on these devices. With MLD proxying configured, the edge device acts as an MLD proxy:

- For the upstream MLD querier, the MLD proxy device acts as a host.
- For the downstream receiver hosts, the MLD proxy device acts as an MLD querier.

Figure 4 Network diagram



The following interfaces are defined in MLD proxying:

- **Host interface**—An interface that is in the direction toward the root of the multicast forwarding tree. A host interface acts as a receiver host that is running MLD. MLD proxying must be enabled on this interface. This interface is also called the "proxy interface."
- **Router interface**—An interface that is in the direction toward the leaf of the multicast forwarding tree. A router interface acts as a router that is running MLD. MLD must be configured on this interface.

An MLD proxy device maintains a group membership database, which stores the group memberships on all the router interfaces. The host interfaces and router interfaces perform actions based on this membership database.

- The host interfaces respond to queries according to the membership database or sends join/done messages when the database changes.
- The router interfaces participate in the querier election, send queries, and maintain memberships based on received MLD reports.

MLD support for VPNs

MLD maintains group memberships on a per-interface basis. After receiving an MLD message on an interface, MLD processes the packet within the VPN to which the interface belongs. MLD only communicates with other multicast protocols within the same VPN instance.

Protocols and standards

- RFC 2710, *Multicast Listener Discovery (MLD) for IPv6*
- RFC 3810, *Multicast Listener Discovery Version 2 (MLDv2) for IPv6*

MLD tasks at a glance

To configure MLD, perform the following tasks:

1. Enabling MLD
2. (Optional.) Configuring basic MLD features
    - Specifying an MLD version
    - Configuring a static group member
    - Configuring an IPv6 multicast group policy
3. (Optional.) Adjusting MLD performance
    - Configuring MLD query and response parameters
    - Enabling fast-leave processing
4. (Optional.) Configuring MLD SSM mappings
5. (Optional.) Configuring MLD proxying
    - Enabling MLD proxying
    - Enabling IPv6 multicast forwarding on a non-querier interface
    - Enabling IPv6 multicast load splitting for MLD proxy interfaces
6. (Optional.) Enabling MLD NSR

Prerequisites for MLD

Before you configure MLD, you must configure an IPv6 unicast routing protocol so that all devices can interoperate at the network layer.

Enabling MLD

Restrictions and guidelines

Perform this task on interfaces where IPv6 multicast group memberships are created and maintained.

Procedure

1. Enter system view.

    `system-view`

2. Enable IPv6 multicast routing and enter IPv6 MRIB view.

    `ipv6 multicast routing` [**`vpn-instance`** *`vpn-instance-name`*]

    By default, IPv6 multicast routing is disabled.

    For more information about this command, see *IP Multicast Command Reference*.

3. Return to system view.

    `quit`

4. Enter interface view.

    `interface` *`interface-type interface-number`*

5. Enable MLD.

    `mld enable`

    By default, MLD is disabled.

Configuring basic MLD features

Specifying an MLD version

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Specify an MLD version on the interface.

   `mld version` *`version-number`*

   By default, the MLD version on an interface is MLDv1.

△ **CAUTION:**

For MLD to operate correctly, specify the same MLD version for all devices on the same subnet.

Configuring a static group member

About this task

You can configure an interface as a static member of an IPv6 multicast group. Then, the interface can always receive IPv6 multicast data for the group.

A static group member does not respond to MLD queries. When you complete or cancel this configuration on an interface, the interface does not send an unsolicited MLD report or done message.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure a static group member.

   `mld static-group` *`ipv6-group-address`* `[` **`source`** *`ipv6-source-address`* `]`

Configuring an IPv6 multicast group policy

About this task

This feature enables an interface to filter MLD reports by using an ACL that specifies IPv6 multicast groups and the optional sources. It is used to control the IPv6 multicast groups that the hosts attached to an interface can join.

Restrictions and guidelines

This configuration does not take effect on static group members, because static group members do not send MLD reports.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

```
interface interface-type interface-number
```

3. Configure an IPv6 multicast group policy on the interface.

```
mld group-policy ipv6-acl-number [ version-number ]
```

Adjusting MLD performance

Configuring MLD query and response parameters

About this task

The following are MLD query and response parameters:

- **MLD querier's robustness variable**—Number of times for retransmitting MLD queries in case of packet loss. A higher robustness variable makes the MLD querier more robust, but increases the timeout time for IPv6 multicast groups.
- **MLD startup query interval**—Interval at which an MLD querier sends MLD general queries at startup.
- **MLD startup query count**—Number of MLD general queries that an MLD querier sends at startup.
- **MLD general query interval**—Interval at which an MLD querier sends MLD general queries to check for IPv6 multicast group members on the network.
- **MLD last listener query interval**—In MLDv1, it sets the interval at which a querier sends multicast-address-specific queries after receiving a done message. In MLDv2, it sets the interval at which a querier sends multicast-address-and-source-specific queries after receiving a report that changes IPv6 multicast source and group mappings.
- **MLD last listener query count**—In MLDv1, it sets the number of multicast-address-specific queries that the querier sends after receiving a done message. In MLDv2, it sets the number of multicast-address-and-source-specific queries that the querier sends after receiving a report that changes IPv6 multicast group and source mappings.
- **MLD maximum response time**—Maximum time before a receiver responds with a report to an MLD general query. This per-group timer is initialized to a random value in the range of 0 to the maximum response time specified in the MLD query. When the timer value decreases to 0, the receiver sends an MLD report to the group.
- **MLD other querier present timer**—Lifetime for an MLD querier after a non-querier receives an MLD general query. If the non-querier does not receive a new query when this timer expires, the non-querier considers that the querier has failed and starts a new querier election.

Restrictions and guidelines

- To avoid frequent MLD querier changes, set the MLD other querier present timer greater than the MLD general query interval. In addition, configure the same MLD other querier present timer for all MLD devices on the same subnet.
- To speed up the response to MLD queries and avoid simultaneous timer expirations that cause MLD report traffic bursts, you must set an appropriate maximum response time.
  - For MLD general queries, the maximum response time is set by the **`max-response-time`** command.
  - For MLD multicast-address-specific queries or MLD multicast-address-and-source-specific queries, the maximum response time equals the MLD last listener query interval.
- You can configure MLD query and response parameters globally for all interfaces in MLD view or for an interface in interface view. The interface-specific configuration takes priority over the global configuration.

Configuring the MLD query and response parameters globally

1. Enter system view.

   system-view

2. Enter MLD view.

   mld [**vpn-instance** *vpn-instance-name*]

3. Set the MLD querier's robustness variable.

   robust-count *count*

   By default, the MLD querier's robustness variable is 2.

4. Set the MLD startup query interval.

   startup-query-interval *interval*

   By default, the MLD startup query interval is equal to one quarter of the MLD general query interval.

5. Set the MLD startup query count.

   startup-query-count *count*

   By default, the MLD startup query count is equal to the MLD querier's robustness variable.

6. Set the MLD general query interval.

   query-interval *interval*

   By default, the MLD general query interval is 125 seconds.

7. Set the MLD last listener query interval.

   last-listener-query-interval *interval*

   By default, the MLD last listener query interval is 1 second.

8. Set the MLD last listener query count.

   last-listener-query-count *count*

   By default, the MLD last listener query count is equal to the MLD querier's robustness variable.

9. Set the maximum response time for MLD general queries.

   max-response-time *time*

   By default, the maximum response time for MLD general queries is 10 seconds.

10. Set the MLD other querier present timer.

    other-querier-present-timeout *time*

    By default, the MLD other querier present timer is calculated by using the following formula: [MLD general query interval] × [MLD robustness variable] + [maximum response time for MLD general queries] / 2.

Configuring the MLD query and response parameters on an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the MLD querier's robustness variable.

   mld robust-count *count*

   By default, the MLD querier's robustness variable is 2.

4. Set the MLD startup query interval.

   mld startup-query-interval *interval*

   By default, the MLD startup query interval is equal to one quarter of the MLD general query interval.

5. Set the MLD startup query count.

   mld startup-query-count *count*

   By default, the MLD startup query count is equal to the MLD querier's robustness variable.

6. Set the MLD general query interval.

   mld query-interval *interval*

   By default, the MLD general query interval is 125 seconds.

7. Set the MLD last listener query interval.

   mld last-listener-query-interval *interval*

   By default, the MLD last listener query interval is 1 second.

8. Set the MLD last listener query count.

   mld last-listener-query-count *count*

   By default, the MLD last listener query count is equal to the MLD querier's robustness variable.

9. Set the maximum response time for MLD general queries.

   mld max-response-time *time*

   By default, the maximum response time for MLD general queries is 10 seconds.

10. Set the MLD other querier present timer.

    mld other-querier-present-timeout *time*

    By default, the MLD other querier present timer is calculated by using the following formula: [MLD general query interval] × [MLD robustness variable] + [maximum response time for MLD general queries] / 2.

Enabling fast-leave processing

About this task

This feature enables an MLD querier to send leave notifications to the upstream without sending multicast-address-specific or multicast-address-and-source-specific queries after receiving a done message. Use this feature to reduce leave latency and to preserve the network bandwidth.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable fast-leave processing.

   mld fast-leave [**group-policy** *ipv6-acl-number*]

   By default, fast-leave processing is disabled.

Configuring MLD SSM mappings

About this task

This feature enables the device to provide SSM services for MLDv1 hosts.

Restrictions and guidelines

This feature does not process MLDv2 messages. Enable MLDv2 on the receiver-side interface to ensure that MLDv2 reports from MLDv2 receiver hosts can be processed.

Procedure

1. Enter system view.

   system-view

2. Enter MLD view.

   mld [**vpn-instance** *vpn-instance-name*]

3. Configure an MLD SSM mapping.

   ssm-mapping *ipv6-source-address ipv6-acl-number*

Configuring MLD proxying

Prerequisites for MLD proxying

Before you configure MLD proxying, determine the router interfaces and host interface based on the network topology. Then, enable MLD on the router interfaces.

Enabling MLD proxying

Restrictions and guidelines

- Enable MLD proxying on the receiver-side interfaces.
- On an interface enabled with MLD proxying, only the **mld version** command takes effect and other MLD commands do not take effect.
- If you enable both MLD proxying and an IPv6 multicast routing protocol on the same device, the IPv6 multicast routing protocol does not take effect.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable MLD proxying.

   mld proxy enable

   By default, MLD proxying is disabled.

Enabling IPv6 multicast forwarding on a non-querier interface

About this task

Typically, only MLD queriers can forward IPv6 multicast traffic and non-queriers cannot. This prevents IPv6 multicast data from being repeatedly forwarded. If a router interface on the MLD proxy failed the querier election, enable IPv6 multicast forwarding on the interface to forward IPv6 multicast data to downstream receivers.

Restrictions and guidelines

A shared-media network might have multiple MLD proxies, including one proxy acting as a querier. To avoid duplicate IPv6 multicast traffic, do not enable IPv6 multicast forwarding on any of the non-querier MLD proxies for the network.

Procedure

1. Enter system view.

system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable IPv6 multicast forwarding on a non-querier interface.

   mld proxy forwarding

   By default, IPv6 multicast forwarding is disabled on a non-querier interface.

Enabling IPv6 multicast load splitting for MLD proxy interfaces

About this task

If multiple MLD proxy interfaces exist on the device, only the proxy interface with the highest IP address forwards IPv6 multicast traffic. You can enable IPv6 multicast load splitting on the device so that all the proxy interfaces can share IPv6 multicast traffic.

Procedure

1. Enter system view.

   system-view

2. Enter MLD view.

   mld [**vpn-instance** *vpn-instance-name*]

3. Enable IPv6 multicast load splitting for MLD proxy interfaces.

   proxy multipath

   By default, IPv6 multicast load splitting is disabled for MLD proxy interfaces.

Enabling MLD NSR

About this task

This feature backs up information about MLD interfaces and MLD multicast groups to the standby process. The device recovers the information without cooperation of other devices when an active/standby switchover occurs. Use this feature to prevent an active/standby switchover from affecting the IPv6 multicast service.

Procedure

1. Enter system view.

   system-view

2. Enable MLD NSR.

   mld non-stop-routing

   By default, MLD NSR is disabled.

Display and maintenance commands for MLD

△ **CAUTION:**

The **reset mld group** command might cause IPv6 multicast data transmission failures.

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about MLD multicast groups.	**display mld** [**vpn-instance** *vpn-instance-name*] **group** [*ipv6-group-address* | **interface** *interface-type interface-number*] [**static** | **verbose**]
Display MLD information for interfaces.	**display mld** [**vpn-instance** *vpn-instance-name*] **interface** [*interface-type interface-number*] [**proxy**] [**verbose**]
Display IPv6 multicast routing entries maintained by the MLD proxy.	**display mld** [**vpn-instance** *vpn-instance-name*] **proxy group** [*ipv6-group-address* | **interface** *interface-type interface-number*] [**verbose**]
Display information about the MLD proxy routing table.	**display mld** [**vpn-instance** *vpn-instance-name*] **proxy routing-table** [*ipv6-source-address* [*prefix-length*] | *ipv6-group-address* [*prefix-length*]] * [**verbose**]
Display MLD SSM mappings.	**display mld** [**vpn-instance** *vpn-instance-name*] **ssm-mapping** *ipv6-group-address*
Clear dynamic MLD multicast group entries.	**reset mld** [**vpn-instance** *vpn-instance-name*] **group** { **all** | **interface** *interface-type interface-number* { **all** | *ipv6-group-address* [*prefix-length*] [*ipv6-source-address* [*prefix-length*]] } }

Troubleshooting MLD

No member information exists on the receiver-side device

Symptom

When a host sends a message to announce that it is joining IPv6 multicast group G, no member information of multicast group G exists on the immediate device.

Solution

To resolve the problem:

1. Use the **display mld interface** command to verify that the networking, interface connections, and IP address configuration are correct.
2. Use the **display current-configuration** command to verify that the IPv6 multicast routing is enabled. If it is not enabled, use the **ipv6 multicast routing** command in system view to enable IPv6 multicast routing. In addition, verify that MLD is enabled on the associated interfaces.

3. Use the **`display mld interface`** command to verify that the MLD version on the interface is lower than that on the host.
4. Use the **`display current-configuration interface`** command to verify that no IPv6 multicast group policies have been configured to filter MLD reports for IPv6 multicast group G.
5. If the problem persists, contact NSFOCUS Support.

Inconsistent membership information on the devices on the same subnet

Symptom

Different memberships are maintained on different MLD devices on the same subnet.

Solution

To resolve the problem:

1. Use the **`display current-configuration`** command to verify the MLD information on the interface. Make sure the devices on the subnet have the same MLD settings on their interfaces.
2. Use the **`display mld interface`** command on all devices on the same subnet to check the MLD timers for inconsistent configurations.
3. Use the **`display mld interface`** command to verify that all devices are running the same MLD version.
4. If the problem persists, contact NSFOCUS Support.

NSFOCUS Firewall Series

NF Network Management and Monitoring Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for network management and monitoring features, including system maintenance and debugging (ping, tracert, and system debugging), NQA, NTP, EAA, process monitoring and maintenance, NETCONF, information center, SNMP, NetStream, RMON, flow log, event MIB, fast log output, mirroring, and CWMP.
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.

Convention	Description
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
❗ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.

Convention	Description
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

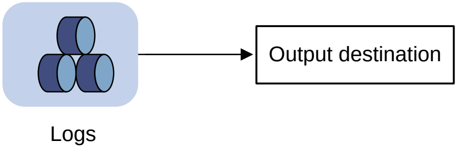
Contents

Configuring the information center

About the information center

The information center on the device receives logs generated by source modules and outputs logs to different destinations according to log output rules. Based on the logs, you can monitor device performance and troubleshoot network problems.

Figure 1 Information center diagram



Log types

Logs are classified into the following types:

- **Standard system logs**—Record common system information. Unless otherwise specified, the term "logs" in this document refers to standard system logs.
- **Diagnostic logs**—Record debugging messages.
- **Security logs**—Record security information, such as authentication and authorization information.
- **Hidden logs**—Record log information not displayed on the terminal, such as input commands.
- **Trace logs**—Record system tracing and debugging messages, which can be viewed only after the devkit package is installed.

Log levels

Logs are classified into eight severity levels from 0 through 7 in descending order. The information center outputs logs with a severity level that is higher than or equal to the specified level. For example, if you specify a severity level of 6 (informational), logs that have a severity level from 0 to 6 are output.

Table 1 Log levels

Severity value	Level	Description
0	Emergency	The system is unusable. For example, the system authorization has expired.
1	Alert	Action must be taken immediately. For example, traffic on an interface exceeds the upper limit.
2	Critical	Critical condition. For example, the device temperature exceeds the upper limit, the power module fails, or the fan tray fails.
3	Error	Error condition. For example, the link state changes.
4	Warning	Warning condition. For example, an interface is disconnected, or the memory resources are used up.
5	Notification	Normal but significant condition. For example, a terminal logs in to the device, or the device reboots.

Severity value	Level	Description
6	Informational	Informational message. For example, a command or a ping operation is executed.
7	Debugging	Debugging message.

Log destinations

The system outputs logs to the following destinations: console, monitor terminal, log buffer, log host, and log file. Log output destinations are independent and you can configure them after enabling the information center. One log can be sent to multiple destinations.

Default output rules for logs

A log output rule specifies the source modules and severity level of logs that can be output to a destination. Logs matching the output rule are output to the destination. Table 2 shows the default log output rules.

Table 2 Default output rules

Destination	Log source modules	Output switch	Severity
Console	All supported modules	Enabled	Debugging
Monitor terminal	All supported modules	Disabled	Debugging
Log host	All supported modules	Enabled	Informational
Log buffer	All supported modules	Enabled	Informational
Log file	All supported modules	Enabled	Informational

Default output rules for diagnostic logs

Diagnostic logs can only be output to the diagnostic log file, and cannot be filtered by source modules and severity levels. Table 3 shows the default output rule for diagnostic logs.

Table 3 Default output rule for diagnostic logs

Destination	Log source modules	Output switch	Severity
Diagnostic log file	All supported modules	Enabled	Debugging

Default output rules for security logs

Security logs can only be output to the security log file, and cannot be filtered by source modules and severity levels. Table 4 shows the default output rule for security logs.

Table 4 Default output rule for security logs

Destination	Log source modules	Output switch	Severity
Security log file	All supported modules	Disabled	Debugging

Default output rules for hidden logs

Hidden logs can be output to the log host, the log buffer, and the log file. Table 5 shows the default output rules for hidden logs.

Table 5 Default output rules for hidden logs

Destination	Log source modules	Output switch	Severity
Log host	All supported modules	Enabled	Informational
Log buffer	All supported modules	Enabled	Informational
Log file	All supported modules	Enabled	Informational

Default output rules for trace logs

Trace logs can only be output to the trace log file, and cannot be filtered by source modules and severity levels. Table 6 shows the default output rules for trace logs.

Table 6 Default output rules for trace logs

Destination	Log source modules	Output switch	Severity
Trace log file	All supported modules	Enabled	Debugging

Log formats and field descriptions

Log formats

The format of logs varies by output destinations. Table 7 shows the original format of log information, which might be different from what you see. The actual format varies by the log resolution tool used.

Table 7 Log formats

Output destination	Format

Console, monitor terminal, log buffer, or log file	`Prefix Timestamp Sysname Module/Level/Mnemonic: Content`
	Example:
	`%Nov 24 14:21:43:502 2016 Sysname SHELL/5/SHELL_LOGIN: VTY logged in from 192.168.1.26`

Log host	**Non-customized format**:
	`<PRI>Timestamp Sysname %%vvModule/Level/Mnemonic: Location; Content`
	Example:
	`<190>Nov 24 16:22:21 2016 Sysname %%10SHELL/5/SHELL_LOGIN: -DevIP=1.1.1.1; VTY logged in from 192.168.1.26<190>Nov 24 16:22:21 2016 Sysname %%10 SHELL/5/SHELL_LOGIN: -DevIP=1.1.1.1; VTY logged in from 192.168.1.26`
	CMCC format:
	`<PRI>Timestamp Sysname %vvModule/Level/Mnemonic: Location; Content`
	Example:
	`<189>Oct 9 14:59:04 2016 Sysname %10SHELL/5/SHELL_LOGIN: VTY logged in from 192.168.1.21`
	SGCC format:
	`<PRI> Timestamp Sysname Devtype Content`

	Example:
	`<189> 2019-03-18 15:39:45 Sysname FW 0 2 admin 10.1.1.1`
	Unicom format:
	`<PRI>Timestamp Hostip vvModule/Level/Serial_number: Content`
	Example:
	`<189>Oct 13 16:48:08 2016 10.1.1.1 10SHELL/5/210231a64jx073000020: VTY logged in from 192.168.1.21`

Log field description

Table 8 Log field description

Field	Description
Prefix (information type)	A log sent to the console, monitor terminal, log buffer, or log file has an identifier in front of the timestamp: • An identifier of percent sign (%) indicates a log with a level equal to or higher than informational. • An identifier of asterisk (*) indicates a debugging log or a trace log. • An identifier of caret (^) indicates a diagnostic log.
PRI (priority)	A log destined for the log host has a priority identifier in front of the timestamp. The priority is calculated by using this formula: facility*8+level, where: • **facility** is the facility name. Facility names local0 through local7 correspond to values 16 through 23. The facility name can be configured using the **`info-center loghost`** command. It is used to identify log sources on the log host, and to query and filter the logs from specific log sources. • **level** is in the range of 0 to 7. See Table 1 for more information about severity levels.
Timestamp	Records the time when the log was generated. Logs sent to the log host and those sent to the other destinations have different timestamp precisions, and their timestamp formats are configured with different commands. For more information, see Table 9 and Table 10.
Hostip	Source IP address of the log. If the **`info-center loghost source`** command is configured, this field displays the IP address of the specified source interface. Otherwise, this field displays the sysname. This field exists only in logs that are sent to the log host in unicom format.
Serial number	Serial number of the master device that generated the log. To view the serial number of the master device, see the DEVICE_SERIAL_NUMBER field in the output of the **`display device manuinfo`** command. This field exists only in logs that are sent to the log host in unicom format.
Sysname (host name or host IP address)	The sysname is the host name or IP address of the device that generated the log. You can use the **`sysname`** command to modify the name of the device.
%% (vendor ID)	Indicates that the information was generated by an NSFOCUS device. This field exists only in logs sent to the log host.
vv (version information)	Identifies the version of the log, and has a value of 10. This field exists only in logs that are sent to the log host.
Module	Specifies the name of the module that generated the log. You can enter the **`info-center source ?`** command in system view to view the module list.
Level	Identifies the level of the log. See Table 1 for more information about severity levels.
Mnemonic	Describes the content of the log. It contains a string of up to 32 characters.

Field	Description
Location	Optional field that identifies the log sender. This field exists only in logs that are sent to the log host in non-customized or CMCC format. The field contains the following information: • **DevIp**—IP address of the log sender. • **Slot**—Member ID of the IRF member device that sent the log. • **SN**—Serial number of the master device that generated the log. To view the serial number of the master device, see the DEVICE_SERIAL_NUMBER field in the output of the **display device manuinfo** command. The **SN** field is available only when the device is configured to add the device serial number to the location field of logs. •
Devtype	Device type. This field exists only in logs that are sent to the log host in SGCC format.
Content	Provides the content of the log. • For most logs, this field is displayed as one or multiple sentences. For example, **VTY logged in from 192.168.1.21.**. • For logs used to record the values of different parameters, this field is displayed in the format of ***key information 1***; ***key information 2***; **…** ***key information n***. Each key information is in the format of ***keyword*(*keyword ID*)=*value*** or ***keyword*(*keyword ID*)=(*description ID*)*description***. A keyword ID identifies a keyword and a description ID identifies a description. The IDs are factory settings to help log host software (such as security management systems) resolve the log key information correctly and efficiently. For example, **streamAlarmType(1032)=(42)Too fast speed of TCP session to destination IP**.

Table 9 Timestamp precisions and configuration commands

Item	Destined for the log host	Destined for the console, monitor terminal, log buffer, and log file
Precision	Seconds	Milliseconds
Command used to set the timestamp format	**info-center timestamp loghost**	**info-center timestamp**

Table 10 Description of the timestamp parameters

Timestamp parameters	Description
boot	Time that has elapsed since system startup, in the format of xxx.yyy. xxx represents the higher 32 bits, and yyy represents the lower 32 bits, of milliseconds elapsed. Logs that are sent to all destinations other than a log host support this parameter. **Example**: `%0.109391473 Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` 0.109391473 is a timestamp in the **boot** format.

Timestamp parameters	Description
date	Current date and time. • For logs output to a log host, the timestamp can be in the format of mmm dd hh:mm:ss yyyy (accurate to seconds) or mmm dd hh:mm:ss.ms yyyy (accurate to milliseconds). • For logs output to other destinations, the timestamp is in the format of MMM DD hh:mm:ss:ms YYYY. All logs support this parameter. **Example**: `%May 30 05:36:29:579 2018 Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` May 30 05:36:29:579 2018 is a timestamp in the **date** format in logs sent to the console.
iso	Timestamp format stipulated in ISO 8601, accurate to seconds (default) or milliseconds. Only logs that are sent to a log host support this parameter. **Example**: `<189>2018-05-30T06:42:44 Sysname %%10FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` 2018-05-30T06:42:44 is a timestamp in the **iso** format accurate to seconds. A timestamp accurate to milliseconds is like 2018-05-30T06:42:44.708.
none	No timestamp is included. All logs support this parameter. **Example**: `% Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` No timestamp is included.
no-year-date	Current date and time without year information, in the format of MMM DD hh:mm:ss:ms. Only logs that are sent to a log host support this parameter. **Example**: `<189>May 30 06:44:22 Sysname %%10FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` May 30 06:44:22 is a timestamp in the **no-year-date** format.

Information center tasks at a glance

Managing standard system logs

1. Enabling the information center
2. Outputting logs to various destinations

   Choose the following tasks as needed:
   - Outputting logs to the console
   - Outputting logs to the monitor terminal
   - Outputting logs to log hosts
   - Outputting logs to the log buffer
   - Saving logs to the log file

3. (Optional.) Setting the minimum storage period for logs
4. (Optional.) Enabling synchronous information output
5. (Optional.) Configuring the character set encoding
6. (Optional.) Configuring log suppression

   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module
   - Disabling an interface from generating link up or link down logs
   - Limiting output of security logs
7. (Optional.) Enabling SNMP notifications for system logs

Managing hidden logs

1. Enabling the information center
2. Outputting logs to various destinations

   Choose the following tasks as needed:
   - Outputting logs to log hosts
   - Outputting logs to the log buffer
   - Saving logs to the log file
3. (Optional.) Setting the minimum storage period for logs
4. (Optional.) Enabling duplicate log suppression

Managing security logs

1. Enabling the information center
2. (Optional.) Enabling duplicate log suppression
3. Managing security logs
   - Saving security logs to the security log file
   - Managing the security log file

Managing diagnostic logs

1. Enabling the information center
2. (Optional.) Enabling duplicate log suppression
3. Saving diagnostic logs to the diagnostic log file

Managing trace logs

1. Enabling the information center
2. (Optional.) Enabling duplicate log suppression
3. Setting the maximum size of the trace log file

Enabling the information center

About this task

The information center can output logs only after it is enabled.

Procedure

1. Enter system view.

   system-view

2. Enable the information center.

   info-center enable

   The information center is enabled by default.

Outputting logs to various destinations

Outputting logs to the console

Restrictions and guidelines

The **terminal monitor**, **terminal debugging**, and **terminal logging** commands take effect only for the current connection between the terminal and the device. If a new connection is established, the default is restored.

Procedure

1. Enter system view.

   system-view

2. Configure an output rule for sending logs to the console.

   info-center source { *module-name* | **default** } **console** { **deny** | **level** *severity* }

   For information about default output rules, see "Default output rules for logs."

3. (Optional.) Configure the timestamp format.

   info-center timestamp { **boot** | **date** | **none** }

   The default timestamp format is **date**.

4. Return to user view.

   quit

5. Enable log output to the console.

   terminal monitor

   By default, log output to the console is enabled.

6. Enable output of debugging messages to the console.

   terminal debugging

   By default, output of debugging messages to the console is disabled.

   This command enables output of debugging-level log messages to the console.

7. Set the lowest severity level of logs that can be output to the console.

   terminal logging level *severity*

   The default setting is 6 (informational).

Outputting logs to the monitor terminal

About this task

Monitor terminals refer to terminals that log in to the device through the VTY line.

Restrictions and guidelines

The **terminal monitor**, **terminal debugging**, and **terminal logging** commands take effect only for the current connection between the terminal and the device. If a new connection is established, the default is restored.

Procedure

1. Enter system view.

   system-view

2. Configure an output rule for sending logs to the monitor terminal.

   info-center source { *module-name* | **default** } **monitor** { **deny** | **level** *severity* }

   For information about default output rules, see "Default output rules for logs."

3. (Optional.) Configure the timestamp format.

   info-center timestamp { **boot** | **date** | **none** }

   The default timestamp format is **date**.

4. Return to user view.

   quit

5. Enable log output to the monitor terminal.

   terminal monitor

   By default, log output to the monitor terminal is disabled.

6. Enable output of debugging messages to the monitor terminal.

   terminal debugging

   By default, output of debugging messages to the monitor terminal is disabled.

   This command enables output of debugging-level log messages to the monitor terminal.

7. Set the lowest level of logs that can be output to the monitor terminal.

   terminal logging level *severity*

   The default setting is 6 (informational).

Outputting logs to log hosts

Restrictions and guidelines

The device supports the following methods (in descending order of priority) for outputting logs of a module to designated log hosts:

- Fast log output.

  For information about the modules that support fast log output and how to configure fast log output, see "Configuring fast log output."

- Flow log.

  For information about the modules that support flow log output and how to configure flow log output, see "Configuring flow log."

- Information center.

If you configure multiple log output methods for a module, only the method with the highest priority takes effect.

Procedure

1. Enter system view.

   system-view

2. Configure a log output filter or a log output rule. Choose one option as needed:

   - Configure a log output filter.

     info-center filter *filter-name* { *module-name* | **default** } { **deny** | **level** *severity* }

     By default, no log output filters exist.

     You can create multiple log output filters. When specifying a log host, you can apply a log output filter to the log host to control log output.

   - Configure a log output rule for the log host output destination.

     info-center source { *module-name* | **default** } **loghost** { **deny** | **level** *severity* }

     For information about default output rules, see "Default output rules for logs."

   The system chooses the settings to control log output to a log host in the following order:

   a. Log output filter applied to the log host.

   b. Log output rules configured for the log host output destination by using the **info-center source** command.

   c. Default log output rules (see "Default output rules for logs").

3. (Optional.) Specify a source IP address for output logs.

   info-center loghost source *interface-type interface-number*

   By default, the source IP address of output logs is the primary IP address of their outgoing interfaces.

4. (Optional.) Specify the format in which logs are output to log hosts.

info-center format { **cmcc** | **sgcc** | **unicom** }

   By default, logs are output to log hosts in non-customized format.

5. (Optional.) Add the device serial number to the location field of logs sent to log hosts.

   info-center loghost locate-info with-sn

   By default, the device does not add the device serial number to the location field of logs sent to log hosts.

6. (Optional.) Configure the timestamp format.

   info-center timestamp loghost { **date** [**with-milliseconds**] | **iso** [**with-milliseconds**] | **no-year-date** | **none** }

   The default timestamp format is **date**.

7. Specify a log host and configure related parameters.

   info-center loghost [**vpn-instance** *vpn-instance-name*] { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } [**facility** *local-number* | **filter** *filter-name* | **format** { **cmcc** | **default** | **sgcc** | **unicom** } | **port** *port-number* | **source-ip** *source-ip-address*] *

   By default, no log hosts or related parameters are specified.

   The value for the *port-number* argument must be the same as the value configured on the log host. Otherwise, the log host cannot receive logs.

The log format specified by this command has a higher priority than that specified by the **info-center format** command. The source IP address specified by this command has a higher priority than that specified by the **info-center loghost source** command.

Outputting logs to the log buffer

About this task

This feature enables log output to log buffers based on the log source modules. Log buffers include the following types:

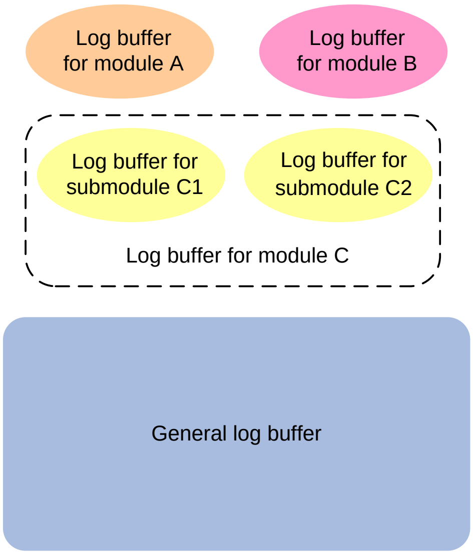
- **Separate module-specific log buffers**—Logs generated by modules or submodules that have separate log buffers are saved to their respective log buffers.

  For example, session logs and attack defense logs are saved to the session log buffer and the attack defense log buffer, respectively. With separate buffers, you can manage and view the module-specific logs and general logs conveniently.

  The modules and submodules that have separate log buffers are determined by factory settings. To view the names of supported modules and submodules, use the **display logbuffer module ?** command and the **display logbuffer module** *module-name* **submodule ?** command, respectively. You can use the **display logbuffer module** *module-name* to view buffered logs of the specified module. You can use the **display logbuffer module** *module-name* and **submodule** *submodule-name* command to view buffered logs of the specified submodule.
- **General log buffer**—Logs generated by the system and the modules other than the modules and submodules that have separate log buffers are saved to the general log buffer.

  You can use the **display logbuffer** command without the **module** keyword to view buffered logs in the general log buffer.

Figure 2 Genratal log buffer and separate log buffers for modules and submodules



Procedure

1. Enter system view.

   system-view
2. (Optional.) Configure an output rule for sending logs to the log buffer.

   info-center source { *module-name* | **default** } **logbuffer** { **deny** | **level** *severity* }

For information about the default output rules, see "Default output rules for logs."

3. (Optional.) Configure the timestamp format.

   info-center timestamp { **boot** | **date** | **none** }

   The default timestamp format is **date**.

4. Enable log output to the log buffer.

   info-center logbuffer

   By default, log output to the log buffer is enabled.

5. (Optional.) Set the maximum size of the log buffer for a module.

   info-center logbuffer module *module-name* **size** *buffersize*

   By default, a maximum of 512 logs can be buffered.

6. (Optional.) Set the maximum size of the general log buffer.

   info-center logbuffer size *buffersize*

   By default, a maximum of 512 logs can be buffered.

Saving logs to the log file

About this task

The log file feature enables log output to log files based on the log source modules. Log files include the following types:

- **Separate module-specific log files**—Logs generated by modules or submodules that have separate log files are output to their respective log files.

  For example, session logs and attack defense logs are output to the session log file and the attack defense log file, respectively. With separate log files, you can manage and view the module-specific logs and general logs conveniently.

  The modules that have separate log files are determined by factory settings. To view the names of supported modules, use the **info-center logfile module ?** command. You can use the **more** command in user view to logs in a module-specified log file.

- **General log file**—Logs generated by the system and the modules other than the modules that have separate log files are output to the general log file.

The system saves logs from the log file buffer to the log file. After saving logs to the log file, the system clears the log file buffer.

Log saving from the log file buffer to the log file is triggered by the following situations:

- Periodic saving.
- A manual immediate saving of buffered logs to the log file.
- The log file buffer is full.

A log file is automatically created when needed and has a maximum capacity. When log file overwrite-protection is disabled and no log file space or storage device space is available, the system will replace the oldest logs with new logs.

TIP:

- Clean up the storage space of the device regularly to ensure sufficient storage space for the log file feature.
- As a best practice, back up the log files regularly to avoid loss of important logs.

Configuring a module-specific log file

1. Enter system view.

system-view

2. Configure an output rule for sending logs to the log file.

   info-center source { *module-name* | **default** } **logfile** { **deny** | **level** *severity* }

   For information about default output rules, see "Default output rules for logs."

3. Enable the log file feature.

   info-center logfile enable

   By default, the log file feature is enabled.

   This command takes effect on both module-specific log files and the general log file.

4. (Optional.) Set the maximum log file size.

   info-center logfile module *module-name* **size-quota** *size*

   By default, the maximum log file size for the general log file and module-specific log file is 10 MB and 1 MB, respectively.

5. (Optional.) Set the alarm threshold for log file usage of a specific module.

   info-center logfile module *module-name* **alarm-threshold** *usage*

   The default alarm threshold for log file usage ratio is 80%. When the usage ratio of the log file reaches 80%, the system outputs a message to inform the user.

   Setting the alarm threshold to 0 means to disable the log file usage alarm feature for the module.

6. (Optional.) Specify the log file directory.

   info-center logfile directory *dir-name*

   By default, the log file is saved in the **logfile** folder under the root directory of the default file system.

   This command takes effect on both independent module log files and the general log file.

   This command cannot survive an IRF reboot or a master/subordinate switchover.

7. Save logs in the log file buffer to the log file. Choose one or both options as needed:

   - Configure the automatic log file saving interval.

     info-center logfile frequency *freq-sec*

     The default log file saving interval is 86400 seconds.

     This command takes effect on both module-specific log files and the general log file.

   - Immediately save logs from the log file buffer to the log file.

     logfile save

     This command is available in any view.

     This command takes effect on both module-specific log files and the general log file.

Configuring the general log file

1. Enter system view.

   system-view

2. (Optional.) Configure an output rule for sending logs to the log file.

   info-center source { *module-name* | **default** } **logfile** { **deny** | **level** *severity* }

   For information about the default output rules, see "Default output rules for logs."

3. Enable the log file feature.

   info-center logfile enable

   By default, the log file feature is enabled.

   This command takes effect on both module-specific log files and the general log file.

4. (Optional.) Set the maximum log file size.

   ```
   info-center logfile size-quota size
   ```

   By default, the maximum log file size for the general log file and module-specific log file is 10 MB and 1 MB, respectively.

5. (Optional.) Specify the log file directory.

   ```
   info-center logfile directory dir-name
   ```

   By default, the log file is saved in the **logfile** folder under the root directory of the default file system.

   This command takes effect on both module-specific log files and the general log file.

   This command cannot survive an IRF reboot or a master/subordinate switchover.

6. Save logs in the log file buffer to the log file. Choose one or both options as needed:

   - Configure the automatic log file saving interval.

     ```
     info-center logfile frequency freq-sec
     ```

     The default log file saving interval is 86400 seconds.

     This command takes effect on both independent module log files and the general log file.

   - Immediately save logs from the log file buffer to the log file.

     ```
     logfile save
     ```

     This command is available in any view.

     This command takes effect on both module-specific log files and the general log file.

Setting the minimum storage period for logs

About setting the minimum storage period

Use this feature to set the minimum storage period for logs in log buffers and log files. This feature ensures that logs will not be overwritten by new logs during a set period of time.

Logs of the modules that have separate log buffers and log files are output to their respective log buffers or log files. Logs of other modules and the system logs are output the general log buffer or log file. By default, when a log buffer or log file is full, new logs will automatically overwrite the oldest logs. After the minimum storage period is set, the system identifies the storage period of a log to determine whether to delete the log. The system current time minus a log's generation time is the log's storage period.

- If the storage period of a log is shorter than or equal to the minimum storage period, the system does not delete the log. The new log will not be saved.
- If the storage period of a log is longer than the minimum storage period, the system deletes the log to save the new log.

Setting the minimum storage period for logs in a module-specific log buffer or log file

1. Enter system view.

   ```
   system-view
   ```

2. Set the minimum storage period for logs stored in the log buffer or log file of a module.

   ```
   info-center syslog module module-name min-age min-age
   ```

   By default, the log minimum storage period is not set.

Setting the minimum storage period for logs in the general log buffer and log file

1. Enter system view.

   system-view

2. Set the minimum storage period for logs stored in the general log buffer and log file.

   info-center syslog min-age *min-age*

   By default, the log minimum storage period is not set.

Enabling synchronous information output

About this task

System log output interrupts ongoing configuration operations, obscuring previously entered commands. Synchronous information output shows the obscured commands. It also provides a command prompt in command editing mode, or a [Y/N] string in interaction mode so you can continue your operation from where you were stopped.

Procedure

1. Enter system view.

   system-view

2. Enable synchronous information output.

   info-center synchronous

   By default, synchronous information output is disabled.

Configuring the character set encoding used on the information center

About this task

The information center supports outputting log messages by using the GB18030 or UTF-8 encoding. By default, the GB18030 encoding is used.

For the login terminal to correctly display Chinese characters in log messages received from the information center, the information center and the terminal must use the same character set encoding.

Procedure

1. Enter system view.

   system-view

2. Enable the information center to use the UTF-8 encoding.

   info-center syslog utf-8 enable

   By default, the information center uses the GB18030 encoding for outputting log messages.

Configuring log suppression

Enabling duplicate log suppression

About this task

Output of consecutive duplicate logs (logs that have the same module name, level, mnemonic, location, and text) wastes system and network resources.

With duplicate log suppression enabled, the system starts a suppression period upon outputting a log:

- If only duplicate logs are received during the suppression period, the information center does not output the duplicate logs. When the suppression period expires, the information center outputs the suppressed log and the number of times the log is suppressed.
- If a different log is received during the suppression period, the information center performs the following operations:
  - Outputs the suppressed log and the number of times the log is suppressed.
  - Outputs the different log and starts a suppression period for that log.
- If no log is received within the suppression period, the information center does not output any message when the suppression period expires.

Procedure

1. Enter system view.

   `system-view`

2. Enable duplicate log suppression.

   `info-center logging suppress duplicates`

   By default, duplicate log suppression is disabled.

Configuring log suppression for a module

About this task

This feature suppresses output of logs. You can use this feature to filter out the logs that you are not concerned with.

Perform this task to configure a log suppression rule to suppress output of all logs or logs with a specific mnemonic value for a module.

Procedure

1. Enter system view.

   `system-view`

2. Configure a log suppression rule for a module.

   `info-center logging suppress module` *`module-name`* **`mnemonic`** { **`all`** | *`mnemonic-value`* }

   By default, the device does not suppress output of any logs from any modules.

Disabling an interface from generating link up or link down logs

About this task

By default, an interface generates link up or link down log information when the interface state changes. In some cases, you might want to disable certain interfaces from generating this information. For example:

- You are concerned about the states of only some interfaces. In this case, you can use this function to disable other interfaces from generating link up and link down log information.
- An interface is unstable and continuously outputs log information. In this case, you can disable the interface from generating link up and link down log information.

Use the default setting in normal cases to avoid affecting interface status monitoring.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Disable the interface from generating link up or link down logs.

   ```
   undo enable log updown
   ```

   By default, an interface generates link up and link down logs when the interface state changes.

Limiting output of security logs

About this task

When the device processes the following security services, a large number of security logs will be generated and sent to the information center, which will cause overload of the information center:

- AFT.
- ASPF.
- Data filtering.
- File filtering.
- URL filtering.
- NAT.
- Session management.
- Anti-virus.
- Application audit and management.
- IPS.
- NetShare Control.
- Server connection detection.
- Attack detection and prevention.

This feature allows you to set the maximum number of security logs that can be sent per second to the information center. With this feature configured, the device will discard the subsequent security logs when the maximum number of security logs that can be sent per second is reached. Please configure the maximum number of security logs that can be sent per second as required.

Procedure

1. Enter system view.

   system-view

2. Set the maximum number of security logs that can be sent per second.

   security syslog rate-limit *max-value*

   By default, the device can send a maximum of 1000 security logs per second to the information center.

Enabling SNMP notifications for system logs

About this task

This feature enables the device to send an SNMP notification for each log message it outputs. The device encapsulates the logs in SNMP notifications and then sends them to the SNMP module and the log trap buffer.

You can configure the SNMP module to send received SNMP notifications in SNMP traps or informs to remote hosts. For more information, see "Configuring SNMP."

To view the traps in the log trap buffer, access the MIB corresponding to the log trap buffer.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for system logs.

   snmp-agent trap enable syslog

   By default, the device does not send SNMP notifications for system logs.

3. Set the maximum number of traps that can be stored in the log trap buffer.

   info-center syslog trap buffersize *buffersize*

   By default, the log trap buffer can store a maximum of 1024 traps.

Managing security logs

Saving security logs to the security log file

About this task

Security logs are very important for locating and troubleshooting network problems. Generally, security logs are output together with other logs. It is difficult to identify security logs among all logs.

To solve this problem, you can save security logs to the security log file without affecting the current log output rules.

After you enable the security log file feature, the system processes security logs as follows:

1. Outputs security logs to the security log file buffer.
2. Saves logs from the security log file buffer to the security log file at the specified interval.

   If you have the security-audit role, you can also manually save security logs to the security log file.

3. Clears the security log file buffer immediately after the security logs are saved to the security log file.

Restrictions and guidelines

The device supports only one security log file. The system will overwrite old logs with new logs when the security log file is full. To avoid security log loss, you can set an alarm threshold for the security log file usage ratio. When the alarm threshold is reached, the system outputs a message to inform you of the alarm. You can log in to the device with the security-audit user role and back up the security log file to prevent the loss of important data.

Procedure

1. Enter system view.

   `system-view`

2. Enable the security log file feature.

   `info-center security-logfile enable`

   By default, the security log file feature is disabled.

3. Set the interval at which the system saves security logs.

   `info-center security-logfile frequency` *`freq-sec`*

   The default security log file saving interval is 86400 seconds.

4. (Optional.) Set the maximum size for the security log file.

   `info-center security-logfile size-quota` *`size`*

   By default, the maximum security log file size is 10 MB.

5. (Optional.) Set the alarm threshold of the security log file usage.

   `info-center security-logfile alarm-threshold` *`usage`*

   By default, the alarm threshold of the security log file usage ratio is 80. When the usage of the security log file reaches 80%, the system will send a message.

Managing the security log file

Restrictions and guidelines

To use the security log file management commands, you must have the security-audit user role. For information about configuring the security-audit user role, see AAA in *Security Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Change the directory of the security log file.

   `info-center security-logfile directory` *`dir-name`*

   By default, the security log file is saved in the **seclog** directory in the root directory of the storage device.

   This command cannot survive an IRF reboot or a master/subordinate switchover.

3. Manually save all logs in the security log file buffer to the security log file.

   `security-logfile save`

   This command is available in any view.

4. (Optional.) Display the summary of the security log file.

   `display security-logfile summary`

   This command is available in any view.

Saving diagnostic logs to the diagnostic log file

About this task

By default, the diagnostic log file feature saves diagnostic logs from the diagnostic log file buffer to the diagnostic log file at the specified saving interval. You can also manually trigger an immediate saving of diagnostic logs to the diagnostic log file. After saving diagnostic logs to the diagnostic log file, the system clears the diagnostic log file buffer.

The device supports only one diagnostic log file. The diagnostic log file has a maximum capacity. When the capacity is reached, the system replaces the oldest diagnostic logs with new logs.

Procedure

1. Enter system view.

   system-view

2. Enable the diagnostic log file feature.

   info-center diagnostic-logfile enable

   By default, the diagnostic log file feature is enabled.

3. (Optional.) Set the maximum diagnostic log file size.

   info-center diagnostic-logfile quota *size*

   By default, the maximum diagnostic log file size is 10 MB.

4. (Optional.) Specify the diagnostic log file directory.

   info-center diagnostic-logfile directory *dir-name*

   By default, the diagnostic log file is saved in the **diagfile** folder under the root directory of the default file system.

   This command cannot survive an IRF reboot or a master/subordinate switchover.

5. Save diagnostic logs in the diagnostic log file buffer to the diagnostic log file. Choose one option as needed:

   - Configure the automatic diagnostic log file saving interval.

     info-center diagnostic-logfile frequency *freq-sec*

     The default diagnostic log file saving interval is 86400 seconds.

   - Manually save diagnostic logs to the diagnostic log file.

     diagnostic-logfile save

     This command is available in any view.

Setting the maximum size of the trace log file

About this task

The device has only one trace log file. When the trace log file is full, the device overwrites the oldest trace logs with new ones.

Procedure

1. Enter system view.

   system-view

2. Set the maximum size for the trace log file.

   info-center trace-logfile quota *size*

   The default maximum trace log file size is 1 MB.

Display and maintenance commands for information center

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the character set encoding used on the device or the login terminal.	**display character-set** [**terminal**]
Display the diagnostic log file configuration.	**display diagnostic-logfile summary**
Display the information center configuration.	**display info-center**
Display information about log output filters.	**display info-center filter** [*filtername*]
Display the log output rules by source modules.	**display info-center source** [**module** *module-name*]
Display log buffer information and buffered logs.	**display logbuffer** [**module** *module-name* [**submodule** *submodule-name*]] [**reverse**] [**level** *severity* | **size** *buffersize* | **slot** *slot-number*] * [**last-mins** *mins*]
Display the log buffer summary.	**display logbuffer summary** [**level** *severity* | **slot** *slot-number*] *
Display the log file configuration.	**display logfile summary**
Display summary information of the security log file (security-audit user role required).	**display security-logfile summary**
Clear the log buffer.	**reset logbuffer** [**module** *module-name* [**submodule** *submodule-name*]]

Contents

Configuring flow log

About flow log

Flow log records session information based on flows.

A flow log entry might contain the following information about a flow:

- Network access quintuple information (source IP address, destination IP address, source port, destination port, and protocol number).
- Statistics about sent and received packets.
- Flow-based link selection information.

Flow log export

You can export flow log entries in the following methods:

- Export flow log entries to log hosts. Flow log entries are sent as binary characters in UDP. One UDP packet can contain multiple log entries.
- Export flow log entries to the information center. Flow log entries are converted to syslog entries in ASCII format, with the informational severity level. The information center specifies the output destinations for the log entries. For more information about the information center, see "Configuring the information center."

Log entries in ASCII format are human readable. However, the log data volume is higher in ASCII format than in binary format. It's recommended to export flow log entries in binary format to log hosts if the log data volume is large.

Flow log packet

The flow log data (including the log header and log body) is carried in the body of a UDP packet. The log header contains the common fields and the log body contains the service-specific log information. The log body of a flow log packet can contain one or multiple log entries of the same type.

Figure 1 Flow log packet

Flow log supports multiple service modules. The log body fields vary with the log type or log version. For more information about flow log fields, see "Appendix A Flow log fields."

Flow log tasks at a glance

To configure flow log, perform the following tasks:

1. Enabling flow log
2. Specifying a flow log export destination

   Choose one of the following tasks:

   - Specifying a log host as the flow log export destination
   - Specifying the information center as the flow log export destination

3. (Optional.) Configuring the flow log version
4. (Optional.) Specifying a source IP address for flow log packets
5. (Optional.) Configuring the timestamp of flow log entries
6. (Optional.) Enabling load balancing for flow log entries
7. (Optional.) Configuring flow log host groups

Enabling flow log

Before you configure the flow log feature, complete the following tasks to enable flow log output for modules:

- Enable NAT flow log output by using the **nat log enable** command. For more information about the NAT logging commands, see *NAT Command Reference*.
- Enable AFT flow log output by using the **aft log enable** command. For more information, see AFT commands in *Layer 3—IP Services Command Reference*.
- Enable load balancing NAT flow log output by using the **loadbalance log enable nat** command. For more information, see load balancing commands in *Load Balancing Command Reference*.

Specifying a flow log export destination

Restrictions and guidelines for flow log export destination configuration

You can export flow log entries to a log host or to the information center, but not both. If you configure both methods, the system exports flow log entries to the information center.

flow log entries exported to the information center has the **informational** severity level.

Specifying a log host as the flow log export destination

1. Enter system view.

   system-view

2. Specify a log host as the destination for flow log export.

   userlog flow export [**vpn-instance** *vpn-instance-name*] **host** { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } **port** *udp-port*

   By default, no log hosts are specified.

   You can specify multiple log hosts.

Specifying the information center as the flow log export destination

1. Enter system view.

   system-view

2. Specify the information center as the destination for flow log export.

   userlog flow syslog

   By default, flow log entries are not exported to the information center.

△ **CAUTION:**

The device might generate a lot of session logs in a short time. If the session logs are exported to the information center for processing, the information center might consume too much performance, affecting normal operations of the device.

Configuring the flow log version

Restrictions and guidelines

Make sure the specified flow log version is supported on the log host.

If you configure the flow log version multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.

   `system-view`

2. Configure the flow log version.

   `userlog flow export version` *`version-number`*

   The default flow log version is 1.0.

Specifying a source IP address for flow log packets

About this task

By default, the source IP address for flow log packets is the IP address of their outgoing interface. For the log hosts to filter log entries by log sender, specify a source IP address for all flow log packets.

Restrictions and guidelines

As a best practice, use a Loopback interface's address as the source IP address for flow log packets. A Loopback interface is always up. The setting avoids export failure on interfaces that might go down.

Procedure

1. Enter system view.

   `system-view`

2. Specify a source IP address for flow log packets.

   `userlog flow export source-ip` { *`ipv4-address`* | **`ipv6`** *`ipv6-address`* }

   By default, the source IP address for flow log packets is the IP address of their outgoing interface.

Configuring the timestamp of flow log entries

About this task

The device uses either the local time or the UTC time in the timestamp of flow logs.

- **UTC time**—Standard Greenwich Mean Time (GMT).
- **Local time**—Standard GMT plus or minus the time zone offset.

The time zone offset can be configured by using the **`clock timezone`** command. For more information, see device management in *Fundamentals Command Reference*.

Procedure

1. Enter system view.

```
system-view
```

2. Configure the device to use the local time in the flow log timestamp.

```
userlog flow export timestamp localtime
```

By default, the UTC time is used in the flow log timestamp.

Enabling load balancing for flow log entries

About this task

By default, the device sends a copy of each flow log entry to all configured log hosts. When one log host fails, other log hosts still have complete flow log entries.

In load balancing mode, flow log entries are distributed among log hosts based on the source IP addresses (before NAT) that are recorded in the entries. The flow log entries generated for the same source IP address are sent to the same log host.

Restrictions and guidelines

In load balancing mode, flow log entries are load balanced among all configured log hosts, regardless of whether the log hosts are reachable. If a log host is unreachable, the flow log entries sent to it will be lost.

Procedure

1. Enter system view.

```
system-view
```

2. Enable load balancing for flow log entries.

```
userlog flow export load-balancing
```

By default, load balancing is disabled.

Configuring flow log host groups

About flow log host group

By default, the device sends a copy of each flow log entry to all available log hosts. To filter logs and reduce the log sending and processing workload of the device, configure the flow log host group feature.

The flow log host group feature allows you to classify flow log hosts into groups and specify an ACL for each group. A flow log matches a log host group if it matches the group's ACL, and it is sent only to the log hosts in the matching group.

If a flow log matches multiple log host groups, the device sends the log to the group that comes first in alphabetical order of the matching group names.

If a flow log does not match any log host groups, the device ignores the log host group configuration and sends the log to all configured log hosts.

If load balancing is enabled, flow logs sent to a log host group will be load-shared among the log hosts in the group. flow logs generated for the same source IP address are sent to the same log host.

Prerequisites for log host group configuration

Before you configure flow log host groups, complete the following tasks:

- Configure the ACLs to be used by the flow log host groups.
- Use the **userlog flow export host** command to configure the log hosts to be assigned to the flow log host groups.

Configuring an IPv4 flow log host group

1. Enter system view.

   system-view
2. Create an IPv4 flow log host group and enter its view.

   userlog host-group *host-group-name* **acl** { **name** *acl-name* | **number** *acl-number* }

   By default, no IPv4 flow log host groups exist.
3. Assign an IPv4 log host to the flow log host group.

   userlog host-group [**vpn-instance** *vpn-instance-name*] **host flow** { *hostname* | *ipv4-address* }

   By default, an IPv4 flow log host group does not contain any log hosts.

Configuring an IPv6 flow log host group

1. Enter system view.

   system-view
2. Create an IPv6 flow log host group and enter its view.

   userlog host-group ipv6 *host-group-name* **acl** { **name** *acl-name* | **number** *acl-number* }

   By default, no IPv6 flow log host groups exist.
3. Assign an IPv6 log host to the flow log host group.

   userlog host-group [**vpn-instance** *vpn-instance-name*] **host flow ipv6** { *hostname* | *ipv6-address* }

   By default, an IPv6 flow log host group does not contain any log hosts.

Display and maintenance commands for flow log

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display flow log configuration and statistics.	**display userlog export**
Display flow log host group information.	**display userlog host-group** [**ipv6**] [*host-group-name*]
Clear flow log statistics.	**reset userlog flow export**

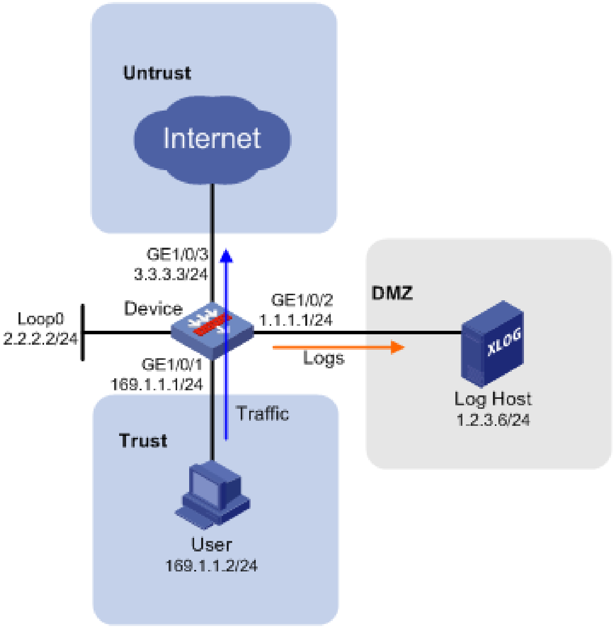
NAT flow log configuration examples

Example: Configuring NAT flow log export

Network configuration

As shown in Figure 2, configure flow log on the device to send flow log entries generated for the user to the log host.

Figure 2 Network diagram



Procedure

1. Assign IP addresses to interfaces.

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface loopback 0
   [Device-LoopBack0] ip address 2.2.2.2 255.255.255.0
   [Device-LoopBack0] quit
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 169.1.1.1 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing.

   This example configures static routes, and the next hops in the routes are 1.1.1.2 and 3.3.3.1, respectively.

   ```
   [Device] ip route-static 1.2.3.0 24 1.1.1.2
   [Device] ip route-static 0.0.0.0 0 3.3.3.1
   ```

3. Add interfaces to security zones.

   ```
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/1
   ```

```
[Device-security-zone-Trust] quit
[Device] security-zone name dmz
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/2
[Device-security-zone-DMZ] quit
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/3
[Device-security-zone-Untrust] quit
```

4. Configure a security policy:

   # Configure a rule named **loglocalout** to allow the device to send log packets to the log host.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name loglocalout
   [Device-security-policy-ip-1-loglocalout] source-zone local
   [Device-security-policy-ip-1-loglocalout] destination-zone dmz
   [Device-security-policy-ip-1-loglocalout] source-ip-host 2.2.2.2
   [Device-security-policy-ip-1-loglocalout] destination-ip-host 1.2.3.6
   [Device-security-policy-ip-1-loglocalout] action pass
   [Device-security-policy-ip-1-loglocalout] quit
   ```

   # Configure a rule named **trust-untrust** to all the user to access the Internet.

   ```
   [Device-security-policy-ip] rule name trust-untrust
   [Device-security-policy-ip-3-trust-untrust] source-zone trust
   [Device-security-policy-ip-3-trust-untrust] destination-zone untrust
   [Device-security-policy-ip-3-trust-untrust] source-ip-subnet 169.1.1.0 24
   [Device-security-policy-ip-3-trust-untrust] action pass
   [Device-security-policy-ip-3-trust-untrust] quit
   [Device-security-policy-ip] quit
   ```

5. Configure flow log settings:

   # Enable NAT logging for session establishment events, session removal events, and active flows. Set the flow log version to **3.0**.

   ```
   [Device] nat log enable
   [Device] nat log flow-begin
   [Device] nat log flow-end
   [Device] nat log flow-active 10
   [Device] userlog flow export version 3
   ```

   # Specify the log host at 1.2.3.6 as the destination for flow log export, set the UDP port number to 2000, and specify 2.2.2.2 as the source IP address for flow log packets.

   ```
   [Device] userlog flow export host 1.2.3.6 port 2000
   [Device] userlog flow export source-ip 2.2.2.2
   ```

Verifying the configuration

# Display the flow log configuration and statistics.

```
[Device] display userlog export
Flow:
  Export flow log as UDP Packet.
  Version: 3.0
  Source ipv4 address: 2.2.2.2
  Log load balance function: Disabled
  Local time stamp: Disabled
  Number of log hosts: 1
```

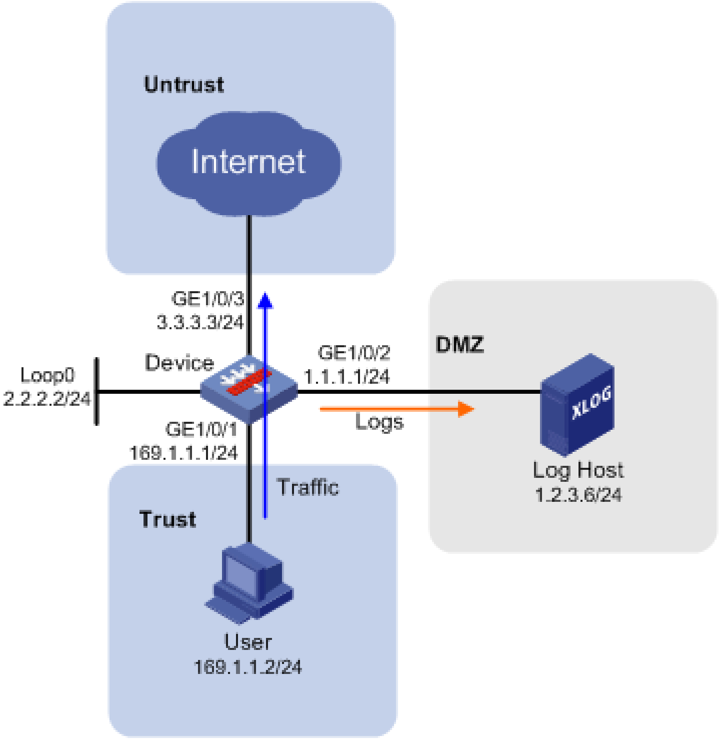
```
Log host 1:
  Host/Port: 1.2.3.6/2000
  Total logs/UDP packets exported: 112/87
```

Example: Configuring session flow log export

Network configuration

As shown in Figure 3, configure flow log on the device to send session flow log entries generated for the user to the log host.

Figure 3 Network diagram



Procedure

1. Assign IP addresses to interfaces.

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface loopback 0
   [Device-LoopBack0] ip address 2.2.2.2 255.255.255.0
   [Device-LoopBack0] quit
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 169.1.1.1 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing.

   This example configures static routes, and the next hops in the routes are 1.1.1.2 and 3.3.3.1, respectively.

   ```
   [Device] ip route-static 1.2.3.0 24 1.1.1.2
   ```

```
[Device] ip route-static 0.0.0.0 0 3.3.3.1
```

3. Add interfaces to security zones.

```
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/1
[Device-security-zone-Trust] quit
[Device] security-zone name dmz
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/2
[Device-security-zone-DMZ] quit
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/3
[Device-security-zone-Untrust] quit
```

4. Configure a security policy.

# Configure a rule named **loglocalout** to allow the device to send log packets to the log host.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name loglocalout
[Device-security-policy-ip-1-loglocalout] source-zone local
[Device-security-policy-ip-1-loglocalout] destination-zone dmz
[Device-security-policy-ip-1-loglocalout] source-ip-host 2.2.2.2
[Device-security-policy-ip-1-loglocalout] destination-ip-host 1.2.3.6
[Device-security-policy-ip-1-loglocalout] action pass
[Device-security-policy-ip-1-loglocalout] quit
```

# Configure a rule named **trust-untrust** to allow the user to access the Internet.

```
[Device-security-policy-ip] rule name trust-untrust
[Device-security-policy-ip-3-trust-untrust] source-zone trust
[Device-security-policy-ip-3-trust-untrust] destination-zone untrust
[Device-security-policy-ip-3-trust-untrust] source-ip-subnet 169.1.1.0 24
[Device-security-policy-ip-3-trust-untrust] action pass
[Device-security-policy-ip-3-trust-untrust] quit
[Device-security-policy-ip] quit
```

5. Configure flow log settings:

# Enable NAT logging for session establishment events and session removal events. Set the flow log version to **3.0**.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] session log enable ipv4 inbound
[Device] session log flow-begin
[Device] session log flow-end
[Device] userlog flow export version 3
```

# Specify the log host at 1.2.3.6 as the destination for flow log export, set the UDP port number to 2000, and specify 2.2.2.2 as the source IP address for flow log packets.

```
[Device] userlog flow export host 1.2.3.6 port 2000
[Device] userlog flow export source-ip 2.2.2.2
```

Verifying the configuration

# Display the flow log configuration and statistics.

```
[Device] display userlog export
Flow:
  Export flow log as UDP Packet.
  Version: 3.0
```

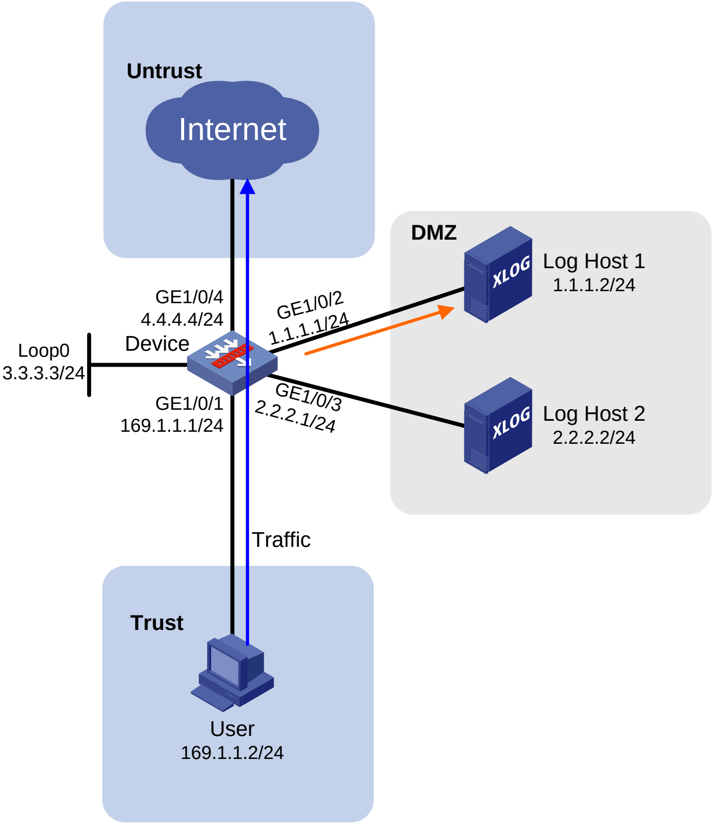
```
Source ipv4 address: 2.2.2.2
Log load balance function: Disabled
Local time stamp: Disabled
Number of log hosts: 1
Log host 1:
  Host/Port: 1.2.3.6/2000
  Total logs/UDP packets exported: 112/87
```

Example: Configuring NAT flow log export to a flow log host group

Network configuration

As shown in Figure 4, configure a flow log host group on the device to send flow log entries generated for the user only to Log Host 1.

Figure 4 Network diagram



Procedure

1. Assign IP addresses to interfaces.

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface loopback 0
   [Device-LoopBack0] ip address 3.3.3.3 255.255.255.0
   [Device-LoopBack0] quit
   [Device] interface gigabitethernet 1/0/1
   ```

```
[Device-GigabitEthernet 1/0/1] ip address 169.1.1.1 255.255.255.0
[Device-GigabitEthernet 1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing.

   This example configures a static route, and the next hop in the routes is 4.4.4.1.

   ```
   [Device] ip route-static 0.0.0.0 0 4.4.4.1
   ```

3. Add interfaces to security zones.

   ```
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/1
   [Device-security-zone-Trust] quit
   [Device] security-zone name dmz
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/2
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/3
   [Device-security-zone-DMZ] quit
   [Device] security-zone name untrust
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/4
   [Device-security-zone-Untrust] quit
   ```

4. Configure a security policy.

   # Configure a rule named **loglocalout** for the device to send log packets to the log hosts.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name loglocalout
   [Device-security-policy-ip-1-loglocalout] source-zone local
   [Device-security-policy-ip-1-loglocalout] destination-zone dmz
   [Device-security-policy-ip-1-loglocalout] source-ip-host 3.3.3.3
   [Device-security-policy-ip-1-loglocalout] destination-ip-host 1.1.1.2
   [Device-security-policy-ip-1-loglocalout] destination-ip-host 2.2.2.2
   [Device-security-policy-ip-1-loglocalout] action pass
   [Device-security-policy-ip-1-loglocalout] quit
   ```

   # Configure a rule named **trust-untrust** for the user to access the Internet.

   ```
   [Device-security-policy-ip] rule name trust-untrust
   [Device-security-policy-ip-3-trust-untrust] source-zone trust
   [Device-security-policy-ip-3-trust-untrust] destination-zone untrust
   [Device-security-policy-ip-3-trust-untrust] source-ip-subnet 169.1.1.0 24
   [Device-security-policy-ip-3-trust-untrust] action pass
   [Device-security-policy-ip-3-trust-untrust] quit
   [Device-security-policy-ip] quit
   ```

5. Configure flow log settings.

   # Enable NAT logging for session establishment events, session removal events, and active flows.

   ```
   [Device] nat log enable
   [Device] nat log flow-begin
   [Device] nat log flow-end
   [Device] nat log flow-active 10
   ```

   # Specify the log hosts as the destinations for flow log export, set the UDP port number to 2000. Specify 3.3.3.3 as the source IP address for flow log packets.

   ```
   [Device] userlog flow export host 1.1.1.2 port 2000
   [Device] userlog flow export host 2.2.2.2 port 2000
   [Device] userlog flow export source-ip 3.3.3.3
   ```

# Create ACL 2000 to match packets sent by the user.

```
[Device] acl basic 2000
[Device-acl-ipv4-basic-2000] rule permit source 169.1.1.2 0.0.0.0
[Device-acl-ipv4-basic-2000] quit
```

# Create an IPv4 flow log host group named **test** and specify ACL 2000 for it. Assign Log Host 1 to flow log host group **test**.

```
[Device] userlog host-group test acl number 2000
[Device-userlog-host-group-test] userlog host-group host flow 1.1.1.2
[Device-userlog-host-group-test] quit
```

Verifying the configuration

# Display information about flow log host group **test**.

```
[Device] display userlog host-group test
Userlog host-group test:
  ACL number: 2000

  Flow log host numbers: 1

    Log host 1:
      Host/port: 1.1.1.2/2000
```

# After the user comes online, display flow log export statistics.

```
[Device] display userlog export
Flow:
  Export flow log as UDP Packet.
  Version: 1.0
  Source ipv4 address: 3.3.3.3
  Log load balance function: Disabled
  Local time stamp: Disabled
  Number of log hosts: 2

  Log host 1:
    Host/Port: 1.1.1.2/2000
    Total logs/UDP packets exported: 13/13

  Log host 2:
    Host/Port: 2.2.2.2/2000
    Total logs/UDP packets exported: 0/0
```

Appendix

Appendix A Flow log fields

The fields described in this section are those in the original log data sent to the log host. The log format might differ from the actual log format displayed on the log host. The displayed log format depends on the log analysis tool.

Log header fields

Table 1 shows the log header fields, and the corresponding length and description.

Table 1 Fields in a log header

Field	Length (Bytes)	Description
Version	1	Version number of the log packet: • **1**—Version 1.0. • **3**—Version 3.0. • **5**—Version 5.0.
LogType	1	Log type: • **4**—NAT flow log. • **5**—NAT66 flow log. • **7**—AFT IPv6 to IPv4 log. • **8**—AFT IPv4 to IPv6 log. • **11**—LB NAT64 flow log. • **12**—LB NAT46 flow log. • **13**—LB NAT44 flow log. • **14**—LB NAT66 flow log. • **15**—RIR flow log.
Count	2	Number of flows recorded in the current packet. The value range is 1 to 100.
Second	4	Number of seconds from 1970-01-01 00:00:00 to the time when the packet was generated.
FlowSequence	4	Sequence number of the log packet, which equals to the count of log packets of all log types and versions.
Chassis	2	Number of chassis sent the log packet.
Slot	1	Number of slot sent the log packet.
Cpu	1	Number of CPU sent the log packet.

NAT flow log fields

NAT flow log has three versions: 1.0, 3.0, and 5.0. Table 2, Table 3, and Table 4 show the fields available in the versions.

Table 2 NAT flow log 1.0 fields

Field	Length (Bytes)	Description
SrcIP	4	Source IP address before NAT.

Field	Length (Bytes)	Description
DestIP	4	Destination IP address before NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
StartTime	4	Start time of the flow, in seconds. The value is counted from 1970/1/1 0:0.
EndTime	4	End time of the flow, in seconds. The value is counted from 1970/1/1 0:0. This field is 0 if the **Operator** field is 6.
Protocol	1	Protocol type carried by IP.
Operator	1	Reasons why a NAT flow log entry was generated: • **0**—Reserved. • **1**—Flow was ended normally. • **2**—Flow was aged out because of aging timer expiration. • **3**—Flow was aged out because of configuration change or manual deletion. • **4**—Flow was aged out because of insufficient resources. • **5**—Reserved. • **6**—Regular connectivity check record for the active flow. • **7**—Flow was deleted because a new flow was created when the flow table was full. • **8**—Flow was created. • **FE**—Other reasons. • **10-FE-1**—Reserved for future use.
Reserved	2	Reserved for future use.

Table 3 NAT flow log 3.0 fields

Field	Length (Bytes)	Description
Protocol	1	Protocol number.
Operator	1	Reasons why a NAT flow log was generated: • **0**—Reserved. • **1**—Flow was ended normally. • **2**—Flow was aged out because of aging timer expiration**.** • **3**—Flow was aged out because of configuration change. • **4**—Flow was aged out because of insufficient resources. • **5**—Reserved. • **6**—Regular connectivity check record for the active flow. • **7**—Flow was deleted because a new flow was created when the flow table was full. • **8**—Flow was created. • **FE**—Other reasons. • **10-FE-1**—Reserved for future use.
IPVersion	1	IP packet version.
TosIPv4	1	ToS field of the IPv4 packet.
SourceIP	4	Source IP address before NAT.
SrcNatIP	4	Source IP address after NAT.

Field	Length (Bytes)	Description
DestIP	4	Destination IP address before NAT.
DestNatIP	4	Destination IP address after NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
SrcNatPort	2	Source TCP/UDP port number after NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
DestNatPort	2	Destination TCP/UDP port number after NAT.
StartTime	4	Start time of the flow, in seconds. The value is counted from 1970/1/1 0:0.
EndTime	4	End time of the flow, in seconds. The value is counted from 1970/1/1 0:0. This field is 0 when the **Operator** field is 6.
InTotalPkg	4	Number of packets received for the session.
InTotalByte	4	Number of bytes received for the session.
OutTotalPkg	4	Number of packets sent for the session.
OutTotalByte	4	Number of bytes sent for the session.
InVPNID	1	ID of the source VPN instance.
OutVPNID	1	ID of the destination VPN instance.
vSystemID	2	vSystem ID.
AppID	4	Application protocol ID.
Reserved3	4	Reserved field.

Table 4 NAT flow log 5.0 fields

Field	Length (Bytes)	Description
Protocol	1	Protocol type carried by IP.
Operator	1	Reasons why a flow log was generated: • **0**—Reserved. • **1**—Flow was ended normally. • **2**—Flow was aged out because of aging timer expiration**.** • **3**—Flow was aged out because of configuration change. • **4**—Flow was aged out because of insufficient resources. • **5**—Reserved. • **6**—Regular connectivity check record for the active flow. • **7**—Flow was deleted because a new flow was created when the flow table was full. • **8**—Flow was created. • **FE**—Other reasons. • **10-FE-1**—Reserved for future use.
IPVersion	1	IP packet version.
TosIPv4	1	ToS field of the IPv4 packet.
SourceIP	4	Source IP address before NAT.
SrcNatIP	4	Source IP address after NAT.

Field	Length (Bytes)	Description
DestIP	4	Destination IP address before NAT.
DestNatIP	4	Destination IP address after NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
SrcNatPort	2	Source TCP/UDP port number after NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
DestNatPort	2	Destination TCP/UDP port number after NAT.
StartTime	4	Start time of the flow, in seconds.
EndTime	4	End time of the flow, in seconds. This field is 0 when the **Operator** field is 6.
InTotalPkg	4	Number of packets received for the session.
InTotalByte	4	Number of bytes received for the session.
OutTotalPkg	4	Number of packets sent for the session.
OutTotalByte	4	Number of bytes sent for the session.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
AppID	4	Application protocol ID.
UserName	56	Username.
vSystemID	2	vSystem ID.
Reserved1	4	Reserved field.
Reserved2	4	Reserved field
Reserved3	4	Reserved field

NAT66 flow log fields

NAT66 flow log has three versions: 1.0, 3.0, and 5.0. Table 5, Table 6, and Table 7 show the fields available in the versions.

Table 5 NAT66 flow log 1.0 fields

Field	Length (Bytes)	Description
SrcIP	16	Source IPv6 address before NAT.
DestIP	16	Destination IPv6 address before NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
StartTime	4	Start time of the flow, in seconds. The value is counted from 1970/1/1 0:0.
EndTime	4	End time of the flow, in seconds. The value is counted from 1970/1/1 0:0. This field is 0 if the **Operator** field is 6.
Protocol	1	Protocol type carried by IP.

Field	Length (Bytes)	Description
Operator	1	Reasons why a NAT flow log entry was generated: • **0**—Reserved. • **1**—Flow was ended normally. • **2**—Flow was aged out because of aging timer expiration. • **3**—Flow was aged out because of configuration change or manual deletion. • **4**—Flow was aged out because of insufficient resources. • **5**—Reserved. • **6**—Regular connectivity check record for the active flow. • **7**—Flow was deleted because a new flow was created when the flow table was full. • **8**—Flow was created. • **FE**—Other reasons. • **10-FE-1**—Reserved for future use.
Reserved	2	Reserved for future use.

Table 6 NAT66 flow log 3.0 fields

Field	Length (Bytes)	Description
Protocol	1	Protocol number.
Operator	1	Reasons why a NAT flow log was generated: • **0**—Reserved. • **1**—Flow was ended normally. • **2**—Flow was aged out because of aging timer expiration**.** • **3**—Flow was aged out because of configuration change. • **4**—Flow was aged out because of insufficient resources. • **5**—Reserved. • **6**—Regular connectivity check record for the active flow. • **7**—Flow was deleted because a new flow was created when the flow table was full. • **8**—Flow was created. • **FE**—Other reasons. • **10-FE-1**—Reserved for future use.
IPVersion	1	IP packet version.
Traffic class	1	Traffic Class field of the IPv6 packet.
SourceIP	16	Source IPv6 address before NAT.
DestIP	16	Destination IPv6 address before NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
StartTime	4	Start time of the flow, in seconds. The value is counted from 1970/1/1 0:0.
EndTime	4	End time of the flow, in seconds. The value is counted from 1970/1/1 0:0. This field is 0 when the **Operator** field is 6.
InTotalPkg	4	Number of packets received for the session.
InTotalByte	4	Number of bytes received for the session.

Field	Length (Bytes)	Description
OutTotalPkg	4	Number of packets sent for the session.
OutTotalByte	4	Number of bytes sent for the session.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
ContextID	4	ID of the context for the session.
AppID	4	Application protocol ID.

Table 7 NAT66 flow log 5.0 fields

Field	Length (Bytes)	Description
Protocol	1	Protocol type carried by IP.
Operator	1	Reasons why a flow log was generated: • **0**—Reserved. • **1**—Flow was ended normally. • **2**—Flow was aged out because of aging timer expiration**.** • **3**—Flow was aged out because of configuration change. • **4**—Flow was aged out because of insufficient resources. • **5**—Reserved. • **6**—Regular connectivity check record for the active flow. • **7**—Flow was deleted because a new flow was created when the flow table was full. • **8**—Flow was created. • **FE**—Other reasons. • **10-FE-1**—Reserved for future use.
IPVersion	1	IP packet version.
Traffic class	1	Traffic Class field of the IPv6 packet.
SourceIP	16	Source IPv6 address before NAT.
DestIP	16	Destination IPv6 address before NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
StartTime	4	Start time of the flow, in seconds. The value is counted from 1970/1/1 0:0.
EndTime	4	End time of the flow, in seconds. The value is counted from 1970/1/1 0:0. This field is 0 when the **Operator** field is 6.
InTotalPkg	4	Number of packets received for the session.
InTotalByte	4	Number of bytes received for the session.
OutTotalPkg	4	Number of packets sent for the session.
OutTotalByte	4	Number of bytes sent for the session.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
ContextID	4	ID of the context for the session.

Field	Length (Bytes)	Description
AppID	4	Application protocol ID.
UserName	56	Username.
Reserved1	4	Reserved field.
Reserved2	4	Reserved field
Reserved3	4	Reserved field

AFT IPv6 to IPv4 flow log fields

AFT IPv6 to IPv4 flow log has three versions: 1.0, 3.0, and 5.0. Table 8, Table 9, and Table 10 show the fields available in the versions.

Table 8 AFT IPv6 to IPv4 flow log 1.0 fields

Field	Length (Bytes)	Description
Protocol	1	Protocol type carried by IP.
Operator	1	Reasons why a NAT flow log entry was generated: • **0**—Reserved. • **1**—Flow was ended normally. • **2**—Flow was aged out because of aging timer expiration. • **3**—Flow was aged out because of configuration change or manual deletion. • **4**—Flow was aged out because of insufficient resources. • **5**—Reserved. • **6**—Regular connectivity check record for the active flow. • **7**—Flow was deleted because a new flow was created when the flow table was full. • **8**—Flow was created. • **FE**—Other reasons. • **10-FE-1**—Reserved for future use.
IPVersion	1	IP packet version.
Traffic class	1	Traffic Class field of the IPv6 packet.
SourceIP	16	Source IPv6 address before NAT.
SrcNatIP	4	Source IPv4 address after NAT.
DestIP	16	Destination IPv6 address before NAT.
DestNatIP	4	Destination IPv4 address after NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
SrcNatPort	2	Source TCP/UDP port number after NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
DestNatPort	2	Destination TCP/UDP port number after NAT.
StartTime	4	Start time of the flow, in seconds. The value is counted from 1970/1/1 0:0.
EndTime	4	End time of the flow, in seconds. The value is counted from 1970/1/1 0:0. This field is 0 when the **Operator** field is 6.

Field	Length (Bytes)	Description
InTotalPkg	4	Number of packets received for the session.
InTotalByte	4	Number of bytes received for the session.
OutTotalPkg	4	Number of packets sent for the session.
OutTotalByte	4	Number of bytes sent for the session.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
ContextID	4	ID of the context for the session.
Reserved	4	Reserved field.

Table 9 AFT IPv6 to IPv4 flow log 3.0 fields

Field	Length (Bytes)	Description
Protocol	1	Protocol type carried by IP.
Operator	1	Reasons why a NAT flow log entry was generated: • **0**—Reserved. • **1**—Flow was ended normally. • **2**—Flow was aged out because of aging timer expiration. • **3**—Flow was aged out because of configuration change or manual deletion. • **4**—Flow was aged out because of insufficient resources. • **5**—Reserved. • **6**—Regular connectivity check record for the active flow. • **7**—Flow was deleted because a new flow was created when the flow table was full. • **8**—Flow was created. • **FE**—Other reasons. • **10-FE-1**—Reserved for future use.
IPVersion	1	IP packet version.
Traffic class	1	Traffic Class field of the IPv6 packet.
SourceIP	16	Source IPv6 address before NAT.
SrcNatIP	4	Source IPv4 address after NAT.
DestIP	16	Destination IPv6 address before NAT.
DestNatIP	4	Destination IPv4 address after NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
SrcNatPort	2	Source TCP/UDP port number after NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
DestNatPort	2	Destination TCP/UDP port number after NAT.
StartTime	4	Start time of the flow, in seconds. The value is counted from 1970/1/1 0:0.
EndTime	4	End time of the flow, in seconds. The value is counted from 1970/1/1 0:0. This field is 0 when the **Operator** field is 6.
InTotalPkg	4	Number of packets received for the session.

Field	Length (Bytes)	Description
InTotalByte	4	Number of bytes received for the session.
OutTotalPkg	4	Number of packets sent for the session.
OutTotalByte	4	Number of bytes sent for the session.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
ContextID	4	ID of the context for the session.
Reserved	4	Reserved field.

Table 10 AFT IPv6 to IPv4 flow log 5.0 fields

Field	Length (Bytes)	Description
Protocol	1	Protocol type carried by IP.
Operator	1	Reasons why a NAT flow log entry was generated: • **0**—Reserved. • **1**—Flow was ended normally. • **2**—Flow was aged out because of aging timer expiration. • **3**—Flow was aged out because of configuration change or manual deletion. • **4**—Flow was aged out because of insufficient resources. • **5**—Reserved. • **6**—Regular connectivity check record for the active flow. • **7**—Flow was deleted because a new flow was created when the flow table was full. • **8**—Flow was created. • **FE**—Other reasons. • **10-FE-1**—Reserved for future use.
IPVersion	1	IP packet version.
Traffic class	1	Traffic Class field of the IPv6 packet.
SourceIP	16	Source IPv6 address before NAT.
SrcNatIP	4	Source IPv4 address after NAT.
DestIP	16	Destination IPv6 address before NAT.
DestNatIP	4	Destination IPv4 address after NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
SrcNatPort	2	Source TCP/UDP port number after NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
DestNatPort	2	Destination TCP/UDP port number after NAT.
StartTime	4	Start time of the flow, in seconds. The value is counted from 1970/1/1 0:0.
EndTime	4	End time of the flow, in seconds. The value is counted from 1970/1/1 0:0. This field is 0 when the **Operator** field is 6.
InTotalPkg	4	Number of packets received for the session.
InTotalByte	4	Number of bytes received for the session.

Field	Length (Bytes)	Description
OutTotalPkg	4	Number of packets sent for the session.
OutTotalByte	4	Number of bytes sent for the session.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
ContextID	4	ID of the context for the session.
UserName	56	Username.
Reserved1	4	Reserved field.
Reserved2	4	Reserved field.
Reserved3	4	Reserved field.

AFT IPv4 to IPv6 flow log fields

AFT IPv4 to IPv6 flow log has three versions: 1.0, 3.0, and 5.0. Table 11, Table 12, and Table 13 show the fields available in the versions.

Table 11 AFT IPv4 to IPv6 flow log 1.0 fields

Field	Length (Bytes)	Description
Protocol	1	Protocol type carried by IP.
Operator	1	Reasons why a NAT flow log entry was generated: • **0**—Reserved. • **1**—Flow was ended normally. • **2**—Flow was aged out because of aging timer expiration. • **3**—Flow was aged out because of configuration change or manual deletion. • **4**—Flow was aged out because of insufficient resources. • **5**—Reserved. • **6**—Regular connectivity check record for the active flow. • **7**—Flow was deleted because a new flow was created when the flow table was full. • **8**—Flow was created. • **FE**—Other reasons. • **10-FE-1**—Reserved for future use.
IPVersion	1	IP packet version.
TosIPv4	1	ToS field of the IPv4 packet.
SourceIP	4	Source IPv4 address before NAT.
SrcNatIP	16	Source IPv6 address after NAT.
DestIP	4	Destination IPv4 address before NAT.
DestNatIP	16	Destination IPv6 address after NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
SrcNatPort	2	Source TCP/UDP port number after NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
DestNatPort	2	Destination TCP/UDP port number after NAT.

Field	Length (Bytes)	Description
StartTime	4	Start time of the flow, in seconds. The value is counted from 1970/1/1 0:0.
EndTime	4	End time of the flow, in seconds. The value is counted from 1970/1/1 0:0. This field is 0 when the **Operator** field is 6.
InTotalPkg	4	Number of packets received for the session.
InTotalByte	4	Number of bytes received for the session.
OutTotalPkg	4	Number of packets sent for the session.
OutTotalByte	4	Number of bytes sent for the session.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
ContextID	4	ID of the context for the session.
Reserved	4	Reserved field.

Table 12 AFT IPv4 to IPv6 flow log 3.0 fields

Field	Length (Bytes)	Description
Protocol	1	Protocol type carried by IP.
Operator	1	Reasons why a NAT flow log entry was generated: • **0**—Reserved. • **1**—Flow was ended normally. • **2**—Flow was aged out because of aging timer expiration. • **3**—Flow was aged out because of configuration change or manual deletion. • **4**—Flow was aged out because of insufficient resources. • **5**—Reserved. • **6**—Regular connectivity check record for the active flow. • **7**—Flow was deleted because a new flow was created when the flow table was full. • **8**—Flow was created. • **FE**—Other reasons. • **10-FE-1**—Reserved for future use.
IPVersion	1	IP packet version.
TosIPv4	1	ToS field of the IPv4 packet.
SourceIP	4	Source IPv4 address before NAT.
SrcNatIP	16	Source IPv6 address after NAT.
DestIP	4	Destination IPv4 address before NAT.
DestNatIP	16	Destination IPv6 address after NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
SrcNatPort	2	Source TCP/UDP port number after NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
DestNatPort	2	Destination TCP/UDP port number after NAT.
StartTime	4	Start time of the flow, in seconds. The value is counted from 1970/1/1

Field	Length (Bytes)	Description
		0:0.
EndTime	4	End time of the flow, in seconds. The value is counted from 1970/1/1 0:0. This field is 0 when the **Operator** field is 6.
InTotalPkg	4	Number of packets received for the session.
InTotalByte	4	Number of bytes received for the session.
OutTotalPkg	4	Number of packets sent for the session.
OutTotalByte	4	Number of bytes sent for the session.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
ContextID	4	ID of the context for the session.
Reserved	4	Reserved field.

Table 13 AFT IPv4 to IPv6 flow log 5.0 fields

Field	Length (Bytes)	Description
Protocol	1	Protocol type carried by IP.
Operator	1	Reasons why a NAT flow log entry was generated: • **0**—Reserved. • **1**—Flow was ended normally. • **2**—Flow was aged out because of aging timer expiration. • **3**—Flow was aged out because of configuration change or manual deletion. • **4**—Flow was aged out because of insufficient resources. • **5**—Reserved. • **6**—Regular connectivity check record for the active flow. • **7**—Flow was deleted because a new flow was created when the flow table was full. • **8**—Flow was created. • **FE**—Other reasons. • **10-FE-1**—Reserved for future use.
IPVersion	1	IP packet version.
TosIPv4	1	ToS field of the IPv4 packet.
SourceIP	4	Source IPv4 address before NAT.
SrcNatIP	16	Source IPv6 address after NAT.
DestIP	4	Destination IPv4 address before NAT.
DestNatIP	16	Destination IPv6 address after NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
SrcNatPort	2	Source TCP/UDP port number after NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
DestNatPort	2	Destination TCP/UDP port number after NAT.
StartTime	4	Start time of the flow, in seconds. The value is counted from 1970/1/1 0:0.

Field	Length (Bytes)	Description
EndTime	4	End time of the flow, in seconds. The value is counted from 1970/1/1 0:0. This field is 0 when the **Operator** field is 6.
InTotalPkg	4	Number of packets received for the session.
InTotalByte	4	Number of bytes received for the session.
OutTotalPkg	4	Number of packets sent for the session.
OutTotalByte	4	Number of bytes sent for the session.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
ContextID	4	ID of the context for the session.
UserName	56	Username.
Reserved1	4	Reserved field.
Reserved2	4	Reserved field.
Reserved3	4	Reserved field.

LB NAT64 flow log fields

LB NAT64 flow log has three versions: 1.0, 3.0, and 5.0. Table 14, Table 15, and Table 16 show the fields available in the versions.

Table 14 LB NAT64 flow log 1.0 fields

Field	Length (Bytes)	Description
LBVersion	1	Version number for the LB log.
Protocol	1	Protocol type carried by IP.
IPVersion	1	IP packet version.
Reserved1	1	Reserved field.
SrcIP	16	Source IPv6 address before NAT.
SrcNatIP	4	Source IPv4 address after NAT.
DestIP	16	Destination IPv6 address before NAT.
DestNatIP	4	Destination IPv4 address after NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
SrcNatPort	2	Source TCP/UDP port number after NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
DestNatPort	2	Destination TCP/UDP port number after NAT.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
ContextID	4	ID of the context for the session.
Reserved2	4	Reserved field.

Table 15 LB NAT64 flow log 3.0 fields

Field	Length (Bytes)	Description
LBVersion	1	Version number for the LB log.
Protocol	1	Protocol type carried by IP.
IPVersion	1	IP packet version.
Reserved1	1	Reserved field.
SrcIP	16	Source IPv6 address before NAT.
SrcNatIP	4	Source IPv4 address after NAT.
DestIP	16	Destination IPv6 address before NAT.
DestNatIP	4	Destination IPv4 address after NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
SrcNatPort	2	Source TCP/UDP port number after NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
DestNatPort	2	Destination TCP/UDP port number after NAT.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
ContextID	4	ID of the context for the session.
Reserved2	4	Reserved field.

Table 16 LB NAT64 flow log 5.0 fields

Field	Length (Bytes)	Description
LBVersion	1	Version number for the LB log.
Protocol	1	Protocol type carried by IP.
IPVersion	1	IP packet version.
Reserved1	1	Reserved field.
SrcIP	16	Source IPv6 address before NAT.
SrcNatIP	4	Source IPv4 address after NAT.
DestIP	16	Destination IPv6 address before NAT.
DestNatIP	4	Destination IPv4 address after NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
SrcNatPort	2	Source TCP/UDP port number after NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
DestNatPort	2	Destination TCP/UDP port number after NAT.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
ContextID	4	ID of the context for the session.
UserName	56	Username.
Reserved1	4	Reserved field.

Field	Length (Bytes)	Description
Reserved2	4	Reserved field.
Reserved3	4	Reserved field.

LB NAT46 flow log fields

LB NAT46 flow log has three versions: 1.0, 3.0, and 5.0. Table 17, Table 18, and Table 19 show the fields available in the versions.

Table 17 LB NAT46 flow log 1.0 fields

Field	Length (Bytes)	Description
LBVersion	1	Version number for the LB log.
Protocol	1	Protocol type carried by IP.
IPVersion	1	IP packet version.
Reserved1	1	Reserved field.
SrcIP	4	Source IPv4 address before NAT.
SrcNatIP	16	Source IPv6 address after NAT.
DestIP	4	Destination IPv4 address before NAT.
DestNatIP	16	Destination IPv6 address after NAT.
SrcPort	2	Source TCP/UDP port number before NAT.
SrcNatPort	2	Source TCP/UDP port number after NAT.
DestPort	2	Destination TCP/UDP port number before NAT.
DestNatPort	2	Destination TCP/UDP port number after NAT.
InVPNID	2	ID of the source VPN instance.
OutVPNID	2	ID of the destination VPN instance.
ContextID	4	ID of the context for the session.
Reserved2	4	Reserved field.

Table 18 LB NAT46 flow log 3.0 fields

Field	Length (Bytes)	Description
LBVersion	1	Version number for the LB log.
Protocol	1	Protocol type carried by IP.
IPVersion	1	IP packet version.
Reserved1	1	Reserved field.
SrcIP	4	Source IPv4 address before NAT.
SrcNatIP	16	Source IPv6 address after NAT.
DestIP	4	Destination IPv4 address before NAT.
DestNatIP	16	Destination IPv6 address after NAT.

Configuring fast log output

About fast log output

The fast log output feature enables fast output of logs to log hosts.

Typically, logs generated by a service module are first sent to the information center, which then outputs the logs to the specified destination (such as to log hosts). When fast log output is configured, logs of service modules are sent directly to log hosts instead of to the information center. Compared to outputting logs to the information center, fast log output saves system resources. For more information about the information center, see "Configuring the information center."

Logs are classified into eight severity levels from 0 through 7 in descending order.

Table 1 Log levels

Severity value	Level	Description
0	Emergency	The system is unusable. For example, the system authorization has expired.
1	Alert	Action must be taken immediately. For example, traffic on an interface exceeds the upper limit.
2	Critical	Critical condition. For example, the device temperature exceeds the upper limit, the power module fails, or the fan tray fails.
3	Error	Error condition. For example, the link state changes.
4	Warning	Warning condition. For example, an interface is disconnected, or the memory resources are used up.
5	Notification	Normal but significant condition. For example, a terminal logs in to the device, or the device reboots.
6	Informational	Informational message. For example, a command or a ping operation is executed.
7	Debugging	Debug message.

Log header formats

The log header formats of fast output logs are as follows:

Table 2 Log header formats

Log header types	Format

Standard format	`<PRI> Timestamp AppName %%10 SN:sn VsysId:id`
	Example:
	`<134> Apr 28 15:35:32 2020 NSFOCUS %%10 SN:10056879 VsysId:1`

Customized format	**URL filtering UNICOM format**:
	`PRI Vision HostName Timestamp AppName MsgID HostName Len`
	Example:
	`142 1 100.0.0.1 2020 Apr 28 15:35:43 NSFOCUS NAT444:SessionU 57`
	NAT CMCC format:
	`<PRI> Vision HostName Timestamp AppName ProcID MsgID`
	Example:
	`<142> 1 100.0.0.1 2020 Apr 28 15:35:32 NSFOCUS - NAT444:SessionA`
	NAT UNICOM format:
	`<PRI> Vision HostName Timestamp AppName ProcID MsgID`
	Example:
	`<142> 1 100.0.0.1 2020 Apr 28 15:35:43 NSFOCUS - NAT444:SessionA`
	NAT TELECOM format:
	`<PRI> Vision Timestamp HostName AppName ProcID MsgID`
	Example:
	`<134> 1 2020 Apr 28 15:35:38 100.0.0.1 NSFOCUS - NAT444:sessionbasedA`

Log field description

Table 3 Log field description

Field	Description
PRI	Log type code. • Standard format and NAT UNICOM format: 134. • URL filtering UNICOM format, NAT CMCC format, and NAT TELECOM format: 142.
Timestamp	Records the time when the log was generated. The timestamp is in the format of YYYY Mon DD hh:mm:ss.
AppName	Name of the device that generated the log.
%%10	Vendor of the device that generated the log.
SN	Serial number of the device that generated the log. To view the device serial number, see the DEVICE_SERIAL_NUMBE field in the output of the **display device manuinfo** command. This field is available only when the device is configured to carry the serial number in fast output logs by using the **customlog with-sn** command.
VsysId	Virtual system that generated the log.
HostName	Source IPv4 address of the device that generated the log.
MsgID	Log type.
Len	Total length of the log header, in bytes.
ProcID	-

Restrictions and guidelines: fast log output configuration

The device supports outputting logs from service modules to log hosts by using the following methods in descending order of priority:

1. Fast log output.
2. Flow log. For more information about flow log and the service modules supported by flow log, see "Configuring flow log."
3. Information center.

If you configure multiple log output methods for a service module, the service module outputs its logs in the method that has the highest priority.

To output NAT logs to a log host, you must specify the log format required by the log host in the **customlog format** and **customlog host** commands.

Configuring fast output of logs to log hosts

1. Enter system view.

   system-view

2. Enable fast log output.

   customlog format { **aft** | **aft-cmcc** | **aft-telecom** | **aft-unicom** | **attack-defense** | **cntm** | **dns** | **dpi** [**anti-virus** | **audit** | **data-filter** | **file-filter** | **ips** [**sgcc** { **policy-hit** | **signature-update** }] | **netshare** | **reputation** | **sandbox** | **terminal** | **traffic-policy** | **url-filter** [**unicom**]] | **keepalive sgcc** | **lb** [**dns-proxy** | **gslb** | **inbound** | **outbound**] | **nat** { **cmcc** | **telecom** | **unicom** } | **packet-filter** [**sgcc**] | **scd** | **security-policy sgcc** | **session** | **trusted-access** { **csap** | **iam** [**authorization** | **notification**] } }

   By default, fast log output is disabled.

3. Configure fast log output parameters.

   customlog host [**vpn-instance** *vpn-instance-name*] { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] **export** { **aft** | **attack-defense** | **cmcc-sessionlog** | **cmcc-userlog** | **dns** | **dpi** [**anti-virus** | **audit** | **ips** | **netshare** | **reputation** | **sandbox** | **traffic-policy** | **url-filter**] * | **keepalive** | **lb** [**dns-proxy** | **gslb** | **inbound** | **outbound**] * | **packet-filter** | **scd** | **security-policy** | **session** | **telecom-sessionlog** | **telecom-userlog** | **unicom-sessionlog** | **unicom-userlog** } *

   By default, no fast log output parameters are configured.

   The value for the *port-number* argument must be the same as the port number configured on the log host. Otherwise, the log host cannot receive logs.

4. (Optional.) Specify the source IP address for fast log output.

   customlog host source *interface-type interface-number*

   By default, the source IP address of fast output logs is the primary IP address of the outgoing interface.

   If this command is configured, the primary IP address of the specified interface is used as the source IP address of fast output logs regardless of the outgoing interface.

   Configure this command when you need to filter logs by source IP address on the log host.

5. (Optional.) Configure the timestamp of fast output logs to show the system time.

   customlog timestamp localtime

   By default, the timestamp of fast output logs shows the Greenwich Mean Time (GMT).

6. (Optional.) Configure the device to carry its serial number in fast output logs.

   customlog with-sn

   By default, the device does not carry its serial number in fast output logs.

   Support for this command depends on the device model. For more information, see the command reference.

Configuring fast log output to use the UTF-8 encoding

About this task

The fast log output module and the log host must use the same character set encoding. If they use different encodings, the log host cannot correctly display Chinese characters in the log messages received from the fast log output module. By default, fast log output uses the GB18030 encoding. You can perform this task to configure fast log output to use the UTF-8 encoding.

Procedure

1. Enter system view.

   system-view

2. Configure fast log output to use UTF-8 encoding.

   customlog character-encoding utf-8

   By default, fast log output uses the GB18030 encoding.

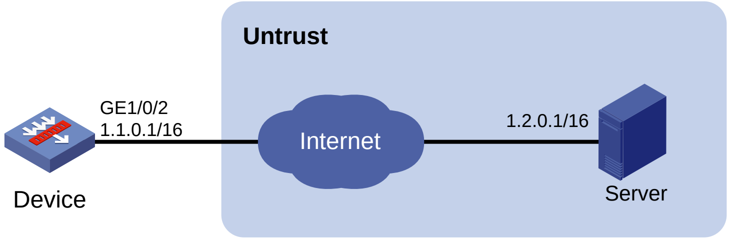
Fast log output configuration examples

Example: Configuring fast log output to a log host

Network configuration

As shown in Figure 1, configure fast log output on the device to send session logs to the log server.

Figure 1 Network diagram



Procedure

1. Assign IP addresses to interface GigabitEthernet 1/0/2.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] ip address 1.1.0.1 255.255.0.0
```

```
[Device-GigabitEthernet1/0/2] quit
```

2. Configure settings for routing.

   This example configures a static route, and the next hop in the router is 1.1.0.2.

   ```
   [Device] ip route-static 1.2.0.0 16 1.1.0.2
   ```

3. Add interface GigabitEthernet 1/0/2 to security zone **untrust**.

   ```
   [Device] security-zone name untrust
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Untrust] quit
   ```

4. Configure a security policy:

   # Configure a rule named **loglocalout** to allow the device to send fast log output messages to the server.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name loglocalout
   [Device-security-policy-ip-1-loglocalout] source-zone local
   [Device-security-policy-ip-1-loglocalout] destination-zone untrust
   [Device-security-policy-ip-1-loglocalout] source-ip-host 1.1.0.1
   [Device-security-policy-ip-1-loglocalout] destination-ip-host 1.2.0.1
   [Device-security-policy-ip-1-loglocalout] action pass
   [Device-security-policy-ip-1-loglocalout] quit
   [Device-security-policy-ip] quit
   ```

5. Configure fast log output. Enable fast log output, configure log output to the log server, and enable logging for session creation and deletion. Enable IPv4 session logging in the inbound direction of the interface connected to the internal network.

   ```
   [Device] customlog format session
   [Device] customlog host 1.2.0.1 port 1000 export session
   [Device] session log flow-begin
   [Device] session log flow-end
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] session log enable ipv4 inbound
   ```

Verifying the configuration

On the server, verify that logs are received from the device successfully.

Contents

Configuring session-based NetStream

About session-based NetStream

Session-based NetStream provides statistics for session-based services and exports the statistics in NetStream v9 format to NetStream servers.

For information about sessions, see session management in *Security Configuration Guide*.

Session-based NetStream aggregation modes

Session-based NetStream aggregates session statistics according to the aggregation criteria of an aggregation mode and exports the statistics to NetStream servers.

Table 1 lists the available aggregation modes. In each mode, the system merges statistics for multiple sessions if each aggregation criterion is of the same value.

Table 1 Session-based NetStream aggregation modes

Aggregation mode	Aggregation criteria
App aggregation	Application layer protocol ID.
App-profile aggregation	• Application layer protocol ID. • Traffic rule ID.
App-user aggregation	• Application layer protocol ID. • User IP address.

Session-based NetStream data export

Session-based NetStream uses an aging mechanism to export flow entry statistics to NetStream servers.

When the aging timer for a session-based NetStream entry expires, statistics about the entry is cleared from the cache and exported to the NetStream servers.

When the session-based NetStream cache is full, the device stops generating new flow entries. Statistics collection for existing flow entries is not affected.

A session-based NetStream entry is also exported in the following situations:

- The session itself ages out.
- The session is manually deleted by the administrator.

Restrictions and guidelines: Session-based NetStream configuration

For session-based NetStream to work, DPI must be enabled on the device. For more information about DPI, see *DPI Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable session-based NetStream.

   session-based netstream enable

   By default, session-based NetStream is disabled.

3. Enable session-based NetStream aggregation modes.

   session-based netstream aggregation { **app** | **app-profile** | **app-user** } *

   By default, all session-based NetStream aggregation modes are disabled.

4. Specify a destination host for session-based NetStream data export.

   session-based netstream export host *ip-address udp-port* [**vpn-instance** *vpn-instance-name*]

   By default, no destination host is specified for session-based NetStream data export.

5. (Optional.) Specify a source IP address for session-based NetStream packets.

   session-based netstream export source ip *ip-address*

   By default, the source IP address of session-based NetStream packets is the primary IP address of the output interface.

6. (Optional.) Set the aging timer for cached session-based NetStream entries.

   session-based netstream timeout *minutes*

   By default, a session-based NetStream entry is can be cached for 5 minutes before being aged out.

Display and maintenance commands session-based NetStream

Execute **display** commands in any view.

Task	Command
Display session-based NetStream statistics in the cache.	**display session-based netstream aggregation-cache** { **app** | **app-profile** | **app-user** } *

Contents

Configuring cloud connections

About cloud connections

A cloud connection is a management tunnel established between a local device and the cloud server. It enables you to manage the local device from the cloud server without accessing the network where the device resides.

Multiple subconnections

After a local device establishes a connection with the cloud server, service modules on the local device can establish multiple subconnections with the microservices on the cloud server. These subconnections are independent from each other and provide separate communication channels for different services. This mechanism avoids interference among different services.

Cloud connection establishment

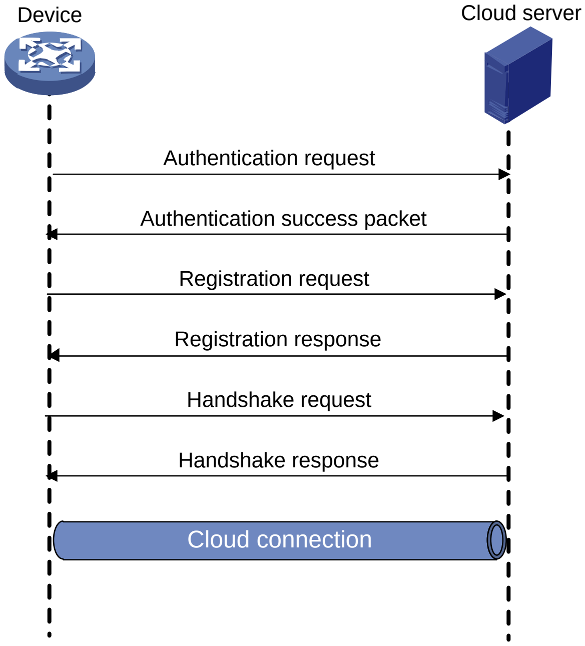
As shown in Figure 1, the cloud connection between the device and the cloud server is established as follows:

1. The device sends an authentication request to the cloud server.
2. The cloud server sends an authentication success packet to the device.

   The device passes the authentication only if the serial number of the device has been added to the cloud server. If the authentication fails, the cloud server sends an authentication failure packet to the device.
3. The device sends a registration request to the cloud server.
4. The cloud server sends a registration response to the device.

   The registration response contains the uniform resource locator (URL) used to establish a cloud connection.
5. The device uses the URL to send a handshake request (changing the protocol from HTTP to WebSocket) to the cloud server.
6. The cloud server sends a handshake response to the device to finish establishing the cloud connection.
7. After the cloud connection is established, the device automatically obtains the subconnection URLs and establishes subconnections with the cloud server based on the service needs.

Figure 1 Establishing a cloud connection



Restrictions: Hardware compatibility with cloud connections

Model	Cloud connection compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Configuring the cloud server

For a successful cloud connection establishment, add the serial number of the device to be managed to the cloud server.

Configuring the local device

About this task

You can specify a cloud server by its domain name and log in to the server through the domain name on a remote PC to manage the local device.

If the local device does not receive a response from the cloud server within three keepalive intervals, the device sends a registration request to re-establish the cloud connection.

To prevent NAT entry aging, the local device sends ping packets to the cloud server periodically.

Restrictions and guidelines

You can specify one primary server by using the **cloud-management server domain** command and a maximum of eight backup servers by repeating the **cloud-management backup-server domain** command.

When establishing a cloud connection, the device connects to one of the primary and backup servers according to the sequence in which they are specified. The first specified server has the highest priority. When the connected server fails, the device switches to another server and does not switch back to the original server even if the original server recovers. To view the connected server, execute the **display cloud-management state** command.

Reduce the ping interval value if the network condition is poor or the NAT entry aging time is short. When you use the ADWAN server for cloud connections, you must set the password for establishing cloud connections to the ADWAN server.

Prerequisites

Before configuring this feature, make sure a DNS server is configured to translate domain names.

Procedure

1. Enter system view.

   system-view

2. Specify the primary cloud server by its domain name.

   cloud-management server domain *domain-name* [**vpn-instance** *vpn-instance-name*] [**source-ip** *ipv4-address*]

3. (Optional.) Specify a backup cloud server by its domain name.

   cloud-management backup-server domain *domain-name* [**vpn-instance** *vpn-instance-name*] [**source-ip** *ipv4-address*]

   By default, no backup cloud server is specified.

4. (Optional.) Set the keepalive interval.

   cloud-management keepalive *interval*

   By default, the keepalive interval is 180 seconds.

5. (Optional.) Set the ping interval.

   cloud-management ping *interval*

   By default, the ping interval is 60 seconds.

6. (Optional.) Specify the TCP port number used to establish cloud connections.

   cloud-management server port *port-number*

   By default, TCP port number 19443 is used to establish cloud connections.

7. (Optional.) Set the password for establishing cloud connections to the ADWAN server.

   cloud-management server password { **cipher** | **simple** } *string*

   By default, no password is set for establishing cloud connections to the ADWAN server.

Unbinding the device from the cloud server

About this task

A device can be registered on the cloud server by only one user.

To register a device that has been registered by another user, you need to take the following steps:

1. Obtain a verification code for device unbinding from the cloud server.
2. Execute the command on the device for sending the verification code to the cloud server.
3. Register the device on the cloud server.

Procedure

1. Enter system view.
   system-view
2. Send the verification code for device unbinding to the cloud server.
   cloud-management unbinding-code *code*

Display and maintenance commands for cloud connections

Execute **display** commands in any view.

Task	Command
Display cloud connection state information.	**display cloud-management state**

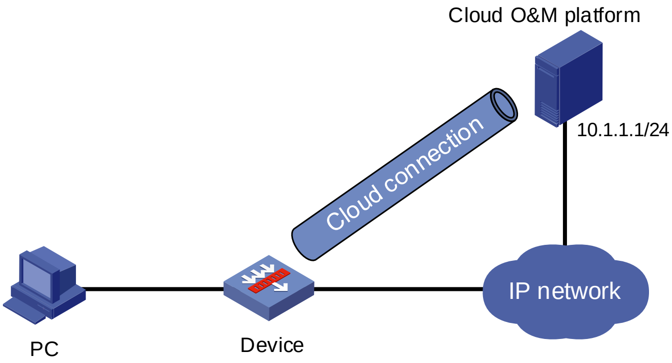
Cloud connection configuration examples

Example: Configuring a cloud connection

Network configuration

As shown in Figure 2, configure the device to establish a cloud connection with the cloud O&M platform.

Figure 2 Network diagram



Procedure

1. Configure IP addresses for interfaces, routes, security domains, and security policies. (Details not shown.)
2. Log in to the cloud O&M platform to add the serial number of the device to the platform. (Details not shown.)
3. Configure the domain name of the cloud O&M platform as **ops.seccloud.**nsfocus**.com** on the device.

```
<Device> system-view
[Device] cloud-management server domain ops.seccloud.nsfocus.com
```

NOTE:

Make sure a DNS server is configured to translate the domain name of the cloud O&M platform.

Verifying the configuration

# Verify that the device and the cloud O&M platform have established a cloud connection.

```
[Device] display cloud-management state
Cloud connection state                       : Established
Device state                                 : Request_success
Cloud server address                         : 10.1.1.1
Cloud server domain name                     : ops.seccloud.nsfocus.com
Cloud connection mode                        : Https

Configuring port mirroring

About port mirroring

Port mirroring copies the packets passing through a port to a port that connects to a data monitoring device for packet analysis.

Terminology

The following terms are used in port mirroring configuration.

Mirroring source

The mirroring sources can be one or more monitored ports (called source ports).

Packets passing through mirroring sources are copied to a port connecting to a data monitoring device for packet analysis. The copies are called mirrored packets.

Source device

The device where the mirroring sources reside is called a source device.

Mirroring destination

The mirroring destination connects to a data monitoring device and is the destination port (also known as the monitor port) of mirrored packets. Mirrored packets are sent out of the monitor port to the data monitoring device.

A monitor port might receive multiple copies of a packet when it monitors multiple mirroring sources. For example, two copies of a packet are received on Port A when the following conditions exist:

- Port A is monitoring bidirectional traffic of Port B and Port C on the same device.
- The packet travels from Port B to Port C.

Destination device

The device where the monitor port resides is called the destination device.

Mirroring direction

The mirroring direction specifies the direction of the traffic that is copied on a mirroring source.

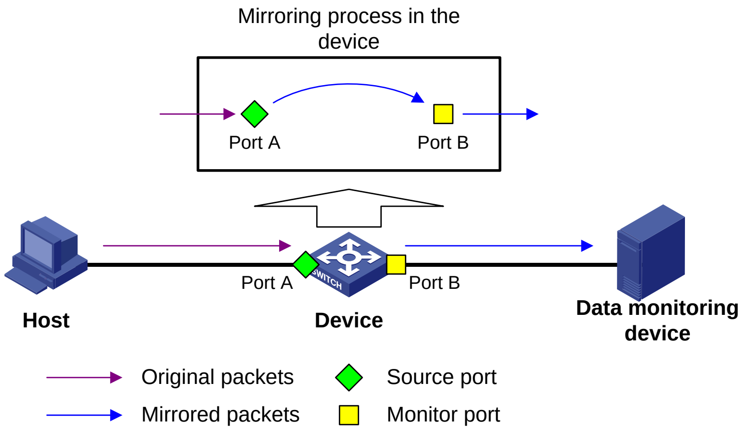
- **Inbound**—Copies packets received.
- **Outbound**—Copies packets sent.
- **Bidirectional**—Copies packets received and sent.

Mirroring group

Port mirroring is implemented through local mirroring groups. The mirroring sources and destination reside on the same device, which is directly connected to a data monitoring device. Packets received on the mirroring sources are sent through the mirroring destination to the data monitoring device.

Local port mirroring

Figure 1 Local port mirroring implementation



As shown in Figure 1, the source port (Port A) and the monitor port (Port B) reside on the same device. Packets received on Port A are copied to Port B. Port B then forwards the packets to the data monitoring device for analysis.

Restrictions: Hardware compatibility with port mirroring

Models	Feature compatibility
NFNX5-HD6480	Yes only on GE 1/0/0 through GE 1/0/13, XGE 1/0/18, XGE 1/0/19, GE 1/0/22 through GE 1/0/29, and interfaces on cards in four interface card slots
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280	Yes only on GE 1/0/0 through GE 1/0/23, XGE 1/0/24, and XGE 1/0/25
NFNX3-HDB1780, NFNX3-HDB3080	Yes only on GE 1/0/0 through GE1/0/23, GE 1/0/25, XGE 1/0/26, and XGE 1/0/27
NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	No

Restrictions and guidelines: Port mirroring configuration

You cannot assign a fixed interface and an interface on an interface module to the same mirroring group.

Port mirroring across member devices in an IRF fabric is not supported, which means that the mirroring sources and destination must reside on the same member device.

Port mirroring is not supported on virtual interfaces.

If you configure an interface shared by multiple contexts as a source port, traffic of the source port will be sent to the monitor port without distinction of contexts.

When configuring a mirroring group, first configure the monitor port and then configure the source ports.

When one port mirroring group is configured to monitor the outbound or bidirectional traffic of source ports, the other mirroring group must be configured to monitor the incoming traffic of source ports.

A mirroring group can be configured with one monitor port and multiple source ports. A monitor port or source port of a mirroring group cannot be configured as the source port or monitor port of another mirroring group.

Configuring local port mirroring

Restrictions and guidelines for local port mirroring configuration

A local mirroring group takes effect only after it is configured with the monitor port and mirroring sources.

Local port mirroring tasks at a glance

To configure local port mirroring, perform the following tasks:

1. Creating a local mirroring group
2. Configuring mirroring sources
3. Configuring the monitor port

Creating a local mirroring group

1. Enter system view.
   `system-view`
2. Create a local mirroring group.
   `mirroring-group` *`group-id`* **`local`**

Configuring mirroring sources

Restrictions and guidelines for mirroring source configuration

When you configure source ports for a local mirroring group, follow these restrictions and guidelines:

- A mirroring group can contain multiple source ports.
- A port can act as a source port for multiple mirroring groups.
- A source port cannot be configured as a monitor port.

Configuring source ports

- Configure source ports in system view.
  a. Enter system view.
     `system-view`
  b. Configure source ports for a local mirroring group.

mirroring-group *group-id* **mirroring-port** *interface-list* { **both** | **inbound** | **outbound** }

By default, no source port is configured for a local mirroring group.

- Configure source ports in interface view.
  a. Enter system view.
  system-view
  b. Enter interface view.
  interface *interface-type interface-number*
  c. Configure the port as a source port for a local mirroring group.
  mirroring-group *group-id* **mirroring-port** { **both** | **inbound** | **outbound** }
  By default, a port does not act as a source port for any local mirroring groups.

Configuring the monitor port

Restrictions and guidelines

Do not enable the spanning tree feature on the monitor port.

Only one monitor port can be specified for a local mirroring group.

Use a monitor port only for port mirroring, so the data monitoring device receives only the mirrored traffic.

Procedure

- Configure the monitor port in system view.
  a. Enter system view.
  system-view
  b. Configure the monitor port for a local mirroring group.
  mirroring-group *group-id* **monitor-port** *interface-type interface-number*
  By default, no monitor port is configured for a local mirroring group.
- Configure the monitor port in interface view.
  a. Enter system view.
  system-view
  b. Enter interface view.
  interface *interface-type interface-number*
  c. Configure the port as the monitor port for a mirroring group.
  mirroring-group *group-id* **monitor-port**
  By default, a port does not act as the monitor port for any local mirroring groups.

Display and maintenance commands for port mirroring

Execute **display** commands in any view.

Task	Command
Display mirroring group information.	**display mirroring-group** { *group-id* | **all** | **local** }

Contents

Configuring packet capture

About packet capture

The packet capture feature captures incoming and outgoing packets, generates packet capture records, and saves the records to a .cap file. The file can reside on the device or a remote file server. You can use a packet analyzer such as Wireshark to view the file for traffic analysis.

The minimum packet capture unit is a packet. The packet capture process is as follows:

1. The device captures a specific number of bytes from a packet and generates a packet capture record, ignoring the remaining part of the packet (if any).
2. The device saves the packet capture record in memory.
3. When the maximum number of packet capture records for a file is reached, the device saves the records to a file and clears the records in memory.

Restrictions and guidelines: Packet capture configuration

Start packet capture only when necessary. Packet capture affects device performance.

Only one packet capture process can run on the device.

You can configure packet capture parameters only when packet capture is not started.

If packet capture saves .cap files on the device, back up the .cap files on the device as required after you finish packet capture. Starting packet capture again deletes the existing .cap files.

Packet capture is supported only for the default context and non-default contexts that use their own respective interfaces. It is not supported on shared interfaces of a non-default context. For more information about contexts, see context configuration in *Virtual Technologies Configuration Guide*.

Packet capture tasks at a glance

To configure packet capture, perform the following tasks:

1. Configuring packet capture settings
2. Starting packet capture
3. Stopping packet capture

Configuring packet capture settings

1. Enter system view.

   system-view

2. Set the maximum packet size for a packet capture record.

   packet-capture max-bytes *bytes*

   By default, the maximum packet size is 1600 bytes for a packet capture record.

   To capture all bytes of packets, make sure the maximum packet size for a packet capture record is equal to or greater than the interface MTU.

3. Set the maximum number of packet capture records for a file.

packet-capture max-file-packets *number*

By default, the maximum number of packet capture records is 100 for a file.

4. Specify the storage directory for the .cap files.

   packet-capture storage { **local** [**limit** *limit-space*] | **remote** *serverpath* [**vpn-instance** *vpn-instance-name*] [**user** *username* [**password** { **cipher** | **simple** } *string*]] }

   The default storage directory is the **pcap** directory of the default file system on the master.

Starting packet capture

1. Enter system view.

   system-view

2. Start packet capture.

   packet-capture start [**acl** { *acl-number* | **ipv6** *acl-number* } | **interface** *interface-type interface-number*] *

   By default, the system does not capture packets.

Stopping packet capture

About this task

Saving packet capture records to a file takes time. The **packet-capture stop** command without the **immediately** keyword saves all packet capture records to a file before stopping packet capture. If you do not want to use the packet capture records in memory, execute the **packet-capture stop immediately** command.

Procedure

1. Enter system view.

   system-view

2. Stop packet capture.

   packet-capture stop [**immediately**]

Display and maintenance commands for packet capture

Execute **display** commands in any view.

Task	Command
Display packet capture settings and status information.	**display packet-capture status**

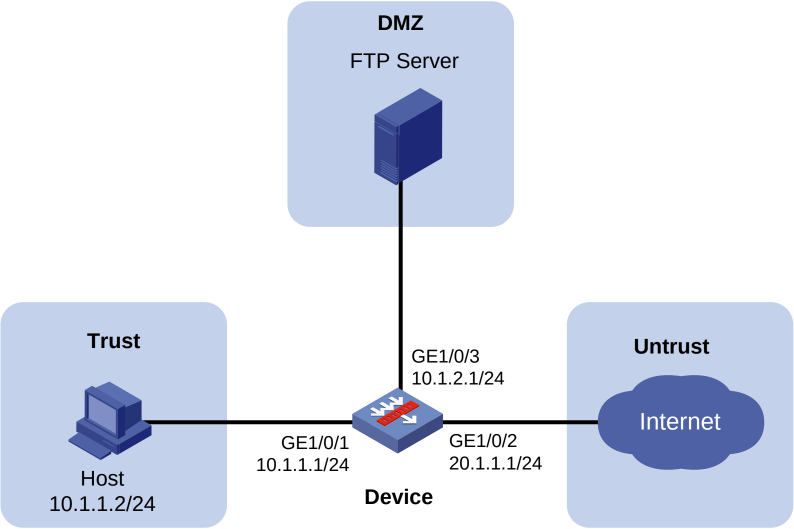
Packet capture configuration examples

Example: Configuring packet capture

Network configuration

As shown in Figure 1, capture packets on GigabitEthernet 1/0/1. Set the maximum packet size for a packet capture record to 3000 bytes. Use a remote file server to save the .cap files.

Figure 1 Network diagram



Procedure

1. Assign IP addresses to interfaces and configure routes, security zones, zone pairs, and interzone policies. Make sure the network connections are available. (Details not shown.)
2. Configure packet capture:

   # Set the storage directory for the .cap files to **ftp://ftp.remote.com/pcap/**. Specify the username and password for accessing the FTP server.

   ```
   [Device] packet-capture storage remote ftp://ftp.remote.com/pcap/ user zhangsan
   password simple 123456TESTplat&!
   ```

   # Set the maximum packet size for a packet capture record to 3000 bytes.

   ```
   [Device] packet-capture max-bytes 3000
   ```

   # Start packet capture on GigabitEthernet 1/0/1.

   ```
   [Device] packet-capture start interface gigabitethernet 1/0/1
   ```

Verifying the configuration

# Display packet capture settings and status information.

```
[Device] display packet-capture status
Capture status: Started
  Filter: Interface GigabitEthernet1/0/1
```

Configuring NQA

About NQA

Network quality analyzer (NQA) allows you to measure network performance, verify the service levels for IP services and applications, and troubleshoot network problems.

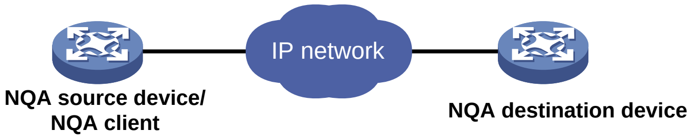
NQA operating mechanism

An NQA operation contains a set of parameters such as the operation type, destination IP address, and port number to define how the operation is performed. Each NQA operation is identified by the combination of the administrator name and the operation tag. You can configure the NQA client to run the operations at scheduled time periods.

As shown in Figure 1, the NQA source device (NQA client) sends data to the NQA destination device by simulating IP services and applications to measure network performance.

All types of NQA operations require the NQA client, but only the TCP, UDP echo, UDP jitter, and voice operations require the NQA server. The NQA operations for services that are already provided by the destination device such as FTP do not need the NQA server. You can configure the NQA server to listen and respond to specific IP addresses and ports to meet various test needs.

Figure 1 Network diagram



After starting an NQA operation, the NQA client periodically performs the operation at the interval specified by using the **`frequency`** command.

You can set the number of probes the NQA client performs in an operation by using the **`probe count`** command.

For the voice and path jitter operations, the NQA client performs only one probe per operation and the **`probe count`** command is not available.

Collaboration with Track

NQA can collaborate with the Track module to notify application modules of state or performance changes so that the application modules can take predefined actions.

The NQA and Track collaboration is available for the following application modules:

- Static routing.
- Policy-based routing.

The following describes how a static route destined for 192.168.0.88 is monitored through collaboration:

1. NQA monitors the reachability to 192.168.0.88.
2. When 192.168.0.88 becomes unreachable, NQA notifies the Track module of the change.
3. The Track module notifies the static routing module of the state change.
4. The static routing module sets the static route to invalid according to a predefined action.

For more information about collaboration, see "Configuring Track."

Threshold monitoring

Threshold monitoring enables the NQA client to take a predefined action when the NQA operation performance metrics violate the specified thresholds.

Table 1 describes the relationships between performance metrics and NQA operation types.

Table 1 Performance metrics and NQA operation types

Performance metric	NQA operation types that can gather the metric
Probe duration	ARP, ICMP echo, DHCP, DNS, FTP, HTTP, SNMP, TCP, UDP echo, and DLSw
Number of probe failures	ARP, ICMP echo, DHCP, DNS, FTP, HTTP, SNMP, TCP, UDP echo, and DLSw
Round-trip time	ICMP jitter, UDP jitter, and voice
Number of discarded packets	ICMP jitter, UDP jitter, and voice
One-way jitter (source-to-destination or destination-to-source)	ICMP jitter, UDP jitter, and voice
One-way delay (source-to-destination or destination-to-source)	ICMP jitter, UDP jitter, and voice
Calculated Planning Impairment Factor (ICPIF) (see "Configuring the voice operation")	Voice
Mean Opinion Scores (MOS) (see "Configuring the voice operation")	Voice

NQA templates

An NQA template is a set of parameters (such as destination address and port number) that defines how an NQA operation is performed. Features such as load balancing and health monitoring can use the NQA template to collect statistics.

You can create multiple NQA templates on the NQA client. Each template must be identified by a unique template name.

Restrictions and guidelines: NQA configuration

To avoid probe failures, follow these restrictions and guidelines when configuring the listening ports on the NQA client and NQA server:

- Do not specify a well-known port.
- Make sure the specified port number is not used by any services on the device.
  - To obtain the IPv4 addresses and the port numbers in use on this device, see the **Local Addr:port** field in the output from the **`display tcp`** and **`display udp`** commands.
  - To obtain the IPv6 addresses and the port numbers in use on this device, see the **LAddr->port** field in the output from the **`display ipv6 tcp`** and **`display ipv6 udp`** commands.

The destination port configured for the operation (with the **`destination port`** command) on the NQA client must be the same as the listening port configured on the server.

NQA tasks at a glance

To configure NQA, perform the following tasks:

1. Configuring the NQA server

   Perform this task on the destination device before you configure the TCP, UDP echo, UDP jitter, and voice operations.

2. Enabling the NQA client
3. Configuring NQA operations or NQA templates

   Choose the following tasks as needed:

   - Configuring NQA operations on the NQA client
   - Configuring NQA templates on the NQA client

   After you configure an NQA operation, you can schedule the NQA client to run the NQA operation.

   An NQA template does not run immediately after it is configured. The template creates and run the NQA operation only when it is required by the feature (such as load balancing) to which the template is applied.

Configuring the NQA server

Restrictions and guidelines

To perform TCP, UDP echo, UDP jitter, and voice operations, you must configure the NQA server on the destination device.

The NQA server listens and responds to requests on the specified IP addresses and ports.

You can configure multiple TCP or UDP listening services on an NQA server, where each corresponds to a specific IP address and port number.

The IP address, port number, and VPN instance for a listening service must be unique on the NQA server and match the configuration on the NQA client.

To perform a UDP jitter operation in high performance mode to the NQA server, enable the high performance mode when configuring the UDP listening service on the NQA server. In this mode, the NQA server cannot process probe packets of the UDP jitter operation if the packet size exceeds 100 bytes and the operation might fail as a result.

Procedure

1. Enter system view.

   system-view

2. Enable the NQA server.

   nqa server enable

   By default, the NQA server is disabled.

3. Configure a TCP listening service.

   nqa server tcp-connect { *ipv4-address* | **ipv6** *ipv6-address* } *port-number* [**vpn-instance** *vpn-instance-name*] [**tos** *tos*]

   This task is required for only TCP and DLSw operations. For the DLSw operation, the port number for the TCP listening service must be 2065.

4. Configure a UDP listening service.

   - Configure a UDP listening service.

     nqa server udp-echo { *ipv4-address* | **ipv6** *ipv6-address* } *port-number* [**vpn-instance** *vpn-instance-name*] [**tos** *tos*]

This task is required for only UDP echo, UDP jitter, and voice operations.

Enabling the NQA client

1. Enter system view.
   `system-view`
2. Enable the NQA client.
   `nqa agent enable`
   By default, the NQA client is enabled.
   The NQA client configuration takes effect after you enable the NQA client.

Configuring NQA operations on the NQA client

NQA operations tasks at a glance

To configure NQA operations, perform the following tasks:

1. Configuring an NQA operation
   - Configuring the ARP operation
   - Configuring the ICMP echo operation
   - Configuring the ICMP jitter operation
   - Configuring the DHCP operation
   - Configuring the DNS operation
   - Configuring the FTP operation
   - Configuring the HTTP operation
   - Configuring the UDP jitter operation
   - Configuring the SNMP operation
   - Configuring the TCP operation
   - Configuring the UDP echo operation
   - Configuring the UDP tracert operation
   - Configuring the voice operation
   - Configuring the DLSw operation
   - Configuring the path jitter operation
2. (Optional.) Configuring optional parameters for the NQA operation
3. (Optional.) Configuring the collaboration feature
4. (Optional.) Configuring threshold monitoring
5. (Optional.) Configuring the NQA statistics collection feature
6. (Optional.) Configuring the saving of NQA history records
7. Scheduling the NQA operation on the NQA client

Configuring the ARP operation

About this task

The ARP operation tests if the ARP service is available on the destination device.

The ARP operation sends an ARP request to the destination device per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the ARP type and enter its view.

   type arp

4. Specify the destination IP address for ARP requests.

   destination ip *ip-address*

   By default, no destination IP address is specified.

5. Specify the source address for ARP requests.

   source ip *ip-address*

   By default, the source IP address of ICMP echo requests is the primary IP address of their output interface.

   The specified source interface must be up.

Configuring the ICMP echo operation

About this task

The ICMP echo operation measures the reachability of a destination device. It has the same function as the **ping** command, but provides more output information. In addition, if multiple paths exist between the source and destination devices, you can specify the next hop for the ICMP echo operation.

The ICMP echo operation sends an ICMP echo request to the destination device per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the ICMP echo type and enter its view.

   type icmp-echo

4. Specify the destination IP address for ICMP echo requests. Choose one option as needed:

   - Specify the destination IP address for ICMP echo requests.

     IPv4:

     destination ip *ip-address*

     IPv6:

     destination ipv6 *ipv6-address*

     By default, no destination IP address is specified.

   - Specify the destination URL for the ICMP echo operation.

     url *url*

     By default, no destination URL is specified for an ICMP echo operation.

     The URL is in the format of *protocol*://*host*:*port, for example, http://host:port.* The *host* parameter is required, and the *protocol* and *port* parameters can be unspecified or be any value.

5. Specify the source address for ICMP echo requests. Choose one option as needed:

- Use the IP address of the specified interface as the source IP address.

  source interface *interface-type interface-number*

  By default, the source IP address of ICMP echo requests is the primary IP address of their output interface.

  The specified source interface must be up.
- Specify the source IPv4 address.

  source ip *ip-address*

  By default, the source IPv4 address of ICMP echo requests is the primary IPv4 address of their output interface.

  The specified source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.
- Specify the source IPv6 address.

  source ipv6 *ipv6-address*

  By default, the source IPv6 address of ICMP echo requests is the IPv6 address of their output interface.

  The specified source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Specify the output interface or the next hop IP address for ICMP echo requests. Choose one option as needed:
   - Specify the output interface.

     out interface *interface-type interface-number*

     By default, the output interface is not specified. The NQA client determines the output interface based on the routing table lookup.
   - Specify the next hop IPv4 address.

     next-hop ip *ip-address*

     By default, no next hop IPv4 address is specified.
   - Specify the next hop IPv6 address.

     next-hop ipv6 *ipv6-address*

     By default, no next hop IPv6 address is specified.
7. (Optional.) Set the payload size for each ICMP echo request.

   data-size *size*

   The default payload size is 100 bytes.
8. (Optional.) Specify the payload fill string for ICMP echo requests.

   data-fill *string*

   The default payload fill string is the hexadecimal string 00010203040506070809.
9. (Optional.) Enable link connectivity probing for a redundant Ethernet (Reth) member interface.

   reth-member probe enable

   By default, the link connectivity probing is disabeld for Reth member interfaces.

   To probe the link connectivity for two Reth member interfaces with their peers respectively, you can configure two ICMP echo operations, each using one Reth member interface as the output interface

Configuring the ICMP jitter operation

About this task

The ICMP jitter operation measures unidirectional and bidirectional jitters. The operation result helps you to determine whether the network can carry jitter-sensitive services such as real-time voice and video services.

The ICMP jitter operation works as follows:

1. The NQA client sends ICMP packets to the destination device.
2. The destination device time stamps each packet it receives, and then sends the packet back to the NQA client.
3. Upon receiving the responses, the NQA client calculates the jitter according to the timestamps.

The ICMP jitter operation sends a number of ICMP packets to the destination device per probe. The number of packets to send is determined by using the **probe packet-number** command.

Restrictions and guidelines

The **display nqa history** command does not display the results or statistics of the ICMP jitter operation. To view the results or statistics of the operation, use the **display nqa result** or **display nqa statistics** command.

Before starting the operation, make sure the network devices are time synchronized by using NTP. For more information about NTP, see "Configuring NTP."

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the ICMP jitter type and enter its view.

   type icmp-jitter

4. Specify the destination IP address for ICMP packets.

   destination ip *ip-address*

   By default, no destination IP address is specified.

5. Set the number of ICMP packets sent per probe.

   probe packet-number *number*

   The default setting is 10.

6. Set the interval for sending ICMP packets.

   probe packet-interval *interval*

   The default setting is 20 milliseconds.

7. Specify how long the NQA client waits for a response from the server before it regards the response times out.

   probe packet-timeout *timeout*

   The default setting is 3000 milliseconds.

8. Specify the source IP address for ICMP packets.

   source ip *ip-address*

   By default, the source IP address of ICMP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no ICMP packets can be sent out.

Configuring the DHCP operation

About this task

The DHCP operation measures whether or not the DHCP server can respond to client requests. DHCP also measures the amount of time it takes the NQA client to obtain an IP address from a DHCP server.

The NQA client simulates the DHCP relay agent to forward DHCP requests for IP address acquisition from the DHCP server. The interface that performs the DHCP operation does not change its IP address. When the DHCP operation completes, the NQA client sends a packet to release the obtained IP address.

The DHCP operation acquires an IP address from the DHCP server per probe.

Procedure

1. Enter system view.

   `system-view`

2. Create an NQA operation and enter NQA operation view.

   `nqa entry` *`admin-name operation-tag`*

3. Specify the DHCP type and enter its view.

   `type dhcp`

4. Specify the IP address of the DHCP server as the destination IP address of DHCP packets.

   `destination ip` *`ip-address`*

   By default, no destination IP address is specified.

5. Specify the output interface for DHCP request packets.

   `out interface` *`interface-type interface-number`*

   By default, the NQA client determines the output interface based on the routing table lookup.

6. Specify the source IP address of DHCP request packets.

   `source ip` *`ip-address`*

   By default, the source IP address of DHCP request packets is the primary IP address of their output interface.

   The specified source IP address must be the IP address of a local interface, and the local interface must be up. Otherwise, no probe packets can be sent out.

Configuring the DNS operation

About this task

The DNS operation simulates domain name resolution, and it measures the time for the NQA client to resolve a domain name into an IP address through a DNS server. The obtained DNS entry is not saved.

The DNS operation resolves a domain name into an IP address per probe.

Procedure

1. Enter system view.

   `system-view`

2. Create an NQA operation and enter NQA operation view.

   `nqa entry` *`admin-name operation-tag`*

3. Specify the DNS type and enter its view.

   `type dns`

4. Specify the IP address of the DNS server as the destination IP address of DNS packets.

   destination ip *ip-address*

   By default, no destination IP address is specified.

5. Specify the domain name to be translated.

   resolve-target *domain-name*

   By default, no domain name is specified.

Configuring the FTP operation

About this task

The FTP operation measures the time for the NQA client to transfer a file to or download a file from an FTP server.

The FTP operation uploads or downloads a file from an FTP server per probe.

Restrictions and guidelines

To upload (**put**) a file to the FTP server, use the **filename** command to specify the name of the file you want to upload. The file must exist on the NQA client.

To download (**get**) a file from the FTP server, include the name of the file you want to download in the **url** command. The file must exist on the FTP server. The NQA client does not save the file obtained from the FTP server.

Use a small file for the FTP operation. A big file might result in transfer failure because of timeout, or might affect other services because of the amount of network bandwidth it occupies.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the FTP type and enter its view.

   type ftp

4. Specify an FTP login username.

   username *username*

   By default, no FTP login username is specified.

5. Specify an FTP login password.

   password { **cipher** | **simple** } *string*

   By default, no FTP login password is specified.

6. Specify the source IP address for FTP request packets.

   source ip *ip-address*

   By default, the source IP address of FTP request packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no FTP requests can be sent out.

7. Set the data transmission mode.

   mode { **active** | **passive** }

   The default mode is **active**.

8. Specify the FTP operation type.

operation { **get** | **put** }

The default FTP operation type is **get**.

9. Specify the destination URL for the FTP operation.

   url *url*

   By default, no destination URL is specified for an FTP operation.

   Enter the URL in one of the following formats:

   - ftp://*host/filename*.
   - ftp://*host:port/filename*.

   The *filename* argument is required only for the **get** operation.

10. Specify the name of the file to be uploaded.

    filename *file-name*

    By default, no file is specified.

    This step is required only for the **put** operation.

    The configuration does not take effect for the **get** operation.

Configuring the HTTP operation

About this task

The HTTP operation measures the time for the NQA client to obtain responses from an HTTP server.

The HTTP operation supports the following operation types:

- **Get**—Retrieves data such as a Web page from the HTTP server.
- **Post**—Sends data to the HTTP server for processing.
- **Raw**—Sends a user-defined HTTP request to the HTTP server. You must manually configure the content of the HTTP request to be sent.

The HTTP operation completes the operation of the specified type per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the HTTP type and enter its view.

   type http

4. Specify the destination URL for the HTTP operation.

   url *url*

   By default, no destination URL is specified for an HTTP operation.

   Enter the URL in one of the following formats:

   - http://host/resource
   - http://host:port/resource

5. Specify an HTTP login username.

   username *username*

   By default, no HTTP login username is specified.

6. Specify an HTTP login password.

   password { **cipher** | **simple** } *string*

By default, no HTTP login password is specified.

7. Specify the HTTP version.

   `version` { **`v1.0`** | **`v1.1`** }

   By default, HTTP 1.0 is used.

8. Specify the HTTP operation type.

   `operation` { **`get`** | **`post`** | **`raw`** }

   The default HTTP operation type is **`get`**.

   If you set the operation type to **`raw`**, the client pads the content configured in raw request view to the HTTP request to send to the HTTP server.

9. Configure the HTTP raw request.

   a. Enter raw request view.

      `raw-request`

      Every time you enter raw request view, the previously configured raw request content is cleared.

   b. Enter or paste the request content.

      By default, no request content is configured.

      For successful HTTP operations, make sure the raw request content is valid and does not contain command aliases configured by using the **`alias`** command. For more information about the **`alias`** command, see CLI commands in *Fundamentals Command Reference*.

   c. Save the input and return to HTTP operation view.

      `quit`

   This step is required only when the operation type is set to **`raw`**.

10. Specify the source IP address for the HTTP packets.

    `source ip` *`ip-address`*

    By default, the source IP address of HTTP packets is the primary IP address of their output interface.

    The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no HTTP packets can be sent out.

Configuring the UDP jitter operation

About this task

The UDP jitter operation measures unidirectional and bidirectional jitters. The operation result helps you determine whether the network can carry jitter-sensitive services such as real-time voice and video services.

The UDP jitter operation works as follows:

1. The NQA client sends UDP packets to the destination port.
2. The destination device time stamps each packet it receives, and then sends the packet back to the NQA client.
3. Upon receiving the responses, the NQA client calculates the jitter according to the timestamps.

The UDP jitter operation sends a number of UDP packets to the destination device per probe. The number of packets to send is determined by using the **`probe packet-number`** command.

The UDP jitter operation requires both the NQA server and the NQA client. Before you perform the UDP jitter operation, configure the UDP listening service on the NQA server. For more information about UDP listening service configuration, see "Configuring the NQA server."

Restrictions and guidelines

To ensure successful UDP jitter operations and avoid affecting existing services, do not perform the operations on well-known ports from 1 to 1023.

The **`display nqa history`** command does not display the results or statistics of the UDP jitter operation. To view the results or statistics of the UDP jitter operation, use the **`display nqa result`** or **`display nqa statistics`** command.

Before starting the operation, make sure the network devices are time synchronized by using NTP. For more information about NTP, see "Configuring NTP."

If you want to enable high performance mode for all UDP jitter operations on the device, use the **`nqa agent udp-jitter high-performance enable`** command in system view.

Procedure

1. Enter system view.

   `system-view`

2. Create an NQA operation and enter NQA operation view.

   `nqa entry` *`admin-name operation-tag`*

3. Specify the UDP jitter type and enter its view.

   `type udp-jitter`

4. Specify the destination IP address and destination port number for UDP packets. Choose one option as needed:

   - Specify the destination IP address and destination port number for UDP jitter requests.

     `destination port` *`port-number`*

     By default, no destination port number is specified.

     The destination port number must be the same as the port number of the UDP listening service on the NQA server.

     IPv4:

     `destination ip` *`ip-address`*

     By default, no destination IPv4 address is specified.

     The destination IPv4 address must be the same as the IP address of the UDP listening service configured on the NQA server.

   IPv6:

   `destination ipv6` *`ipv6-address`*

   By default, no destination IPv6 address is specified.

   The destination IPv6 address must be the same as the IPv6 address of the UDP listening service configured on the NQA server.

   - Specify the destination URL for the UDP jitter operation.

     `url` *`url`*

     By default, no destination URL is specified for a UDP jitter operation.

     The URL is in the format of *protocol://host:port*, for example, http://host:port. The *host* and *port* parameters are required, and the *protocol* parameter can be unspecified or any value.

5. Specify the source IP address for UDP packets.

   IPv4:

   `source ip` *`ip-address`*

   By default, the source IPv4 address of UDP packets is the primary IPv4 address of their output interface.

The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no UDP packets can be sent out.

IPv6:

`source ipv6` *`ipv6-address`*

By default, the source IPv6 address of UDP packets is the IPv6 address of their output interface.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no UDP packets can be sent out.

6. Specify the source port number for UDP packets.

   `source port` *`port-number`*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

7. Specify an output interface for UDP packets.

   `out interface` *`interface-type interface-number`*

   By default, the NQA client determines the output interface based on the routing table lookup.

8. Set the number of UDP packets sent per probe.

   `probe packet-number` *`number`*

   The default setting is 10.

9. Set the interval for sending UDP packets.

   `probe packet-interval` *`interval`*

   The default setting is 20 milliseconds.

10. Specify how long the NQA client waits for a response from the server before it regards the response times out.

    `probe packet-timeout` *`timeout`*

    The default setting is 3000 milliseconds.

11. (Optional.) Set the payload size for each UDP packet.

    `data-size` *`size`*

    The default payload size is 100 bytes.

12. (Optional.) Specify the payload fill string for UDP packets.

    `data-fill` *`string`*

    The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the SNMP operation

About this task

The SNMP operation tests whether the SNMP service is available on an SNMP agent.

The SNMP operation sends one SNMPv1 packet, one SNMPv2c packet, and one SNMPv3 packet to the SNMP agent per probe.

Procedure

1. Enter system view.

   `system-view`

2. Create an NQA operation and enter NQA operation view.

   `nqa entry` *`admin-name operation-tag`*

3. Specify the SNMP type and enter its view.

   type snmp

4. Specify the destination IP address for SNMP packets.

   destination ip *ip-address*

   By default, no destination IP address is specified.

5. Specify the destination port number for SNMP packets.

   destination port *port-number*

   The default destination port number of SNMP packets is 161.

6. Specify the source IP address for SNMP packets.

   source ip *ip-address*

   By default, the source IP address of SNMP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no SNMP packets can be sent out.

7. Specify the source port number for SNMP packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

8. Specify the community name carried in the SNMPv1 and SNMPv2c packets.

   community read { **cipher** | **simple** } *community-name*

   By default, the SNMPv1 and SNMPv2c packets carry community name **public**.

   Make sure the specified community name is the same as the community name configured on the SNMP agent.

Configuring the TCP operation

About this task

The TCP operation measures the time for the NQA client to establish a TCP connection to a port on the NQA server.

The TCP operation requires both the NQA server and the NQA client. Before you perform a TCP operation, configure a TCP listening service on the NQA server. For more information about the TCP listening service configuration, see "Configuring the NQA server."

The TCP operation sets up a TCP connection per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the TCP type and enter its view.

   type tcp

4. Specify the destination address for TCP packets.

   IPv4:

   destination ip *ip-address*

By default, no destination IPv4 address is specified.

The destination IPv4 address must be the same as the IPv4 address of the TCP listening service configured on the NQA server.

IPv6:

destination ipv6 *ipv6-address*

By default, no destination IPv6 address is specified.

The destination IPv6 address must be the same as the IPv6 address of the TCP listening service configured on the NQA server.

5. Specify the destination port number for TCP packets.

   destination port *port-number*

   By default, no destination port number is configured.

   The destination port number must be the same as the port number of the listening service on the NQA server.

6. Specify the source IP address for TCP packets.

   IPv4:

   source ip *ip-address*

   By default, the source IPv4 address of TCP packets is the primary IPv4 address of their output interface.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no TCP packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the source IPv6 address of TCP packets is the IPv6 address of their output interface.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no TCP packets can be sent out.

Configuring the UDP echo operation

About this task

The UDP echo operation measures the round-trip time between the client and a UDP port on the NQA server.

The UDP echo operation requires both the NQA server and the NQA client. Before you perform a UDP echo operation, configure a UDP listening service on the NQA server. For more information about the UDP listening service configuration, see "Configuring the NQA server."

The UDP echo operation sends a UDP packet to the destination device per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the UDP echo type and enter its view.

   type udp-echo

4. Specify the destination address for UDP packets.

   IPv4:

   destination ip *ip-address*

   By default, no destination IPv4 address is specified.

The destination IPv4 address must be the same as the IPv4 address of the UDP listening service configured on the NQA server.

IPv6:

destination ipv6 *ipv6-address*

By default, no destination IPv6 address is specified.

The destination IPv6 address must be the same as the IPv6 address of the UDP listening service configured on the NQA server.

5. Specify the destination port number for UDP packets.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the listening service on the NQA server.

6. Specify the source IP address for UDP packets.

   IPv4:

   source ip *ip-address*

   By default, the source IPv4 address of UDP packets is the primary IPv4 address of their output interface.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no UDP packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the source IPv6 address of UDP packets is the IPv6 address of their output interface.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no UDP packets can be sent out.

7. Specify the source port number for UDP packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

8. (Optional.) Set the payload size for each UDP packet.

   data-size *size*

   The default setting is 100 bytes.

9. (Optional.) Specify the payload fill string for UDP packets.

   data-fill *string*

   The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the UDP tracert operation

About this task

The UDP tracert operation determines the routing path from the source device to the destination device.

The UDP tracert operation sends a UDP packet to a hop along the path per probe.

Restrictions and guidelines

The UDP tracert operation is not supported on IPv6 networks. To determine the routing path that the IPv6 packets traverse from the source to the destination, use the **tracert ipv6** command. For more information about the command, see *Network Management and Monitoring Command Reference.*

Prerequisites

Before you configure the UDP tracert operation, you must perform the following tasks:

- Enable sending ICMP time exceeded messages on the intermediate devices between the source and destination devices. If the intermediate devices are NSFOCUS devices, use the **ip ttl-expires enable** command.
- Enable sending ICMP destination unreachable messages on the destination device. If the destination device is an NSFOCUS device, use the **ip unreachables enable** command.

  For more information about the **ip ttl-expires enable** and **ip unreachables enable** commands, see *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.

   system-view
2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*
3. Specify the UDP tracert operation type and enter its view.

   type udp-tracert
4. Specify the destination IP address for the UDP packets.

   destination ip *ip-address*

   By default, no destination IP address is specified.
5. Specify the destination port number for the UDP packets.

   destination port *port-number*

   By default, the destination port number is 33434.

   The specified port number must be an unused port number on the destination device, so the destination device can reply with an ICMP port unreachable message.
6. Specify an output interface for UDP packets.

   out interface *interface-type interface-number*

   By default, the NQA client determines the output interface based on the routing table lookup.
7. Specify the source IP address for UDP packets.
   - Specify the IP address of the specified interface as the source IP address.

     source interface *interface-type interface-number*

     By default, the source IP address of UDP packets is the primary IP address of their output interface.
   - Specify the source IP address.

     source ip *ip-address*

     The specified source interface must be up. The source IP address must be the IP address of a local interface, and the local interface must be up. Otherwise, no probe packets can be sent out.
8. Specify the source port number for UDP packets.

   source port *port-number*

By default, the NQA client randomly picks an unused port as the source port when the operation starts.

For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

9. Set the maximum number of consecutive probe failures.

   `max-failure` *`times`*

   The default setting is 5.

10. Set the initial TTL value for UDP packets.

    `init-ttl` *`value`*

    The default setting is 1.

11. (Optional.) Set the payload size for each UDP packet.

    `data-size` *`size`*

    The default setting is 100 bytes.

12. (Optional.) Enable the no-fragmentation feature.

    `no-fragment enable`

    By default, the no-fragmentation feature is disabled.

Configuring the voice operation

About this task

The voice operation measures VoIP network performance.

The voice operation works as follows:

1. The NQA client sends voice packets at sending intervals to the destination device (NQA server).

   The voice packets are of one of the following codec types:

   - G.711 A-law.
   - G.711 μ-law.
   - G.729 A-law.

2. The destination device time stamps each voice packet it receives and sends it back to the source.
3. Upon receiving the packet, the source device calculates the jitter and one-way delay based on the timestamp.

The voice operation sends a number of voice packets to the destination device per probe. The number of packets to send per probe is determined by using the **`probe packet-number`** command.

The following parameters that reflect VoIP network performance can be calculated by using the metrics gathered by the voice operation:

- **Calculated Planning Impairment Factor (ICPIF)**—Measures impairment to voice quality on a VoIP network. It is decided by packet loss and delay. A higher value represents a lower service quality.
- **Mean Opinion Scores (MOS)**—A MOS value can be evaluated by using the ICPIF value, in the range of 1 to 5. A higher value represents a higher service quality.

The evaluation of voice quality depends on users' tolerance for voice quality. For users with higher tolerance for voice quality, use the **`advantage-factor`** command to set an advantage factor. When the system calculates the ICPIF value, it subtracts the advantage factor to modify ICPIF and MOS values for voice quality evaluation.

The voice operation requires both the NQA server and the NQA client. Before you perform a voice operation, configure a UDP listening service on the NQA server. For more information about UDP listening service configuration, see "Configuring the NQA server."

Restrictions and guidelines

To ensure successful voice operations and avoid affecting existing services, do not perform the operations on well-known ports from 1 to 1023.

The **`display nqa history`** command does not display the results or statistics of the voice operation. To view the results or statistics of the voice operation, use the **`display nqa result`** or **`display nqa statistics`** command.

Before starting the operation, make sure the network devices are time synchronized by using NTP. For more information about NTP, see "Configuring NTP."

Procedure

1. Enter system view.

   `system-view`

2. Create an NQA operation and enter NQA operation view.

   `nqa entry` *`admin-name operation-tag`*

3. Specify the voice type and enter its view.

   `type voice`

4. Specify the destination IP address for voice packets.

   `destination ip` *`ip-address`*

   By default, no destination IP address is configured.

   The destination IP address must be the same as the IP address of the UDP listening service on the NQA server.

5. Specify the destination port number for voice packets.

   `destination port` *`port-number`*

   By default, no destination port number is configured.

   The destination port number must be the same as the port number of the listening service on the NQA server.

6. Specify the source IP address for voice packets.

   `source ip` *`ip-address`*

   By default, the source IP address of voice packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no voice packets can be sent out.

7. Specify the source port number for voice packets.

   `source port` *`port-number`*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

8. Configure the basic voice operation parameters.

   - Specify the codec type.

     `codec-type` `{` **`g711a`** `|` **`g711u`** `|` **`g729a`** `}`

     By default, the codec type is G.711 A-law.

   - Set the advantage factor for calculating MOS and ICPIF values.

     `advantage-factor` *`factor`*

By default, the advantage factor is 0.

9. Configure the probe parameters for the voice operation.
   - Set the number of voice packets to be sent per probe.

     probe packet-number *number*

     The default setting is 1000.
   - Set the interval for sending voice packets.

     probe packet-interval *interval*

     The default setting is 20 milliseconds.
   - Specify how long the NQA client waits for a response from the server before it regards the response times out.

     probe packet-timeout *timeout*

     The default setting is 5000 milliseconds.
10. Configure the payload parameters.
    a. Set the payload size.

     data-size *size*

     For the G.711A-law and G.711 µ-law codec types, the default payload size is 172 bytes.

     For the G.729 A-law codec type, the default payload size is 32 bytes.

    b. (Optional.) Specify the payload fill string for voice packets.

     data-fill *string*

     The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the DLSw operation

About this task

The DLSw operation measures the response time of a DLSw device.

It sets up a DLSw connection to the DLSw device per probe.

Restrictions and guidelines

For the successful DLSw operation, configure the **nqa server tcp-connect** command on the NQA server and make sure the port number for the TCP listening service is 2065.

Procedure

1. Enter system view.

   system-view
2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*
3. Specify the DLSw type and enter its view.

   type dlsw
4. Specify the destination IP address for the probe packets.

   destination ip *ip-address*

   By default, no destination IP address is specified.
5. Specify the source IP address for the probe packets.

   source ip *ip-address*

   By default, the source IP address of the probe packets is the primary IP address of their output interface.

The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring the path jitter operation

About this task

The path jitter operation measures the jitter, negative jitters, and positive jitters from the NQA client to each hop on the path to the destination.

The path jitter operation performs the following steps per probe:

1. Obtains the path from the NQA client to the destination through tracert. A maximum of 64 hops can be detected.
2. Sends a number of ICMP echo requests to each hop along the path. The number of ICMP echo requests to send is set by using the **`probe packet-number`** command.

Prerequisites

Before you configure the path jitter operation, you must perform the following tasks:

- Enable sending ICMP time exceeded messages on the intermediate devices between the source and destination devices. If the intermediate devices are NSFOCUS devices, use the **`ip ttl-expires enable`** command.
- Enable sending ICMP destination unreachable messages on the destination device. If the destination device is an NSFOCUS device, use the **`ip unreachables enable`** command.

  For more information about the **`ip ttl-expires enable`** and **`ip unreachables enable`** commands, see *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.

   `system-view`

2. Create an NQA operation and enter NQA operation view.

   `nqa entry` *`admin-name operation-tag`*

3. Specify the path jitter type and enter its view.

   `type path-jitter`

4. Specify the destination IP address for ICMP echo requests.

   `destination ip` *`ip-address`*

   By default, no destination IP address is specified.

5. Specify the source IP address for ICMP echo requests.

   `source ip` *`ip-address`*

   By default, the source IP address of ICMP echo requests is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no ICMP echo requests can be sent out.

6. Configure the probe parameters for the path jitter operation.

   a. Set the number of ICMP echo requests to be sent per probe.

      `probe packet-number` *`number`*

      The default setting is 10.

   b. Set the interval for sending ICMP echo requests.

      `probe packet-interval` *`interval`*

      The default setting is 20 milliseconds.

c. Specify how long the NQA client waits for a response from the server before it regards the response times out.

   probe packet-timeout *timeout*

   The default setting is 3000 milliseconds.

7. (Optional.) Specify an LSR path.

   lsr-path *ip-address*&<1-8>

   By default, no LSR path is specified.

   The path jitter operation uses tracert to detect the LSR path to the destination, and sends ICMP echo requests to each hop on the LSR path.

8. Configure the NQA client to perform the path jitter operation only on the destination address.

   target-only

   By default, the path jitter operation is performed on each hop on the path to the destination.

9. (Optional.) Set the payload size for each ICMP echo request.

   data-size *size*

   The default setting is 100 bytes.

10. (Optional.) Specify the payload fill string for ICMP echo requests.

    data-fill *string*

    The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring optional parameters for the NQA operation

Restrictions and guidelines

The parameter settings take effect only on the current operation.

The supported parameters vary by NQA operation type. For information about supported parameters, see NQA commands in *Network Management and Monitoring Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*

3. Specify an NQA operation type and enter its view.

   type { **arp** | **dhcp** | **dlsw** | **dns** | **ftp** | **http** | **icmp-echo** | **icmp-jitter** | **path-jitter** | **snmp** | **tcp** | **udp-echo** | **udp-jitter** | **udp-tracert** | **voice** }

4. Configure a description for the operation.

   description *text*

   By default, no description is configured.

5. Set the interval at which the NQA operation repeats.

   frequency *interval*

   For a voice or path jitter operation, the default setting is 60000 milliseconds.

   For other types of operations, the default setting is 0 milliseconds, and only one operation is performed.

   When the interval expires, but the operation is not completed or is not timed out, the next operation does not start.

6. Specify the probe times.

   probe count *times*

In an UDP tracert operation, the NQA client performs three probes to each hop to the destination by default.

In other types of operations, the NQA client performs one probe to the destination per operation by default.

This command is not available for the voice and path jitter operations. Each of these operations performs only one probe.

7. Set the probe timeout time.

   probe timeout *timeout*

   The default setting is 3000 milliseconds.

8. Set the maximum number of hops that the probe packets can traverse.

   ttl *value*

   The default setting is 30 for probe packets of the UDP tracert operation, and is 20 for probe packets of other types of operations.

9. Set the ToS value in the IP header of the probe packets.

   tos *value*

   The default setting is 0.

10. Enable the routing table bypass feature.

    route-option bypass-route

    By default, the routing table bypass feature is disabled.

    This command does not take effect if the destination address of the NQA operation is an IPv6 address.

11. Specify the VPN instance where the operation is performed.

    vpn-instance *vpn-instance-name*

    By default, the operation is performed on the public network.

Configuring the collaboration feature

About this task

Collaboration is implemented by associating a reaction entry of an NQA operation with a track entry. The reaction entry monitors the NQA operation. If the number of operation failures reaches the specified threshold, the configured action is triggered.

Restrictions and guidelines

The collaboration feature is not available for the following types of operations:

- ICMP jitter operation.
- UDP jitter operation.
- UDP tracert operation.
- Voice operation.
- Path jitter operation.

A reaction entry cannot be modified after it is created.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*

3. Configure a reaction entry.

reaction *item-number* **checked-element probe-fail threshold-type consecutive** *consecutive-occurrences* **action-type trigger-only**

You cannot modify the content of an existing reaction entry.

4. Return to system view.

   quit

5. Associate Track with NQA.

   For information about the configuration, see "Configuring Track."

6. Associate Track with an application module.

   For information about the configuration, see "Configuring Track."

Configuring threshold monitoring

About this task

This feature allows you to monitor the NQA operation running status.

An NQA operation supports the following threshold types:

- **average**—If the average value for the monitored performance metric either exceeds the upper threshold or goes below the lower threshold, a threshold violation occurs.
- **accumulate**—If the total number of times that the monitored performance metric is out of the specified value range reaches or exceeds the specified threshold, a threshold violation occurs.
- **consecutive**—If the number of consecutive times that the monitored performance metric is out of the specified value range reaches or exceeds the specified threshold, a threshold violation occurs.

Threshold violations for the average or accumulate threshold type are determined on a per NQA operation basis. The threshold violations for the consecutive type are determined from the time the NQA operation starts.

The following actions might be triggered:

- **none**—NQA displays results only on the terminal screen. It does not send traps to the NMS.
- **trap-only**—NQA displays results on the terminal screen, and meanwhile it sends traps to the NMS.

  To send traps to the NMS, the NMS address must be specified by using the **snmp-agent target-host** command. For more information about the command, see *Network Management and Monitoring Command Reference*.
- **trigger-only**—NQA displays results on the terminal screen, and meanwhile triggers other modules for collaboration.

In a reaction entry, configure a monitored element, a threshold type, and an action to be triggered to implement threshold monitoring.

The state of a reaction entry can be invalid, over-threshold, or below-threshold.

- Before an NQA operation starts, the reaction entry is in invalid state.
- If the threshold is violated, the state of the entry is set to over-threshold. Otherwise, the state of the entry is set to below-threshold.

Restrictions and guidelines

The threshold monitoring feature is not available for the path jitter operation.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA operation.

nqa entry *admin-name operation-tag*

3. Enable sending traps to the NMS when specific conditions are met.

   reaction trap { **path-change** | **probe-failure** *consecutive-probe-failures* | **test-complete** | **test-failure** [*accumulate-probe-failures*] }

   By default, no traps are sent to the NMS.

   The ICMP jitter, UDP jitter, and voice operations support only the **test-complete** keyword.

   The following parameters are not available for the UDP tracert operation:

   - The **probe-failure** *consecutive-probe-failures* option.
   - The *accumulate-probe-failures* argument.

4. Configure threshold monitoring. Choose the options to configure as needed:

   - Monitor the operation duration.

     reaction *item-number* **checked-element probe-duration threshold-type** { **accumulate** *accumulate-occurrences* | **average** | **consecutive** *consecutive-occurrences* } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

     This reaction entry is not supported in the ICMP jitter, UDP jitter, UDP tracert, or voice operations.

   - Monitor failure times.

     reaction *item-number* **checked-element probe-fail threshold-type** { **accumulate** *accumulate-occurrences* | **consecutive** *consecutive-occurrences* } [**action-type** { **none** | **trap-only** }]

     This reaction entry is not supported in the ICMP jitter, UDP jitter, UDP tracert, or voice operations.

   - Monitor the round-trip time.

     reaction *item-number* **checked-element rtt threshold-type** { **accumulate** *accumulate-occurrences* | **average** } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

     Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

   - Monitor packet loss.

     reaction *item-number* **checked-element packet-loss threshold-type accumulate** *accumulate-occurrences* [**action-type** { **none** | **trap-only** }]

     Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

   - Monitor the one-way jitter.

     reaction *item-number* **checked-element** { **jitter-ds** | **jitter-sd** } **threshold-type** { **accumulate** *accumulate-occurrences* | **average** } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

     Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

   - Monitor the one-way delay.

     reaction *item-number* **checked-element** { **owd-ds** | **owd-sd** } **threshold-value** *upper-threshold lower-threshold*

     Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

   - Monitor the ICPIF value.

     reaction *item-number* **checked-element icpif threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

     Only the voice operation supports this reaction entry.

- Monitor the MOS value.

  reaction *item-number* **checked-element mos threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the voice operation supports this reaction entry.

The DNS operation does not support the action of sending trap messages. For the DNS operation, the action type can only be **none**.

Configuring the NQA statistics collection feature

About this task

NQA forms statistics within the same collection interval as a statistics group. To display information about the statistics groups, use the **display nqa statistics** command.

When the maximum number of statistics groups is reached, the NQA client deletes the oldest statistics group to save a new one.

A statistics group is automatically deleted when its hold time expires.

Restrictions and guidelines

The NQA statistics collection feature is not available for the UDP tracert operation.

If you use the **frequency** command to set the interval to 0 milliseconds for an NQA operation, NQA does not generate any statistics group for the operation.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*

3. Set the statistics collection interval.

   statistics interval *interval*

   The default setting is 60 minutes.

4. Set the maximum number of statistics groups that can be saved.

   statistics max-group *number*

   By default, the NQA client can save a maximum of two statistics groups for an operation.

   To disable the NQA statistics collection feature, set the *number* argument to 0.

5. Set the hold time of statistics groups.

   statistics hold-time *hold-time*

   The default setting is 120 minutes.

Configuring the saving of NQA history records

About this task

This task enables the NQA client to save NQA history records. You can use the **display nqa history** command to display the NQA history records.

Restrictions and guidelines

The NQA history record saving feature is not available for the following types of operations:

- ICMP jitter operation.
- UDP jitter operation.

- Voice operation.
- Path jitter operation.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*

3. Enable the saving of history records for the NQA operation.

   history-record enable

   By default, this feature is enabled only for the UDP tracert operation.

4. Set the lifetime of history records.

   history-record keep-time *keep-time*

   The default setting is 120 minutes.

   A record is deleted when its lifetime is reached.

5. Set the maximum number of history records that can be saved.

   history-record number *number*

   The default setting is 50.

   When the maximum number of history records is reached, the system will delete the oldest record to save a new one.

Scheduling the NQA operation on the NQA client

About this task

The NQA operation runs between the specified start time and end time (the start time plus operation duration). If the specified start time is ahead of the system time, the operation starts immediately. If both the specified start and end time are ahead of the system time, the operation does not start. To display the current system time, use the **display clock** command.

Restrictions and guidelines

You cannot enter the operation type view or the operation view of a scheduled NQA operation.

A system time adjustment does not affect started or completed NQA operations. It affects only the NQA operations that have not started.

Procedure

1. Enter system view.

   system-view

2. Specify the scheduling parameters for an NQA operation.

   nqa schedule *admin-name operation-tag* **start-time** { *hh:mm:ss* [*yyyy/mm/dd* | *mm/dd/yyyy*] | **now** } **lifetime** { *lifetime* | **forever** } [**recurring**]

Configuring NQA templates on the NQA client

Restrictions and guidelines

Some operation parameters for an NQA template can be specified by the template configuration or the feature (such as load balancing) that uses the template. When both are specified, the parameters in the template configuration take effect.

NQA template tasks at a glance

To configure NQA templates, perform the following tasks:

1. Perform at least one of the following tasks:
   - Configuring the ARP template
   - Configuring the ICMP template
   - Configuring the IMAP template
   - Configuring the DNS template
   - Configuring the POP3 template
   - Configuring the SMTP template
   - Configuring the TCP template
   - Configuring the TCP half open template
   - Configuring the UDP template
   - Configuring the HTTP template
   - Configuring the HTTPS template
   - Configuring the FTP template
   - Configuring the RADIUS authentication template
   - Configuring the RTSP template
   - Configuring the SIP template
   - Configuring the SNMP template
   - Configuring the SNMP DCA template
   - Configuring the SSL template
   - Configuring the WAP template
2. (Optional.) Configuring optional parameters for the NQA template

Configuring the ARP template

About this task

A feature that uses the ARP template performs the ARP operation to test whether the ARP service is available on the destination device.

In the ARP operation, the NQA client sends an ARP request to the destination device. If the client receives an ARP reply, it determines that the ARP service is available on the destination device.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Create an ARP template and enter its view.

nqa template arp *name*

3. (Optional.) Specify the destination IP address for the probe packets.

   destination ip *ip-address*

   By default, no destination IP address is specified.

4. (Optional.) Specify the source IP address for the probe packets.

   source ip *ip-address*

   By default, the source IP address of the probe packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring the ICMP template

About this task

A feature that uses the ICMP template performs the ICMP operation to measure the reachability of a destination device. The ICMP template is supported on both IPv4 and IPv6 networks.

Procedure

1. Enter system view.

   system-view

2. Create an ICMP template and enter its view.

   nqa template icmp *name*

3. Specify the destination IP address for the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is configured.

4. Specify the source IP address for ICMP echo requests. Choose one option as needed:

   - Use the IP address of the specified interface as the source IP address.

     source interface *interface-type interface-number*

     By default, the primary IP address of the output interface is used as the source IP address of ICMP echo requests.

     The specified source interface must be up.

   - Specify the source IPv4 address.

     source ip *ip-address*

     By default, the primary IPv4 address of the output interface is used as the source IPv4 address of ICMP echo requests.

     The specified source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   - Specify the source IPv6 address.

     source ipv6 *ipv6-address*

     By default, the IPv6 address of the output interface is used as the source IPv6 address of ICMP echo requests.

     The specified source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

5. Specify the next hop IP address for ICMP echo requests.

   IPv4:

   next-hop ip *ip-address*

   IPv6:

   next-hop ipv6 *ipv6-address*

   By default, no IP address of the next hop is configured.

6. Configure the probe result sending on a per-probe basis.

   reaction trigger per-probe

   By default, the probe result is sent to the feature that uses the template after three consecutive failed or successful probes.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-pass** commands multiple times, the most recent configuration takes effect.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-fail** commands multiple times, the most recent configuration takes effect.

7. (Optional.) Set the payload size for each ICMP request.

   data-size *size*

   The default setting is 100 bytes.

8. (Optional.) Specify the payload fill string for ICMP echo requests.

   data-fill *string*

   The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the IMAP template

About this task

A feature that uses the IMAP template performs the IMAP operation to determine the availability of the IMAP service on the IMAP server.

Before you perform an IMAP operation, enable the IMAP Server service on the IMAP server and configure related settings, including the login username, password, and mailbox name.

Procedure

1. Enter system view.

   system-view

2. Create an IMAP template and enter IMAP template view.

   nqa template imap name

3. (Optional.) Specify the destination address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination address is specified.

4. (Optional.) Specify the destination port number for the probe packets.

   destination port *port-number*

   The default destination port number is 143.

5. (Optional.) Specify the source address for the probe packets.

   IPv4:

source ip *ip-address*

By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

IPv6:

source ipv6 *ipv6-address*

By default, the source IPv6 address of the probe packets is the IPv6 address of their output interface.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. (Optional.) Specify the login username.

   username *username*

   By default, no login username is specified.

7. (Optional.) Specify the login password.

   password { **cipher** | **simple** } *string*

   By default, no login password is specified.

8. (Optional.) Specify the mailbox name.

   mailbox *mailbox-name*

   By default, mailbox **INBOX** is used.

Configuring the DNS template

About this task

A feature that uses the DNS template performs the DNS operation to determine the status of the server. The DNS template is supported on both IPv4 and IPv6 networks.

In DNS template view, you can specify the address expected to be returned. If the returned IP addresses include the expected address, the DNS server is valid and the operation succeeds. Otherwise, the operation fails.

Prerequisites

Create a mapping between the domain name and an address before you perform the DNS operation. For information about configuring the DNS server, see documents about the DNS server configuration.

Procedure

1. Enter system view.

   system-view

2. Create a DNS template and enter DNS template view.

   nqa template dns *name*

3. Specify the destination IP address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination address is specified.

4. Specify the destination port number for the probe packets.

destination port *port-number*

By default, the destination port number is 53.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the source IPv4 address of the probe packets is the primary IPv4 address of their output interface.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the source IPv6 address of the probe packets is the IPv6 address of their output interface.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Specify the source port number for the probe packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

7. Specify the domain name to be translated.

   resolve-target *domain-name*

   By default, no domain name is specified.

8. Specify the domain name resolution type.

   resolve-type { **A** | **AAAA** }

   By default, the type is type A.

   A type A query resolves a domain name to a mapped IPv4 address, and a type AAAA query to a mapped IPv6 address.

9. (Optional.) Specify the IP address that is expected to be returned.

   IPv4:

   expect ip *ip-address*

   IPv6:

   expect ipv6 *ipv6-address*

   By default, no expected IP address is specified.

10. Configure the probe result sending on a per-probe basis.

    reaction trigger per-probe

    By default, the probe result is sent to the feature that uses the template after three consecutive failed or successful probes.

    If you execute the **reaction trigger per-probe** and **reaction trigger probe-pass** commands multiple times, the most recent configuration takes effect.

    If you execute the **reaction trigger per-probe** and **reaction trigger probe-fail** commands multiple times, the most recent configuration takes effect.

Configuring the POP3 template

About this task

A feature that uses the POP3 template performs the POP3 operation to determine the availability of the POP3 service on the POP3 server.

Before you perform a POP3 operation, enable the POP3 Server service on the POP3 server and configure related settings, including the login username and password.

Procedure

1. Enter system view.

   system-view

2. Create a POP3 template and enter POP3 template view.

   nqa template pop3 *name*

3. (Optional.) Specify the destination address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination address is specified.

4. (Optional.) Specify the destination port number for the probe packets.

   destination port *port-number*

   The default destination port number is 110.

5. (Optional.) Specify the source address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the source IPv6 address of the probe packets is the IPv6 address of their output interface.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Specify the login username.

   username *username*

   By default, no login username is specified.

7. Specify the login password.

   password { **cipher** | **simple** } *string*

   By default, no login password is specified.

Configuring the SMTP template

About the SMTP template

A feature that uses the SMTP template performs the SMTP operation to determine the availability of the SMTP service on the SMTP server.

Procedure

1. Enter system view.

   system-view

2. Create a SMTP template and enter SMTP template view.

   nqa template smtp *name*

3. (Optional.) Specify the destination address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination address is specified.

4. (Optional.) Specify the destination port number for the probe packets.

   destination port *port-number*

   The default destination port number is 25.

5. (Optional.) Specify the source address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the source IPv6 address of the probe packets is the IPv6 address of their output interface.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring the TCP template

About this task

A feature that uses the TCP template performs the TCP operation to test whether the NQA client can establish a TCP connection to a specific port on the server.

In TCP template view, you can specify the expected string to be returned. If you do not specify the expected string, the TCP operation tests only whether the client can establish a TCP connection to the server.

The TCP operation requires both the NQA server and the NQA client. Before you perform a TCP operation, configure a TCP listening service on the NQA server. For more information about the TCP listening service configuration, see "Configuring the NQA server."

Procedure

1. Enter system view.

   system-view

2. Create a TCP template and enter its view.

   nqa template tcp *name*

3. Specify the destination IP address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the TCP listening service configured on the NQA server.

4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the TCP listening service on the NQA server.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. (Optional.) Specify the payload fill string for the probe packets. Choose one option as needed:
   - Specify the payload fill string.

     data-fill *string*
   - Specify the hexadecimal payload fill string.

     hex-data-fill *hex* [**raw**]

   The default payload fill string is the hexadecimal string 00010203040506070809.

7. (Optional.) Configure the expected response string.
   - Configure the expected response string to determine a successful NQA operation:

     expect { **data** | **hex-data** } *string* [{ **offset** | **strict-offset** } *number*]
   - Configure the expected response string to determine a failed NQA operation:

     expect { **failed-data** | **hex-failed-data** } *string* [{ **offset** | **strict-offset** } *number*]

   By default, no expected response string is configured.

The expected response string check takes effect only if the **data-fill** or **hex-data-fill** command is also configured.

If you configure both commands, the **expect** { **failed-data** | **hex-failed-data** } command takes effect.

8. (Optional.) Enable the NQA client to send resource release notifications to the NQA server when the operation is complete.

   resource-release { **data-fill** | **hex-data-fill** } *string*

   By default, the NQA client does not send resource release notifications to the NQA server when an NQA operation is complete.

9. Set a TCP connection termination mode.

   disconnect-mode { **fin** | **rst** }

   By default, the TCP operation uses the RST mode to terminate TCP connections.

Configuring the TCP half open template

About this task

A feature that uses the TCP half open template performs the TCP half open operation to test whether the TCP service is available on the server. The TCP half open operation is used when the feature cannot get a response from the TCP server through an existing TCP connection.

The TCP half open operation works as follows:

- If port detection is disabled, the NQA client sends a TCP ACK packet to the server. If the client receives an RST packet, it considers that the TCP service is available on the server.
- If port detection is enabled, the NQA client sends a TCP SYN packet to the server. If the client receives a SYN-ACK packet, it considers that the destination TCP port is operating correctly on the server.

Procedure

1. Enter system view.

   system-view

2. Create a TCP half open template and enter its view.

   nqa template tcphalfopen *name*

3. (Optional.) Enable port detection.

   port-detect enable

   By default, port detection is disabled.

   To use the port detection feature, you must specify a destination port number for the TCP half open template.

4. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the listening service configured on the NQA server.

5. Specify the destination port number.

   destination port *port-number*

   By default, no destination port number is specified.

The destination port number must be the same as the port number of the listening service on the NQA server.

For the port detection feature to take effect, the destination port number must be specified.

6. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

7. Specify the output interface for the probe packets.

   out interface *interface-type interface-number*

   By default, the NQA client determines the output interface based on the routing table lookup.

8. Specify the next hop IP address for the probe packets.

   IPv4:

   next-hop ip *ip-address*

   IPv6:

   next-hop ipv6 *ipv6-address*

   By default, the IP address of the next hop is configured.

9. Configure the probe result sending on a per-probe basis.

   reaction trigger per-probe

   By default, the probe result is sent to the feature that uses the template after three consecutive failed or successful probes.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-pass** commands multiple times, the most recent configuration takes effect.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-fail** commands multiple times, the most recent configuration takes effect.

Configuring the UDP template

About this task

A feature that uses the UDP template performs the UDP operation to test the following items:

- Reachability of a specific port on the NQA server.
- Availability of the requested service on the NQA server.

The UDP operation requires both the NQA server and the NQA client. Before you perform a UDP operation, configure a UDP listening service on the NQA server. For more information about the UDP listening service configuration, see "Configuring the NQA server."

(For devices that do not support UDP port detection.) A UDP operation result varies by the configuration of the expected string:

- If the expected string that determines a failed UDP operation is configured, the UDP operation fails when either of the conditions is met:
  - The UDP response string contains the expected string.
  - The UDP response string is shorter than the expected string.

  If none conditions are met, the operation is successful.
- If the expected string that determines a successful UDP operation is configured, the UDP operation is successful when the UDP response packet matches the expected string. Otherwise, the operation fails.
- If no expected string is configured, the UDP operation is successful when the client receives the response packet from the server.

(For devices that support UDP port detection.) The UDP port detection tests the availability of the requested UDP service on the peer port. A UDP operation result varies by the configuration of the expected string and the status of the port detection:

- With port detection enabled for the UDP operation, the operation succeeds if the NQA client does not receive any ICMP port unreachable messages within the probe timeout time. If the client receives an ICMP port unreachable message, the UDP operation fails.
- With port detection disabled for the UDP operation, the following rules apply:
- If the expected string that determines a failed UDP operation is configured, the UDP operation fails when either of the conditions is met:
  - The UDP response string contains the expected string.
  - The UDP response string is shorter than the expected string.

  If none conditions are met, the operation is successful.
  - If the expected string that determines a successful UDP operation is configured, the UDP operation is successful when the UDP response packet matches the configured expected string. Otherwise, the operation fails.
  - If no expected string is configured, the UDP operation is successful when the client receives the response packet from the server.

Restrictions and guidelines

If the destination device is an NSFOCUS device, you must also perform the following tasks for the UDP operation:

- Execute the **`ip unreachables enable`** command on the destination device to enable sending ICMP destination unreachable messages. For more information about the **`ip unreachables enable`** command, see IP performance optimization commands in *Layer 3 IP Services Command Reference*.
- Execute the **`data-fill`** or **`hex-data-fill`** command on the NQA client with the **`raw`** keyword specified. The specified payload fill string can be any value in the value range.

Procedure

1. Enter system view.

   `system-view`
2. Create a UDP template and enter its view.

   `nqa template udp` *`name`*
3. (Optional.) Enable port detection for the UDP operation.

   `port-detect enable`

   By default, port detection is disabled.
4. Specify the destination IP address of the operation.

   IPv4:

   `destination ip` *`ip-address`*

IPv6:

destination ipv6 *ipv6-address*

By default, no destination IP address is specified.

The destination address must be the same as the IP address of the listening service configured on the NQA server.

5. Specify the destination port number for the probe packets.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the listening service on the NQA server.

6. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

7. Specify the payload fill string for the probe packets. Choose one option as needed:

   - Specify the payload fill string.

     data-fill *string* [**raw**]

     The default payload fill string is the hexadecimal string 00010203040506070809.

   - Specify the hexadecimal payload fill string.

     hex-data-fill *hex* [**raw**]

   The default payload fill string is the hexadecimal string 00010203040506070809.

   For port detection to take effect for the UDP operation, specify the **raw** keyword in the **data-fill** or **hex-data-fill** command, and the string is not required to be format compliant.

8. (Optional.) Set the payload size for the probe packets.

   data-size *size*

   The default setting is 100 bytes.

9. (Optional.) Configure the expected response string.

   - Configure the expected response string to determine a successful NQA operation:

     expect { **data** | **hex-data** } *string* [{ **offset** | **strict-offset** } *number*]

   - Configure the expected response string to determine a failed NQA operation:

     expect { **failed-data** | **hex-failed-data** } *string* [{ **offset** | **strict-offset** } *number*]

   By default, no expected response string is configured.

   The expected response string check takes effect only if the **data-fill** or **hex-data-fill** command is also configured.

If you configure both commands, the **expect { failed-data | hex-failed-data }** command takes effect.

10. (Optional.) Enable the NQA client to send resource release notifications to the NQA server when the operation is complete.

    resource-release { data-fill | hex-data-fill } *string*

    By default, the NQA client does not send resource release notifications to the NQA server when an NQA operation is complete.

Configuring the HTTP template

About this task

A feature that uses the HTTP template performs the HTTP operation to measure the time it takes the NQA client to obtain data from an HTTP server.

The expected string is checked only when the data is configured and the HTTP response contains the Content-Length field in the HTTP header.

The status code of the HTTP packet is a three-digit field in decimal notation, and it includes the status information for the HTTP server. The first digit defines the class of response.

Prerequisites

Before you perform the HTTP operation, you must configure the HTTP server.

Procedure

1. Enter system view.

   system-view

2. Create an HTTP template and enter its view.

   nqa template http *name*

3. Specify the URL of the HTTP proxy server.

   proxy-url *url*

   By default, the URL of the HTTP proxy server is not specified.

   The URL of the HTTP proxy server is in the format of http://*host* or http://*host:port*.

   This command is required if an HTTP proxy server is required for Internet access.

   After the HTTP proxy server URL is specified, the NQA client will send probe packets to the HTTP proxy server, which acts on behalf of the HTTP server.

4. Specify the URL of the destination HTTP server for the HTTP template.

   url *url*

   By default, the URL of the destination HTTP server is not specified for an HTTP template.

   The URL can be in one of the following formats:

   - http://host/resource
   - http://host:port/resource

5. Specify an HTTP login username.

   username *username*

   By default, no HTTP login username is specified.

6. Specify an HTTP login password.

   password { cipher | simple } *string*

   By default, no HTTP login password is specified.

7. Specify the HTTP version.

   version { v1.0 | v1.1 }

By default, HTTP 1.0 is used.

8. Specify the HTTP operation type.

   operation { **get** | **post** | **raw** }

   By default, the HTTP operation type is **get**.

   If you set the operation type to raw, the client pads the content configured in raw request view to the HTTP request to send to the HTTP server.

9. Configure the content of the HTTP raw request.

   a. Enter raw request view.

      raw-request

      Every time you enter raw request view, the previously configured raw request content is cleared.

   b. Enter or paste the request content.

      By default, no request content is configured.

      For successful HTTP operations, make sure the raw request content is valid and does not contain command aliases configured by using the **alias** command. For more information about the **alias** command, see CLI commands in *Fundamentals Command Reference*.

   c. Return to HTTP template view.

      quit

      The system automatically saves the configuration in raw request view before it returns to HTTP template view.

   This step is required only when the operation type is set to **raw**.

10. Specify the source IP address for the probe packets.

    IPv4:

    source ip *ip-address*

    By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

    The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

    IPv6:

    source ipv6 *ipv6-address*

    By default, the IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

    The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

11. (Optional.) Configure the expected status codes to determine a successful NQA operation.

    expect status *status-list*

    By default, no expected status code is configured to determine a successful NQA operation.

    Do not configure both this command and the **expect failed-status** command.

12. (Optional.) Configure the expected status codes to determine a failed NQA operation.

    expect failed-status *status-list*

    By default, no expected status code is configured to determine a failed NQA operation.

    Do not configure both this command and the **expect status** command.

13. (Optional.) Configure the expected response string to determine a successful NQA operation.

    expect data *string* [{ **offset** | **strict-offset** } *number*]

    By default, no expected response string is configured to determine a successful NQA operation.

Do not configure both this command and the **expect failed-data** command.

14. (Optional.) Configure the expected response string to determine a failed NQA operation.

    expect failed-data *string* [{ **offset** | **strict-offset** } *number*]

    By default, no expected response string is configured to determine a failed NQA operation..

    Do not configure both this command and the **expect data** command.

Configuring the HTTPS template

About this task

A feature that uses the HTTPS template performs the HTTPS operation to measure the time it takes for the NQA client to obtain data from an HTTPS server.

The expected string is checked only when the expected string is configured and the HTTPS response contains the Content-Length field in the HTTPS header.

The status code of the HTTPS packet is a three-digit field in decimal notation, and it includes the status information for the HTTPS server. The first digit defines the class of response.

Prerequisites

Before you perform the HTTPS operation, configure the HTTPS server and the SSL client policy for the SSL client. For information about configuring SSL client policies, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create an HTTPS template and enter its view.

   nqa template https *name*

3. Specify the URL of the HTTPS proxy server.

   proxy-url *url*

   By default, the URL of the HTTPS proxy server is not specified.

   The URL of the HTTPS proxy server is in the format of https://*host* or https://*host:port*.

   This command is required if an HTTPS proxy server is required for Internet access.

   After the HTTPS proxy server URL is specified, the NQA client will send probe packets to the HTTPS proxy server, which acts on behalf of the HTTPS server.

4. Specify the URL of the destination HTTPS server for the HTTPS template.

   url *url*

   By default, the URL of the destination HTTPS server is not specified for an HTTPS template.

   Enter the URL in one of the following formats:

   - https://host/resource
   - https://host:port/resource

5. Specify an HTTPS login username.

   username *username*

   By default, no HTTPS login username is specified.

6. Specify an HTTPS login password.

   password { **cipher** | **simple** } *string*

   By default, no HTTPS login password is specified.

7. Specify an SSL client policy.

ssl-client-policy *policy-name*

By default, no SSL client policy is specified.

8. Specify the HTTPS version.

version { **v1.0** | **v1.1** }

By default, HTTPS 1.0 is used.

9. Specify the HTTPS operation type.

operation { **get** | **post** | **raw** }

By default, the HTTPS operation type is **get**.

If you set the operation type to raw, the client pads the content configured in raw request view to the HTTPS request to send to the HTTPS server.

10. Configure the content of the HTTPS raw request.

a. Enter raw request view.

raw-request

Every time you enter raw request view, the previously configured raw request content is cleared.

b. Enter or paste the request content.

By default, no request content is configured.

For successful HTTP operations, make sure the raw request content is valid and does not contain command aliases configured by using the **alias** command. For more information about the **alias** command, see CLI commands in *Fundamentals Command Reference*.

c. Return to HTTPS template view.

quit

The system automatically saves the configuration in raw request view before it returns to HTTPS template view.

This step is required only when the operation type is set to **raw**.

11. Specify the source IP address for the probe packets.

IPv4:

source ip *ip-address*

By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

IPv6:

source ipv6 *ipv6-address*

By default, the IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

12. (Optional.) Configure the expected status codes to determine a successful NQA operation.

expect status *status-list*

By default, no expected status code is configured to determine a successful NQA operation.

Do not configure both this command and the **expect failed-status** command.

13. (Optional.) Configure the expected status codes to determine a failed NQA operation.

expect failed-status *status-list*

By default, no expected status code is configured to determine a failed NQA operation.

Do not configure both this command and the **expect status** command.

14. (Optional.) Configure the expected response string to determine a successful NQA operation.

    expect data *string* [{ **offset** | **strict-offset** } *number*]

    By default, no expected response string is configured to determine a successful NQA operation.

    Do not configure both this command and the **expect failed-data** command.

15. (Optional.) Configure the expected response string to determine a failed NQA operation.

    expect failed-data *string* [{ **offset** | **strict-offset** } *number*]

    By default, no expected response string is configured to determine a failed NQA operation..

    Do not configure both this command and the **expect data** command.

Configuring the FTP template

About this task

A feature that uses the FTP template performs the FTP operation. The operation measures the time it takes the NQA client to transfer a file to or download a file from an FTP server.

Configure the username and password for the FTP client to log in to the FTP server before you perform an FTP operation. For information about configuring the FTP server, see *Fundamentals Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create an FTP template and enter its view.

   nqa template ftp *name*

3. Specify an FTP login username.

   username *username*

   By default, no FTP login username is specified.

4. Specify an FTP login password.

   password { **cipher** | **simple** } *sting*

   By default, no FTP login password is specified.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Set the data transmission mode.

   mode { **active** | **passive** }

   The default mode is **active**.

7. Specify the FTP operation type.

   operation { **get** | **put** }

   By default, the FTP operation type is **get**, which means obtaining files from the FTP server.

8. Specify the destination URL for the FTP template.

   url *url*

   By default, no destination URL is specified for an FTP template.

   Enter the URL in one of the following formats:

   - ftp://*host*/*filename*.
   - ftp://*host*:*port*/*filename*.

   When you perform the **get** operation, the file name is required.

   When you perform the **put** operation, the *filename* argument does not take effect, even if it is specified. The file name for the **put** operation is determined by using the **filename** command.

9. Specify the name of a file to be transferred.

   filename *filename*

   By default, no file is specified.

   This task is required only for the **put** operation.

   The configuration does not take effect for the **get** operation.

Configuring the RADIUS authentication template

About this task

A feature that uses the RADIUS authentication template performs the RADIUS authentication operation to check the availability of the authentication service on the RADIUS server.

The RADIUS authentication operation workflow is as follows:

1. The NQA client sends an authentication request (Access-Request) to the RADIUS server. The request includes the username and the password. The password is encrypted by using the MD5 algorithm and the shared key.
2. The RADIUS server authenticates the username and password.
   - If the authentication succeeds, the server sends an Access-Accept packet to the NQA client.
   - If the authentication fails, the server sends an Access-Reject packet to the NQA client.
3. The NQA client determines the availability of the authentication service on the RADIUS server based on the response packet it received:
   - If an Access-Accept packet is received, the authentication service is available on the RADIUS server.
   - If an Access-Reject packet is received, the authentication service is not available on the RADIUS server.

Prerequisites

Before you configure the RADIUS authentication template, specify a username, password, and shared key on the RADIUS server. For more information about configuring the RADIUS server, see AAA in *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create a RADIUS authentication template and enter its view.

nqa template radius *name*

3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, the destination port number is 1812.

5. Specify a username.

   username *username*

   By default, no username is specified.

6. Specify a password.

   password { **cipher** | **simple** } *string*

   By default, no password is specified.

7. Specify a shared key for secure RADIUS authentication.

   key { **cipher** | **simple** } *string*

   By default, no shared key is specified for RADIUS authentication.

8. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring the RADIUS accounting template

About this task

A feature that uses the RADIUS accounting template performs the RADIUS accounting operation to check the availability of the accounting service on the RADIUS server.

The RADIUS accounting operation workflow is as follows:

1. The NQA client sends a stop-accounting request (Accounting-Request) to the RADIUS server.
2. The RADIUS server returns an acknowledgment (Accounting-Response) to the NQA client.
3. The NQA client determines the availability of the accounting service on the RADIUS server based on whether it can receive the accounting response packet from the RADIUS server.
   - If the accounting response packet is received, the accounting service is available on the RADIUS server.

- If no accounting response packet is received, the accounting service is not available on the RADIUS server.

Prerequisites

Before you configure the RADIUS accounting template, specify a username and the shared key on the RADIUS server. For more information about configuring the RADIUS server, see AAA in *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create a RADIUS accounting template and enter its view.

   nqa template radius-account *name*

3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is configured.

4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, the destination port number is 1813.

5. Specify a username.

   username *username*

   By default, no username is specified.

6. Specify a shared key for secure RADIUS accounting.

   key { **cipher** | **simple** } *string*

   By default, no shared key is specified for RADIUS accounting.

7. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring the RTSP template

About this task

The Real Time Streaming Protocol (RTSP) is a network control protocol designed for real-time control (such as play/pause and forward/playback) of media streaming on the Internet.

A feature that uses the RTSP template performs the RTSP operation to test the availability of the RTSP server.

Procedure

1. Enter system view.

   system-view

2. Create an RTSP template and enter RTSP template view.

   nqa template rtsp *name*

3. (Optional.) Specify the source address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the source IPv6 address of the probe packets is the IPv6 address of their output interface.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

4. (Optional.) Specify the request method.

   - Specify the OPTIONS method.

     request-method options

   - Specify the DESCRIBE method.

     request-method describe

   By default, the OPTIONS method is used.

5. (Optional.) Configure the expected status codes to determine a successful NQA operation.

   expect status *status-list*

   By default, no expected status code is configured to determine a successful NQA operation.

6. (Optional.) Specify the destination URL.

   url *url*

   By default, no destination URL is specified.

   Valid formats for the destination URL are:

   - rtsp://*host*/*resource*
   - rtsp: //*host*:*port*/*resource*

Configuring the SIP template

About this task

The Session Initiation Protocol (SIP) is a communications protocol for signaling that controls multimedia communication sessions over IP networks. SIP messages can be transported over UDP or TCP.

A feature that uses the SIP template performs the SIP operation to test the availability of the SIP service on the SIP server.

Procedure

1. Enter system view.

   system-view

2. Create a SIP template and enter SIP template view.

   nqa template sip *name*

3. Specify the transport protocol.

   transport-protocol { **tcp** | **udp** }

   By default, the UDP transport protocol is used.

4. (Optional.) Specify the destination address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination address is specified.

5. (Optional.) Specify the destination port number for the probe packets.

   destination port *port-number*

   The default destination port number is 5060.

6. (Optional.) Specify the source address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the source IPv6 address of the probe packets is the IPv6 address of their output interface.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

7. (Optional.) Configure the expected status codes to determine a successful NQA operation.

   expect status *status-list*

   By default, no expected status code is configured to determine a successful NQA operation.

Configuring the SNMP template

About this task

A feature that uses the SNMP template performs the SNMP operation to determine the availability of the SNMP service on an SNMP agent.

Procedure

1. Enter system view.

   system-view

2. Create an SNMP template and enter SNMP template view.

   nqa template snmp *name*

3. (Optional.) Specify the destination address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination address is specified.

4. (Optional.) Specify the destination port number for the probe packets.

   destination port *port-number*

   The default destination port number is 161.

5. (Optional.) Specify the source address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the source IPv6 address of the probe packets is the IPv6 address of their output interface.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. (Optional.) Specify the community name for SNMPv1 or SNMPv2c probe packets.

   community read { **cipher** | **simple** } *community-name*

   By default, the SNMP template uses community name **public**.

   Make sure the specified community name is the same as the community name configured on the SNMP agent.

Configuring the SNMP DCA template

About this task

A feature that uses the SNMP Data Collection Agent (DCA) template performs the SNMP DCA operation to measure the performance of a device running an SNMP agent. The SNMP DCA operation involves the following steps:

1. The NQA client sends queries to collect SNMP object values from the SNMP agent.

   The query message contains the OID that identifies the object to collect on the SNMP agent. Typically, the CPU, memory, and disk usage objects are collected.

2. The NQA client determines the performance of the device based on the collected object values and the threshold and weight values configured for the objects. Then, the NQA client reports the information to the associated feature for the feature to act accordingly.

Before you start the SNMP DCA operation, you must configure the SNMP agent.

Procedure

1. Enter system view.

   system-view

2. Create an SNMP DCA template and enter its view.

   nqa template snmpdca *name*

3. (Optional.) Specify the destination address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination address is specified.

4. (Optional.) Specify the destination port number for the probe packets.

   destination port *port-number*

   The default destination port number is 161.

5. (Optional.) Specify the source address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the source IPv6 address of the probe packets is the IPv6 address of their output interface.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. (Optional.) Specify the SNMP community name.

   community read { **cipher** | **simple** } *community-name*

   The default SNMP community name is **public**.

   Make sure the specified community name is the same as the community name configured on the SNMP agent.

7. (Optional.) Specify the SNMP agent type.

   agent-type { **net-snmp** | **user-defined** | **windows** }

   The default SNMP agent type is Net-SNMP.

8. (Optional.) Specify the SNMP version.

   version { **v1** | **v2c** }

   By default, SNMPv1 is used.

9. (Optional.) Specify the threshold and weight for the CPU usage object.

   cpu { **threshold** *threshold-value* | **weight** *weight-value* }

   By default, the CPU usage threshold is 80 and the weight is 3.

10. (Optional.) Specify the threshold and weight for the memory usage object.

    memory { **threshold** *threshold-value* | **weight** *weight-value* } *

    By default, the memory usage threshold is 70 and the weight is 2.

11. (Optional.) Specify the threshold and weight for the disk usage object.

    disk { **threshold** *threshold-value* | **weight** *weight-value* } *

    By default, the disk usage threshold is 90 and the weight is 4.

12. (Optional.) Configure a custom SNMP object for the SNMP DCA to collect and set the threshold and weight for the object.

    oid *oid* **threshold** *threshold-value* **weight** *weight-value*

By default, an SNMP DCA template does not contain custom SNMP objects.

This step is required if the **`user-defined`** SNMP agent type is used.

Configuring the SSL template

About this task

A feature that uses the SSL template performs the SSL operation to measure the time required to establish an SSL connection to an SSL server.

Prerequisites

Before you configure the SSL template, you must configure the SSL client policy. For information about configuring SSL client policies, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Create an SSL template and enter its view.

   `nqa template ssl` *`name`*

3. Specify the destination IP address of the operation.

   IPv4:

   `destination ip` *`ip-address`*

   IPv6:

   `destination ipv6` *`ipv6-address`*

   By default, no destination IP address is specified.

4. Specify the destination port number for the operation.

   `destination port` *`port-number`*

   By default, the destination port number is not specified.

5. Specify an SSL client policy.

   `ssl-client-policy` *`policy-name`*

   By default, no SSL client policy is specified.

6. Specify the source IP address for the probe packets.

   IPv4:

   `source ip` *`ip-address`*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   `source ipv6` *`ipv6-address`*

   By default, the IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring the WAP template

About this task

Wireless Application Protocol (WAP) is a technical standard for accessing information over a mobile wireless network. It describes a protocol suite allowing the interoperability of WAP equipment, and software with different network technologies.

A feature that uses the WAP template performs the WAP operation to determine the availability of the WAP gateway.

Before you start the WAP operation, you must configure the WAP gateway.

Procedure

1. Enter system view.

   system-view

2. Create an WAP template and enter its view.

   nqa template wap *name*

3. (Optional.) Specify the destination address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination address is specified.

4. (Optional.) Specify the destination port number for the probe packets.

   destination port *port-number*

   The default destination port number is 161.

5. (Optional.) Specify the source address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the source IPv6 address of the probe packets is the IPv6 address of their output interface.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. (Optional.) Specify the destination URL.

   url *url*

   By default, no destination URL is specified.

   Valid formats for the destination URL are:

   - http://host/resource
   - http://host:port/resource
   - https://host/resource
   - https://host:port/resource

7. (Optional.) Configure the expected response string to determine a successful NQA operation.

expect { **data** | **hex-data** } *string* [{ **offset** | **strict-offset** } *number*]

By default, no expected response string is configured to determine a successful NQA operation.

This step is required if the **url** command is configured.

Configuring optional parameters for the NQA template

Restrictions and guidelines

Unless otherwise specified, the following optional parameters apply to all types of NQA templates.

The parameter settings take effect only on the current NQA template.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA template.

   nqa template { **arp** | **dns** | **ftp** | **http** | **https** | **icmp** | **imap** | **pop3** | **radius** | **radius-account** | **rtsp** | **sip** | **smtp** | **snmp** | **snmpdca** | **ssl** | **tcp** | **tcphalfopen** | **udp** | **wap** } *name*

3. Configure a description.

   description *text*

   By default, no description is configured.

4. Set the interval at which the NQA operation repeats.

   frequency *interval*

   The default setting is 5000 milliseconds.

   When the interval expires, but the operation is not completed or is not timed out, the next operation does not start.

5. Specify the adjusted interval for NQA to start two consecutive NQA operations after a failed operation.

   frequency-adjustment *adj-interval*

   By default, no adjusted interval is specified.

6. Set the probe timeout time.

   probe timeout *timeout*

   The default setting is 3000 milliseconds.

7. Set the TTL for the probe packets.

   ttl *value*

   The default setting is 20.

   This command is not available for the ARP template.

8. Set the ToS value in the IP header of the probe packets.

   tos *value*

   The default setting is 0.

   This command is not available for the ARP template.

9. Specify the VPN instance where the operation is performed.

   vpn-instance *vpn-instance-name*

   By default, the operation is performed on the public network.

10. Set the number of consecutive successful probes to determine a successful operation event.

reaction trigger probe-pass *count*

The default setting is 3.

If the number of consecutive successful probes for an NQA operation is reached, the NQA client notifies the feature that uses the template of the successful operation event.

11. Set the number of consecutive probe failures to determine an operation failure.

reaction trigger probe-fail *count*

The default setting is 3.

If the number of consecutive probe failures for an NQA operation is reached, the NQA client notifies the feature that uses the NQA template of the operation failure.

Display and maintenance commands for NQA

Execute **display** commands in any view.

Task	Command
Display history records of NQA operations.	**display nqa history** [*admin-name operation-tag*]
Display the current monitoring results of reaction entries.	**display nqa reaction counters** [*admin-name operation-tag* [*item-number*]]
Display the most recent result of the NQA operation.	**display nqa result** [*admin-name operation-tag*]
Display NQA server status.	**display nqa server status**
Display NQA statistics.	**display nqa statistics** [*admin-name operation-tag*]

Configuring TWAMP Light

About TWAMP Light

Two-Way Active Measurement Protocol (TWAMP) defines a standard to measure the network performance between network devices on an IP network. It uses UDP packets to measure the two-way Frame Transfer Delay (FTD), Frame Delay Variation (FDV), and Frame Loss Ratio (FLR). The TWAMP Light provides a simple structure of TWAMP. It simplifies the control protocol for establishing performance measurement sessions and improves test performance.

TWAMP Light architecture

TWAMP Light uses the client-server model.

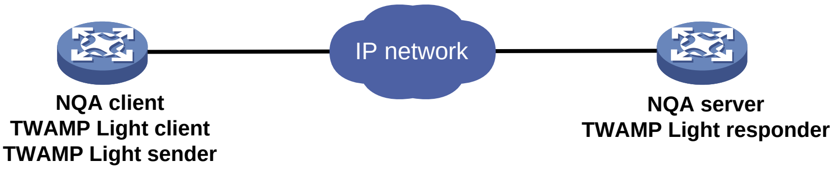
Figure 2 describes the TWAMP Light roles and the typical network diagram.

On the client, the following roles are configured:

- **TWAMP Light client**—Configures TWAMP Light test sessions.
- **TWAMP Light sender**—Starts and stops TWAMP Light test sessions, and collect statistics.

On the server, the TWAMP Light responder, also known as the destination device, is configured. The responder reflects the packets back to the TWAMP Light sender. You must enable the NQA server on the destination device, and create the TWAMP Light responder and test sessions.

Figure 2 Network diagram



TWAMP Light operating mechanism

A TWAMP Light test contains a set of parameters for a test session such as the source IP address and destination IP address.

Each TWAMP Light test session is uniquely identified by the test session ID. You can create and run multiple test sessions on one TWAMP Light client.

The TWAMP Light client and TWAMP Light responder interact as follows:

1. The TWAMP Light client constructs TWAMP Light test packets, and sends them to the TWAMP Light responder.
2. The TWAMP Light responder reflects the test packets to the TWAMP Light client.
3. Upon receiving the reflected packets, the TWAMP Light client calculates the packet loss ratio and round-trip time to determine the service quality from source to destination.

After a TWAMP Light test starts, the TWAMP light client runs the tests permanently or repeats the test at the specified interval. Each test sends one test packet. You can set the test duration and number of test packets to be sent.

Threshold monitoring

Threshold monitoring enables the TWAMP Light client to take a predefined action when the TWAMP Light test performance metrics violate the specified thresholds.

The TWAMP Light test monitors the following metrics:

- Two-way frame delay variation.
- Two-way frame transfer delay.
- Two-way frame loss rate.

In a TWAMP test, the device monitors the test result, and starts the monitoring time when either of the following conditions is met:

- The monitoring result goes beyond the threshold upper limit.
- The monitoring result drops below the threshold lower limit from a monitoring result higher than the lower limit.

If either condition is always true during the monitoring time, a threshold violation occurs and a trap or inform message is generated and sent to the NMS. You set the monitoring time by using the corresponding command.

Protocols and standards

- RFC 5357, *A Two-Way Active Measurement Protocol (TWAMP)*

Restrictions: Hardware compatibility with TWAMP Light

Models	**TWAMP Light compatibility**
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB1180, NFNX3-HDB1480	No

Restrictions and guidelines: TWAMP Light configuration

To avoid probe failures, follow these restrictions and guidelines when configuring the listening port on the TWAMP Light server and the TWAMP Light client:

- Do not specify a well-known port.
- Make sure the specified port number is not used by any services on the device.
  - To obtain the IPv4 addresses and the port numbers in use on this device, see the **Local Addr:port** field in the output from the **`display tcp`** and **`display udp`** commands.
  - To obtain the IPv6 addresses and the port numbers in use on this device, see the **LAddr->port** field in the output from the **`display ipv6 tcp`** and **`display ipv6 udp`** commands.

The destination port configured for the test (with the **destination port** command) on the TWAMP Light client must be the same as the listening port configured on the server.

TWAMP Light tasks at a glance

To configure TWAMP Light, perform the following tasks:

1. Configuring the TWAMP Light server
2. Configuring the TWAMP Light client
3. (Optional.) Configuring threshold monitoring
4. Start the test on the TWAMP Light sender
5. (Optional.) Stop the test on the TWAMP Light sender

Configuring the TWAMP Light server

1. Enter system view.
   system-view
2. Enable the TWAMP Light responder on the NQA server and enter its view.
   nqa twamp-light responder
3. Create a test session on the TWAMP Light responder.
   test-session *session-id* [**interface** *interface-type interface-number* [**service-instance** *instance-id*]] { { **ip** | **ipv6** } **destination** *address* **source** *address* **destination-port** *port-number* **source-port** *port-number* [**vpn-instance** *vpn-instance-name*] | **destination-mac** *mac-address* **source-mac** *mac-address* } * [**vlan** { *vlan-id* | **s-vid** *vlan-id* **c-vid** *vlan-id* } | **timestamp-format** { **ntp** | **ptp** } | **description** *text*] *
4. Return to system view.
   quit
5. Enable the NQA server.
   nqa server enable
   By default, the NQA server is disabled.

Configuring the TWAMP Light client

Restrictions and guidelines

In the TWAMP Light test, a test session is identified by the combination of its address and port number. To ensure the test result, you cannot specify the same combination of address and port number for multiple test sessions.

Procedure

1. Enter system view.
   system-view
2. Enable the NQA client.
   nqa agent enable
   By default, the NQA client is enabled.
   After the NQA client is enabled, the TWAMP Light test session configuration can takes effect.
3. Enable the TWAMP Light client and enter its view.

nqa twamp-light client

4. Create a test session on the TWAMP Light client and enter the client-session view.

   test-session *session-id*

5. (Optional.) Specify the description for the test.

   description *text*

   By default, no description is specified for the test.

6. Specify the IP address and port number for the TWAMP Light test session.

   a. Specify the source IP address for the probe packets.

      IPv4:

      source ip *ip-address*

      By default, no source IPv4 address for the probe packets is specified.

      IPv6:

      source ipv6 *ipv6-address*

      By default, no source IPv6 address for the probe packets is specified.

   b. Specify the destination IP address for the probe packets.

      IPv4:

      destination ip *ipv4-address*

      By default, no destination IPv4 address for the probe packets is specified.

      IPv6:

      destination ipv6 *ipv6-address*

      By default, no destination IPv6 address for the probe packets is specified.

   c. Specify the source interface for the probe packets.

      source interface *interface-type interface-number* [**service-instance** *instance-id*]

      By default, no source interface for the probe packets is specified.

      The specified source interface must be up.

   d. Specify the source port number for the probe packets.

      source port *port-number*

      By default, no source port number for the probe packets is specified.

      For TWAMP Light tests, you must configure this command. For the test to succeed, make sure the specified port number is not used by any services on the device.

   e. Specify the destination port number for the probe packets.

      destination port *port-number*

      By default, no destination port number for the probe packets is specified.

   f. Specify the source MAC address for the probe packets.

      source mac *mac-address*

      By default, no source MAC address for the probe packets is specified.

   g. Specify the destination MAC address for the probe packets.

      destination mac *mac-address*

      By default, no destination MAC address for the probe packets is specified.

   h. (Optional.) Specify the VPN instance where the test is performed.

      vpn-instance *vpn-instance-name*

      By default, no VPN instance is specified. The test is performed on the public network.

7. Specify the timestamp format for the TWAMP Light test session.

timestamp-format { **ntp** | **ptp** }

By default, the timestamp format for the TWAMP Light test is PTP.

8. Specify the payload parameters for the TWAMP Light probe packets.
   - Set the payload size for each probe packet.

     data-size *size*

     The default payload size is 142 bytes.
   - Specify the payload fill string for each probe packet.
     - **data-fill** *string*
     - **hex-data-fill** *hex*

     The default hexadecimal packet payload fill string is 00010203040506070809.

     The two commands have the same function. If you execute them multiple times, the most recent configuration takes effect.
9. (Optional.) Set the priority for the probe packets.
   - Set the 802.1p priority for the probe packets.

     priority 8021p *value*

     By default, the 802.1p priority of the probe packets is 0.
   - Set the ToS value in the IP header of the probe packets.

     tos *value*

     The default setting is 0.
10. (Optional.) Specify the ID of the VLAN to which the probe packets belong.

    vlan { *vlan-id* | **s-vid** *vlan-id* **c-vid** *vlan-id* }

    By default, no VLAN ID is specified.

Configuring threshold monitoring

1. Enter system view.

   system-view
2. Enable the TWAMP Light client and enter its view.

   nqa twamp-light client
3. Create a test session on the TWAMP Light client and enter the client-session view.

   test-session *session-id*
4. Configure a reaction entry. Choose the following tasks as needed:
   - Configure a reaction entry for monitoring the two-way delay.

     reaction *item-number* **checked-element two-way-delay threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

     By default, no reaction entry is configured for monitoring the two-way delay.
   - Configure a reaction entry for monitoring the two-way packet loss.

     reaction *item-number* **checked-element two-way-loss threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

     By default, no reaction entry is configured for monitoring the two-way packet loss.
   - Configure a reaction entry for monitoring the two-way jitter.

reaction *item-number* **checked-element two-way-jitter threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

By default, no reaction entry is configured for monitoring the two-way jitter.

Start the test on the TWAMP Light sender

Restrictions and guidelines

In the TWAMP Light test, a test session is identified by the combination of source IP address, source port number, destination IP address, and destination port number. To ensure the test result, do not specify the same combination for multiple test sessions.

With the **data-fill** command configured, the packet sending interval cannot be 10 or 100 milliseconds.

Procedure

1. Enter system view.

   system-view

2. Enable the TWAMP Light sender and enter its view.

   nqa twamp-light sender

3. Start a TWAMP Light test.

   start test-session *session-id* { **permanent** | **duration** *duration* | **packet-count** *count* } [**tx-interval** { **10** | **100** | **1000** | **30000** }] [**timeout** *timeout*] [[**statistics-interval** *statistics-interval*] **monitor-time** *time*]

Stop the test on the TWAMP Light sender

1. Enter system view.

   system-view

2. Enter the TWAMP Light sender view.

   nqa twamp-light sender

3. Stop the TWAMP Light test.

   stop { **all** | **test-session** *session-id* }

Display and maintenance commands for TWAMP Light

Execute **display** commands in any view on the TWAMP Light responder.

Task	Command
Display test sessions on the TWAMP Light responder.	**display nqa twamp-light responder** [**test-session** *session-id*]

Execute **display** commands in any view and **reset** commands in user view on the TWAMP Light client.

Task	Command
Display test session information on the TWAMP Light client.	**display nqa twamp-light client** [**test-session** *session-id* | **verbose**]
Display test session statistics on the TWAMP Light client, including two-way delay, two-way jitter, and two-way packet loss.	**display nqa twamp-light client statistics** { **two-way-delay** | **two-way-loss** } **test-session** *session-id*
Display the current monitoring results of reaction entries for the TWAMP Light test sessions.	**display nqa twamp-light client test-session reaction counters** [*session-id* [*item-number*]]
Clear TWAMP Light test session statistics.	**reset nqa twamp-light statistics** { **all** | **test-session** *session-id* }

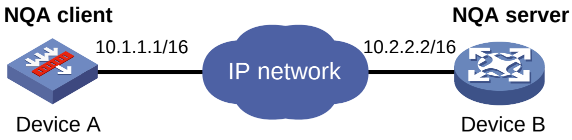
TWAMP Light configuration examples

Example: Configuring TWAMP Light test

Network configuration

As shown in Figure 3, configure a TWAMP Light test to measure the service quality from Device A to Device B.

Figure 3 Network diagram



Procedure

1. Assign IP addresses to interfaces, as shown in Figure 3. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Create test session **1** on the TWAMP Light responder with the destination IP address 10.2.2.2, source IP address 10.1.1.1, destination port 20000, and source port 10000.

   ```
   [DeviceB] nqa twamp-light responder
   [DeviceB-twamp-light-responder] test-session 1 ip destination 10.2.2.2 source
   10.1.1.1 destination-port 20000 source-port 10000
   [DeviceB-twamp-light-responder] quit
   ```
4. Configure Device A:

   # Create test session **1** on the TWAMP Light client.

   ```
   <DeviceA> system-view
   ```

```
[DeviceA] nqa twamp-light client
[DeviceA-nqa-twamp-light-client] test-session 1
```

# Specify 10.1.1.1 as the source IP address for the probe packets.

```
[DeviceA-nqa-twamp-light-client-session1] source ip 10.1.1.1
```

# Specify 10.2.2.2 as the destination IP address for the probe packets.

```
[DeviceA-nqa-twamp-light-client-session1] destination ip 10.2.2.2
```

# Specify 10000 as the source port number for the probe packets.

```
[DeviceA-nqa-twamp-light-client-session1] source port 10000
```

# Specify 20000 as the destination port number for the probe packets.

```
[DeviceA-nqa-twamp-light-client-session1] destination port 20000
```

# Create a TWAMP Light sender and enter its view.

```
<DeviceA> system-view
[DeviceA] nqa twamp-light sender
```

# Start the TWAMP Light test with the packet sending interval, statistics collection interval, and monitoring time set to 100, 10000, and 20000 in milliseconds, respectively.

```
<DeviceA> system-view
[DeviceA] nqa twamp-light sender
[DeviceA-nqa-twamp-light-sender] start test-session 1 permanent tx-interval 100
statistics-interval 10000 monitor-time 20000
[DeviceA-nqa-twamp-light-sender] quit
```

Verifying the configuration

# Display test session information on the TWAMP Light client.

```
[DeviceA-nqa-twamp-light-sender] display nqa twamp-light client
Brief information about all test sessions:
Total sessions: 1
Active sessions: 1
------------------------------------------------------------------------------------
ID    Status     Source IP/Port         Destination IP/Port
1     Active     10.1.1.1/10000         10.2.2.2/20000
```

# Display the test session statistics about the two-way packet loss for the test session **1**.

```
[DeviceA-nqa-twamp-light-sender] display nqa twamp-light client statistics two-way-loss
test-session 1
Latest two-way loss statistics:
    Index      Loss count      Loss ratio      Error count  Error ratio
    11006      5               50.0000%        0            0.0000%
    11007      3               30.0000%        0            0.0000%
    11008      4               40.0000%        0            0.0000%
    11009      8               80.0000%        0            0.0000%
--------------------------------------------------------------------
Average loss count :          5      Average loss ratio :  55.3333%
Maximum loss count :         10      Maximum loss ratio : 100.0000%
Minimum loss count :          1      Minimum loss ratio :  10.0000%
Average error count:          0      Average error ratio:   0.0000%
Maximum error count:          0      Maximum error ratio:   0.0000%
Minimum error count:          0      Minimum error ratio:   0.0000%
```

Configuring Track

About Track

The Track module works between application modules and detection modules. It shields the differences between various detection modules from application modules.

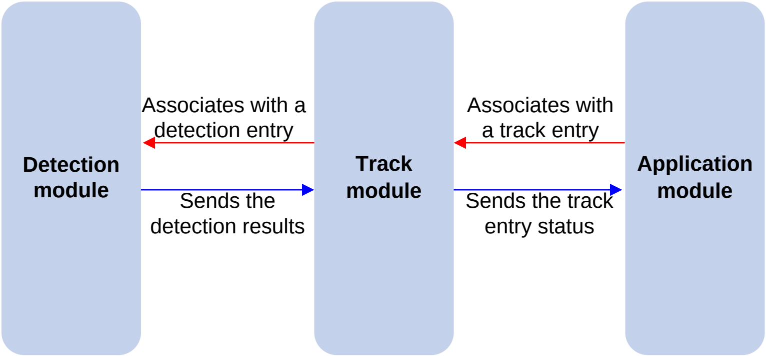
Collaboration mechanism

The Track module collaborates with detection modules and application modules.

As shown in Figure 1, collaboration is enabled when you associate the Track module with a detection module and an application module, and it operates as follows:

1. The detection module probes specific objects such as interface status, link status, network reachability, and network performance, and informs the Track module of detection results.
2. The Track module sends the detection results to the application module.
3. When notified of changes for the tracked object, the application modules can react to avoid communication interruption and network performance degradation.

Figure 1 Collaboration through the Track module



Detection module
Associates with a detection entry
Sends the detection results
Track module
Associates with a track entry
Sends the track entry status
Application module

Collaboration between the Track module and a detection module

The detection module sends the detection result of the tracked object to the Track module. The Track module changes the status of the track entry as follows:

- If the tracked object operates correctly, the state of the track entry is Positive. For example, the track entry state is Positive in one of the following conditions:
  - The target interface is up.
  - The target network is reachable.
- If the tracked object does not operate correctly, the state of the track entry is Negative. For example, the track entry state is Negative in one of the following conditions:
  - The target interface is down.
  - The target network is unreachable.
- If the detection result is invalid, the state of the track entry is NotReady. For example, the track entry state is NotReady if its associated NQA operation does not exist.

Collaboration between the Track module and an application module

The track module reports the track entry status changes to the application module. The application module can then take correct actions to avoid communication interruption and network performance degradation.

Supported detection modules

The following detection modules can be associated with the Track module:

- NQA.
- BFD.
- Interface management.
- Route management.

You can associate a track entry with an object of a detection module, such as the state of an interface or reachability of an IP route. The state of the track entry is determined by the state of the tracked object.

You can also associate a track entry with a list of objects called a tracked list. The state of a tracked list is determined by the states of all objects in the list. The following types of tracked lists are supported:

- **Boolean AND list**—The state of a Boolean AND list is determined by the states of the tracked objects using the Boolean AND operation.
- **Boolean OR list**—The state of a Boolean OR list is determined by the states of the tracked objects using the Boolean OR operation.
- **Percentage threshold list**—The state of a percentage threshold list is determined by comparing the percentage of Positive and Negative objects in the list with the percentage thresholds configured for the list.
- **Weight threshold list**—The state of a weight threshold list is determined by comparing the weight of Positive and Negative objects in the list with the weight thresholds configured for the list.

Supported application modules

The following application modules can be associated with the Track module:

- Static routing.
- PBR.
- Interface backup.
- Redundancy group.
- EAA.
- Security policy.

Restrictions and guidelines: Track configuration

When configuring a track entry for an application module, you can set a notification delay to avoid immediate notification of status changes.

When the delay is not configured and the route convergence is slower than the link state change notification, communication failures occur.

Collaboration application example

The following is an example of collaboration between NQA, Track, and static routing.

Configure a static route with next hop 192.168.0.88 on the device. If the next hop is reachable, the static route is valid. If the next hop becomes unreachable, the static route is invalid. For this purpose, configure NQA-Track-static routing collaboration as follows:

1. Create an NQA operation to monitor the accessibility of IP address 192.168.0.88.
2. Create a track entry and associate it with the NQA operation.
   - When next hop 192.168.0.88 is reachable, NQA sends the result to the Track module. The Track module sets the track entry to Positive state.
   - When the next hop becomes unreachable, NQA sends the result to the Track module. The Track module sets the track entry to Negative state.
3. Associate the track entry with the static route.
   - When the track entry is in Positive state, the static routing module considers the static route to be valid.
   - When the track entry is in Negative state, the static routing module considers the static route to be invalid.

Track tasks at a glance

To implement the collaboration function, establish associations between the Track module and detection modules, and between the Track module and application modules.

To configure the Track module, perform the following tasks:

1. Associating Track with a detection module object
   - Associating Track with NQA
   - Associating Track with BFD
   - Associating Track with interface management
   - Associating Track with route management
2. Associating Track with a tracked list
   - Associating Track with a Boolean list
   - Associating Track with a percentage threshold list
   - Associating Track with a weight threshold list
3. Associating the Track module with an application module
   - Associating Track with static routing
   - Associating Track with PBR
   - Associating Track with interface backup
   - Associating Track with the redundancy group module
   - Associating Track with EAA
   - Associating Track with a security policy rule

Associating Track with a detection module object

Associating Track with NQA

About this task

NQA supports multiple operation types to analyze network performance and service quality. For example, an NQA operation can periodically detect whether a destination is reachable, or whether a TCP connection can be established.

An NQA operation operates as follows when it is associated with a track entry:

- If the consecutive probe failures reach the specified threshold, the NQA module notifies the Track module that the tracked object has malfunctioned. The Track module then sets the track entry to Negative state.

- If the specified threshold is not reached, the NQA module notifies the Track module that the tracked object is operating correctly. The Track module then sets the track entry to Positive state.

For more information about NQA, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

If you associate a track entry with a nonexistent NQA operation or reaction entry, the state of the track entry is NotReady.

Procedure

1. Enter system view.

   `system-view`

2. Create a track entry, associate it with an NQA reaction entry, and enter its view.

   track *track-entry-number* **nqa entry** *admin-name operation-tag* **reaction** *item-number*

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with BFD

About this task

BFD supports the control packet mode and echo packet mode. A track entry can be associated only with the echo-mode BFD session. For more information about BFD, see *Network Management and Monitoring Configuration Guide*.

The associated Track and BFD operate as follows:

- If the BFD detects that the link fails, it informs the Track module of the link failure. The Track module sets the track entry to Negative state.
- If the BFD detects that the link is operating correctly, the Track module sets the track entry to Positive state.

Restrictions and guidelines

When you associate a track entry with BFD, do not configure the virtual IP address of a VRRP group as the local or remote address of the BFD session.

Prerequisites

Before you associate Track with BFD, configure the source IP address of BFD echo packets. For more information, see BFD configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Create a track entry, associate it with a BFD session, and enter its view.

   track *track-entry-number* **bfd echo interface** *interface-type interface-number* **remote ip** *remote-ip-address* **local ip** *local-ip-address*

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with interface management

About this task

The interface management module monitors the link status, physical status, or network-layer protocol status of interfaces. The associated Track and interface management operate as follows:

- When the link status, physical status, or network-layer protocol status of the interface changes to up, the interface management module informs the Track module of the change. The Track module sets the track entry to Positive state.
- When the link status, physical status, or network-layer protocol status of the interface changes to down, the interface management module informs the Track module of the change. The Track module sets the track entry to Negative state.

Procedure

1. Enter system view.

   `system-view`

2. Create a track entry, associate it with an interface, and enter its view.
   - Create a track entry to monitor the link status of an interface.

     track *track-entry-number* **interface** *interface-type interface-number*
   - Create a track entry to monitor the physical status of an interface.

     track *track-entry-number* **interface** *interface-type interface-number* **physical**
   - Create a track entry to monitor the network layer protocol status of an interface.

     track *track-entry-number* **interface** *interface-type interface-number* **protocol** { **ipv4** | **ipv6** }

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with route management

About this task

The route management module monitors route entry changes in the routing table. The associated Track and route management operate as follows:

- When a monitored route entry is found in the routing table, the route management module informs the Track module. The Track module sets the track entry to Positive state.
- When a monitored route entry is removed from the routing table, the route management module informs the Track module of the change. The Track module sets the track entry to Negative state.

Procedure

1. Enter system view.

   `system-view`

2. Create a track entry, associate it with an IP route, and enter its view.

track *track-entry-number* **ip route** [**vpn-instance** *vpn-instance-name*] **ip-address** { *mask-length* | *mask* } **reachability**

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with a tracked list

Associating Track with a Boolean list

About this task

A Boolean list is a list of tracked objects based on a Boolean logic. It can be further divided into the following types:

- **Boolean AND list**—A Boolean AND list is set to the Positive state only when all objects are in Positive state. If one or more objects are in Negative state, the tracked list is set to the Negative state.
- **Boolean OR list**—A Boolean OR list is set to the Positive state if any object is in Positive state. If all objects are in Negative state, the tracked list is set to the Negative state.

Procedure

1. Enter system view.

   system-view

2. Create a track entry.

   See "Associating Track with a detection module object."

   Create a track entry before you add it as a tracked object to a tracked list.

   A minimum of one track entry must be created.

3. Create a Boolean tracked list and enter its view.

   track *track-entry-number* **list boolean** { **and** | **or** }

4. Add the track entry as an object to the tracked list.

   object *track-entry-number* [**not**]

   Repeat this step to add all interested objects to the tracked list.

5. (Optional.) Set the delay for notifying the application module of tracked list state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the tracked list state changes.

Associating Track with a percentage threshold list

About this task

A percentage threshold list uses a percentage threshold to measure the state of the list.

- If the percentage of Positive objects is equal to or above the positive state threshold, the list is set to the Positive state.
- If the percentage of Positive objects is equal to or below the negative state threshold, the list is set to the Negative state.
- The state of a percentage threshold list remains unchanged if the percentage of Positive objects is below the positive state threshold and above the negative state threshold.

Procedure

1. Enter system view.

   system-view

2. Create a track entry.

   See "Associating Track with a detection module object."

   Create a track entry before you add it as an tracked object to a tracked list.

   A minimum of one track entry must be created.

3. Create a percentage threshold list and enter its view.

   track *track-entry-number* **list threshold percentage**

4. Add the track entry as an object to the tracked list.

   object *track-entry-number*

   Repeat this step to add all interested objects to the tracked list.

5. Configure the threshold values used to determine the state of the percentage threshold list.

   threshold percentage { **negative** *negative-threshold* | **positive** *positive-threshold* } *

   By default, the negative state threshold is 0% and the positive state threshold is 1%.

6. (Optional.) Set the delay for notifying the application module of tracked list state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the tracked list state changes.

Associating Track with a weight threshold list

About this task

A weight threshold list uses a weight threshold to measure the state of the list.

- If the total weight of Positive objects is equal to or above the positive state threshold, the list is set to the Positive state.
- If the total weight of Positive objects is equal to or below the negative state threshold, the list is set to the Negative state.
- The state of a weight threshold list remains unchanged if the total weight of Positive objects is below the positive state threshold and above the negative state threshold.

Procedure

1. Enter system view.

   system-view

2. Create a track entry.

   See "Associating Track with a detection module object."

   Create a track entry before you add it as an tracked object to a tracked list.

   A minimum of one track entry must be created.

3. Create a weight threshold list and enter its view.

   track *track-entry-number* **list threshold weight**

4. Add the track entry as an object to the tracked list.

   object *track-entry-number* [**weight** *weight*]

   Repeat this step to add all interested objects to the tracked list.

5. Configure the threshold values used to determine the state of the weight threshold list.

threshold weight { **negative** *negative-threshold* | **positive** *positive-threshold* } *

By default, the negative state threshold is 0 and the positive state threshold is 1.

6. (Optional.) Set the delay for notifying the application module of tracked list state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the tracked list state changes.

Associating the Track module with an application module

Before you associate the Track module with an application module, make sure the associated track entry has been created.

Prerequisites for associating the Track module with an application module

Create a track entry first before you associate it with an application module.

An application module might obtain incorrect track entry status information if the associated track entry does not exist.

Associating Track with static routing

About this task

A static route is a manually configured route to route packets. For more information about static route configuration, see *Layer 3—IP Routing Configuration Guide*.

Static routes cannot adapt to network topology changes. Link failures or network topological changes can make the routes unreachable and cause communication interruption.

To resolve this problem, configure another route to back up the static route. When the static route is reachable, packets are forwarded through the static route. When the static route is unreachable, packets are forwarded through the backup route.

To check the accessibility of a static route in real time, associate the Track module with the static route.

If you specify the next hop but not the output interface when configuring a static route, you can configure the static routing-Track-detection module collaboration. This collaboration enables you to verify the accessibility of the static route based on the track entry state.

- If the track entry is in Positive state, the following conditions exist:
  - The next hop of the static route is reachable.
  - The configured static route is valid.
- If the track entry is in Negative state, the following conditions exist:
  - The next hop of the static route is not reachable.
  - The configured static route is invalid.
- If the track entry is in NotReady state, the following conditions exist:
  - The accessibility of the next hop of the static route is unknown.
  - The static route is valid.

Restrictions and guidelines

In static routing-Track-NQA collaboration, you must configure the same VPN instance name for the NQA operation and the next hop of the static route. Otherwise, the accessibility detection cannot operate correctly.

If a static route needs route recursion, the associated track entry must monitor the next hop of the recursive route. The next hop of the static route cannot be monitored. Otherwise, a valid route might be considered invalid.

Associating Track with an IPv4 static route

1. Enter system view.

   ```
   system-view
   ```

2. Associate an IPv4 static route with a track entry to check the accessibility of the next hop.

   Public network:

   ```
   ip route-static { dest-address { mask-length | mask } | group group-name }
   { interface-type interface-number [ next-hop-address ] track
   track-entry-number | next-hop-address track track-entry-number |
   vpn-instance d-vpn-instance-name next-hop-address track
   track-entry-number } [ preference preference ] [ tag tag-value ]
   [ description text ]
   ```

   VPN:

   ```
   ip route-static vpn-instance s-vpn-instance-name { dest-address
   { mask-length | mask } | group group-name } { interface-type
   interface-number [ next-hop-address ] track track-entry-number |
   next-hop-address [ public ] track track-entry-number | vpn-instance
   d-vpn-instance-name next-hop-address track track-entry-number }
   [ preference preference ] [ tag tag-value ] [ description text ]
   ```

   By default, Track is not associated with any IPv4 static routes.

Associating Track with an IPv6 static route

1. Enter system view.

   ```
   system-view
   ```

2. Associate an IPv6 static route with a track entry to check the accessibility of the next hop.

   Public network:

   ```
   ipv6 route-static ipv6-address prefix-length { interface-type
   interface-number [ next-hop-address ] track track-entry-number |
   [ vpn-instance d-vpn-instance-name ] next-hop-address track
   track-entry-number } [ preference preference ] [ tag tag-value ]
   [ description text ]
   ```

   VPN:

   ```
   ipv6 route-static vpn-instance s-vpn-instance-name ipv6-address
   prefix-length { interface-type interface-number [ next-hop-address ]
   track track-entry-number | vpn-instance d-vpn-instance-name
   next-hop-address track track-entry-number } [ preference preference ]
   [ tag tag-value ] [ description text ]
   ```

   By default, Track is not associated with any IPv6 static routes.

Associating Track with PBR

About this task

PBR uses user-defined policies to route packets. You can specify parameters in a PBR policy to guide the forwarding of the packets that match specific criteria. For more information about PBR, see *Layer 3—IP Routing Configuration Guide*.

PBR cannot detect the availability of any action taken on packets. When an action is not available, packets processed by the action might be discarded. For example, if the output interface specified for PBR fails, PBR cannot detect the failure, and continues to forward matching packets out of the interface.

To enable PBR to detect topology changes and improve the flexibility of the PBR application, configure Track-PBR-detection module collaboration.

After you associate a track entry with an apply clause, the detection module associated with the track entry sends Track the detection result of the availability of the tracked object.

- The Positive state of the track entry indicates that the object is available, and the apply clause is valid.
- The Negative state of the track entry indicates that the object is not available, and the apply clause is invalid.
- The NotReady state of the track entry indicates that the apply clause is valid.

The following objects can be associated with a track entry:

- Output interface.
- Next hop.
- Default output interface.
- Default next hop.

Prerequisites for Track association with PBR

Before you associate Track with PBR, create a policy node, and set the match criteria.

Associating Track with PBR

1. Enter system view.

   system-view

2. Create a policy node and enter its view.

   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Set match criteria. Choose the options to configure as needed:

   - Set an ACL match criterion.

     if-match acl { *acl-number* | **name** *acl-name* }

     By default, no ACL match criterion is set.

     The ACL match criterion cannot match Layer 2 information.

   - Set a packet length match criterion.

     if-match packet-length *min-len max-len*

     By default, no packet length match criterion is set.

4. Set actions and associate the policy node with a track entry. Choose the options to configure as needed:

   - Set the output interface.

     apply output-interface { *interface-type interface-number* [**track** *track-entry-number*] }&<1-4>

     By default, no output interface is set.

- Set the next hop.

  ```
  apply next-hop [ vpn-instance vpn-instance-name | inbound-vpn ]
  { ip-address [ direct ] [ track track-entry-number ] [ weight
  weight-value ] }&<1-4>
  ```

  By default, no next hop is set.

- Set the default output interface.

  ```
  apply default-output-interface { interface-type interface-number
  [ track track-entry-number ] }&<1-4>
  ```

  By default, no default output interface is set.

- Set the default next hop.

  ```
  apply default-next-hop [ vpn-instance vpn-instance-name |
  inbound-vpn ] { ip-address [ direct ] [ track
  track-entry-number ] }&<1-4>
  ```

  By default, no default next hop is set.

Associating Track with IPv6 PBR

1. Enter system view.

   ```
   system-view
   ```

2. Create an IPv6 policy node and enter its view.

   ```
   ipv6 policy-based-route policy-name [ deny | permit ] node node-number
   ```

3. Set match criteria. Choose the options to configure as needed:

   - Set an ACL match criterion.

     ```
     if-match acl { ipv6-acl-number | name ipv6-acl-name }
     ```

     By default, no ACL match criterion is set.

     The ACL match criterion cannot match Layer 2 information.

   - Set an IPv6 packet length match criterion.

     ```
     if-match packet-length min-len max-len
     ```

     By default, no packet length match criterion is set.

4. Set actions and associate the policy node with a track entry. Choose the options to configure as needed:

   - Set the output interface.

     ```
     apply output-interface { interface-type interface-number [ track
     track-entry-number ] }&<1-4>
     ```

     By default, no output interface is set.

   - Set the next hop.

     ```
     apply next-hop [ vpn-instance vpn-instance-name | inbound-vpn ]
     { ipv6-address [ direct ] [ track track-entry-number ] [ weight
     weight-value ] } &<1-4>
     ```

     By default, no next hop is set.

   - Set the default output interface.

     ```
     apply default-output-interface { interface-type interface-number
     [ track track-entry-number ] }&<1-4>
     ```

     By default, no default output interface is set.

   - Set the default next hop.

     ```
     apply default-next-hop [ vpn-instance vpn-instance-name |
     inbound-vpn ] { ipv6-address [ direct ] [ track
     track-entry-number ] }&<1-4>
     ```

By default, no default next hop is set.

Associating Track with interface backup

About this task

To enable a standby interface to detect the status of the active interface, you can associate the standby interface with a track entry.

- If the track entry is in Positive state, the following conditions exist:
  - The link where the active interface resides operates correctly.
  - The standby interfaces stay in backup state.
- If the track entry is in Negative state, the following conditions exist:
  - The link where the active interface resides has failed.
  - A standby interface changes to the active interface for data transmission.
- If the track entry is in always NotReady state, the following conditions exist:
  - The association does not take effect.
  - Each interface keeps its original forwarding state.

  When the track entry turns to NotReady from other state, a standby interface becomes the active interface.

For more information about configuring interface backup, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Associate the interface with a track entry.

   `backup track` *`track-entry-number`*

   By default, no track entry is associated with an interface.

   You can associate an interface with only one track entry.

   If you execute this command multiple times, the most recent configuration takes effect.

Associating Track with the redundancy group module

About this task

The redundancy group can fast detect the link and interface failures after you associate it with Track.

Track changes the track entry state based on the monitoring result of a detection module, and notifies the track entry state change to the redundancy group.

- If the track entry state changes to Positive, the system increases the weight value of the redundancy group node. When the value of the redundancy group is greater than 0, the node can operate correctly.
- If the track entry state changes to Negative or NotReady, the system reduces the weight value of redundancy group node. If the value of the redundancy group is less than 0, the node cannot operate correctly. A node switchover occurs. The members (including Reth interfaces) on the other node take over.

For more information about redundancy groups, see *Virtual Technologies Configuration Guide*.

Restrictions and guidelines

To associate Track with a redundancy group configured with automatic node switchover, you must specify the **interface** *interface-type interface-number* option in the **track** command. When the specified interface fails, it will not be shut down by the Reth module.

Procedure

1. Enter system view.

   system-view

2. Create a redundancy group and enter its view.

   redundancy group *group-name*

3. Create a redundancy group node and enter its view.

   node *node-id*

4. Associate Track with the redundancy group.

   track *track-entry-number* [**reduced** *weight-reduced*] [**interface** *interface-type interface-number*]

   By default, no track entry is associated with a redundancy group.

Associating Track with EAA

About this task

You can configure EAA track event monitor policies to monitor the positive-to-negative or negative-to-positive state changes of track entries.

- If you specify only one track entry for a policy, EAA triggers the policy when it detects the specified state change on the track entry.
- If you specify multiple track entries for a policy, EAA triggers the policy when it detects the specified state change on the last monitored track entry. For example, if you configure a policy to monitor the positive-to-negative state change of multiple track entries, EAA triggers the policy when the last positive track entry monitored by the policy is changed to the Negative state.

You can set a suppression time for a track event monitor policy. The timer starts when the policy is triggered. The system does not process messages that report the monitored track event until the timer times out.

For more information about EAA, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create a CLI-defined monitor policy and enter its view, or enter the view of an existing CLI-defined monitor policy.

   rtm cli-policy *policy-name*

3. Configure a track event.

   event track *track-entry-number-list* **state** { **negative** | **positive** } [**suppress-time** *suppress-time*]

   By default, a monitor policy does not monitor any track event.

Associating Track with a security policy rule

About this task

Perform this task to enable the collaboration between Track and a security policy rule. The collaboration operates as follows:

- If the rule is associated with the Negative state of a track entry, the device takes the following actions:
  - Sets the rule state to Active if the track entry is in Negative state.
  - Sets the rule state to Inactive if the track entry is in Positive state.
- If the rule is associated with the Positive state of a track entry, the device takes the following actions:
  - Sets the rule state to Active if the track entry is in Positive state.
  - Sets the rule state to Inactive if the track entry is in Negative state.

Procedure

1. Enter system view.
   system-view
2. Enter IPv4 or IPv6 security policy view.
   security-policy { **ip** | **ipv6** }
3. Enter security policy rule view.
   rule { *rule-id* | **name** *name* } *
4. Associate the rule with a track entry.
   track { **negative** | **positive** } *track-entry-number*
   By default, no track entry is associated with a security policy rule.

Display and maintenance commands for Track

Execute **display** commands in any view.

Task	Command
Display information about track entries.	**display track** { *track-entry-number* | **all** [**negative** | **positive**] } [**brief**]

Track configuration examples

Example: Configuring static routing-Track-NQA collaboration

Network configuration

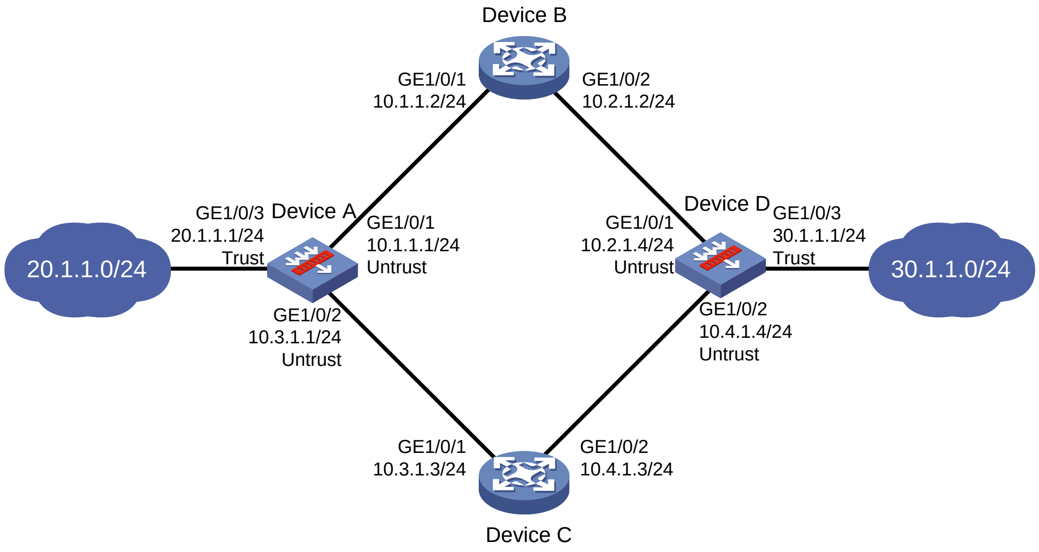
As shown in Figure 2:

- Device A is the default gateway of the hosts in network 20.1.1.0/24.
- Device D is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-NQA collaboration on Device A and Device D as follows:

- On Device A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Device B. This route is the master route. The static route to 30.1.1.0/24 with next hop Device C acts as the backup route. When the master route is unavailable, the backup route takes effect.
- On Device D, assign a higher priority to the static route to 20.1.1.0/24 with next hop Device B. This route is the master route. The static route to 20.1.1.0/24 with next hop Device C acts as the backup route. When the master route is unavailable, the backup route takes effect.

Figure 2 Network diagram



Configuring Device A

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 10.1.1.1 255.255.255.0
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing:

   # Configure a main static route to 30.1.1.0/24 with next hop 10.1.1.2 and default priority 60, and associate the static route with track entry 1.

   ```
   [DeviceA] ip route-static 30.1.1.0 24 10.1.1.2 track 1
   ```

   # Configure a backup static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [DeviceA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Configure a static route to 10.2.1.4/24 with next hop 10.1.1.2 and default priority 60. This static route will be used in an NQA operation.

   ```
   [DeviceA] ip route-static 10.2.1.4 24 10.1.1.2
   ```

3. Add interfaces to security zones.

   ```
   [DeviceA] security-zone name untrust
   [DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
   [DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/2
   [DeviceA-security-zone-Untrust] quit
   [DeviceA] security-zone name trust
   [DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/3
   [DeviceA-security-zone-Trust] quit
   ```

4. Configure a security policy:

   # Configure a rule named **trust-untrust** to permit packets from network 20.1.1.0/24 to network 30.1.1.0/24.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-1-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-1-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-1-trust-untrust] source-ip-subnet 20.1.1.0 24
[DeviceA-security-policy-ip-1-trust-untrust] destination-ip-subnet 30.1.1.0 24
[DeviceA-security-policy-ip-1-trust-untrust] action pass
[DeviceA-security-policy-ip-1-trust-untrust] quit
```

   # Configure a rule named **untrust-trust** to permit packets from network 30.1.1.0/24 to network 20.1.1.0/24.

```
[DeviceA-security-policy-ip] rule name untrust-trust
[DeviceA-security-policy-ip-2-untrust-trust] source-zone untrust
[DeviceA-security-policy-ip-2-untrust-trust] destination-zone trust
[DeviceA-security-policy-ip-2-untrust-trust] source-ip-subnet 30.1.1.0 24
[DeviceA-security-policy-ip-2-untrust-trust] destination-ip-subnet 20.1.1.0 24
[DeviceA-security-policy-ip-2-untrust-trust] action pass
[DeviceA-security-policy-ip-2-untrust-trust] quit
```

   # Configure a rule named **nqalocalout** to allow Device A to send NQA probe packets to Device D.

```
[DeviceA-security-policy-ip] rule name nqalocalout
[DeviceA-security-policy-ip-3-nqalocalout] source-zone local
[DeviceA-security-policy-ip-3-nqalocalout] destination-zone untrust
[DeviceA-security-policy-ip-2-nqalocalout] service ping
[DeviceA-security-policy-ip-3-nqalocalout] action pass
[DeviceA-security-policy-ip-3-nqalocalout] quit
```

   # Configure a rule named **nqalocalin** to allow Device A to receive the NQA probe packets from Device D.

```
[DeviceA-security-policy-ip] rule name nqalocalin
[DeviceA-security-policy-ip-4-nqalocalin] source-zone untrust
[DeviceA-security-policy-ip-4-nqalocalin] destination-zone local
[DeviceA-security-policy-ip-4-nqalocalin] service ping
[DeviceA-security-policy-ip-4-nqalocalin] action pass
[DeviceA-security-policy-ip-4-nqalocalin] quit
[DeviceA-security-policy-ip] quit
```

5. Create an NQA operation to test connectivity of path Device A—Device B—Device D.

```
[DeviceA] nqa entry admin test
[DeviceA-nqa-admin-test] type icmp-echo
[DeviceA-nqa-admin-test-icmp-echo] destination ip 10.2.1.4
[DeviceA-nqa-admin-test-icmp-echo] next-hop ip 10.1.1.2
[DeviceA-nqa-admin-test-icmp-echo] frequency 100
[DeviceA-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
threshold-type consecutive 5 action-type trigger-only
[DeviceA-nqa-admin-test-icmp-echo] quit
[DeviceA] nqa schedule admin test start-time now lifetime forever
```

6. Associate track entry 1 with reaction entry 1 of the NQA operation.

```
[DeviceA] track 1 nqa entry admin test reaction 1
```

```
[DeviceA-track-1] quit
```

Configuring Device B

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceB> system-view
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] ip address 10.1.1.2 255.255.255.0
   [DeviceB-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing:

   # Configure a static route to 30.1.1.0/24 with next hop 10.2.1.4.

   ```
   [DeviceB] ip route-static 30.1.1.0 24 10.2.1.4
   ```

   # Configure a static route to 20.1.1.0/24 with next hop 10.1.1.1.

   ```
   [DeviceB] ip route-static 20.1.1.0 24 10.1.1.1
   ```

Configuring Device C

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceC> system-view
   [DeviceC] interface gigabitethernet 1/0/1
   [DeviceC-GigabitEthernet1/0/1] ip address 10.3.1.3 255.255.255.0
   [DeviceC-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing:

   # Configure a static route to 30.1.1.0/24 with next hop 10.4.1.4.

   ```
   [DeviceC] ip route-static 30.1.1.0 24 10.4.1.4
   ```

   # Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

   ```
   [DeviceC] ip route-static 20.1.1.0 24 10.3.1.1
   ```

Configuring Device D

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceD> system-view
   [DeviceD] interface gigabitethernet 1/0/1
   [DeviceD-GigabitEthernet1/0/1] ip address 10.2.1.4 255.255.255.0
   [DeviceD-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing:

   # Configure a main static route to 20.1.1.0/24 with next hop 10.2.1.2 and default priority 60, and associate the static route with track entry 1.

   ```
   [DeviceD] ip route-static 20.1.1.0 24 10.2.1.2 track 1
   ```

   # Configure a backup static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

   ```
   [DeviceD] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
   ```

   # Configure a static route to 10.1.1.1/24 with next hop 10.2.1.2 and default priority 60. This static route will be used in an NQA operation.

   ```
   [DeviceD] ip route-static 10.1.1.1 24 10.2.1.2
   ```

3. Add interfaces to security zones.

```
[DeviceD] security-zone name untrust
[DeviceD-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceD-security-zone-Untrust] import interface gigabitethernet 1/0/2
[DeviceD-security-zone-Untrust] quit
[DeviceD] security-zone name trust
[DeviceD-security-zone-Trust] import interface gigabitethernet 1/0/3
[DeviceD-security-zone-Trust] quit
```

4. Configure a security policy:

   # Configure a rule named **trust-untrust** to permit packets from network 30.1.1.0/24 to network 20.1.1.0/24.

```
[DeviceD] security-policy ip
[DeviceD-security-policy-ip] rule name trust-untrust
[DeviceD-security-policy-ip-1-trust-untrust] source-zone trust
[DeviceD-security-policy-ip-1-trust-untrust] destination-zone untrust
[DeviceD-security-policy-ip-1-trust-untrust] source-ip-subnet 30.1.1.0 24
[DeviceD-security-policy-ip-1-trust-untrust] destination-ip-subnet 20.1.1.0 24
[DeviceD-security-policy-ip-1-trust-untrust] action pass
[DeviceD-security-policy-ip-1-trust-untrust] quit
```

   # Configure a rule named **untrust-trust** to permit packets from network 20.1.1.0/24 to network 30.1.1.0/24.

```
[DeviceD-security-policy-ip] rule name untrust-trust
[DeviceD-security-policy-ip-2-untrust-trust] source-zone untrust
[DeviceD-security-policy-ip-2-untrust-trust] destination-zone trust
[DeviceD-security-policy-ip-2-untrust-trust] source-ip-subnet 20.1.1.0 24
[DeviceD-security-policy-ip-2-untrust-trust] destination-ip-subnet 30.1.1.0 24
[DeviceD-security-policy-ip-2-untrust-trust] action pass
[DeviceD-security-policy-ip-2-untrust-trust] quit
```

   # Configure a rule named **nqalocalout** to allow Device D to send NQA probe packets to Device A.

```
[DeviceD-security-policy-ip] rule name nqalocalout
[DeviceD-security-policy-ip-3-nqalocalout] source-zone local
[DeviceD-security-policy-ip-3-nqalocalout] destination-zone untrust
[DeviceD-security-policy-ip-3-nqalocalout] service ping
[DeviceD-security-policy-ip-3-nqalocalout] action pass
[DeviceD-security-policy-ip-3-nqalocalout] quit
```

   # Configure a rule named **nqalocalin** to allow Device D to receive the NQA probe packets from Device A.

```
[DeviceD-security-policy-ip] rule name nqalocalin
[DeviceD-security-policy-ip-4-nqalocalin] source-zone untrust
[DeviceD-security-policy-ip-4-nqalocalin] destination-zone local
[DeviceD-security-policy-ip-4-nqalocalin] service ping
[DeviceD-security-policy-ip-4-nqalocalin] action pass
[DeviceD-security-policy-ip-4-nqalocalin] quit
[DeviceD-security-policy-ip] quit
```

5. Create an NQA operation to test connectivity of path Device D—Device B—Device A.

```
[DeviceD] nqa entry admin test
[DeviceD-nqa-admin-test] type icmp-echo
[DeviceD-nqa-admin-test-icmp-echo] destination ip 10.1.1.1
[DeviceD-nqa-admin-test-icmp-echo] next-hop ip 10.2.1.2
```

```
[DeviceD-nqa-admin-test-icmp-echo] frequency 100
[DeviceD-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
threshold-type consecutive 5 action-type trigger-only
[DeviceD-nqa-admin-test-icmp-echo] quit
[DeviceD] nqa schedule admin test start-time now lifetime forever
```

6. Associate track entry 1 with reaction entry 1 of the NQA operation.

```
[DeviceD] track 1 nqa entry admin test reaction 1
[DeviceD-track-1] quit
```

Verifying the configuration

# Display track entry information on Device A.

```
[DeviceA] display track all
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: NQA
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test
    Reaction: 1
    Remote IP/URL: 10.2.1.4
    Local IP:--
    Interface:--
```

The output shows that the status of track entry 1 is Positive, indicating that the NQA operation has succeeded and the master route is available.

# Display the routing table of Device A.

```
[DeviceA] display ip routing-table

Destinations : 10       Routes : 10

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.1.1.0/24         Direct 0    0            10.1.1.1        GE1/0/1
10.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
10.2.1.0/24         Static 60   0            10.1.1.2        GE1/0/1
10.3.1.0/24         Direct 0    0            10.3.1.1        GE1/0/2
10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        GE1/0/3
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 60   0            10.1.1.2        GE1/0/1
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Device A forwards packets to 30.1.1.0/24 through Device B.

# Remove the IP address of GigabitEthernet 1/0/1 on Device B.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] undo ip address
```

# Display information about the track entry on Device A.

```
[DeviceA] display track all
```

```
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: NQA
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test
    Reaction: 1
    Remote IP/URL: 10.2.1.4
    Local IP:--
    Interface:--
```

The output shows that the status of the track entry is Negative, indicating that the NQA operation has failed and the master route is unavailable.

# Display the routing table of Device A.

```
[DeviceA] display ip routing-table

Destinations : 10       Routes : 10

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.1.1.0/24         Direct 0    0            10.1.1.1        GE1/0/1
10.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
10.2.1.0/24         Static 60   0            10.1.1.2        GE1/0/1
10.3.1.0/24         Direct 0    0            10.3.1.1        GE1/0/2
10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        GE1/0/3
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 80   0            10.3.1.3        GE1/0/2
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Device A forwards packets to 30.1.1.0/24 through Device C. The backup static route has taken effect.

# Verify that hosts in 20.1.1.0/24 can communicate with the hosts in 30.1.1.0/24 when the master route fails.

```
[DeviceA] ping -a 20.1.1.1 30.1.1.1
Ping 30.1.1.1: 56  data bytes, press CTRL_C to break

Reply from 20.1.1.1: bytes=56 Sequence=5 ttl=254 time=1 ms

--- Ping statistics for 20.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

Example: Configuring static routing-Track-BFD collaboration

Network configuration

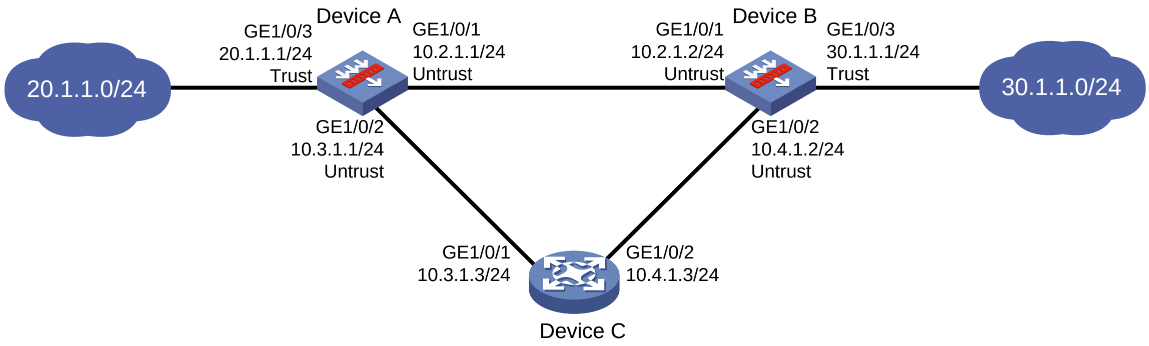
As shown in Figure 3:

- Device A is the default gateway of the hosts in network 20.1.1.0/24.
- Device B is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-BFD collaboration on Device A and Device B as follows:

- On Device A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Device B. This route is the master route. The static route to 30.1.1.0/24 with next hop Device C acts as the backup route. When the master route is unavailable, BFD can quickly detect the route failure to make the backup route take effect.
- On Device B, assign a higher priority to the static route to 20.1.1.0/24 with next hop Device A. This route is the master route. The static route to 20.1.1.0/24 with next hop Device C acts as the backup route. When the master route is unavailable, BFD can quickly detect the route failure to make the backup route take effect.

Figure 3 Network diagram



Configuring Device A

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 10.2.1.1 255.255.255.0
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing:

# Configure a main static route to 30.1.1.0/24 with next hop 10.2.1.2 and default priority 60, and associate the static route with track entry 1.

```
[DeviceA] ip route-static 30.1.1.0 24 10.2.1.2 track 1
```

# Configure a backup static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

```
[DeviceA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
```

3. Add interfaces to security zones.

```
[DeviceA] security-zone name untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/2
[DeviceA-security-zone-Untrust] quit
[DeviceA] security-zone name trust
[DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/3
[DeviceA-security-zone-Trust] quit
```

4. Configure a security policy:

# Configure a rule named **trust-untrust** to permit packets from network 20.1.1.0/24 to network 30.1.1.0/24.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-1-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-1-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-1-trust-untrust] source-ip-subnet 20.1.1.0 24
[DeviceA-security-policy-ip-1-trust-untrust] destination-ip-subnet 30.1.1.0 24
[DeviceA-security-policy-ip-1-trust-untrust] action pass
[DeviceA-security-policy-ip-1-trust-untrust] quit
```

# Configure a rule named **untrust-trust** to permit packets from network 30.1.1.0/24 to network 20.1.1.0/24.

```
[DeviceA-security-policy-ip] rule name untrust-trust
[DeviceA-security-policy-ip-2-untrust-trust] source-zone untrust
[DeviceA-security-policy-ip-2-untrust-trust] destination-zone trust
[DeviceA-security-policy-ip-2-untrust-trust] source-ip-subnet 30.1.1.0 24
[DeviceA-security-policy-ip-2-untrust-trust] destination-ip-subnet 20.1.1.0 24
[DeviceA-security-policy-ip-2-untrust-trust] action pass
[DeviceA-security-policy-ip-2-untrust-trust] quit
```

# Configure a rule named **bfdlocalout** to allow Device A to send BFD echo packets to Device B.

```
[DeviceA-security-policy-ip] rule name bfdlocalout
[DeviceA-security-policy-ip-3-bfdlocalout] source-zone local
[DeviceA-security-policy-ip-3-bfdlocalout] destination-zone untrust
[DeviceA-security-policy-ip-2-bfdlocalout] service bfd-echo
[DeviceA-security-policy-ip-3-bfdlocalout] action pass
[DeviceA-security-policy-ip-3-bfdlocalout] quit
```

# Configure a rule named **bfdlocalin** to allow Device A to receive BFD echo packets.

```
[DeviceA-security-policy-ip] rule name bfdlocalin
[DeviceA-security-policy-ip-4-bfdlocalin] source-zone untrust
[DeviceA-security-policy-ip-4-bfdlocalin] destination-zone local
[DeviceA-security-policy-ip-2-bfdlocalin] service bfd-echo
[DeviceA-security-policy-ip-4-bfdlocalin] action pass
[DeviceA-security-policy-ip-4-bfdlocalin] quit
```

# Configure a rule named **untrust-untrust** to allow Device A to respond to the BFD echo packets from Device B.

```
[DeviceA-security-policy-ip] rule name untrust-untrust
[DeviceA-security-policy-ip-5-untrust-untrust] source-zone untrust
[DeviceA-security-policy-ip-5-untrust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-5-untrust-untrust] source-ip-host 1.1.1.1
[DeviceA-security-policy-ip-5-untrust-untrust] destination-ip-host 10.2.1.2
[DeviceA-security-policy-ip-5-untrust-untrust] action pass
[DeviceA-security-policy-ip-5-untrust-untrust] quit
```

# Configure a rule named **pinglocalout** to allow Device A to send ping packets to Device B.

```
[DeviceA-security-policy-ip] rule name pinglocalout
[DeviceA-security-policy-ip-6-pinglocalout] source-zone local
[DeviceA-security-policy-ip-6-pinglocalout] destination-zone untrust
[DeviceA-security-policy-ip-6-pinglocalout] service ping
[DeviceA-security-policy-ip-6-pinglocalout] action pass
[DeviceA-security-policy-ip-6-pinglocalout] quit
```

# Configure a rule named **pinglocalin** to allow Device A to respond to the ping packets from Device B.

```
[DeviceA-security-policy-ip] rule name pinglocalin
[DeviceA-security-policy-ip-7-pinglocalin] source-zone untrust
[DeviceA-security-policy-ip-7-pinglocalin] destination-zone local
[DeviceA-security-policy-ip-7-pinglocalin] service ping
[DeviceA-security-policy-ip-7-pinglocalin] action pass
[DeviceA-security-policy-ip-7-pinglocalin] quit
[DeviceA-security-policy-ip] quit
```

5. Specify 10.10.10.10 as the source address for BFD echo packets.

```
[DeviceA] bfd echo-source-ip 10.10.10.10
```

6. Configure track entry 1, and associate it with the BFD session to verify the connectivity between Device A and Device B.

```
[DeviceA] track 1 bfd echo interface gigabitethernet 1/0/1 remote ip 10.2.1.2 local
ip 10.2.1.1
[DeviceA-track-1] quit
```

Configuring Device B

1. Assign IP addresses to interfaces:

# Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 10.2.1.2 255.255.255.0
[DeviceB-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing:

# Configure a main static route to 20.1.1.0/24 with next hop 10.2.1.1 and default priority 60, and associate the static route with track entry 1.

```
[DeviceB] ip route-static 20.1.1.0 24 10.2.1.1 track 1
```

# Configure a backup static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

```
[DeviceB] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
```

3. Add interfaces to security zones.

```
[DeviceB] security-zone name untrust
```

```
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/3
[DeviceB-security-zone-Trust] quit
```

4. Configure a security policy:

# Configure a rule named **trust-untrust** to permit packets from network 30.1.1.0/24 to network 20.1.1.0/24.

```
[DeviceB] security-policy ip
[DeviceB-security-policy-ip] rule name trust-untrust
[DeviceB-security-policy-ip-1-trust-untrust] source-zone trust
[DeviceB-security-policy-ip-1-trust-untrust] destination-zone untrust
[DeviceB-security-policy-ip-1-trust-untrust] source-ip-subnet 30.1.1.0 24
[DeviceB-security-policy-ip-1-trust-untrust] destination-ip-subnet 20.1.1.0 24
[DeviceB-security-policy-ip-1-trust-untrust] action pass
[DeviceB-security-policy-ip-1-trust-untrust] quit
```

# Configure a rule named **untrust-trust** to permit packets from network 20.1.1.0/24 to network 30.1.1.0/24.

```
[DeviceB-security-policy-ip] rule name untrust-trust
[DeviceB-security-policy-ip-2-untrust-trust] source-zone untrust
[DeviceB-security-policy-ip-2-untrust-trust] destination-zone trust
[DeviceB-security-policy-ip-2-untrust-trust] source-ip-subnet 20.1.1.0 24
[DeviceB-security-policy-ip-2-untrust-trust] destination-ip-subnet 30.1.1.0 24
[DeviceB-security-policy-ip-2-untrust-trust] action pass
[DeviceB-security-policy-ip-2-untrust-trust] quit
```

# Configure a rule named **bfdlocalout** to allow Device B to send BFD echo packets to Device A.

```
[DeviceB-security-policy-ip] rule name bfdlocalout
[DeviceB-security-policy-ip-3-bfdlocalout] source-zone local
[DeviceB-security-policy-ip-3-bfdlocalout] destination-zone untrust
[DeviceB-security-policy-ip-3-bfdlocalout] service bfd-echo
[DeviceB-security-policy-ip-3-bfdlocalout] action pass
[DeviceB-security-policy-ip-3-bfdlocalout] quit
```

# Configure a rule named **bfdlocalin** to allow Device B to receive BFD echo packets.

```
[DeviceB-security-policy-ip] rule name bfdlocalin
[DeviceB-security-policy-ip-4-bfdlocalin] source-zone untrust
[DeviceB-security-policy-ip-4-bfdlocalin] destination-zone local
[DeviceB-security-policy-ip-4-bfdlocalin] service bfd-echo
[DeviceB-security-policy-ip-4-bfdlocalin] action pass
[DeviceB-security-policy-ip-4-bfdlocalin] quit
```

# Configure a rule named **untrust-untrust** to allow Device B to respond to the BFD echo packets from Device A.

```
[DeviceB-security-policy-ip] rule name untrust-untrust
[DeviceB-security-policy-ip-5-untrust-untrust] source-zone untrust
[DeviceB-security-policy-ip-5-untrust-untrust] destination-zone untrust
[DeviceB-security-policy-ip-5-untrust-untrust] source-ip-host 10.10.10.10
[DeviceB-security-policy-ip-5-untrust-untrust] destination-ip-host 10.2.1.1
[DeviceB-security-policy-ip-5-untrust-untrust] action pass
```

```
[DeviceB-security-policy-ip-5-untrust-untrust] quit
```

# Configure a rule named **pinglocalout** to allow Device B to send ping packets to Device A.

```
[DeviceB-security-policy-ip] rule name pinglocalout
[DeviceB-security-policy-ip-6-pinglocalout] source-zone local
[DeviceB-security-policy-ip-6-pinglocalout] destination-zone untrust
[DeviceB-security-policy-ip-6-pinglocalout] service ping
[DeviceB-security-policy-ip-6-pinglocalout] action pass
[DeviceB-security-policy-ip-6-pinglocalout] quit
```

# Configure a rule named **pinglocalin** to allow Device B to respond to the ping packets from Device A.

```
[DeviceB-security-policy-ip] rule name pinglocalin
[DeviceB-security-policy-ip-7-pinglocalin] source-zone untrust
[DeviceB-security-policy-ip-7-pinglocalin] destination-zone local
[DeviceB-security-policy-ip-7-pinglocalin] service ping
[DeviceB-security-policy-ip-7-pinglocalin] action pass
[DeviceB-security-policy-ip-7-pinglocalin] quit
[DeviceB-security-policy-ip] quit
```

5. Specify 1.1.1.1 as the source address of BFD echo packets.

```
[DeviceB] bfd echo-source-ip 1.1.1.1
```

6. Configure track entry 1, and associate it with the BFD session to verify the connectivity between Device B and Device A.

```
[DeviceB] track 1 bfd echo interface gigabitethernet 1/0/1 remote ip 10.2.1.1 local
ip 10.2.1.2
[DeviceB-track-1] quit
```

Configuring Device C

1. Assign IP addresses to interfaces:

# Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceC> system-view
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] ip address 10.3.1.3 255.255.255.0
[DeviceC-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing:

# Configure a static route to 30.1.1.0/24 with next hop 10.4.1.2.

```
[DeviceC] ip route-static 30.1.1.0 24 10.4.1.2
```

# Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

```
[DeviceC] ip route-static 20.1.1.0 24 10.3.1.1
```

Verifying the configuration

# Display information about the track entry on Device A.

```
[DeviceA] display track all
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: BFD
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    BFD session mode: Echo
    Outgoing interface: GigabitEthernet1/0/1
    VPN instance name: --
    Remote IP: 10.2.1.2
    Local IP: 10.2.1.1
```

The output shows that the status of the track entry is Positive, indicating that next hop 10.2.1.2 is reachable.

# Display the routing table of Device A.

```
[DeviceA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0            10.2.1.1        GE1/0/1
10.2.1.1/32         Direct 0    0            127.0.0.1       InLoop0
10.3.1.0/24         Direct 0    0            10.3.1.1        GE1/0/2
10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        GE1/0/3
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 60   0            10.2.1.2        GE1/0/1

127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Device A forwards packets to 30.1.1.0/24 through Device B. The master static route has taken effect.

# Remove the IP address of GigabitEthernet 1/0/1 on Device B.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] undo ip address
```

# Display information about the track entry on Device A.

```
[DeviceA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: BFD
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    BFD session mode: Echo
    Outgoing interface: GigabitEthernet1/0/1
    VPN instance name: --
    Remote IP: 10.2.1.2
    Local IP: 10.2.1.1
```

The output shows that the status of the track entry is Negative, indicating that next hop 10.2.1.2 is unreachable.

# Display the routing table of Device A.

```
[DeviceA] display ip routing-table

Destinations : 9        Routes : 9
```

```
Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0            10.2.1.1        GE1/0/1
10.2.1.1/32         Direct 0    0            127.0.0.1       InLoop0
10.3.1.0/24         Direct 0    0            10.3.1.1        GE1/0/2
10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        GE1/0/3
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 80   0            10.3.1.3        GE1/0/2
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Device A forwards packets to 30.1.1.0/24 through Device C. The backup static route has taken effect.

# Verify that the hosts in 20.1.1.0/24 can communicate with the hosts in 30.1.1.0/24 when the master route fails.

```
[DeviceA] ping -a 20.1.1.1 30.1.1.1

Configuring BFD

About BFD

Bidirectional forwarding detection (BFD) provides a general-purpose, standard, medium- and protocol-independent fast failure detection mechanism. It can detect and monitor the connectivity of forwarding paths to detect communication failures quickly so that measures can be taken to ensure service continuity and enhance network availability.

BFD can uniformly and quickly detect the failures of the bidirectional forwarding paths between two devices for upper-layer protocols such as routing protocols. The hello mechanism used by upper-layer protocols needs seconds to detect a link failure, while BFD can provide detection measured in milliseconds.

Single-hop detection and multihop detection

BFD can be used for single-hop and multihop detections.

- **Single-hop detection**—Detects the IP connectivity between two directly connected systems.
- **Multihop detection**—Detects any of the paths between two systems. These paths have multiple hops, and might overlap.

BFD session modes

BFD sessions use echo packets and control packets.

Echo packet mode

Echo packets are encapsulated into UDP packets with port number 3785.

The local end of the link sends echo packets to establish BFD sessions and monitor link status. The peer end does not establish BFD sessions and only forwards the packets back to the originating end. If the local end does not receive echo packets from the peer end within the detection time, it considers the session to be down.

In echo packet mode, BFD supports only single-hop detection and the BFD session is independent of the operating mode.

Control packet mode

Control packets are encapsulated into UDP packets with port number 3784 for single-hop detection or port number 4784 for multihop detection.

The two ends of the link negotiate the establishment of BFD sessions by using the session parameters carried in control packets. Session parameters include session discriminators, desired minimum packet sending and receiving intervals, and local BFD session state.

Before a BFD session is established, BFD has two operating modes—active and passive.

- **Active mode**—BFD actively sends BFD control packets regardless of whether any BFD control packet is received from the peer.
- **Passive mode**—BFD does not send control packets until a BFD control packet is received from the peer.

At least one end must operate in active mode for a BFD session to be established.

After a BFD session is established, the two ends can operate in the following BFD operating modes:

- **Asynchronous mode**—The device periodically sends BFD control packets. The device considers that the session is down if it does not receive any BFD control packets within a specific interval.
- **Demand mode**—The device periodically sends BFD control packets with the D bit set. If the peer end is operating in Asynchronous mode (default), the peer end stops sending BFD control packets after receiving control packets with the D bit set. In this case, BFD detects only the connectivity from the local end to the peer end. If the peer end does not receive control packets within the detection time, the session is declared down. If the peer end is operating in Demand mode, both ends stop sending BFD control packets. The system uses other mechanisms such as Hello mechanism and hardware detection to detect links. The Demand mode can be used to reduce the overhead when a large number of BFD sessions exist.

Supported features

Features	Reference
Static routing IS-IS OSPF RIP BGP IP fast reroute (FRR)	*Layer 3—IP Routing Configuration Guide*
IPv6 static routing OSPFv3	*Layer 3—IP Routing Configuration Guide*
PIM	*IP Multicast Configuration Guide*
Track	*Network Management and Monitoring Configuration Guide*.

Protocols and standards

- RFC 5880, *Bidirectional Forwarding Detection (BFD)*
- RFC 5881, *Bidirectional Forwarding Detection (BFD) for IPv4 and IPv6 (Single Hop)*
- RFC 5882, *Generic Application of Bidirectional Forwarding Detection (BFD)*
- RFC 5883, *Bidirectional Forwarding Detection (BFD) for Multihop Paths*

Restrictions and guidelines: BFD configuration

- By default, the device runs BFD version 1 and is compatible with BFD version 0. You cannot change the BFD version to 0 through commands. When the peer device runs BFD version 0, the local device automatically switches to BFD version 0.
- BFD cannot detect a link over NAT.
- After a BFD session is established, the two ends negotiate BFD parameters, including minimum sending interval, minimum receiving interval, initialization mode, and packet authentication, by exchanging negotiation packets. They use the negotiated parameters without affecting the session status.

Configuring BFD sessions in echo packet mode

About this task

A static BFD session can be created manually by using the **bfd static** command or created dynamically when an application module collaborates with BFD.

Restrictions and guidelines

If you also configure uRPF on the device, follow these restrictions and guidelines:

- For the collaboration between an application module and a BFD session in echo packet mode, use an ACL for uRPF to permit echo packets from the peer device. Without the ACL configuration, uRPF will drop these echo packets.
- For a static BFD session, make sure the source IPv4/IPv6 address specified in the session can pass the uRPF check. If the source IPv4/IPv6 address cannot pass the check, uRPF will drop the echo packets from the peer device.

For more information about uRPF, see *Security Configuration Guide*.

Creating a static BFD session

About this task

A static BFD session in echo packet mode can be used to perform single-hop detection and multihop detection.

Restrictions and guidelines

You need to create a static BFD session in echo packet mode on only the local device to perform detection.

When creating a static BFD session, you must specify a peer IPv4 or IPv6 address. The system checks only the format of the IP address but not its correctness. If the peer IPv4 or IPv6 address is incorrect, the static BFD session cannot be established.

Different static BFD sessions cannot have the same local discriminator.

As a best practice, specify the source IP address for echo packets when creating a static BFD session. If you do not specify the source IP address, the device uses the IP address specified in the **bfd echo-source-ip** or **bfd echo-source-ipv6** command as the source IP address of echo packets.

Make sure the source IP address is not on the same network segment as any local interfaces. This avoids the following situations:

- A large number of ICMP redirect packets might be sent from the peer, resulting in link congestion.
- With malformed packet attack detection and prevention enabled, the local end might filter echo packets sent from the peer as malformed packets, resulting in BFD session establishment failure. For more information about malformed packet attack detection and prevention, see attack detection and prevention in *Security Configuration Guide*.

Creating a static BFD session for single-hop detection

1. Enter system view.
   ```
   system-view
   ```
2. Configure the source IP address of echo packets.
   - Configure the source IP address of echo packets.

bfd echo-source-ip *ip-address*

By default, no source IPv4 address is configured for echo packets.

- Configure the source IPv6 address of echo packets.

  bfd echo-source-ipv6 *ipv6-address*

  By default, no source IPv6 address is configured for echo packets.

  The source IPv6 address of echo packets can only be a global unicast address.

3. Create a static BFD session and enter static BFD session view.

   IPv4:

   bfd static *session-name* [**peer-ip** *ipv4-address* **interface** *interface-type interface-number* **destination-ip** *ipv4-address* [**source-ip** *ipv4-address*] **one-arm-echo discriminator** { **local** *local-value* | **auto** }]

   IPv6:

   bfd static *session-name* [**peer-ipv6** *ipv6-address* **interface** *interface-type interface-number* **destination-ipv6** *ipv6-address* [**source-ipv6** *ipv6-address*] **one-arm-echo discriminator** { **local** *local-value* | **auto** }]

Creating a static BFD session for multihop detection

1. Enter system view.

   system-view

2. Configure the source IP address of echo packets.

   - Configure the source IP address of echo packets.

     bfd echo-source-ip *ip-address*

     By default, no source IPv4 address is configured for echo packets.

   - Configure the source IPv6 address of echo packets.

     bfd echo-source-ipv6 *ipv6-address*

     By default, no source IPv6 address is configured for echo packets.

     The source IPv6 address of echo packets can only be a global unicast address.

3. Create a static BFD session and enter static BFD session view.

   IPv4:

   bfd static *session-name* [**peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*] **destination-ip** *ipv4-address* [**source-ip** *ipv4-address*] **one-arm-echo discriminator** { **local** *local-value* | **auto** }]

   IPv6:

   bfd static *session-name* [**peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] **destination-ipv6** *ipv6-address* [**source-ipv6** *ipv6-address*] **one-arm-echo discriminator** { **local** *local-value* | **auto** }]

Configuring BFD session parameters for single-hop detection

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the minimum interval for receiving BFD echo packets.

   bfd min-echo-receive-interval *interval*

   The default setting is 400 milliseconds.

4. Set the detection time multiplier.

   bfd detect-multiplier *value*

   The default setting is 5.

Configuring BFD session parameters for multihop detection

1. Enter system view.

   system-view

2. Set the minimum interval for receiving BFD echo packets.

   bfd multi-hop min-echo-receive-interval *interval*

   The default setting is 400 milliseconds.

3. Set the detection time multiplier.

   bfd multi-hop detect-multiplier *value*

   The default setting is 5.

Configuring BFD sessions in control packet mode

About BFD session creation methods

BFD sessions in control packet mode can be created statically or established dynamically.

BFD sessions are distinguished by the local discriminator and remote discriminator in control packets. The main difference between a statically created session and a dynamically established session is that they obtain the local discriminator and remote discriminator in different ways.

- The local discriminator and remote discriminator of a static BFD session are specified manually in the **bfd static** command or in features associated with BFD.
- The local discriminator of a dynamic BFD session is assigned by the device, and the remote discriminator is obtained during BFD session negotiation. A created session without manually specified local and remote discriminators is a dynamic BFD session.

Restrictions and guidelines

BFD version 0 does not support the following commands:

- **bfd session init-mode**.
- **bfd authentication-mode**.
- **bfd demand enable**.
- **bfd echo enable**.

Configuring a static BFD session

About this task

A static BFD session can be used for single-hop detection and multihop detection.

Restrictions and guidelines for static BFD session configuration

If a static BFD session is created on the remote end, the static BFD session must be created on the local end.

When creating a static BFD session, you must specify a peer IPv4 or IPv6 address. The system checks only the format of the IP address but not its correctness. If the peer IPv4 or IPv6 address is incorrect, the static BFD session cannot be established.

Different static BFD sessions cannot have the same local discriminator.

Creating a static BFD session for single-hop detection of network layer connectivity

1. Enter system view.

   system-view

2. Create a static BFD session and enter static BFD session view.

   IPv4:

   bfd static *session-name* **peer-ip** *ipv4-address* **interface** *interface-type interface-number* **source-ip** *ipv4-address* **discriminator local** *local-value* **remote** *remote-value*

   For a static BFD session to be established, specify the IPv4 address of the peer interface where the static BFD session resides for the **peer-ip** *ipv4-address* option. Specify the IPv4 address of the local interface where the static BFD session resides for the **source-ip** *ipv4-address* option.

   IPv6:

   bfd static *session-name* **peer-ipv6** *ipv6-address* **interface** *interface-type interface-number* **source-ipv6** *ipv6-address* **discriminator local** *local-value* **remote** *remote-value*

   For a static BFD session to be established, specify the IPv6 address of the peer interface where the static BFD session resides for the **peer-ipv6** *ipv6-address* option. Specify the IPv6 address of the local interface where the static BFD session resides for the **source-ipv6** *ipv6-address* option.

Creating a static BFD session for single-hop detection of data link layer connectivity

1. Enter system view.

   system-view

2. Create a static BFD session and enter static BFD session view.

   bfd static *session-name* **peer-ip default-ip interface** *interface-type interface-number* **source-ip** *ip-address* **discriminator local** *discr-value* **remote** *discr-value*

   For a static BFD session to be established, specify the IPv6 address of the local interface where the static BFD session resides for the **source-ip** *ip-address* option.

3. (Optional.) Associate the interface state with the static BFD session.

   process-interface-status

   By default, the state of a static BFD session does not affect the state of the data link layer of the interface.

   Support for this command depends on the device model. For more information, see the command reference.

4. (Optional.) Configure the timer that delays reporting the first static BFD session establishment failure to the data link layer.

   first-fail-timer *seconds*

   By default, the first static BFD session establishment failure is not reported to the data link layer.

This command takes effect only after you configure the **process-interface-status** command.

Support for this command depends on the device model. For more information, see the command reference.

5. (Optional.) Enable special processing for the static BFD session.

   special-processing [**admin-down** | **authentication-change** | **session-up**] *

   By default, all types of special processing are disabled for a static BFD session.

   Support for this command depends on the device model. For more information, see the command reference.

Creating a static BFD session for multihop detection

1. Enter system view.

   system-view

2. Create a static BFD session and enter static BFD session view.

   IPv4:

   bfd static *session-name* **peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*] **source-ip** *ipv4-address* **discriminator local** *local-value* **remote** *remote-value*

   For a static BFD session to be established, specify the IPv4 address of the peer interface where the static BFD session resides for the **peer-ip** *ipv4-address* option. Specify the IPv4 address of the local interface where the static BFD session resides for the **source-ip** *ipv4-address* option.

   IPv6:

   bfd static *session-name* **peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] **source-ipv6** *ipv6-address* **discriminator local** *local-value* **remote** *remote-value*

   For a static BFD session to be established, specify the IPv6 address of the peer interface where the static BFD session resides for the **peer-ipv6** *ipv6-address* option. Specify the IPv6 address of the local interface where the static BFD session resides for the **source-ipv6** *ipv6-address* option.

Configuring BFD session parameters for single-hop detection

1. Enter system view.

   system-view

2. Specify the mode for establishing a BFD session.

   bfd session init-mode { **active** | **passive** }

   By default, **active** is specified.

3. Enter interface view or static BFD session view.

   - Enter interface view.

     interface *interface-type interface-number*

   - Enter static BFD session view.

     bfd static *session-name*

     The static BFD session must already exist.

4. (Optional.) Configure the authentication mode for single-hop control packets.

bfd authentication-mode { **hmac-md5** | **hmac-mmd5** | **hmac-msha1** | **hmac-sha1** | **m-md5** | **m-sha1** | **md5** | **sha1** | **simple** } *key-id* { **cipher** *cipher-string* | **plain** *plain-string* }

By default, single-hop BFD packets are not authenticated.

5. Enable the Demand BFD session mode.

   bfd demand enable

   By default, the BFD session is in Asynchronous mode.

6. Set the minimum interval for transmitting single-hop BFD control packets.

   bfd min-transmit-interval *interval*

   The default setting is 400 milliseconds.

7. Set the minimum interval for receiving single-hop BFD control packets.

   bfd min-receive-interval *interval*

   The default setting is 400 milliseconds.

8. Set the single-hop detection time multiplier.

   bfd detect-multiplier *value*

   The default setting is 5.

9. (Optional.) Set the delay timer for BFD to notify upper-layer protocols of session establishment failures.

   bfd init-fail-timer *seconds*

   By default, BFD does not notify upper-layer protocols of session establishment failures.

△ **CAUTION:**

For session establishment failures caused by configuration mismatches at the two ends, this command can cause the upper-layer protocol to act incorrectly. Therefore, use this command with caution. BFD status mismatch and BFD authentication configuration mismatch are examples of configuration mismatches.

Configuring BFD session parameters for multihop detection

1. Enter system view.

   system-view

2. Specify the mode for establishing a BFD session.

   bfd session init-mode { **active** | **passive** }

   By default, **active** is specified.

3. Configure the authentication mode for multihop BFD control packets.

   bfd multi-hop authentication-mode { **m-md5** | **m-sha1** | **md5** | **sha1** | **simple** } *key-id* { **cipher** *cipher-string* | **plain** *plain-string* }

   By default, no authentication is performed.

4. Configure the destination port number for multihop BFD control packets.

   bfd multi-hop destination-port *port-number*

   The default setting is 4784.

5. Set the multihop detection time multiplier.

   bfd multi-hop detect-multiplier *value*

   The default setting is 5.

6. Set the minimum interval for receiving multihop BFD control packets.

bfd multi-hop min-receive-interval *interval*

The default setting is 400 milliseconds.

7. Set the minimum interval for transmitting multihop BFD control packets.

   bfd multi-hop min-transmit-interval *interval*

   The default setting is 400 milliseconds.

8. (Optional.) Set the delay timer for BFD to notify upper-layer protocols of session establishment failures.

   bfd init-fail-timer *seconds*

   By default, BFD does not notify upper-layer protocols of session establishment failures.

△ **CAUTION:**

For session establishment failures caused by configuration mismatches at the two ends, this command can cause the upper-layer protocol to act incorrectly. Therefore, use this command with caution. BFD status mismatch and BFD authentication configuration mismatch are examples of configuration mismatches.

Enabling the echo function

About this task

This function enables the local system to periodically send echo packets to the remote system. The remote system loops back the echo packets to the local system without processing them. If the local system does not receive the looped-back echo packets, it declares the BFD session down.

This function is supported only for single-hop detection.

Restrictions and guidelines

This function does not take effect on BFD sessions associated with interface states.

Procedure

1. Enter system view.

   system-view

2. Enter interface view or static BFD session view.

   - Enter interface view.

     interface *interface-type interface-number*

   - Enter static BFD session view.

     bfd static *session-name*

     The static BFD session must be an existing session used to detect data link layer connectivity.

3. Enable the echo function.

   bfd echo [**receive** | **send**] **enable**

   By default, the echo function is disabled.

Associating the interface state with BFD

About this task

By creating a BFD session for single-hop detection through exchange of BFD control packets, this feature implements fast link detection. When BFD detects a link fault, it sets the link layer protocol state to DOWN(BFD). This behavior helps applications relying on the link layer protocol state achieve fast convergence. The source IP address of control packets is specified manually, and the destination IP address is fixed at 224.0.0.184. As a best practice, specify the IP address of the interface as the source IP address. If the interface does not have an IP address, specify a unicast IP address other than 0.0.0.0 as the source IP address.

You can associate the state of the following interfaces with BFD:

- Layer 3 Ethernet interfaces and subinterfaces. For BFD detection to take effect, do not configure this feature on both a Layer 3 Ethernet interface and its subinterface.
- Layer 3 aggregate interfaces, Layer 3 aggregate subinterfaces, and member ports (Layer 3 Ethernet interfaces only) in a Layer 3 aggregation group. For BFD detection to take effect, do not configure this feature on any two of the interface types at the same time.
- VLAN interfaces.

Restrictions and guidelines

The echo function does not take effect on BFD sessions associated with interface states.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Associate the interface state with BFD.

   bfd detect-interface source-ip *ip-address* [**discriminator local** *local-value* **remote** *remote-value*] [**template** *template-name*]

   By default, the interface state is not associated with BFD. BFD does not set the link layer protocol of the interface to DOWN(BFD) state when detecting a failure.

4. (Optional.) Configure the timer that delays reporting the first BFD session establishment failure to the data link layer.

   bfd detect-interface first-fail-timer *seconds*

   By default, the first BFD session establishment failure is not reported to the data link layer.

5. (Optional.) Enable special processing for BFD sessions.

   bfd detect-interface special-processing [**admin-down** | **authentication-change** | **session-up**] *

   By default, all types of special processing are disabled for BFD sessions.

Configuring a BFD template

About this task

Perform this task to specify BFD parameters in a template for sessions without next hops. You can configure BFD parameters for LSPs and PWs through a BFD template.

Procedure

1. Enter system view.

   system-view

2. Create a BFD template and enter BFD template view.

   bfd template *template-name*

3. (Optional.) Configure the authentication mode for BFD control packets.

   bfd authentication-mode { **hmac-md5** | **hmac-mmd5** | **hmac-msha1** | **hmac-sha1** | **m-md5** | **m-sha1** | **md5** | **sha1** | **simple** } *key-id* { **cipher** *cipher-string* | **plain** *plain-string* }

By default, no authentication is performed.

4. Set the detection time multiplier.

   `bfd detect-multiplier` *`value`*

   The default setting is 5.

5. Set the minimum interval for receiving BFD echo packets.

   `bfd min-echo-receive-interval` *`interval`*

   The default setting is 400 milliseconds.

6. Set the minimum interval for receiving BFD control packets.

   `bfd min-receive-interval` *`interval`*

   The default setting is 400 milliseconds.

7. Set the minimum interval for transmitting BFD control packets.

   `bfd min-transmit-interval` *`interval`*

   The default setting is 400 milliseconds.

Enabling SNMP notifications for BFD

About this task

To report critical BFD events to an NMS, enable SNMP notifications for BFD. For BFD event notifications to be sent correctly, you must also configure SNMP as described in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enable SNMP notifications for BFD.

   `snmp-agent trap enable bfd`

   By default, SNMP notifications are enabled for BFD.

Display and maintenance commands for BFD

Execute the **`display`** command in any view and the **`reset`** command in user view.

Task	Command
Display BFD session information.	**display bfd session** [**discriminator local** *local-value* | **static name** *session-name* | **verbose**] **display bfd session** [[**dynamic**] [**control** | **echo**] [**ip**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**]] **display bfd session** [[**dynamic**] [**control** | **echo**] [**ipv6**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**]] **display bfd session** [[**dynamic**] [**control** | **echo**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [[**peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*]] | [**peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*]]] [**verbose**]] **display bfd session** [[**static**] [**ip**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**] **display bfd session** [[**static**] [**ipv6**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**]
Clear BFD session statistics.	**reset bfd session statistics**

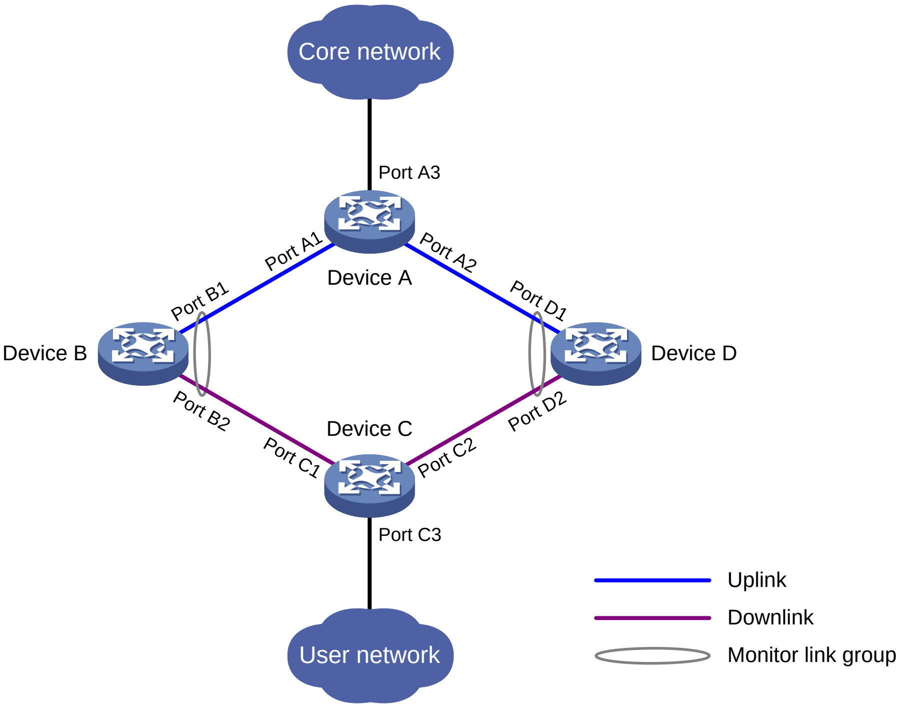
Contents

Configuring Monitor Link

About Monitor Link

Monitor Link is an NSFOCUS-proprietary solution that associates the state of downlink interfaces with the state of uplink interfaces in a monitor link group. When Monitor Link shuts down the downlink interfaces because of an uplink failure, the downstream device changes connectivity to another link.

Figure 1 Monitor Link application scenario



A monitor link group contains uplink and downlink interfaces. An interface can belong to only one monitor link group.

- Uplink interfaces are the monitored interfaces.
- Downlink interfaces are the monitoring interfaces.

As shown in Figure 1:

- Port B1 and Port B2 of Device B form a monitor link group. Port B1 is an uplink interface, and Port B2 is a downlink interface.
- Port D1 and Port D2 of Device D form another monitor link group. Port D1 is an uplink interface, and Port D2 is a downlink interface.

A monitor link group works independently of other monitor link groups. When a monitor link group does not contain any uplink interface or all its uplink interfaces are down, the monitor link group goes down. It forces all downlink interfaces down at the same time. When any uplink interface comes up, the monitor link group comes up and brings up all the downlink interfaces.

Restrictions and guidelines: Monitor Link configuration

Follow these restrictions and guidelines when you configure Monitor Link:

- Do not manually shut down or bring up the downlink interfaces in a monitor link group.
- To avoid frequent state changes of downlink interfaces in the event that uplink interfaces in the monitor link group flap, you can configure a switchover delay. The switchover delay is the time that the downlink interfaces wait before they come up following an uplink interface.

Monitor Link tasks at a glance

To configure Monitor Link, perform the following tasks:

- Enabling Monitor Link globally
- Creating a monitor link group
- Configuring monitor link group member interfaces
- (Optional.) Configuring the switchover delay for the downlink interfaces in a monitor link group

Enabling Monitor Link globally

About this task

All monitor link groups can operate only after you enable Monitor Link globally. When you disable Monitor Link globally, all monitor link groups cannot operate and the downlink interfaces brought down by the monitor link groups resume their original states.

Procedure

1. Enter system view.
   `system-view`
2. Enable Monitor Link globally.
   `undo monitor-link disable`
   By default, Monitor Link is enabled globally.

Creating a monitor link group

1. Enter system view.
   `system-view`
2. Create a monitor link group and enter monitor link group view.
   `monitor-link group` *`group-id`*

Configuring monitor link group member interfaces

Restrictions and guidelines

- An interface can be assigned to only one monitor link group.

- To avoid undesired down/up state changes on the downlink interfaces, configure uplink interfaces before you configure downlink interfaces.
- If you have configured an interface as the downlink interface of a monitor link group, do not configure its subinterfaces as the uplink interfaces of any monitor link group. Otherwise, the Monitor Link operation might be interrupted.
- The state of subinterfaces is associated with the state of the interface. Do not add the interface and its subinterfaces to the same monitor link group. Otherwise, the monitor link group performance might be affected.
- If you have configured a Selected port of an aggregation group as the downlink interface of a monitor link group, do not configure an Unselected port of the aggregation group as the uplink interface of the monitor link group.
- Do not add an aggregate interface and its member ports to the same monitor link group.
- You can configure member interfaces for a monitor link group in monitor link group view or interface view. Configurations made in these views have the same effect. The configuration is supported by the following interfaces:
  - Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces.
  - Layer 3 Ethernet interfaces/subinterfaces.
  - Layer 3 aggregate interfaces/subinterfaces.

Configuring monitor link group member interfaces in monitor link group view

1. Enter system view.

   system-view

2. Enter monitor link group view.

   monitor-link group *group-id*

3. Configure member interfaces for the monitor link group.

   port *interface-type* { *interface-number* | *interface-number.subnumber* } { **downlink** | **uplink** }

   By default, no member interfaces exist in a monitor link group.

Configuring monitor link group member interfaces in interface view

1. Enter system view.

   system-view

2. Enter interface view or subinterface view.

   interface *interface-type* { *interface-number* | *interface-number.subnumber* }

3. Configure the interface as a member of a monitor link group.

   port monitor-link group *group-id* { **downlink** | **uplink** }

   By default, the interface is not a monitor link group member.

Configuring the switchover delay for the downlink interfaces in a monitor link group

1. Enter system view.

   system-view

2. Enter monitor link group view.

   monitor-link group *group-id*

3. Configure the switchover delay for the downlink interfaces in the monitor link group.

   downlink up-delay *delay*

   By default, the switchover delay is 0 seconds. The downlink interfaces come up as soon as an uplink interface comes up.

Display and maintenance commands for Monitor Link

Execute the **display** command in any view:

Task	Command
Display monitor link group information.	**display monitor-link group** { *group-id* | **all** }

Contents

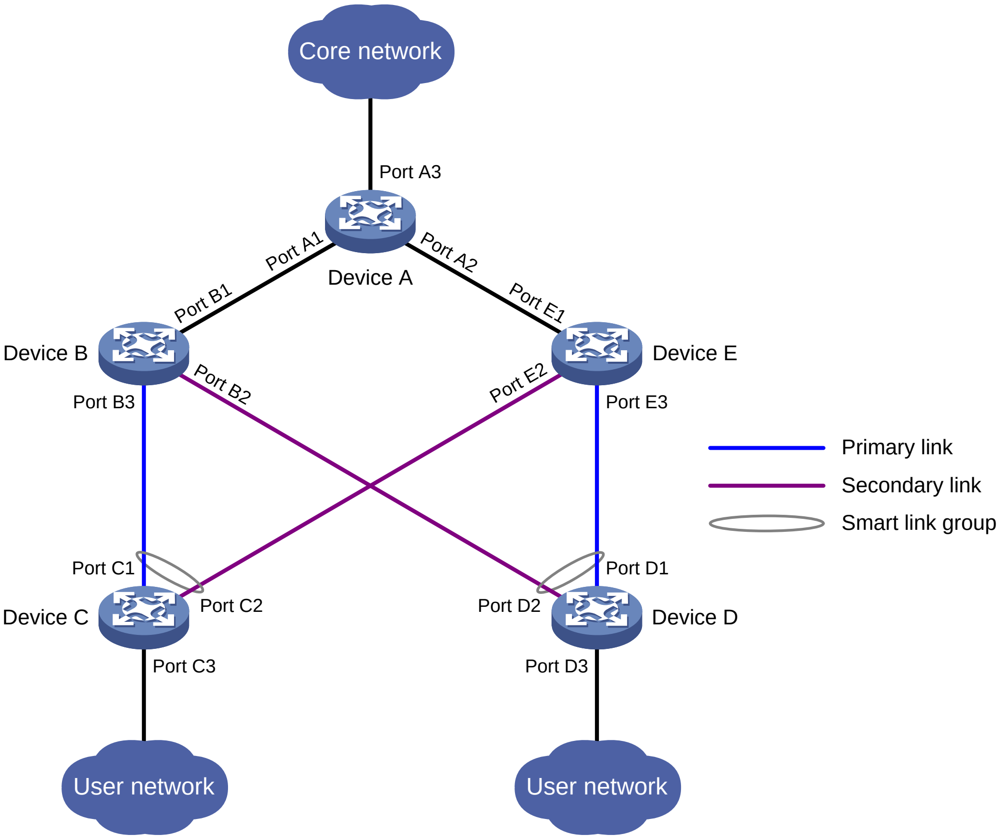
Configuring Smart Link

About Smart Link

Application scenario

Smart Link is an NSFOCUS-proprietary protocol that provides link redundancy and subsecond convergence time in a dual uplink network. As shown in Figure 1, Smart Link is configured on Device C and Device D. The secondary link takes over quickly when the primary link fails.

Figure 1 Dual uplink network diagram



A Smart Link network has the following devices:

- **Smart Link devices**—A Smart Link device has two uplinks. A Smart Link device must be configured with a smart link group and a transmit control VLAN to transmit flush messages. Device C and Device D in Figure 1 are Smart Link devices.
- **Associated devices**—An associated device is an uplink device to which Smart Link devices are connected. An associated device supports Smart Link, and receives flush messages sent from the specified control VLAN. When a primary/secondary link switchover occurs, the associated device updates the MAC address entries and ARP/ND entries according to received flush messages. Device A, Device B, and Device E in Figure 1 are associated devices.

Terminology

Smart link group

A smart link group consists of only two member ports: the primary and the secondary ports. Only one port is active for forwarding at a time, and the other port is blocked and in standby state. When link failure occurs on the active portdue to port shutdown, the standby port becomes active and takes over. The original active port transits to the blocked state.

As shown in Figure 1, Port C1 and Port C2 of Device C form a smart link group. Port C1 is active, and Port C2 is standby. Port D1 and Port D2 of Device D form another smart link group. Port D1 is active, and Port D2 is standby.

Primary/secondary port

Primary port and secondary port are two port types in a smart link group. When both ports in a smart link group are up, the primary port preferentially transits to the forwarding state. The secondary port stays in standby state. When the primary port fails, the secondary port takes over to forward traffic.

As shown in Figure 1, Port C1 of Device C and Port D1 of Device D are primary ports. Port C2 of Device C and Port D2 of Device D are secondary ports.

Primary/secondary link

The link that connects the primary port in a smart link group is the primary link. The link that connects the secondary port is the secondary link.

Flush message

When link switchover occurs, the smart link group uses flush messages to notify other devices to refresh their MAC address entries and ARP/ND entries. Flush messages are common multicast data packets, and will be dropped by a blocked receiving port.

Protected VLAN

A smart link group controls the forwarding state of protected VLANs. Each smart link group on a port controls a different protected VLAN. The state of the port in a protected VLAN is determined by the state of the port in the smart link group.

Transmit control VLAN

The transmit control VLAN is used for transmitting flush messages. When link switchover occurs, the devices (such as Device C and Device D in Figure 1) send flush messages within the transmit control VLAN.

Receive control VLAN

The receive control VLAN is used for receiving and processing flush messages. When link switchover occurs, the devices (such as Device A, Device B, and Device E in Figure 1) receive and process flush messages in the receive control VLAN. In addition, they refresh their MAC address entries and ARP/ND entries.

How Smart Link works

Link backup

As shown in Figure 1, the link on Port C1 of Device C is the primary link. The link on Port C2 of Device C is the secondary link. Port C1 is in forwarding state, and Port C2 is in standby state. When the primary link fails, Port C2 takes over to forward traffic and Port C1 is blocked and placed in standby state.

When a port switches to the forwarding state, the system outputs log information to notify the user of the port state change.

Topology change

Link switchover might outdate the MAC address entries and ARP/ND entries on all devices. A flush update mechanism is provided to ensure correct packet transmission. With this mechanism, a Smart Link-enabled device updates its information by transmitting flush messages over the backup link to its upstream devices. This mechanism requires the upstream devices to be capable of recognizing Smart Link flush messages to update their MAC address forwarding entries and ARP/ND entries.

Preemption mode

As shown in Figure 1, the link on Port C1 of Device C is the primary link. The link on Port C2 of Device C is the secondary link. When the primary link fails, Port C1 is automatically blocked and placed in standby state, and Port C2 takes over to forward traffic. When the primary link recovers, one of the following actions occurs:

- If the smart link group is not configured with a preemption mode, Port C1 stays blocked to keep traffic forwarding stable. Port C1 does not take over to forward traffic until the next link switchover.
- If the smart link group is configured with a preemption mode and the preemption conditions are met, Port C1 takes over to forward traffic as soon as its link recovers. Port C2 is automatically blocked and placed in standby state.

Load sharing

A ring network might carry traffic of multiple VLANs. Smart Link can forward traffic from different VLANs in different smart link groups for load sharing.

To implement load sharing, you can assign a port to multiple smart link groups. Configure each group with a different protected VLAN. Make sure the state of the port is different in these smart link groups, so traffic from different VLANs can be forwarded along different paths.

You can configure protected VLANs for a smart link group by referencing Multiple Spanning Tree Instances (MSTIs). For more information about MSTIs, see *Layer 2—LAN Switching Configuration Guide*.

Collaboration between Smart Link and Monitor Link for port status detection

Smart Link cannot detect when faults occur on the uplink of the upstream devices or when faults are cleared. You can configure the Monitor Link function to monitor the status of the uplink ports of the upstream devices. Monitor Link adapts the up/down state of downlink ports to uplink ports, and triggers Smart Link to perform link switchover on the downstream device. For more information about Monitor Link, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines: Smart Link configuration

If you configure a port as both an aggregation group member and a smart link group member, only the aggregation group configuration takes effect. The port is not shown in the output from the **`display smart-link group`** command. The smart link group configuration takes effect after the port leaves the aggregation group.

Smart Link tasks at a glance

To configure Smart Link, perform the following tasks:

1. Configuring a Smart Link device

   a. Configuring protected VLANs for a smart link group
   b. Configuring member ports for a smart link group
   c. (Optional.) Configuring a preemption mode for a smart link group
   d. (Optional.) Enabling the sending of flush messages
2. Enabling an associated device to receive flush messages

Configuring a Smart Link device

Prerequisites for Smart Link device configuration

Before configuring a Smart Link device, complete the following tasks:

- To prevent loops, shut down a port before configuring it as a smart link group member. You can bring up the port only after completing the smart link group configuration.
- Disable the spanning tree feature on the ports you want to add to the smart link group.

Configuring protected VLANs for a smart link group

Prerequisites

Before you configure protected VLANs, you must configure an MST region and the VLAN-to-instance mapping table. For more information about MST regions, see spanning tree configuration in *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Create a smart link group and enter smart link group view.
   smart-link group *group-id*
3. Configure protected VLANs for the smart link group.
   protected-vlan reference-instance *instance-id-list*

Configuring member ports for a smart link group

Restrictions and guidelines

You can configure member ports for a smart link group either in smart link group view or in interface view. The configurations made in these two views have the same effect.

In smart link group view

1. Enter system view.
   system-view
2. Create a smart link group and enter smart link group view.
   smart-link group *group-id*
3. Configure member ports for a smart link group.
   port *interface-type interface-number* { **primary** | **secondary** }
   By default, no member port is configured for a smart link group.

In interface view

1. Enter system view.

system-view

2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*

3. Configure member ports for a smart link group.

   port smart-link group *group-id* { **primary** | **secondary** }

   By default, an interface is not a smart link group member.

Configuring a preemption mode for a smart link group

1. Enter system view.

   system-view

2. Enter smart link group view.

   smart-link group *group-id*

3. Configure a preemption mode for the smart link group.

   preemption mode { **role** | **speed** [**threshold** *threshold-value*] }

   By default, preemption is disabled.

4. Configure the preemption delay.

   preemption delay *delay*

   By default, the preemption delay is 1 second.

   The preemption delay configuration takes effect only after a preemption mode is configured.

Enabling the sending of flush messages

Restrictions and guidelines

- The control VLAN configured for a smart link group must be different from the control VLAN configured for any other smart link group.
- Make sure the configured control VLAN already exists, and assign the smart link group member ports to the control VLAN.
- The control VLAN of a smart link group must also be one of its protected VLANs. Do not remove the control VLAN. Otherwise, flush messages cannot be sent correctly.

Procedure

1. Enter system view.

   system-view

2. Enter smart link group view.

   smart-link group *group-id*

3. Enable flush update.

   flush enable [**control-vlan** *vlan-id*]

   By default, flush update is enabled, and VLAN 1 is the control VLAN.

Enabling an associated device to receive flush messages

Restrictions and guidelines

- You do not need to enable all ports on the associated devices to receive flush messages. Enable the feature only on all control VLANs of ports on the primary and secondary links between the Smart Link device and the destination device.
- If no control VLAN is specified for processing flush messages, the device forwards the received flush messages without any processing.
- Make sure the receive control VLAN is the same as the transmit control VLAN configured on the Smart Link device. If they are not the same, the associated device will forward the received flush messages directly without any processing.
- Do not remove the control VLANs. Otherwise, flush messages cannot be sent correctly.
- Make sure the control VLANs are existing VLANs, and assign the ports capable of receiving flush messages to the control VLANs.

Prerequisites

Disable the spanning tree feature on the associated device's ports that connect to the member ports of the smart link group. Otherwise, the ports will discard flush messages when they are not in forwarding state if a topology change occurs.

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   `interface` *`interface-type interface-number`*

3. Configure the control VLANs for receiving flush messages.

   `smart-link flush enable` [**`control-vlan`** *`vlan-id-list`*]

   By default, no control VLAN receives flush messages.

Display and maintenance commands for Smart Link

Execute **`display`** commands in any view and the **`reset`** command in user view:

Task	Command
Display information about the received flush messages.	**`display smart-link flush`**
Display smart link group information.	**`display smart-link group`** { *`group-id`* | **`all`** }
Clear the statistics about flush messages.	**`reset smart-link statistics`**

Contents

Configuring interface backup

About interface backup

Interface backup enables you to configure multiple backup interfaces for a Layer 3 interface to increase link availability. When the primary interface fails or is overloaded, its backup interfaces can take over or participate in traffic forwarding.

Compatible interfaces

Table 1 Interfaces that support interface backup

Category	Interfaces	Remarks
Ethernet	Layer 3 Ethernet interfaces/subinterfaces	N/A
Others	Dialer interfaces Tunnel interfaces	A dialer interface can be used as the primary interface only when it is a PPPoE client in permanent session mode.

Backup modes

The primary interface and its backup interfaces can operate in strict active/standby mode or load sharing mode.

- **Strict active/standby mode**—Only one interface transmits traffic. All the other interfaces are in STANDBY state.
- **Load sharing mode**—Backup interfaces participate in traffic forwarding when the amount of traffic on the primary interface reaches the upper threshold. They are activated and deactivated depending on the amount of traffic.

In strict active/standby mode, traffic loss occurs when the active interface is overloaded. Load sharing mode improves link efficiency and reduces the risk of packet loss.

Strict active/standby mode

In strict active/standby mode, the primary interface always has higher priority than all backup interfaces.

- When the primary interface is operating correctly, all traffic is transmitted through the primary interface.
- When the primary interface fails, the highest-priority backup interface takes over. If the highest-priority backup interface also fails, the second highest-priority backup interface takes over, and so forth.

NOTE:

If two backup interfaces have the same priority, the one configured first has preference.

An active backup interface is always preempted by the primary interface. However, a higher-priority backup interface cannot preempt a lower-priority backup interface that has taken over the primary interface.

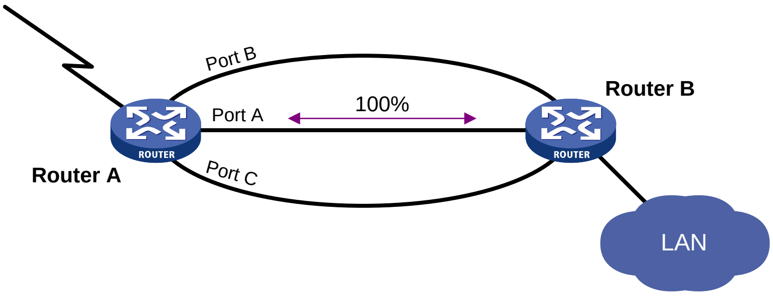
- The primary interface takes over when it recovers from a failure condition.

- The higher-priority backup interface cannot take over when it recovers from a failure condition while the primary interface is still down.

As shown in Figure 1, Port A on Router A is the primary interface. Port B (with a priority of 30) and Port C (with a priority of 20) are its backup interfaces.

- When Port A is operating correctly, all traffic is transmitted through Port A.
- When Port A fails, Port B takes over because it has higher priority than Port C. If Port B also fails, Port C takes over.
- When Port A is recovered, it preempts the active backup interface because it is the primary interface. If Port B is recovered while Port A is still down, Port B cannot preempt Port C to forward traffic.

Figure 1 Strict active/backup mode



Load sharing mode

In load sharing mode, the backup interfaces are activated to transmit traffic depending on the traffic load on the primary interface.

- When the amount of traffic on the primary interface exceeds the upper threshold, the backup interfaces are activated in descending order of priority. This action continues until the traffic drops below the upper threshold.
- When the total amount of traffic on all load-shared interfaces decreases below the lower threshold, the backup interfaces are deactivated in ascending order of priority. This action continues until the total amount of traffic exceeds the lower threshold.
- When the primary interface fails (in DOWN state), the strict active/standby mode applies. Only one backup interface can forward traffic.

The upper and lower thresholds are user configurable.

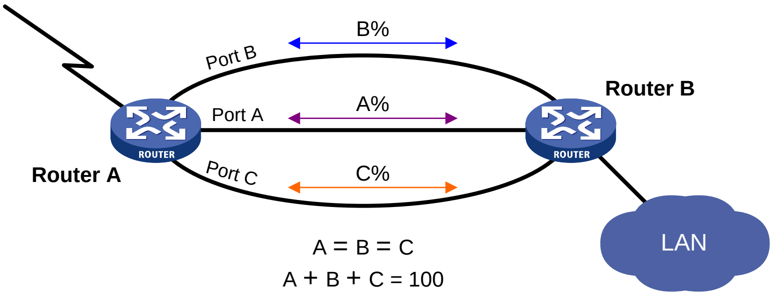
NOTE:

- "Traffic" on an interface refers to the amount of incoming or outgoing traffic, whichever is higher.
- If two backup interfaces have the same priority, the one configured first has preference.

As shown in Figure 2, Port A on Router A is the primary interface. Port B (with a priority of 30) and Port C (with a priority of 20) are its backup interfaces.

- When the amount of traffic on Port A exceeds the upper threshold, Port B is activated, because it has higher priority than Port C. If the amount of traffic on Port A still exceeds the upper threshold, Port C is activated.
- When the total amount of traffic on all load-shared interfaces decreases below the lower threshold, Port C is first deactivated, because its priority is lower than Port B. If the total amount of traffic on Port A and Port B is still below the lower threshold, Port B is deactivated.

Figure 2 Load sharing mode



Restrictions and guidelines: Interface backup configuration

When you configure interface backup, follow these restrictions and guidelines:

- The device supports up to 10 primary interfaces.
- An interface can be configured as a backup only for one interface.
- An interface cannot be both a primary and backup interface.
- The strict active/standby mode and load sharing mode cannot be configured at the same time.

Interface backup tasks at a glance

To configure interface backup, perform the following tasks:

- Configuring strict active/standby interface backup

  Choose one of the following tasks:

  - Explicitly specifying backup interfaces without traffic thresholds

    Use this method if you want to monitor the interface state of the primary interface for a switchover to occur.

  - Using interface backup with the Track module

    Use this method if you want to monitor any other state, such as the link state of the primary interface.

- Configuring load-shared interface backup

Prerequisites for configuring interface backup

Make sure the primary and backup interfaces have routes to the destination network.

Explicitly specifying backup interfaces without traffic thresholds

About this task

Perform this task if you want to monitor the interface state of the primary interface for a switchover to occur. For the primary and backup interfaces to operate in strict active/standby mode, do not specify the traffic thresholds on the primary interface. If the traffic thresholds are configured, the interfaces will operate in load sharing mode.

You can assign priority to backup interfaces. When the primary interface fails, the backup interfaces are activated in descending order of priority, with the highest-priority interface activated first. If two backup interfaces have the same priority, the one configured first has preference.

To prevent link flapping from causing frequent interface switchovers, you can configure the following switchover delay timers:

- **Up delay timer**—Number of seconds that the primary or backup interface must wait before it can come up.
- **Down delay timer**—Number of seconds that the active primary or backup interface must wait before it is set to down state.

When the link of the active interface fails, the interface state does not change immediately. Instead, a down delay timer starts. If the link recovers before the timer expires, the interface state does not change. If the link is still down when the timer expires, the interface state changes to down.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

   This interface must be the primary interface.

3. Specify a backup interface.

   ```
   backup interface interface-type interface-number [ priority ]
   ```

   By default, an interface does not have any backup interfaces.

   Repeat this command to specify up to three backup interfaces for the interface.

4. Set the switchover delay timers.

   ```
   backup timer delay up-delay down-delay
   ```

   By default, the up and down delay timers are both 5 seconds.

Using interface backup with the Track module

About this task

Perform this task if you want to monitor any other state, such as the link state of the primary interface. To use interface backup with the Track module to provide strict active/standby backup for a primary interface:

- Configure a track entry to monitor state information of the primary interface. For example, monitor its link state.
- Associate the track entry with a backup interface.

Interface backup changes the state of the backup interface in response to the track entry state, as shown in Table 2.

Table 2 Action on the backup interface in response to the track entry state change

Track entry state	State of the monitored primary link	Action on the backup interface
Positive	The primary link is operating correctly.	Places the backup interface in STANDBY state.
Negative	The primary link has failed.	Activates the backup interface to take over.

Track entry state	State of the monitored primary link	Action on the backup interface
NotReady	The primary link is not monitored. This situation occurs when the track module or the monitoring module is not ready, for example, because the Track module is restarting or the monitoring settings are incomplete. In this situation, interface backup cannot obtain information about the primary link from the track module.	• If the track entry state stays in NotReady state after it is created, interface backup does not change the state of the backup interface. • If the track entry state changes to NotReady from Positive or Negative, the backup interface changes back to the forwarding state before it was used for interface backup.

For more information about configuring a track entry, see Track configuration in *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

- You can associate an interface with only one track entry.
- You can create the associated track entry before or after the association. The association takes effect after the track entry is created.
- To maintain performance, limit the number of associations to 64.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

   This interface must be the interface you are using as a backup.

3. Associate the interface with a track entry.

   `backup track` *`track-entry-number`*

   By default, an interface is not associated with a track entry.

Configuring load-shared interface backup

About this task

To implement load-balanced interface backup, you must configure the traffic thresholds on the primary interface. Interface backup regularly compares the amount of traffic with the thresholds to determine whether to activate or deactivate a backup interface. The traffic polling interval is user configurable.

You can assign priority to backup interfaces.

- When the amount of traffic on the primary interface exceeds the upper threshold, the backup interfaces are activated in descending order of priority.
- When the total amount of traffic on all load-shared interfaces decreases below the lower threshold, the backup interfaces are deactivated in ascending order of priority.

If two backup interfaces have the same priority, the one configured first has preference.

If a traffic flow has a fast forwarding entry, all packets of the flow will be forwarded out of the outgoing interface in the entry. The packets of the flow will not be distributed between interfaces when the upper threshold is reached. For more information about fast forwarding, see *Layer 3—IP Services Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

   You must enter the view of the primary interface.

3. Configure a backup interface for the interface.

   backup interface *interface-type interface-number* [*priority*]

   By default, an interface does not have any backup interfaces.

   Repeat this command to specify up to three backup interfaces.

4. Set backup load sharing thresholds.

   backup threshold *upper-threshold lower-threshold*

   By default, no traffic thresholds are configured.

5. Set the traffic polling interval.

   backup timer flow-check *interval*

   The default interval is 30 seconds.

Display and maintenance commands for interface backup

Execute **display** commands in any view.

Task	Command
Display traffic statistics for load-shared interfaces.	**display interface-backup statistics**
Display the status of primary and backup interfaces.	**display interface-backup state**

Contents

Configuring interface collaboration

About interface collaboration

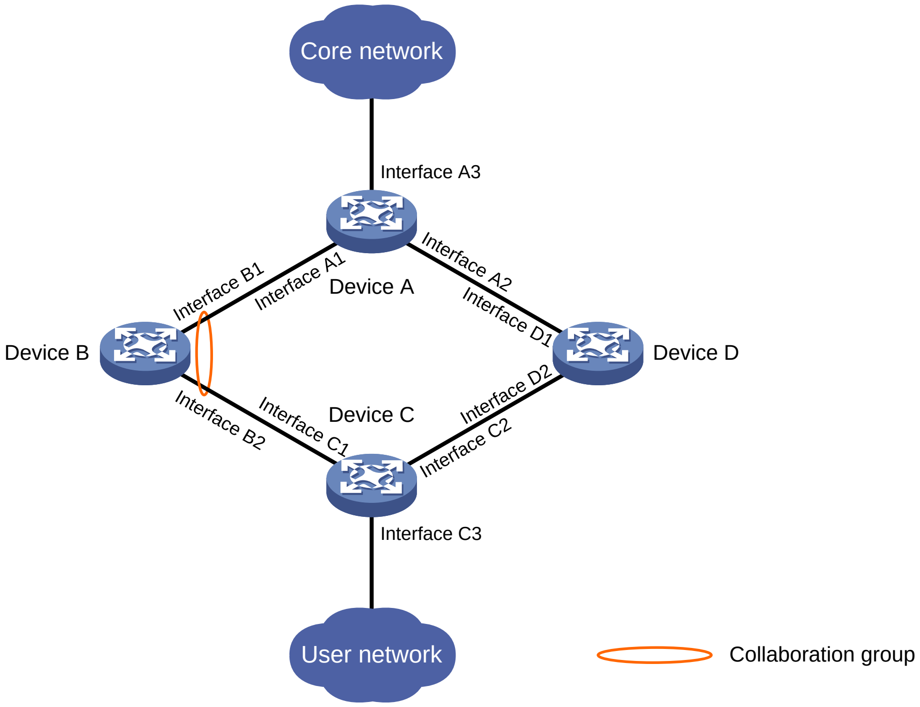
The interface collaboration feature assigns different interfaces on a device to a collaboration group and associates the states of these interfaces. All member interfaces in a collaboration group can or cannot transmit packets at the same time. This feature is typically used to associate the states of downlink and uplink interfaces.

Typical application

As shown in Figure 1, Device C accesses the core network through Device B. When Interface B1 goes down, the switchover of traffic from Device C to Device D is slow because Interface B2 is still up.

If Interface B1 and Interface B2 belong to one collaboration group, Device B brings down Interface B2 when Interface B1 goes down to achieve fast traffic switchover. Similarly, the device brings down Interface B1 when Interface B2 goes down.

Figure 1 Interface collaboration application scenario



How interface collaboration works

The interface collaboration feature works as follows:

- When any member interface in a collaboration group goes down, the device sets all other member interfaces in the collaboration group to the **Collaboration-down** state. The state of the collaboration group is down, and no member interfaces in the collaboration group can transmit packets.

- When any member interface in **DOWN** or **Collaboration-down** state comes up, the device attempts to bring up all other member interfaces in the collaboration group.
  - If all other member interfaces come up in 10 seconds, the collaboration group comes up. All member interfaces in the collaboration group can transmit packets.
  - If any member interface cannot come up in 10 seconds, the device sets that member interface to **DOWN** state and sets all other member interfaces to the **Collaboration-down** state. The collaboration group goes down, and no member interfaces in the collaboration group can transmit packets.

Restrictions and guidelines: Interface collaboration configuration

This feature cannot be used together with the external security service bypass feature. For more information about external security service bypass see Layer 2 forwarding configuration in *Layer 2—LAN Switching Configuration Guide*.

Interface collaboration tasks at a glance

To configure interface collaboration, perform the following tasks:

- Creating a collaboration group
- Configuring collaboration group member interfaces
- (Optional.) Configuring the delay for the member interfaces in a collaboration group
- (Optional.) Removing ineffective member interfaces from all collaboration groups

Prerequisites for interface collaboration

Before configuring interface collaboration, you must enable Monitor Link globally (see *Network Monitoring and Management Configuration Guide*).

Creating a collaboration group

1. Enter system view.
   `system-view`
2. Create a collaboration group and enter collaboration group view.
   `collaboration-group` *`group-id`*
   By default, no collaboration groups exist.

Configuring collaboration group member interfaces

Restrictions and guidelines

An interface can belong to only one collaboration group.

For a collaboration group to work correctly, do not assign its member interfaces to a redundancy group.

Do not add both an aggregate interface and its member ports to the same collaboration group.

Do not add both Selected ports and Unselected ports in a dynamic aggregation group to the same collaboration group.

If you have configured a member interface as the uplink/downlink interface of a monitor link group, do not configure any other member interface in the same collaboration group as the downlink/uplink interface of any monitor link group.

You can assign only one interface of a link to a collaboration group.

You can configure member interfaces for a collaboration group in collaboration group view or interface view. Configurations made in these views have the same effect.

Configuring a collaboration group member interface in collaboration group view

1. Enter system view.

   system-view

2. Enter collaboration group view.

   collaboration-group *group-id*

3. Configure an interface as a member of the collaboration group.

   port *interface-type interface-number*

   By default, no member interfaces exist in a collaboration group.

Configuring a collaboration group member interface in interface view

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the interface as a member of a collaboration group.

   port collaboration-group *group-id*

   By default, an interface is not a collaboration group member.

Configuring the delay for the member interfaces in a collaboration group to come up

About this task

By default, member interfaces in a collaboration group come up and forward service traffic immediately after the device restarts. Traffic loss occurs if the service modules have not returned to normal state.

Perform this task to enable the member interfaces to come up after a configurable delay time upon a device restart.

Procedure

1. Enter system view.

   system-view

2. Enter collaboration group view.

   collaboration-group *group-id*

3. Configure the delay for the member interfaces in a collaboration group to come up.

   up-delay *delay*

   By default, the delay time is 0 seconds. The member interfaces come up as soon as the device restarts.

Removing ineffective member interfaces from all collaboration groups

About this task

A member interface in a collaboration group becomes ineffective when the card that hosts the interface is removed or changed to another slot or the ID of the IRF member device that hosts the interface changes. This task prevents an ineffective interface from causing all other member interfaces in the same collaboration group to go down.

An ineffective interface cannot be automatically assigned to the original collaboration group when its hosting card is reinstalled or changed back to the original slot or the IRF member ID is changed back to the original ID. You must assign it to the original collaboration group manually.

Procedure

1. Enter system view.

   system-view

2. Enter collaboration group view.

   collaboration-group clean

Display and maintenance commands for interface collaboration

Execute the **display** command in any view:

Task	Command
Display collaboration group information.	**display collaboration-group** { *group-id* | **all** } [**verbose**]

Contents

Using ping, tracert, and system debugging

This chapter covers ping, tracert, and information about debugging the system.

Ping

About ping

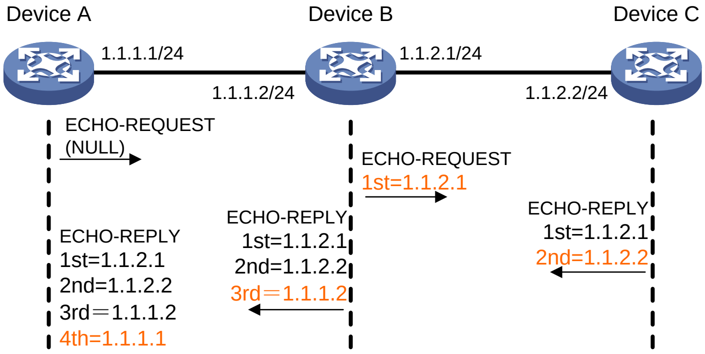
Use the ping utility to determine if an address is reachable.

Ping sends ICMP echo requests (ECHO-REQUEST) to the destination device. Upon receiving the requests, the destination device responds with ICMP echo replies (ECHO-REPLY) to the source device. The source device outputs statistics about the ping operation, including the number of packets sent, number of echo replies received, and the round-trip time. You can measure the network performance by analyzing these statistics.

You can use the **`ping –r`** command to display the routers through which ICMP echo requests have passed. The test procedure of **`ping –r`** is as shown in Figure 1:

1. The source device (Device A) sends an ICMP echo request to the destination device (Device C) with the RR option empty.
2. The intermediate device (Device B) adds the IP address of its outbound interface (1.1.2.1) to the RR option of the ICMP echo request, and forwards the packet.
3. Upon receiving the request, the destination device copies the RR option in the request and adds the IP address of its outbound interface (1.1.2.2) to the RR option. Then the destination device sends an ICMP echo reply.
4. The intermediate device adds the IP address of its outbound interface (1.1.1.2) to the RR option in the ICMP echo reply, and then forwards the reply.
5. Upon receiving the reply, the source device adds the IP address of its inbound interface (1.1.1.1) to the RR option. The detailed information of routes from Device A to Device C is formatted as: 1.1.1.1 <-> {1.1.1.2; 1.1.2.1} <-> 1.1.2.2.

Figure 1 Ping operation



Using a ping command to test network connectivity

Perform the following tasks in any view:

- Determine if an IPv4 address is reachable.

ping [**ip**] [**-a** *source-ip* | **-c** *count* | **-f** | **-h** *ttl* | **-i** *interface-type interface-number* | **-m** *interval* | **-n** | **-p** *pad* | **-q** | **-r** | **-s** *packet-size* | **-t** *timeout* | **-tos** *tos* | **-v** | **-vpn-instance** *vpn-instance-name*] * *host*

Increase the timeout time (indicated by the **-t** keyword) on a low-speed network.

- Determine if an IPv6 address is reachable.

  ping ipv6 [**-a** *source-ipv6* | **-c** *count* | **-i** *interface-type interface-number* | **-m** *interval* | **-q** | **-s** *packet-size* | **-t** *timeout* | **-tc** *traffic-class* | **-v** | **-vpn-instance** *vpn-instance-name*] * *host*

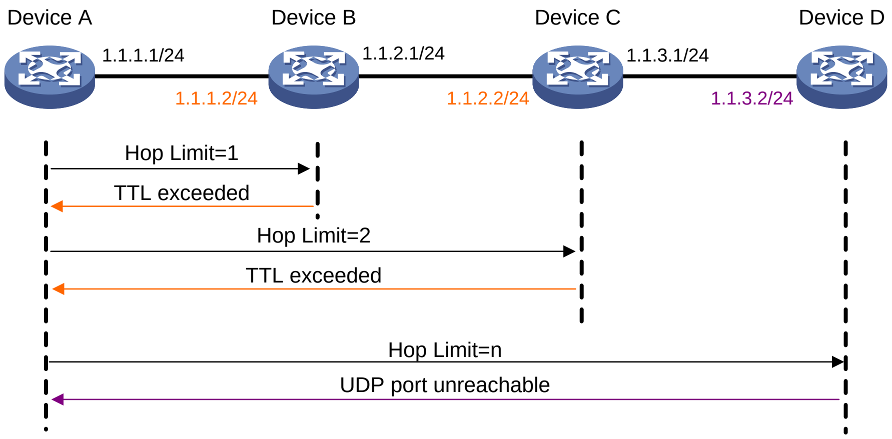
  Increase the timeout time (indicated by the **-t** keyword) on a low-speed network.

Tracert

About tracert

Tracert (also called Traceroute) enables retrieval of the IP addresses of Layer 3 devices in the path to a destination. In the event of network failure, use tracert to test network connectivity and identify failed nodes.

Figure 2 Tracert operation



Tracert uses received ICMP error messages to get the IP addresses of devices. Tracert works as shown in Figure 2:

6. The source device sends a UDP packet with a TTL value of 1 to the destination device. The destination UDP port is not used by any application on the destination device.
7. The first hop (Device B, the first Layer 3 device that receives the packet) responds by sending a TTL-expired ICMP error message to the source, with its IP address (1.1.1.2) encapsulated. This way, the source device can get the address of the first Layer 3 device (1.1.1.2).
8. The source device sends a packet with a TTL value of 2 to the destination device.
9. The second hop (Device C) responds with a TTL-expired ICMP error message, which gives the source device the address of the second Layer 3 device (1.1.2.2).
10. This process continues until a packet sent by the source device reaches the ultimate destination device. Because no application uses the destination port specified in the packet, the destination device responds with a port-unreachable ICMP message to the source device, with its IP address encapsulated. This way, the source device gets the IP address of the destination device (1.1.3.2).
11. The source device determines that:
    - The packet has reached the destination device after receiving the port-unreachable ICMP message.

- The path to the destination device is 1.1.1.2 to 1.1.2.2 to 1.1.3.2.

Prerequisites

Before you use a tracert command, perform the tasks in this section.

For an IPv4 network:

- Enable sending of ICMP timeout packets on the intermediate devices (devices between the source and destination devices). If the intermediate devices are NSFOCUS devices, execute the **ip ttl-expires enable** command on the devices. For more information about this command, see IP performance optimazition commands in *Layer 3—IP Services Command Reference*.
- Enable sending of ICMP destination unreachable packets on the destination device. If the destination device is an NSFOCUS device, execute the **ip unreachables enable** command. For more information about this command, see IP performance optimization commands in *Layer 3—IP Services Command Reference*.

For an IPv6 network:

- Enable sending of ICMPv6 timeout packets on the intermediate devices (devices between the source and destination devices). If the intermediate devices are NSFOCUS devices, execute the **ipv6 hoplimit-expires enable** command on the devices. For more information about this command, see IPv6 basics commands in *Layer 3—IP Services Command Reference*.
- Enable sending of ICMPv6 destination unreachable packets on the destination device. If the destination device is an NSFOCUS device, execute the **ipv6 unreachables enable** command. For more information about this command, see IPv6 basics commands in *Layer 3—IP Services Command Reference*.

Using a tracert command to identify failed or all nodes in a path

Perform the following tasks in any view:

- Trace the route to an IPv4 destination.

  tracert [**-a** *source-ip* | **-f** *first-ttl* | **-i** *interface-type interface-number* | **-m** *max-ttl* | **-p** *port* | **-q** *packet-number* | **-t** *tos* | **-vpn-instance** *vpn-instance-name* [**-resolve-as** { **global** | **none** | **vpn** }] | **-w** *timeout*] * *host*

- Trace the route to an IPv6 destination.

  tracert ipv6 [**-f** *first-hop* | **-i** *interface-type interface-number* | **-m** *max-hops* | **-p** *port* | **-q** *packet-number* | **-t** *traffic-class* | **-vpn-instance** *vpn-instance-name* [**-resolve-as** { **global** | **none** | **vpn** }] | **-w** *timeout*] * *host*

System debugging

About system debugging

The device supports debugging for the majority of protocols and features, and provides debugging information to help users diagnose errors.

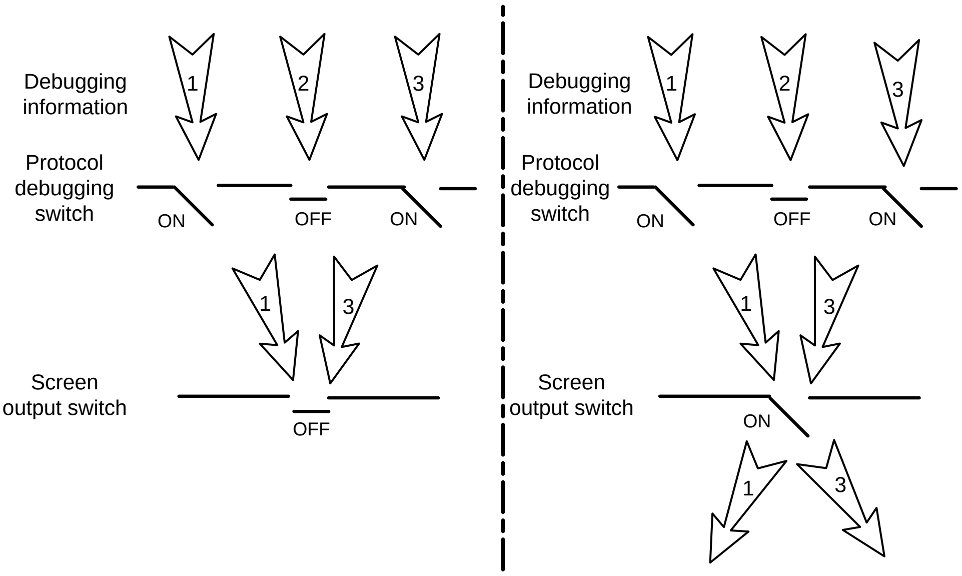
The following switches control the display of debugging information:

- **Module debugging switch**—Controls whether to generate the module-specific debugging information.
- **Screen output switch**—Controls whether to display the debugging information on a certain screen. Use the **`terminal monitor`** and **`terminal logging level`** commands to turn on the screen output switch. For more information about the commands, see information center commands in *Network Management and Monitoring Command Reference*.

As shown in Figure 3, the device can provide debugging for the three modules 1, 2, and 3. The debugging information can be output on a terminal only when both the module debugging switch and the screen output switch are turned on.

Debugging information is typically displayed on a console. You can also send debugging information to other destinations. For more information, see "Configuring the information center."

Figure 3 Relationship between the module and screen output switch



Configuring debugging

Restrictions and guidelines

△ **CAUTION:**

Output of excessive debugging messages increases the CPU usage and downgrades the system performance. To guarantee system performance, enable debugging only for modules that are in an exceptional condition.

Enable debugging for modules for troubleshooting purposes. When debugging is complete, use the **`undo debugging all`** command to disable all the debugging functions.

Procedure

Perform the following tasks in user view:

1. Enable debugging for a module.

   `debugging` *`module-name`* [*`option`*]

   By default, debugging is disabled for all modules.

2. (Optional.) Enable the debugging-auto-off feature to automatically disable all types of debugging when the CPU usage reaches or exceeds the lowest CPU usage alarm threshold.

   `debugging-auto-off enable cpu-usage-alarm`

By default, the debugging-auto-off feature is disabled.

Display and maintenance commands for debugging

Execute **display** commands in any view.

Task	Command
Display the enabled debugging features.	**display debugging** [*module-name*]
Display the enabling status of the debugging-auto-off feature.	**display debugging-auto-off**

Contents

Configuring NTP

The device is inadequate in clock precision. As a best practice, do not use the device as a time server to synchronize the time of the other devices.

About NTP

NTP is used to synchronize system clocks among distributed time servers and clients on a network. NTP runs over UDP and uses UDP port 123.

NTP application scenarios

Various tasks, including network management, charging, auditing, and distributed computing depend on accurate and synchronized system time setting on the network devices. NTP is typically used in large networks to dynamically synchronize time among network devices.

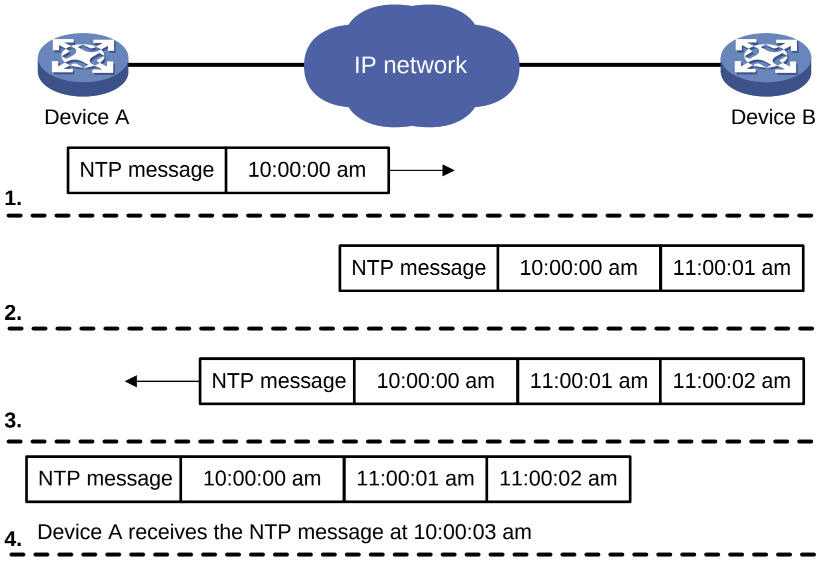
NTP guarantees higher clock accuracy than manual system clock setting. In a small network that does not require high clock accuracy, you can keep time synchronized among devices by changing their system clocks one by one.

NTP working mechanism

Figure 1 shows how NTP synchronizes the system time between two devices (Device A and Device B, in this example). Assume that:

- Prior to the time synchronization, the time is set to 10:00:00 am for Device A and 11:00:00 am for Device B.
- Device B is used as the NTP server. Device A is to be synchronized to Device B.
- It takes 1 second for an NTP message to travel from Device A to Device B, and from Device B to Device A.
- It takes 1 second for Device B to process the NTP message.

Figure 1 Basic work flow



The synchronization process is as follows:

1. Device A sends Device B an NTP message, which is timestamped when it leaves Device A. The time stamp is 10:00:00 am (T1).
2. When this NTP message arrives at Device B, Device B adds a timestamp showing the time when the message arrived at Device B. The timestamp is 11:00:01 am (T2).
3. When the NTP message leaves Device B, Device B adds a timestamp showing the time when the message left Device B. The timestamp is 11:00:02 am (T3).
4. When Device A receives the NTP message, the local time of Device A is 10:00:03 am (T4).

Up to now, Device A can calculate the following parameters based on the timestamps:

- The roundtrip delay of the NTP message: Delay = (T4 – T1) – (T3 – T2) = 2 seconds.
- Time difference between Device A and Device B: Offset = [(T2 – T1) + (T3 – T4)] /2 = 1 hour.

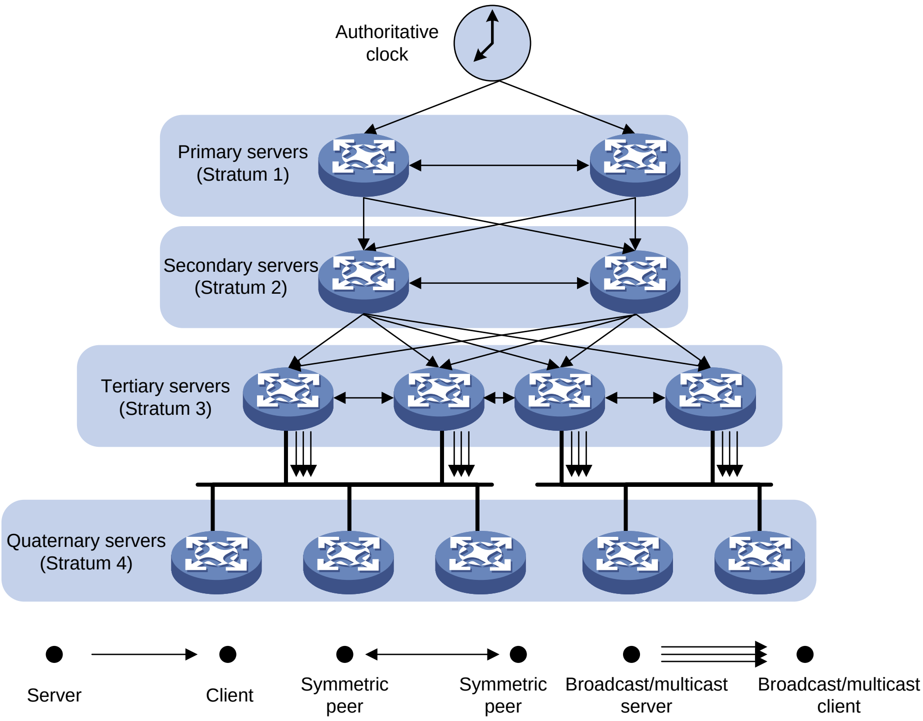
Based on these parameters, Device A can be synchronized to Device B.

This is only a rough description of the work mechanism of NTP. For more information, see the related protocols and standards.

NTP architecture

NTP uses stratums 1 to 16 to define clock accuracy, as shown in Figure 2. A lower stratum value represents higher accuracy. Clocks at stratums 1 through 15 are in synchronized state, and clocks at stratum 16 are not synchronized.

Figure 2 NTP architecture



Authoritative clock
Primary servers (Stratum 1)
Secondary servers (Stratum 2)
Tertiary servers (Stratum 3)
Quaternary servers (Stratum 4)
Server
Client
Symmetric peer
Symmetric peer
Broadcast/multicast server
Broadcast/multicast client

A stratum 1 NTP server gets its time from an authoritative time source, such as an atomic clock. It provides time for other devices as the primary NTP server. A stratum 2 time server receives its time from a stratum 1 time server, and so on.

To ensure time accuracy and availability, you can specify multiple NTP servers for a device. The device selects an optimal NTP server as the clock source based on parameters such as stratum. The clock that the device selects is called the reference source. For more information about clock selection, see the related protocols and standards.

If the devices in a network cannot synchronize to an authoritative time source, you can perform the following tasks:

- Select a device that has a relatively accurate clock from the network.
- Use the local clock of the device as the reference clock to synchronize other devices in the network.

NTP association modes

NTP supports the following association modes:

- Client/server mode
- Symmetric active/passive mode
- Broadcast mode
- Multicast mode

You can select one or more association modes for time synchronization. Table 1 provides detailed description for the four association modes.

In this document, an "NTP server" or a "server" refers to a device that operates as an NTP server in client/server mode. Time servers refer to all the devices that can provide time synchronization, including NTP servers, NTP symmetric peers, broadcast servers, and multicast servers.

Table 1 NTP association modes

Mode	Working process	Principle	Application scenario
Client/server	On the client, specify the IP address of the NTP server. A client sends a clock synchronization message to the NTP servers. Upon receiving the message, the servers automatically operate in server mode and send a reply. If the client can be synchronized to multiple time servers, it selects an optimal clock and synchronizes its local clock to the optimal reference source after receiving the replies from the servers.	A client can synchronize to a server, but a server cannot synchronize to a client.	As Figure 2 shows, this mode is intended for configurations where devices of a higher stratum synchronize to devices with a lower stratum.
Symmetric active/passive	On the symmetric active peer, specify the IP address of the symmetric passive peer. A symmetric active peer periodically sends clock synchronization messages to a symmetric passive peer. The symmetric passive peer automatically operates in symmetric passive mode and sends a reply. If the symmetric active peer can be synchronized to multiple time servers, it selects an optimal clock and synchronizes its local clock to the optimal reference source after receiving the replies from the servers.	A symmetric active peer and a symmetric passive peer can be synchronized to each other. If both of them are synchronized, the peer with a higher stratum is synchronized to the peer with a lower stratum.	As Figure 2 shows, this mode is most often used between servers with the same stratum to operate as a backup for one another. If a server fails to communicate with all the servers of a lower stratum, the server can still synchronize to the servers of the same stratum.

Mode	Working process	Principle	Application scenario
Broadcast	A server periodically sends clock synchronization messages to the broadcast address 255.255.255.255. Clients listen to the broadcast messages from the servers to synchronize to the server according to the broadcast messages. When a client receives the first broadcast message, the client and the server start to exchange messages to calculate the network delay between them. Then, only the broadcast server sends clock synchronization messages.	A broadcast client can synchronize to a broadcast server, but a broadcast server cannot synchronize to a broadcast client.	A broadcast server sends clock synchronization messages to synchronize clients in the same subnet. As Figure 2 shows, broadcast mode is intended for configurations involving one or a few servers and a potentially large client population. The broadcast mode has lower time accuracy than the client/server and symmetric active/passive modes because only the broadcast servers send clock synchronization messages.
Multicast	A multicast server periodically sends clock synchronization messages to the user-configured multicast address. Clients listen to the multicast messages from servers and synchronize to the server according to the received messages.	A multicast client can synchronize to a multicast server, but a multicast server cannot synchronize to a multicast client.	A multicast server can provide time synchronization for clients in the same subnet or in different subnets. The multicast mode has lower time accuracy than the client/server and symmetric active/passive modes.

NTP security

To improve time synchronization security, NTP provides the access control and authentication functions.

NTP access control

You can control NTP access by using an ACL. The access rights are in the following order, from the least restrictive to the most restrictive:

- **Peer**—Allows time requests and NTP control queries (such as alarms, authentication status, and time server information) and allows the local device to synchronize itself to a peer device.
- **Server**—Allows time requests and NTP control queries, but does not allow the local device to synchronize itself to a peer device.
- **Synchronization**—Allows only time requests from a system whose address passes the access list criteria.
- **Query**—Allows only NTP control queries from a peer device to the local device.

When the device receives an NTP request, it matches the request against the access rights in order from the least restrictive to the most restrictive: **peer**, **server**, **synchronization**, and **query**.

- If no NTP access control is configured, the **peer** access right applies.
- If the IP address of the peer device matches a **permit** statement in an ACL, the access right is granted to the peer device. If a **deny** statement or no ACL is matched, no access right is granted.
- If no ACL is specified for an access right or the ACL specified for the access right is not created, the access right is not granted.

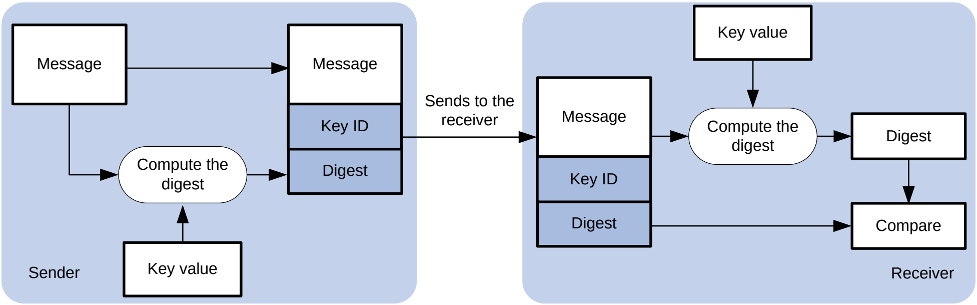
- If none of the ACLs specified for the access rights is created, the **peer** access right applies.
- If none of the ACLs specified for the access rights contains rules, no access right is granted.

This feature provides minimal security for a system running NTP. A more secure method is NTP authentication.

NTP authentication

Use this feature to authenticate the NTP messages for security purposes. If an NTP message passes authentication, the device can receive it and get time synchronization information. If not, the device discards the message. This function makes sure the device does not synchronize to an unauthorized time server.

Figure 3 NTP authentication



As shown in Figure 3, NTP authentication is performed as follows:

1. The sender uses the key identified by the key ID to calculate a digest for the NTP message through the MD5 authentication algorithm. Then it sends the calculated digest together with the NTP message and key ID to the receiver.
2. Upon receiving the message, the receiver performs the following actions:
   a. Finds the key according to the key ID in the message.
   b. Uses the key and the MD5 authentication algorithm to calculate the digest for the message.
   c. Compares the digest with the digest contained in the NTP message.
      – If they are different, the receiver discards the message.
      – If they are the same, the local device determines whether the sender is allowed to use the authentication ID. If the sender is allowed to use the authentication ID, the receiver accepts the message. If the sender is not allowed to use the authentication ID, the receiver discards the message.

Protocols and standards

- RFC 1305, *Network Time Protocol (Version 3) Specification, Implementation and Analysis*
- RFC 5905, *Network Time Protocol Version 4: Protocol and Algorithms Specification*

Restrictions and guidelines: NTP configuration

- You cannot configure both NTP and SNTP on the same device.
- NTP is supported only on the following Layer 3 interfaces:
  - Layer 3 Ethernet interfaces.
  - Layer 3 Ethernet subinterfaces.
  - Layer 3 aggregate interfaces.
  - Layer 3 aggregate subinterfaces.

  - VLAN interfaces.
  - Tunnel interfaces.
- Do not configure NTP settings on an aggregate member port.
- To avoid frequent time changes or even synchronization failures, do not specify more than one reference source on a network.
- For correct time synchronization, make sure the time offset between the system time and the NTP clock source is less than 68 years.
- You must specify a context in the **clock protocol** command for using NTP to obtain the time. For more information about the **clock protocol** command, see device management commands in *Fundamentals Command Reference*.
- You can configure NTP on only one context.

NTP tasks at a glance

To configure NTP, perform the following tasks:

1. Enabling the NTP service
2. Configuring NTP association mode
   - Configuring NTP in client/server mode
   - Configuring NTP in symmetric active/passive mode
   - Configuring NTP in broadcast mode
   - Configuring NTP in multicast mode
3. (Optional.) Configuring the local clock as the reference source
4. (Optional.) Configuring access control rights
5. (Optional.) Configuring NTP authentication
   - Configuring NTP authentication in client/server mode
   - Configuring NTP authentication in symmetric active/passive mode
   - Configuring NTP authentication in broadcast mode
   - Configuring NTP authentication in multicast mode
6. (Optional.) Controlling NTP packet sending and receiving
   - Specifying the source interface for NTP messages
   - Disabling an interface from receiving NTP messages
   - Configuring the maximum number of dynamic associations
   - Setting a DSCP value for NTP packets
7. (Optional.) Controlling output of logs and traps during time synchronization

Enabling the NTP service

Restrictions and guidelines

NTP and SNTP are mutually exclusive. Before you enable NTP, make sure SNTP is disabled.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable the NTP service.
   ```
   ntp-service enable
   ```

By default, the NTP service is disabled.

Configuring NTP association mode

Configuring NTP in client/server mode

Restrictions and guidelines

To configure NTP in client/server mode, specify an NTP server for the client.

For a client to synchronize to an NTP server, make sure the server is synchronized by other devices or uses its local clock as the reference source.

If the stratum level of a server is higher than or equal to a client, the client will not synchronize to that server.

You can specify multiple servers for a client by executing the **ntp-service unicast-server** or **ntp-service ipv6 unicast-server** command multiple times.

Procedure

1. Enter system view.

   system-view

2. Specify an NTP server for the device.

   IPv4:

   ntp-service unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number* | **version** *number*] *

   IPv6:

   ntp-service ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number*] *

   By default, no NTP server is specified.

Configuring NTP in symmetric active/passive mode

Restrictions and guidelines

To configure NTP in symmetric active/passive mode, specify a symmetric passive peer for the active peer.

For a symmetric passive peer to process NTP messages from a symmetric active peer, execute the **ntp-service enable** command on the symmetric passive peer to enable NTP.

For time synchronization between the symmetric active peer and the symmetric passive peer, make sure either or both of them are in synchronized state.

You can specify multiple symmetric passive peers by executing the **ntp-service unicast-peer** or **ntp-service ipv6 unicast-peer** command multiple times.

Procedure

1. Enter system view.

   system-view

2. Specify a symmetric passive peer for the device.

IPv4:

```
ntp-service unicast-peer { peer-name | ip-address } [ vpn-instance vpn-instance-name ] [ authentication-keyid keyid | maxpoll maxpoll-interval | minpoll minpoll-interval | priority | source interface-type interface-number | version number ] *
```

IPv6:

```
ntp-service ipv6 unicast-peer { peer-name | ipv6-address } [ vpn-instance vpn-instance-name ] [ authentication-keyid keyid | maxpoll maxpoll-interval | minpoll minpoll-interval | priority | source interface-type interface-number ] *
```

By default, no symmetric passive peer is specified.

Configuring NTP in broadcast mode

Restrictions and guidelines

To configure NTP in broadcast mode, you must configure an NTP broadcast client and an NTP broadcast server.

For a broadcast client to synchronize to a broadcast server, make sure the broadcast server is synchronized by other devices or uses its local clock as the reference source.

Configuring the broadcast client

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Configure the device to operate in broadcast client mode.

   ```
   ntp-service broadcast-client
   ```

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device receives NTP broadcast messages from the specified interface.

Configuring the broadcast server

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Configure the device to operate in NTP broadcast server mode.

   ```
   ntp-service broadcast-server [ authentication-keyid keyid | version number ] *
   ```

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device sends NTP broadcast messages from the specified interface.

Configuring NTP in multicast mode

Restrictions and guidelines

To configure NTP in multicast mode, you must configure an NTP multicast client and an NTP multicast server.

For a multicast client to synchronize to a multicast server, make sure the multicast server is synchronized by other devices or uses its local clock as the reference source.

Configuring a multicast client

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the device to operate in multicast client mode.

   IPv4:

   ntp-service multicast-client [*ip-address*]

   IPv6:

   ntp-service ipv6 multicast-client *ipv6-address*

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device receives NTP multicast messages from the specified interface.

Configuring the multicast server

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the device to operate in multicast server mode.

   IPv4:

   ntp-service multicast-server [*ip-address*] [**authentication-keyid** *keyid* | **ttl** *ttl-number* | **version** *number*] *

   IPv6:

   ntp-service ipv6 multicast-server *ipv6-address* [**authentication-keyid** *keyid* | **ttl** *ttl-number*] *

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device sends NTP multicast messages from the specified interface.

Configuring the local clock as the reference source

About this task

This task enables the device to use the local clock as the reference so that the device is synchronized.

Restrictions and guidelines

Make sure the local clock can provide the time accuracy required for the network. After you configure the local clock as the reference source, the local clock is synchronized, and can operate as a time server to synchronize other devices in the network. If the local clock is incorrect, timing errors occur.

The system time reverts to the initial BIOS default after a reboot. As a best practice, do not configure the local clock as the reference source or configure the device as a time server.

The system time reverts to the initial BIOS default after a cold reboot. The system clock stops and does not record the passing of time during a warm reboot. As a best practice, do not configure the local clock as the reference source or configure the device as a time server.

Devices differ in clock precision. As a best practice to avoid network flapping and clock synchronization failure, configure only one reference clock on the same network segment and make sure the clock has high precision.

Prerequisites

Before you configure this feature, adjust the local system time to ensure that it is accurate.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Configure the local clock as the reference source.

   ntp-service refclock-master [*ip-address*] [*stratum*]

   By default, the device does not use the local clock as the reference source.

Configuring access control rights

Prerequisites

Before you configure the right for peer devices to access the NTP services on the local device, create and configure ACLs associated with the access right. For information about configuring an ACL, see *ACL and QoS Configuration Guide*.

Restrictions and guidelines

Follow the restrictions and guidelines as described in Table 2 to configure the NTP access control rights.

Table 2 Restrictions and guidelines for configuring access control rights

Access control right	Whether the time can be synchronized (whether configurable on a client)	Whether to synchronize the time of other devices (whether configurable on a time server)	Whether control queries are allowed
Peer	Yes	Yes	Yes
Server	Yes	No	Yes
Synchronization	Yes	No	No
Query	No	No	Yes

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Configure the right for peer devices to access the NTP services on the local device.

   IPv4:

   ntp-service access { **peer** | **query** | **server** | **synchronization** } **acl** *ipv4-acl-number*

   IPv6:

```
ntp-service ipv6 { peer |query | server | synchronization } acl
ipv6-acl-number
```

By default, the right for peer devices to access the NTP services on the local device is **peer**.

Configuring NTP authentication

Configuring NTP authentication in client/server mode

Restrictions and guidelines

To ensure a successful NTP authentication in client/server mode, configure the same authentication key ID and key on the server and client. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on client and server. For more information, see Table 3. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 3 NTP authentication results

Client			Server	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Successful authentication				
Yes	Yes	Yes	Yes	Yes
Failed authentication				
Yes	Yes	Yes	Yes	No
Yes	Yes	Yes	No	N/A
Yes	Yes	No	N/A	N/A
Authentication not performed				
Yes	No	N/A	N/A	N/A
No	N/A	N/A	N/A	N/A

Configuring NTP authentication for a client

1. Enter system view.

```
system-view
```

2. Enable NTP authentication.

```
ntp-service authentication enable
```

By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

```
ntp-service authentication-keyid keyid authentication-mode md5
{ cipher | simple } string [ acl ipv4-acl-number | ipv6 acl
ipv6-acl-number ] *
```

By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

```
ntp-service reliable authentication-keyid keyid
```

By default, no authentication key is configured as a trusted key.

5. Associate the specified key with an NTP server.

   IPv4:

   ntp-service unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   IPv6:

   ntp-service ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

Configuring NTP authentication for a server

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode md5** { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication in symmetric active/passive mode

Restrictions and guidelines

To ensure a successful NTP authentication in symmetric active/passive mode, configure the same authentication key ID and key on the active peer and passive peer. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on active peer and passive peer. For more information, see Table 4. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 4 NTP authentication results

Active peer				Passive peer	
Enable NTP authentication	**Specify the peer and key**	**Trusted key**	**Stratum level**	**Enable NTP authentication**	**Trusted key**
Successful authentication					
Yes	Yes	Yes	N/A	Yes	Yes
Failed authentication					
Yes	Yes	Yes	N/A	Yes	No
Yes	Yes	Yes	N/A	No	N/A
Yes	No	N/A	N/A	Yes	N/A
No	N/A	N/A	N/A	Yes	N/A

Active peer				Passive peer	
Enable NTP authentication	**Specify the peer and key**	**Trusted key**	**Stratum level**	**Enable NTP authentication**	**Trusted key**
Yes	Yes	No	Larger than the passive peer	N/A	N/A
Yes	Yes	No	Smaller than the passive peer	Yes	N/A
Authentication not performed					
Yes	No	N/A	N/A	No	N/A
No	N/A	N/A	N/A	No	N/A
Yes	Yes	No	Smaller than the passive peer	No	N/A

Configuring NTP authentication for an active peer

1. Enter system view.

   ```
   system-view
   ```

2. Enable NTP authentication.

   ```
   ntp-service authentication enable
   ```

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ```
   ntp-service authentication-keyid keyid authentication-mode md5
   { cipher | simple } string [ acl ipv4-acl-number | ipv6 acl
   ipv6-acl-number ] *
   ```

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ```
   ntp-service reliable authentication-keyid keyid
   ```

   By default, no authentication key is configured as a trusted key.

5. Associate the specified key with a passive peer.

   IPv4:

   ```
   ntp-service unicast-peer { ip-address | peer-name } [ vpn-instance
   vpn-instance-name ] authentication-keyid keyid
   ```

   IPv6:

   ```
   ntp-service ipv6 unicast-peer { ipv6-address | peer-name }
   [ vpn-instance vpn-instance-name ] authentication-keyid keyid
   ```

Configuring NTP authentication for a passive peer

1. Enter system view.

   ```
   system-view
   ```

2. Enable NTP authentication.

   ```
   ntp-service authentication enable
   ```

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ```
   ntp-service authentication-keyid keyid authentication-mode md5
   { cipher | simple } string [ acl ipv4-acl-number | ipv6 acl
   ipv6-acl-number ] *
   ```

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication in broadcast mode

Restrictions and guidelines

To ensure a successful NTP authentication in broadcast mode, configure the same authentication key ID and key on the broadcast server and client. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on broadcast client and server. For more information, see Table 5. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 5 NTP authentication results

Broadcast server			**Broadcast client**	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Successful authentication				
Yes	Yes	Yes	Yes	Yes
Failed authentication				
Yes	Yes	Yes	Yes	No
Yes	Yes	Yes	No	N/A
Yes	Yes	No	Yes	N/A
Yes	No	N/A	Yes	N/A
No	N/A	N/A	Yes	N/A
Authentication not performed				
Yes	Yes	No	No	N/A
Yes	No	N/A	No	N/A
No	N/A	N/A	No	N/A

Configuring NTP authentication for a broadcast client

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode md5** { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

By default, no authentication key is configured as a trusted key.

Configuring NTP authentication for a broadcast server

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode md5** { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

5. Enter interface view.

   interface *interface-type interface-number*

6. Associate the specified key with the broadcast server.

   ntp-service broadcast-server authentication-keyid *keyid*

   By default, the broadcast server is not associated with a key.

Configuring NTP authentication in multicast mode

Restrictions and guidelines

To ensure a successful NTP authentication in multicast mode, configure the same authentication key ID and key on the multicast server and client. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on broadcast client and server. For more information, see Table 6. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 6 NTP authentication results

Multicast server			Multicast client	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Successful authentication				
Yes	Yes	Yes	Yes	Yes
Failed authentication				
Yes	Yes	Yes	Yes	No
Yes	Yes	Yes	No	N/A
Yes	Yes	No	Yes	N/A
Yes	No	N/A	Yes	N/A
No	N/A	N/A	Yes	N/A

Multicast server			Multicast client	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Authentication not performed				
Yes	Yes	No	No	N/A
Yes	No	N/A	No	N/A
No	N/A	N/A	No	N/A

Configuring NTP authentication for a multicast client

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode md5** { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication for a multicast server

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode md5** { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

5. Enter interface view.

   interface *interface-type interface-number*

6. Associate the specified key with a multicast server.

   IPv4:

   ntp-service multicast-server [*ip-address*] **authentication-keyid** *keyid*

   IPv6:

   ntp-service ipv6 multicast-server *ipv6-multicast-address* **authentication-keyid** *keyid*

By default, no multicast server is associated with the specified key.

Controlling NTP packet sending and receiving

Specifying the source interface for NTP messages

Restrictions and guidelines

To prevent interface status changes from causing NTP communication failures, configure the device to use the IP address of an interface that is always up. For example, you can configure the device to use a loopback interface as the source IP address for the NTP messages to be sent.

When the device responds to an NTP request, the source IP address of the NTP response is always the IP address of the interface that has received the NTP request.

If you have specified the source interface for NTP messages in the **ntp-service unicast-server**/**ntp-service ipv6 unicast-server** or **ntp-service unicast-peer**/**ntp-service ipv6 unicast-peer** command, the specified interface acts as the source interface for NTP messages.

If you have configured the **ntp-service broadcast-server** or **ntp-service multicast-server**/**ntp-service ipv6 multicast-server** command in an interface view, this interface acts as the source interface for broadcast or multicast NTP messages.

Procedure

1. Enter system view.

   `system-view`

2. Specify the source interface for NTP packets.

   IPv4:

   `ntp-service source` *`interface-type interface-number`*

   IPv6:

   `ntp-service ipv6 source` *`interface-type interface-number`*

   By default, no source interface is specified for NTP messages.

Disabling an interface from receiving NTP messages

About this task

When NTP is enabled, all interfaces by default can receive NTP messages. For security purposes, you can disable some of the interfaces from receiving NTP messages.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Disable the interface from receiving NTP packets.

   IPv4:

   `undo ntp-service inbound enable`

   IPv6:

   `undo ntp-service ipv6 inbound enable`

   By default, an interface receives NTP messages.

Configuring the maximum number of dynamic associations

About this task

Perform this task to restrict the number of dynamic associations to prevent dynamic associations from occupying too many system resources.

NTP has the following types of associations:

- **Static association**—A manually created association.
- **Dynamic association**—Temporary association created by the system during NTP operation. A dynamic association is removed if no messages are exchanged within about 12 minutes.

The following describes how an association is established in different association modes:

- **Client/server mode**—After you specify an NTP server, the system creates a static association on the client. The server simply responds passively upon the receipt of a message, rather than creating an association (static or dynamic).
- **Symmetric active/passive mode**—After you specify a symmetric passive peer on a symmetric active peer, static associations are created on the symmetric active peer, and dynamic associations are created on the symmetric passive peer.
- **Broadcast or multicast mode**—Static associations are created on the server, and dynamic associations are created on the client.

Restrictions and guidelines

A single device can have a maximum of 128 concurrent associations, including static associations and dynamic associations.

Procedure

1. Enter system view.
   system-view
2. Configure the maximum number of dynamic sessions.
   ntp-service max-dynamic-sessions *number*
   By default, the maximum number of dynamic sessions is 100.

Setting a DSCP value for NTP packets

About this task

The DSCP value determines the sending precedence of an NTP packet.

Procedure

1. Enter system view.
   system-view
2. Set a DSCP value for NTP packets.
   IPv4:
   ntp-service dscp *dscp-value*
   IPv6:
   ntp-service ipv6 dscp *dscp-value*
   The default DSCP value is 48 for IPv4 packets and 56 for IPv6 packets.

Controlling output of logs and traps during time synchronization

About this task

With this feature configured, the system synchronizes the client's time to the server when the time offset exceeds 128 ms, but outputs logs and traps only when the time offset exceeds the specified thresholds, respectively.

Procedure

1. Enter system view.

   system-view

2. Set the time offset thresholds for outputting logs and traps during time synchronization.

   ntp-service time-offset-threshold { **log** *log-threshold* | **trap** *trap-threshold* } *

   By default, no time offset thresholds are set for outputting logs and traps during time synchronization.

Display and maintenance commands for NTP

Execute **display** commands in any view.

Task	Command
Display information about IPv6 NTP associations.	**display ntp-service ipv6 sessions** [**verbose**]
Display information about IPv4 NTP associations.	**display ntp-service sessions** [**verbose**]
Display information about NTP service status.	**display ntp-service status**
Display brief information about the NTP servers from the local device back to the primary NTP server.	**display ntp-service trace** [**source** *interface-type interface-number*]

Configuring SNTP

About SNTP

SNTP is a simplified, client-only version of NTP specified in RFC 4330. It uses the same packet format and packet exchange procedure as NTP, but provides faster synchronization at the price of time accuracy.

SNTP working mode

SNTP supports only the client/server mode. An SNTP-enabled device can receive time from NTP servers, but cannot provide time services to other devices.

If you specify multiple NTP servers for an SNTP client, the server with the best stratum is selected. If multiple servers are at the same stratum, the NTP server whose time packet is first received is selected.

Protocols and standards

RFC 4330, *Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI*

Restrictions and guidelines: SNTP configuration

When you configure SNTP, follow these restrictions and guidelines:

- You cannot configure both NTP and SNTP on the same device.
- You must specify a context in the **`clock protocol`** command for using NTP to obtain the time. For more information about the **`clock protocol`** command, see device management commands in *Fundamentals Command Reference*.
- You can specify only one context to use NTP for time synchronization.

SNTP tasks at a glance

To configure SNTP, perform the following tasks:

1. Enabling the SNTP service
2. Specifying an NTP server for the device
3. (Optional.) Configuring SNTP authentication

Enabling the SNTP service

Restrictions and guidelines

The NTP service and SNTP service are mutually exclusive. Before you enable SNTP, make sure NTP is disabled.

Procedure

1. Enter system view.

```
system-view
```

2. Enable the SNTP service.

   `sntp enable`

   By default, the SNTP service is disabled.

Specifying an NTP server for the device

Restrictions and guidelines

To use an NTP server as the time source, make sure its clock has been synchronized. If the stratum level of the NTP server is greater than or equal to that of the client, the client does not synchronize with the NTP server.

Procedure

1. Enter system view.

   `system-view`

2. Specify an NTP server for the device.

   IPv4:

   sntp unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **source** *interface-type interface-number* | **version** *number*] *

   IPv6:

   sntp ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **source** *interface-type interface-number*] *

   By default, no NTP server is specified for the device.

   You can specify multiple NTP servers for the client by repeating this step.

   To perform authentication, you need to specify the **authentication-keyid** *keyid* option.

Configuring SNTP authentication

About this task

SNTP authentication ensures that an SNTP client is synchronized only to an authenticated trustworthy NTP server.

Restrictions and guidelines

Enable authentication on both the NTP server and the SNTP client.

Use the same authentication key ID and key on the NTP server and SNTP client. Specify the key as a trusted key on both the NTP server and the SNTP client. For information about configuring NTP authentication on an NTP server, see "Configuring NTP."

On the SNTP client, associate the specified key with the NTP server. Make sure the server is allowed to use the key ID for authentication on the client.

With authentication disabled, the SNTP client can synchronize with the NTP server regardless of whether the NTP server is enabled with authentication.

Procedure

1. Enter system view.

   `system-view`

2. Enable SNTP authentication.

   `sntp authentication enable`

By default, SNTP authentication is disabled.

3. Configure an SNTP authentication key.

   sntp authentication-keyid *keyid* **authentication-mode md5** { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no SNTP authentication key exists.

4. Specify the key as a trusted key.

   sntp reliable authentication-keyid *keyid*

   By default, no trusted key is specified.

5. Associate the SNTP authentication key with an NTP server.

   IPv4:

   sntp unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   IPv6:

   sntp ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   By default, no NTP server is specified.

Controlling output of logs and traps during time synchronization

About this task

With this feature configured, the system synchronizes the client's time to the server when the time offset exceeds 128 ms, but outputs logs and traps only when the time offset exceeds the specified thresholds, respectively.

Procedure

1. Enter system view.

   system-view

2. Set the time offset thresholds for outputting logs and traps during time synchronization.

   sntp time-offset-threshold { **log** *log-threshold* | **trap** *trap-threshold* } *

   By default, no time offset thresholds are set for outputting logs and traps during time synchronization.

Display and maintenance commands for SNTP

Execute **display** commands in any view.

Task	Command
Display information about all IPv6 SNTP associations.	**display sntp ipv6 sessions**
Display information about all IPv4 SNTP associations.	**display sntp sessions**

Contents

Configuring EAA

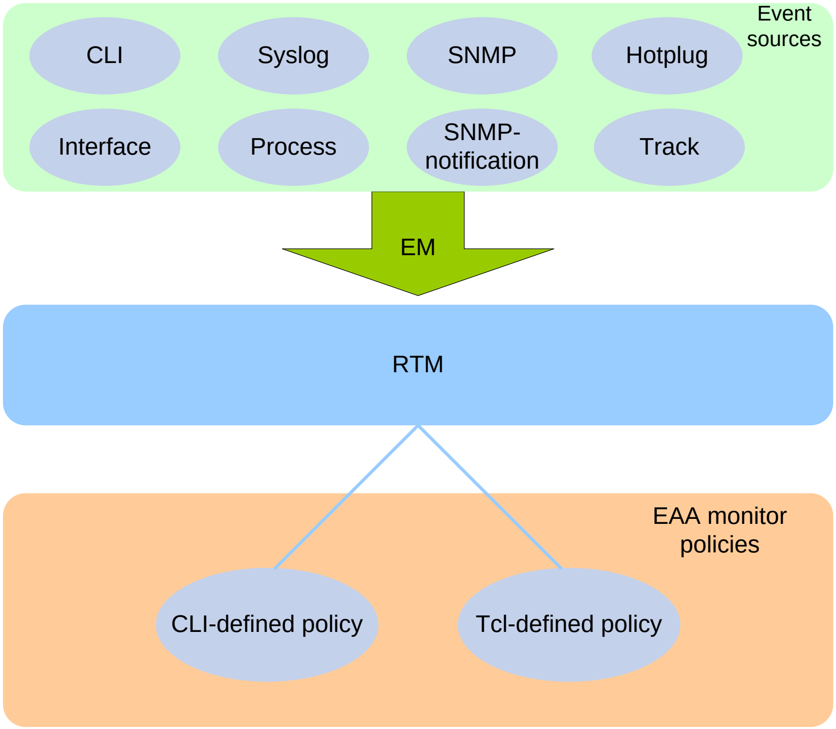
About EAA

Embedded Automation Architecture (EAA) is a monitoring framework that enables you to self-define monitored events and actions to take in response to an event. It allows you to create monitor policies by using the CLI or Tcl scripts.

EAA framework

EAA framework includes a set of event sources, a set of event monitors, a real-time event manager (RTM), and a set of user-defined monitor policies, as shown in Figure 1.

Figure 1 EAA framework



Event sources

Event sources are software or hardware modules that trigger events (see Figure 1).

For example, the CLI module triggers an event when you enter a command. The Syslog module (the information center) triggers an event when it receives a log message.

Event monitors

EAA creates one event monitor to monitor the system for the event specified in each monitor policy. An event monitor notifies the RTM to run the monitor policy when the monitored event occurs.

RTM

RTM manages the creation, state machine, and execution of monitor policies.

EAA monitor policies

A monitor policy specifies the event to monitor and actions to take when the event occurs.

You can configure EAA monitor policies by using the CLI or Tcl.

A monitor policy contains the following elements:

- One event.
- A minimum of one action.
- A minimum of one user role.
- One running time setting.

For more information about these elements, see "Elements in a monitor policy."

Elements in a monitor policy

Elements in an EAA monitor policy include event, action, user role, and runtime.

Event

Table 1 shows types of events that EAA can monitor.

Table 1 Monitored events

Event type	Description
CLI	CLI event occurs in response to monitored operations performed at the CLI. For example, a command is entered, a question mark (?) is entered, or the **Tab** key is pressed to complete a command.
Syslog	Syslog event occurs when the information center receives the monitored log within a specific period. NOTE: The log that is generated by the EAA RTM does not trigger the monitor policy to run.
Process	Process event occurs in response to a state change of the monitored process (such as an exception, shutdown, start, or restart). Both manual and automatic state changes can cause the event to occur.
Hotplug	Hot-swapping event occurs when the monitored member device joins or leaves the IRF fabric.
Interface	Each interface event is associated with two user-defined thresholds: start and restart. An interface event occurs when the monitored interface traffic statistic crosses the start threshold in the following situations: • The statistic crosses the start threshold for the first time. • The statistic crosses the start threshold each time after it crosses the restart threshold.
SNMP	Each SNMP event is associated with two user-defined thresholds: start and restart. SNMP event occurs when the monitored MIB variable's value crosses the start threshold in the following situations: • The monitored variable's value crosses the start threshold for the first time. • The monitored variable's value crosses the start threshold each time after it crosses the restart threshold.
SNMP-Notification	SNMP-Notification event occurs when the monitored MIB variable's value in an SNMP notification matches the specified condition. For example, the broadcast traffic rate on an Ethernet interface reaches or exceeds 30%.
Track	Track event occurs when the state of the track entry changes from Positive to Negative or from Negative to Positive. If you specify multiple track entries for a policy, EAA triggers the policy only when the state of all the track entries changes from Positive

Event type	Description
	(Negative) to Negative (Positive). If you set a suppress time for a policy, the timer starts when the policy is triggered. The system does not process the messages that report the track entry state change from Positive (Negative) to Negative (Positive) until the timer times out.

Action

You can create a series of order-dependent actions to take in response to the event specified in the monitor policy.

The following are available actions:

- Executing a command.
- Sending a log.
- Enabling an active/standby switchover.
- Executing a reboot without saving the running configuration.

User role

For EAA to execute an action in a monitor policy, you must assign the policy the user role that has access to the action-specific commands and resources. If EAA lacks access to an action-specific command or resource, EAA does not perform the action and all the subsequent actions.

For example, a monitor policy has four actions numbered from 1 to 4. The policy has user roles that are required for performing actions 1, 3, and 4. However, it does not have the user role required for performing action 2. When the policy is triggered, EAA executes only action 1.

For more information about user roles, see RBAC in *Fundamentals Configuration Guide*.

Runtime

The runtime limits the amount of time that the monitor policy runs its actions from the time it is triggered. This setting prevents a policy from running its actions permanently to occupy resources.

EAA environment variables

EAA environment variables decouple the configuration of action arguments from the monitor policy so you can modify a policy easily.

An EAA environment variable is defined as a <*variable_name variable_value*> pair and can be used in different policies. When you define an action, you can enter a variable name with a leading dollar sign (**$***variable_name*). EAA will replace the variable name with the variable value when it performs the action.

To change the value for an action argument, modify the value specified in the variable pair instead of editing each affected monitor policy.

EAA environment variables include system-defined variables and user-defined variables.

System-defined variables

System-defined variables are provided by default, and they cannot be created, deleted, or modified by users. System-defined variable names start with an underscore (_) sign. The variable values are set automatically depending on the event setting in the policy that uses the variables.

System-defined variables include the following types:

- **Public variable**—Available for any events.
- **Event-specific variable**—Available only for a type of event. The hotplug event-specific variable is _slot. When a member device in slot 1 joins or leaves the IRF fabric, the value of _slot is 1. When a member device in slot 2 joins or leaves the IRF fabric, the value of _slot is 2.

Table 2 shows all system-defined variables.

Table 2 System-defined EAA environment variables by event type

Event	Variable name and description
Any event	_event_id: Event ID _event_type: Event type _event_type_string: Event type description _event_time: Time when the event occurs _event_severity: Severity level of an event
CLI	_cmd: Commands that are matched
Syslog	_syslog_pattern: Log message content
Hotplug	_slot: ID of the member device that joins or leaves the IRF fabric
Interface	_ifname: Interface name
SNMP	_oid: OID of the MIB variable where an SNMP operation is performed _oid_value: Value of the MIB variable
SNMP-Notification	_oid: OID that is included in the SNMP notification.
Process	_process_name: Process name

User-defined variables

You can use user-defined variables for all types of events.

User-defined variable names can contain digits, characters, and the underscore sign (_), except that the underscore sign cannot be the leading character.

Configuring a user-defined EAA environment variable

About this task

Configure user-defined EAA environment variables so that you can use them when creating EAA monitor policies.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Configure a user-defined EAA environment variable.

   ```
   rtm environment var-name var-value
   ```

   For the system-defined variables, see Table 2.

Configuring a monitor policy

Restrictions and guidelines

Make sure the actions in different policies do not conflict. Policy execution result will be unpredictable if policies that conflict in actions are running concurrently.

You can assign the same policy name to a CLI-defined policy and a Tcl-defined policy. However, you cannot assign the same name to policies that are the same type.

A monitor policy supports only one event and runtime. If you configure multiple events for a policy, the most recent one takes effect.

A monitor policy supports a maximum of 64 valid user roles. User roles added after this limit is reached do not take effect.

Configuring a monitor policy from the CLI

Restrictions and guidelines

You can configure a series of actions to be executed in response to the event specified in a monitor policy. EAA executes the actions in ascending order of action IDs. When you add actions to a policy, you must make sure the execution order is correct. If two actions have the same ID, the most recent one takes effect.

Procedure

1. Enter system view.

   system-view

2. Create a CLI-defined policy and enter its view.

   rtm cli-policy *policy-name*

3. Configure an event for the policy.

   - Configure a CLI event.

     event cli { **async** [**skip**] | **sync** } **mode** { **execute** | **help** | **tab** } **pattern** *regular-exp*

   - Configure a hot-swapping event.

     event hotplug [**insert** | **remove**] **slot** *slot-number*

     Support for this command depends on the device model. For more information, see EAA commands in *Network Management and Monitoring Command Reference*.

   - Configure an interface event.

     event interface *interface-type interface-number* **monitor-obj** *monitor-obj* **start-op** *start-op* **start-val** *start-val* **restart-op** *restart-op* **restart-val** *restart-val* [**interval** *interval*]

   - Configure a process event.

     event process { **exception** | **restart** | **shutdown** | **start** } [**name** *process-name* [**instance** *instance-id*]] [**slot** *slot-number*]

   - Configure an SNMP event.

     event snmp oid *oid* **monitor-obj** { **get** | **next** } **start-op** *start-op* **start-val** *start-val* **restart-op** *restart-op* **restart-val** *restart-val* [**interval** *interval*]

     For the command to take effect, enable SNMP before you execute this command. The device automatically deletes this command after you disable SNMP.

   - Configure an SNMP-Notification event.

     event snmp-notification oid *oid* **oid-val** *oid-val* **op** *op* [**drop**]

     For the command to take effect, enable SNMP before you execute this command. The device automatically deletes this command after you disable SNMP.

   - Configure a Syslog event.

     event syslog priority *priority* **msg** *msg* **occurs** *times* **period** *period*

   - Configure a track event.

event track *track-list* **state { negative** | **positive** } [**suppress-time** *suppress-time*]

By default, a monitor policy does not contain an event.

If you configure multiple events for a policy, the most recent one takes effect.

4. Configure the actions to take when the event occurs.

Choose the following tasks as needed:

- Configure a CLI action.

  action *number* **cli** *command-line*
- Configure a reboot action.

  action *number* **reboot** [**slot** *slot-number*]
- Configure an active/standby switchover action.

  action *number* **switchover**
- Configure a logging action.

  action *number* **syslog priority** *priority* **facility** *local-number* **msg** *msg-body*

By default, a monitor policy does not contain any actions.

5. (Optional.) Assign a user role to the policy.

user-role *role-name*

By default, a monitor policy contains user roles that its creator had at the time of policy creation.

An EAA policy cannot have both the **security-audit** user role and any other user roles. Any previously assigned user roles are automatically removed when you assign the **security-audit** user role to the policy. The previously assigned **security-audit** user role is automatically removed when you assign any other user roles to the policy.

6. (Optional.) Configure the policy action runtime.

running-time *time*

The default policy action runtime is 20 seconds.

If you configure multiple action runtimes for a policy, the most recent one takes effect.

7. Enable the policy.

commit

By default, CLI-defined policies are not enabled.

A CLI-defined policy can take effect only after you perform this step.

Configuring a monitor policy by using Tcl

About this task

A Tcl script contains two parts: Line 1 and the other lines.

- Line 1

  Line 1 defines the event, user roles, and policy action runtime. After you create and enable a Tcl monitor policy, the device immediately parses, delivers, and executes Line 1.

  Line 1 must use the following format:

  ::platformtools::rtm::event_register *event-type arg1 arg2 arg3* … **user-role** *role-name1* | [**user-role** *role-name2* | […]] [**running-time** *running-time*]

  - The *arg1 arg2 arg3* … arguments represent event matching rules. If an argument value contains spaces, use double quotation marks ("") to enclose the value. For example, "a b c."

    - The configuration requirements for the *`event-type`*, *`user-role`*, and *`running-time`* arguments are the same as those for a CLI-defined monitor policy.
- The other lines

  From the second line, the Tcl script defines the actions to be executed when the monitor policy is triggered. You can use multiple lines to define multiple actions. The system executes these actions in sequence. The following actions are available:
    - Standard Tcl commands.
    - EAA-specific Tcl actions:
        - switchover (**`::platformtools::rtm::action switchover`**)
        - syslog (**`::platformtools::rtm::action syslog priority`** *`priority`* **`facility`** *`local-number`* **`msg`** *`msg-body`*). For more information about these arguments, see EAA commands in *Network Management and Monitoring Command Reference*.
    - Commands supported by the device.

Restrictions and guidelines

To revise the Tcl script of a policy, you must suspend all monitor policies first, and then resume the policies after you finish revising the script. The system cannot execute a Tcl-defined policy if you edit its Tcl script without first suspending these policies.

Procedure

1. Download the Tcl script file to the device by using FTP or TFTP.

   For more information about using FTP and TFTP, see *Fundamentals Configuration Guide*.
2. Create and enable a Tcl monitor policy.
   a. Enter system view.

      `system-view`

   b. Create a Tcl-defined policy and bind it to the Tcl script file.

      `rtm tcl-policy` *`policy-name tcl-filename`*

   By default, no Tcl policies exist.

   Make sure the script file is saved on all IRF member devices. This practice ensures that the policy can run correctly after a master/subordinate switchover occurs or the member device where the script file resides leaves the IRF.

Suspending monitor policies

About this task

This task suspends all CLI-defined and Tcl-defined monitor policies. If a policy is running when you perform this task, the system suspends the policy after it executes all the actions.

Restrictions and guidelines

To restore the operation of the suspended policies, execute the **`undo rtm scheduler suspend`** command.

Procedure

1. Enter system view.

   `system-view`
2. Suspend monitor policies.

   `rtm scheduler suspend`

Display and maintenance commands for EAA

Execute **display** commands except for the **display this** command in any view.

Task	Command
Display the running configuration of all CLI-defined monitor policies.	**display current-configuration**
Display user-defined EAA environment variables.	**display rtm environment** [*var-name*]
Display EAA monitor policies.	**display rtm policy** { **active** | **registered** [**verbose**] } [*policy-name*]
Display the running configuration of a CLI-defined monitor policy in CLI-defined monitor policy view.	**display this**

Contents

Monitoring and maintaining processes

About monitoring and maintaining processes

The system software of the device is a full-featured, modular, and scalable network operating system based on the Linux kernel. The system software features run the following types of independent processes:

- **User process**—Runs in user space. Most system software features run user processes. Each process runs in an independent space so the failure of a process does not affect other processes. The system automatically monitors user processes. The system supports preemptive multithreading. A process can run multiple threads to support multiple activities. Whether a process supports multithreading depends on the software implementation.
- **Kernel thread**—Runs in kernel space. A kernel thread executes kernel code. It has a higher security level than a user process. If a kernel thread fails, the system breaks down. You can monitor the running status of kernel threads.

Process monitoring and maintenance tasks at a glance

To monitor and maintain processes, perform the following tasks:

- Monitoring and maintaining user processes
  - Monitoring and maintaining processes

    The commands in this section apply to both user processes and kernel threads.
  - Monitoring and maintaining user processes

    The commands in this section apply only to user processes.
- Monitoring and maintaining kernel threads
  - Monitoring and maintaining processes

    The commands in this section apply to both user processes and kernel threads.
  - Monitoring and maintaining kernel threads

    The commands in this section apply only to kernel threads.

Monitoring and maintaining processes

About this task

The commands in this section apply to both user processes and kernel threads. You can use the commands for the following purposes:

- Display the overall memory usage.
- Display the running processes and their memory and CPU usage.
- Locate abnormal processes.

If a process consumes excessive memory or CPU resources, the system identifies the process as an abnormal process.

- If an abnormal process is a user process, troubleshoot the process as described in "Monitoring and maintaining user processes."

- If an abnormal process is a kernel thread, troubleshoot the process as described in "Monitoring and maintaining kernel threads."

Procedure

Execute the following commands in any view.

Task	Command
Display memory usage. (For more information about this command, see *Fundamentals Command Reference*.)	**display memory** [**summary**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display process state information.	**display process** [**all** | **job** *job-id* | **name** *process-name*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display CPU usage for all processes.	**display process cpu** [**slot** *slot-number* [**cpu** *cpu-number*]]
Monitor process running state.	**monitor process** [**dumbtty**] [**iteration** *number*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Monitor thread running state.	**monitor thread** [**dumbtty**] [**iteration** *number*] [**slot** *slot-number* [**cpu** *cpu-number*]]

Monitoring and maintaining user processes

About monitoring and maintaining user processes

Use this feature to monitor abnormal user processes and locate problems.

Configuring core dump

About this task

The core dump feature enables the system to generate a core dump file each time a process crashes until the maximum number of core dump files is reached. A core dump file stores information about the process. You can send the core dump files to NSFOCUS Support to troubleshoot the problems.

Restrictions and guidelines

Core dump files consume storage resources. Enable core dump only for processes that might have problems.

Procedure

Execute the following commands in user view:

1. (Optional.) Specify the directory for saving core dump files.

   exception filepath *directory*

   The directory for saving core dump files is the root directory of the default file system. For more information about the default file system, see file system management in *Fundamentals Configuration Guide*.

   This command is supported only on the default context.

2. Enable core dump for a process and specify the maximum number of core dump files, or disable core dump for a process.

process core { **maxcore** *value* | **off** } { **job** *job-id* | **name** *process-name* }

By default, a process generates a core dump file for the first exception and does not generate any core dump files for subsequent exceptions.

Display and maintenance commands for user processes

Execute **display** commands in any view and other commands in user view.

Task	Command
Display context information for process exceptions.	**display exception context** [**count** *value*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display the core dump file directory.	**display exception filepath** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display log information for all user processes.	**display process log** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory usage for all user processes.	**display process memory** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display heap memory usage for a user process.	**display process memory heap job** *job-id* [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory content starting from a specified memory block for a user process.	**display process memory heap job** *job-id* **address** *starting-address* **length** *memory-length* [**slot** *slot-number* [**cpu** *cpu-number*]]
Display the addresses of memory blocks with a specified size used by a user process.	**display process memory heap job** *job-id* **size** *memory-size* [**offset** *offset-size*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear context information for process exceptions.	**reset exception context** [**slot** *slot-number* [**cpu** *cpu-number*]]

Monitoring and maintaining kernel threads

Restrictions and guidelines for monitoring and maintaining kernel threads

This command is supported only on the default context.

Configuring kernel thread deadloop detection

About this task

Kernel threads share resources. If a kernel thread monopolizes the CPU, other threads cannot run, resulting in a deadloop.

This feature enables the device to detect deadloops. If a thread occupies the CPU for a specific interval, the device determines that a deadloop has occurred, logs the event, and reboots to remove the deadloop.

Restrictions and guidelines

Change kernel thread deadloop detection settings only under the guidance of NSFOCUS Support. Inappropriate configuration can cause system breakdown. As a best practice, leave the default unchanged.

Procedure

1. Enter system view.

   system-view

2. Enable kernel thread deadloop detection.

   monitor kernel deadloop enable [**slot** *slot-number* [**cpu** *cpu-number* [**core** *core-number*&<1-64>]]]

   By default, kernel thread deadloop detection is enabled.

3. (Optional.) Set the interval for identifying a kernel thread deadloop.

   monitor kernel deadloop time *time* [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, the threshold for identifying a kernel thread deadloop is 28 seconds.

4. (Optional.) Exclude a kernel thread from kernel thread deadloop detection.

   monitor kernel deadloop exclude-thread *tid* [**slot** *slot-number* [**cpu** *cpu-number*]]

   When enabled, kernel thread deadloop detection monitors all kernel threads by default.

5. Set kernel thread deadloop protection thresholds.

   monitor kernel deadloop action threshold *threshold* [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, the kernel thread deadloop protection threshold is 1. The device takes protection actions immediately after detecting a kernel thread deadloop.

   When the number of detected kernel thread deadloops reaches the kernel thread deadloop protection threshold, the device takes protection actions to remove the deadloops.

Configuring kernel thread starvation detection

About this task

Starvation occurs when a thread is unable to access shared resources.

Kernel thread starvation detection enables the system to detect and report thread starvation. If a thread is not executed within a specific interval, the system determines that a starvation has occurred and generates a starvation message.

Thread starvation does not impact system operation. A starved thread can automatically run when certain conditions are met.

Restrictions and guidelines

Configure kernel thread starvation detection only under the guidance of NSFOCUS Support. Inappropriate configuration can cause system breakdown. As a best practice, leave the default unchanged.

Procedure

1. Enter system view.

   system-view

2. Enable kernel thread starvation detection.

   monitor kernel starvation enable [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, kernel thread starvation detection is disabled.

3. (Optional.) Set the interval for identifying a kernel thread starvation.

   monitor kernel starvation time *time* [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, the threshold for identifying a kernel thread starvation is 120 seconds.

4. (Optional.) Exclude a kernel thread from kernel thread starvation detection.

   monitor kernel starvation exclude-thread *tid* [**slot** *slot-number* [**cpu** *cpu-number*]]

   When enabled, kernel thread starvation detection monitors all kernel threads by default.

Display and maintenance commands for kernel threads

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display kernel thread deadloop detection configuration.	**display kernel deadloop configuration** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread deadloop information.	**display kernel deadloop** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread exception information.	**display kernel exception** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread reboot information.	**display kernel reboot** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread starvation detection configuration.	**display kernel starvation configuration** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread starvation information.	**display kernel starvation** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear kernel thread deadloop information.	**reset kernel deadloop** [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear kernel thread exception information.	**reset kernel exception** [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear kernel thread reboot information.	**reset kernel reboot** [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear kernel thread starvation information.	**reset kernel starvation** [**slot** *slot-number* [**cpu** *cpu-number*]]

Configuring NETCONF

About NETCONF

Network Configuration Protocol (NETCONF) is an XML-based network management protocol. It provides programmable mechanisms to manage and configure network devices. Through NETCONF, you can configure device parameters, retrieve parameter values, and collect statistics. For a network that has devices from vendors, you can develop a NETCONF-based NMS system to configure and manage devices in a simple and effective way.

NETCONF structure

NETCONF has the following layers: content layer, operations layer, RPC layer, and transport protocol layer.

Table 1 NETCONF layers and XML layers

NETCONF layer	XML layer	Description
Content	Configuration data, status data, and statistics information	Contains a set of managed objects, which can be configuration data, status data, and statistics information. For information about the operable data, see the NETCONF XML API references for the device.
Operations	<get>,<get-config>, <edit-config>…	Defines a set of base operations invoked as RPC methods with XML-encoded parameters. NETCONF base operations include data retrieval operations, configuration operations, lock operations, and session operations. For the device supported operations, see "Supported NETCONF operations."
RPC	<rpc>,<rpc-reply>	Provides a simple, transport-independent framing mechanism for encoding RPCs. The <rpc> and <rpc-reply> elements are used to enclose NETCONF requests and responses (data at the operations layer and the content layer).
Transport protocol	Console/Telnet/SSH/HTTP/HTTPS/TLS	Provides reliable connection-oriented data links. The following transport layer sessions are available: • CLI sessions, including NETCONF over Telnet, NETCONF over SSH, and NETCONF over console sessions. • NETCONF over HTTP sessions and NETCONF over HTTPS sessions. • NETCONF over SOAP sessions, including NETCONF over SOAP over HTTP and NETCONF over SOAP over HTTPS sessions.

NETCONF message format

NETCONF

All NETCONF messages are XML-based and comply with RFC 4741. Any incoming NETCONF messages must pass XML Schema check before it can be processed. If a NETCONF message fails XML Schema check, the device sends an error message to the client.

For information about the NETCONF operations supported by the device and the operable data, see the NETCONF XML API reference for the device.

The following example shows a NETCONF message for getting all parameters of all interfaces on the device:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
                 <Interface/>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

NETCONF over SOAP

All NETCONF over SOAP messages are XML-based and comply with RFC 4741. NETCONF messages are contained in the <Body> element of SOAP messages. NETCONF over SOAP messages also comply with the following rules:

- SOAP messages must use the SOAP Envelope namespaces.
- SOAP messages must use the SOAP Encoding namespaces.
- SOAP messages cannot contain the following information:
  - DTD reference.
  - XML processing instructions.

The following example shows a NETCONF over SOAP message for getting all parameters of all interfaces on the device:

```
<env:Envelope xmlns:env="http://www.w3.org/2003/05/soap-envelope">
  <env:Header>
    <auth:Authentication env:mustUnderstand="1"
xmlns:auth="http://www.nsfocus.com.cn/netconf/base:1.0">
      <auth:AuthInfo>800207F0120020C</auth:AuthInfo>
    </auth:Authentication>
  </env:Header>
  <env:Body>
    <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <get-bulk>
        <filter type="subtree">
          <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
            <Ifmgr>
              <Interfaces>
                <Interface/>
              </Interfaces>
            </Ifmgr>
          </top>
        </filter>
      </get-bulk>
    </rpc>
  </env:Body>
</env:Envelope>
```

How to use NETCONF

You can use NETCONF to manage and configure the device by using the methods in Table 2.

Table 2 NETCONF methods for configuring the device

Configuration tool	Login method	Remarks
CLI	• Console port • SSH • Telnet	To perform NETCONF operations, copy valid NETCONF messages to the CLI in XML view.
Standard Web interface for the device	• HTTP • HTTPS	The system automatically converts the configuration operations on the Web interface to NETCONF messages and sends them to the device to perform NETCONF operations.
Custom user interface	N/A	To use this method, you must enable NETCONF over SOAP. NETCONF messages will be encapsulated in SOAP for transmission.

Protocols and standards

- RFC 3339, *Date and Time on the Internet: Timestamps*
- RFC 4741, *NETCONF Configuration Protocol*
- RFC 4742, *Using the NETCONF Configuration Protocol over Secure SHell (SSH)*
- RFC 4743, *Using NETCONF over the Simple Object Access Protocol (SOAP)*
- RFC 5277, *NETCONF Event Notifications*
- RFC 5381, *Experience of Implementing NETCONF over SOAP*
- RFC 5539, *NETCONF over Transport Layer Security (TLS)*
- RFC 6241, *Network Configuration Protocol*

NETCONF tasks at a glance

To configure the device through NETCONF, perform the following tasks:

1. Configuring NETCONF to use module-specific namespaces
2. Establishing a NETCONF session
   a. (Optional.) Setting NETCONF session attributes
   b. Establishing NETCONF over SOAP sessions
   c. Establishing NETCONF over SSH sessions
   d. Establishing NETCONF over Telnet or NETCONF over console sessions
   e. Exchanging capabilities
3. (Optional.) Retrieving device configuration information
   - Retrieving device configuration and state information
   - Retrieving non-default settings
   - Retrieving NETCONF information
   - Retrieving NETCONF session information

4. (Optional.) Filtering data
   - Table-based filtering
   - Column-based filtering
5. (Optional.) Locking or unlocking the running configuration
   a. Locking the running configuration
   b. Unlocking the running configuration
6. (Optional.) Modifying the configuration
7. (Optional.) Managing configuration files
   - Saving the running configuration
   - Loading the configuration
   - Rolling back the configuration
8. (Optional.) Performing CLI operations through NETCONF
9. (Optional.) Subscribing to events
   - Subscribing to syslog events
   - Subscribing to events monitored by NETCONF
   - Subscribing to events reported by modules
10. (Optional.) Terminating NETCONF sessions
11. (Optional.) Returning to the CLI

Configuring NETCONF to use module-specific namespaces

About this task

NETCONF supports the following types of namespaces:

- **Common namespace**—The common namespace is shared by all modules. In a packet that uses the common namespace, the namespace is indicated in the <top> element, and the modules are listed under the <top> element.

  Example:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
         <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
            <Ifmgr>
               <Interfaces>
               </Interfaces>
            </Ifmgr>
         </top>
      </filter>
   </get-bulk>
</rpc>
```

- **Module-specific namespace**—Each module has its own namespace. A packet that uses a module-specific namespace does not have the <top> element. The namespace follows the module name.

  Example:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
```

```
   <get-bulk>
      <filter type="subtree">
            <Ifmgr xmlns="http://www.nsfocus.com.cn/netconf/data:1.0-Ifmgr">
               <Interfaces>
               </Interfaces>
            </Ifmgr>
      </filter>
   </get-bulk>
</rpc>
```

The common namespace is incompatible with module-specific namespaces. To set up a NETCONF session, the device and the client must use the same type of namespaces. By default, the common namespace is used. If the client does not support the common namespace, use this feature to configure the device to use module-specific namespaces.

Restrictions and guidelines

For this feature to take effect, you must reestablish the NETCONF session.

Procedure

1. Enter system view.
   `system-view`
2. Configure NETCONF to use module-specific namespaces.
   `netconf capability specific-namespace`
   By default, the common namespace is used.

Establishing a NETCONF session

Restrictions and guidelines for NETCONF session establishment

After a NETCONF session is established, the device automatically sends its capabilities to the client. You must send the capabilities of the client to the device before you can perform any other NETCONF operations.

Before performing a NETCONF operation, make sure no other users are configuring or managing the device. If multiple users simultaneously configure or manage the device, the result might be different from what you expect.

You can use the **`aaa session-limit`** command to set the maximum number of NETCONF sessions that the device can support. If the upper limit is reached, new NETCONF users cannot access the device. For information about this command, see AAA in *Security Configuration Guide*.

Setting NETCONF session attributes

About this task

NETCONF supports the following types of namespaces:

- **Common namespace**—The common namespace is shared by all modules. In a packet that uses the common namespace, the namespace is indicated in the <top> element, and the modules are listed under the <top> element.

  Example:

  ```
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  ```

```
   <get-bulk>
      <filter type="subtree">
         <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
            <Ifmgr>
               <Interfaces>
               </Interfaces>
            </Ifmgr>
         </top>
      </filter>
   </get-bulk>
</rpc>
```

- **Module-specific namespace**—Each module has its own namespace. A packet that uses a module-specific namespace does not have the <top> element. The namespace follows the module name.

  Example:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
            <Ifmgr xmlns="http://www.nsfocus.com.cn/netconf/data:1.0-Ifmgr">
               <Interfaces>
               </Interfaces>
            </Ifmgr>
      </filter>
   </get-bulk>
</rpc>
```

The common namespace is incompatible with module-specific namespaces. To set up a NETCONF session, the device and the client must use the same type of namespaces. By default, the common namespace is used. If the client does not support the common namespace, use this feature to configure the device to use module-specific namespaces.

Procedure

1. Enter system view.

   system-view

2. Set the NETCONF session idle timeout time.

   netconf { **agent** | **soap** } **idle-timeout** *minute*

Parameter	Description
agent	Specifies the following sessions: • NETCONF over SSH sessions. • NETCONF over Telnet sessions. • NETCONF over console sessions. By default, the idle timeout time is 0, and the sessions never time out.
soap	Specifies the following sessions: • NETCONF over SOAP over HTTP sessions. • NETCONF over SOAP over HTTPS sessions. The default setting is 10 minutes.

3. Enable NETCONF logging.

netconf log source { **all** | { **agent** | **soap** | **web** } * } { **protocol-operation** { **all** | { **action** | **config** | **get** | **set** | **session** | **syntax** | **others** } * } | **row-operation** | **verbose** }

By default, NETCONF logging is disabled.

4. Configure NETCONF to use module-specific namespaces.

   netconf capability specific-namespace

   By default, the common namespace is used.

   For the setting to take effect, you must reestablish the NETCONF session.

Establishing NETCONF over SOAP sessions

About this task

You can use a custom user interface to establish a NETCONF over SOAP session to the device and perform NETCONF operations. NETCONF over SOAP encapsulates NETCONF messages into SOAP messages and transmits the SOAP messages over HTTP or HTTPS.

Restrictions and guidelines

You can add an authentication domain to the <UserName> parameter of a SOAP request. The authentication domain takes effect only on the current request.

The mandatory authentication domain configured by using the **netconf soap domain** command takes precedence over the authentication domain specified in the <UserName> parameter of a SOAP request.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Apply an SSL server policy to the NETCONF over SOAP over HTTPS service.

   netconf soap https ssl-server-policy *policy-name*

   By default, no SSL server policy is applied to the NETCONF over SOAP over HTTPS service.

   The NETCONF over SOAP over HTTPS service will use the SSL server policy to enhance service security. For more information about SSL server policies, see SSL configuration in *Security Configuration Guide*.

   After NETCONF over SOAP over HTTPS is enabled, changes to the applied SSL server policy do not affect established NETCONF over SOAP over HTTPS sessions. The changes affect only NETCONF over SOAP over HTTPS sessions established after the changes are made.

3. Enable NETCONF over SOAP.

   netconf soap { **http** | **https** } **enable**

   By default, the NETCONF over SOAP feature is disabled.

4. (Optional.) Specify the NETCONF over SOAP over HTTP port number.

   netconf soap http port *port-number*

   By default, the NETCONF over SOAP over HTTP port number is 80.

5. (Optional.) Use an ACL to control NETCONF over SOAP access so only clients permitted by the ACL can establish NETCONF over SOAP sessions.

   netconf soap { **http** | **https** } [**ipv6**] **acl** { *acl-number* | **name** *acl-name* }

   By default, no ACL is applied to control NETCONF over SOAP access.

   The **ipv6** keyword is supported only if you have specified the **http** keyword.

6. (Optional.) Specify a mandatory authentication domain for NETCONF users.

   netconf soap domain *domain-name*

By default, no mandatory authentication domain is specified for NETCONF users. For information about authentication domains, see *Security Configuration Guide*.

7. Use the custom user interface to establish a NETCONF over SOAP session with the device.

   For information about the custom user interface, see the user guide for the interface.

Establishing NETCONF over SSH sessions

Prerequisites

Before establishing a NETCONF over SSH session, make sure the custom user interface can access the device through SSH.

Procedure

1. Enter system view.

   `system-view`

2. Enable NETCONF over SSH.

   `netconf ssh server enable`

   By default, NETCONF over SSH is disabled.

3. Specify the listening port for NETCONF over SSH packets.

   `netconf ssh server port` *`port-number`*

   By default, the listening port number is 830.

4. Use an IPv4 ACL to control NETCONF over SSH access.

   `netconf ssh acl` { *`ipv4-acl-number`* | **name** *`ipv4-acl-name`* }

   By default, no IPv4 ACL is specified to control NETCONF over SSH access.

5. Use the custom user interface to establish a NETCONF over SSH session with the device.

   For information about the custom user interface, see the user guide for the interface.

Establishing NETCONF over Telnet or NETCONF over console sessions

Restrictions and guidelines

To ensure the format correctness of a NETCONF message, do not enter the message manually. Copy and paste the message.

While the device is performing a NETCONF operation, do not perform any other operations, such as pasting a NETCONF message or pressing **Enter**.

For the device to identify NETCONF messages, you must add end mark **]]>]]>** at the end of each NETCONF message. Examples in this document do not necessarily have this end mark. Do add the end mark in actual operations.

Prerequisites

To establish a NETCONF over Telnet session or a NETCONF over console session, first log in to the device through Telnet or the console port.

Procedure

To enter XML view, execute the following command in user view:

`xml`

If the XML view prompt appears, the NETCONF over Telnet session or NETCONF over console session is established successfully.

Exchanging capabilities

About this task

After a NETCONF session is established, the device sends its capabilities to the client. You must use a hello message to send the capabilities of the client to the device before you can perform any other NETCONF operations.

Hello message from the device to the client

```
<?xml version="1.0" encoding="UTF-8"?><hello
xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"><capabilities><capability>urn:ietf:pa
rams:netconf:base:1.1</capability><capability>urn:ietf:params:netconf:writable-runnin
g</capability><capability>urn:ietf:params:netconf:capability:notification:1.0</capabi
lity><capability>urn:ietf:params:netconf:capability:validate:1.1</capability><capabil
ity>urn:ietf:params:netconf:capability:interleave:1.0</capability><capability>urn:nsf
ocus:params:netconf:capability:nsfocus-netconf-ext:1.0</capability></capabilities><se
ssion-id>1</session-id></hello>]]>]]>
```

The <capabilities> element carries the capabilities supported by the device. The supported capabilities vary by device model.

The <session-id> element carries the unique ID assigned to the NETCONF session.

Hello message from the client to the device

After receiving the hello message from the device, copy the following hello message to notify the device of the capabilities supported by the client:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
     capability-set
   </capability>
 </capabilities>
</hello>
```

Item	Description
capability-set	Specifies a set of capabilities supported by the client. Use the <capability> and </capability> tags to enclose each user-defined capability set.

Retrieving device configuration information

Restrictions and guidelines for device configuration retrieval

During a <get>, <get-bulk>, <get-config>, or <get-bulk-config> operation, NETCONF replaces unidentifiable characters in the retrieved data with question marks (?) before sending the data to the client. If the relevant module process is not started yet, the following message is sent to the client:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data/>
</rpc-reply>
```

The <get><netconf-state/></get> operation does not support data filtering.

For more information about the NETCONF operations, see the NETCONF XML API references for the device.

Retrieving device configuration and state information

You can use the following NETCONF operations to retrieve device configuration and state information:

- **<get> operation**—Retrieves all device configuration and state information that match the specified conditions.
- **<get-bulk> operation**—Retrieves data entries starting from the data entry next to the one with the specified index. One data entry contains a device configuration entry and a state information entry. The returned output does not include the index information.

The <get> message and <get-bulk> message share the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <getoperation>
    <filter>
      <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
          Specify the module, submodule, table name, and column name
      </top>
    </filter>
  </getoperation>
</rpc>
```

Item	Description
getoperation	Operation name, **get** or **get-bulk**.
filter	Specifies the filtering conditions, such as the module name, submodule name, table name, and column name. • If you specify a module name, the operation retrieves the data for the specified module. If you do not specify a module name, the operation retrieves the data for all modules. • If you specify a submodule name, the operation retrieves the data for the specified submodule. If you do not specify a submodule name, the operation retrieves the data for all submodules. • If you specify a table name, the operation retrieves the data for the specified table. If you do not specify a table name, the operation retrieves the data for all tables. • If you specify only the index column, the operation retrieves the data for all columns. If you specify the index column and any other columns, the operation retrieves the data for the index column and the specified columns.

A <get-bulk> message can carry the **count** and **index** attributes.

Item	Description
index	Specifies the index. If you do not specify this item, the index value starts with 1 by default.
count	Specifies the data entry quantity. The **count** attribute complies with the following rules: • The **count** attribute can be placed in the module node and table node. In other nodes, it cannot be resolved.

Item	Description
	- When the **count** attribute is placed in the module node, a descendant node inherits this count attribute if the descendant node does not contain the count attribute. - The <get-bulk> operation retrieves all the rest data entries starting from the data entry next to the one with the specified index if either of the following conditions occurs: ○ You do not specify the **count** attribute. ○ The number of matching data entries is less than the value of the **count** attribute.

The following <get-bulk> message example specifies the **count** and **index** attributes:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="http://www.nsfocus.com.cn/netconf/base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0"
xmlns:base="http://www.nsfocus.com.cn/netconf/base:1.0">
        <Syslog>
          <Logs xc:count="5">
            <Log>
              <Index>10</Index>
           </Log>
             </Logs>
        </Syslog>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

When retrieving interface information, the device cannot identify whether an integer value for the <IfIndex> element represents an interface name or index. When retrieving VPN instance information, the device cannot identify whether an integer value for the <vrfindex> element represents a VPN name or index. To resolve the issue, you can use the **valuetype** attribute to specify the value type.

The **valuetype** attribute has the following values:

Value	Description
name	The element is carrying a name.
index	The element is carrying an index.
auto	Default value. The device uses the value of the element as a name for information matching. If no match is found, the device uses the value as an index for interface or information matching.

The following example specifies an index-type value for the <IfIndex> element:

```
<rpc xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <getoperation>
    <filter>
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0"
xmlns:base="http://www.nsfocus.com.cn/netconf/base:1.0">
       <VLAN>
```

```
        <TrunkInterfaces>
          <Interface>
            <IfIndex base:valuetype="index">1</IfIndex>
          </Interface>
        </TrunkInterfaces>
       </VLAN>
      </top>
    </filter >
  </getoperation>
</rpc>
```

If the <get> or < get-bulk> operation succeeds, the device returns the retrieved data in the following format:

```
<?xml version="1.0"?>
 <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
     Device state and configuration data
  </data>
</rpc-reply>
```

Retrieving non-default settings

The <get-config> and <get-bulk-config> operations are used to retrieve all non-default settings. The <get-config> and <get-bulk-config> messages can contain the <filter> element for filtering data.

The <get-config> and <get-bulk-config> messages are similar. The following is a <get-config> message example:

```
<?xml version="1.0"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter>
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
          Specify the module name, submodule name, table name, and column name
      </top>
    </filter>
  </get-config>
</rpc>
```

If the <get-config> or <get-bulk-config> operation succeeds, the device returns the retrieved data in the following format:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    Data matching the specified filter
  </data>
</rpc-reply>
```

Retrieving NETCONF information

Use the <get><netconf-state/></get> message to retrieve NETCONF information.

# Copy the following text to the client to retrieve NETCONF information:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc message-id="m-641" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <get>
      <filter type='subtree'>
        <netconf-state xmlns='urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring'>
             <getType/>
        </netconf-state>
      </filter>
    </get>
  </rpc>
```

If you do not specify a value for *getType*, the retrieval operation retrieves all NETCONF information.

The value for *getType* can be one of the following operations:

Operation	Description
capabilities	Retrieves device capabilities.
datastores	Retrieves databases from the device.
schemas	Retrieves the list of the YANG file names from the device.
sessions	Retrieves session information from the device.
statistics	Retrieves NETCONF statistics.

If the <get><netconf-state/></get> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0"?>
 <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
     Retrieved NETCONF information
  </data>
</rpc-reply>
```

Retrieving NETCONF session information

Use the <get-sessions> operation to retrieve NETCONF session information of the device.

# Copy the following message to the client to retrieve NETCONF session information from the device:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-sessions/>
</rpc>
```

If the <get-sessions> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
```

```
  <get-sessions>
    <Session>
      <SessionID>Configuration session ID</SessionID>
      <Line>Line information</Line>
      <UserName>Name of the user creating the session</UserName>
      <Since>Time when the session was created</Since>
      <LockHeld>Whether the session holds a lock</LockHeld>
    </Session>
  </get-sessions>
</rpc-reply>
```

Example: Retrieving a data entry for the interface table

Network configuration

Retrieve a data entry for the interface table.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
  </capabilities>
</hello>
```

# Retrieve a data entry for the interface table.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0"
xmlns:web="http://www.nsfocus.com.cn/netconf/base:1.0">
        <Ifmgr>
          <Interfaces web:count="1">
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <get-bulk> operation is successful:

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
  <data>
    <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
      <Ifmgr>
        <Interfaces>
```

```
          <Interface>
            <IfIndex>3</IfIndex>
            <Name>GigabitEthernet1/0/2</Name>
            <AbbreviatedName>GE1/0/2</AbbreviatedName>
            <PortIndex>3</PortIndex>
            <ifTypeExt>22</ifTypeExt>
            <ifType>6</ifType>
            <Description>GigabitEthernet1/0/2 Interface</Description>
            <AdminStatus>2</AdminStatus>
            <OperStatus>2</OperStatus>
            <ConfigSpeed>0</ConfigSpeed>
            <ActualSpeed>100000</ActualSpeed>
            <ConfigDuplex>3</ConfigDuplex>
            <ActualDuplex>1</ActualDuplex>
          </Interface>
        </Interfaces>
      </Ifmgr>
    </top>
  </data>
</rpc-reply>
```

Example: Retrieving non-default configuration data

Network configuration

Retrieve all non-default configuration data.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

# Retrieve all non-default configuration data.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
  </get-config>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <get-config> operation is successful:

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
            <Ifmgr>
                <Interfaces>
                    <Interface>
                        <IfIndex>1307</IfIndex>
                        <Shutdown>1</Shutdown>
                    </Interface>
                    <Interface>
                        <IfIndex>1308</IfIndex>
                        <Shutdown>1</Shutdown>
                    </Interface>
                    <Interface>
                        <IfIndex>1309</IfIndex>
                        <Shutdown>1</Shutdown>
                    </Interface>
                    <Interface>
                        <IfIndex>1311</IfIndex>
                            <VlanType>2</VlanType>
                    </Interface>
                    <Interface>
                        <IfIndex>1313</IfIndex>
                            <VlanType>2</VlanType>
                    </Interface>
                </Interfaces>
            </Ifmgr>
            <Syslog>
                <LogBuffer>
                    <BufferSize>120</BufferSize>
                </LogBuffer>
            </Syslog>
            <System>
                <Device>
                    <SysName>Sysname</SysName>
                    <TimeZone>
                        <Zone>+11:44</Zone>
                        <ZoneName>beijing</ZoneName>
                    </TimeZone>
                </Device>
            </System>
        </top>
    </data>
</rpc-reply>
```

Example: Retrieving syslog configuration data

Network configuration

Retrieve configuration data for the Syslog module.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

# Retrieve configuration data for the Syslog module.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
        <Syslog/>
      </top>
    </filter>
  </get-config>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <get-config> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
            <Syslog>
                    <LogBuffer>
                        <BufferSize>120</BufferSize>
                    </LogBuffer>
            </Syslog>
        </top>
    </data>
</rpc-reply>
```

Example: Retrieving NETCONF session information

Network configuration

Get NETCONF session information.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Copy the following message to the client to exchange capabilities with the device:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

# Copy the following message to the client to get the current NETCONF session information on the device:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-sessions/>
</rpc>
```

Verifying the configuration

If the client receives a message as follows, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <get-sessions>
        <Session>
            <SessionID>1</SessionID>
            <Line>vty0</Line>
            <UserName></UserName>
            <Since>2017-01-07T00:24:57</Since>
            <LockHeld>false</LockHeld>
        </Session>
    </get-sessions>
</rpc-reply>
```

The output shows the following information:

- The session ID of an existing NETCONF session is 1.
- The login user type is vty0.
- The login time is 2017-01-07T00:24:57.
- The user does not hold the lock of the configuration.

Filtering data

About data filtering

You can define a filter to filter information when you perform a <get>, <get-bulk>, <get-config>, or <get-bulk-config> operation. Data filtering includes the following types:

- **Table-based filtering**—Filters table information.
- **Column-based filtering**—Filters information for a single column.

Restrictions and guidelines for data filtering

For table-based filtering to take effect, you must configure table-based filtering before column-based filtering.

Table-based filtering

About this task

The namespace is **http://www.nsfocus.com.cn/netconf/base:1.0**. The attribute name is **filter**. For information about the support for table-based match, see the NETCONF XML API references.

# Copy the following text to the client to retrieve the longest data with IP address **1.1.1.0** and mask length **24** from the IPv4 routing table:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:nsfocus="http://www.nsfocus.com.cn/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
        <Route>
         <Ipv4Routes>
           <RouteEntry nsfocus:filter="IP 1.1.1.0 MaskLen 24 longer"/>
         </Ipv4Routes>
        </Route>
      </top>
    </filter>
  </get>
</rpc>
```

Restrictions and guidelines

To use table-based filtering, specify a match criterion for the **filter** row attribute.

Column-based filtering

About this task

Column-based filtering includes full match filtering, regular expression match filtering, and conditional match filtering. Full match filtering has the highest priority and conditional match filtering has the lowest priority. When more than one filtering criterion is specified, the one with the highest priority takes effect.

Full match filtering

You can specify an element value in an XML message to implement full match filtering. If multiple element values are provided, the system returns the data that matches all the specified values.

# Copy the following text to the client to retrieve configuration data of all interfaces in UP state:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <AdminStatus>1</AdminStatus>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

You can also specify an attribute name that is the same as a column name of the current table at the row to implement full match filtering. The system returns only configuration data that matches this attribute name. The XML message equivalent to the above element-value-based full match filtering is as follows:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <top
xmlns="http://www.nsfocus.com.cn/netconf/data:1.0"xmlns:data="http://www.nsfocus.com.
cn/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface data:AdminStatus="1"/>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

The above examples show that both element-value-based full match filtering and attribute-name-based full match filtering can retrieve the same index and column information for all interfaces in up state.

Regular expression match filtering

To implement a complex data filtering with characters, you can add a **regExp** attribute for a specific element.

The supported data types include integer, date and time, character string, IPv4 address, IPv4 mask, IPv6 address, MAC address, OID, and time zone.

# Copy the following text to the client to retrieve the descriptions of interfaces, of which all the characters must be upper-case letters from A to Z:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:nsfocus="http://www.nsfocus.com.cn/netconf/base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <Description nsfocus:regExp="^[A-Z]*$"/>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-config>
</rpc>
```

Conditional match filtering

To implement a complex data filtering with digits and character strings, you can add a **match** attribute for a specific element. Table 3 lists the conditional match operators.

Table 3 Conditional match operators

Operation	**Operator**	**Remarks**
More than	match="more:*value*"	More than the specified value. The supported data types include date, digit, and character string.
Less than	match="less:*value*"	Less than the specified value. The supported data types include date, digit, and character string.
Not less than	match="notLess:*value*"	Not less than the specified value. The supported data types include date, digit, and character string.
Not more than	match="notMore:*value*"	Not more than the specified value. The supported data types include date, digit, and character string.
Equal	match="equal:*value*"	Equal to the specified value. The supported data types include date, digit, character string, OID, and BOOL.
Not equal	match="notEqual:*value*"	Not equal to the specified value. The supported data types include date, digit, character string, OID, and BOOL.
Include	match="include:*string*"	Includes the specified string. The supported data types include only character string.
Not include	match="exclude:*string*"	Excludes the specified string. The supported data types include only character string.
Start with	match="startWith:*string*"	Starts with the specified string. The supported data types include character string and OID.
End with	match="endWith:*string*"	Ends with the specified string. The supported data types include only character string.

# Copy the following text to the client to retrieve extension information about the entity whose CPU usage is more than 50%:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:nsfocus="http://www.nsfocus.com.cn/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
        <Device>
          <ExtPhysicalEntities>
            <Entity>
              <CpuUsage nsfocus:match="more:50"></CpuUsage>
            </Entity>
          </ExtPhysicalEntities>
        </Device>
      </top>
    </filter>
  </get>
</rpc>
```

Example: Filtering data with regular expression match

Network configuration

Retrieve all data including **Gigabit** in the **Description** column of the Interfaces table under the Ifmgr module.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

# Retrieve all data including **Gigabit** in the **Description** column of the Interfaces table under the Ifmgr module.

```
<?xml version="1.0"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:nsfocus="http://www.nsfocus.com.cn/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <Description nsfocus:regExp="(Gigabit)+"/>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

Verifying the configuration

If the client receives the following text, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:nsfocus="http://www.nsfocus.com.cn/netconf/base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
            <Ifmgr>
                <Interfaces>
                    <Interface>
                        <IfIndex>2681</IfIndex>
                        <Description>GigabitEthernet1/0/1 Interface</Description>
                    </Interface>
                    <Interface>
                        <IfIndex>2685</IfIndex>
                        <Description>GigabitEthernet1/0/2 Interface</Description>
                    </Interface>
                    <Interface>
                        <IfIndex>2689</IfIndex>
                        <Description>GigabitEthernet1/0/3 Interface</Description>
                    </Interface>
                 <Interface>
            </Ifmgr>
        </top>
    </data>
</rpc-reply>
```

Example: Filtering data by conditional match

Network configuration

Retrieve data in the **Name** column with the ifindex value not less than 5000 in the Interfaces table under the Ifmgr module.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

# Retrieve data in the **Name** column with the ifindex value not less than 5000 in the Interfaces table under the Ifmgr module.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:nsfocus="http://www.nsfocus.com.cn/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <IfIndex nsfocus:match="notLess:5000"/>
              <Name/>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

Verifying the configuration

If the client receives the following text, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:nsfocus="http://www.nsfocus.com.cn/netconf/base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
            <Ifmgr>
                <Interfaces>
                    <Interface>
                        <IfIndex>7241</IfIndex>
                        <Name>NULL0</Name>
                    </Interface>
                </Interfaces>
            </Ifmgr>
        </top>
    </data>
</rpc-reply>
```

Locking or unlocking the running configuration

About configuration locking and unlocking

Multiple methods are available for configuring the device, such as CLI, NETCONF, and SNMP. Before configuring, managing, or troubleshooting the device, you can lock the configuration to prevent other users from changing the device configuration. After you lock the configuration, only you can perform <edit-config> operations to change the configuration or unlock the configuration. Other users can only read the configuration.

If you close your NETCONF session, the system unlocks the configuration. You can also manually unlock the configuration.

Restrictions and guidelines for configuration locking and unlocking

The <lock> operation locks the running configuration of the device. You cannot use it to lock the configuration for a specific module.

Locking the running configuration

# Copy the following text to the client to lock the running configuration:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <lock>
      <target>
        <running/>
      </target>
    </lock>
  </rpc>
```

If the <lock> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
     <ok/>
</rpc-reply>
```

Unlocking the running configuration

# Copy the following text to the client to unlock the running configuration:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <unlock>
      <target>
        <running/>
      </target>
    </unlock>
  </rpc>
```

If the <unlock> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Example: Locking the running configuration

Network configuration

Lock the device configuration so other users cannot change the device configuration.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <capabilities>
        <capability>
            urn:ietf:params:netconf:base:1.0
        </capability>
    </capabilities>
</hello>
```

# Lock the configuration.

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <lock>
      <target>
        <running/>
      </target>
    </lock>
  </rpc>
```

Verifying the configuration

If the client receives the following response, the <lock> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

If another client sends a lock request, the device returns the following response:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<rpc-error>
  <error-type>protocol</error-type>
  <error-tag>lock-denied</error-tag>
  <error-severity>error</error-severity>
  <error-message xml:lang="en"> Lock failed because the NETCONF lock is held by another
session.</error-message>
  <error-info>
    <session-id>1</session-id>
  </error-info>
  </rpc-error>
</rpc-reply>
```

The output shows that the <lock> operation failed. The client with session ID 1 is holding the lock,

Modifying the configuration

About the <edit-config> operation

The <edit-config> operation includes the following operations: merge, create, replace, remove, delete, default-operation, error-option, test-option, and incremental. For more information about the operations, see "Supported NETCONF operations."

Procedure

# Copy the following text to perform the <edit-config> operation:

```
<?xml version="1.0"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target><running></running></target>
    <error-option>
       error-option
    </error-option>
    <config>
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
        Specify the module name, submodule name, table name, and column name
      </top>
    </config>
  </edit-config>
</rpc>
```

The <error-option> element indicates the action to be taken in response to an error that occurs during the operation. It has the following values:

Value	Description
stop-on-error	Stops the <edit-config> operation.
continue-on-error	Continues the <edit-config> operation.
rollback-on-error	Rolls back the configuration to the configuration before the <edit-config> operation was performed. By default, an <edit-config> operation cannot be performed while the device is rolling back the configuration. If the rollback time exceeds the maximum time that the client can wait, the client determines that the <edit-config> operation has failed and performs the operation again. Because the previous rollback is not completed, the operation triggers another rollback. If this process repeats itself, CPU and memory resources will be exhausted and the device will reboot. To allow an <edit-config> operation to be performed during a configuration rollback, perform an <action> operation to change the value of the **DisableEditConfigWhenRollback** attribute to **false**.

If the <edit-config> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0">
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
    </rpc-reply>
```

You can also perform the <get> operation to verify that the current element value is the same as the value specified through the <edit-config> operation.

Example: Modifying the configuration

Network configuration

Change the log buffer size for the Syslog module to 512.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
  </capabilities>
</hello>
```

# Change the log buffer size for the Syslog module to 512.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config>
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0" web:operation="merge">
        <Syslog>
          <LogBuffer>
            <BufferSize>512</BufferSize>
          </LogBuffer>
        </Syslog>
      </top>
    </config>
  </edit-config>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <edit-config> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Saving the running configuration

About the <save> operation

A <save> operation saves the running configuration to a configuration file and specifies the file as the main next-startup configuration file.

Restrictions and guidelines

The <save> operation is resource intensive. Do not perform this operation when system resources are heavily occupied.

Procedure

# Copy the following text to the client:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save OverWrite="false" Binary-only="false">
    <file>Configuration file name</file>
  </save>
</rpc>
```

Item	Description
OverWrite	Determines whether to overwrite the specified file if the file already exists. Available values: • **true**—Overwrites the file. • **false**—Does not overwrite the file. If a file with the same name already exists, the system returns an error message without saving the running configuration. The default value is **true**.
Binary-only	Determines whether to save the running configuration only to the binary configuration file to accelerate the saving process. Available values: • **true**—Saves the running configuration only to the binary configuration file. ○ If you specify a nonexistent configuration file for the **file** attribute, the <save> operation fails. ○ If you do not specify the **file** attribute, the device searches for the .cfg next-startup configuration file. If the file exists, the device saves the running configuration to its corresponding binary file. If the file does not exist, the <save> operation fails. • **false**—Save the running configuration to both the .cfg text configuration file (.cfg file) and .mdb binary configuration file. Saving the running configuration only to the binary configuration file requires less time than saving the running configuration to both the text and binary configuration files. The default value is **false**.
file	Specifies a .cfg configuration file by its name or by its path. If you specify a file by its path, make sure you specify the absolute path of the file. If you include the **file** attribute in the RPC message, you must specify a configuration file. If the specified configuration file does not exist, the device creates binary and text configuration files to save the running configuration.

Item	Description
	If you do not include the **file** attribute in the RPC message, the device saves the running configuration to the text and binary next-startup configuration files.

If the <save> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Example: Saving the running configuration

Network configuration

Save the running configuration to the **config.cfg** file.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

# Save the running configuration of the device to the **config.cfg** file.

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save>
    <file>config.cfg</file>
  </save>
</rpc>
```

Verifying the configuration

If the client receives the following response, the <save> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Loading the configuration

About the <load> operation

The <load> operation merges the configuration from a configuration file into the running configuration as follows:

- Loads settings that do not exist in the running configuration.
- Overwrites settings that already exist in the running configuration.

Restrictions and guidelines

When you perform a <load> operation, follow these restrictions and guidelines:

- The <load> operation is resource intensive. Do not perform this operation when the system resources are heavily occupied.
- Some settings in a configuration file might conflict with the existing settings. For the settings in the file to take effect, delete the existing conflicting settings, and then load the configuration file.

Procedure

# Copy the following text to the client to load a configuration file for the device:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <load>
   <file>Configuration file name</file>
  </load>
</rpc>
```

The configuration file name must start with the storage media name and end with the **.cfg** extension.

If the <load> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Rolling back the configuration

Restrictions and guidelines

The <rollback> operation is resource intensive. Do not perform this operation when the system is busy.

By default, an <edit-config> operation cannot be performed while the device is rolling back the configuration. To allow an <edit-config> operation to be performed during a configuration rollback, perform an <action> operation to change the value of the **DisableEditConfigWhenRollback** attribute to **false**.

Rolling back the configuration based on a configuration file

# Copy the following text to the client to roll back the running configuration to the configuration in a configuration file:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <rollback>
    <file>Specify the configuration file name</file>
  </rollback>
</rpc>
```

If the <rollback> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Rolling back the configuration based on a rollback point

About this task

You can roll back the running configuration based on a rollback point when one of the following situations occurs:

- A NETCONF client sends a rollback request.
- The NETCONF session idle time is longer than the rollback idle timeout time.
- A NETCONF client is unexpectedly disconnected from the device.

Restrictions and guidelines

Multiple users might simultaneously configure the device. As a best practice, lock the system before rolling back the configuration to prevent other users from modifying the running configuration.

Procedure

1. Lock the running configuration. For more information, see "Locking or unlocking the running configuration."
2. Enable configuration rollback based on a rollback point.

   # Copy the following text to the client to perform a <save-point>/<begin> operation:

   ```
   <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
         <save-point>
           <begin>
             <confirm-timeout>100</confirm-timeout>
          </begin>
         </save-point>
   </rpc>
   ```

Item	Description
confirm-timeout	Specifies the rollback idle timeout time in the range of 1 to 65535 seconds. The default is 600 seconds. This item is optional.

   If the <save-point/begin> operation succeeds, the device returns a response in the following format:

   ```
   <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
     <data>
       <save-point>
          <commit>
             <commit-id>1</commit-id>
          </commit>
       </save-point>
     </data>
   </rpc-reply>
   ```
3. Modify the running configuration. For more information, see "Modifying the configuration."
4. Mark the rollback point.

The system supports a maximum of 50 rollback points. If the limit is reached, specify the **force** attribute for the <save-point>/<commit> operation to overwrite the earliest rollback point.

# Copy the following text to the client to perform a <save-point>/<commit> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <commit>
      <label>SUPPORT VLAN<label>
      <comment>vlan 1 to 100 and interfaces.</comment>
     </commit>
  </save-point>
</rpc>
```

The <label> and <comment> elements are optional.

If the <save-point>/<commit> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <save-point>
       <commit>
          <commit-id>2</commit-id>
       </commit>
    </save-point>
  </data>
</rpc-reply>
```

5. Retrieve the rollback point configuration records.

The following text shows the message format for a <save-point/get-commits> request:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commits>
      <commit-id/>
      <commit-index/>
      <commit-label/>
    </get-commits>
  </save-point>
</rpc>
```

Specify the <commit-id/>, <commit-index/>, or <commit-label/> element to retrieve the specified rollback point configuration records. If no element is specified, the operation retrieves records for all rollback point settings.

# Copy the following text to the client to perform a <save-point>/<get-commits> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commits>
      <commit-label>SUPPORT VLAN</commit-label>
    </get-commits>
  </save-point>
</rpc>
```

If the <save-point/get-commits> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <data>
      <save-point>
         <commit-information>
```

```
           <CommitID>2</CommitID>
           <TimeStamp>Sun Jan 1 11:30:28 2017</TimeStamp>
           <UserName>test</UserName>
           <Label>SUPPORT VLAN</Label>
         </commit-information>
    </save-point>
  </data>
</rpc-reply>
```

6. Retrieve the configuration data corresponding to a rollback point.

   The following text shows the message format for a <save-point>/<get-commit-information> request:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commit-information>
       <commit-information>
         <commit-id/>
         <commit-index/>
         <commit-label/>
      </commit-information>
      <compare-information>
         <commit-id/>
         <commit-index/>
         <commit-label/>
      </compare-information>
    </get-commit-information>
  </save-point>
</rpc>
```

   Specify one of the following elements: <commit-id/>, <commit-index/>, and <commit-label/>. The <compare-information> element is optional.

Item	Description
commit-id	Uniquely identifies a rollback point.
commit-index	Specifies 50 most recently configured rollback points. The value of 0 indicates the most recently configured one and 49 indicates the earliest configured one.
commit-label	Specifies a unique label for a rollback point.
get-commit-information	Retrieves the configuration data corresponding to the most recently configured rollback point.

   # Copy the following text to the client to perform a <save-point>/<get-commit-information> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commit-information>
               <commit-information>
                  <commit-label>SUPPORT VLAN</commit-label>
               </commit-information>
    </get-commit-information>
  </save-point>
</rpc>
```

If the <save-point/get-commit-information> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <data>
     <save-point>
        <commit-information>
           <content>
              …
              interface vlan 1
              …
           </content>
        </commit-information>
     </save-point>
   </data>
</rpc-reply>
```

7. Roll back the configuration based on a rollback point.

   The configuration can also be automatically rolled back based on the most recently configured rollback point when the NETCONF session idle timer expires.

   # Copy the following text to the client to perform a <save-point>/<rollback> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <rollback>
      <commit-id/>
      <commit-index/>
      <commit-label/>
    </rollback>
  </save-point>
</rpc>
```

   Specify one of the following elements: <commit-id/>, <commit-index/>, and <commit-label/>. If no element is specified, the operation rolls back configuration based on the most recently configured rollback point.

Item	Description
commit-id	Uniquely identifies a rollback point.
commit-index	Specifies 50 most recently configured rollback points. The value of 0 indicates the most recently configured one and 49 indicates the earliest configured one.
commit-label	Specifies the unique label of a rollback point.

   If the <save-point/rollback> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok></ok>
</rpc-reply>
```

8. End the rollback configuration.

   # Copy the following text to the client to perform a <save-point>/<end> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <end/>
  </save-point>
</rpc>
```

If the <save-point/end> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
</rpc-reply>
```

9. Unlock the configuration. For more information, see "Locking or unlocking the running configuration."

Performing CLI operations through NETCONF

About CLI operations through NETCONF

You can enclose command lines in XML messages to configure the device.

Restrictions and guidelines

Performing CLI operations through NETCONF is resource intensive. As a best practice, do not perform the following tasks:

- Enclose multiple command lines in one XML message.
- Use NETCONF to perform a CLI operation when other users are performing NETCONF CLI operations.

Procedure

# Copy the following text to the client to execute the commands:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution>
      Commands
    </Execution>
  </CLI>
</rpc>
```

The <Execution> element can contain multiple commands, with one command on one line.

If the CLI operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution>
      <![CDATA[Responses to the commands]]>
    </Execution>
  </CLI>
</rpc-reply>
```

Example: Performing CLI operations

Network configuration

Send the **`display vlan`** command to the device.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

# Copy the following text to the client to execute the **`display vlan`** command:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution>
          display vlan
    </Execution>
  </CLI>
</rpc>
```

Verifying the configuration

If the client receives the following text, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution><![CDATA[
<Sysname>display vlan
 Total VLANs: 1
 The VLANs include:
 1(default)
   ]]>
   </Execution>
  </CLI>
</rpc-reply>
```

Subscribing to events

About event subscription

When an event takes place on the device, the device sends information about the event to NETCONF clients that have subscribed to the event.

Restrictions and guidelines

The device does not support subscribing to events for NETCONF over SOAP sessions.

A subscription takes effect only on the current session. It is canceled when the session is terminated.

If you do not specify the event stream to be subscribed, the device sends syslog event notifications to the NETCONF client.

Subscribing to syslog events

# Copy the following message to the client to complete the subscription:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>NETCONF</stream>
      <filter>
        <event xmlns="http://www.nsfocus.com.cn/netconf/event:1.0">
          <Code>code</Code>
            <Group>group</Group>
              <Severity>severity</Severity>
        </event>
      </filter>
      <startTime>start-time</startTime>
      <stopTime>stop-time</stopTime>
   </create-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream. The name for the syslog event stream is **NETCONF**.
event	Specifies the event. For information about the events to which you can subscribe, see the system log message references for the device.
code	Specifies the mnemonic symbol of the log message.
group	Specifies the module name of the log message.
severity	Specifies the severity level of the log message.
start-time	Specifies the start time of the subscription.
stop-time	Specifies the end time of the subscription.

If the subscription succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns:netconf="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

If the subscription fails, the device returns an error message in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
```

```
<rpc-error>
   <error-type>error-type</error-type>
   <error-tag>error-tag</error-tag>
   <error-severity>error-severity</error-severity>
   <error-message xml:lang="en">error-message</error-message>
</rpc-error>
</rpc-reply>
```

For more information about error messages, see RFC 4741.

Subscribing to events monitored by NETCONF

After you subscribe to events as described in this section, NETCONF regularly polls the subscribed events and sends the events that match the subscription condition to the NETCONF client.

# Copy the following message to the client to complete the subscription:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<create-subscription xmlns='urn:ietf:params:xml:ns:netconf:notification:1.0'>
  <stream>NETCONF_MONITOR_EXTENSION</stream>
  <filter>
    <NetconfMonitor xmlns='http://www.nsfocus.com.cn/netconf/monitor:1.0'>
      <XPath>XPath</XPath>
      <Interval>interval</Interval>
      <ColumnConditions>
        <ColumnCondition>
          <ColumnName>ColumnName</ColumnName>
          <ColumnValue>ColumnValue</ColumnValue>
          <ColumnCondition>ColumnCondition</ColumnCondition>
        </ColumnCondition>
      </ColumnConditions>
      <MustIncludeResultColumns>
        <ColumnName>columnName</ColumnName>
      </MustIncludeResultColumns>
    </NetconfMonitor>
  </filter>
<startTime>start-time</startTime>
<stopTime>stop-time</stopTime>
</create-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream. The name for the event stream is **NETCONF_MONITOR_EXTENSION**.
NetconfMonitor	Specifies the filtering information for the event.
XPath	Specifies the path of the event in the format of *ModuleName*[/*SubmoduleName*]/*TableName*.
interval	Specifies the interval for NETCONF to obtain events that matches the subscription condition. The value range is 1 to 4294967 seconds. The default

Item	Description
	value is 300 seconds.
ColumnName	Specifies the name of a column in the format of [*GroupName*.]*ColumnName*.
ColumnValue	Specifies the baseline value.
ColumnCondition	Specifies the operator: • **more**. • **less**. • **notLess**. • **notMore**. • **equal**. • **notEqual**. • **include**. • **exclude**. • **startWith**. • **endWith**. Choose an operator according to the type of the baseline value.
start-time	Specifies the start time of the subscription.
stop-time	Specifies the end time of the subscription.

If the subscription succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns:netconf="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Subscribing to events reported by modules

After you subscribe to events as described in this section, the specified modules report subscribed events to NETCONF. NETCONF sends the events to the NETCONF client.

# Copy the following message to the client to complete the subscription:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xs="http://www.nsfocus.com.cn/netconf/base:1.0">
<create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
<stream>XXX_STREAM</stream>
   <filter type="subtree">
<event xmlns="http://www.nsfocus.com.cn/netconf/event:1.0/xxx-features-list-name:1.0">
       <ColumnName xs:condition="Condition">value</ColumnName>
</event>
</filter>
<startTime>start-time</startTime>
<stopTime>stop-time</stopTime>
</create-subscription>
</rpc>
```

Item	Description
`stream`	Specifies the event stream. Supported event streams vary by device model.
`event`	Specifies the event name. An event stream includes multiple events. The events use the same namespaces as the event stream.
`ColumnName`	Specifies the name of a column.
`Condition`	Specifies the operator: • **more**. • **less**. • **notLess**. • **notMore**. • **equal**. • **notEqual**. • **include**. • **exclude**. • **startWith**. • **endWith**. Choose an operator according to the type of the baseline value.
`value`	Specifies the baseline value for the column.
`start-time`	Specifies the start time of the subscription.
`stop-time`	Specifies the end time of the subscription.

If the subscription succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns:netconf="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Canceling an event subscription

# Copy the following message to the client to cancel a subscription:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <cancel-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>XXX_STREAM</stream>
  </cancel-subscription>
</rpc>
```

Item	Description
`stream`	Specifies the event stream.

If the cancelation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <ok/>
</rpc-reply>
```

If the subscription to be canceled does not exist, the device returns an error message in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<rpc-error>
   <error-type>error-type</error-type>
   <error-tag>error-tag</error-tag>
   <error-severity>error-severity</error-severity>
<error-message xml:lang="en">The subscription stream to be canceled doesn't exist: Stream
name=XXX_STREAM.</error-message>
</rpc-error>
</rpc-reply>
```

Example: Subscribing to syslog events

Network configuration

Configure a client to subscribe to syslog events with no time limitation. After the subscription is successful, all events on the device are sent to the client before the session between the device and client is terminated.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

# Subscribe to syslog events with no time limitation.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>NETCONF</stream>
  </create-subscription>
</rpc>
```

Verifying the configuration

# If the client receives the following response, the subscription is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <ok/>
</rpc-reply>
```

# When another client (192.168.100.130) logs in to the device, the device sends a notification to the client that has subscribed to all events:

```
<?xml version="1.0" encoding="UTF-8"?>
<notification xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <eventTime>2011-01-04T12:30:52</eventTime>
    <event xmlns="http://www.nsfocus.com.cn/netconf/event:1.0">
        <Group>SHELL</Group>
        <Code>SHELL_LOGIN</Code>
        <Slot>1</Slot>
        <Severity>Notification</Severity>
        <context>VTY logged in from 192.168.100.130.</context>
    </event>
</notification>
```

Example: Subscribing to events reported by modules

Network configuration

Configure a client to subscribe to InterfaceEvent events reported by the interface management module. After the subscription is successful, all relevant InterfaceEvent events are sent to the client before the session between the device and client is terminated.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
      urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

# Subscribe to InterfaceEvent events with no time limitation.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xs="http://www.nsfocus.com.cn/netconf/base:1.0">
  <create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>Ifmgr</stream>
    <filter type="subtree">
      <InterfaceEvent xmlns="http://www.nsfocus.com.cn/netconf/event:1.0/Ifmgr:1.0">
      </InterfaceEvent>
    </filter>
  </create-subscription>
</rpc>
```

Verifying the configuration

# If the client does not have the privilege for the operation, the following response is displayed on the client:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xs="http://www.nsfocus.com.cn/netconf/base:1.0" message-id="100">
    <rpc-error xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
        <error-type>application</error-type>
        <error-tag>access-denied</error-tag>
        <error-severity>error</error-severity>
        <error-message xml:lang="en">You don't have the privilege to subscribe the InterfaceEvent event.</error-message>
    </rpc-error>
</rpc-reply>
```

# If the client receives the following response, the subscription is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <ok/>
</rpc-reply>
```

# When the status of an Ethernet interface changes, the client receives the following response:

```
<?xml version="1.0" encoding="UTF-8"?>
<notification xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <eventTime>2019-04-28T17:31:03</eventTime>
    <InterfaceEvent xmlns="Ifmgr:1.0">
    <Interface>
        <Name>GigabitEthernet1/0/1</Name>
        <Status>IF_ACTIVE</Status>
        <IfIndex>261</IfIndex>
        <AdminStatus>ADMIN_UP</AdminStatus>
        <OperStatus>OPER_DOWN</OperStatus>
        <Description>The Interface GigabitEthernet1/0/1 occurred IF_ACTIVE event,the administration status is ADMIN_UP,operation status is OPER_DOWN.</Description>
    </Interface>
    </InterfaceEvent>
</notification>
```

Terminating NETCONF sessions

About NETCONF session termination

NETCONF allows one client to terminate the NETCONF sessions of other clients. A client whose session is terminated returns to user view.

Procedure

# Copy the following message to the client to terminate a NETCONF session:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>
      Specified session-ID
    </session-id>
  </kill-session>
</rpc>
```

If the <kill-session> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
```

```
</rpc-reply>
```

Example: Terminating another NETCONF session

Network configuration

The user whose session's ID is 1 terminates the session with session ID 2.

Procedure

# Enter XML view.

```
<Sysname> xml
```

# Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

# Terminate the session with session ID 2.

```
<rpc message-id="100"xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>2</session-id>
  </kill-session>
</rpc>
```

Verifying the configuration

If the client receives the following text, the NETCONF session with session ID 2 has been terminated, and the client with session ID 2 has returned from XML view to user view:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Returning to the CLI

Restrictions and guidelines

Once you enter XML view, you must complete capability exchange between the device and the client before you can return to the CLI.

Procedure

# Copy the following text to the client to return from XML view to the CLI:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <close-session/>
</rpc>
```

When the device receives the close-session request, it sends the following response and returns to CLI's user view:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
</rpc-reply>
```

Example: Returning to the CLI

Network configuration

Return to the CLI after entering XML view.

Procedure

1. Perform capability exchange between the device and the client.

   Copy the following text to the client:

   ```
   <hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
     <capabilities>
       <capability>urn:ietf:params:netconf:base:1.0</capability>
     </capabilities>
   </hello>]]>]]>
   ```

2. Return to the CLI.

   Copy the following text to the client:

   ```
   <rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
     <close-session/>
   </rpc>]]>]]>
   ```

Verifying the configuration

# Verify that the <Sysname> prompt appears.

```
<Sysname>
```

Display and maintenance commands for NETCONF

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display current NETCONF service status and global NETCONF service statistics.	**display netconf service**
Display NETCONF session status and statistics.	**display netconf session**
Clear NETCONF service statistics.	**reset netconf service statistics**
Clear NETCONF session statistics.	**reset netconf session statistics**

Supported NETCONF operations

This chapter describes NETCONF operations available with NF

action

Usage guidelines

This operation issues actions for non-default settings, for example, reset action.

XML example

# Clear statistics information for all interfaces.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <action>
    <top xmlns="http://www.nsfocus.com.cn/netconf/action:1.0">
      <Ifmgr>
            <ClearAllIfStatistics>
                <Clear>
                </Clear>
        </ClearAllIfStatistics>
      </Ifmgr>
    </top>
  </action>
</rpc>
```

CLI

Usage guidelines

This operation executes CLI commands.

A request message encloses commands in the <CLI> element. A response message encloses the command output in the <CLI> element.

You can use the following elements to execute commands:

- **Execution**—Executes commands in user view.
- **Configuration**—Executes commands in system view.

  To use this element, include the **exec-use-channel** attribute and specify a value for the attribute:

  - **false**—Executes commands without using a channel.
  - **true**—Executes commands by using a temporary channel. The channel is automatically closed after the execution.
  - **persist**—Executes commands by using the persistent channel for the session.

    To use the persistent channel, first perform an <Open-channel> operation to open the persistent channel. If you do not do so, the system will automatically open the persistent channel.

    After using the persistent channel, perform a <Close-channel> operation to close the channel and return to system view. If you do not perform an <Open-channel> operation, the system stays in the view and will execute subsequent commands in the view.

NOTE:

To execute commands in a lower-level view of the system view, use the <Configuration> element to enter the view first.

A NETCONF session can have multiple temporary channels, but it can have only one persistent channel.

NETCONF does not support executing interactive commands.

You cannot execute the **quit** command by using a channel to exit user view.

XML example

# Execute the **display this** command in system view without using a channel.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
     <Configuration exec-use-channel="false">display this</Configuration>
  </CLI>
</rpc>
```

close-session

Usage guidelines

This operation terminates the current NETCONF session, unlock the configuration, and release the resources (for example, memory) used by the session. After this operation, you exit the XML view.

XML example

# Terminate the current NETCONF session.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<close-session/>
</rpc>
```

edit-config: create

Usage guidelines

This operation creates target configuration items.

To use the **create** attribute in an <edit-config> operation, you must specify the target configuration item.

- If the table supports creating a target configuration item and the item does not exist, the operation creates the item and configures the item.
- If the specified item already exists, a data-exist error message is returned.

XML example

# Set the buffer size to 120.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config>
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
```

```
        <Syslog xmlns="http://www.nsfocus.com.cn/netconf/config:1.0"
xc:operation="create">
           <LogBuffer>
             <BufferSize>120</BufferSize>
          </LogBuffer>
        </Syslog>
      </top>
    </config>
  </edit-config>
</rpc>
```

edit-config: delete

Usage guidelines

This operation deletes the specified configuration.

- If the specified target has only the table index, the operation removes all configuration of the specified target, and the target itself.
- If the specified target has the table index and configuration data, the operation removes the specified configuration data of this target.
- If the specified target does not exist, an error message is returned, showing that the target does not exist.

XML example

The syntax is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **delete**.

edit-config: merge

Usage guidelines

This operation commits target configuration items to the running configuration.

To use the **merge** attribute in an <edit-config> operation, you must specify the target configuration item (on a specific level):

- If the specified item exists, the operation directly updates the setting for the item.
- If the specified item does not exist, the operation creates the item and configures the item.
- If the specified item does not exist and it cannot be created, an error message is returned.

XML example

The XML data format is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **merge**.

edit-config: remove

Usage guidelines

This operation removes the specified configuration.

- If the specified target has only the table index, the operation removes all configuration of the specified target, and the target itself.
- If the specified target has the table index and configuration data, the operation removes the specified configuration data of this target.

- If the specified target does not exist, or the XML message does not specify any targets, a success message is returned.

XML example

The syntax is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **remove**.

edit-config: replace

Usage guidelines

This operation replaces the specified configuration.

- If the specified target exists, the operation replaces the configuration of the target with the configuration carried in the message.
- If the specified target does not exist but is allowed to be created, the operation creates the target and then applies the configuration.
- If the specified target does not exist and is not allowed to be created, the operation is not conducted and an invalid-value error message is returned.

XML example

The syntax is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **replace**.

edit-config: test-option

Usage guidelines

This operation determines whether to commit a configuration item in an <edit-configure> operation. The <test-option> element has one of the following values:

- **test-then-set**—Performs a syntax check, and commits an item if the item passes the check. If the item fails the check, the item is not committed. This is the default test-option value.
- **set**—Commits the item without performing a syntax check.
- **test-only**—Performs only a syntax check. If the item passes the check, a success message is returned. Otherwise, an error message is returned.

XML example

# Test the configuration for an interface.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <test-option>test-only</test-option>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
        <Ifmgr xc:operation="merge">
          <Interfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <Description>222</Description>
                <ConfigSpeed>2</ConfigSpeed>
                <ConfigDuplex>1</ConfigDuplex>
               </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </config>
  </edit-config>
</rpc>
```

edit-config: default-operation

Usage guidelines

This operation modifies the running configuration of the device by using the default operation method.

NETCONF uses one of the following operation attributes to modify configuration: **merge**, **create**, **delete**, and **replace** If you do not specify an operation attribute for an edit-config message, NETCONF uses the default operation method. Your setting of the value for the <default-operation> element takes effect only once. If you do not specify an operation attribute or the default operation method for an <edit-config> message, **merge** always applies.

The <default-operation> element has the following values:

- **merge**—Default value for the <default-operation> element.
- **replace**—Value used when the operation attribute is not specified and the default operation method is specified as **replace**.
- **none**—Value used when the operation attribute is not specified and the default operation method is specified as **none**. If this value is specified, the <edit-config> operation is used only for schema verification rather than issuing a configuration. If the schema verification is passed, a successful message is returned. Otherwise, an error message is returned.

XML example

# Issue an empty operation for schema verification purposes.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <default-operation>none</default-operation>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <Description>222222</Description>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </config>
  </edit-config>
</rpc>
```

edit-config: error-option

Usage guidelines

This operation determines the action to take in case of a configuration error.

The <error-option> element has the following values:

- **stop-on-error**—Stops the operation and returns an error message. This is the default error-option value.
- **continue-on-error**—Continues the operation and returns an error message.
- **rollback-on-error**—Rolls back the configuration.

XML example

# Issue the configuration for two interfaces with the <error-option> element value as **continue-on-error**.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>   <error-option>continue-on-error</error-option>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
        <Ifmgr xc:operation="merge">
          <Interfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <Description>222</Description>
                <ConfigSpeed>1024</ConfigSpeed>
                <ConfigDuplex>1</ConfigDuplex>
            </Interface>
            <Interface>
              <IfIndex>263</IfIndex>
              <Description>333</Description>
                <ConfigSpeed>1024</ConfigSpeed>
                <ConfigDuplex>1</ConfigDuplex>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </config>
  </edit-config>
</rpc>
```

edit-config: incremental

Usage guidelines

This operation adds configuration data to a column without affecting the original data.

The **incremental** attribute applies to a list column such as the vlan permitlist column.

You can use the **incremental** attribute for <edit-config> operations except the <replace> operation.

Support for the **incremental** attribute varies by module. For more information, see NETCONF XML API documents.

XML example

# Add VLANs 1 through 10 to an untagged VLAN list that has untagged VLANs 12 through 15.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:nsfocus="http://www.nsfocus.com.cn/netconf/base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
        <VLAN xc:operation="merge">
          <HybridInterfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <UntaggedVlanList  nsfocus:incremental="true">1-10</UntaggedVlanList>
               </Interface>
          </HybridInterfaces>
        </VLAN>
      </top>
    </config>
  </edit-config>
</rpc>
```

get

Usage guidelines

This operation retrieves device configuration and state information.

XML example

# Retrieve device configuration and state information for the Syslog module.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="http://www.nsfocus.com.cn/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
        <Syslog>
        </Syslog>
      </top>
    </filter>
  </get>
</rpc>
```

get-bulk

Usage guidelines

This operation retrieves a number of data entries (including device configuration and state information) starting from the data entry next to the one with the specified index.

XML example

# Retrieve device configuration and state information for all interfaces.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/data:1.0">
        <Ifmgr>
          <Interfaces xc:count="5"
xmlns:xc="http://www.nsfocus.com.cn/netconf/base:1.0">
            <Interface/>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

get-bulk-config

Usage guidelines

This operation retrieves a number of non-default configuration data entries starting from the data entry next to the one with the specified index.

XML example

# Retrieve non-default configuration for all interfaces.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
        <Ifmgr>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk-config>
</rpc>
```

get-config

Usage guidelines

This operation retrieves non-default configuration data. If no non-default configuration data exists, the device returns a response with empty data.

XML example

# Retrieve non-default configuration data for the interface table.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="http://www.nsfocus.com.cn/netconf/base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.nsfocus.com.cn/netconf/config:1.0">
        <Ifmgr>
           <Interfaces>
              <Interface/>
            </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-config>
</rpc>
```

get-sessions

Usage guidelines

This operation retrieves information about all NETCONF sessions in the system. You cannot specify a session ID to retrieve information about a specific NETCONF session.

XML example

# Retrieve information about all NETCONF sessions in the system.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<get-sessions/>
</rpc>
```

kill-session

Usage guidelines

This operation terminates the NETCONF session for another user. This operation cannot terminate the NETCONF session for the current user.

XML example

# Terminate the NETCONF session with session ID 1.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>1</session-id>
  </kill-session>
</rpc>
```

load

Usage guidelines

This operation loads the configuration. After the device finishes a <load> operation, the configuration in the specified file is merged into the running configuration of the device.

XML example

# Merge the configuration in file **a1.cfg** to the running configuration of the device.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <load>
    <file>a1.cfg</file>
  </load>
</rpc>
```

lock

Usage guidelines

This operation locks the configuration. After the configuration is locked, you cannot perform <edit-config> operations. Other operations are allowed.

After a user locks the configuration, other users cannot use NETCONF or any other configuration methods such as CLI and SNMP to configure the device.

XML example

# Lock the configuration.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
 <lock>
    <target>
        <running/>
    </target>
</lock>
</rpc>
```

rollback

Usage guidelines

This operation rolls back the configuration. To do so, you must specify the configuration file in the <file> element. After the device finishes the <rollback> operation, the current device configuration is totally replaced with the configuration in the specified configuration file.

XML example

# Roll back the running configuration to the configuration in file **1A.cfg**.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <rollback>
    <file>1A.cfg</file>
  </rollback>
</rpc>
```

save

Usage guidelines

This operation saves the running configuration. You can use the <file> element to specify a file for saving the configuration. If the text does not include the file column, the running configuration is automatically saved to the main next-startup configuration file.

The **OverWrite** attribute determines whether the running configuration overwrites the original configuration file when the specified file already exists.

The **Binary-only** attribute determines whether to save the running configuration only to the binary configuration file.

XML example

# Save the running configuration to file **test.cfg**.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save OverWrite="false" Binary-only="true">
    <file>test.cfg</file>
  </save>
</rpc>
```

unlock

Usage guidelines

This operation unlocks the configuration, so other users can configure the device.

Terminating a NETCONF session automatically unlocks the configuration.

XML example

# Unlock the configuration.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<unlock>
    <target>
        <running/>
    </target>
</unlock>
</rpc>
```

Contents

Configuring CWMP

About CWMP

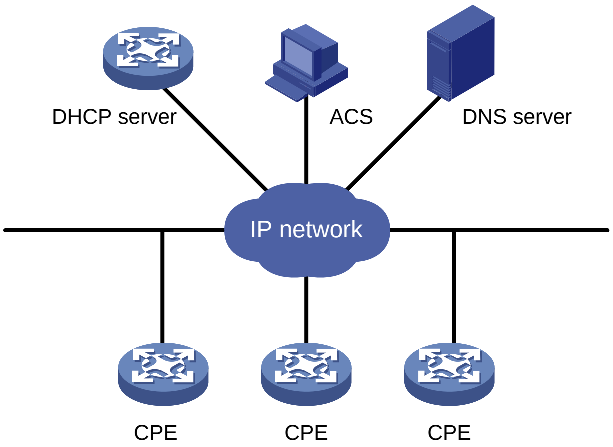
CPE WAN Management Protocol (CWMP), also called "TR-069," is a DSL Forum technical specification for remote management of network devices.

The protocol was initially designed to provide remote autoconfiguration through a server for large numbers of dispersed end-user devices in a network. CWMP can be used on different types of networks, including Ethernet.

CWMP network framework

Figure 1 shows a basic CWMP network framework.

Figure 1 CWMP network framework



A basic CWMP network includes the following network elements:

- **ACS**—Autoconfiguration server, the management device in the network.
- **CPE**—Customer premises equipment, the managed device in the network.
- **DNS server**—Domain name system server. CWMP defines that the ACS and the CPE use URLs to identify and access each other. DNS is used to resolve the URLs.
- **DHCP server**—Assigns ACS attributes along with IP addresses to CPEs when the CPEs are powered on. DHCP server is optional in CWMP. With a DHCP server, you do not need to configure ACS attributes manually on each CPE. The CPEs can contact the ACS automatically when they are powered on for the first time.

The device is operating as a CPE in the CWMP framework.

Basic CWMP functions

You can autoconfigure and upgrade CPEs in bulk from the ACS.

Autoconfiguration

You can create configuration files for different categories of CPEs on the ACS. Based on the device models and serial numbers of the CPEs, the ACS verifies the categories of the CPEs and issues the associated configuration to them.

The following are methods available for the ACS to issue configuration to the CPE:

- Transfers the configuration file to the CPE, and specifies the file as the next-startup configuration file. At a reboot, the CPE starts up with the ACS-specified configuration file.
- Runs the configuration in the CPE's RAM. The configuration takes effect immediately on the CPE. For the running configuration to survive a reboot, you must save the configuration on the CPE.

CPE software management

The ACS can manage CPE software upgrade.

When the ACS finds a software version update, the ACS notifies the CPE to download the software image file from a specific location. The location can be the URL of the ACS or an independent file server.

If the CPE successfully downloads the software image file and the file is validated, the CPE notifies the ACS of a successful download. If the CPE fails to download the software image file or the file is invalidated, the CPE notifies the ACS of an unsuccessful download.

Data backup

The ACS can require the CPE to upload a configuration file or log file to a specific location. The destination location can be the ACS or a file server.

CPE status and performance monitoring

The ACS can monitor the status and performance of CPEs. Table 1 shows the available CPE status and performance objects for the ACS to monitor.

Table 1 CPE status and performance objects available for the ACS to monitor

Category	Objects	Remarks
Device information	Manufacturer ManufacturerOUI SerialNumber HardwareVersion SoftwareVersion	N/A
Operating status and information	DeviceStatus UpTime	N/A
Configuration file	ConfigFile	Local configuration file stored on CPE for upgrade. The ACS can issue configuration to the CPE by transferring a configuration file to the CPE or running the configuration in CPE's RAM.
CWMP settings	ACS URL	URL address of the ACS to which the CPE initiates a CWMP connection. This object is also used for main/backup ACS switchover.
	ACS username ACS password	When the username and password of the ACS are changed, the ACS changes the ACS username and password on the CPE to the new username and password. When a main/backup ACS switchover occurs, the main ACS also changes the ACS username and password to the backup ACS username and password.
	PeriodicInformEnable	Whether to enable or disable the periodic Inform feature.
	PeriodicInformInterval	Interval for periodic connection from the CPE

Category	Objects	Remarks
		to the ACS for configuration and software update.
	PeriodicInformTime	Scheduled time for connection from the CPE to the ACS for configuration and software update.
	ConnectionRequestURL (CPE URL)	N/A
	ConnectionRequestUsername (CPE username) ConnectionRequestPassword (CPE password)	CPE username and password for authentication from the ACS to the CPE.

How CWMP works

RPC methods

CWMP uses remote procedure call (RPC) methods for bidirectional communication between CPE and ACS. The RPC methods are encapsulated in HTTP or HTTPS.

Table 2 shows the primary RPC methods used in CWMP.

Table 2 RPC methods

RPC method	Description
Get	The ACS obtains the values of parameters on the CPE.
Set	The ACS modifies the values of parameters on the CPE.
Inform	The CPE sends an Inform message to the ACS for the following purposes: • Initiates a connection to the ACS. • Reports configuration changes to the ACS. • Periodically updates CPE settings to the ACS.
Download	The ACS requires the CPE to download a configuration or software image file from a specific URL for software or configuration update.
Upload	The ACS requires the CPE to upload a file to a specific URL.
Reboot	The ACS reboots the CPE remotely for the CPE to complete an upgrade or recover from an error condition.

Autoconnect between ACS and CPE

The CPE automatically initiates a connection to the ACS when one of the following events occurs:

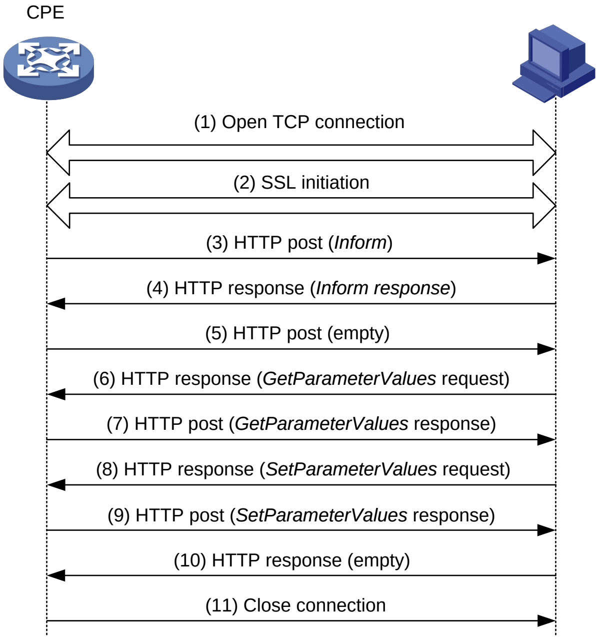
- ACS URL change. The CPE initiates a connection request to the new ACS URL.
- CPE startup. The CPE initiates a connection to the ACS after the startup.
- Timeout of the periodic Inform interval. The CPE re-initiates a connection to the ACS at the Inform interval.
- Expiration of the scheduled connection initiation time. The CPE initiates a connection to the ACS at the scheduled time.

CWMP connection establishment

Step 1 through step 5 in Figure 2 show the procedure of establishing a connection between the CPE and the ACS.

1. After obtaining the basic ACS parameters, the CPE initiates a TCP connection to the ACS.
2. If HTTPS is used, the CPE and the ACS initialize SSL for a secure HTTP connection.
3. The CPE sends an Inform message in HTTPS to initiate a CWMP session.
4. After the CPE passes authentication, the ACS returns an Inform response to establish the session.
5. After sending all requests, the CPE sends an empty HTTP post message.

Figure 2 CWMP connection establishment



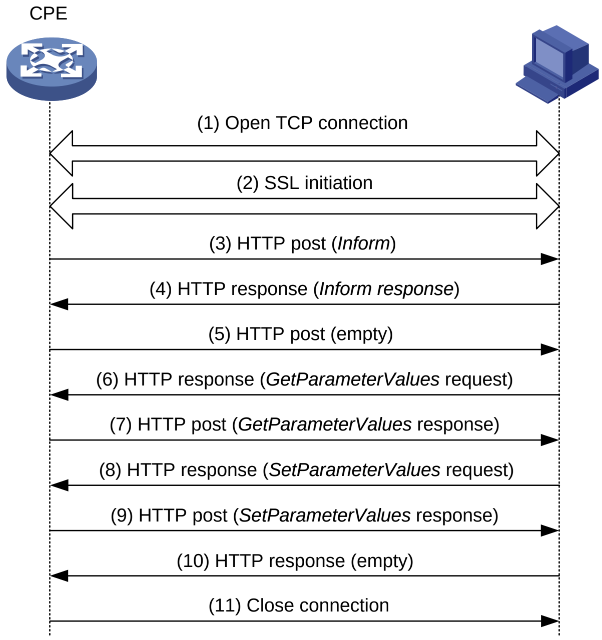
CPE
(1) Open TCP connection
(2) SSL initiation
(3) HTTP post (*Inform*)
(4) HTTP response (*Inform response*)
(5) HTTP post (empty)
(6) HTTP response (*GetParameterValues* request)
(7) HTTP post (*GetParameterValues* response)
(8) HTTP response (*SetParameterValues* request)
(9) HTTP post (*SetParameterValues* response)
(10) HTTP response (empty)
(11) Close connection

Main/backup ACS switchover

Typically, two ACSs are used in a CWMP network for consecutive monitoring on CPEs. When the main ACS needs to reboot, it points the CPE to the backup ACS. Step 6 through step 11 in Figure 3 show the procedure of a main/backup ACS switchover.

1. Before the main ACS reboots, it queries the ACS URL set on the CPE.
2. The CPE replies with its ACS URL setting.
3. The main ACS sends a Set request to change the ACS URL on the CPE to the backup ACS URL.
4. After the ACS URL is modified, the CPE sends a response.
5. The main ACS sends an empty HTTP message to notify the CPE that it has no other requests.
6. The CPE closes the connection, and then initiates a new connection to the backup ACS URL.

Figure 3 Main and backup ACS switchover



CPE
(1) Open TCP connection
(2) SSL initiation
(3) HTTP post (*Inform*)
(4) HTTP response (*Inform response*)
(5) HTTP post (empty)
(6) HTTP response (*GetParameterValues* request)
(7) HTTP post (*GetParameterValues* response)
(8) HTTP response (*SetParameterValues* request)
(9) HTTP post (*SetParameterValues* response)
(10) HTTP response (empty)
(11) Close connection

Restrictions and guidelines: CWMP configuration

You can configure ACS and CPE attributes from the CPE's CLI, the DHCP server, or the ACS. For an attribute, the CLI- and ACS-assigned values have higher priority than the DHCP-assigned value. The CLI- and ACS-assigned values overwrite each other, whichever is assigned later.

This document only describes configuring ACS and CPE attributes from the CLI and DHCP server. For more information about configuring and using the ACS, see ACS documentation.

CWMP tasks at a glance

To configure CWMP, perform the following tasks:

1. Enabling CWMP from the CLI

   You can also enable CWMP from a DHCP server.
2. Configuring ACS attributes
   a. Configuring the preferred ACS attributes
   b. (Optional.) Configuring the default ACS attributes from the CLI
3. Configuring CPE attributes
   a. Specifying an SSL client policy for HTTPS connection to ACS

      This task is required when the ACS uses HTTPS for secure access.
   b. (Optional.) Configuring ACS authentication parameters
   c. (Optional.) Configuring the provision code
   d. (Optional.) Configuring the CWMP connection interface
   e. (Optional.) Configuring autoconnect parameters
   f. (Optional.) Setting the close-wait timer
   g. (Optional.) Enabling NAT traversal for the CPE

Enabling CWMP from the CLI

4. Enter system view.

   system-view

5. Enter CWMP view.

   cwmp

6. Enable CWMP.

   cwmp enable

   By default, CWMP is disabled.

Configuring ACS attributes

About ACS attributes

You can configure two sets of ACS attributes for the CPE: preferred and default.

- The preferred ACS attributes are configurable from the CPE's CLI, the DHCP server, and ACS.
- The default ACS attributes are configurable only from the CLI.

If the preferred ACS attributes are not configured, the CPE uses the default ACS attributes for connection establishment.

Configuring the preferred ACS attributes

Assigning ACS attributes from the DHCP server

The DHCP server in a CWMP network assigns the following information to CPEs:

- IP addresses for the CPEs.
- DNS server address.
- ACS URL and ACS login authentication information.

This section introduces how to use DHCP option 43 to assign the ACS URL and ACS login authentication username and password. For more information about DHCP and DNS, see *Layer 3—IP Services Configuration Guide*.

If the DHCP server is an NSFOCUS device, you can configure DHCP option 43 by using the **option 43 hex 01***length URL username password* command.

- *length*—A hexadecimal number that indicates the total length of the *length*, *URL*, *username*, and *password* arguments, including the spaces between these arguments. No space is allowed between the **01** keyword and the length value.
- *URL*—ACS URL.
- *username*—Username for the CPE to authenticate to the ACS.
- *password*—Password for the CPE to authenticate to the ACS.

NOTE:

The ACS URL, username and password must use the hexadecimal format and be space separated.

The following example configures the ACS address as **http://169.254.76.31:7547**, username as **1234**, and password as **5678**:

```
<Sysname> system-view
```

```
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] option 43 hex
0123687474703A2F2F3136392E3235342E37362E33313A3735343720313233342035363738
```

Table 3 Hexadecimal forms of the ACS attributes

Attribute	Attribute value	Hexadecimal form
Length	35 characters	23
ACS URL	http://169.254.76.31:7547	687474703A2F2F3136392E3235342E37362E33313A3735343720 **NOTE:** The two ending digits (20) represent the space.
ACS connect username	1234	3132333420 **NOTE:** The two ending digits (20) represent the space.
ACS connect password	5678	35363738

Configuring the preferred ACS attributes from the CLI

1. Enter system view.

   `system-view`

2. Enter CWMP view.

   `cwmp`

3. Configure the preferred ACS URL.

   `cwmp acs url` *`url`*

   By default, no preferred ACS URL has been configured.

4. Configure the username for authentication to the preferred ACS URL.

   `cwmp acs username` *`username`*

   By default, no username has been configured for authentication to the preferred ACS URL.

5. (Optional.) Configure the password for authentication to the preferred ACS URL.

   `cwmp acs password` { **`cipher`** | **`simple`** } *`string`*

   By default, no password has been configured for authentication to the preferred ACS URL.

Configuring the default ACS attributes from the CLI

1. Enter system view.

   `system-view`

2. Enter CWMP view.

   `cwmp`

3. Configure the default ACS URL.

   `cwmp acs default url` *`url`*

   By default, no default ACS URL has been configured.

4. Configure the username for authentication to the default ACS URL.

   `cwmp acs default username` *`username`*

   By default, no username has been configured for authentication to the default ACS URL.

5. (Optional.) Configure the password for authentication to the default ACS URL.

cwmp acs default password { **cipher** | **simple** } *string*

By default, no password has been configured for authentication to the default ACS URL.

Configuring CPE attributes

About CPE attributes

You can configure the following CPE attributes only from the CPE's CLI.

- CWMP connection interface.
- NAT traversal.
- Maximum number of connection retries.
- SSL client policy for HTTPS connection to ACS.

For other CPE attribute values, you can assign them to the CPE from the CPE's CLI or the ACS. The CLI- and ACS-assigned values overwrite each other, whichever is assigned later.

Specifying an SSL client policy for HTTPS connection to ACS

About this task

This task is required when the ACS uses HTTPS for secure access. CWMP uses HTTP or HTTPS for data transmission. When HTTPS is used, the ACS URL begins with **https://**. You must specify an SSL client policy for the CPE to authenticate the ACS for HTTPS connection establishment.

Restrictions and guidelines

Versions B64D028 and higher use upgraded SSL cipher suites and require the DH parameters to contain a minimum of 1024 bits. If the ACS still uses the old version, SSL connections might fail to be established and CPEs might fail to connect to the ACS.

To solve this issue, upgrade the ACS or execute the **prefer-cipher** command on CPEs to specify the SSL client policy to prefer an non-DHE RSA algorithm. For more information about the **prefer-cipher** command, see *Security Command Reference*.

Prerequisites

Before you perform this task, first create an SSL client policy. For more information about configuring SSL client policies, see *Security Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter CWMP view.
   cwmp
3. Specify an SSL client policy.
   ssl client-policy *policy-name*
   By default, no SSL client policy is specified.

Configuring ACS authentication parameters

About this task

To protect the CPE against unauthorized access, configure a CPE username and password for ACS authentication. When an ACS initiates a connection to the CPE, the ACS must provide the correct username and password.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Configure the username for authentication to the CPE.

   cwmp cpe username *username*

   By default, no username has been configured for authentication to the CPE.

4. (Optional.) Configure the password for authentication to the CPE.

   cwmp cpe password { **cipher** | **simple** } *string*

   By default, no password has been configured for authentication to the CPE.

   The password setting is optional. You can specify only a username for authentication.

Configuring the provision code

About this task

The ACS can use the provision code to identify services assigned to each CPE. For correct configuration deployment, make sure the same provision code is configured on the CPE and the ACS. For information about the support of your ACS for provision codes, see the ACS documentation.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Configure the provision code.

   cwmp cpe provision-code *provision-code*

   The default provision code is **PROVISIONINGCODE**.

Configuring the CWMP connection interface

About this task

The CWMP connection interface is the interface that the CPE uses to communicate with the ACS. To establish a CWMP connection, the CPE sends the IP address of this interface in the Inform messages, and the ACS replies to this IP address.

Typically, the CPE selects the CWMP connection interface automatically. If the CWMP connection interface is not the interface that connects the CPE to the ACS, the CPE fails to establish a CWMP connection with the ACS. In this case, you need to manually set the CWMP connection interface.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Specify the interface that connects to the ACS as the CWMP connection interface.

   cwmp cpe connect interface *interface-type interface-number*

   By default, no CWMP connection interface is specified.

Configuring autoconnect parameters

About this task

You can configure the CPE to connect to the ACS periodically, or at a scheduled time for configuration or software update.

The CPE retries a connection automatically when one of the following events occurs:

- The CPE fails to connect to the ACS. The CPE considers a connection attempt as having failed when the close-wait timer expires. This timer starts when the CPE sends an Inform request. If the CPE fails to receive a response before the timer expires, the CPE resends the Inform request.
- The connection is disconnected before the session on the connection is completed.

To protect system resources, limit the number of retries that the CPE can make to connect to the ACS.

Configuring the periodic Inform feature

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Enable the periodic Inform feature.

   cwmp cpe inform interval enable

   By default, this function is disabled.

4. Set the Inform interval.

   cwmp cpe inform interval *interval*

   By default, the CPE sends an Inform message to start a session every 600 seconds.

Scheduling a connection initiation

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Schedule a connection initiation.

   cwmp cpe inform time *time*

   By default, no connection initiation has been scheduled.

Setting the maximum number of connection retries

1. Enter system view.

```
system-view
```

2. Enter CWMP view.

```
cwmp
```

3. Set the maximum number of connection retries.

```
cwmp cpe connect retry retries
```

By default, the CPE retries a failed connection until the connection is established.

Setting the close-wait timer

About this task

The close-wait timer specifies the following:

- The maximum amount of time the CPE waits for the response to a session request. The CPE determines that its session attempt has failed when the timer expires.
- The amount of time the connection to the ACS can be idle before it is terminated. The CPE terminates the connection to the ACS if no traffic is sent or received before the timer expires.

Procedure

1. Enter system view.

```
system-view
```

2. Enter CWMP view.

```
cwmp
```

3. Set the close-wait timer.

```
cwmp cpe wait timeout seconds
```

By default, the close-wait timer is 30 seconds.

Enabling NAT traversal for the CPE

About this task

For the connection request initiated from the ACS to reach the CPE, you must enable NAT traversal on the CPE when a NAT gateway resides between the CPE and the ACS.

The NAT traversal feature complies with RFC 3489 Simple Traversal of UDP Through NATs (STUN). The feature enables the CPE to discover the NAT gateway, and obtain an open NAT binding (a public IP address and port binding) through which the ACS can send unsolicited packets. The CPE sends the binding to the ACS when it initiates a connection to the ACS. For the connection requests sent by the ACS at any time to reach the CPE, the CPE maintains the open NAT binding. For more information about NAT, see *NAT Configuration Guide*.

Procedure

1. Enter system view.

```
system-view
```

2. Enter CWMP view.

```
cwmp
```

3. Enable NAT traversal.

```
cwmp cpe stun enable
```

By default, NAT traversal is disabled on the CPE.

Display and maintenance commands for CWMP

Execute **display** commands in any view.

Task	Command
Display CWMP configuration.	**display cwmp configuration**
Display the current status of CWMP.	**display cwmp status**

CWMP configuration examples

Example: Configuring CWMP

Network configuration

As shown in Figure 4, use IMC BIMS as the ACS to bulk-configure the devices (CPEs), and assign ACS attributes to the CPEs from the DHCP server.

The configuration files for the devices in equipment rooms A and B are **configure1.cfg** and **configure2.cfg**, respectively.

Figure 4 Network diagram

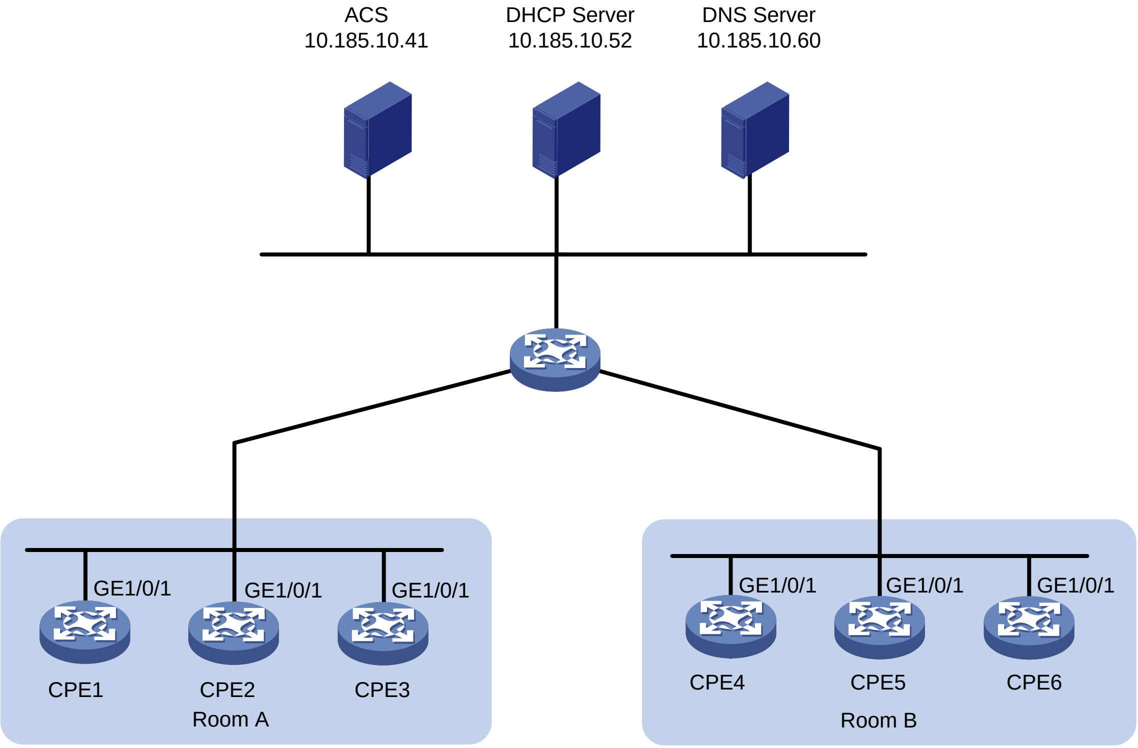


Table 4 shows the ACS attributes for the CPEs to connect to the ACS.

Table 4 ACS attributes

Item	Setting

Configuring the ACS

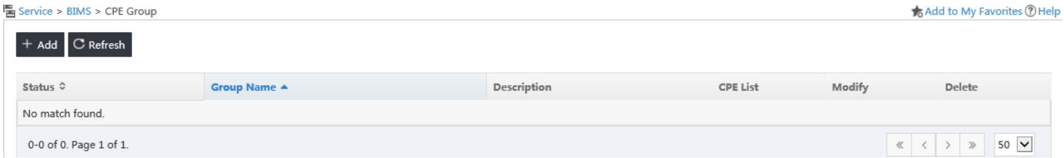
Figures in this section are for illustration only.

To configure the ACS:

1. Log in to the ACS:
   a. Launch a Web browser on the ACS configuration terminal.
   b. In the address bar of the Web browser, enter the ACS URL and port number. This example uses **http://10.185.10.41:8080/imc**.
   c. On the login page, enter the ACS login username and password, and then click **Login**.
2. Create a CPE group for each equipment room:
   a. Select **Service** > **BIMS** > **CPE Group** from the top navigation bar.

      The **CPE Group** page appears.

      Figure 5 CPE Group page

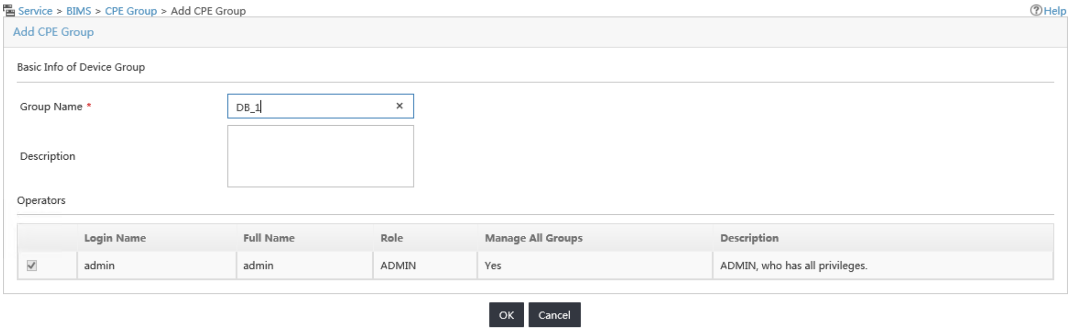


Status	Group Name	Description	CPE List	Modify	Delete
No match found.					

0-0 of 0. Page 1 of 1.

   b. Click **Add**.
   c. Enter a username, and then click **OK**.

      Figure 6 Adding a CPE group



Basic Info of Device Group

Group Name * DB_1

Description

Operators

	Login Name	Full Name	Role	Manage All Groups	Description
☑	admin	admin	ADMIN	Yes	ADMIN, who has all privileges.

d. Repeat the previous two steps to create a CPE group for CPEs in Room B.

3. Add CPEs to the CPE group for each equipment room:

a. Select **Service** > **BIMS** > **Resource Management** > **Add CPE** from the top navigation bar.

b. On the **Add CPE** page, configure the following parameters:

- **Authentication Type**—Select **ACS UserName**.
- **CPE Name**—Enter a CPE name.
- **ACS Username**—Enter **admin**.
- **ACS Password Generated**—Select **Manual Input**.
- **ACS Password**—Enter a password for ACS authentication.
- **ACS Confirm Password**—Re-enter the password.
- **CPE Model**—Select the CPE model.
- **CPE Group**—Select the CPE group.

Target File *: wb2320x-t0010.ipe

Software Version:

Applicable CPEs *: WB2320X-AGE

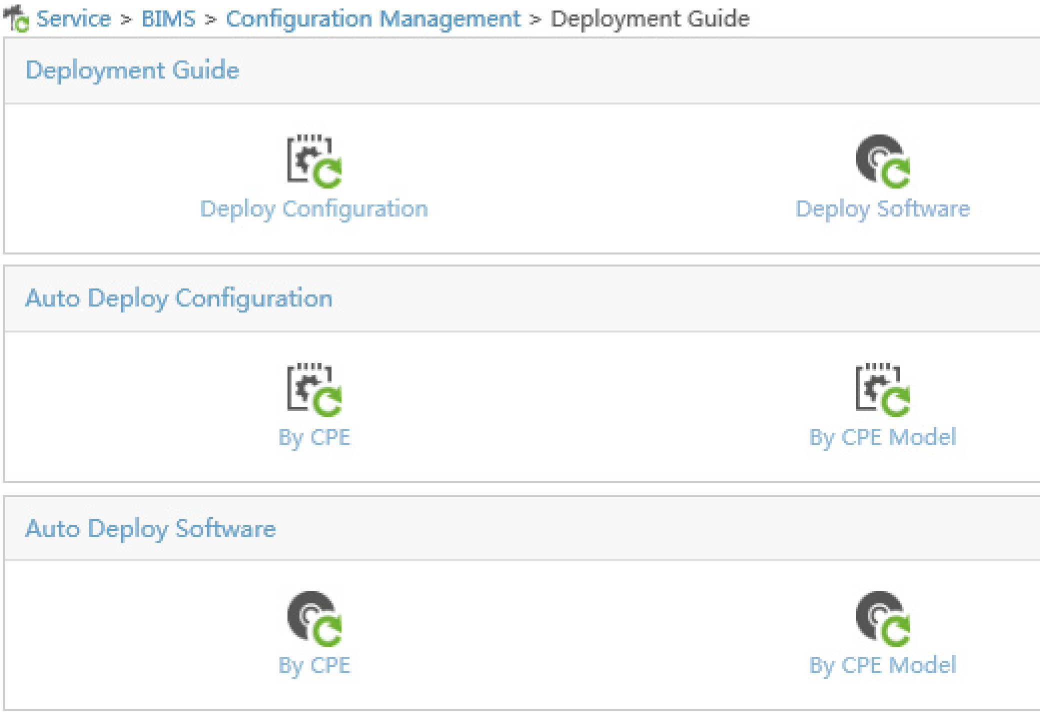
Description:

d. Repeat the previous steps to add software library entries for CPEs of different models.

6. Create an auto-deployment task for each equipment room:

a. Select **Service** > **BIMS** > **Configuration Management** > **Deployment Guide** from the top navigation bar.

Figure 14 Deployment Guide



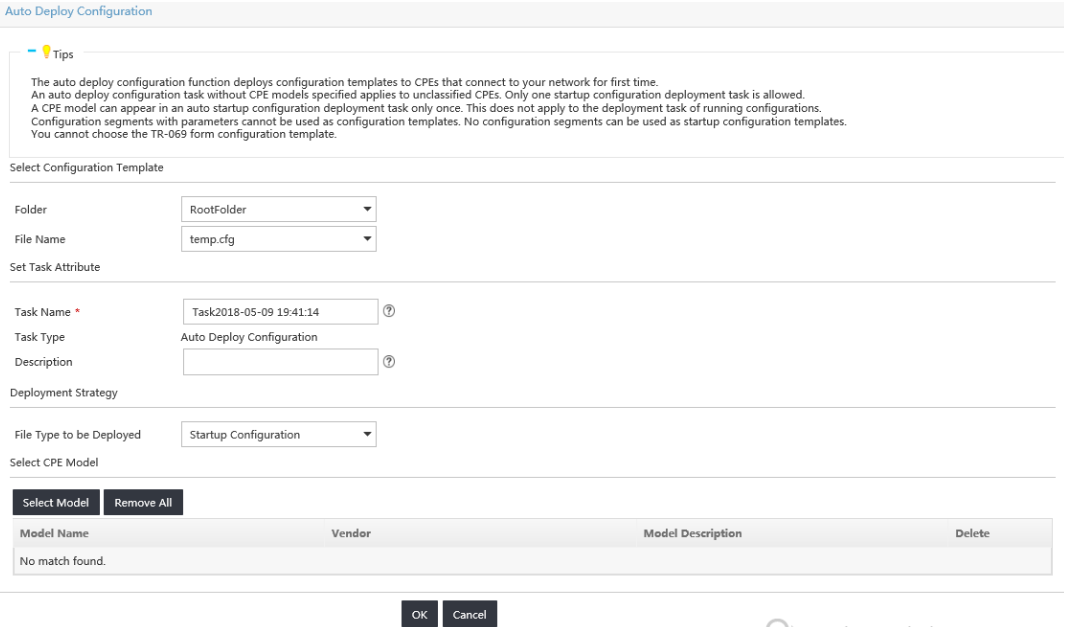
Service > BIMS > Configuration Management > Deployment Guide

b. Click **By CPE** from the **Auto Deployment Configuration** field.

c. Select a configuration template, select **Startup Configuration** from the **File Type to be Deployed** list, and click **Select Model** to select CPEs in Room A. Then, click **OK**.

You can search for CPEs by CPE group.

Figure 15 Auto deployment configuration



Auto Deploy Configuration

Tips

The auto deploy configuration function deploys configuration templates to CPEs that connect to your network for first time.
An auto deploy configuration task without CPE models specified applies to unclassified CPEs. Only one startup configuration deployment task is allowed.
A CPE model can appear in an auto startup configuration deployment task only once. This does not apply to the deployment task of running configurations.
Configuration segments with parameters cannot be used as configuration templates. No configuration segments can be used as startup configuration templates.
You cannot choose the TR-069 form configuration template.

Select Configuration Template

Folder: RootFolder

File Name: temp.cfg

Set Task Attribute

Task Name *: Task2018-05-09 19:41:14

Task Type: Auto Deploy Configuration

Adding deployment task completed. You can proceed with the following operations:

Task Details	View the detailed information of the deployment task added just now.
Clone to Add	Copy the deployment task added just now.
Add Deployment Task	Use default parameters to add a deployment task.

e. Repeat the previous steps to add a deployment task for CPEs in Room B.

Configuring the DHCP server

1. Configure an IP address pool to assign IP addresses and DNS server address to the CPEs. This example uses subnet 10.185.10.0/24 for IP address assignment.

# Enable DHCP.

```
<DHCP_server> system-view
[DHCP_server] dhcp enable
```

# Enable DHCP server on VLAN-interface 1.

```
[DHCP_server] interface vlan-interface 1
[DHCP_server-Vlan-interface1] dhcp select server
[DHCP_server-Vlan-interface1] quit
```

# Exclude the DNS server address 10.185.10.60 and the ACS IP address 10.185.10.41 from dynamic allocation.

```
[DHCP_server] dhcp server forbidden-ip 10.185.10.41
[DHCP_server] dhcp server forbidden-ip 10.185.10.60
```

# Create DHCP address pool 0.

```
[DHCP_server] dhcp server ip-pool 0
```

# Assign subnet 10.185.10.0/24 to the address pool, and specify the DNS server address 10.185.10.60 in the address pool.

```
[DHCP_server-dhcp-pool-0] network 10.185.10.0 mask 255.255.255.0
[DHCP_server-dhcp-pool-0] dns-list 10.185.10.60
```

2. Configure DHCP Option 43 to contain the ACS URL, username, and password in hexadecimal format.

```
[DHCP_server-dhcp-pool-0] option 43 hex
013B687474703A2F2F6163732E64617461626173653A393039302F616373207669636B79203132333
435
```

Configuring the DNS server

Map http://acs.database:9090 to http://10.185.1.41:9090 on the DNS server. For more information about DNS configuration, see DNS server documentation.

Connecting the CPEs to the network

# Connect CPE 1 to the network, and then power on the CPE. (Details not shown.)

# Log in to CPE 1 and configure its interface GigabitEthernet 1/0/1 to use DHCP for IP address acquisition. At startup, the CPE obtains the IP address and ACS information from the DHCP server to initiate a connection to the ACS. After the connection is established, the CPE interacts with the ACS to complete autoconfiguration.

```
<CPE1> system-view
[CPE1] interface gigabitethernet 1/0/1
[CPE1-GigabitEthernet1/0/1] ip address dhcp-alloc
```

# Repeat the previous steps to configure the other CPEs.

Verifying the configuration

# Execute the **display current-configuration** command to verify that the running configurations on CPEs are the same as the configurations issued by the ACS.

Contents

Configuring SNMP

About SNMP

Simple Network Management Protocol (SNMP) is used for a management station to access and operate the devices on a network, regardless of their vendors, physical characteristics, and interconnect technologies.

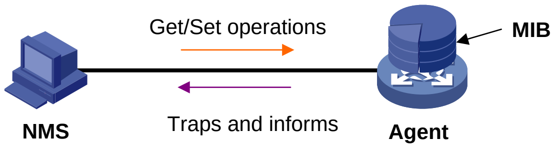
SNMP enables network administrators to read and set the variables on managed devices for state monitoring, troubleshooting, statistics collection, and other management purposes.

SNMP framework

The SNMP framework contains the following elements:

- **SNMP manager**—Works on an NMS to monitor and manage the SNMP-capable devices in the network. It can get and set values of MIB objects on the agent.
- **SNMP agent**—Works on a managed device to receive and handle requests from the NMS, and sends notifications to the NMS when events, such as an interface state change, occur.
- **Management Information Base (MIB)**—Specifies the variables (for example, interface status and CPU usage) maintained by the SNMP agent for the SNMP manager to read and set.

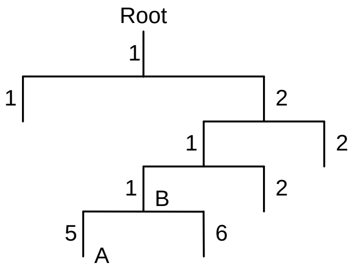
Figure 1 Relationship between NMS, agent, and MIB



MIB and view-based MIB access control

A MIB stores variables called "nodes" or "objects" in a tree hierarchy and identifies each node with a unique OID. An OID is a dotted numeric string that uniquely identifies the path from the root node to a leaf node. For example, object B in Figure 2 is uniquely identified by the OID {1.2.1.1}.

Figure 2 MIB tree



A MIB view represents a set of MIB objects (or MIB object hierarchies) with certain access privileges and is identified by a view name. The MIB objects included in the MIB view are accessible while those excluded from the MIB view are inaccessible.

A MIB view can have multiple view records each identified by a *view-name oid-tree* pair.

You control access to the MIB by assigning MIB views to SNMP groups or communities.

SNMP operations

SNMP provides the following basic operations:

- **Get**—NMS retrieves the value of an object node in an agent MIB.
- **Set**—NMS modifies the value of an object node in an agent MIB.
- **Notification**—SNMP notifications include traps and informs. The SNMP agent sends traps or informs to report events to the NMS. The difference between these two types of notification is that informs require acknowledgment but traps do not. Informs are more reliable but are also resource-consuming. Traps are available in SNMPv1, SNMPv2c, and SNMPv3. Informs are available only in SNMPv2c and SNMPv3.

Protocol versions

The device supports SNMPv1, SNMPv2c, and SNMPv3. An NMS and an SNMP agent must use the same SNMP version to communicate with each other.

- **SNMPv1**—Uses community names for authentication. To access an SNMP agent, an NMS must use the same community name as set on the SNMP agent. If the community name used by the NMS differs from the community name set on the agent, the NMS cannot establish an SNMP session to access the agent or receive traps from the agent.
- **SNMPv2c**—Uses community names for authentication. SNMPv2c is compatible with SNMPv1, but supports more operation types, data types, and error codes.
- **SNMPv3**—Uses a user-based security model (USM) to secure SNMP communication. You can configure authentication and privacy mechanisms to authenticate and encrypt SNMP packets for integrity, authenticity, and confidentiality.

Access control modes

SNMP uses the following modes to control access to MIB objects:

- **View-based Access Control Model**—VACM mode controls access to MIB objects by assigning MIB views to SNMP communities or users.
- **Role based access control**—RBAC mode controls access to MIB objects by assigning user roles to SNMP communities or users.
  - SNMP communities or users with predefined user role network-admin, context-admin, or level-15 have read and write access to all MIB objects.
  - SNMP communities or users with predefined user role network-operator or context-operator have read-only access to all MIB objects.
  - SNMP communities or users with a user-defined user role have access rights to MIB objects as specified by the **rule** command.

RBAC mode controls access on a per MIB object basis, and VACM mode controls access on a MIB view basis. As a best practice to enhance MIB security, use the RBAC mode.

If you create the same SNMP community or user with both modes multiple times, the most recent configuration takes effect. For more information about RBAC, see *Fundamentals Command Reference*.

SNMP silence

SNMP silence enables the device to automatically detect and defend against SNMP attacks.

After you enable SNMP, the device automatically starts an SNMP silence timer and counts the number of packets that fail SNMP authentication within 1 minute.

- If the number of the packets is smaller than 100, the device restarts the timer and counting.
- If the number of the packets is equal to or greater than 100, the SNMP module enters a silence period of 4 to 5 minutes, during which the device does not respond to any SNMP packets. After the silence period expires, the device restarts the timer and counting.

SNMP tasks at a glance

To configure SNMP, perform the following tasks:

1. Enabling the SNMP agent
2. Enabling SNMP versions
3. Configuring SNMP basic parameters
   - (Optional.) Configuring SNMP common parameters
   - Configuring an SNMPv1 or SNMPv2c community
   - Configuring an SNMPv3 group and user
4. (Optional.) Configuring SNMP notifications
5. (Optional.) Configuring SNMP logging
6. (Optional.) Enabling VA interface query and configuration by using MIB objects

Enabling the SNMP agent

Restrictions and guidelines

The SNMP agent is enabled when you use any command that begins with **snmp-agent** except for the **snmp-agent calculate-password** command.

The SNMP agent will fail to be enabled when the port that the agent will listen on is used by another service. You can use the **snmp-agent port** command to specify a listening port. To view the UDP port use information, execute the **display udp verbose** command. For more information about the **display udp verbose** command, see IP performance optimization commands in *Layer 3—IP Services Configuration Guide*.

If you disable the SNMP agent, the SNMP settings do not take effect. The **display current-configuration** command does not display the SNMP settings and the SNMP settings will not be saved in the configuration file. For the SNMP settings to take effect, enable the SNMP agent.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable the SNMP agent.

   ```
   snmp-agent
   ```

   By default, the SNMP agent is disabled.

Enabling SNMP versions

Restrictions and guidelines

The devices supports SNMPv1, SNMPv2c, and SNMPv3. An NMS and an SNMP agent must use the same SNMP version to communicate with each other.

The community name and data carried in SNMPv1 and SNMPv2c messages are in plaintext form, putting the SNMP communication at risks. As a best practice, use SNMPv3.

SNMP notifications over IPv6 is supported only when you specify SNMPv2c or SNMPv3.

Procedure

1. Enter system view.

   system-view

2. Specify the SNMP version.

   snmp-agent sys-info version { **all** | { **v1** | **v2c** | **v3** } * }

   By default, SNMPv3 is enabled.

   If you execute the command multiple times with different options, all the configurations take effect, but only one SNMP version is used by the agent and NMS for communication.

Configuring SNMP common parameters

Restrictions and guidelines

An SNMP engine ID uniquely identifies a device in an SNMP managed network. Make sure the local SNMP engine ID is unique within your SNMP managed network to avoid communication problems. By default, the device is assigned a unique SNMP engine ID.

If you have configured SNMPv3 users, change the local SNMP engine ID only when necessary. The change can void the SNMPv3 usernames and encrypted keys you have configured.

The SNMP agent will fail to be enabled when the port that the agent will listen on is used by another service. You can use the **snmp-agent port** command to change the SNMP listening port. As a best practice, execute the **display udp verbose** command to view the UDP port use information before specifying a new SNMP listening port. For more information about the **display udp verbose** command, see IP performance optimization commands in *Layer 3—IP Services Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Specify an SNMP listening port.

   snmp-agent port *port-number*

   By default, the SNMP listening port is UDP port 161.

3. Set a local SNMP engine ID.

   snmp-agent local-engineid *engineid*

   By default, the local SNMP engine ID is the company ID plus the device ID.

4. Set an engine ID for a remote SNMP entity.

   snmp-agent remote { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **engineid** *engineid*

   By default, no remote entity engine IDs exist.

   This step is required for the device to send SNMPv3 notifications to a host, typically NMS.

5. Create or update a MIB view.

   snmp-agent mib-view { **excluded** | **included** } *view-name oid-tree* [**mask** *mask-value*]

   By default, the MIB view **ViewDefault** is predefined. In this view, all the MIB objects in the **iso** subtree but the **snmpUsmMIB**, **snmpVacmMIB**, and **snmpModules.18** subtrees are accessible.

Each *view-name oid-tree* pair represents a view record. If you specify the same record with different MIB sub-tree masks multiple times, the most recent configuration takes effect.

6. Configure the system management information.

- Configure the system contact.

  snmp-agent sys-info contact *sys-contact*

  By default, the system contact is **NSFOCUS**

- Configure the system location.

  snmp-agent sys-info location *sys- location*

  By default, the system location is **Beijing, China**.

7. Create an SNMP context.

snmp-agent context *context-name*

By default, no SNMP contexts exist.

8. Configure the maximum SNMP packet size (in bytes) that the SNMP agent can handle.

snmp-agent packet max-size *byte-count*

By default, an SNMP agent can process SNMP packets with a maximum size of 1500 bytes.

Configuring an SNMPv1 or SNMPv2c community

About configuring an SNMPv1 or SNMPv2c community

You can create an SNMPv1 or SNMPv2c community by using a community name or by creating an SNMPv1 or SNMPv2c user. After you create an SNMPv1 or SNMPv2c user, the system automatically creates a community by using the username as the community name.

Restrictions and guidelines for configuring an SNMPv1 or SNMPv2c community

Make sure the NMS and agent use the same SNMP community name.

Only users with the network-admin, context-admin, or level-15 user role can create SNMPv1 or SNMPv2c communities, users, or groups. Users with other user roles cannot create SNMPv1 or SNMPv2c communities, users, or groups even if these roles are granted access to related commands or commands of the SNMPv1 or SNMPv2c feature.

Configuring an SNMPv1/v2c community by a community name

1. Enter system view.

system-view

2. Create an SNMPv1/v2c community. Choose one option as needed.

- In VACM mode:

  snmp-agent community { **read** | **write** } [**simple** | **cipher**] *community-name* [**mib-view** *view-name*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

- In RBAC mode:

```
snmp-agent community [ simple | cipher ] community-name user-role
role-name [ acl { ipv4-acl-number | name ipv4-acl-name } | acl ipv6
{ ipv6-acl-number | name ipv6-acl-name } ] *
```

3. (Optional.) Map the SNMP community name to an SNMP context.

```
snmp-agent community-map community-name context context-name
```

Configuring an SNMPv1/v2c community by creating an SNMPv1/v2c user

1. Enter system view.

```
system-view
```

2. Create an SNMPv1/v2c group.

```
snmp-agent group { v1 | v2c } group-name [ notify-view view-name |
read-view view-name | write-view view-name ] * [ acl { ipv4-acl-number |
name ipv4-acl-name } | acl ipv6 { ipv6-acl-number | name
ipv6-acl-name } ] *
```

3. Add an SNMPv1/v2c user to the group.

```
snmp-agent usm-user { v1 | v2c } user-name group-name [ acl
{ ipv4-acl-number | name ipv4-acl-name } | acl ipv6 { ipv6-acl-number
| name ipv6-acl-name } ] *
```

The system automatically creates an SNMP community by using the username as the community name.

4. (Optional.) Map the SNMP community name to an SNMP context.

```
snmp-agent community-map community-name context context-name
```

Configuring an SNMPv3 group and user

Restrictions and guidelines for configuring an SNMPv3 group and user

Only users with the network-admin, context-admin, or level-15 user role can create SNMPv3 users or groups.Users with other user roles cannot create SNMPv3 users or groups even if these roles are granted access to related commands or commands of the SNMPv3 feature.

SNMPv3 users are managed in groups. All SNMPv3 users in a group share the same security model, but can use different authentication and encryption algorithms and keys. Table 1 describes the basic configuration requirements for different security models.

Table 1 Basic configuration requirements for different security models

Security model	Keyword for the group	Parameters for the user	Remarks
Authentication with privacy	`privacy`	Authentication and encryption algorithms and keys	For an NMS to access the agent, make sure the NMS and agent use the same authentication and encryption keys.

Security model	Keyword for the group	Parameters for the user	Remarks
Authentication without privacy	**authentication**	Authentication algorithm and key	For an NMS to access the agent, make sure the NMS and agent use the same authentication key.
No authentication, no privacy	N/A	N/A	The authentication and encryption keys, if configured, do not take effect.

Configuring an SNMPv3 group and user

1. Enter system view.

   system-view

2. Create an SNMPv3 group.

   snmp-agent group v3 *group-name* [**authentication** | **privacy**] [**notify-view** *view-name* | **read-view** *view-name* | **write-view** *view-name*] * [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. (Optional.) Calculate the encrypted form for the key in plaintext form.

   snmp-agent calculate-password *plain-password* **mode** { **3desmd5** | **3dessha** | **md5** | **sha** } { **local-engineid** | **specified-engineid** *engineid* }

4. Create an SNMPv3 user. Choose one option as needed.

   - In VACM mode:

     snmp-agent usm-user v3 *user-name group-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] [{ **cipher** | **simple** } **authentication-mode** { **md5** | **sha** } *auth-password* [**privacy-mode** { **3des** | **aes128** | **des56** } *priv-password*]] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   - In RBAC mode:

     snmp-agent usm-user v3 *user-name* **user-role** *role-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] [{ **cipher** | **simple** } **authentication-mode** { **md5** | **sha** } *auth-password* [**privacy-mode** { **3des** | **aes128** | **des56** } *priv-password*]] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   To send notifications to an SNMPv3 NMS, you must specify the **remote** keyword.

5. (Optional.) Assign a user role to the SNMPv3 user created in RBAC mode.

   snmp-agent usm-user v3 *user-name* **user-role** *role-name*

   By default, an SNMPv3 user has the user role assigned to it at its creation.

Configuring SNMP notifications

About SNMP notifications

The SNMP agent sends notifications (traps and informs) to inform the NMS of significant events, such as link state changes and user logins or logouts. After you enable notifications for a module, the module sends the generated notifications to the SNMP agent. The SNMP agent sends the received notifications as traps or informs based on the current configuration. Unless otherwise stated, the **trap** keyword in the command line includes both traps and informs.

Enabling SNMP notifications

Restrictions and guidelines

Enable SNMP notifications only if necessary. SNMP notifications are memory-intensive and might affect device performance.

To generate linkUp or linkDown notifications when the link state of an interface changes, you must perform the following tasks:

- Enable linkUp or linkDown notification globally by using the **snmp-agent trap enable standard** [**linkdown** | **linkup**] * command.
- Enable linkUp or linkDown notification on the interface by using the **enable snmp trap updown** command.

After you enable notifications for a module, whether the module generates notifications also depends on the configuration of the module. For more information, see the configuration guide for each module.

SNMP notifications over IPv6 is supported only when you specify SNMPv2c or SNMPv3.

Procedure

1. Enter system view.

   system-view
2. Enable SNMP notifications.

   snmp-agent trap enable [**configuration** | *protocol* | **standard** [**authentication** | **coldstart** | **linkdown** | **linkup** | **warmstart**] * | **system**]

   By default, SNMP configuration notifications, standard notifications, and system notifications are enabled. Whether other SNMP notifications are enabled varies by modules.

   To enable the device to send SNMP notifications for a protocol, first enable the protocol.
3. Enter interface view.

   interface *interface-type interface-number*
4. Enable link state notifications.

   enable snmp trap updown

   By default, link state notifications are enabled.

Configuring parameters for sending SNMP notifications

About this task

You can configure the SNMP agent to send notifications as traps or informs to a host, typically an NMS, for analysis and management. Traps are less reliable and use fewer resources than informs, because an NMS does not send an acknowledgment when it receives a trap.

When network congestion occurs or the destination is not reachable, the SNMP agent buffers notifications in a queue. You can set the queue size and the notification lifetime (the maximum time that a notification can stay in the queue). A notification is deleted when its lifetime expires. When the notification queue is full, the oldest notifications are automatically deleted.

By default, the device monitors the values of the variables in a trap. When the values reach the specified thresholds, the device enters alarm state and sends a trap to the NMS, The device sends a trap only when it enters alarm state or alarm removed state. The trap retransmission mechanism enables the device to send traps at the specified intervals to notify the NMS as long as the device is in alarm state. Only CPU usage and memory usage traps are supported.

Configuring the parameters for sending SNMP traps

1. Enter system view.

   system-view

2. Configure a target host.

   snmp-agent target-host trap address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**source-ip** *source-ip-address* | **udp-port** *port-number* | **vpn-instance** *vpn-instance-name*] * **params securityname** *security-string* [**v1** | **v2c** | **v3** [**authentication** | **privacy**]]

   By default, no target host is configured.

3. (Optional.) Configure a source address for sending traps.

   snmp-agent trap source *interface-type* { *interface-number* | *interface-number.subnumber* }

   By default, SNMP uses the IP address of the outgoing routed interface as the source IP address.

   For a trap sent to a particular NMS, the source IP address specified by using the **snmp-agent target-host** command overrides that specified by using this command.

Configuring the parameters for sending SNMP informs

1. Enter system view.

   system-view

2. Configure a target host.

   snmp-agent target-host inform address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**source-ip** *source-ip-address* | **udp-port** *port-number* | **vpn-instance** *vpn-instance-name*] ***params securityname** *security-string* { **v2c** | **v3** [**authentication** | **privacy**] }

   By default, no target host is configured.

   Only SNMPv2c and SNMPv3 support inform packets.

3. (Optional.) Configure a source address for sending informs.

   snmp-agent inform source *interface-type* { *interface-number* | *interface-number.subnumber* }

   By default, SNMP uses the IP address of the outgoing routed interface as the source IP address.

For an inform sent to a particular NMS, the source IP address specified by using the **snmp-agent target-host** command overrides that specified by using this command.

Configuring common parameters for sending notifications

1. Enter system view.

   system-view

2. (Optional.) Enable extended linkUp/linkDown notifications.

   snmp-agent trap if-mib link extended

   By default, the SNMP agent sends standard linkUp/linkDown notifications.

   An extended linkUp/linkDown notification adds the interface name, interface type, and interface description to the linkUp/linkDown notification. If the NMS does not support extended linkUp/linkDown notifications, do not use this command.

3. (Optional.) Set the notification queue size.

   snmp-agent trap queue-size *size*

   By default, the notification queue can hold 100 notification messages.

4. (Optional.) Set the notification lifetime.

   snmp-agent trap life *seconds*

   The default notification lifetime is 120 seconds.

Configuring SNMP logging

About this task

The SNMP agent logs Get requests, Set requests, Set responses, SNMP notifications, and SNMP authentication failures, but does not log Get responses.

- **Get operation**—The agent logs the IP address of the NMS, name of the accessed node, and node OID.
- **Set operation**—The agent logs the NMS' IP address, name of accessed node, node OID, variable value, and error code and index for the Set operation.
- **Notification tracking**—The agent logs the SNMP notifications after sending them to the NMS.
- **SNMP authentication failure**—The agent logs related information when an NMS fails to be authenticated by the agent.

The SNMP module sends these logs to the information center. You can configure the information center to output these messages to certain destinations, such as the console and the log buffer. The total output size for the node field (MIB node name) and the value field (value of the MIB node) in each log entry is 1024 bytes. If this limit is exceeded, the information center truncates the data in the fields. For more information about the information center, see "Configuring the information center."

Restrictions and guidelines

Enable SNMP logging only if necessary. SNMP logging is memory-intensive and might impact device performance.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP logging.

   snmp-agent log { **all** | **authfail** | **get-operation** | **set-operation** }

   By default, SNMP logging is disabled.

3. Enable SNMP notification logging.

snmp-agent trap log

By default, SNMP notification logging is disabled.

Enabling VA interface query and configuration by using MIB objects

About this task

By default, VA interfaces cannot be queried and configured by using MIB objects. The device ignores the query and configuration requests from the NMS for VA interfaces. This not only enhances the device efficiency to obtain other interface information and improves user experiences, but also reduces the device workload and avoids waster of CPU resources.

To enable VA interface query and configuration by using MIB objects, execute this command.

For more information about VA interfaces, see PPP configuration in *Layer 2—WAN Access Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable VA interface query and configuration by using MIB objects.

   snmp virtual-access visible

   By default, VA interfaces cannot be queried and configured by using MIB objects.

Display and maintenance commands for SNMP

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display SNMPv1 or SNMPv2c community information.	**display snmp-agent community** [**read** | **write**]
Display SNMP contexts.	**display snmp-agent context** [*context-name*]
Display SNMP group information.	**display snmp-agent group** [*group-name*]
Display the local engine ID.	**display snmp-agent local-engineid**
Display SNMP MIB node information.	**display snmp-agent mib-node** [**details** | **index-node** | **trap-node** | **verbose**]
Display MIB view information.	**display snmp-agent mib-view** [**exclude** | **include** | **viewname** *view-name*]
Display remote engine IDs.	**display snmp-agent remote** [{ *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]]
Display SNMP agent statistics.	**display snmp-agent statistics**

Task	Command
Display SNMP agent system information.	**display snmp-agent sys-info** [**contact** | **location** | **version**] *
Display basic information about the notification queue.	**display snmp-agent trap queue**
Display SNMP notifications drop records.	**display snmp-agent trapbuffer drop**
Display SNMP notifications sending records.	**display snmp-agent trapbuffer send**
Display SNMP notifications enabling status for modules.	**display snmp-agent trap-list**
Display SNMPv3 user information.	**display snmp-agent usm-user** [**engineid** *engineid* | **username** *user-name* | **group** *group-name*] *
Clear all records from the SNMP trap buffer.	**reset snmp-agent trapbuffer**

Contents

Configuring RMON

About RMON

Remote Network Monitoring (RMON) is an SNMP-based network management protocol. It enables proactive remote monitoring and management of network devices.

RMON working mechanism

RMON can periodically or continuously collect traffic statistics for an Ethernet port and monitor the values of MIB objects on a device. When a value reaches the threshold, the device automatically logs the event or sends a notification to the NMS. The NMS does not need to constantly poll MIB variables and compare the results.

RMON uses SNMP notifications to notify NMSs of various alarm conditions. SNMP reports function and interface operating status changes such as link up, link down, and module failure to the NMS.

RMON groups

Among standard RMON groups, the device implements the statistics group, history group, event group, alarm group, probe configuration group, and user history group. The NF system also implements a private alarm group, which enhances the standard alarm group. The probe configuration group and user history group are not configurable from the CLI. To configure these two groups, you must access the MIB.

Statistics group

The statistics group samples traffic statistics for monitored Ethernet interfaces and stores the statistics in the Ethernet statistics table (ethernetStatsTable). The statistics include:

- Number of collisions.
- CRC alignment errors.
- Number of undersize or oversize packets.
- Number of broadcasts.
- Number of multicasts.
- Number of bytes received.
- Number of packets received.

The statistics in the Ethernet statistics table are cumulative sums.

History group

The history group periodically samples traffic statistics on interfaces and saves the history samples in the history table (etherHistoryTable). The statistics include:

- Bandwidth utilization.
- Number of error packets.
- Total number of packets.

The history table stores traffic statistics collected for each sampling interval.

Event group

The event group controls the generation and notifications of events triggered by the alarms defined in the alarm group and the private alarm group. The following are RMON alarm event handling methods:

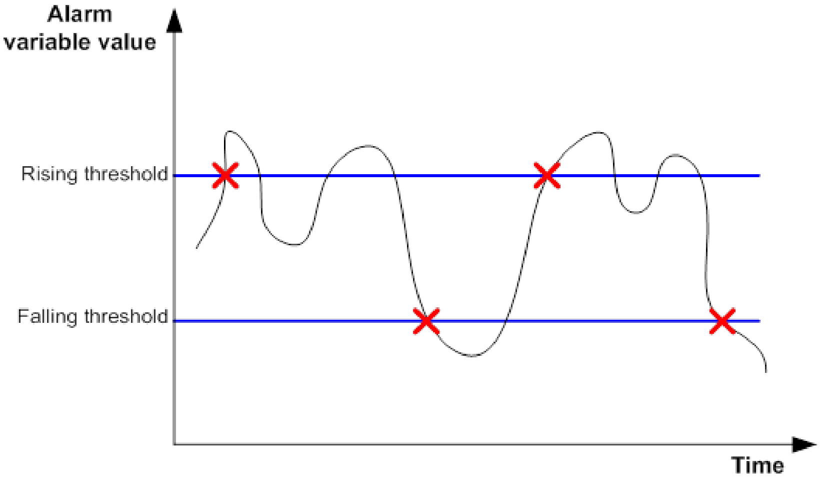
- **Log**—Logs event information (including event time and description) in the event log table so the management device can get the logs through SNMP.
- **Trap**—Sends an SNMP notification when the event occurs.
- **Log-Trap**—Logs event information in the event log table and sends an SNMP notification when the event occurs.
- **None**—Takes no actions.

Alarm group

The RMON alarm group monitors alarm variables, such as the count of incoming packets (etherStatsPkts) on an interface. After you create an alarm entry, the RMON agent samples the value of the monitored alarm variable regularly. If the value of the monitored variable is greater than or equal to the rising threshold, a rising alarm event is triggered. If the value of the monitored variable is smaller than or equal to the falling threshold, a falling alarm event is triggered. The event group defines the action to take on the alarm event.

If an alarm entry crosses a threshold multiple times in succession, the RMON agent generates an alarm event only for the first crossing. For example, if the value of a sampled alarm variable crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event, as shown in Figure 1.

Figure 1 Rising and falling alarm events



Private alarm group

The private alarm group enables you to perform basic math operations on multiple variables, and compare the calculation result with the rising and falling thresholds.

The RMON agent samples variables and takes an alarm action based on a private alarm entry as follows:

1. Samples the private alarm variables in the user-defined formula.
2. Processes the sampled values with the formula.
3. Compares the calculation result with the predefined thresholds, and then takes one of the following actions:
    - Triggers the event associated with the rising alarm event if the result is equal to or greater than the rising threshold.
    - Triggers the event associated with the falling alarm event if the result is equal to or less than the falling threshold.

If a private alarm entry crosses a threshold multiple times in succession, the RMON agent generates an alarm event only for the first crossing. For example, if the value of a sampled alarm variable crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event.

Sample types for the alarm group and the private alarm group

The RMON agent supports the following sample types:

- **absolute**—RMON compares the value of the monitored variable with the rising and falling thresholds at the end of the sampling interval.
- **delta**—RMON subtracts the value of the monitored variable at the previous sample from the current value, and then compares the difference with the rising and falling thresholds.

Protocols and standards

- RFC 4502, *Remote Network Monitoring Management Information Base Version 2*
- RFC 2819, *Remote Network Monitoring Management Information Base Status of this Memo*

Configuring the RMON statistics function

About the RMON statistics function

RMON implements the statistics function through the Ethernet statistics group and the history group.

The Ethernet statistics group provides the cumulative statistic for a variable from the time the statistics entry is created to the current time.

The history group provides statistics that are sampled for a variable for each sampling interval. The history group uses the history control table to control sampling, and it stores samples in the history table.

Creating an RMON Ethernet statistics entry

Restrictions and guidelines

The index of an RMON statistics entry must be globally unique. If the index has been used by another interface, the creation operation fails.

You can create only one RMON statistics entry for an Ethernet interface.

Procedure

1. Enter system view.

   `system-view`

2. Enter Ethernet interface view.

   `interface` *`interface-type interface-number`*

3. Create an RMON Ethernet statistics entry.

   `rmon statistics` *`entry-number`* [**`owner`** *`text`*]

   By default, no RMON Ethernet statistics entry exists.

Creating an RMON history control entry

Restrictions and guidelines

You can configure multiple history control entries for one interface, but you must make sure their entry numbers and sampling intervals are different.

You can create a history control entry successfully even if the specified bucket size exceeds the available history table size. RMON will set the bucket size as closely to the expected bucket size as possible.

Procedure

1. Enter system view.

   `system-view`

2. Enter Ethernet interface view.

   `interface` *`interface-type interface-number`*

3. Create an RMON history control entry.

   `rmon history` *`entry-number`* **`buckets`** *`number`* **`interval`** *`interval`* [**`owner`** *`text`*]

   By default, no RMON history control entries exist.

   You can create multiple RMON history control entries for an Ethernet interface.

Configuring the RMON alarm function

Restrictions and guidelines

When you create a new event, alarm, or private alarm entry, follow these restrictions and guidelines:

- The entry must not have the same set of parameters as an existing entry.
- The maximum number of entries is not reached.

Table 1 shows the parameters to be compared for duplication and the entry limits.

Table 1 RMON configuration restrictions

Entry	Parameters to be compared	Maximum number of entries
Event	• Event description (**`description`** *`string`*) • Event type (**`log`**, **`trap`**, **`logtrap`**, or **`none`**) • Community name (*`security-string`*)	60
Alarm	• Alarm variable (*`alarm-variable`*) • Sampling interval (*`sampling-interval`*) • Sample type (**`absolute`** or **`delta`**) • Rising threshold (*`threshold-value1`*) • Falling threshold (*`threshold-value2`*)	60

Entry	Parameters to be compared	Maximum number of entries
Private alarm	• Alarm variable formula (*prialarm-formula*) • Sampling interval (*sampling-interval*) • Sample type (**absolute** or **delta**) • Rising threshold (*threshold-value1*) • Falling threshold (*threshold-value2*)	50

Prerequisites

To send notifications to the NMS when an alarm is triggered, configure the SNMP agent as described in "Configuring SNMP" before configuring the RMON alarm function.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Create an RMON event entry.

   rmon event *entry-number* [**description** *string*] { **log** | **log-trap** *security-string* | **none** | **trap** *security-string* } [**owner** *text*]

   By default, no RMON event entries exist.

3. Create an RMON alarm entry.

   - Create an RMON alarm entry.

     rmon alarm *entry-number alarm-variable sampling-interval* { **absolute** | **delta** } [**startup-alarm** { **falling** | **rising** | **rising-falling** }] **rising-threshold** *threshold-value1 event-entry1* **falling-threshold** *threshold-value2 event-entry2* [**owner** *text*]

   - Create an RMON private alarm entry.

     rmon prialarm *entry-number prialarm-formula prialarm-des sampling-interval* { **absolute** | **delta** } [**startup-alarm** { **falling** | **rising** | **rising-falling** }] **rising-threshold** *threshold-value1 event-entry1* **falling-threshold** *threshold-value2 event-entry2* **entrytype** { **forever** | **cycle** *cycle-period* } [**owner** *text*]

   By default, no RMON alarm entries or RMON private alarm entries exist.

   You can associate an alarm with an event that has not been created yet. The alarm will trigger the event only after the event is created.

Display and maintenance commands for RMON

Execute **display** commands in any view.

Task	Command
Display RMON alarm entries.	**display rmon alarm** [*entry-number*]
Display RMON event entries.	**display rmon event** [*entry-number*]
Display log information for event entries.	**display rmon eventlog** [*entry-number*]

Task	Command
Display RMON history control entries and history samples.	**display rmon history** [*interface-type interface-number*]
Display RMON private alarm entries.	**display rmon prialarm** [*entry-number*]
Display RMON statistics.	**display rmon statistics** [*interface-type interface-number*]

Contents

Configuring the Event MIB

About the Event MIB

The Event Management Information Base (Event MIB) is an SNMPv3-based network management protocol and is an enhancement to remote network monitoring (RMON). The Event MIB uses Boolean tests, existence tests, and threshold tests to monitor MIB objects on a local or remote system. It triggers the predefined notification or set action when a monitored object meets the trigger condition.

Trigger

The Event MIB uses triggers to manage and associate the three elements of the Event MIB: monitored object, trigger condition, and action.

Monitored objects

The Event MIB can monitor the following MIB objects:

- Table node.
- Conceptual row node.
- Table column node.
- Simple leaf node.
- Parent node of a leaf node.

To monitor a single MIB object, specify it by its OID or name. To monitor a set of MIB objects, specify the common OID or name of the group and enable wildcard matching. For example, specify ifDescr.2 to monitor the description for the interface with index 2. Specify ifDescr and enable wildcard matching to monitor the descriptions for all interfaces.

Trigger test

A trigger supports Boolean, existence, and threshold tests.

Boolean test

A Boolean test compares the value of the monitored object with the reference value and takes actions according to the comparison result. The comparison types include **unequal**, **equal**, **less**, **lessorequal**, **greater**, and **greaterorequal**. For example, if the comparison type is **equal**, an event is triggered when the value of the monitored object equals the reference value. The event will not be triggered again until the value becomes unequal and comes back to equal.

Existence test

An existence test monitors and manages the absence, presence, and change of a MIB object, for example, interface status. When a monitored object is specified, the system reads the value of the monitored object regularly.

- If the test type is **Absent**, the system triggers an alarm event and takes the specified action when the state of the monitored object changes to absent.
- If the test type is **Present**, the system triggers an alarm event and takes the specified action when the state of the monitored object changes to present.
- If the test type is **Changed**, the system triggers an alarm event and takes the specified action when the value of the monitored object changes.

Threshold test

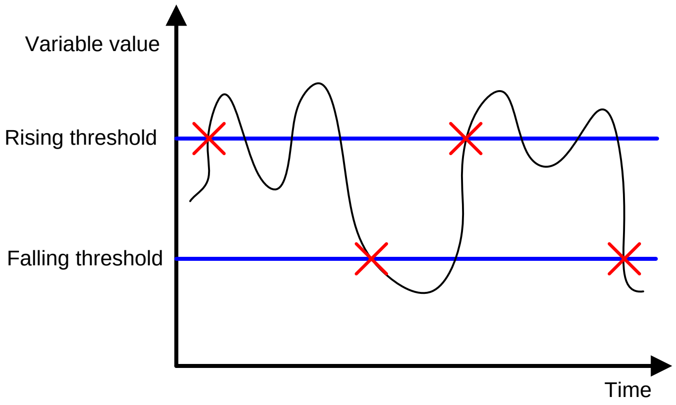
A threshold test regularly compares the value of the monitored object with the threshold values.

- A rising alarm event is triggered if the value of the monitored object is greater than or equal to the rising threshold.
- A falling alarm event is triggered if the value of the monitored object is smaller than or equal to the falling threshold.
- A rising alarm event is triggered if the difference between the current sampled value and the previous sampled value is greater than or equal to the delta rising threshold.
- A falling alarm event is triggered if the difference between the current sampled value and the previous sampled value is smaller than or equal to the delta falling threshold.
- A falling alarm event is triggered if the values of the monitored object, the rising threshold, and the falling threshold are the same.
- A falling alarm event is triggered if the delta rising threshold, the delta falling threshold, and the difference between the current sampled value and the previous sampled value is the same.

The alarm management module defines the set or notification action to take on alarm events.

If the value of the monitored object crosses a threshold multiple times in succession, the managed device triggers an alarm event only for the first crossing. For example, if the value of a sampled object crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event, as shown in Figure 1.

Figure 1 Rising and falling alarm events



Event actions

The Event MIB triggers one or both of the following actions when the trigger condition is met:

- **Set action**—Uses SNMP to set the value of the monitored object.
- **Notification action**—Uses SNMP to send a notification to the NMS. If an object list is specified for the notification action, the notification will carry the specified objects in the object list.

Object list

An object list is a set of MIB objects. You can specify an object list in trigger view, trigger-test view (including trigger-Boolean view, trigger existence view, and trigger threshold view), and action-notification view. If a notification action is triggered, the device sends a notification carrying the object list to the NMS.

If you specify an object list respectively in any two of the views or all the three views, the object lists are added to the triggered notifications in this sequence: trigger view, trigger-test view, and action-notification view.

Object owner

Trigger, event, and object list use an owner and name for unique identification. The owner must be an SNMPv3 user that has been created on the device. If you specify a notification action for a trigger, you must establish an SNMPv3 connection between the device and NMS by using the SNMPv3 username. For more information about SNMPv3 user, see "SNMP configuration".

Restrictions and guidelines: Event MIB configuration

The Event MIB and RMON are independent of each other. You can configure one or both of the features for network management.

You must specify the same owner for a trigger, object lists of the trigger, and events of the trigger.

Event MIB tasks at a glance

To configure the Event MIB, perform the following tasks:

1. Configuring the Event MIB global sampling parameters
2. (Optional.) Configuring Event MIB object lists

   Perform this task so that the device sends a notification that carries the specified object list to the NMS when a notification action is triggered.
3. Configuring an event

   The device supports set and notification actions. Choose one or two of the following actions:
   - Creating an event
   - Configuring a set action for an event
   - Configuring a notification action for an event
   - Enabling the event
4. Configuring a trigger

   A trigger supports Boolean, existence, and threshold tests. Choose one or more of the following tests:
   - Creating a trigger and configuring its basic parameters
   - Configuring a Boolean trigger test
   - Configuring an existence trigger test
   - Configuring a threshold trigger test
   - Enabling trigger sampling
5. (Optional.) Enabling SNMP notifications for the Event MIB module

Prerequisites for configuring the Event MIB

Before you configure the Event MIB, perform the following tasks:

- Create an SNMPv3 user. Assign the user the rights to read and set the values of the specified MIB objects and object lists.

- Make sure the SNMP agent and NMS are configured correctly and the SNMP agent can send notifications to the NMS correctly.

Configuring the Event MIB global sampling parameters

Restrictions and guidelines

This tasks takes effect only on monitored instances to be created.

Procedure

1. Enter system view.

   `system-view`

2. Set the minimum sampling interval.

   `snmp mib event sample minimum` *min-number*

   By default, the minimum sampling interval is 1 second.

   The sampling interval of a trigger must be greater than the minimum sampling interval.

3. Configure the maximum number of object instances that can be concurrently sampled.

   `snmp mib event sample instance maximum` *max-number*

   By default, the value is 0. The maximum number of object instances that can be concurrently sampled is limited by the available resources.

Configuring Event MIB object lists

About this task

Perform this task so that the device sends a notification that carries the specified objects to the NMS when a notification action is triggered.

Procedure

1. Enter system view.

   `system-view`

2. Configure an Event MIB object list.

   `snmp mib event object list owner` *group-owner* **`name`** *group-name object-index* **`oid`** *object-identifier* [**`wildcard`**]

   The object can be a table node, conceptual row node, table column node, simple leaf node, or parent node of a leaf node.

Configuring an event

Creating an event

1. Enter system view.

   `system-view`

2. Create an event and enter its view.

   `snmp mib event owner` *event-owner* **`name`** *event-name*

3. (Optional.) Configure a description for the event.

`description` *text*

By default, an event does not have a description.

Configuring a set action for an event

1. Enter system view.

   `system-view`

2. Enter event view.

   `snmp mib event owner` *event-owner* **name** *event-name*

3. Enable the set action and enter set action view.

   `action set`

   By default, no action is specified for an event.

4. Specify an object by its OID for the set action.

   `oid` *object-identifier*

   By default, no object is specified for a set action.

   The object can be a table node, conceptual row node, table column node, simple leaf node, or parent node of a leaf node.

5. Enable OID wildcarding.

   `wildcard oid`

   By default, OID wildcarding is disabled.

6. Set the value for the object.

   `value` *integer-value*

   The default value for the object is 0.

7. (Optional.) Specify a context for the object.

   `context` *context-name*

   By default, no context is specified for an object.

8. (Optional.) Enable context wildcarding.

   `wildcard context`

   By default, context wildcarding is disabled.

   A wildcard context contains the specified context and the wildcarded part.

Configuring a notification action for an event

1. Enter system view.

   `system-view`

2. Enter event view

   `snmp mib event owner` *event-owner* **name** *event-name*

3. Enable the notification action and enter notification action view.

   `action notification`

   By default, no action is specified for an event.

4. Specify an object to execute the notification action by its OID.

   `oid` *object-identifier*

   By default, no object is specified for executing the notification action.

   The object must be a notification object.

5. Specify an object list to be added to the notification triggered by the event.

   `object list owner` *group-owner* **`name`** *group-name*

   By default, no object list is specified for the notification action.

   If you do not specify an object list for the notification action or the specified object list does not contain variables, no variables will be carried in the notification.

Enabling the event

Restrictions and guidelines

The Boolean, existence, and threshold events can be triggered only after you perform this task.

To change an enabled event, first disable the event.

Procedure

1. Enter system view.

   `system-view`

2. Enter event view.

   `snmp mib event owner` *`event-owner`* **`name`** *`event-name`*

3. Enable the event.

   `event enable`

   By default, an event is disabled.

Configuring a trigger

Creating a trigger and configuring its basic parameters

1. Enter system view.

   `system-view`

2. Create a trigger and enter its view.

   `snmp mib event trigger owner` *trigger-owner* **`name`** *trigger-name*

   The trigger owner must be an existing SNMPv3 user.

3. (Optional.) Configure a description for the trigger.

   `description` *text*

   By default, a trigger does not have a description.

4. Set a sampling interval for the trigger.

   `frequency` *interval*

   By default, the sampling interval is 600 seconds.

   Make sure the sampling interval is greater than or equal to the Event MIB minimum sampling interval.

5. Specify a sampling method.

   `sample` { **`absolute`** | **`delta`** }

   The default sampling method is **`absolute`**.

6. Specify an object to be sampled by its OID.

   `oid` *object-identifier*

   By default, the OID is 0.0. No object is specified for a trigger.

   If you execute this command multiple times, the most recent configuration takes effect.

7. (Optional.) Enable OID wildcarding.

   `wildcard oid`

   By default, OID wildcarding is disabled.

8. (Optional.) Configure a context for the monitored object.

   `context` *context-name*

   By default, no context is configured for a monitored object.

9. (Optional.) Enable context wildcarding.

   `wildcard context`

   By default, context wildcarding is disabled.

10. (Optional.) Specify the object list to be added to the triggered notification.

    `object list owner` *group-owner* **name** *group-name*

    By default, no object list is specified for a trigger.

Configuring a Boolean trigger test

1. Enter system view.

   `system-view`

2. Enter trigger view.

   `snmp mib event trigger owner` *trigger-owner* **name** *trigger-name*

3. Specify a Boolean test for the trigger and enter trigger-Boolean view.

   `test boolean`

   By default, no test is configured for a trigger.

4. Specify a Boolean test comparison type.

   `comparison` { **`equal`** | **`greater`** | **`greaterorequal`** | **`less`** | **`lessorequal`** | **`unequal`** }

   The default Boolean test comparison type is **`unequal`**.

5. Set a reference value for the Boolean trigger test.

   `value` *integer-value*

   The default reference value for a Boolean trigger test is 0.

6. Specify an event for the Boolean trigger test.

   `event owner` *event-owner* **name** *event-name*

   By default, no event is specified for a Boolean trigger test.

7. (Optional.) Specify the object list to be added to the notification triggered by the test.

   `object list owner` *group-owner* **name** *group-name*

   By default, no object list is specified for a Boolean trigger test.

8. Enable the event to be triggered when the trigger condition is met at the first sampling.

   `startup enable`

   By default, the event is triggered when the trigger condition is met at the first sampling.

   Before the first sampling, you must enable this command to allow the event to be triggered.

Configuring an existence trigger test

1. Enter system view.

   `system-view`

2. Enter trigger view.

   snmp mib event trigger owner *trigger-owner* **name** *trigger-name*

3. Specify an existence test for the trigger and enter trigger-existence view.

   test existence

   By default ,no test is configured for a trigger.

4. Specify an event for the existence trigger test.

   event owner *event-owner* **name** *event-name*

   By default, no event is specified for an existence trigger test.

5. (Optional.) Specify the object list to be added to the notification triggered by the test.

   object list owner *group-owner* **name** *group-name*

   By default, no object list is specified for an existence trigger test.

6. Specify an existence trigger test type.

   type { **absent** | **changed** | **present** }

   The default existence trigger test types are **present** and **absent**.

7. Specify an existence trigger test type for the first sampling.

   startup { **absent** | **present** }

   By default, both the **present** and **absent** existence trigger test types are allowed for the first sampling.

Configuring a threshold trigger test

1. Enter system view.

   system-view

2. Enter trigger view.

   snmp mib event trigger owner *trigger-owner* **name** *trigger-name*

3. Specify a threshold test for the trigger and enter trigger-threshold view.

   test boolean

   By default ,no test is configured for a trigger.

4. Specify the object list to be added to the notification triggered by the test.

   object list owner *group-owner* **name** *group-name*

   By default, no object list is specified for a threshold trigger test.

5. (Optional.) Specify the type of the threshold trigger test for the first sampling.

   startup { **falling** | **rising** | **rising-or-falling** }

   The default threshold trigger test type for the first sampling is **rising-or-falling**.

6. Specify the delta falling threshold and the falling alarm event triggered when the delta value (difference between the current sampled value and the previous sampled value) is smaller than or equal to the delta falling threshold.

   delta falling { **event owner** *event-owner* **name** *event-name* | **value** *integer-value* }

   By default, the delta falling threshold is 0, and no falling alarm event is specified.

7. Specify the delta rising threshold and the rising alarm event triggered when the delta value is greater than or equal to the delta rising threshold.

   delta rising { **event owner** *event-owner* **name** *event-name* | **value** *integer-value* }

   By default, the delta rising threshold is 0, and no rising alarm event is specified.

8. Specify the falling threshold and the falling alarm event triggered when the sampled value is smaller than or equal to the threshold.

falling { **event owner** *event-owner* **name** *event-name* | **value** *integer-value* }

By default, the falling threshold is 0, and no falling alarm event is specified.

9. Specify the rising threshold and the ring alarm event triggered when the sampled value is greater than or equal to the threshold.

   rising { **event owner** *event-owner* **name** *event-name* | **value** *integer-value* }

   By default, the rising threshold is 0, and no rising alarm event is specified.

Enabling trigger sampling

Restrictions and guidelines

Enable trigger sampling after you complete trigger parameters configuration. You cannot modify trigger parameters after trigger sampling is enabled. To modify trigger parameters, first disable trigger sampling.

Procedure

1. Enter system view.

   system-view

2. Enter trigger view.

   snmp mib event trigger owner *trigger-owner* **name** *trigger-name*

3. Enable trigger sampling.

   trigger enable

   By default, trigger sampling is disabled.

Enabling SNMP notifications for the Event MIB module

About this task

To report critical Event MIB events to an NMS, enable SNMP notifications for the Event MIB module. For Event MIB event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.

   system-view

2. Enable snmp notifications for the Event MIB module.

   snmp-agent trap enable event-mib

   By default, SNMP notifications are enabled for the Event MIB module.

Display and maintenance commands for Event MIB

Execute **display** commands in any view.

Task	Command
Display Event MIB configuration and statistics.	**display snmp mib event**
Display event information.	**display snmp mib event event** [**owner** *event-owner* **name** *event-name*]
Display object list information.	**display snmp mib event object list** [**owner** *group-owner* **name** *group-name*]
Display global Event MIB configuration and statistics.	**display snmp mib event summary**
Display trigger information.	**display snmp mib event trigger** [**owner** *trigger-owner* **name** *trigger-name*]

Contents

Configuring process placement

About process placement

Process

A process contains a set of codes and provides specific functionality. For example, an AAA process provides AAA functions.

Each process runs in a protected memory space to prevent problems with one process from impacting the entire system.

Node

The term "node" in this document refers to CPUs that run the NF system. If the IRF fabric has multiple member devices, each member device has a node.

Process redundancy

The system backs up each active process running on one node to all the other nodes. When an active process fails, one of its standby processes promptly takes over without impacting any other service.

Process redundancy provides the following benefits:

- Improves service availability.
- Enables the system to quickly regain reliability after device status changes in such conditions as leave of an IRF member device.

Process placement

The execution of process placement policies varies by the location of active processes.

- An active process running only on the master device does not support placement optimization. If you configure a process placement policy for the process, the system displays a configuration failure message. When such an active process fails, the system automatically restarts the process. The standby processes are used for active/standby switchover and ISSU.
- Some active processes can run on either the master or subordinate device. When such an active process fails, the system uses a placement policy to select a new active process among standby processes.

Default process placement policy

The system provides a default process placement policy that takes effect for all processes. By default, the default process placement policy defines the following rules:

- The active process runs on the CPU of the master, and the standby processes run on the CPU of the subordinate device.
- A process runs at the location where it ran the last time and does not move to any other location during startup or operation.

- The addition of a new node does not impact current active processes. A new active process selects one node with sufficient CPU and memory resources. (You can use the **`display cpu-usage`** and **`display memory`** commands to view CPU and memory usage information.)

You can modify the default placement policy in the view you enter by using the **`placement program default`** command. You can also configure a placement policy for a specific process in the view you enter by using the **`placement program`** *`program-name`* `[` **`instance`** *`instance-name`* `]` command. A placement policy for a process takes precedence over the default process placement policy.

Process placement affinities

You can configure the following settings for a process placement policy to optimize process placement:

- **affinity location-set**—Location affinity, the preference for the process to run on a specific node.
- **affinity location-type**—Location type affinity, the preference for the process to run on a particular type of node. For more information about node types, see "Configuring a location type affinity."
- **affinity program**—Process affinity, the preference for the process to run on the same node as a particular process.
- **affinity self**—Self affinity, the preference for one instance of the process to run on the same node as any other instance of the process.

Affinities include positive affinities (**attract**) and negative affinities (**repulse**), all represented by integers in the range of 1 to 100000.

- The higher the attract value, the stronger the preference.
- The higher the repulse value, the weaker the preference.

Process placement optimization

After you apply new placement policies, the system makes placement decisions based on the new policies, node resources, and topology status. If the new location for an active process is different from the current node, the system changes the state of the process to standby, and uses the standby process on the preferred location as the new active process.

Restrictions: Hardware compatibility with process placement

Models	**Process placement compatibility**
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Restrictions and guidelines: process placement configuration

- Configuring process placement on an IRF fabric with only one member device does not change the location of processes. All processes run on the CPU of the IRF member device.
- Configuring process placement on an IRF fabric with multiple member devices places specific active processes to specific CPUs. In case of multiple CPUs, the system performs process redundancy. The number of standby processes and their CPU locations vary by function module. The system by default automatically determines the location for each active process, and process placement optimization is not required. If optimization is required, contact NSFOCUS Support to avoid service interruption.
- For an instance of a process, the priorities of the settings in placement policy view of an instance, placement policy view of a process, and the default placement policy view are in descending order. For a process, the settings in placement policy view of the process take precedence over the settings in the default placement policy view.
- To view the current location of an active process and its predicted new location after optimization, use the **display placement reoptimize** command.

Process placement tasks at a glance

To configure process placement, perform the following tasks:

1. Configuring process placement policy

   Choose the following tasks as needed:

   - Configuring a location affinity
   - Configuring a location type affinity
   - Configuring a process affinity
   - Configuring a self affinity
2. Optimizing process placement

Configuring process placement policy

Configuring a location affinity

1. Enter system view.

   system-view
2. Enter placement process view.
   - Enter default placement process view.

     placement program default
   - Enter specified placement process view.

     placement program { *program-name* [**instance** *instance-name*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.
3. Set the location affinity.

   affinity location-set { **slot** *slot-number* }&<1-5> { **attract** *strength* | **default** | **none** | **repulse** *strength* }

   By default, no location affinity is set.

Configuring a location type affinity

About this task

The following location types are available:

- **current**—Current location of the active process, which can be displayed with the **`display placement program`** command.
- **paired**—Locations of standby processes.
- **primary**—Master device.

Procedure

1. Enter system view.

   `system-view`

2. Enter placement process view.
   - Enter default placement process view.

     `placement program default`

   - Enter specified placement process view.

     `placement program` { *`program-name`* [**`instance`** *`instance-name`*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.

3. Set the location type affinity.

   `affinity location-type` { **`current`** | **`paired`** | **`primary`** } { **`attract`** *`strength`* | **`repulse`** *`strength`* | **`default`** | **`none`** }

   By default, no location type affinity is set.

Configuring a process affinity

1. Enter system view.

   `system-view`

2. Enter placement process view.
   - Enter default placement process view.

     `placement program default`

   - Enter specified placement process view.

     `placement program` { *`program-name`* [**`instance`** *`instance-name`*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.

3. Configure the affinity for the process to run on the same location as another process.

   `affinity program` *`program-name`* { **`attract`** *`strength`* | **`default`** | **`none`** | **`repulse`** *`strength`* }

   By default, no process affinity is set.

Configuring a self affinity

About this task

A self affinity determines the preference for one instance of a process to run on the same node as any other instance of the process. The self affinity setting does not take effect for a process that has only one instance.

Procedure

1. Enter system view.

   system-view

2. Enter placement process view.

   ○ Enter default placement process view.

   placement program default

   ○ Enter specified placement process view.

   placement program { *program-name* [**instance** *instance-name*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.

3. Configure a self affinity.

   affinity self { **attract** *strength* | **repulse** *strength* | **default** | **none** }

   By default, no self affinity is set.

Optimizing process placement

Restrictions and guidelines

To keep the system stable, do not perform any tasks that require process restart when you optimize process placement.

Procedure

1. Enter system view.

   system-view

2. Optimize process placement.

   placement reoptimize

△ **CAUTION:**

To avoid neighbor flapping of related protocols, make sure HA features such as NSR or GR are configured for the processes and are stable before optimizing process placement.

Display and maintenance commands for process placement

Execute **display** commands in any view.

Task	Command
Display service group information.	**display ha service-group** { *program-name* [**instance** *instance-name*] | **all** }
Display the running processes on a specific location.	**display placement location** { **all** | **slot** *slot-number* }
Display process placement policy information.	**display placement policy program** { program-name | **all** | **default** }

Task	Command
Display the location of a process.	**display placement program** { *program-name* | **all** }
Display the predicted location of a process after process placement optimization.	**display placement reoptimize program** { *program-name* [**instance** *instance-name*] | **all** }

NF VPN Instance Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for VPN instance features.
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
ⓘ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Configuring VPN instances

Basic concepts

Site

A site has the following features:

- A site is a group of IP systems with IP connectivity that does not rely on any service provider networks.
- The classification of a site depends on the topology relationship of the devices, rather than the geographical positions. However, the devices at a site are, in most cases, adjacent to each other geographically.
- The devices at a site can belong to multiple VPNs, which means that a site can belong to multiple VPNs.

Sites connected to the same provider network can be classified into different sets by policies. Only the sites in the same set can access each other through the provider network. Such a set is called a VPN.

VPN instance

In MPLS L3VPN, VPN instances implement route isolation for VPNs. A VPN instance is also called a Virtual Routing and Forwarding (VRF) instance.

Configuring VPN instances

Creating a VPN instance

A VPN instance is a collection of the VPN membership and routing rules of its associated site. A VPN instance might correspond to more than one VPN.

To create a VPN instance:

Step	Command	Remarks
1. Enter system view.	**system-view**	N/A
2. Create a VPN instance and enter its view.	**ip vpn-instance** *vpn-instance-name*	By default, no VPN instances exist.
3. (Optional.) Configure a description for the VPN instance.	**description** *text*	By default, no description is configured for a VPN instance.

Associating a VPN instance with an interface

To associate a VPN instance with an interface:

Step	Command	Remarks
1. Enter system view.	**system-view**	N/A
2. Enter interface view.	**interface** *interface-type interface-number*	N/A

Step	Command	Remarks
3. Associate a VPN instance with the interface.	**ip binding vpn-instance** *vpn-instance-name*	By default, an interface is not associated with a VPN instance and belongs to the public network. The **ip binding vpn-instance** command deletes the IP address of the interface. You must reconfigure an IP address for the interface after configuring the command.

Displaying and maintaining VPN instances

Execute **display** commands in any view.

Task	Command
Display VPN instance information.	**display ip vpn-instance** [**instance-name** *vpn-instance-name*]

VXLAN overview

Virtual eXtensible LAN (VXLAN) is a MAC-in-UDP technology that provides Layer 2 connectivity between distant network sites across an IP network. VXLAN is typically used in data centers for multitenant services.

VXLAN benefits

VXLAN provides the following benefits:

- **Support for more virtual switched domains than VLANs**—Each VXLAN is uniquely identified by a 24-bit VXLAN ID. The total number of VXLANs can reach 16777216 (2^{24}). This specification makes VXLAN a better choice than 802.1Q VLAN to isolate traffic for user terminals.
- **Easy deployment and maintenance**—VXLAN requires deployment only on the edge devices of the transport network. Devices in the transport network perform typical Layer 3 forwarding.

VXLAN network model

As shown in Figure 1, a VXLAN is a virtual Layer 2 network (known as the overlay network) built on top of an existing physical Layer 3 network (known as the underlay network). The overlay network encapsulates inter-site Layer 2 frames into VXLAN packets and forwards the packets to the destination along the Layer 3 forwarding paths provided by the underlay network. The underlay network is transparent to tenants, and geographically dispersed sites of a tenant are merged into a Layer 2 network.

The transport edge devices assign user terminals to different VXLANs, and then forward traffic between sites for user terminals by using VXLAN tunnels. Supported user terminals include PCs, wireless terminals, and VMs on servers.

NOTE:

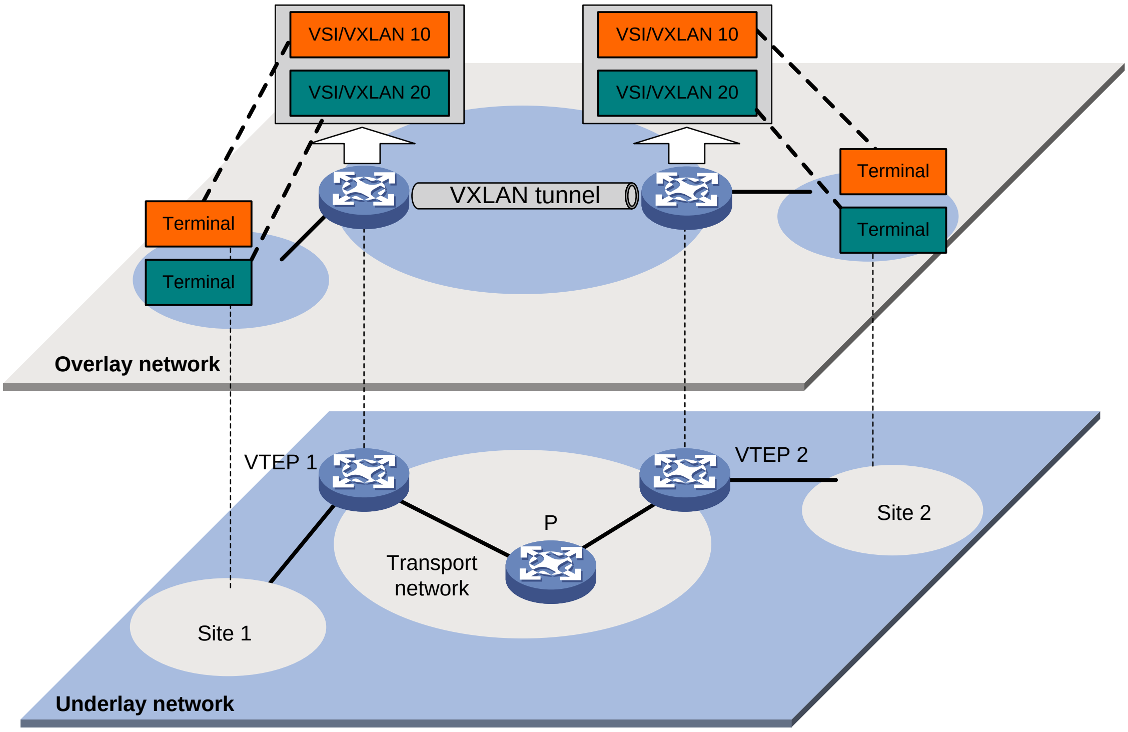
This document uses VMs as examples to describe the mechanisms of VXLAN. The mechanisms do not differ between different kinds of user terminals.

The transport edge devices are VXLAN tunnel endpoints (VTEP). The VTEP implementation of the device uses ACs, VSIs, and VXLAN tunnels to provide VXLAN services.

- **VSI**—A virtual switch instance is a virtual Layer 2 switched domain. Each VSI provides switching services only for one VXLAN. VSIs learn MAC addresses and forward frames independently of one another. VMs in different sites have Layer 2 connectivity if they are in the same VXLAN.
- **Attachment circuit (AC)**—An AC is a physical or virtual link that connects a VTEP to a local site. Typically, ACs are site-facing Layer 3 interfaces that are associated with the VSI of a VXLAN. Traffic received from an AC is assigned to the VSI associated with the AC.
- **VXLAN tunnel**—Logical point-to-point tunnels between VTEPs over the transport network. Each VXLAN tunnel can trunk multiple VXLANs.

VTEPs encapsulate VXLAN traffic in the VXLAN, outer UDP, and outer IP headers. The devices in the transport network forward VXLAN traffic only based on the outer IP header.

Figure 1 VXLAN network model

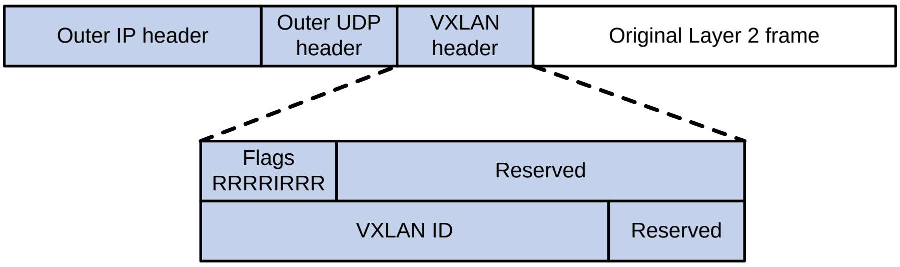


VXLAN packet format

As shown in Figure 2, a VTEP encapsulates a frame in the following headers:

- **8-byte VXLAN header**—VXLAN information for the frame.
  - **Flags**—If the I bit is 1, the VXLAN ID is valid. If the I bit is 0, the VXLAN ID is invalid. All other bits are reserved and set to 0.
  - **24-bit VXLAN ID**—Identifies the VXLAN of the frame. It is also called the virtual network identifier (VNI).
- **8-byte outer UDP header for VXLAN**—The default VXLAN destination UDP port number is 4789.
- **20-byte outer IPv4 or 40-byte outer IPv6 header**—Valid addresses of VTEPs or VXLAN multicast groups on the transport network. Devices in the transport network forward VXLAN packets based on the outer IP header.

Figure 2 VXLAN packet format



VXLAN working mechanisms

Generic VXLAN network establishment and forwarding process

The VTEP uses the following process to establish the VXLAN network and forward an inter-site frame:

1. Discovers remote VTEPs, establishes VXLAN tunnels, and assigns the VXLAN tunnels to VXLANs.
2. Assigns the frame to its matching VXLAN if the frame is sent between sites.
3. Performs MAC learning on the VXLAN's VSI.
4. Forwards the frame through VXLAN tunnels.

This section describes this process in detail. For intra-site frames in a VSI, the system performs typical Layer 2 forwarding, and it processes 802.1Q VLAN tags as described in "Access modes of VSIs."

VXLAN tunnel establishment and assignment

To provide Layer 2 connectivity for a VXLAN between two sites, you must create a VXLAN tunnel between the sites and assign the tunnel to the VXLAN.

VXLAN tunnel establishment

VXLAN supports manual VXLAN tunnel establishment. You must manually create a VXLAN tunnel interface, and specify the tunnel source and destination IP addresses on the peer VTEPs.

VXLAN tunnel assignment

VXLAN supports manual VXLAN tunnel assignment. You must manually assign VXLAN tunnels to VXLANs.

Assignment of traffic to VXLANs

Traffic from the local site to a remote site

The VTEP uses Layer 3 interface-to-VSI mapping to assign customer frames to a VXLAN. This method maps a site-facing Layer 3 interface to a VSI. The VTEP assigns all frames received from the interface to the VXLAN of the VSI.

Traffic from a remote site to the local site

When a frame arrives at a VXLAN tunnel, the VTEP uses the VXLAN ID in the frame to identify its VXLAN.

MAC learning

The VTEP performs source MAC learning on the VSI as a Layer 2 switch.

- For traffic from the local site to the remote site, the VTEP learns the source MAC address before VXLAN encapsulation.
- For traffic from the remote site to the local site, the VTEP learns the source MAC address after removing the VXLAN header.

A VSI's MAC address table includes the following types of MAC address entries:

- **Local MAC**—MAC entries dynamically learned from the local site. The outgoing interfaces for the MAC address entries are site-facing interfaces. VXLAN does not support static local-MAC entries.
- **Remote MAC**—MAC entries learned from a remote site. The outgoing interfaces for the MAC addresses are VXLAN tunnel interfaces.
  - **Static**—Manually added MAC entries.
  - **Dynamic**—MAC entries learned in the data plane from incoming traffic on VXLAN tunnels. The learned MAC addresses are contained in the inner Ethernet header.

  The following shows the priority order of different types of remote MAC address entries:

  a. Static MAC address entries.

  b. Dynamic MAC address entries.

Unicast forwarding

Intra-site unicast forwarding

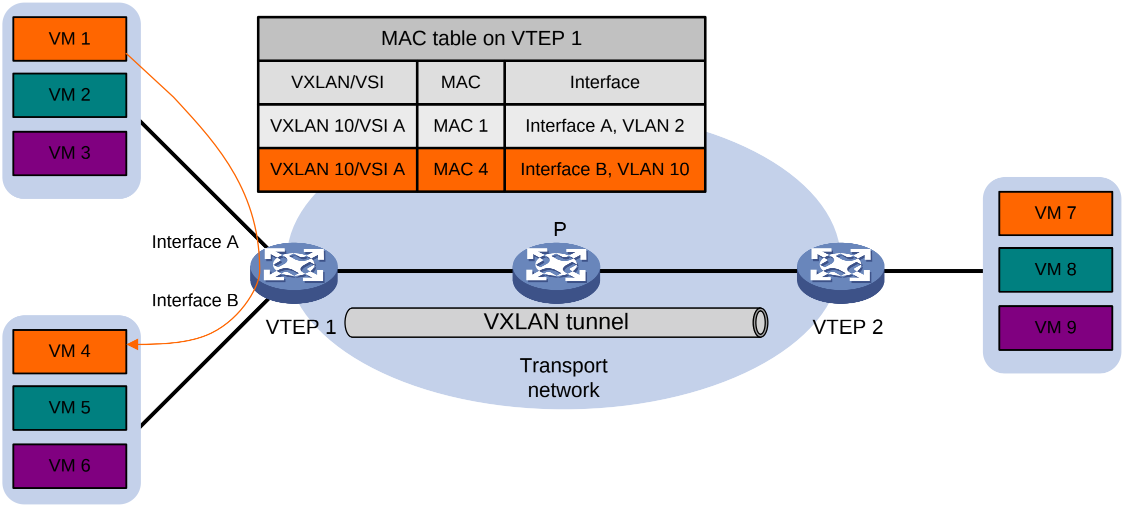
The VTEP uses the following process to forward a known unicast frame within a site:

1. Identifies the VSI of the frame.
2. Looks up the destination MAC address in the VSI's MAC address table for the outgoing interface.
3. Sends the frame out of the matching outgoing interface.

As shown in Figure 3, VTEP 1 forwards a frame from VM 1 to VM 4 within the local site in VLAN 10 as follows:

1. Identifies that the frame belongs to VSI A when the frame arrives at Interface A.
2. Looks up the destination MAC address (MAC 4) in the MAC address table of VSI A for the outgoing interface.
3. Sends the frame out of the matching outgoing interface (Interface B) to VM 4 in VLAN 10.

Figure 3 Intra-site unicast



MAC table on VTEP 1

VXLAN/VSI	MAC	Interface
VXLAN 10/VSI A	MAC 1	Interface A, VLAN 2
VXLAN 10/VSI A	MAC 4	Interface B, VLAN 10

Inter-site unicast forwarding

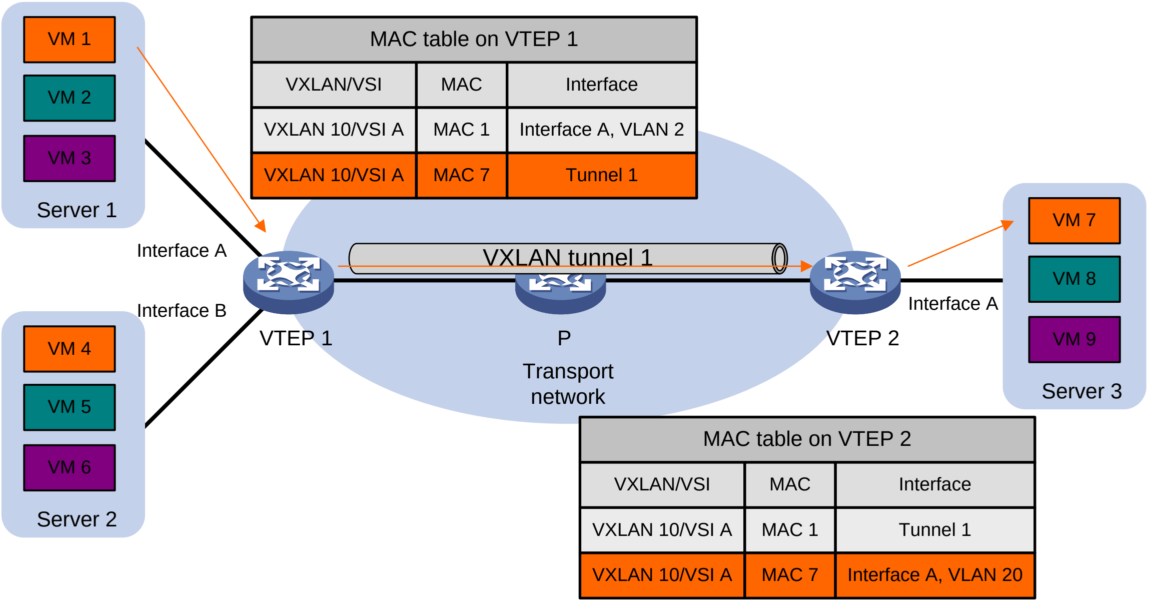
The following process (see Figure 4) applies to a known unicast frame between sites:

1. The source VTEP encapsulates the Ethernet frame in the VXLAN/UDP/IP header.

   In the outer IP header, the source IP address is the source VTEP's VXLAN tunnel source IP address. The destination IP address is the VXLAN tunnel destination IP address.

2. The source VTEP forwards the encapsulated packet out of the outgoing VXLAN tunnel interface found in the VSI's MAC address table.
3. The intermediate transport devices (P devices) forward the frame to the destination VTEP by using the outer IP header.
4. The destination VTEP removes the headers on top of the inner Ethernet frame. It then performs MAC address table lookup in the VXLAN's VSI to forward the frame out of the matching outgoing interface.

Figure 4 Inter-site unicast



MAC table on VTEP 1

VXLAN/VSI	MAC	Interface
VXLAN 10/VSI A	MAC 1	Interface A, VLAN 2
VXLAN 10/VSI A	MAC 7	Tunnel 1

MAC table on VTEP 2

VXLAN/VSI	MAC	Interface
VXLAN 10/VSI A	MAC 1	Tunnel 1
VXLAN 10/VSI A	MAC 7	Interface A, VLAN 20

Flood

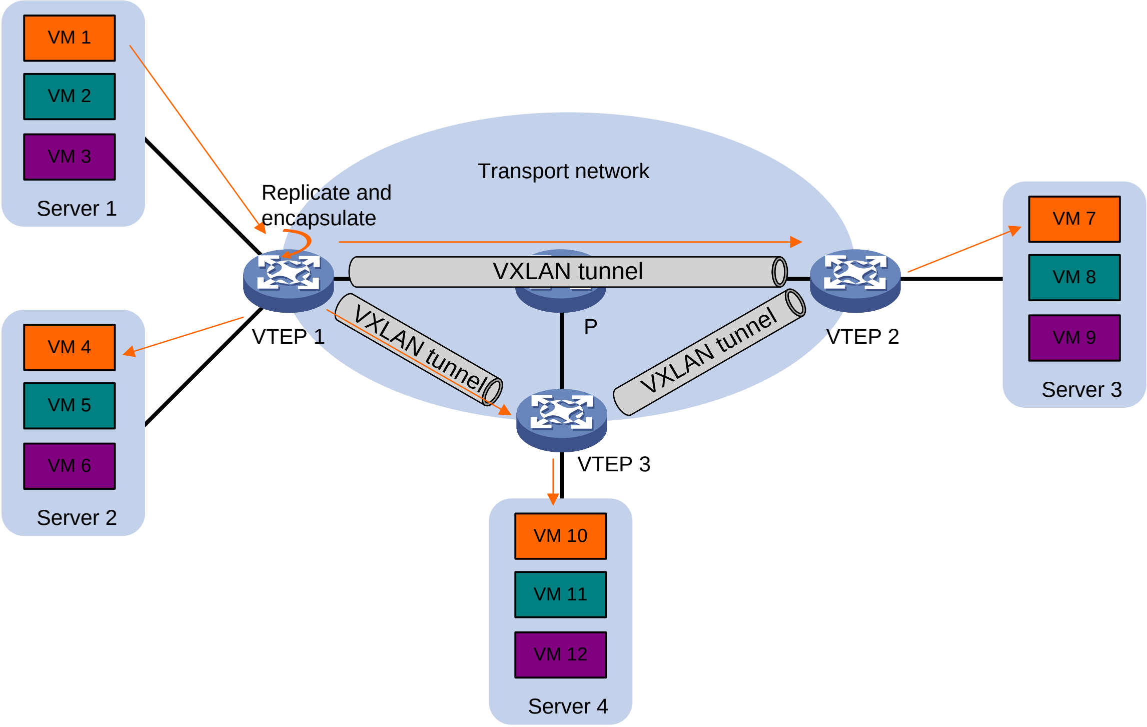
The source VTEP floods a broadcast, multicast, or unknown unicast frame to all site-facing interfaces and VXLAN tunnels in the VXLAN, except for the incoming interface. Each destination VTEP floods the inner Ethernet frame to all site-facing interfaces in the VXLAN. To avoid loops, the destination VTEPs do not flood the frame back to VXLAN tunnels.

VXLAN supports unicast mode (also called head-end replication) and flood proxy mode for flood traffic.

Unicast mode (head-end replication)

As shown in Figure 5, the source VTEP replicates the flood frame, and then sends one replica to the destination IP address of each VXLAN tunnel in the VXLAN.

Figure 5 Unicast mode

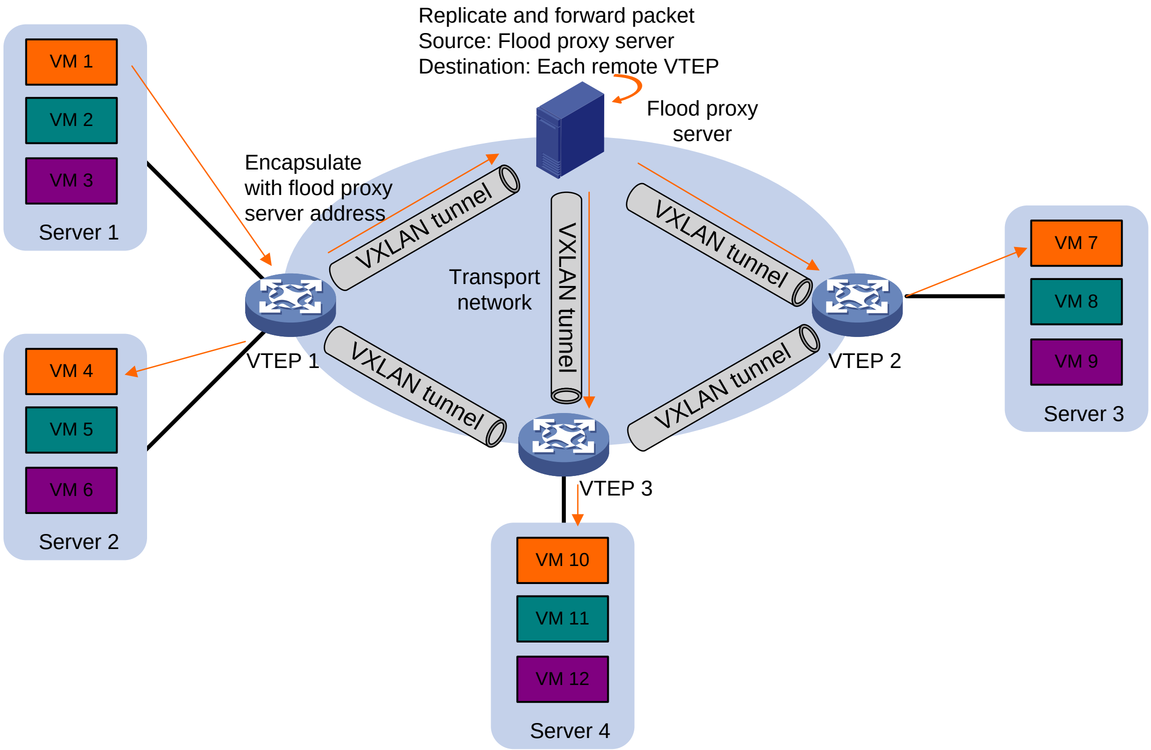


Flood proxy mode (proxy server replication)

As shown in Figure 6, the source VTEP sends the flood frame in a VXLAN packet over a VXLAN tunnel to a flood proxy server. The flood proxy server replicates and forwards the packet to each remote VTEP through its VXLAN tunnels.

The flood proxy mode applies to VXLANs that have many sites. This mode reduces flood traffic in the transport network without using a multicast protocol. To use a flood proxy server, you must set up a VXLAN tunnel to the server on each VTEP.

Figure 6 Flood proxy mode



The flood proxy mode is typically used in SDN transport networks that have a virtual server as the flood proxy server. For VTEPs to forward packets based on the MAC address table issued by an SDN controller, you must perform the following tasks on the VTEPs:

- Disable remote-MAC address learning by using the **`vxlan tunnel mac-learning disable`** command.
- Disable source MAC check on all transport-facing interfaces by using the **`undo mac-address static source-check enable`** command. If the VTEP is an IRF fabric, you must also disable the feature on all IRF ports.

Access modes of VSIs

The access mode of a VSI determines how the VTEP processes the 802.1Q VLAN tags in the Ethernet frames.

VLAN access mode

In this mode, Ethernet frames received from or sent to the local site must contain 802.1Q VLAN tags.

- For an Ethernet frame received from the local site, the VTEP removes all its 802.1Q VLAN tags before forwarding the frame.
- For an Ethernet frame destined for the local site, the VTEP adds 802.1Q VLAN tags to the frame before forwarding the frame.

In VLAN access mode, VXLAN packets sent between sites do not contain 802.1Q VLAN tags. You can use different 802.1Q VLANs to provide the same service in different sites.

Ethernet access mode

The VTEP does not process the 802.1Q VLAN tags of Ethernet frames received from or sent to the local site.

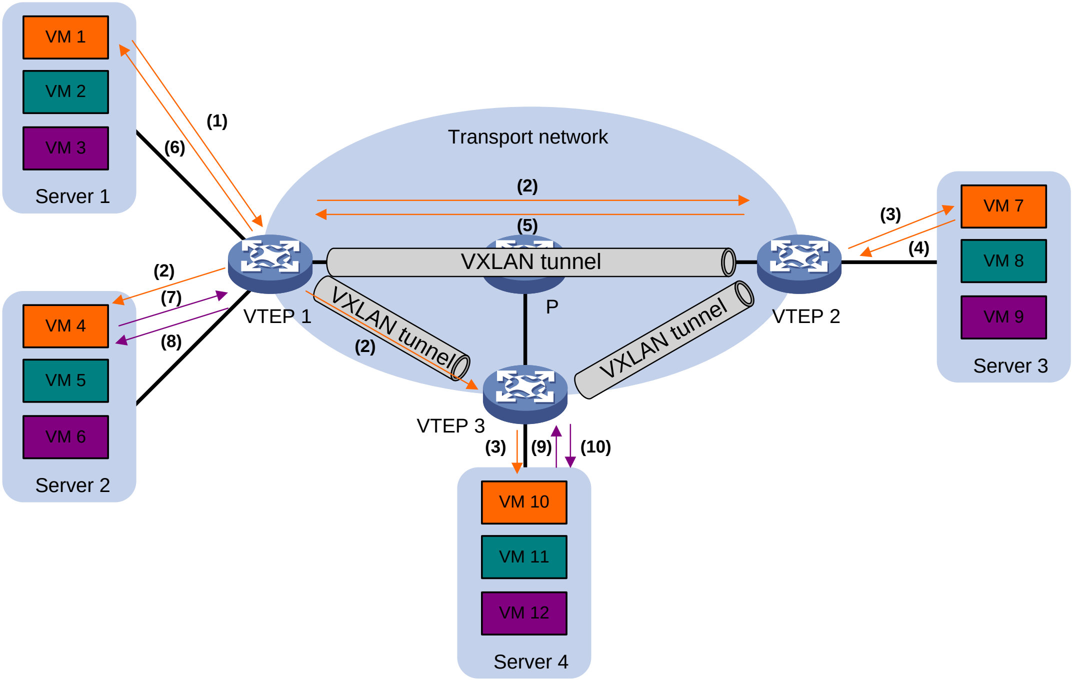
- For an Ethernet frame received from the local site, the VTEP forwards the frame with the 802.1Q VLAN tags intact.
- For an Ethernet frame destined for the local site, the VTEP forwards the frame without adding 802.1Q VLAN tags.

In Ethernet access mode, VXLAN packets sent between VXLAN sites contain 802.1Q VLAN tags. You must use the same VLAN to provide the same service between sites.

ARP flood suppression reduces ARP request broadcasts by enabling the VTEP to reply to ARP requests on behalf of VMs.

As shown in Figure 7, this feature snoops ARP packets to populate the ARP flood suppression table with local and remote MAC addresses. If an ARP request has a matching entry, the VTEP replies to the request on behalf of the VM. If no match is found, the VTEP floods the request to both local and remote sites.

Figure 7 ARP flood suppression



ARP flood suppression uses the following workflow:

1. VM 1 sends an ARP request to obtain the MAC address of VM 7.
2. VTEP 1 creates a suppression entry for VM 1, and floods the ARP request in the VXLAN.
3. VTEP 2 and VTEP 3 de-encapsulate the ARP request. The VTEPs create a suppression entry for VM 1, and broadcast the request in the local site.
4. VM 7 sends an ARP reply.
5. VTEP 2 creates a suppression entry for VM 7 and forwards the ARP reply to VTEP 1.
6. VTEP 1 de-encapsulates the ARP reply, creates a suppression entry for VM 7, and forwards the ARP reply to VM 1.
7. VM 4 sends an ARP request to obtain the MAC address of VM 1 or VM 7.
8. VTEP 1 creates a suppression entry for VM 4 and replies to the ARP request.
9. VM 10 sends an ARP request to obtain the MAC address of VM 1.
10. VTEP 3 creates a suppression entry for VM 10 and replies to the ARP request.

VXLAN IP gateways

A VXLAN IP gateway provides Layer 3 forwarding services for VMs in VXLANs. A VXLAN IP gateway can be an independent device or be collocated with a VTEP. For more information about VXLAN IP gateway placement, see "Configuring VXLAN IP gateways."

Protocols and standards

RFC 7348, *Virtual eXtensible Local Area Network (VXLAN): A Framework for Overlaying Virtualized Layer 2 Networks over Layer 3 Networks*

Configuring basic VXLAN features

VXLAN tasks at a glance

To configure basic VXLAN settings, perform the following tasks on VTEPs:

1. Setting the forwarding mode for VXLANs
2. Creating a VXLAN on a VSI
3. Configuring a VXLAN tunnel
4. Manually assigning VXLAN tunnels to a VXLAN
5. Assigning customer frames to a VSI
6. (Optional.) Managing MAC address entries
   - Configuring static remote-MAC address entries
   - Disabling remote-MAC address learning
   - Enabling local-MAC logging
7. (Optional.) Configuring VXLAN packet parameters
   - Setting the destination UDP port number of VXLAN packets
   - Setting the source UDP port number of VXLAN packets
   - Setting a service class value for outgoing VXLAN packets
   - Configuring VXLAN packet check
8. (Optional.) Reducing flood traffic in the transport network
   - Confining unknown-unicast floods to the local site
   - Enabling ARP flood suppression
9. (Optional.) Enabling VXLAN packet statistics
10. (Optional.) Enabling VXLAN fast forwarding

Prerequisites for VXLAN

Configure a routing protocol on the devices in the transport network to make sure the VTEPs can reach one another.

Setting the forwarding mode for VXLANs

About this task

A VXLAN tunnel supports the following modes:

- **Layer 3 forwarding mode**—The device uses the ARP table (IPv4 network) or ND table (IPv6 network) to forward traffic for VXLANs.
- **Layer 2 forwarding mode**—The device uses the MAC address table to forward traffic for VXLANs.

If the device is a VTEP, enable Layer 2 forwarding for VXLANs. If the device is a VXLAN IP gateway, enable Layer 3 forwarding for VXLANs. For more information about VXLAN IP gateways, see "Configuring VXLAN IP gateways."

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Restrictions and guidelines

You must delete all VSIs, VSI interfaces, and VXLAN tunnel interfaces before you can change the forwarding mode. As a best practice, finish VXLAN network planning and determine the VXLAN forwarding mode of each device before your configuration, and set the VXLAN forwarding mode before other VXLAN settings.

Procedure

1. Enter system view.

   `system-view`

2. Set the forwarding mode of VXLANs.
   - Enable Layer 2 forwarding.

     `undo vxlan ip-forwarding`
   - Enable Layer 3 forwarding.

     `vxlan ip-forwarding`

   By default, Layer 3 forwarding is enabled for VXLANs.

Creating a VXLAN on a VSI

1. Enter system view.

   `system-view`

2. Enable L2VPN.

   `l2vpn enable`

   By default, L2VPN is disabled.

3. Create a VSI and enter VSI view.

   `vsi` *`vsi-name`*

4. Enable the VSI.

   `undo shutdown`

   By default, a VSI is enabled.

5. Create a VXLAN and enter VXLAN view.

   `vxlan` *`vxlan-id`*

   You can create only one VXLAN on a VSI.

   The VXLAN ID must be unique for each VSI.

6. (Optional.) Configure VSI parameters:

   a. Return to VSI view.

      `quit`

   b. Configure a VSI description.

      `description` *`text`*

      By default, a VSI does not have a description.

c. Set the MTU for the VSI.

```
mtu mtu
```

The default MTU for a VSI is 1500 bytes.

The MTU set by using this command limits the maximum length of the packets that a VSI receives from ACs and forwards through VXLAN tunnels. The MTU does not limit the maximum length of other packets in the VXLAN VSI.

d. Enable MAC address learning for the VSI.

```
mac-learning enable
```

By default, MAC address learning is enabled for a VSI.

e. Set a limit for the VSI's MAC address table.

```
mac-table limit mac-limit
```

By default, no limit is set for a VSI's MAC address table.

Configuring a VXLAN tunnel

Manually creating a VXLAN tunnel

About this task

When you manually create a VXLAN tunnel, specify addresses on the local VTEP and the remote VTEP as the tunnel source and destination addresses, respectively.

Restrictions and guidelines

As a best practice, do not configure multiple VXLAN tunnels to use the same source and destination IP addresses.

This task provides basic VXLAN tunnel configuration. For more information about tunnel configuration and commands, see *Layer 3—IP Services Configuration Guide* and *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.

   ```
   system-view
   ```

   A VXLAN tunnel uses the global source address if you do not specify a source interface or source address for the tunnel.

2. Create a VXLAN tunnel interface and enter tunnel interface view.

   ```
   interface tunnel tunnel-number mode vxlan
   ```

   The endpoints of a tunnel must use the same tunnel mode.

3. Specify a source address for the tunnel. Choose one of the following methods:

   - Specify a source IP address for the tunnel.

     ```
     source { ipv4-address | ipv6-address }
     ```

     The specified IP address is used in the outer IP header of tunneled VXLAN packets.

   - Specify a source interface for the tunnel.

     ```
     source interface-type interface-number
     ```

     The primary IP address of the specified interface is used in the outer IP header of tunneled VXLAN packets.

   By default, no source IP address or source interface is specified for a tunnel.

4. Specify a destination IP address for the tunnel.

   ```
   destination { ipv4-address | ipv6-address }
   ```

By default, no destination IP address is specified for a tunnel.

Specify the remote VTEP's IP address. This IP address will be the destination IP address in the outer IP header of tunneled VXLAN packets.

Enabling BFD on a VXLAN tunnel

About this task

Enable BFD on both ends of a VXLAN tunnel for quick link connectivity detection. The VTEPs periodically send BFD single-hop control packets to each other through the VXLAN tunnel. A VTEP sets the tunnel state to Defect if it has not received control packets from the remote end for 5 seconds. In this situation, the tunnel interface state is still Up. The tunnel state will change from Defect to Up if the VTEP can receive BFD control packets again.

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Restrictions and guidelines

You must enable BFD on both ends of a VXLAN tunnel.

Procedure

1. Enter system view.

   `system-view`

2. Specify the reserved VXLAN.

   `reserved vxlan` *`vxlan-id`*

   By default, no VXLAN has been reserved.

   For BFD sessions to come up, you must reserve a VXLAN.

   You can specify only one reserved VXLAN on the VTEP. The reserved VXLAN cannot be the VXLAN created on any VSI.

   The reserved VXLAN ID cannot be the same as any remote VXLAN ID specified by using the **`mapping vni`** command. For more information about the **`mapping vni`** command, see *EVPN Command Reference*.

3. Enter VXLAN tunnel interface view.

   `interface tunnel` *`tunnel-number`*

4. Enable BFD on the tunnel.

   `tunnel bfd enable destination-mac` *`mac-address`*

   By default, BFD is disabled on a tunnel.

Manually assigning VXLAN tunnels to a VXLAN

About this task

To provide Layer 2 connectivity for a VXLAN between two sites, you must assign the VXLAN tunnel between the sites to the VXLAN.

You can assign multiple VXLAN tunnels to a VXLAN, and configure a VXLAN tunnel to trunk multiple VXLANs. For a unicast-mode VXLAN, the system floods unknown unicast, multicast, and broadcast traffic to each tunnel associated with the VXLAN.

Restrictions and guidelines

For full Layer 2 connectivity in the VXLAN, make sure the VXLAN contains the VXLAN tunnel between each pair of sites in the VXLAN.

Procedure

1. Enter system view.

   `system-view`

2. Enter VSI view.

   `vsi` *`vsi-name`*

3. Enter VXLAN view.

   `vxlan` *`vxlan-id`*

4. Assign VXLAN tunnels to the VXLAN.

   `tunnel` *`tunnel-number`*

   By default, a VXLAN does not contain any VXLAN tunnels.

Assigning customer frames to a VSI

Mapping a Layer 3 interface to a VSI

About this task

To assign the customer traffic on a Layer 3 interface to a VXLAN, map the interface to the VXLAN's VSI. The VSI uses its MAC address table to forward the customer traffic.

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 3 interface view.

   `interface` *`interface-type interface-number`*

3. Map the Layer 3 interface to a VSI.

   `xconnect vsi` *`vsi-name`* `[` **`track`** *`track-entry-number`*`&<1-3> ]`

   By default, a Layer 3 interface is not mapped to any VSI.

   If the AC is a Layer 3 subinterface, you can specify the access mode. The default access mode is VLAN. If the AC is a Layer 3 interface, you cannot specify the access mode.

Mapping an Ethernet service instance to a VSI

About this task

An Ethernet service instance matches a list of VLANs on a site-facing interface. The VTEP assigns customer traffic from the VLANs to a VXLAN by mapping the Ethernet service instance to a VSI.

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Restrictions and guidelines

An Ethernet service instance can contain only one match criterion. To change the match criterion, you must remove the original criterion first. When you remove the match criterion in an Ethernet service instance, the mapping between the service instance and the VSI is removed automatically.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.

     interface bridge-aggregation *interface-number*

3. Create an Ethernet service instance and enter Ethernet service instance view.

   service-instance *instance-id*

4. Configure a frame match criterion. Choose one of the following options:
   - Match frames tagged with the specified inner 802.1Q VLAN IDs.

     encapsulation c-vid *vlan-id-list*
   - Match frames tagged with the specified outer 802.1Q VLAN IDs.

     encapsulation s-vid *vlan-id-list* [**only-tagged**]
   - Match frames tagged with the specified outer and inner 802.1Q VLAN IDs.

     encapsulation s-vid *vlan-id* **c-vid** { *vlan-id-list* | **all** }
   - Match any 802.1Q tagged or untagged frames.

     encapsulation { **tagged** | **untagged** }
   - Match frames that do not match any other service instance on the interface.

     encapsulation default

     An interface can contain only one Ethernet service instance that uses the **encapsulation default** match criterion.

     An Ethernet service instance that uses the **encapsulation default** match criterion matches any frames if it is the only instance on the interface.

   By default, an Ethernet service instance does not contain a frame match criterion.

5. Map the Ethernet service instance to a VSI.

xconnect vsi *vsi-name* [**access-mode** { **ethernet** | **vlan** }] [**track** *track-entry-number*&<1-3>]

By default, an Ethernet service instance is not mapped to any VSI.

Managing MAC address entries

About MAC address entry management

Local-MAC address entries are only learned dynamically. You can log local MAC addresses and local-MAC changes.

Remote-MAC address entries have a variety of types, including manually added entries and dynamically learned entries.

Configuring static remote-MAC address entries

1. Enter system view.

   system-view

2. Add a static remote-MAC address entry.

   mac-address static *mac-address* **interface tunnel** *tunnel-number* **vsi** *vsi-name*

   For the setting to take effect, make sure the VSI's VXLAN has been specified on the VXLAN tunnel.

Disabling remote-MAC address learning

About this task

When network attacks occur, disable remote-MAC address learning to prevent the device from learning incorrect remote MAC addresses. You can manually add static remote-MAC address entries.

Procedure

1. Enter system view.

   system-view

2. Disable remote-MAC address learning.

   vxlan tunnel mac-learning disable

   By default, remote-MAC address learning is enabled.

Enabling local-MAC logging

About this task

When the local-MAC logging feature is enabled, the VXLAN module immediately sends a log message with its local MAC addresses to the information center. When a local MAC address is added or removed, a log message is also sent to the information center to notify the local-MAC change.

With the information center, you can set log message filtering and output rules, including output destinations. For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable local-MAC logging.

   vxlan local-mac report

   By default, local-MAC logging is disabled.

Setting the destination UDP port number of VXLAN packets

1. Enter system view.

   system-view

2. Set a destination UDP port for VXLAN packets.

   vxlan udp-port *port-number*

   By default, the destination UDP port number is 4789 for VXLAN packets.

   You must configure the same destination UDP port number on all VTEPs in a VXLAN.

Setting the source UDP port number of VXLAN packets

About this task

Perform this task to enable a VXLAN tunnel interface to encapsulate different source UDP port numbers for traffic flows. This allows IPsec to identify the VXLAN packets to encrypt by the source UDP port number in the VXLAN encapsulation.

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Restrictions and guidelines

The commands used for setting the source UDP port number of VXLAN packets take effect only on IPv4-based VXLAN. Only manually created VXLAN tunnel interfaces support these commands.

The **vxlan source udp-port acl** command has a higher priority than the **vxlan source udp-port five-tuple** command. If you use both commands on a VXLAN tunnel interface, the **vxlan source udp-port five-tuple** command takes effect only on the frames that fail to match the ACL specified by using the **vxlan source udp-port acl** command.

Procedure

1. Enter system view.

   system-view

2. Enter VXLAN tunnel interface view.

   interface tunnel *tunnel-number* **mode vxlan** [**ipv6**]

3. Set a source UDP port for VXLAN packets.
   - Configure an ACL match criterion and specify the source UDP port number in the VXLAN encapsulation for matching frames.

     ```
     vxlan source udp-port port-number acl acl-number
     ```

     If you execute this command multiple times, the most recent configuration takes effect.

     If the ACL specified by using this command does not exist or does not contain an IP address-related rule, frames are encapsulated based on the default setting.
   - Generate the source UDP port number in the VXLAN encapsulation based on the IP five-tuple of the inner Ethernet frame.

     ```
     vxlan source udp-port five-tuple
     ```

   By default, the source UDP port number in the VXLAN encapsulation is generated based on the source and destination MAC addresses of the inner Ethernet frame.

Setting a service class value for outgoing VXLAN packets

About this task

Class Based Tunnel Selection (CBTS) compares the service class value of VXLAN packets with the service class values of MPLS TE tunnels. CBTS uses the following rules to select a tunnel to forward the traffic:

- If the packets match only one MPLS TE tunnel, CBTS uses this tunnel.
- If the packets match multiple MPLS TE tunnels, CBTS randomly selects one tunnel from them.
- If the packets do not match any MPLS TE tunnel, CBTS selects the MPLS TE tunnel that meets the following requirements:
  - Its service class value is smaller than the service class value of the traffic.
  - Its service class value is the nearest to the service class value of the traffic.

  If multiple qualified tunnels exist, CBTS randomly selects one of them to forward the packets. If an MPLS TE tunnel is not configured with a service class value, this tunnel has the smallest service class value.

The service class value is used only when MPLS TE tunnels are used to forward the VXLAN packets. This value is meaningless if any other tunnel is used to forward the VXLAN packets.

To set the service class value for an MPLS TE tunnel, use the **`mpls te service-class`** command. For more information about this command, see MPLS TE commands in *MPLS Command Reference*.

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter VSI view.

```
vsi vsi-name
```

3. Set a service class value for outgoing VXLAN packets.

   ```
   service-class service-class-value
   ```

   By default, no service class value is set for outgoing VXLAN packets.

Configuring VXLAN packet check

About this task

The device always sets the UDP checksum of VXLAN packets to zero. For compatibility with third-party devices, a VXLAN packet can pass the check if its UDP checksum is zero or correct. If its UDP checksum is incorrect, the VXLAN packet fails the check and is dropped.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable the VTEP to drop VXLAN packets that fail UDP checksum check.

   ```
   vxlan invalid-udp-checksum discard
   ```

   By default, the VTEP does not check the UDP checksum of VXLAN packets.

Confining unknown-unicast floods to the local site

About this task

By default, the VTEP floods unknown unicast frames received from the local site to the following interfaces in the frame's VXLAN:

- All site-facing interfaces except for the incoming interface.
- All VXLAN tunnel interfaces.

To exclude a remote MAC address from the flood suppression done by using this feature, enable selective flood for the MAC address. The VTEP will flood the frames destined for the MAC address to remote sites.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter VSI view.

   ```
   vsi vsi-name
   ```

3. Disable the VSI to flood unknown unicast traffic to VXLAN tunnel interfaces.

   ```
   flooding disable
   ```

   By default, unknown unicast traffic is flooded to all interfaces in the VXLAN, except for the incoming interface.

4. (Optional.) Enable selective flood for a MAC address.

   ```
   selective-flooding mac-address mac-address
   ```

Enabling ARP flood suppression

Restrictions and guidelines

The aging timer is fixed at 25 minutes for ARP flood suppression entries. If the suppression table is full, the VTEP stops learning new entries. For the VTEP to learn new entries, you must wait for old entries to age out, or use the **reset arp suppression vsi** command to clear the table.

If the **flooding disable** command is configured, set the MAC aging timer to a higher value than the aging timer for ARP flood suppression entries on all VTEPs. This setting prevents the traffic blackhole that occurs when a MAC address entry ages out before its ARP flood suppression entry ages out. To set the MAC aging timer, use the **mac-address timer** command.

When remote ARP learning is disabled for VXLANs, the device does not use ARP flood suppression entries to respond to ARP requests received on VXLAN tunnels.

Procedure

1. Enter system view.

   system-view

2. Enter VSI view.

   vsi *vsi-name*

3. Enable ARP flood suppression.

   arp suppression enable

   By default, ARP flood suppression is disabled.

Enabling VXLAN packet statistics

Hardware compatibility with VXLAN packet statistics

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Enabling packet statistics for a VSI

Restrictions and guidelines

To display the packet statistics for a VSI, use the **display l2vpn vsi verbose** command in any view.

To clear the packet statistics for a VSI, use the **reset l2vpn statistics vsi** command in user view.

Procedure

1. Enter system view.

   system-view

2. Enter VSI view.

   vsi *vsi-name*

3. Enable packet statistics for the VSI.

   `statistics enable`

   By default, the packet statistics feature is disabled for all VSIs.

Enabling packet statistics for an AC

Restrictions and guidelines

For the **`ac statistics enable`** command to take effect on a Layer 3 interface, you must map the Layer 3 interface to a VSI. When you modify the VSI mapping, the packet statistics of the interface are cleared.

For the **`statistics enable`** command to take effect on an Ethernet service instance, you must configure a frame match criterion for the Ethernet service instance and map it to a VSI. When you modify the frame match criterion or VSI mapping, the packet statistics of the instance are cleared.

Enabling packet statistics for a Layer 3 interface

1. Enter system view.

   `system-view`

2. Enter Layer 3 interface view.

   `interface` *`interface-type interface-number`*

3. Enable packet statistics for the Layer 3 interface.

   `ac statistics enable`

   By default, the packet statistics feature is disabled for Layer 3 interfaces that act as ACs.

Enabling packet statistics for an Ethernet service instance

1. Enter system view.

   `system-view`

2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

     `interface` *`interface-type interface-number`*
   - Enter Layer 2 aggregate interface view.

     `interface bridge-aggregation` *`interface-number`*

3. Enter Ethernet service instance view.

   `service-instance` *`instance-id`*

4. Enable packet statistics for the Ethernet service instance.

   `statistics enable`

   By default, the packet statistics feature is disabled for all Ethernet service instances.

Enable packet statistics for all VXLAN tunnels of a VSI

About this task

VXLAN tunnels can be manually or automatically created. You can enable packet statistics for all VXLAN tunnels of a VSI.

If you enable packet statistics in VSI view, follow these guidelines:

- To display the packet statistics for VXLAN tunnels, use the **`display vxlan tunnel`** command in any view.

- To clear the packet statistics for VXLAN tunnels, use the **`reset l2vpn statistics tunnel`** command in user view.

Procedure

1. Enter system view.

   `system-view`

2. Enter VSI view.

   `vsi` *`vsi-name`*

3. Enable packet statistics for all VXLAN tunnels associated with the VSI.

   `tunnel statistics enable`

   By default, the packet statistics feature is disabled for the VXLAN tunnels associated with a VSI.

   This command enables packet statistics only for VXLAN tunnels. It does not take effect on VXLAN-DCI tunnels.

Setting the VXLAN statistics collection interval

1. Enter system view.

   `system-view`

2. Set the VXLAN statistics collection interval.

   `l2vpn statistics interval` *`interval`*

   By default, the VXLAN statistics collection interval is 15 minutes.

Enabling VXLAN fast forwarding

About this task

VXLAN fast forwarding enables the device to bypass QoS and security services when the device forwards data traffic over VXLAN tunnels based on the software. As a best practice, enable this feature to improve forwarding speed only when QoS and security services are not configured on the following interfaces:

- VSI interfaces.
- Traffic outgoing interfaces for VXLAN tunnels.

Restrictions and guidelines

When VXLAN fast forwarding is enabled, a VXLAN tunnel cannot use ECMP routes to load share traffic. Instead, it selects one route from the ECMP routes to forward VXLAN packets.

Procedure

1. Enter system view.

   `system-view`

2. Enable VXLAN fast forwarding.

   `vxlan fast-forwarding enable`

   By default, VXLAN fast forwarding is disabled.

Display and maintenance commands for VXLANs

Execute **`display`** commands in any view and **`reset`** commands in user view.

IMPORTANT:

For support of hardware platforms for the display and maintenance commands, see the command reference.

Task	Command
Display ARP flood suppression entries on VSIs.	**display arp suppression vsi** [**name** *vsi-name*] [**slot** *slot-number*] [**count**]
Display information about tunnel interfaces.	**display interface** [**tunnel** [*number*]] [**brief** [**description** | **down**]]
Display L2VPN information for Layer 3 interfaces that are mapped to VSIs.	**display l2vpn interface** [**vsi** *vsi-name* | *interface-type interface-number*] [**verbose**]
Display MAC address entries for VSIs.	**display l2vpn mac-address** [**vsi** *vsi-name*] [**dynamic**] [**count**]
Display information about Ethernet service instances.	**display l2vpn service-instance** [**interface** *interface-type interface-number* [**service-instance** *instance-id*]] [**verbose**]
Display information about VSIs.	**display l2vpn vsi** [**name** *vsi-name*] [**verbose**]
Display VXLAN tunnel information for VXLANs.	**display vxlan tunnel** [**vxlan** *vxlan-id* [**tunnel** *tunnel-number*]]
Clear ARP flood suppression entries on VSIs.	**reset arp suppression vsi** [**name** *vsi-name*]
Clear dynamic MAC address entries on VSIs.	**reset l2vpn mac-address** [**vsi** *vsi-name*]
Clear packet statistics on ACs.	**reset l2vpn statistics ac** [**interface** *interface-type interface-number* [**service-instance** *instance-id*]]
Clear packet statistics on VXLAN tunnel interfaces.	**reset l2vpn statistics tunnel** [**vsi** *vsi-name*]
Clear packet statistics on VSIs.	**reset l2vpn statistics vsi** [**name** *vsi-name*]

NOTE:

For more information about the **display interface tunnel** command, see tunneling commands in *Layer 3—IP Services Command Reference*.

Configuring VXLAN IP gateways

About VXLAN IP gateways

The following are available IP gateway placement designs for VXLANs:

- **VXLAN IP gateways separated from VTEPs**—Use a VXLAN-unaware device as a gateway to the external network for VXLANs. On the gateway, you do not need to configure VXLAN settings.
- **VXLAN IP gateways collocated with VTEPs**—Include the following placement designs:
  - **Centralized VXLAN IP gateway deployment**—Use one VTEP to provide Layer 3 forwarding for VXLANs. Typically, the gateway-collocated VTEP connects to other VTEPs and the external network. To use this design, make sure the IP gateway has sufficient bandwidth and processing capability. Centralized VXLAN IP gateways provide services only for IPv4 networks.
  - **Centralized VXLAN gateway group deployment**—Use one VTEP group that contains redundant centralized VXLAN IP gateways to provide reliable gateway services for VXLANs.
  - **Distributed VXLAN IP gateway deployment**—Deploy one VXLAN IP gateway on each VTEP to provide Layer 3 forwarding for VXLANs at their respective sites. This design distributes the Layer 3 traffic load across VTEPs. However, its configuration is more complex than the centralized VXLAN IP gateway design. Distributed gateways can provide services for both IPv4 and IPv6 networks.

In a collocation design, the VTEPs use virtual Layer 3 VSI interfaces as gateway interfaces to provide services for VXLANs.

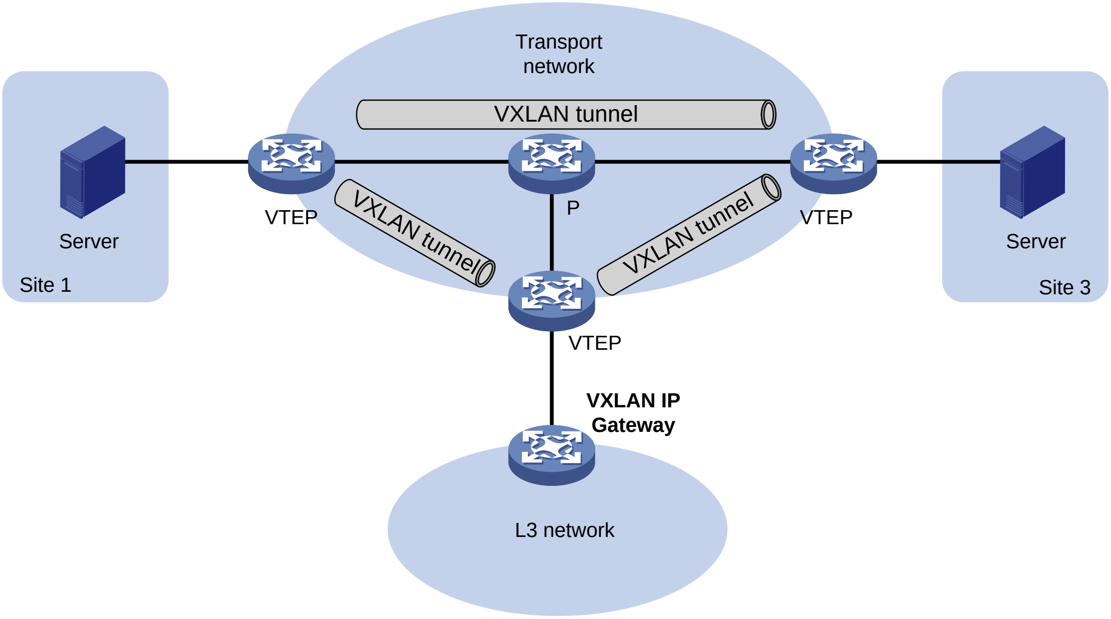
NOTE:

The following information describes traffic forwarding of VXLAN IP gateways in IPv4 networks. Traffic forwarding of VXLAN IP gateways in IPv6 networks is similar to that in IPv4 networks.

VXLAN IP gateways separated from VTEPs

As shown in Figure 8, an independent VXLAN IP gateway connects a Layer 3 network to a VTEP. VMs send Layer 3 traffic in Layer 2 frames to the gateway through VXLAN tunnels. When the tunneled VXLAN packets arrive, the VTEP terminates the VXLANs and forwards the inner frames to the gateway. In this gateway placement design, the VTEP does not perform Layer 3 forwarding for VXLANs.

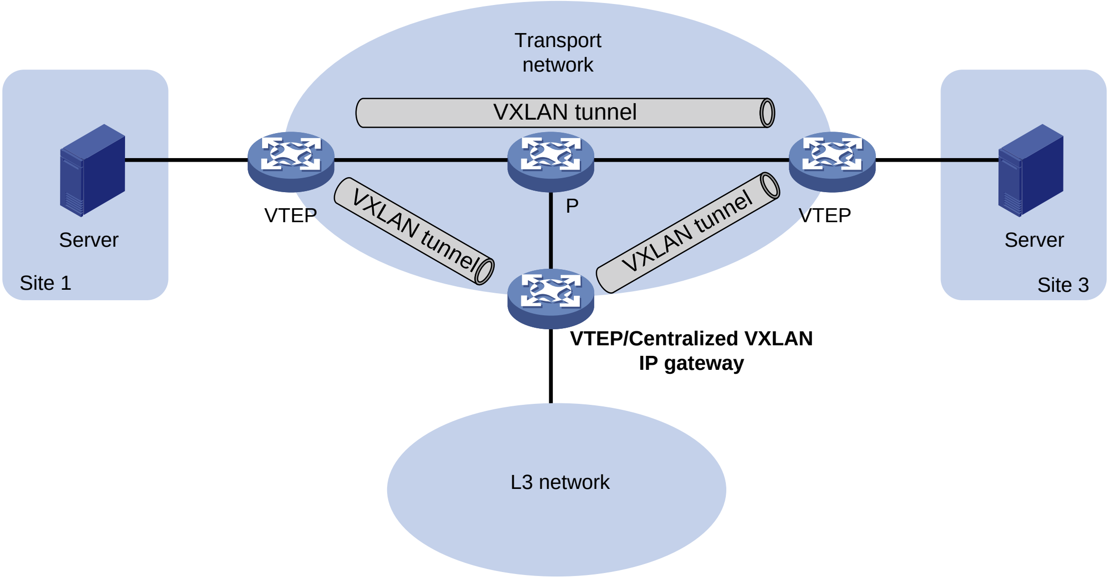
Figure 8 VXLAN IP gateway separated from VTEPs



Centralized VXLAN IP gateway deployment

As shown in Figure 9, a VTEP acts as a gateway for VMs in the VXLANs. The VTEP both terminates the VXLANs and performs Layer 3 forwarding for the VMs.

Figure 9 Centralized VXLAN IP gateway placement design



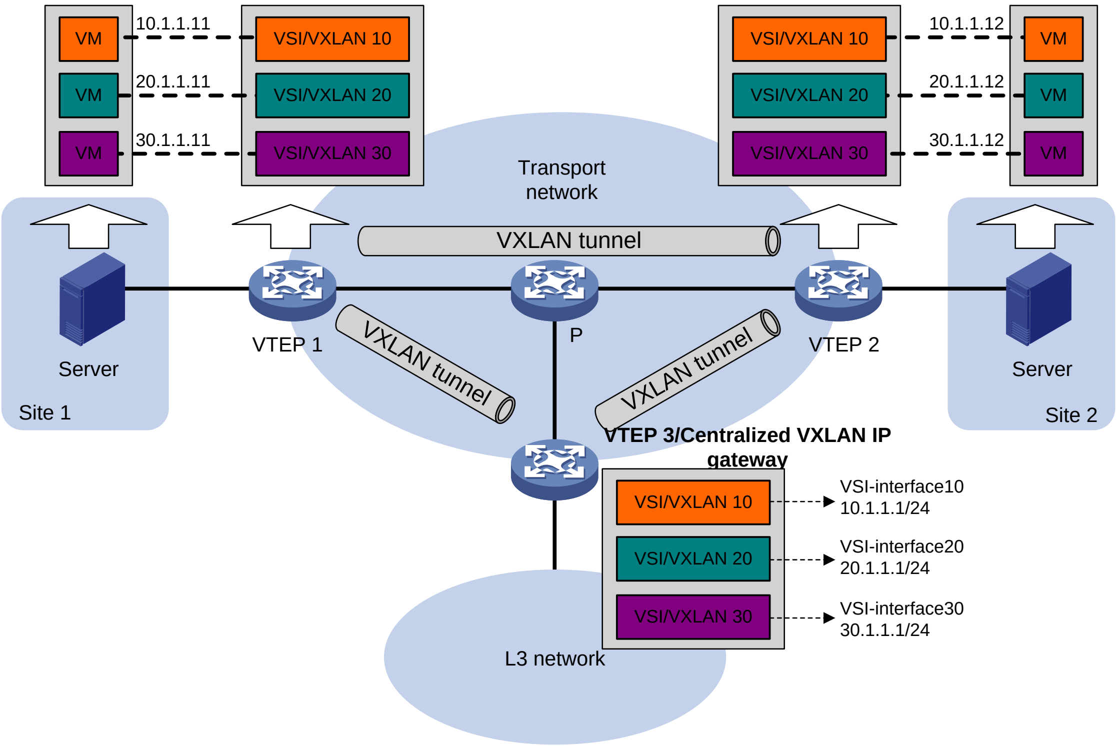
As shown in Figure 10, the network uses the following process to forward Layer 3 traffic from VM 10.1.1.11 to the Layer 3 network:

1. The VM sends an ARP request to obtain the MAC address of the gateway (VTEP 3) at 10.1.1.1.
2. VTEP 1 floods the ARP request to all remote VTEPs.
3. VTEP 3 de-encapsulates the ARP request, creates an ARP entry for the VM, and sends an ARP reply to the VM.

4. VTEP 1 forwards the ARP reply to the VM.
5. The VM learns the MAC address of the gateway, and sends the Layer 3 traffic to the gateway.
6. VTEP 3 removes the VXLAN encapsulation and inner Ethernet header for the traffic, and forwards the traffic to the destination node.

Inter-VXLAN forwarding is the same as this process except for the last step. At the last step of inter-VLAN forwarding, the gateway replaces the source-VXLAN encapsulation with the destination-VXLAN encapsulation, and then forwards the traffic.

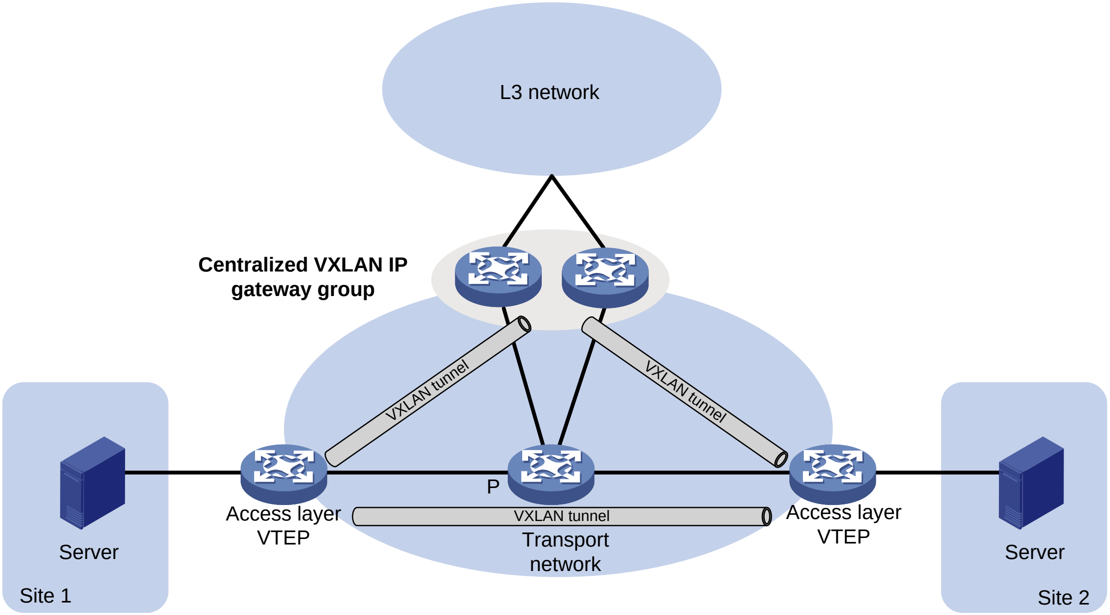
Figure 10 Example of centralized VXLAN IP gateway deployment



Centralized VXLAN gateway group deployment

As shown in Figure 11, a VTEP group uses redundant centralized VXLAN IP gateways to provide reliable gateway services for VMs in the VXLANs. All member VTEPs in the group participate in Layer 3 forwarding and load share traffic between the Layer 3 network and the VXLANs. This design distributes processing among multiple VTEPs and prevents single points of failure.

Figure 11 Example of centralized VXLAN IP gateway group deployment



The VTEP group is a virtual gateway that provides services at a group IP address. Access layer VTEPs set up VXLAN tunnels to the group IP address for data traffic forwarding. Each VTEP in the group automatically uses its member IP address to set up tunnels to the other member VTEPs and access layer VTEPs. The tunnels are used to transmit protocol packets and synchronize ARP entries.

Distributed VXLAN IP gateway deployment

About distributed VXLAN IP gateway deployment

As shown in Figure 12, each site's VTEP acts as a gateway to perform Layer 3 forwarding for the VXLANs of the local site. A VTEP acts as a border gateway to the Layer 3 network for the VXLANs.

Figure 12 Distributed VXLAN IP gateway placement design

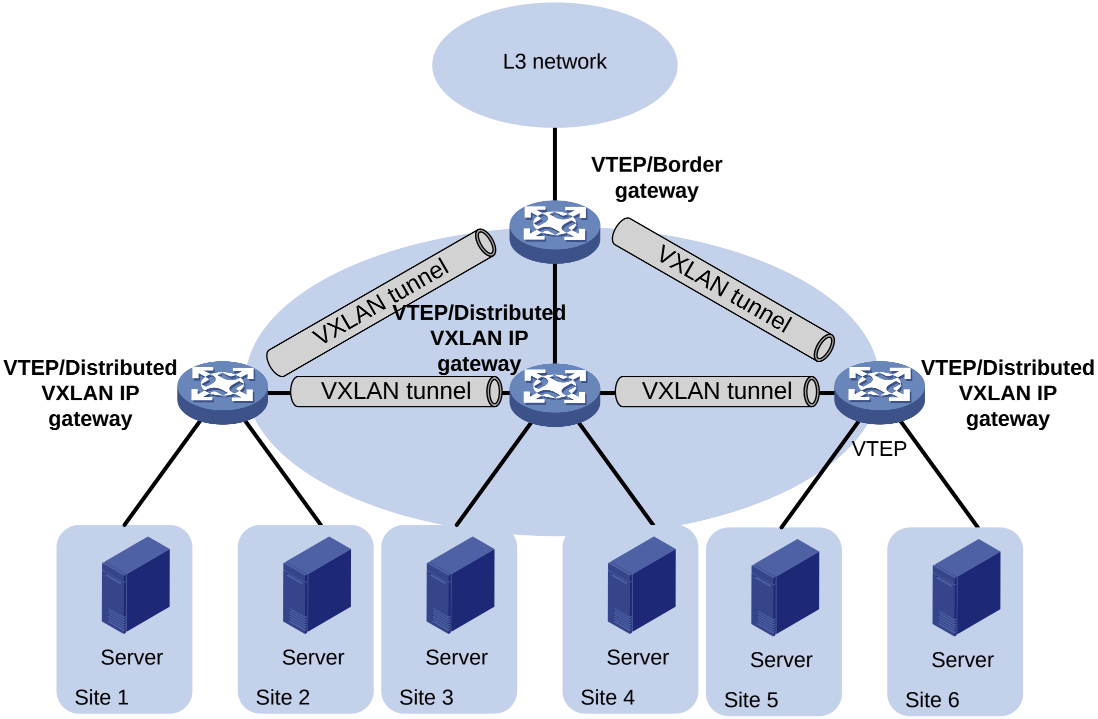


Figure 13 shows an example of distributed VXLAN IP gateway deployment. Create VSI interfaces on each distributed VXLAN IP gateway and the border gateway as gateway interfaces. Assign the same IP address to the same VSI interface on the distributed VXLAN IP gateways. You must enable local proxy ARP or local ND proxy on a distributed VXLAN IP gateway. The gateway performs Layer 3 forwarding based on ARP or ND entries. The following sections use distributed VXLAN IP gateways enabled with the local proxy ARP or local ND proxy feature to describe the forwarding processes for intra-VXLAN traffic, inter-VXLAN traffic, and traffic from a VXLAN to an external network.

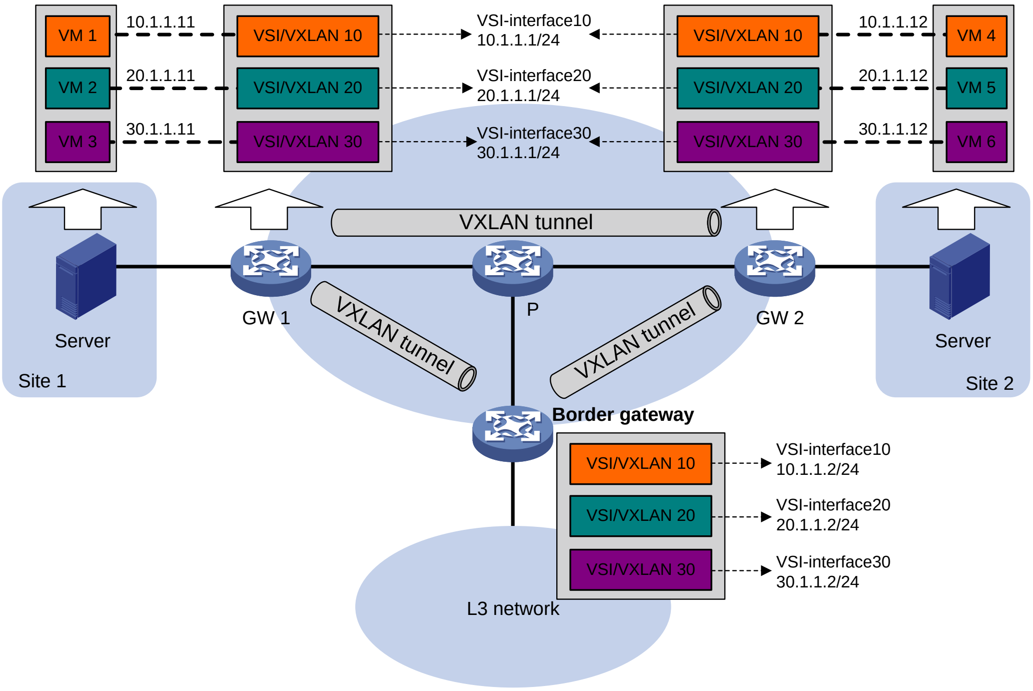
A distributed VXLAN IP gateway can generate ARP or ND entries by a variety of methods. The following sections use dynamically learned ARP or ND entries to describe the forwarding processes.

Figure 13 Example of distributed VXLAN IP gateway deployment



Intra-VXLAN traffic forwarding between sites

As shown in Figure 13, the network uses the following process to forward traffic in a VXLAN between sites (for example, from VM 1 to VM 4 in VXLAN 10):

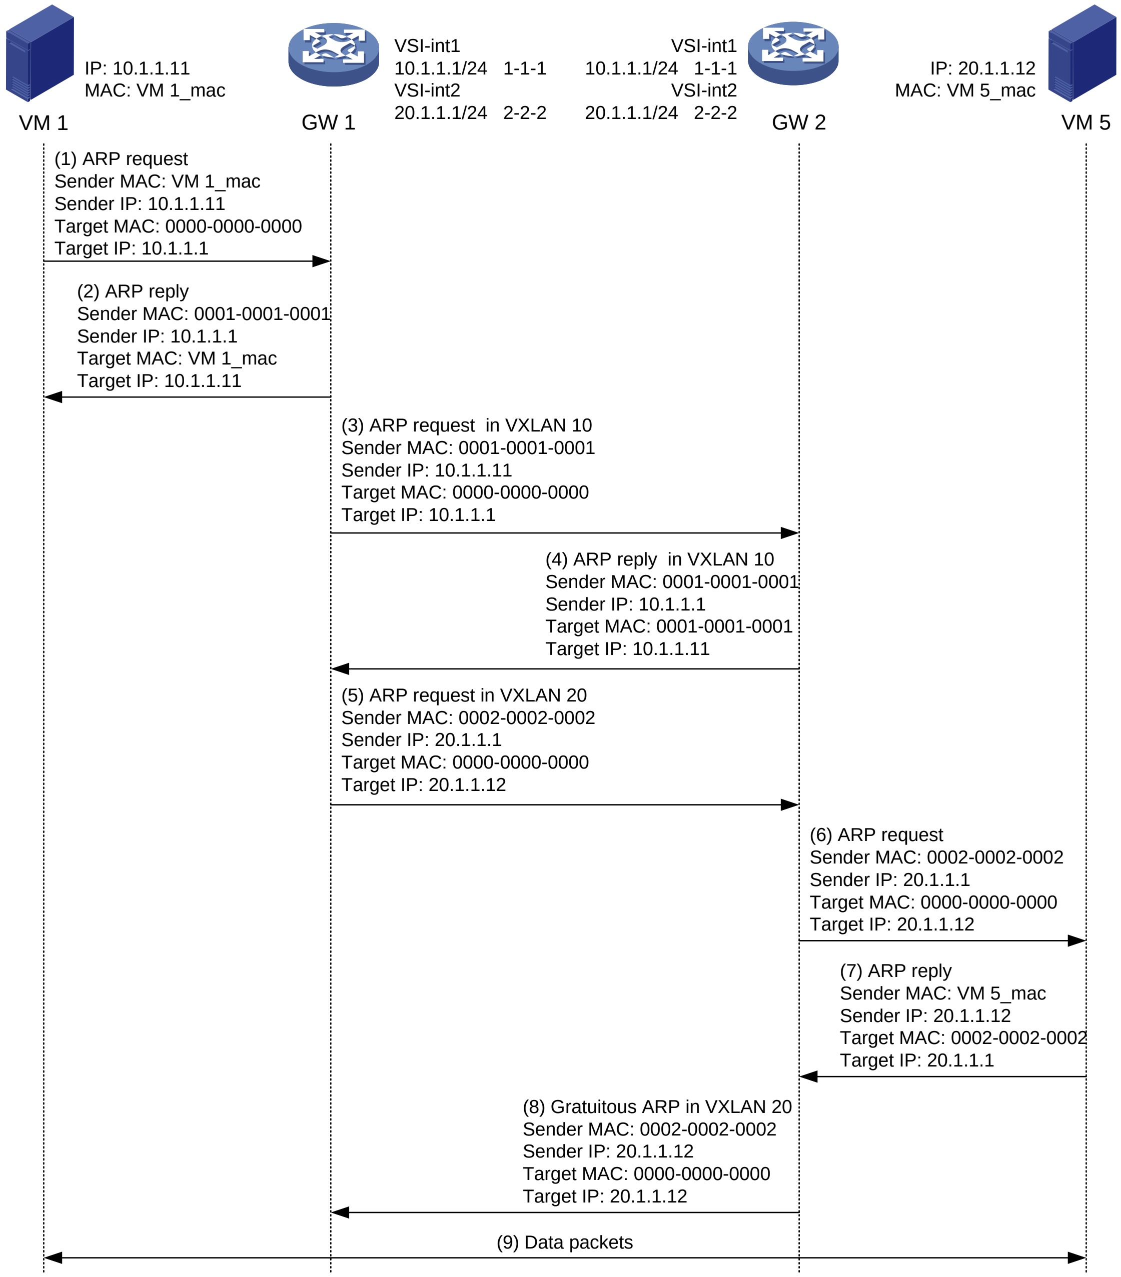
1. VM 1 sends an ARP request to obtain the MAC address of VM 4.
2. GW 1 performs the following operations:
   a. Creates an ARP entry for VM 1 and replies with the MAC address of VSI-interface 10 (the gateway interface for VXLAN 10).
   b. Replaces the sender MAC address of the ARP request with the MAC address of VSI-interface 10, and then floods the request to all sites in VXLAN 10.
3. VM 1 creates an ARP entry for VM 4. The MAC address in the entry is the MAC address of VSI-interface 10 on GW 1.
4. GW 2 (the VTEP for VM 4) performs the following operations:
   a. De-encapsulates the ARP request and creates an ARP entry for VM 1. The entry contains VM 1's IP address (10.1.1.11), the MAC address of VSI-interface 10 on GW 1, and the incoming tunnel interface.
   b. Replaces the sender MAC address of the request with the MAC address of VSI-interface 10 on GW 2, and then floods the request to the local site in VXLAN 10.
5. VM 4 creates an ARP entry for VM 1, and then sends a reply to GW 2. The MAC address in the ARP entry is the MAC address of VSI-interface 10 on GW 2.
6. GW 2 performs the following operations:
   a. Creates an ARP entry for VM 4.
   b. Replaces the sender MAC address of the reply with the MAC address of VSI-interface 10 on GW 2, and sends the reply to GW 1.
7. GW 1 de-encapsulates the ARP reply and creates an ARP entry for VM 4. The entry contains VM 4's IP address (10.1.1.12), the MAC address of VSI-interface 10 on GW 2, and the incoming tunnel interface.
8. For subsequent traffic between VM 1 and VM 4, GW 1 and GW 2 use their respective ARP tables to make the forwarding decision.

Inter-VXLAN traffic forwarding between sites

As shown in Figure 14, the network uses the following process to forward traffic between VXLANs (for example, from VM 1 in VXLAN 10 to VM 5 in VXLAN 20):

1. VM 1 sends an ARP request to obtain the MAC address of the gateway at 10.1.1.1.
2. GW 1 creates an ARP entry for VM 1 and replies with the MAC address of VSI-interface 10 (the gateway interface for VXLAN 10) so VM 1 will send the packets destined for VM 5 to GW 1.
3. GW 1 sends an ARP request to the local and remote sites in VXLAN 10. In the ARP request, the sender IP address is 10.1.1.11, and the sender MAC address is the MAC address of VSI-interface 10 on GW 1.
4. GW 2 performs the following operations:
    a. De-encapsulates the ARP request and creates an ARP entry for VM 1. The entry contains IP address 10.1.1.11 and MAC address of VSI-interface 10 on GW 1, and the incoming tunnel interface.
    b. Replaces the sender MAC address of the request with the MAC address of VSI-interface 10 on GW 2, and then floods the request to the local site in VXLAN 10.
    c. Sends an ARP reply to GW 1. The reply contains IP address 10.1.1.1 and MAC address of VSI-interface 10 on GW 2).
5. When sending an ARP request in VXLAN 10, GW 1 also sends an ARP request to the local and remote sites in VXLAN 20 to obtain the MAC address of VM 5. In the ARP request, the sender IP address is 20.1.1.1, and the sender MAC address is the MAC address of VSI-interface 20 on GW 1.
6. GW 2 de-encapsulates the ARP request of VXLAN 20, replaces the sender MAC address of the request with the MAC address of VSI-interface 20 on GW 2, and then floods the request to the local site in VXLAN 20.
7. VM 5 creates an ARP entry for GW 2, and then sends a reply to GW 2. The entry contains IP address 20.1.1.1 and MAC address of VSI-interface 20 on GW 2.
8. GW 2 performs the following operations:
    a. Creates an ARP entry for VM 5.
    b. Sends a gratuitous ARP packet to the local and remote sites. In the packet, the sender IP address is 20.1.1.12, and the sender MAC address is the MAC address of VSI-interface 20 on GW 2.
9. GW 1 de-encapsulates the gratuitous ARP packet and creates an ARP entry for VM 5. The entry contains VM 5's IP address 20.1.1.12, the MAC address of VSI-interface 20 on GW 2, and the incoming tunnel interface.
10. For subsequent traffic between VM 1 and VM 5, GW 1 and GW 2 use their respective ARP tables to make the forwarding decision.

Figure 14 Inter-VXLAN traffic forwarding between sites



VXLAN-to-external network traffic forwarding

As shown in Figure 13, the network uses the following process to forward traffic from a VXLAN to the Layer 3 network (for example, from VM 1 to the host at 50.1.1.1):

1. VM 1 sends an ARP request to obtain the MAC address of the gateway at 10.1.1.1.
2. GW 1 creates an ARP entry for VM 1 and replies with the MAC address of VSI-interface 10 (the gateway interface for VXLAN 10).
3. VM 1 sends a packet destined for the host to GW 1.
4. GW 1 performs the following operations:
   a. Searches the IP routing policies or routing table for the next hop. In this example, the next hop for the packet is 10.1.1.2 (the border gateway).

    b. Floods an ARP request to the local and remote sites in VXLAN 10 to obtain the MAC address of 10.1.1.2.

5. The border gateway de-encapsulates the ARP request, creates an ARP entry for GW 1, and tunnels a reply to GW 1.
6. GW 1 de-encapsulates the ARP reply and creates an ARP entry for 10.1.1.2.
7. GW 1 sends the packet destined for the host to the border gateway.
8. The border gateway de-encapsulates the packet and forwards it to the host.

Restrictions and guidelines: VXLAN IP gateway configuration

Do not configure both centralized VXLAN IP gateway settings and centralized VXLAN IP gateway group settings on a device.

As a best practice to avoid forwarding failure, set a large MTU on the traffic outgoing interfaces for VXLAN tunnels on VXLAN IP gateways.

VXLAN IP gateway tasks at a glance

To configure a VXLAN IP gateway, perform the following tasks:

1. Configure a VXLAN IP gateway

   Choose one of the following tasks:

   - Configuring a centralized VXLAN IP gateway
   - Configuring a centralized VXLAN IP gateway group
   - Configuring a distributed VXLAN IP gateway
2. (Optional.) Disabling remote ARP learning for VXLANs
3. (Optional.) Configuring a VSI interface

Prerequisites for VXLAN IP gateway configuration

Before you configure a centralized or distributed VXLAN IP gateway, you must perform the following tasks on VTEPs:

- Enable Layer 3 forwarding for VXLANs.
- Create VSIs and VXLANs.

Configuring a centralized VXLAN IP gateway

Restrictions and guidelines

Do not execute the **`local-proxy-arp enable`** command on the VSI interfaces of a centralized VXLAN IP gateway.

Configuring a gateway interface on a centralized VXLAN IP gateway

1. Enter system view.

system-view

2. Create a VSI interface and enter VSI interface view.

   interface vsi-interface *vsi-interface-id*

3. Assign an IPv4 address to the VSI interface.

   ip address *ip-address* { *mask* | *mask-length* }

   By default, no IPv4 address is assigned to a VSI interface.

4. Return to system view.

   quit

5. Enter VSI view.

   vsi *vsi-name*

6. Specify a gateway interface for the VSI.

   gateway vsi-interface *vsi-interface-id*

   By default, no gateway interface is specified for a VSI.

Assigning a subnet to a VSI

About this task

Perform this task on VSIs that share a gateway interface. This task enables the VSI interface to identify the VSI of a packet.

You can assign a maximum of eight IPv4 subnets to a VSI. Make sure these subnets are on the same network as one of the IP addresses on the gateway interface.

For VSIs that share a gateway interface, the subnets must be unique.

If you remove the gateway interface from the VSI, the VSI's subnet settings are automatically deleted.

Procedure

1. Enter system view.

   system-view

2. Enter VSI view.

   vsi *vsi-name*

3. Assign a subnet to the VSI.

   gateway subnet *ipv4-address wildcard-mask*

   By default, no subnet exists on a VSI.

Configuring a centralized VXLAN IP gateway group

Configuring a VTEP group

Restrictions and guidelines

Make sure the member VTEPs use the same VXLAN settings.

Procedure

1. Enter system view.

   system-view

2. Create a VSI interface and enter VSI interface view.

   interface vsi-interface *vsi-interface-id*

   This interface will be used as the gateway interface for the VSI.

3. Assign an IP address to the VSI interface.

   ip address *ip-address* { *mask* | *mask-length* }

   By default, no IP address is assigned to a VSI interface.

   You must assign the same IP address to the VSI interface on each VTEP in the VTEP group.

4. Assign a MAC address to the VSI interface.

   mac-address *mac-address*

   By default, a VSI interface does not have a MAC address.

   You must assign the same MAC address to the VSI interface on each VTEP in the VTEP group.

5. Return to system view.

   quit

6. Enter VSI view.

   vsi *vsi-name*

7. Specify the VSI interface as the gateway interface for the VSI.

   gateway vsi-interface *vsi-interface-id*

   By default, no gateway interface is specified for a VSI.

8. Return to system view.

   quit

9. Assign the local VTEP to a VTEP group and specify a member IP address for the VTEP.

   vtep group *group-ip* **member local** *member-ip*

   By default, a VTEP is not assigned to any VTEP group.

   The specified member IP address must already exist on the local VTEP and be unique in the VTEP group. You must configure a routing protocol to advertise the IP address to the transport network.

10. Specify the member IP address of all the other VTEPs in the VTEP group.

    vtep group *group-ip* **member remote** *member-ip*&<1-8>

    By default, the list of remote VTEPs is not configured.

Specifying a VTEP group as the gateway for an access layer VTEP

Prerequisites

Before you specify a VTEP group on an access layer VTEP, perform the following tasks on the VTEP:

- Enable Layer 2 forwarding for VXLANs.
- Configure VSIs and VXLANs.
- Set up VXLAN tunnels to remote sites and the VTEP group, and assign the tunnels to VXLANs.

Procedure

1. Enter system view.

   system-view

2. Specify a VTEP group and all its member VTEPs.

   vtep group *group-ip* **member remote** *member-ip*&<1-8>

By default, no VTEP group is specified.

Perform this task to specify all member VTEPs in the VTEP group.

Configuring a distributed VXLAN IP gateway

Restrictions and guidelines for distributed VXLAN IP gateway configuration

For a VXLAN that requires access to the external network, specify the VXLAN's VSI interface on the border gateway as the next hop by using one of the following methods:

- Configure a static route.
- Configure a routing policy, and apply the policy by using the **`apply default-next-hop`** command. For more information about configuring routing policies, see routing policy configuration in *Layer 3—IP Routing Configuration Guide*.

Make sure a VSI interface uses the same MAC address to provide service on distributed VXLAN IP gateways connected to IPv4 sites. Make sure a VSI interface uses different link-local addresses to provide service on distributed VXLAN IP gateways connected to both IPv4 and IPv6 sites.

Configuring a gateway interface on a distributed VXLAN IP gateway

1. Enter system view.

   `system-view`

2. Create a VSI interface and enter VSI interface view.

   `interface vsi-interface` *`vsi-interface-id`*

3. Assign an IP address to the VSI interface.

   IPv4:

   `ip address` *`ip-address`* `{` *`mask`* `|` *`mask-length`* `} [` **`sub`** `]`

   IPv6:

   See IPv6 basics in *Layer 3—IP Services Configuration Guide*.

   By default, no IP address is assigned to a VSI interface.

4. Specify the VSI interface as a distributed gateway.

   `distributed-gateway local`

   By default, a VSI interface is not a distributed gateway.

5. Enable local proxy ARP or local ND proxy.

   IPv4:

   `local-proxy-arp enable` `[` **`ip-range`** *`startIP`* **`to`** *`endIP`* `]`

   By default, local proxy ARP is disabled.

   For more information about this command, see proxy ARP commands in *Layer 3—IP Services Command Reference*.

   IPv6:

   `local-proxy-nd enable`

   By default, local ND proxy is disabled.

   For more information about this command, see IPv6 basics commands in *Layer 3—IP Services Command Reference*.

6. Bring up the VSI interface.

   undo shutdown

   By default, a VSI interface is up.

7. Return to system view.

   quit

8. Enter VSI view.

   vsi *vsi-name*

9. Specify the VSI interface as the gateway interface for the VSI.

   gateway vsi-interface *vsi-interface-id*

   By default, no gateway interface is specified for a VSI.

Enabling dynamic ARP entry synchronization for distributed VXLAN IP gateways

About this task

When local proxy ARP is enabled on distributed VXLAN IP gateways, enable this feature for all gateways to have the same ARP entries.

A controller can also synchronize ARP entries among distributed VXLAN IP gateways. When you use a controller, do not enable dynamic ARP entry synchronization.

Procedure

1. Enter system view.

   system-view

2. Enable dynamic ARP entry synchronization for distributed VXLAN IP gateways.

   arp distributed-gateway dynamic-entry synchronize

   By default, dynamic ARP entry synchronization is disabled for distributed VXLAN IP gateways.

Assigning a subnet to a VSI

About this task

Perform this task on VSIs that share a gateway interface. This task enables the VSI interface to identify the VSI of a packet.

You can assign a maximum of eight IPv4 and IPv6 subnets to a VSI. Make sure these subnets are on the same network as one of the IP addresses on the gateway interface.

For VSIs that share a gateway interface, the subnets must be unique.

If you remove the gateway interface from the VSI, the VSI's subnet settings are automatically deleted.

Procedure

1. Enter system view.

   system-view

2. Enter VSI view.

   vsi *vsi-name*

3. Assign a subnet to the VSI.

   gateway subnet { *ipv4-address wildcard-mask* | *ipv6-address prefix-length* }

By default, no subnet exists on a VSI.

Disabling remote ARP learning for VXLANs

About this task

By default, the device learns ARP information of remote user terminals from packets received on VXLAN tunnel interfaces. To save resources on VTEPs in an SDN transport network, you can temporarily disable remote ARP learning when the controller and VTEPs are synchronizing entries. After the entry synchronization is completed, enable remote ARP learning.

Restrictions and guidelines

As a best practice, disable remote ARP learning for VXLANs only when the controller and VTEPs are synchronizing entries.

Procedure

1. Enter system view.

   `system-view`

2. Disable remote ARP learning for VXLANs.

   `vxlan tunnel arp-learning disable`

   By default, remote ARP learning is enabled for VXLANs.

Configuring a VSI interface

Configuring optional parameters for a VSI interface

1. Enter system view.

   `system-view`

2. Enter VSI interface view.

   `interface vsi-interface` *`vsi-interface-id`*

3. Assign a MAC address to the VSI interface.

   `mac-address` *`mac-address`*

   By default, the MAC address of a VSI interface is the bridge MAC address.

4. Configure the description of the VSI interface.

   `description` *`text`*

   The default description of a VSI interface is *`interface-name`* plus **`Interface`** (for example, **`Vsi-interface100 Interface`**).

5. Set the MTU for the VSI interface.

   `mtu` *`mtu-value`*

   The default MTU of a VSI interface is 1500 bytes.

6. Set the expected bandwidth for the VSI interface.

   `bandwidth` *`bandwidth-value`*

   The default expected bandwidth (in kbps) equals the interface baudrate divided by 1000.

   The expected bandwidth is an informational parameter used only by higher-layer protocols for calculation. You cannot adjust the actual bandwidth of an interface by using this command.

Restoring the default settings of the VSI interface

Restrictions and guidelines

△ **CAUTION:**

This operation might interrupt ongoing network services. Make sure you are fully aware of the impact of this operation when you perform it on a live network.

This operation might fail to restore the default settings for some commands for reasons such as command dependencies or system restrictions. Use the **`display this`** command in interface view to identify these commands. Use their **`undo`** forms or follow the command reference to restore their default settings. If your restoration attempt still fails, follow the error message instructions to resolve the problem.

Procedure

1. Enter system view.
   `system-view`
2. Enter VSI interface view.
   `interface vsi-interface` *`vsi-interface-id`*
3. Restore the default settings of the VSI interface.
   `default`

Display and maintenance commands for VXLAN IP gateways

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display information about VSI interfaces.	**`display interface`** [**`vsi-interface`** [*`vsi-interface-id`*]] [**`brief`** [**`description`** | **`down`**]]
Clear statistics on VSI interfaces.	**`reset counters interface`** [**`vsi-interface`** [*`vsi-interface-id`*]]

Configuring the VTEP as an OVSDB VTEP

About OVSDB VTEP

An NSFOCUS network virtualization controller can use the Open vSwitch Database (OVSDB) management protocol to deploy and manage VXLANs on VTEPs. To work with a controller, you must configure the VTEP as an OVSDB VTEP.

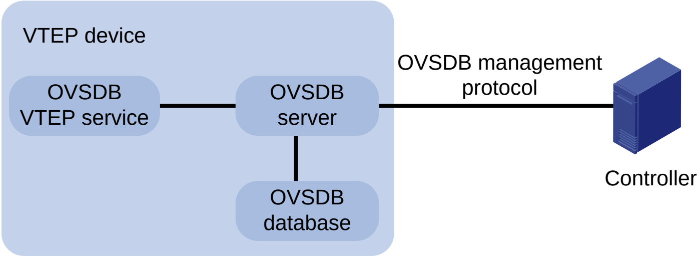
Working mechanisms

As shown in Figure 15, an OVSDB VTEP stores all of its VXLAN settings in the form of entries in an OVSDB database. The OVSDB database, OVSDB VTEP service, and the controller interact through the OVSDB server. The controller communicates with the OVSDB server through the OVSDB protocol to manage the OVSDB database. The OVSDB VTEP service reads and writes data in the OVSDB database through the OVSDB server.

The OVSDB VTEP service performs the following operations to manage the VXLAN settings on the VTEP:

- Converts data in the OVSDB database into VXLAN configuration and deploys the configuration to the VTEP. For example, create or remove a VXLAN or VXLAN tunnel.
- Adds site-facing interface information and the global source address of VXLAN tunnels to the OVSDB database. The information is reported to the controller by the OVSDB server.

Figure 15 OVSDB network model



Protocols and standards

RFC 7047, *The Open vSwitch Database Management Protocol*

Restrictions: Hardware compatibility with OVSDB VTEP

Models	**OVSDB VTEP compatibility**
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Restrictions and guidelines: OVSDB VTEP configuration

You can configure a VTEP both at the CLI and through a controller. As a best practice, do not manually remove the VXLAN configuration issued by the controller.

OVSDB VTEP tasks at a glance

To configure OVSDB VTEPs, perform the following tasks:

1. Setting up an OVSDB connection to a controller
   - Configuring active SSL connection settings
   - Configuring passive SSL connection settings
   - Configuring active TCP connection settings
   - Configuring passive TCP connection settings
2. Enabling the OVSDB server
3. Enabling the OVSDB VTEP service
4. Specifying a global source address for VXLAN tunnels
5. Specifying a VTEP access port
6. Enabling flood proxy on multicast VXLAN tunnels

   If you use a flood proxy server, you must enable flood proxy globally on multicast tunnels.

Prerequisites for OVSDB VTEP configuration

Before you configure the VTEP as an OVSDB VTEP, enable L2VPN by using the **`l2vpn enable`** command.

Before you set up SSL connections to controllers, you must configure SSL as described in *Security Configuration Guide*.

Setting up an OVSDB connection to a controller

About OVSDB connection types

The OVSDB server supports the following types of OVSDB connections:

- **Active SSL connection**—The OVSDB server initiates an SSL connection to the controller.
- **Passive SSL connection**—The OVSDB server accepts the SSL connection from the controller.
- **Active TCP connection**—The OVSDB server initiates a TCP connection to the controller.
- **Passive TCP connection**—The OVSDB server accepts the TCP connection from the controller.

Restrictions and guidelines for OVSDB controller connection setup

When you set up OVSDB connections, follow these restrictions and guidelines:

- You can set up multiple OVSDB connections. For the device to establish the connections, you must enable the OVSDB server. You must disable and then re-enable the OVSDB server if it has been enabled.
- You must specify the same PKI domain and CA certificate file for all active and passive SSL connections.

Prerequisites for OVSDB controller connection setup

Make sure you have configured a PKI domain before specifying it for SSL. For more information about configuring a PKI domain, see *Security Configuration Guide*.

Configuring active SSL connection settings

1. Enter system view.

   system-view

2. Specify a PKI domain for SSL.

   ovsdb server pki domain *domain-name*

   By default, no PKI domain is specified for SSL.

3. (Optional.) Specify a CA certificate file for SSL.

   ovsdb server bootstrap ca-certificate *ca-filename*

   By default, SSL uses the CA certificate file in the PKI domain.

   If the specified CA certificate file does not exist, the device obtains a self-signed certificate from the controller. The obtained file uses the name specified for the *ca-filename* argument.

4. Set up an active SSL connection.

   ovsdb server ssl ip *ip-address* **port** *port-number*

   By default, the device does not have active OVSDB SSL connections.

   You can set up a maximum of eight OVSDB SSL connections.

Configuring passive SSL connection settings

1. Enter system view.

   system-view

2. Specify a PKI domain for SSL.

   ovsdb server pki domain *domain-name*

   By default, no PKI domain is specified for SSL.

3. (Optional.) Specify a CA certificate file for SSL.

   ovsdb server bootstrap ca-certificate *ca-filename*

   By default, SSL uses the CA certificate file in the PKI domain.

   If the specified CA certificate file does not exist, the device obtains a self-signed certificate from the controller. The obtained file uses the name specified for the *ca-filename* argument.

4. Enable the device to listen for SSL connection requests.

   ovsdb server pssl [**port** *port-number*]

   By default, the device does not listen for SSL connection requests.

   You can specify only one port to listen for OVSDB SSL connection requests.

Configuring active TCP connection settings

1. Enter system view.

   system-view

2. Set up an active TCP connection.

   ovsdb server tcp ip *ip-address* **port** *port-number*

   By default, the device does not have active OVSDB TCP connections.

   You can set up a maximum of eight active OVSDB TCP connections.

Configuring passive TCP connection settings

1. Enter system view.

   system-view

2. Enable the device to listen for TCP connection requests.

   ovsdb server ptcp [**port** *port-number*]

   By default, the device does not listen for TCP connection requests.

   You can specify only one port to listen for OVSDB TCP connection requests.

Enabling the OVSDB server

Prerequisites

Make sure you have complete OVSDB connection setup before you enable the OVSDB server. If you change OVSDB connection settings after the OVSDB server is enabled, you must disable and then re-enable the OVSDB server for the change to take effect.

Procedure

1. Enter system view.

   system-view

2. Enable the OVSDB server.

   ovsdb server enable

   By default, the OVSDB server is disabled.

Enabling the OVSDB VTEP service

1. Enter system view.

   system-view

2. Enable the OVSDB VTEP service.

   vtep enable

   By default, the OVSDB VTEP service is disabled.

Specifying a global source address for VXLAN tunnels

About this task

The VTEP reports the global VXLAN tunnel source address to the controller for VXLAN tunnel setup.

Restrictions and guidelines

For correct VXLAN deployment and VTEP management, do not manually specify tunnel-specific source addresses for VXLAN tunnels if OVSDB is used.

Procedure

1. Enter system view.

   `system-view`

2. Specify a global source address for VXLAN tunnels.

   `tunnel global source-address` { *`ipv4-address`* | **`ipv6`** *`ipv6-address`* }

   By default, no global source address is specified for VXLAN tunnels.

Specifying a VTEP access port

About this task

For the controller to manage a site-facing interface, you must specify the interface as a VTEP access port.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Specify the interface as a VTEP access port.

   `vtep access port`

   By default, an interface is not a VTEP access port.

Enabling flood proxy on multicast VXLAN tunnels

About this task

If you use a flood proxy server, you must enable flood proxy globally on multicast tunnels. Then the multicast tunnels are converted into flood proxy tunnels. The VTEP sends broadcast, multicast, and unknown unicast traffic for a VXLAN to the flood proxy server through the tunnels. The flood proxy server then replicates and forwards flood traffic to remote VTEPs.

Procedure

1. Enter system view.

   `system-view`

2. Enable flood proxy on multicast VXLAN tunnels.

   `vxlan tunnel flooding-proxy`

   By default, flood proxy is disabled on multicast VXLAN tunnels.

NSFOCUS Firewall Series

NF Service Chain Instance Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for Service Chain instance features.
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
ⓘ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Configuring service chains

About service chains

The service chain technology is used to guide network service packets through service nodes. The technology is used in combination with software defined network (SDN) for service orchestration. Service packets in a service chain are forwarded and processed by service nodes in a specific order.

Inter-device service chain

Inter-device service chains apply only to VXLAN packets. Service chain policies are used to control packets in the Overlay network as follows:

1. Encapsulate IP packets into VXLAN packets for service chain processing.
2. Deliver the VXLAN packets through all service nodes in a service chain.

You can deploy service chain policies from a VCF controller to tenants by context through OpenFlow.

For more information about VXLAN, see *VXLAN Configuration Guide*. For more information about VCF controllers, see the VCF controller manuals.

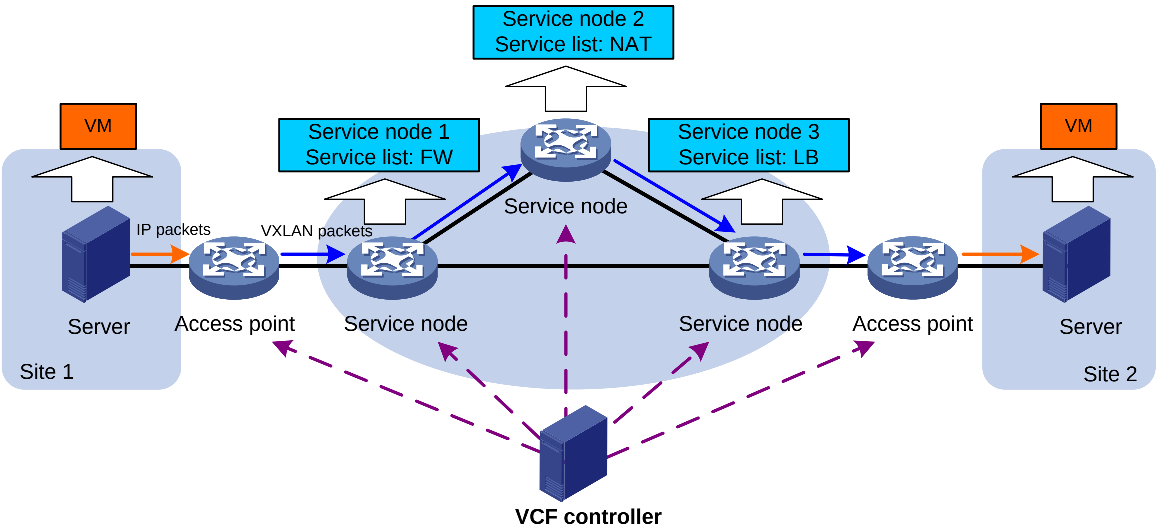
NOTE:

A service chain applied to contexts of different users on a device is an inter-device service chain.

Network model

As shown in Figure 1, an inter-device service chain includes access points and service nodes.

Figure 1 Inter-device service chain network diagram



Access point

An access point is a VXLAN tunnel end point (VTEP) that processes packets based on the service chain policy deployed by a VCF controller.

Service node

A service node is a physical device or a network function virtualization (NFV) device that applies services in a service list to the received VXLAN packets. An inter-device service chain can have multiple service nodes.

A service list on a service node specifies the types and order of services to be applied to the VXLAN packets. Available services include FW and LB.

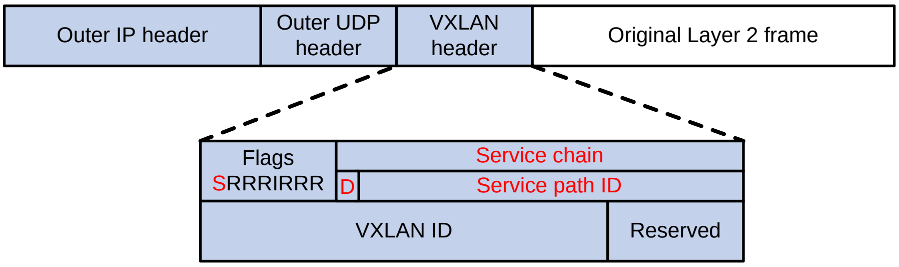
An inter-device service chain supports the following special types of service nodes:

- **Head node**—The first service node in a service chain that processes the VXLAN packets.
- **End node**—The last service node in a service chain that processes the VXLAN packets.

Packet format

Inter-device service chain packets use the VXLAN header. Figure 2 shows the format of a service chain packet.

Figure 2 Service chain packet format



The service chain modifies the following fields in a VXLAN header:

- **Flags**—If the **S** bit is 1, the **Service chain** field is valid. If the **S** bit is 0, the **Service chain** field is invalid.
- **Service chain**—A 24-bit field that includes the **D** bit and service path ID. If the **D** bit is 0, the packet is a forward packet. If the **D** bit is 1, the packet is a backward packet. The 23-bit service path ID is used to identify an inter-device service chain.

Operating mechanisms

An inter-device service chain processes a packet in the following procedure:

1. Based on the service chain policy deployed from the VCF controller, the access point in the inbound packet direction (inbound access point) processes the received packet as follows:
   a. Encapsulates the packet into a VXLAN packet.
   b. Forwards the VXLAN packet to the head node.
2. The head node compares the service path ID in the VXLAN header of the received packet with the path IDs of the service chains.
   - If the packet matches a service chain, the head node forwards the packet into the service chain.
   - If the packet does not match any service chain, the head node performs a VXLAN forwarding for the packet.
3. After a service node completes processing the received VXLAN packet, it forwards the packet in one of the following ways:
   - If the IP address of the next service node is specified, the node forwards the packet to the next service node.

- If no next service node address is specified, the current service node is the end node. The service node removes the service path ID field from the packet and forwards the packet to the access point in the outbound packet direction (outbound access point).

4. The outbound access point decapsulates the VXLAN packet and performs an IP forwarding for the packet.

Configuring an inter-device service chain

You can configure an inter-device service chain through VCF controller deployment or at the CLI. This document describes inter-device service chain configuration at the CLI. As a best practice, use a VCF controller to deploy the service chain configuration through a NETCONF session. For more information about the VCF controller deployment method, see the VCF controller configuration guide.

Configuring an access point

You can only use a VCF controller to deploy the service chain configuration to a device that acts as an access point. For more information, see the relevant VCF controller manuals.

Configuring a service node

Restrictions and guidelines

If the device is the end node in an inter-device service chain, you only need to specify the previous service node address.

If the device is the head node in an inter-device service chain, you only need to specify the next service node address.

Procedure

1. Enter system view.

   system-view

2. Create a service chain and enter its view.

   service-chain path *path-id*

3. Specify the next service node address for forward packets.

   next-service-node *ip-address*

   By default, no next service node address is specified for forward packets.

4. Specify the previous service node address for backward packets.

   previous-service-node *ip-address*

   By default, no previous service node address is specified for backward packets.

5. Create a service node and enter its view.

   service function *function-id*

6. Configure a service list.

   service list { **fw** | **lb** } *

Display and maintenance commands for service chains

Execute **display** commands in any view.

Task	Command
Display service chain information.	**display service-chain path** { *path-id* | **all** }
Display service chain statistics.	**display service-chain statistics**

Service chain configuration examples

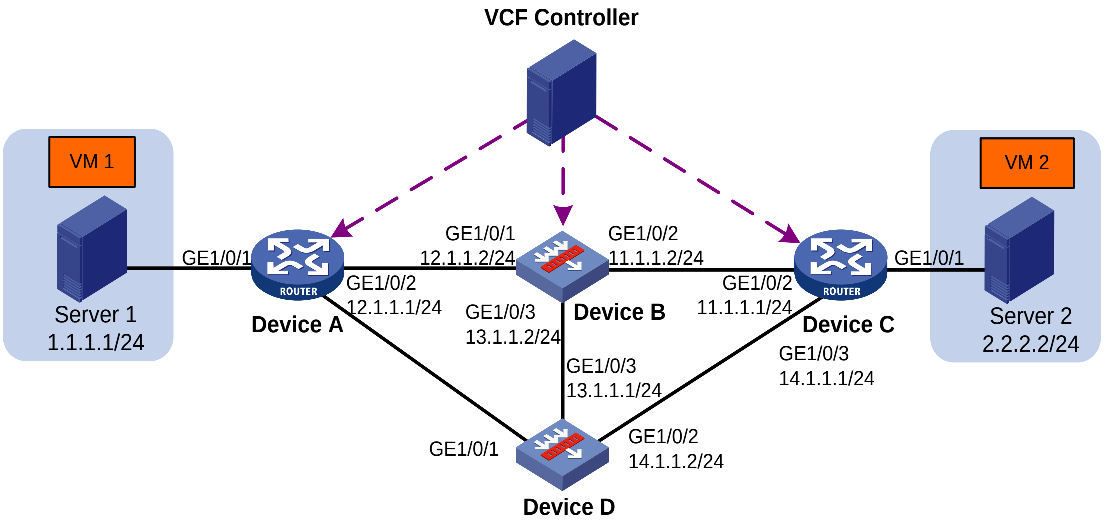
Example: Configuring an inter-device service chain

Network configuration

As shown in Figure 3, Device A and Device C act as access points. Device B and Device D act as service nodes. VM 1 and VM 2 are internal network devices. The inter-device service chain processes the traffic from VM 1 to VM 2 as follows:

1. On Device B, apply the FW service to the traffic.
2. On Device D, apply the LB service to the traffic.

Figure 3 Network diagram



Procedure

1. Configure IP addresses for interfaces to ensure IP connectivity between neighboring nodes. (Details not shown.)
2. Use a VCF controller to deploy service chain policies to Device A and Device C and label the VXLAN packets from VM 1 to VM 2 with service path ID 1. (Details not shown.)
3. Configure Device B:
   a. Assign IP addresses to interfaces:

      # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 12.1.1.2 24
[DeviceB-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

b. Add interfaces to security zones.

```
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/3
[DeviceB-security-zone-Trust] quit
```

c. Configure settings for routing.

This example configures a static route, and the next hop in the route is 12.1.1.1.

```
[DeviceB] ip route-static 1.1.1.0 24 12.1.1.1
```

d. Configure a security policy:

# Configure a rule named **trust-trust** to permit the packets from VM 1 to VM 2.

```
[DeviceB] security-policy ip
[DeviceB-security-policy-ip] rule name trust-trust
[DeviceB-security-policy-ip-1-trust-trust] source-zone trust
[DeviceB-security-policy-ip-1-trust-trust] destination-zone trust
[DeviceB-security-policy-ip-1-trust-trust] source-ip-subnet 1.1.1.0 24
[DeviceB-security-policy-ip-1-trust-trust] destination-ip-subnet 2.2.2.0 24
[DeviceB-security-policy-ip-1-trust-untrust] action pass
[DeviceB-security-policy-ip-1-trust-trust] quit
[DeviceB-security-policy-ip] quit
```

e. Configure service chain settings:

# Create service chain 1 and enter its view.

```
[DeviceB] service-chain path 1
```

# Specify the next service node address as 20.1.1.1, which is the loopback interface address of Device D. The loopback interface is specified as the VXLAN tunnel source interface.

```
[DeviceB-spath1] next-service-node 20.1.1.1
```

# Create service node 1.

```
[DeviceB-spath1] service function 1
```

# Create a service list that includes the FW service.

```
[DeviceB-spath1-func1] service list fw
```

4. Configure Device D:

a. Assign IP addresses to interfaces:

# Assign an IP address to interface GigabitEthernet 1/0/2.

```
<DeviceD> system-view
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] ip address 14.1.1.2 24
[DeviceD-GigabitEthernet1/0/2] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

b. Add interfaces to security zones.

```
[DeviceD] security-zone name trust
[DeviceD-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceD-security-zone-Trust] import interface gigabitethernet 1/0/3
[DeviceD-security-zone-Trust] quit
```

c. Configure settings for routing.

This example configures a static route, and the next hop in the route is 14.1.1.1.

```
[DeviceD] ip route-static 2.2.2.0 24 14.1.1.1
```

d. Configure a security policy:

# Configure a rule named **trust-trust** to permit the packets from VM 1 to VM 2.

```
[DeviceD] security-policy ip
[DeviceD-security-policy-ip] rule name trust-trust
[DeviceD-security-policy-ip-1-trust-trust] source-zone trust
[DeviceD-security-policy-ip-1-trust-trust] destination-zone trust
[DeviceD-security-policy-ip-1-trust-trust] source-ip-subnet 1.1.1.0 24
[DeviceD-security-policy-ip-1-trust-trust] destination-ip-subnet 2.2.2.0 24
[DeviceD-security-policy-ip-1-trust-trust] action pass
[DeviceD-security-policy-ip-1-trust-untrust] quit
[DeviceD-security-policy-ip] quit
```

e. Configure service chain settings:

# Create service chain 1 and enter its view..

```
[DeviceD] service-chain path 1
```

# Specify the previous service node address as 20.1.1.2, which is the loopback interface address of Device B. The loopback interface is specified as the VXLAN tunnel source interface.

```
[DeviceD-spath1] previous-service-node 20.1.1.2
```

# Create service node 1.

```
[DeviceD-spath1] service function 1
```

# Create a service list that includes the LB service.

```
[DeviceD-spath1-func1] service list lb
```

Verifying the configuration

# Verify the following information: (Details not shown.)

- VXLAN packets from VM 1 to VM 2 are labeled with the path ID of the service chain.
- The FW and LB services are applied to the packets in sequential order.
