After a link group references the SNAT address pool, the LB device replaces the source address of the packets it receives with an SNAT address before forwarding the packets.

Restrictions and guidelines

An SNAT address pool can have multiple address ranges. Each address range can have a maximum of 256 IPv4 addresses or 65536 IPv6 addresses. No overlapping IPv4 or IPv6 addresses are allowed in the same SNAT address pool or different SNAT address pools.

As a best practice, do not use SNAT because its application scope is limited for outbound link load balancing.

Procedure

1. Enter system view.

   system-view
2. Create a SNAT address pool and enter SNAT address pool view.

   loadbalance snat-pool *pool-name*
3. (Optional.) Configure a description for the SNAT address pool.

   description *text*

By default, no description is configured for a SNAT address pool.

4. Specify an address range for the SNAT address pool.

   IPv4:

   ip range start *start-ipv4-address* **end** *end-ipv4-address*

   IPv6:

   ipv6 range start *start-ipv6-address* **end** *end-ipv6-address*

   By default, a SNAT address pool does not contain address ranges.

5. (Optional.) Specify a VPN instance for the SNAT address pool.

   vpn-instance *vpn-instance-name*

   By default, a SNAT address pool belongs to the public network.

   Use this command to separate overlapping SNAT address pools.

6. Return to system view.

   quit

7. Enter link group view.

   loadbalance link-group *link-group-name*

8. Specify the SNAT address pool to be referenced by the link group.

   snat-pool *pool-name*

   By default, no SNAT address pool is referenced by a link group.

Enabling the slow online feature

About this task

Links newly added to a link group might be unable to immediately process large numbers of services assigned by the LB device. To resolve this issue, enable the slow online feature for the link group. The feature uses the standby timer and ramp-up timer. When the links are brought online, the LB device does not assign any services to the links until the standby timer expires.

When the standby timer expires, the ramp-up timer starts. During the ramp-up time, the LB device increases the service amount according to the processing capability of the links, until the ramp-up timer expires.

Procedure

1. Enter system view.

   system-view

2. Enter link group view.

   loadbalance link-group *link-group-name*

3. Enable the slow online feature for the link group.

   slow-online [**standby-time** *standby-time* **ramp-up-time** *ramp-up-time*]

   By default, the slow online feature is disabled for a link group.

Configuring health monitoring

About this task

Perform this task to enable health monitoring to detect the availability of links.

Restrictions and guidelines

The health monitoring configuration in link view takes precedence over the configuration in link group view.

You can specify an NQA template for health monitoring. For information about NQA templates, see NQA configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter link group view.

   `loadbalance link-group` *`link-group-name`*

3. Specify a health monitoring method for the link group.

   `probe` *`template-name`*

   By default, no health monitoring method is specified for a link group.

4. Specify the health monitoring success criteria for the link group.

   `success-criteria` { **`all`** | **`at-least`** *`min-number`* }

   By default, health monitoring succeeds only when all the specified health monitoring methods succeed.

Specifying a fault processing method

About this task

Perform this task to specify one of the following fault processing methods for a link group:

- **Keep**—Does not actively terminate the connection with the failed link. Keeping or terminating the connection depends on the timeout mechanism of the protocol.
- **Reschedule**—Redirects the connection to another available link in the link group.
- **Reset**—Terminates the connection with the failed link by sending RST packets (for TCP packets) or ICMP unreachable packets (for other types of packets).

Procedure

1. Enter system view.

   `system-view`

2. Enter link group view.

   `loadbalance link-group` *`link-group-name`*

3. Specify a fault processing method for the link group.

   `fail-action` { **`keep`** | **`reschedule`** | **`reset`** }

   By default, the fault processing method is **`keep`**. All available connections are kept.

Configuring the proximity feature

About this task

The proximity feature performs link detection to select the optimal link to a destination. If no proximity information for a destination is available, the load balancing module selects a link based on the scheduling algorithm. It then performs proximity detection to generate proximity entries for forwarding subsequent traffic.

You can specify an NQA template or load-balancing probe template to perform link detection. The device generates proximity entries according to the detection results and proximity parameter settings. For information about NQA templates, see NQA configuration in *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

To configure the proximity feature, first configure proximity parameters in proximity view, and then enable the proximity feature in link group view.

Configuring an LB probe template

1. Enter system view.

   system-view
2. Create an LB probe template and enter LB probe template view.

   loadbalance probe-template icmp *template-name*
3. Set the probe interval.

   frequency *interval*

   The default setting is 300 seconds.
4. Set the timeout time for probe responses.

   timeout *timeout-value*

   The default setting is 3 seconds.

Configuring the proximity probe method

1. Enter system view.

   system-view
2. Enter proximity view.

   loadbalance proximity [**vpn-instance** *vpn-instance-name*]
3. Specify the proximity probe method for packets.

   match [*match-id*] { **tcp** } { **lb-probe** *lb-template* | **probe** *nqa-template* }

   By default, no proximity probe method is specified.
4. Specify the default proximity probe method.

   match default { **lb-probe** *lb-template* | **probe** *nqa-template* }

   By default, the default proximity probe method is not specified.

Configuring proximity parameters

1. Enter system view.

   system-view
2. Enter proximity view.

   loadbalance proximity [**vpn-instance** *vpn-instance-name*]
3. Set the mask length for IPv4 proximity entries.

   ip mask { *mask-length* | *mask* }

   By default, the mask length for IPv4 proximity entries is 24.
4. Set the prefix length for IPv6 proximity entries.

   ipv6 prefix *prefix-length*

   By default, the prefix length for IPv6 proximity entries is 96.
5. Set the network delay weight for proximity calculation.

   rtt weight *rtt-weight*

   By default, the network delay weight for proximity calculation is 100.
6. Set the TTL weight for proximity calculation.

   ttl weight *ttl-weight*

   By default, the TTL weight for proximity calculation is 100.
7. Set the bandwidth weight for proximity calculation.

bandwidth { **inbound** | **outbound** } **weight** *bandwidth-weight*

By default, the inbound or outbound bandwidth weight for proximity calculation is 100.

8. Set the cost weight for proximity calculation.

   cost weight *cost-weight*

   By default, the cost weight for proximity calculation is 100.

9. Set the aging timer for proximity entries.

   timeout *timeout-value*

   By default, the aging timer for proximity entries is 60 seconds.

10. Set the maximum number of proximity entries.

    max-number *number*

    By default, the maximum number of proximity entries is 65535.

Enabling the proximity feature

1. Enter system view.

   system-view

2. Enter link group view.

   loadbalance link-group *link-group-name*

3. Enable the proximity feature.

   proximity enable

   By default, the proximity feature is disabled for a link group.

Configuring a link

A link is a physical link provided by an ISP. A link can belong to multiple link groups. A link group can have multiple links.

Restrictions and guidelines

In a network where hot backup cooperates with VRRP, as a best practice, make sure the IP address of the link-attached output interface is on the same network segment as the virtual IP address of the VRRP group. For more information about hot backup and VRRP association, see hot backup configuration in *High Availability Configuration Guide*.

Link tasks at a glance

To configure a link, perform the following tasks:

1. Creating a link and specifying a link group
2. Specifying a next hop IP address or an outgoing interface

   Choose one of the following tasks:

   - Specifying an outbound next hop for a link
   - Specifying an outgoing interface for a link
3. Setting a weight and priority
4. (Optional.) Configuring the bandwidth and connection parameters
5. (Optional.) Configuring health monitoring
6. (Optional.) Enabling the slow offline feature
7. (Optional.) Setting the link cost for proximity calculation

8. (Optional.) Setting the bandwidth ratio and maximum expected bandwidth
9. (Optional.) Disabling VPN instance inheritance for a link

Creating a link and specifying a link group

1. Enter system view.

   system-view
2. Create a link and enter link view.

   loadbalance link *link-name*

   By default, no links exist.
3. (Optional.) Configure a description for the link.

   description *text*

   By default, no description is configured for a link.
4. Specify a link group for the link.

   link-group *link-group-name*

   By default, a link does not belong to any link group.

Specifying an outbound next hop for a link

1. Enter system view.

   system-view
2. Enter link view.

   loadbalance link *link-name*
3. Specify an outbound next hop for the link.

   IPv4:

   router ip *ipv4-address*

   IPv6:

   router ipv6 *ipv6-address*

   By default, a link does not have an outbound next hop.

Specifying an outgoing interface for a link

About this task

In scenarios where IP addresses are obtained through PPPoE, an LB device can dynamically obtain the outbound next hop IP address through the specified outgoing interface.

Procedure

1. Enter system view.

   system-view
2. Enter link view.

   loadbalance link *link-name*
3. Specify an outgoing interface for the link.

   router interface *interface-type interface-number*

   By default, no outgoing interface is specified for a link.

Setting a weight and priority

About this task

Perform this task to configure a weight for the weighted round robin and weighted least connection algorithms of a link, and the scheduling priority in the link group for the server.

Procedure

1. Enter system view.

   `system-view`

2. Enter link view.

   `loadbalance link` *`link-name`*

3. Set a weight for the link.

   `weight` *`weight-value`*

   By default, the weight of a link is 100.

4. Set a priority for the link.

   `priority` *`priority`*

   By default, the priority of a link is 4.

Configuring the bandwidth and connection parameters

1. Enter system view.

   `system-view`

2. Enter link view.

   `loadbalance link` *`link-name`*

3. Set the maximum bandwidth for the link.

   `rate-limit bandwidth` [**`inbound`** | **`outbound`**] *`bandwidth-value`* **`kbps`**

   By default, the maximum bandwidth, inbound bandwidth, and outbound bandwidth are 0 for a link. The bandwidths are not limited.

4. Set the maximum number of connections for the link.

   `connection-limit max` *`max-number`*

   By default, the maximum number of connections is 0 for a link. The number is not limited.

5. Set the maximum number of connections per second for the link.

   `rate-limit connection` *`connection-number`*

   By default, the maximum number of connections per second is 0 for a link. The number is not limited.

Configuring health monitoring

About this task

Perform this task to enable health monitoring to detect the availability of a link.

Restrictions and guidelines

The health monitoring configuration in link view takes precedence over the configuration in link group view.

Procedure

1. Enter system view.

system-view

2. Enter link view.

   loadbalance link *link-name*

3. Specify a health monitoring method for the link.

   probe *template-name*

   By default, no health monitoring method is specified for a link.

4. Specify the health monitoring success criteria for the link.

   success-criteria { **all** | **at-least** *min-number* }

   By default, the health monitoring succeeds only when all the specified health monitoring methods succeed.

Enabling the slow offline feature

About this task

The **shutdown** command immediately terminates existing connections of a link. The slow offline feature ages out the connections, and does not establish new connections.

Restrictions and guidelines

To enable the slow offline feature for a link, you must execute the **slow-shutdown enable** command and then the **shutdown** command. If you execute the **shutdown** command and then the **slow-shutdown enable** command, the slow offline feature does not take effect and the link is shut down.

Procedure

1. Enter system view.

   system-view

2. Enter link view.

   loadbalance link *link-name*

3. Enable the slow offline feature for the link.

   slow-shutdown enable

   By default, the slow offline feature is disabled.

4. Shut down the link.

   shutdown

   By default, the link is activated.

Setting the link cost for proximity calculation

1. Enter system view.

   system-view

2. Enter link view.

   loadbalance link *link-name*

3. Set the link cost for proximity calculation.

   cost *cost-value*

   By default, the link cost for proximity calculation is 0.

Setting the bandwidth ratio and maximum expected bandwidth

About this task

When the traffic exceeds the maximum expected bandwidth multiplied by the bandwidth ratio of a link, new traffic (traffic that does not match any sticky entries) is not distributed to the link. When the traffic drops below the maximum expected bandwidth multiplied by the bandwidth recovery ratio of the link, the link participates in scheduling again.

In addition to being used for link protection, the maximum expected bandwidth is used for remaining bandwidth calculation in the bandwidth algorithm, maximum bandwidth algorithm, and dynamic proximity algorithm.

Procedure

1. Enter system view.

`system-view`

2. Enter link view.

`loadbalance link` *`link-name`*

3. Set the bandwidth ratio.

`bandwidth` [**`inbound`** | **`outbound`**] **`busy-rate`** *`busy-rate-number`* [**`recovery`** *`recovery-rate-number`*]

By default, the total bandwidth ratio is 70.

4. Set the maximum expected bandwidth.

`max-bandwidth` [**`inbound`** | **`outbound`**] *`bandwidth-value`* **`kbps`**

By default, the maximum expected bandwidth, maximum uplink expected bandwidth, and maximum downlink expected bandwidth are 0. The bandwidths are not limited.

Disabling VPN instance inheritance for a link

About this task

When VPN instance inheritance is enabled, a link without a VPN instance specified inherits the VPN instance of the virtual server. When VPN instance inheritance is disabled, a link without a VPN instance specified belongs to the public network.

Procedure

1. Enter system view.

`system-view`

2. Enter link view.

`loadbalance link` *`link-name`*

3. Disable VPN instance inheritance for the link.

`inherit vpn-instance disable`

By default, VPN instance inheritance is enabled for a link.

Configuring a virtual server

A virtual server is a virtual service provided by the LB device to determine whether to perform load balancing for packets received on the LB device. Only the packets that match a virtual server are load balanced.

Restrictions and guidelines

Outbound link load balancing supports only the link-IP virtual server.

Virtual server tasks at a glance

To configure a virtual server, perform the following tasks:

1. Creating a virtual server
2. Specifying the VSIP and port number
3. (Optional.) Specifying a VPN instance
4. Configuring a packet processing policy

   Choose the following tasks as needed:

   - Specifying link groups
   - Specifying an LB policy
5. (Optional.) Specifying a parameter profile
6. (Optional.) Configuring the bandwidth and connection parameters
7. (Optional.) Enabling the link protection feature
8. (Optional.) Enabling bandwidth statistics collection by interfaces
9. (Optional.) Specifying a DPI application profile
10. (Optional.) Configuring hot backup
11. Enabling a virtual server

Creating a virtual server

1. Enter system view.

   system-view
2. Create a link-IP virtual server and enter virtual server view.

   virtual-server *virtual-server-name* **type link-ip**
3. (Optional.) Configure a description for the virtual server.

   description *text*

   By default, no description is configured for the virtual server.

Specifying the VSIP and port number

1. Enter system view.

   system-view
2. Enter link-IP virtual server view.

   virtual-server *virtual-server-name*
3. Specify the VSIP for the virtual server.

   IPv4:

   virtual ip address *ipv4-address* [*mask-length* | *mask*]

   IPv6:

   virtual ipv6 address *ipv6-address* [*prefix-length*]

   By default, no IPv4 or IPv6 address is specified for a virtual server.
4. Specify the port number for the virtual server.

port *port-number*

By default, the port number is 0 (meaning any port number) for a link-IP virtual server.

Specifying a VPN instance

1. Enter system view.
   system-view
2. Enter virtual server view.
   virtual-server *virtual-server-name*
3. Specify a VPN instance for the virtual server.
   vpn-instance *vpn-instance-name*

   By default, a virtual server belongs to the public network.

Specifying link groups

About this task

When the primary link group is available (contains available links), the virtual server forwards packets through the primary link group. When the primary link group is not available, the virtual server forwards packets through the backup link group.

Procedure

1. Enter system view.
   system-view
2. Enter virtual server view.
   virtual-server *virtual-server-name*
3. Specify link groups.
   default link-group *link-group-name* [**backup** *backup-link-group-name*] [**sticky** *sticky-name*]

   By default, no link group is specified for a virtual server.

Specifying an LB policy

About this task

By referencing an LB policy, the virtual server load balances matching packets based on the packet contents.

Procedure

1. Enter system view.
   system-view
2. Enter virtual server view.
   virtual-server *virtual-server-name*
3. Specify an LB policy for the virtual server.
   lb-policy *policy-name*

   By default, the virtual server does not reference any LB policies.

   A virtual server can only reference a policy profile of the specified type. For example, a virtual server of the link-IP type can only reference a policy profile of the link-generic type.

Specifying a parameter profile

About this task

You can configure advanced parameters through a parameter profile. The virtual server references the parameter profile to analyze, process, and optimize service traffic.

Procedure

1. Enter system view.

   system-view

2. Enter virtual server view.

   virtual-server *virtual-server-name*

3. Specify a parameter profile for the virtual server.

   parameter ip *profile-name*

   By default, the virtual server does not reference any parameter profiles.

Configuring the bandwidth and connection parameters

1. Enter system view.

   system-view

2. Enter virtual server view.

   virtual-server *virtual-server-name*

3. Set the maximum bandwidth for the virtual server.

   rate-limit bandwidth [**inbound** | **outbound**] *bandwidth-value* **kbps**

   By default, the maximum bandwidth, inbound bandwidth, and outbound bandwidth for the virtual server are 0. The bandwidths are not limited.

4. Set the maximum number of connections for the virtual server.

   connection-limit max *max-number*

   By default, the maximum number of connections of the virtual server is 0. The number is not limited.

5. Set the maximum number of connections per second for the virtual server.

   rate-limit connection *connection-number*

   By default, the maximum number of connections per second for the virtual server is 0. The number is not limited.

Enabling the link protection feature

About this task

The link protection feature limits packets that exceed the bandwidth busy rate in the inbound or outbound direction of a link. When a link is busy in only the outbound direction, new traffic (traffic that does not match any sticky entry) is not distributed to the link. However, existing traffic is still distributed to the link. When a link is busy in only the inbound direction, new traffic can be distributed to the link.

When a link becomes busy in at least one direction, the link state becomes busy. When a link is not busy in both directions, the link sate is normal.

Restrictions and guidelines

This feature takes effect only when bandwidth statistics collection by interfaces is enabled.

Procedure

1. Enter system view.

   system-view

2. Enter virtual server view.

   virtual-server *virtual-server-name*

3. Enable the link protection feature.

   bandwidth busy-protection enable

   By default, the link protection feature is disabled.

Enabling bandwidth statistics collection by interfaces

About this task

By default, the load balancing module automatically collects link bandwidth statistics. Perform this task to enable interfaces to collect bandwidth statistics.

Procedure

1. Enter system view.

   system-view

2. Enter virtual server view.

   virtual-server *virtual-server-name*

3. Enable bandwidth statistics collection by interfaces.

   bandwidth interface statistics enable

   By default, bandwidth statistics collection by interfaces is disabled.

Specifying a DPI application profile

About this task

This task allows you to perform DPI on the traffic of a virtual server, including IPS, anti-virus,. DPI helps you identify network attacks and security risks to secure the LB device and internal servers. For more information about DPI application profiles, see DPI engine in *DPI Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter virtual server view.

   virtual-server *virtual-server-name*

3. Specify a DPI application profile for the virtual server.

   dpi-app-profile *dpi-app-profile-name*

   By default, a virtual server does not reference any DPI application profiles.

Configuring hot backup

About this task

To implement hot backup for two LB devices, you must enable synchronization for session extension information and sticky entries to avoid service interruption.

Restrictions and guidelines

For successful sticky entry synchronization, if you want to specify a sticky group, enable sticky entry synchronization before specifying a sticky group on both LB devices. You can specify a sticky group by using the **sticky** *sticky-name* option when specifying link groups.

In a VRRP network, you must specify the **global** keyword for the sticky entry synchronization feature to take effect.

The following configuration changes will cause the device to delete existing sticky entries and generate new ones based on subsequent traffic:

- Disable sticky entry synchronization.
- Change the sticky entry synchronization type.

Procedure

1. Enter system view.
   system-view
2. Enter virtual server view.
   virtual-server *virtual-server-name*
3. Enable session extension information synchronization.
   connection-sync enable
   By default, session extension information synchronization is disabled.
4. Enable sticky entry synchronization.
   sticky-sync enable [**global**]
   By default, sticky entry synchronization is disabled.

Enabling a virtual server

About this task

After you configure a virtual server, you must enable the virtual server for it to work.

Procedure

1. Enter system view.
   system-view
2. Enter virtual server view.
   virtual-server *virtual-server-name*
3. Enable the virtual server.
   service enable
   By default, the virtual server is disabled.

Configuring an LB class

An LB class classifies packets by comparing packets against specific rules. Matching packets are further processed by LB actions. You can create a maximum of 65535 rules for an LB class.

LB class tasks at a glance

To configure an LB class, perform the following tasks:

1. Creating an LB class

2. Creating a match rule

   Choose the following tasks as needed:

   - Creating a match rule that references an LB class
   - Creating a source IP address match rule
   - Creating a destination IP address match rule
   - Creating an ACL match rule
   - Creating an input interface match rule
   - Creating a user match rule
   - Creating a user group match rule
   - Creating a domain name match rule
   - Creating an ISP match rule
   - Creating an application group match rule

Creating an LB class

1. Enter system view.

   system-view

2. Create a link-generic LB class, and enter LB class view.

   loadbalance class *class-name* **type link-generic** [**match-all** | **match-any**]

   When you create an LB class, you must specify the class type. You can enter an existing LB class view without specifying the class type. If you specify the class type when entering an existing LB class view, the class type must be the one specified when you create the LB class.

3. (Optional.) Configure a description for the LB class.

   description *text*

   By default, no description is configured for the LB class.

Creating a match rule that references an LB class

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create a match rule that references an LB class.

   match [*match-id*] **class** *class-name*

Creating a source IP address match rule

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create a source IP address match rule.

   match [*match-id*] **source** { **ip address** *ipv4-address* [*mask-length* | *mask*] | **ipv6 address** *ipv6-address* [*prefix-length*] }

Creating a destination IP address match rule

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create a destination IP address match rule.

   match [*match-id*] **destination** { **ip address** *ipv4-address* [*mask-length* | *mask*] | **ipv6 address** *ipv6-address* [*prefix-length*] }

Creating an ACL match rule

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create an ACL match rule.

   match [*match-id*] **acl** [**ipv6**] { *acl-number* | **name** *acl-name* }

Creating an input interface match rule

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create an input interface match rule.

   match [*match-id*] **interface** *interface-type interface-number*

Creating a user match rule

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create a user match rule.

   match [*match-id*] [**identity-domain** *domain-name*] **user** *user-name*

Creating a user group match rule

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create a user group match rule.

match [*match-id*] [**identity-domain** *domain-name*] **user-group** *user-group-name*

Creating a domain name match rule

About this task

The LB device stores mappings between domain names and IP addresses in the DNS cache. If the destination IP address of an incoming packet matches an IP address in the DNS cache, the LB device queries the domain name for the IP address. If the queried domain name matches the domain name configured in a match rule, the LB device takes the LB action on the packet.

Procedure

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create a domain name match rule.

   match [*match-id*] **destination domain-name** *domain-name*

   By default, an LB class does not have any match rules.

Creating an ISP match rule

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create an ISP match rule.

   match [*match-id*] **isp** *isp-name*

Creating an application group match rule

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create an application group match rule.

   match [*match-id*] **app-group** *group-name*

   After you execute this configuration, hardware fast forwarding cannot process traffic processed by outbound link load balancing.

Configuring an LB action

About LB actions

LB actions include the following modes:

- **Forwarding mode**—Determines whether and how to forward packets. If no forwarding action is specified, packets are dropped.
- **Modification mode**—Modifies packets. To prevent the LB device from dropping the modified packets, the modification action must be used together with a forwarding action.

If you create an LB action without specifying any of the previous action modes, packets are dropped.

Restrictions and guidelines

The "Configuring the forwarding mode" and "Specifying link groups" tasks are mutually exclusive. Configuring one task automatically cancels the other task that you have configured.

LB action tasks at a glance

To configure an LB action, perform the following tasks:

1. Creating an LB action
2. (Optional.) Configuring a forwarding LB action
   - Configuring the forwarding mode
   - Specifying link groups
   - (Optional.) Matching the next rule upon failure to find a link
   - (Optional.) Matching the next rule when all links are busy
3. (Optional.) Configuring a modification LB action
   - Configuring the ToS field in IP packets sent to the server

Creating an LB action

1. Enter system view.

   system-view

2. Create a link-generic LB action and enter LB action view.

   loadbalance action *action-name* **type link-generic**

   When you create an LB action, you must specify the action type. You can enter an existing LB action view without specifying the action type. If you specify the action type when entering an existing LB action view, the action type must be the one specified when you create the LB action.

3. (Optional.) Configure a description for the LB action.

   description *text*

   By default, no description is configured for the LB action.

Configuring a forwarding LB action

About this task

Three forwarding LB action types are available:

- **Forward**—Forwards matching packets.
- **Specify link groups**—When the primary link group is available (contains available real servers), the primary link group is used to guide packet forwarding. When the primary link group is not available, the backup link group is used to guide packet forwarding.
- **Match the next rule upon failure to find a link**—If the device fails to find a link according to the LB action, it matches the packet with the next rule in the LB policy.

- Match the next rule when all links are busy.

Configuring the forwarding mode

1. Enter system view.

   system-view

2. Enter LB action view.

   loadbalance action *action-name*

3. Configure the forwarding mode.

   forward all

   By default, the forwarding mode is to discard packets.

Specifying link groups

1. Enter system view.

   system-view

2. Enter LB action view.

   loadbalance action *action-name*

3. Specify link groups.

   link-group *link-group-name* [**backup** *backup-link-group-name*] [**sticky** *sticky-name*]

   By default, no link group is specified.

Matching the next rule upon failure to find a link

1. Enter system view.

   system-view

2. Enter LB action view.

   loadbalance action *action-name*

3. Match the next rule upon failure to find a link.

   fallback-action continue

   By default, the next rule is not matched when no links are available for the current LB action.

   This command does not apply to SIP virtual servers.

Matching the next rule when all links are busy

1. Enter system view.

   system-view

2. Enter LB action view.

   loadbalance action *action-name*

3. Match the next rule when all links are busy.

   busy-action continue

   By default, the device assigns packets to links regardless of whether they are busy.

Configuring the ToS field in IP packets sent to the server

1. Enter system view.

   system-view

2. Enter LB action view.

   loadbalance action *action-name*

3. Configure the ToS field in IP packets sent to the server.

set ip tos *tos-number*

By default, the ToS field in IP packets sent to the server is not changed.

Configuring an LB policy

About LB policies

An LB policy associates an LB class with an LB action to guide packet forwarding. In an LB policy, you can configure an LB action for packets matching the specified LB class, and configure the default action for packets matching no LB class.

You can specify multiple LB classes for an LB policy. Packets match the LB classes in the order the LB classes are configured. If an LB class is matched, the specified LB action is performed. If no LB class is matched, the default LB action is performed.

LB policy tasks at a glance

To configure an LB policy, perform the following tasks:

1. Creating an LB policy
2. Specifying an LB action
3. Specifying the default LB action

Creating an LB policy

1. Enter system view.

   system-view

2. Create a link-generic LB policy, and enter LB action view.

   loadbalance policy *policy-name* **type link-generic**

   When you create an LB policy, you must specify the policy type. You can enter an existing LB policy view without specifying the policy type. If you specify the policy type when entering an existing LB policy view, the policy type must be the one specified when you create the LB policy.

3. (Optional.) Configure a description for the LB policy.

   description *text*

   By default, no description is configured for an LB policy.

Specifying an LB action

Restrictions and guidelines

A link-generic LB policy can reference only link-generic LB classes and link-generic LB actions.

Procedure

1. Enter system view.

   system-view

2. Enter LB policy view.

   loadbalance policy *policy-name*

3. Specify an LB action for the specified LB class.

   class *class-name* [**insert-before** *before-class-name* | **insert-after** [*after-class-name*]] **action** *action-name*

By default, no LB action is specified for any LB classes.

You can specify an LB action for different LB classes.

Specifying the default LB action

Restrictions and guidelines

A link-generic LB policy can only reference link-generic LB actions.

Procedure

1. Enter system view.

   `system-view`

2. Enter LB policy view.

   `loadbalance policy` *`policy-name`*

3. Specify the default LB action.

   `default-class action` *`action-name`*

   By default, no default LB action is specified.

Configuring a sticky group

A sticky group uses a sticky method to distribute similar sessions to the same link according to sticky entries. The sticky method applies to the first packet of a session. Other packets of the session are distributed to the same link.

Sticky group tasks at a glance

To configure a sticky group, perform the following tasks:

1. Creating a sticky group
2. Configuring the IP sticky method
3. (Optional.) Configuring the timeout time for sticky entries
4. (Optional.) Ignoring the limits for sessions that match sticky entries
5. (Optional.) Enabling stickiness-over-busyness

Creating a sticky group

1. Enter system view.

   `system-view`

2. Create an address- and port-type sticky group and enter sticky group view.

   `sticky-group` *`group-name`* **`type address-port`**

   When you create a sticky group, you must specify the group type. You can enter an existing sticky group view without specifying the group type. If you specify the group type when entering an existing sticky group view, the group type must be the one specified when you create the sticky group.

3. (Optional.) Configure a description for the sticky group.

   `description` *`text`*

   By default, no description is configured for the sticky group.

Configuring the IP sticky method

1. Enter system view.

   system-view

2. Enter sticky group view.

   sticky-group *group-name*

3. Configure the IP sticky method.

   IPv4:

   ip [**port**] { **both** | **destination** | **source** } [**mask** *mask-length*]

   IPv6:

   ipv6 [**port**] { **both** | **destination** | **source** } [**prefix** *prefix-length*]

   By default, no IP sticky method is configured.

Configuring the timeout time for sticky entries

1. Enter system view.

   system-view

2. Enter sticky group view.

   sticky-group *group-name*

3. Configure the timeout time for sticky entries.

   timeout *timeout-value*

   By default, the timeout time for sticky entries is 60 seconds.

Ignoring the limits for sessions that match sticky entries

About this task

Perform this task to ignore the following limits for sessions that match sticky entries:

- Bandwidth and connection parameters on links.
- LB connection limit policies on virtual servers.

Procedure

1. Enter system view.

   system-view

2. Enter sticky group view.

   sticky-group *group-name*

3. Ignore the limits for sessions that match sticky entries.

   override-limit enable

   By default, the session limits apply to sessions that match sticky entries.

Enabling stickiness-over-busyness

About stickiness-over-busyness

This feature enables the device to assign client requests to links based on sticky entries, regardless of whether the links are busy.

When this feature is disabled, the device assigns client requests to only links in normal state.

Procedure

1. Enter system view.

   system-view

2. Enter sticky group view.

   sticky-group *group-name*

3. Enable stickiness-over-busyness.

   sticky-over-busy enable

   By default, stickiness-over-busyness is disabled.

Configuring a parameter profile

About configuring a parameter profile

You can configure advanced parameters through a parameter profile. The virtual server references the parameter profile to analyze, process, and optimize service traffic.

Creating a parameter profile

1. Enter system view.

   system-view

2. Create an IP-type parameter profile and enter parameter profile view.

   parameter-profile *profile-name* **type ip**

   By default, no parameter profiles exist.

   When you create a parameter profile, you must specify the profile type. You can enter an existing parameter profile view without specifying the profile type. If you specify the profile type when entering an existing parameter profile view, the profile type must be the one specified when you create the parameter profile.

3. (Optional.) Configure a description for the parameter profile.

   description *text*

   By default, no description is configured for the parameter profile.

Configuring the ToS field in IP packets sent to the client

1. Enter system view.

   system-view

2. Enter IP parameter profile view.

   parameter-profile *profile-name*

3. Configure the ToS field in IP packets sent to the client.

   set ip tos *tos-number*

   By default, the ToS field in IP packets sent to the client is not changed.

Configuring ISP information

About configuring ISP information

Perform this task to configure IP address information for an ISP. The IP address information can be used by an ISP match rule. When the destination IP address of packets matches the ISP match rule of an LB class, the LB device takes the action associated with the class. The device supports the following methods to configure IP address information:

- **Manual configuration**—The administrator manually specifies IP address information.
- **ISP auto update**—With ISP auto update enabled, the device regularly queries IP address information from the whois server according to the whois maintainer object of the ISP.
- **ISP file import**—The administrator manually imports an ISP file in .tp format. The ISP file can be obtained from the official website.

Restrictions and guidelines

You can configure ISP information manually, by importing an ISP file, by auto update, or use the combination of these methods..

Configuring ISP information manually

1. Enter system view.

   `system-view`

2. Create an ISP and enter ISP view.

   `loadbalance isp name` *`isp-name`*

3. Specify the IP address for the ISP.

   IPv4:

   `ip address` *`ipv4-address`* { *`mask-length`* | *`mask`* }

   IPv6:

   `ipv6 address` *`ipv6-address prefix-length`*

   By default, an ISP does not contain IPv4 or IPv6 addresses.

   An ISP does not allow overlapping network segments.

4. (Optional.) Configure a description for the ISP.

   `description` *`text`*

   By default, no description is configured for the ISP.

Configuring ISP auto update

1. Enter system view.

   `system-view`

2. Create an ISP and enter ISP view.

   `loadbalance isp name` *`isp-name`*

3. Specify a whois maintainer object for the ISP.

   `whois-mntner` *`mntner-name`*

   By default, no whois maintainer object is specified.

   You can specify a maximum of 10 whois maintainer objects for an ISP.

4. Return to system view.

   quit

5. Enable ISP auto update.

   loadbalance isp auto-update enable

   By default, ISP auto update is disabled.

6. Configure the ISP auto update frequency.

   loadbalance isp auto-update frequency { *per-day* | *per-week* | *per-month* }

   By default, the ISP auto update is performed once per week.

7. Specify the whois server to be queried for ISP auto update.

   loadbalance isp auto-update whois-server { **domain** *domain-name* | **ip** *ip-address* }

   By default, no whois server is specified for ISP auto update.

Importing an ISP file

1. Enter system view.

   system-view

2. Import an ISP file.

   loadbalance isp file *isp-file-name*

Setting the aging time for DNS cache entries

About this task

A DNS cache entry records the mapping between a domain name and the IP address of the outbound next hop.

Procedure

1. Enter system view.

   system-view

2. Set the aging time for DNS cache entries.

   loadbalance dns-cache aging-time *aging-time*

   By default, the aging time for DNS cache entries is 60 minutes.

Configuring the ALG feature

About this task

The Application Level Gateway (ALG) feature distributes parent and child sessions to the same link.

Procedure

1. Enter system view.

   system-view

2. Enable ALG.

   - Enable ALG for the specified protocol:
     loadbalance alg { **dns** | **ftp** | **h323** | **icmp-error** | **ils** | **mgcp** | **nbt** | **pptp** | **rsh** | **rtsp** | **sccp** | **sip** | **sqlnet** | **tftp** | **xdmcp** }

- Enable ALG for all protocols:
  `loadbalance alg all-enable`

By default, ALG is enabled for the DNS, FTP, PPTP, and RTSP protocols and ICMP error packets.

Performing a load balancing test

About performing a load balancing test

Perform this task in any view to test the load balancing result.

Performing an IPv4 load balancing test

To perform an IPv4 load balancing test, execute the following command in any view:

loadbalance schedule-test ip [**vpn-instance** *vpn-instance-name*] { **application http** { **message-file** *file-name* | **method** { **get** | **post** } **url** *url* [**header** *header*]&<1-10> [**content** *content-value*] } | **protocol** { *protocol-number* | **icmp** | **tcp** | **udp** } } **destination** *destination-address* **destination-port** *destination-port* **source** *source-address* **source-port** *source-port* [**slot** *slot-number*]

Performing an IPv6 load balancing test

To perform an IPv6 load balancing test, execute the following command in any view:

loadbalance schedule-test ipv6 [**vpn-instance** *vpn-instance-name*] { **application http** { **message-file** *file-name* | **method** { **get** | **post** } **url** *url* [**header** *header*]&<1-10> [**content** *content-value*] } | **protocol** { *protocol-number* | **icmpv6** | **tcp** | **udp** } } **destination** *destination-address* **destination-port** *destination-port* **source** *source-address* **source-port** *source-port* [**slot** *slot-number*]

Enabling SNMP notifications

About this task

To report critical load balancing events to an NMS, enable SNMP notifications for load balancing. For load balancing event notifications to be sent correctly, you must also configure SNMP as described in *Network Management and Monitoring Configuration Guide*.

The SNMP notifications configuration tasks for Layer 4 and Layer 7 server load balancing are the same.

Procedure

1. Enter system view.
   `system-view`
2. Enable SNMP notifications for load balancing.
   `snmp-agent trap enable loadbalance`
   By default, SNMP notifications are enabled for load balancing.

Enabling load balancing logging

About load balancing logging

For security auditing purposes, enable load balancing logging to record load balancing information. Load balancing logging includes the following types:

- Basic logging.
- Link flow logging.
- NAT logging.
- Link busy state logging.

Basic logging generates logs for the following events:

- The state of a link or link group changes.
- The health monitoring result of a link changes.
- The number of connections on a link or virtual server reaches or drops below the upper limit.
- The connection establishment rate on a link or virtual server reaches or drops below the upper limit.
- A primary/backup server farm switchover occurs between server farms specified for a virtual server.
- A primary/backup server farm switchover occurs between server farms specified for an LB action.

Link flow logging records flows forwarded through all links.

NAT logging records NAT session information, including IP address and port translation information and access information.

Link busy state logging records busy states for all links.

Enabling load balancing basic logging

1. Enter system view.
   ```
   system-view
   ```
2. Enable load balancing basic logging.
   ```
   loadbalance log enable base
   ```
   By default, load balancing basic logging is enabled.

Enabling load balancing link flow logging

1. Enter system view.
   ```
   system-view
   ```
2. Enable load balancing link flow logging.
   ```
   loadbalance log enable link-flow
   ```
   By default, load balancing link flow logging is enabled.

Enabling load balancing NAT logging

1. Enter system view.
   ```
   system-view
   ```

2. Enable load balancing NAT logging.

   loadbalance log enable nat

   By default, load balancing NAT logging is disabled.

Enabling load balancing link busy state logging

1. Enter system view.

   system-view

2. Enable load balancing link busy state logging.

   loadbalance log enable bandwidth-busy

   By default, load balancing link busy state logging is disabled.

Displaying and maintaining outbound link load balancing

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display LB action information.	**display loadbalance action** [**name** *action-name*]
Display LB class information.	**display loadbalance class** [**name** *class-name*]
Display LB hot backup statistics.	**display loadbalance hot-backup statistics** [**slot** *slot-number*]
Display ISP information.	**display loadbalance isp** [**ip** *ipv4-address* | **ipv6** *ipv6-address* | **name** *isp-name*]
Display LB policy information.	**display loadbalance policy** [**name** *policy-name*]
Display proximity entry information.	**display loadbalance proximity** [**vpn-instance** *vpn-instance-name*] [**ip** [*ipv4-address*] | **ipv6** [*ipv6-address*]] [**slot** *slot-number*]
Display parameter profile information.	**display parameter-profile** [**name** *parameter-name*]
Display link information.	**display loadbalance link** [**brief** | **name** *link-name*]
Display link group member information.	**display loadbalance link link-group** *link-group-name* [**name** *link-name*]
Display link statistics.	**display loadbalance link statistics** [**name** *link-name*] [**slot** *slot-number*]
Display link group member statistics.	**display loadbalance link statistics link-group** *link-group-name* [**name** *link-name*] [**slot** *slot-number*]
Display link outbound interface statistics.	**display loadbalance link out-interface statistics** [**name** *link-name*]
Display link group information.	**display loadbalance link-group** [**brief** | **name**

Task	Command
	link-group-name]
Display sticky entry information.	**display sticky virtual-server** [*virtual-server-name*] [**class** *class-name* | **default-class** | **default-link-group**] [**slot** *slot-number*]
Display sticky group information.	**display sticky-group** [**name** *group-name*]
Display virtual server information.	**display virtual-server** [**brief** | **name** *virtual-server-name*]
Display virtual server statistics.	**display virtual-server statistics** [**name** *virtual-server-name*] [**slot** *slot-number*]
Display the ALG status for all protocols.	**display loadbalance alg**
Display DNS cache information.	**display loadbalance dns-cache** [**vpn-instance** *vpn-instance-name*] [**domain-name** *domain-name*] [**slot** *slot-number*]
Clear LB hot backup statistics.	**reset loadbalance hot-backup statistics**
Clear proximity entry information.	**reset loadbalance proximity** [**vpn-instance** *vpn-instance-name*] [**ip** [*ipv4-address*] | **ipv6** [*ipv6-address*]]
Clear all Layer 7 connections.	**reset loadbalance connections**
Clear link statistics.	**reset loadbalance link statistics** [*link-name*]
Clear link group member statistics.	**reset loadbalance link statistics link-group** *link-group-name* [**name** *link-name*]
Clear virtual server statistics.	**reset virtual-server statistics** [*virtual-server-name*]
Clear DNS cache information.	**reset loadbalance dns-cache** [**vpn-instance** *vpn-instance-name*] [**domain-name** *domain-name*]

Outbound link load balancing configuration examples

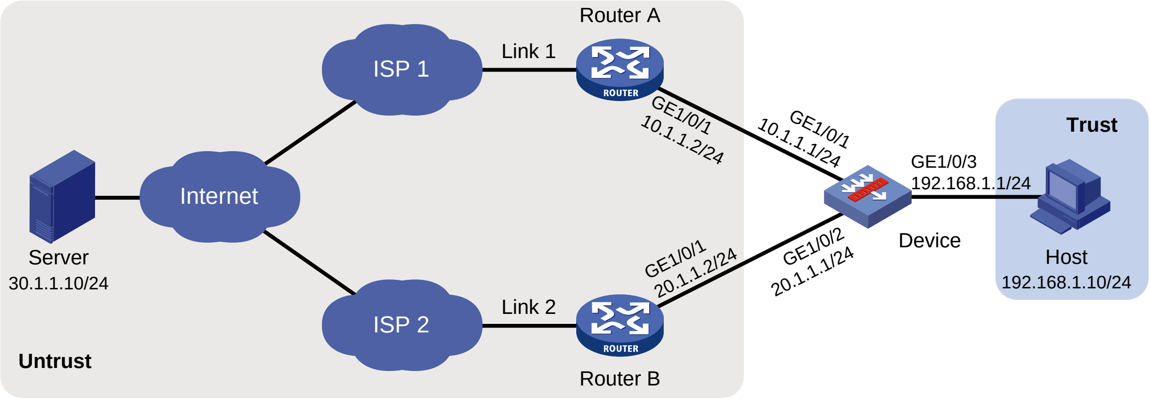
Example: Configuring outbound link load balancing

Network configuration

In Figure 4, ISP 1 and ISP 2 provide two links, Link 1 and Link 2, with the same router hop count, bandwidth, and cost. Link 1 has lower network delay.

Configure link load balancing for the device to select an optimal link for traffic from the client host to the server.

Figure 4 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 10.1.1.1 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [Device] security-zone name untrust
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/1
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Untrust] quit
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/3
   [Device-security-zone-Trust] quit
   ```

3. Configure a security policy:

   Configure rules to permit traffic from the **Trust** security zone to the **Untrust** security zone and traffic from the **Local** security zone to the **Untrust** security zone, so the users can access the server:

   # Configure a rule named **lbrule1** to allow the users to access the server.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name lbrule1
   [Device-security-policy-ip-1-lbrule1] source-zone trust
   [Device-security-policy-ip-1-lbrule1] destination-zone untrust
   [Device-security-policy-ip-1-lbrule1] source-ip-subnet 192.168.1.0 255.255.255.0
   [Device-security-policy-ip-1-lbrule1] action pass
   [Device-security-policy-ip-1-lbrule1] quit
   ```

   # Configure a rule named **lblocalout** to allow the device to send probe packets to the next hop.

   ```
   [Device-security-policy-ip] rule name lblocalout
   [Device-security-policy-ip-2-lblocalout] source-zone local
   [Device-security-policy-ip-2-lblocalout] destination-zone untrust
   [Device-security-policy-ip-2-lblocalout] destination-ip-subnet 10.1.1.0
   255.255.255.0
   ```

```
[Device-security-policy-ip-2-lblocalout] destination-ip-subnet 20.1.1.0
255.255.255.0
[Device-security-policy-ip-2-lblocalout] action pass
[Device-security-policy-ip-2-lblocalout] quit
[Device-security-policy-ip] quit
```

4. Configure a link group:

   # Create the ICMP-type NQA template **t1**, and configure the NQA client to send the probe result to the feature that uses the template on a per-probe basis.

   ```
   [Device] nqa template icmp t1
   [Device-nqatplt-icmp-t1] reaction trigger per-probe
   [Device-nqatplt-icmp-t1] quit
   ```

   # Specify the default proximity probe method as **t1**, and set the network delay weight for proximity calculation to 200.

   ```
   [Device] loadbalance proximity
   [Device-lb-proximity] match default probe t1
   [Device-lb-proximity] rtt weight 200
   [Device-lb-proximity] quit
   ```

   # Create the link group **lg**, and enable the proximity feature.

   ```
   [Device] loadbalance link-group lg
   [Device-lb-lgroup-lg] proximity enable
   ```

   # Disable the NAT feature.

   ```
   [Device-lb-lgroup-lg] transparent enable
   [Device-lb-lgroup-lg] quit
   ```

5. Configure links:

   # Create the link **link1** with next hop address 10.1.1.2, and add it to the link group **lg**.

   ```
   [Device] loadbalance link link1
   [Device-lb-link-link1] router ip 10.1.1.2
   [Device-lb-link-link1] link-group lg
   [Device-lb-link-link1] quit
   ```

   # Create the link **link2** with next hop address 20.1.1.2, and add it to link group **lg**.

   ```
   [Device] loadbalance link link2
   [Device-lb-link-link2] router ip 20.1.1.2
   [Device-lb-link-link2] link-group lg
   [Device-lb-link-link2] quit
   ```

6. Create the link-IP virtual server **vs** with VSIP 0.0.0.0/0, specify its default master link group **lg**, and enable the virtual server.

   ```
   [Device] virtual-server vs type link-ip
   [Device-vs-link-ip-vs] virtual ip address 0.0.0.0 0
   [Device-vs-link-ip-vs] default link-group lg
   [Device-vs-link-ip-vs] service enable
   [Device-vs-link-ip-vs] quit
   ```

Verifying the configuration

# Display brief information about all links.

```
[Device] display loadbalance link brief
Link             Route IP            State        VPN instance   Link group
link1            10.1.1.2            Active                      lg
link2            20.1.1.2            Active                      lg
```

# Display detailed information about all link groups.

```
[Device] display loadbalance link-group
Link group: lg
  Description:
  Predictor: Round robin
  Proximity: Enabled
  NAT: Disabled

```

Configuring transparent DNS proxies

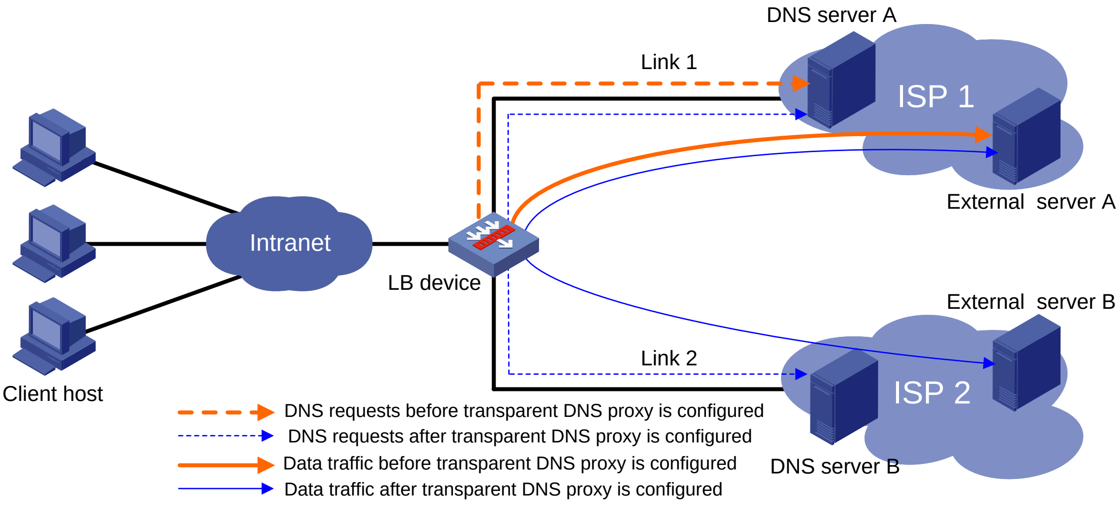
About transparent DNS proxies

Application scenario

As shown in Figure 5, intranet users of an enterprise can access external servers A and B through link 1 of ISP 1 and link 2 of ISP 2. External servers A and B provide the same services. All DNS requests of intranet users are forwarded to DNS server A, which returns the resolved IP address of external server A to the requesting users. In this way, all traffic of intranet users is forwarded on one link. Link congestion might occur.

The transparent DNS proxy feature can solve this problem by forwarding DNS requests to DNS servers in different ISPs. All traffic from intranet users is evenly distributed on multiple links. This feature can prevent link congestion and ensure service continuity upon a link failure.

Figure 5 Transparent DNS proxy working mechanism

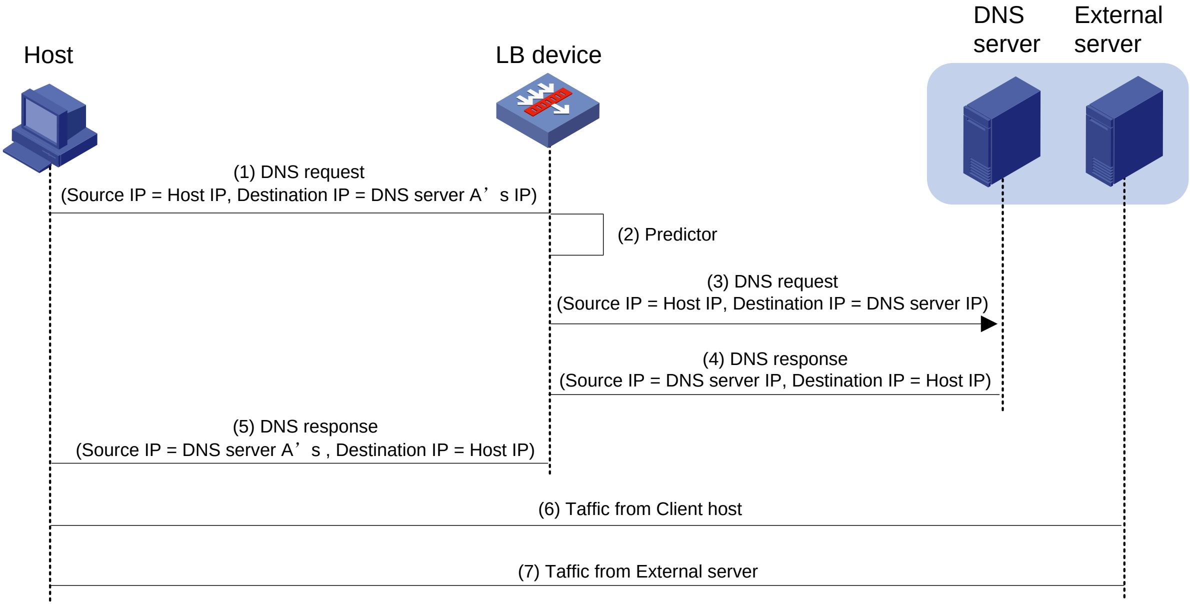


DNS server A
Link 1
ISP 1
External server A
Intranet
LB device
External server B
Link 2
ISP 2
Client host
DNS server B
DNS requests before transparent DNS proxy is configured
DNS requests after transparent DNS proxy is configured
Data traffic before transparent DNS proxy is configured
Data traffic after transparent DNS proxy is configured

Workflow

The transparent DNS proxy is implemented by changing the destination IP address of DNS requests.

Figure 6 Transparent DNS proxy workflow



Host
LB device
DNS server
External server
(1) DNS request
(Source IP = Host IP, Destination IP = DNS server A’ s IP)
(2) Predictor
(3) DNS request
(Source IP = Host IP, Destination IP = DNS server IP)
(4) DNS response
(Source IP = DNS server IP, Destination IP = Host IP)
(5) DNS response
(Source IP = DNS server A’ s , Destination IP = Host IP)
(6) Taffic from Client host
(7) Taffic from External server

Table 1 Workflow description

Step	Source IP address	Destination IP address
1. An intranet user on the client host sends a DNS request to the LB device.	Host IP address	IP address of DNS server A
2. The LB device selects a DNS server to forward the DNS request according to the scheduling algorithm.	N/A	N/A
3. The LB device changes the destination IP address of the DNS request as the IP address of the selected DNS server.	Host IP address	IP address of the selected DNS server
4. The DNS server processes the DNS request and replies with a DNS response.	IP address of the selected DNS server	Host IP address
5. The LB device changes the source IP address of the DNS response as the destination IP address of the DNS request.	IP address of DNS server A	Host IP address
6. The intranet user accesses the external server according to the resolved IP address in the DNS response.	Host IP address	IP address of the external server
7. The external server responds to the intranet user.	IP address of the external server	Host IP address

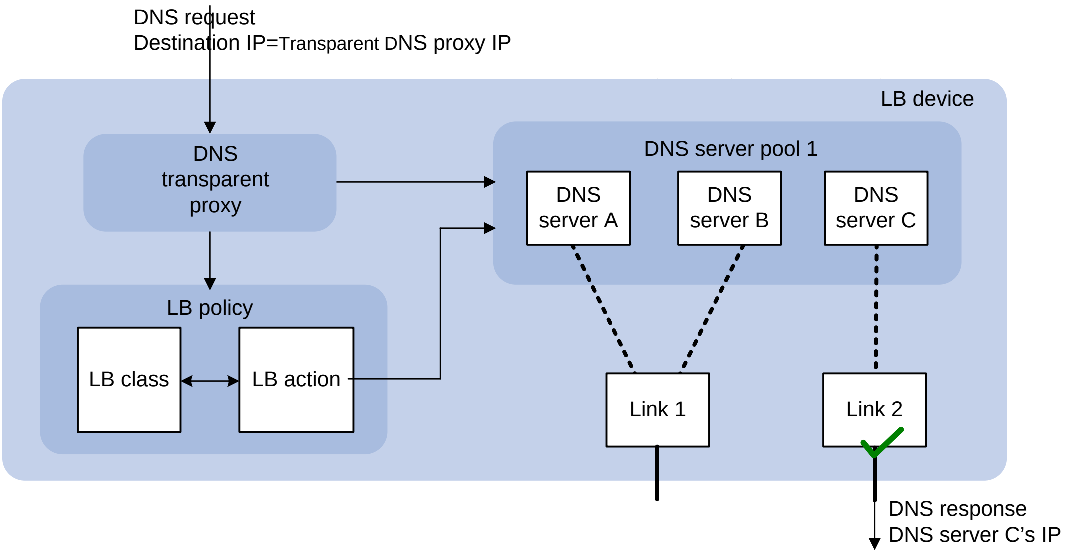
Transparent DNS proxy on the LB device

The LB device distributes DNS requests to multiple links by changing the destination IP address of DNS requests.

As shown in Figure 7, the LB device contains the following elements:

- **Transparent DNS proxy**—The LB device performs transparent DNS proxy for a DNS request only when the port number of the DNS request matches the port number of the transparent DNS proxy.
- **DNS server pool**—A group of DNS servers.
- **DNS server**—Entity that processes DNS requests.
- **Link**—Physical link provided by an ISP.
- **LB class**—Classifies packets to implement load balancing based on packet type.
- **LB action**—Drops, forwards, or modifies packets.
- **LB policy**—Associates an LB class with an LB action. An LB policy can be referenced by the transparent DNS proxy.

Figure 7 Transparent DNS proxy on the LB device



If the destination IP address and port number of a DNS request match those of the transparent DNS proxy, the LB device processes the DNS request as follows:

1. The LB device finds the DNS server pool associated with the transparent DNS proxy.
2. The LB device selects a DNS server according to the scheduling algorithm configured for the DNS server pool.
3. The LB device uses the IP address of the selected DNS server as the destination IP address of the DNS request, and sends the request to the DNS server.
4. The DNS server receives and processes the DNS request, and replies with a DNS response.

   The intranet user can now access the external server after receiving the DNS response.

Transparent DNS proxy tasks at a glance

To configure the transparent DNS proxy feature, perform the following tasks:

1. Configuring a transparent DNS proxy
2. Configuring a DNS server pool
3. Configuring a DNS server
4. Configuring a link
5. (Optional.) Configuring an LB policy
   a. Configuring an LB class

    b. Configuring an LB action
    c. Configuring an LB policy
6. (Optional.) Configuring a sticky group
7. (Optional.) Enabling load balancing logging

Configuring a transparent DNS proxy

By configuring a transparent DNS proxy, you can load balance DNS requests that match the transparent DNS proxy.

Restrictions and guidelines

If both the "Specifying the default DNS server pool" and "Specifying an LB policy" tasks are configured, packets are processed by the LB policy first. If the processing fails, the packets are processed by the default DNS server pool.

Transparent DNS proxy tasks at a glance

To configure a transparent DNS proxy, perform the following tasks:

1. Creating a transparent DNS proxy
2. Specifying an IP address and port number
3. Configuring a packet processing policy
   Choose the following tasks as needed:
   - Specifying the default DNS server pool
   - Specifying an LB policy
4. (Optional.) Specifying a VPN instance
5. (Optional.) Enabling the link protection feature
6. (Optional.) Configuring hot backup
7. Enabling the transparent DNS proxy

Creating a transparent DNS proxy

1. Enter system view.
   `system-view`
2. Create a transparent DNS proxy and enter its view.
   `loadbalance dns-proxy` *`dns-proxy-name`* **`type udp`**

Specifying an IP address and port number

Restrictions and guidelines

As a best practice, configure an all-zero IP address for a transparent DNS proxy. In this case, all DNS requests are processed by the transparent DNS proxy.

Procedure

1. Enter system view.
   `system-view`
2. Enter transparent DNS proxy view.

```
loadbalance dns-proxy dns-proxy-name
```

3. Specify an IP address for the transparent DNS proxy.

   IPv4:

   ```
   ip address ipv4-address [ mask-length | mask ]
   ```

   IPv6:

   ```
   ipv6 address ipv6-address [ prefix-length ]
   ```

   By default, no IP address is specified for a transparent DNS proxy.

4. Specify the port number for the transparent DNS proxy.

   ```
   port port-number
   ```

   By default, the port number is 53 for a transparent DNS proxy.

Specifying the default DNS server pool

1. Enter system view.

   ```
   system-view
   ```

2. Enter transparent DNS proxy view.

   ```
   loadbalance dns-proxy dns-proxy-name
   ```

3. Specify the default DNS server pool for the transparent DNS proxy.

   ```
   default dns-server-pool pool-name [ sticky sticky-name ]
   ```

   By default, no default DNS server pool is specified for a transparent DNS proxy.

Specifying an LB policy

About this task

By referencing an LB policy, the transparent DNS proxy load balances matching DNS requests based on the packet contents. For more information about configuring an LB policy, see "Configuring an LB policy."

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter transparent DNS proxy view.

   ```
   loadbalance dns-proxy dns-proxy-name
   ```

3. Specify an LB policy for the transparent DNS proxy.

   ```
   lb-policy policy-name
   ```

   By default, a transparent DNS proxy does not reference any LB policies.

Specifying a VPN instance

1. Enter system view.

   ```
   system-view
   ```

2. Enter transparent DNS proxy view.

   ```
   loadbalance dns-proxy dns-proxy-name
   ```

3. Specify a VPN instance for the transparent DNS proxy.

   ```
   vpn-instance vpn-instance-name
   ```

   By default, a transparent DNS proxy belongs to the public network.

Enabling the link protection feature

About this task

This feature enables a transparent DNS proxy to select a DNS server based on the link bandwidth ratio. If the bandwidth ratio of a link is exceeded, the DNS server is not selected.

If the traffic volume on the link to a DNS server exceeds the maximum expected bandwidth multiplied by the bandwidth ratio, the DNS server is busy and will not be selected. If the traffic volume drops below the maximum expected bandwidth multiplied by the bandwidth recovery ratio, the DNS server participates in scheduling again. For more information about setting the bandwidth ratio, see "Setting the bandwidth ratio and maximum expected bandwidth."

Procedure

1. Enter system view.

   `system-view`

2. Enter transparent DNS proxy view.

   `loadbalance dns-proxy` *`dns-proxy-name`*

3. Enable the link protection feature.

   `bandwidth busy-protection enable`

   By default, the link protection feature is disabled.

Configuring hot backup

About this task

To implement hot backup for two LB devices, you must enable synchronization for session extension information and sticky entries to avoid service interruption.

Restrictions and guidelines

For successful sticky entry synchronization, if you want to specify a sticky group, enable sticky entry synchronization before specifying a sticky group on both LB devices. You can specify a sticky group by using the **`sticky`** *`sticky-name`* option when specifying the default DNS server pool.

The following configuration changes will cause the device to delete existing sticky entries and generate new ones based on subsequent traffic:

- Disable sticky entry synchronization.
- Change the sticky entry synchronization type.

Procedure

1. Enter system view.

   `system-view`

2. Enter transparent DNS proxy view.

   `loadbalance dns-proxy` *`dns-proxy-name`*

3. Enable session extension information synchronization.

   `connection-sync enable`

   By default, session extension information synchronization is disabled.

4. Enable sticky entry synchronization.

   `sticky-sync enable`

   By default, sticky entry synchronization is disabled.

Enabling the transparent DNS proxy

About this task

After configuring a transparent DNS proxy, you must enable the transparent DNS proxy for it to work.

Procedure

1. Enter system view.
   system-view
2. Enter transparent DNS proxy view.
   loadbalance dns-proxy *dns-proxy-name*
3. Enable the transparent DNS proxy.
   service enable
   By default, a transparent DNS proxy is disabled.

Configuring a DNS server pool

By configuring a DNS server pool, you can perform centralized management on DNS servers that have similar functions.

Creating a DNS server pool

1. Enter system view.
   system-view
2. Create a DNS server pool and enter its view.
   loadbalance dns-server-pool *pool-name*
3. (Optional.) Configure a description for the DNS server pool.
   description *text*
   By default, no description is configured for a DNS server pool.

Adding and configuring a DNS server pool member

About this task

Perform this task to create a DNS server pool member or add an existing DNS server as a DNS server pool member in DNS server pool view. You can also specify a DNS server pool for a DNS server in DNS server view to achieve the same purpose (see "Creating a DNS server and specifying a DNS server pool").

After adding a DNS server pool member, you can configure the following parameters and features for the DNS server in the DNS server pool:

- Weight.
- Priority.
- Health monitoring.

The member-based scheduling algorithm selects the best DNS server based on these configurations.

Adding a DNS server pool member

1. Enter system view.

system-view

2. Enter DNS server pool view.

   loadbalance dns-server-pool *pool-name*

3. Create and add a DNS server pool member and enter DNS server pool member view.

   dns-server *dns-server-name* **port** *port-number*

   If the DNS server already exists, the command adds the existing DNS server as a DNS server pool member.

4. (Optional.) Configure a description for the DNS server pool member.

   description *text*

   By default, no description is configured for the DNS server pool member.

Setting the weight and priority of the DNS server pool member

1. Enter system view.

   system-view

2. Enter DNS server pool view.

   loadbalance dns-server-pool *pool-name*

3. Enter DNS server pool member view.

   dns-server *dns-server-name* **port** *port-number*

4. Set the weight of the DNS server pool member.

   weight *weight-value*

   The default setting is 100.

5. Set the priority of the DNS server pool member.

   priority *priority*

   The default setting is 4.

Configuring health monitoring for the DNS server pool member

1. Enter system view.

   system-view

2. Enter DNS server pool view.

   loadbalance dns-server-pool *pool-name*

3. Enter DNS server pool member view.

   dns-server *dns-server-name* **port** *port-number*

4. Specify a health monitoring method for the DNS server pool member.

   probe *template-name*

   By default, no health monitoring method is specified for the DNS server pool member.

   You can specify an NQA template for health monitoring. For information about NQA templates, see NQA configuration in *Network Management and Monitoring Configuration Guide*.

5. Specify the health monitoring success criteria for the DNS server pool member.

   success-criteria { **all** | **at-least** *min-number* }

   By default, health monitoring succeeds only when all the specified health monitoring methods succeed.

Configuring a scheduling algorithm for a DNS server pool

About this task

Perform this task to specify a scheduling algorithm for a DNS server pool and specify the number of DNS servers to participate in scheduling. The LB device calculates the DNS servers to process DNS requests based on the following scheduling algorithms:

- **Source IP address hash algorithm**—Hashes the source IP address of DNS requests and distributes DNS requests to different DNS servers according to the hash values. This hash algorithm ensures that DNS requests with the same source IP address are distributed to the same DNS server.
- **Source IP address and port hash algorithm**—Hashes the source IP address and port number of DNS requests and distributes DNS requests to different DNS servers according to the hash values. This hash algorithm ensures that DNS requests with the same source IP address and port number are distributed to the same DNS server.
- **Destination IP address hash algorithm**—Hashes the destination IP address of DNS requests and distributes DNS requests to different DNS servers according to the hash values. This hash algorithm ensures that DNS requests with the same destination IP address are distributed to the same DNS server.
- **Random algorithm**—Distributes DNS requests to DNS servers randomly.
- **Weighted round-robin algorithm**—Distributes DNS requests to DNS servers in a round-robin manner according to the weights of DNS servers. For example, you can assign weight values 2 and 1 to DNS server A and DNS server B, respectively. This algorithm distributes two DNS requests to DNS server A and then distributes one DNS request to DNS server B. This algorithm applies to scenarios where DNS servers have different performance and bear similar load for each session.
- **Bandwidth algorithm**—Distributes DNS requests to DNS servers according to the weights and remaining bandwidths of DNS servers. When the remaining bandwidths of two DNS servers are the same, this algorithm is equivalent to the round-robin algorithm. When the weights of two DNS servers are the same, this algorithm always distributes DNS requests to the DNS server that has larger remaining bandwidth.
- **Maximum bandwidth algorithm**—Distributes DNS requests always to an idle DNS server that has the largest remaining bandwidth.

Procedure

1. Enter system view.

   system-view

2. Enter DNS server pool view.

   loadbalance dns-server-pool *pool-name*

3. Specify a scheduling algorithm for the DNS server pool.

   predictor hash address { **destination** | **source** | **source-ip-port** } [**mask** *mask-length*] [**prefix** *prefix-length*]

   predictor { **random** | **round-robin** | { **bandwidth** | **max-bandwidth** } [**inbound** | **outbound**] }

   By default, the scheduling algorithm for a DNS server pool is weighted round robin.

4. Specify the number of DNS servers to participate in scheduling.

   selected-server min *min-number* **max** *max-number*

   By default, the DNS servers with the highest priority participate in scheduling.

Configuring health monitoring

About this task

Perform this task to enable health monitoring to detect the availability of DNS servers in a DNS server pool.

Restrictions and guidelines

The health monitoring configuration in DNS server view takes precedence over the configuration in DNS server pool view.

You can specify an NQA template for health monitoring. For information about NQA templates, see NQA configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter DNS server pool view.

   `loadbalance dns-server-pool` *`pool-name`*

3. Specify a health monitoring method for the DNS server pool.

   `probe` *`template-name`*

   By default, no health monitoring method is specified for a DNS server pool.

4. Specify the health monitoring success criteria for the DNS server pool.

   `success-criteria` { **`all`** | **`at-least`** *`min-number`* }

   By default, health monitoring succeeds only when all the specified health monitoring methods succeed.

Configuring a DNS server

Perform this task to configure an entity on the LB device for processing DNS requests. DNS servers configured on the LB device correspond to DNS servers in ISP networks. A DNS server can belong to multiple DNS server pools. A DNS server pool can contain multiple DNS servers.

DNS server tasks at a glance

To configure a DNS server, perform the following tasks:

1. Creating a DNS server and specifying a DNS server pool
2. Configuring an IP address for a DNS server

   Choose one of the following tasks:

   - Specifying an IP address and port number
   - Enabling the device to automatically obtain the IP address of a DNS server
3. Specifying a VPN instance
4. Associating a link with a DNS server
5. (Optional.) Setting a weight and priority
6. (Optional.) Configuring health monitoring

Creating a DNS server and specifying a DNS server pool

1. Enter system view.

system-view

2. Create a DNS server and enter its view.

   loadbalance dns-server *dns-server-name*

3. (Optional.) Configure a description for the DNS server.

   description *text*

   By default, no description is configured for a DNS server.

4. Specify a DNS server pool for the DNS server.

   dns-server-pool *pool-name*

   By default, a DNS server does not belong to any DNS server pool.

Specifying an IP address and port number

1. Enter system view.

   system-view

2. Enter DNS server view.

   loadbalance dns-server *dns-server-name*

3. Specify an IP address for the DNS server.

   IPv4:

   ip address *ipv4-address*

   IPv6:

   ipv6 address *ipv6-address*

   By default, no IP address is specified for a DNS server.

4. Specify the port number for the DNS server.

   port *port-number*

   By default, the port number of a DNS server is 0. Packets use their own port numbers.

Specifying a VPN instance

1. Enter system view.

   system-view

2. Enter DNS server view.

   loadbalance dns-server *dns-server-name*

3. Specify a VPN instance for the DNS server.

   vpn-instance *vpn-instance-name*

   By default, a DNS server belongs to the public network.

Enabling the device to automatically obtain the IP address of a DNS server

About this task

In scenarios where IP addresses are obtained through PPPoE, an LB device can dynamically obtain the IP address of a DNS server.

Before configuring this task, you must specify the outgoing interface for the link associated with the DNS server. Otherwise, the IP address of the DNS server cannot be obtained.

Procedure

1. Enter system view.

   `system-view`

2. Enter DNS server view.

   `loadbalance dns-server` *`dns-server-name`*

3. Enable the device to automatically obtain the IP address of the DNS server.

   `auto-alloc address`

   By default, the device does not automatically obtain the IP address of a DNS server.

Associating a link with a DNS server

Restrictions and guidelines

A DNS server can be associated with only one link. A link can be associated with multiple DNS servers.

Procedure

1. Enter system view.

   `system-view`

2. Enter DNS server view.

   `loadbalance dns-server` *`dns-server-name`*

3. Associate a link with the DNS server.

   `link` *`link-name`*

   By default, no link is associated with a DNS server.

Setting a weight and priority

About this task

Perform this task to set a weight for the weighted round robin algorithm and bandwidth algorithm of a DNS server, and set the scheduling priority in the DNS server pool for the DNS server.

Procedure

1. Enter system view.

   `system-view`

2. Enter DNS server view.

   `loadbalance dns-server` *`dns-server-name`*

3. Set a weight for the DNS server.

   `weight` *`weight-value`*

   By default, the weight of a DNS server is 100.

4. Set a priority for the DNS server.

   `priority` *`priority`*

   By default, the priority of a DNS server is 4.

Configuring health monitoring

About this task

Perform this task to enable health monitoring to detect the availability of a DNS server.

Restrictions and guidelines

The health monitoring configuration in DNS server view takes precedence over the configuration in DNS server pool view.

Procedure

1. Enter system view.

   system-view

2. Enter DNS server view.

   loadbalance dns-server *dns-server-name*

3. Specify a health monitoring method for the DNS server.

   probe *template-name*

   By default, no health monitoring method is specified for a DNS server.

4. Specify the health monitoring success criteria for the DNS server.

   success-criteria { **all** | **at-least** *min-number* }

   By default, health monitoring succeeds only when all the specified health monitoring methods succeed.

Configuring a link

A link is a physical link provided by an ISP. You can guide traffic forwarding by specifying an outbound next hop for a link. You can enhance link performance by configuring the maximum bandwidth, health monitoring, bandwidth ratio, and maximum expected bandwidth.

Link tasks at a glance

To configure a link, perform the following tasks:

1. Creating a link
2. Specifying a next hop IP address or an outgoing interface

   Choose one of the following tasks:

   - Specifying an outbound next hop for a link
   - Specifying an outgoing interface for a link
3. (Optional.) Specifying a VPN instance
4. (Optional.) Configuring the maximum bandwidth
5. (Optional.) Configuring health monitoring
6. (Optional.) Setting the bandwidth ratio and maximum expected bandwidth

Creating a link

1. Enter system view.

   system-view

2. Create a link and enter link view.

   loadbalance link *link-name*

3. (Optional.) Configure a description for the link.

   description *text*

   By default, no description is configured for a link.

Specifying an outbound next hop for a link

1. Enter system view.

   system-view

2. Enter link view.

   loadbalance link *link-name*

3. Specify an outbound next hop for the link.

   IPv4:

   router ip *ipv4-address*

   IPv6:

   router ipv6 *ipv6-address*

   By default, no outbound next hop is specified for a link.

Specifying an outgoing interface for a link

About this task

In scenarios where IP addresses are obtained through PPPoE, an LB device can dynamically obtain the outbound next hop IP address through the specified outgoing interface.

Procedure

1. Enter system view.

   system-view

2. Enter link view.

   loadbalance link *link-name*

3. Specify an outgoing interface for the link.

   router interface *interface-type interface-number*

   By default, no outgoing interface is specified for a link.

Specifying a VPN instance

1. Enter system view.

   system-view

2. Enter link view.

   loadbalance link *link-name*

3. Specify a VPN instance for the link.

   vpn-instance *vpn-instance-name*

   By default, a link belongs to the public network.

Configuring the maximum bandwidth

1. Enter system view.

   system-view

2. Enter link view.

   loadbalance link *link-name*

3. Set the maximum bandwidth for the link.

rate-limit bandwidth [**inbound** | **outbound**] *bandwidth-value* **kbps**

By default, the maximum bandwidth for a link is not limited.

Configuring health monitoring

About this task

Perform this task to enable health monitoring to detect the availability of a link.

Procedure

1. Enter system view.

   system-view
2. Enter link view.

   loadbalance link *link-name*
3. Specify a health monitoring method for the link.

   probe *template-name*

   By default, no health monitoring method is specified for a link.
4. Specify the health monitoring success criteria for the link.

   success-criteria { **all** | **at-least** *min-number* }

   By default, the health monitoring succeeds only when all the specified health monitoring methods succeed.

Setting the bandwidth ratio and maximum expected bandwidth

About this task

When the traffic exceeds the maximum expected bandwidth multiplied by the bandwidth ratio of a link, new traffic (traffic that does not match any sticky entries) is not distributed to the link. When the traffic drops below the maximum expected bandwidth multiplied by the bandwidth recovery ratio of the link, the link participates in scheduling again.

In addition to being used for link protection, the maximum expected bandwidth is used for remaining bandwidth calculation in the bandwidth algorithm and maximum bandwidth algorithm.

Procedure

1. Enter system view.

   system-view
2. Enter link view.

   loadbalance link *link-name*
3. Set the bandwidth ratio.

   bandwidth [**inbound** | **outbound**] **busy-rate** *busy-rate-number* [**recovery** *recovery-rate-number*]

   By default, the total bandwidth ratio is 70.
4. Set the maximum expected bandwidth.

   max-bandwidth [**inbound** | **outbound**] *bandwidth-value* **kbps**

   By default, the maximum expected bandwidth is not limited.

Configuring an LB class

An LB class classifies packets by comparing packets against specific rules. Matching packets are further processed by LB actions. You can create a maximum of 65535 rules for an LB class.

LB class tasks at a glance

To configure an LB class, perform the following tasks:

1. Creating an LB class
2. Creating a match rule

   Choose the following tasks as needed:

   - Creating a match rule that references an LB class
   - Creating a source IP address match rule
   - Creating a destination IP address match rule
   - Creating an ACL match rule
   - Creating a domain name match rule

Creating an LB class

1. Enter system view.

   system-view
2. Create a DNS LB class, and enter LB class view.

   loadbalance class *class-name* **type dns** [**match-all** | **match-any**]

   When you create an LB class, you must specify the class type. You can enter an existing LB class view without specifying the class type. If you specify the class type when entering an existing LB class view, the class type must be the one specified when you create the LB class.
3. (Optional.) Configure a description for the LB class.

   description *text*

   By default, no description is configured for an LB class.

Creating a match rule that references an LB class

1. Enter system view.

   system-view
2. Enter LB class view.

   loadbalance class *class-name*
3. Create a match rule that references an LB class.

   match [*match-id*] **class** *class-name*

Creating a source IP address match rule

1. Enter system view.

   system-view
2. Enter LB class view.

   loadbalance class *class-name*

3. Create a source IP address match rule.

   match [*match-id*] **source** { **ip address** *ipv4-address* [*mask-length* | *mask*] | **ipv6 address** *ipv6-address* [*prefix-length*] }

Creating a destination IP address match rule

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create a destination IP address match rule.

   match [*match-id*] **destination** { **ip address** *ipv4-address* [*mask-length* | *mask*] | **ipv6 address** *ipv6-address* [*prefix-length*] }

Creating an ACL match rule

Restrictions and guidelines

If the specified ACL does not exist, the ACL match rule does not take effect.

Procedure

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create an ACL match rule.

   match [*match-id*] **acl** [**ipv6**] { *acl-number* | **name** *acl-name* }

   By default, an LB class does not have any match rules.

Creating a domain name match rule

1. Enter system view.

   system-view

2. Enter LB class view.

   loadbalance class *class-name*

3. Create a domain name match rule.

   match [*match-id*] **domain-name** *domain-name*

Configuring an LB action

About LB actions

LB actions include the following modes:

- **Forwarding mode**—Determines whether and how to forward packets. If no forwarding action is specified, packets are dropped.
- **Modification mode**—Modifies packets. To prevent the LB device from dropping the modified packets, the modification action must be used together with a forwarding action.

If you create an LB action without specifying any of the previous action modes, packets are dropped.

Restrictions and guidelines

The following tasks are mutually exclusive:

- Configuring the forwarding mode
- Specifying a DNS server pool for guiding packet forwarding
- Skipping the current transparent DNS proxy

Configuring one task automatically cancels the other task that you have configured.

LB action tasks at a glance

To configure an LB action, perform the following tasks:

1. Creating an LB action
2. (Optional.) Configuring a forwarding LB action
   - Configuring the forwarding mode
   - Specifying a DNS server pool for guiding packet forwarding
   - Skipping the current transparent DNS proxy
   - Matching the next rule upon failure to find a DNS server
   - (Optional.) Matching the next rule when all DNS servers are busy
3. (Optional.) Configuring a modification LB action
   - Configuring the ToS field in IP packets sent to the DNS server

Creating an LB action

1. Enter system view.

   `system-view`

2. Create a DNS LB action and enter LB action view.

   `loadbalance action` *`action-name`* **`type dns`**

   When you create an LB action, you must specify the action type. You can enter an existing LB action view without specifying the action type. If you specify the action type when entering an existing LB action view, the action type must be the one specified when you create the LB action.

3. (Optional.) Configure a description for the LB action.

   `description` *`text`*

   By default, no description is configured for an LB action.

Configuring a forwarding LB action

About this task

Three forwarding LB action types are available:

- **Forward**—Forwards matching packets.
- Specify a DNS server pool for guiding packet forwarding.
- **Skip the current transparent DNS proxy**—Skips the current transparent DNS proxy and match the next transparent DNS proxy or virtual server.

- **Match the next rule upon failure to find a DNS server**—If the device fails to find a DNS server according to the LB action, it matches the packet with the next rule in the LB policy.
- Match the next rule when all DNS servers are busy.

Configuring the forwarding mode

1. Enter system view.

   `system-view`

2. Enter DNS LB action view.

   `loadbalance action` *`action-name`*

3. Configure the forwarding mode.

   `forward all`

   By default, the forwarding mode is to discard packets.

   This command does not apply to SIP virtual servers.

Specifying a DNS server pool for guiding packet forwarding

1. Enter system view.

   `system-view`

2. Enter DNS LB action view.

   `loadbalance action` *`action-name`*

3. Specify a DNS server pool for guiding packet forwarding.

   `dns-server-pool` *`pool-name`* [**`sticky`** *`sticky-name`*]

   By default, no DNS server pool is specified for guiding packet forwarding.

Skipping the current transparent DNS proxy

1. Enter system view.

   `system-view`

2. Enter DNS LB action view.

   `loadbalance action` *`action-name`*

3. Skip the current transparent DNS proxy.

   `skip current-dns-proxy`

   By default, the forwarding mode is to discard packets.

Matching the next rule upon failure to find a DNS server

1. Enter system view.

   `system-view`

2. Enter DNS LB action view.

   `loadbalance action` *`action-name`*

3. Match the next rule upon failure to find a DNS server.

   `fallback-action continue`

   By default, the next rule is not matched (packets are dropped) when no DNS servers are available for an LB action.

Matching the next rule when all DNS servers are busy

1. Enter system view.

   `system-view`

2. Enter LB action view.

   `loadbalance action` *`action-name`*

3. Match the next rule when all DNS servers are busy.

   ```
   busy-action continue
   ```

   By default, the device assigns DNS requests to DNS servers regardless of whether they are busy.

Configuring the ToS field in IP packets sent to the DNS server

1. Enter system view.

   ```
   system-view
   ```

2. Enter DNS LB action view.

   ```
   loadbalance action action-name
   ```

3. Configure the ToS field in IP packets sent to the DNS server.

   ```
   set ip tos tos-number
   ```

   By default, the ToS field in IP packets sent to the DNS server is not changed.

Configuring an LB policy

LB policy tasks at a glance

To configure an LB policy, perform the following tasks:

1. Creating an LB policy
2. Specifying an LB action
3. Specifying the default LB action

Creating an LB policy

1. Enter system view.

   ```
   system-view
   ```

2. Create a DNS LB policy and enter LB action view.

   ```
   loadbalance policy policy-name type dns
   ```

   When you create an LB policy, you must specify the policy type. You can enter an existing LB policy view without specifying the policy type. If you specify the policy type when entering an existing LB policy view, the policy type must be the one specified when you create the LB policy.

3. (Optional.) Configure a description for the LB policy.

   ```
   description text
   ```

   By default, no description is configured for an LB policy.

Specifying an LB action

Restrictions and guidelines

A DNS LB policy can reference only DNS LB classes and DNS LB actions.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter DNS LB policy view.

   loadbalance policy *policy-name*

3. Specify an LB action for an LB class.

   class *class-name* [**insert-before** *before-class-name* | **insert-after** [*after-class-name*]] **action** *action-name*

   By default, no LB action is specified for an LB class.

Specifying the default LB action

Restrictions and guidelines

The default LB action takes effect on packets that do not match any LB classes.

A DNS LB policy can reference only a DNS LB action as the default LB action.

Procedure

1. Enter system view.

   system-view

2. Enter DNS LB policy view.

   loadbalance policy *policy-name*

3. Specify the default LB action.

   default-class action *action-name*

   By default, no default LB action is specified.

Configuring a sticky group

A sticky group uses a sticky method to distribute similar sessions to the same DNS server according to sticky entries. The sticky method applies to the first packet of a session. Other packets of the session are distributed to the same DNS server.

Sticky group tasks at a glance

To configure a sticky group, perform the following tasks:

1. Creating a sticky group
2. Configuring the IP sticky method
3. (Optional.) Configuring the timeout time for sticky entries

Creating a sticky group

1. Enter system view.

   system-view

2. Create an address- and port-type sticky group and enter sticky group view.

   sticky-group *group-name* **type address-port**

   When you create a sticky group, you must specify the group type. You can enter an existing sticky group view without specifying the group type. If you specify the group type when entering an existing sticky group view, the group type must be the one specified when you create the sticky group.

3. (Optional.) Configure a description for the sticky group.

   description *text*

By default, no description is configured for a sticky group.

Configuring the IP sticky method

1. Enter system view.

   system-view

2. Enter sticky group view.

   sticky-group *group-name*

3. Configure the IP sticky method.

   IPv4:

   ip [**port**] { **both** | **destination** | **source** } [**mask** *mask-length*]

   IPv6:

   ipv6 [**port**] { **both** | **destination** | **source** } [**prefix** *prefix-length*]

   By default, no IP sticky method is configured.

Configuring the timeout time for sticky entries

1. Enter system view.

   system-view

2. Enter sticky group view.

   sticky-group *group-name*

3. Configure the timeout time for sticky entries.

   timeout *timeout-value*

   By default, the timeout time for sticky entries is 60 seconds.

Enabling load balancing logging

About load balancing logging

For security auditing purposes, enable load balancing logging to record load balancing information. Load balancing logging includes NAT logging and link busy state logging.

NAT logging records NAT session information, including IP address and port translation information and access information.

Link busy state logging records busy states for all links.

Enabling load balancing NAT logging

1. Enter system view.

   system-view

2. Enable load balancing NAT logging.

   loadbalance log enable nat

   By default, load balancing NAT logging is disabled.

Enabling load balancing link busy state logging

1. Enter system view.
   system-view
2. Enable load balancing link busy state logging.
   loadbalance log enable bandwidth-busy
   By default, load balancing link busy state logging is disabled.

Displaying and maintaining transparent DNS proxy

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display DNS server pool information.	**display loadbalance dns-server-pool** [**brief** | **name** *pool-name*]
Display DNS server information.	**display loadbalance dns-server** [**brief** | **name** dns-*server-name*]
Display DNS server pool member information.	**display loadbalance dns-server dns-server-pool** *dns-server-pool-name* [**name** *dns-server-name* **port** *port-number*]
Display DNS server statistics.	**display loadbalance dns-server statistics** [**name** *dns-server-name*] [**slot** *slot-number*]
Display DNS server pool member statistics.	**display loadbalance dns-server statistics dns-server-pool** *dns-server-pool-name* [**name** *dns-server-name* **port** *port-number*] [**slot** *slot-number*]
Display transparent DNS proxy information.	**display loadbalance dns-proxy** [**brief** | **name** *dns-proxy-name*]
Display transparent DNS proxy statistics.	**display loadbalance dns-proxy statistics** [**name** *dns-proxy-name*] [**slot** *slot-number*]
Display link information.	**display loadbalance link** [**brief** | **name** *link-name*]
Display link statistics.	**display loadbalance link statistics** [**name** *link-name*] [**slot** *slot-number*]
Display LB class information.	**display loadbalance class** [**name** *class-name*]
Display LB action information.	**display loadbalance action** [**name** *action-name*]
Display LB policy information.	**display loadbalance policy** [**name** *policy-name*]
Display sticky entry information for transparent DNS proxies.	**display sticky dns-proxy** [**dns-proxy-name** *dns-proxy-name*] [**class** { *class-name* | **default-class** } | **client-addr** { *ipv4-address*

Task	Command
	| *ipv6-address* } | **dns-server-addr** { *ipv4-address* | *ipv6-address* } | **dns-server-pool** *pool-name* | **dns-server-port** *port-number* | **key** *sticky-key*] * [**brief**] **display sticky dns-proxy** [**dns-proxy-name** *dns-proxy-name*] [**class** { *class-name* | **default-class** } | **client-addr** { *ipv4-address* | *ipv6-address* } | **dns-server-addr** { *ipv4-address* | *ipv6-address* } | **dns-server-pool** *pool-name* | **dns-server-port** *port-number* | **key** *sticky-key*] * [**brief**] [**slot** *slot-number*]
Display sticky entry information for transparent DNS proxies.	**display sticky dns-proxy** [*dns-proxy-name*] [**class** *class-name* | **default-class** | **default-dns-server-pool**] [**slot** *slot-number*]
Display sticky group information.	**display sticky-group** [**name** *group-name*]
Display LB hot backup statistics.	**display loadbalance hot-backup statistics** [**slot** *slot-number*]
Clear DNS server statistics.	**reset loadbalance dns-server statistics** [*dns-server-name*]
Clear DNS server pool member statistics.	**reset loadbalance dns-server statistics dns-server-pool** *dns-server-pool-name* [**name** *dns-server-name* **port** *port-number*]
Clear transparent DNS proxy statistics.	**reset loadbalance dns-proxy statistics** [*dns-proxy-name*]
Clear link statistics.	**reset loadbalance link statistics** [*link-name*]
Clear LB hot backup statistics.	**reset loadbalance hot-backup statistics**
Clear sticky entry information for transparent DNS proxies.	**reset sticky dns-proxy** [**dns-proxy-name** *dns-proxy-name*] [**class** { *class-name* | **default-class** } | **client-addr** { *ipv4-address* | *ipv6-address* } | **dns-server-addr** { *ipv4-address* | *ipv6-address* } | **dns-server-pool** *pool-name* | **dns-server-port** *port-number* | **key** *sticky-key*] * **reset sticky dns-proxy** [**dns-proxy-name** *dns-proxy-name*] [**class** { *class-name* | **default-class** } | **client-addr** { *ipv4-address* | *ipv6-address* } | **dns-server-addr** { *ipv4-address* | *ipv6-address* } | **dns-server-pool** *pool-name* | **dns-server-port** *port-number* | **key** *sticky-key*] * [**slot** *slot-number*]

Transparent DNS proxy configuration examples

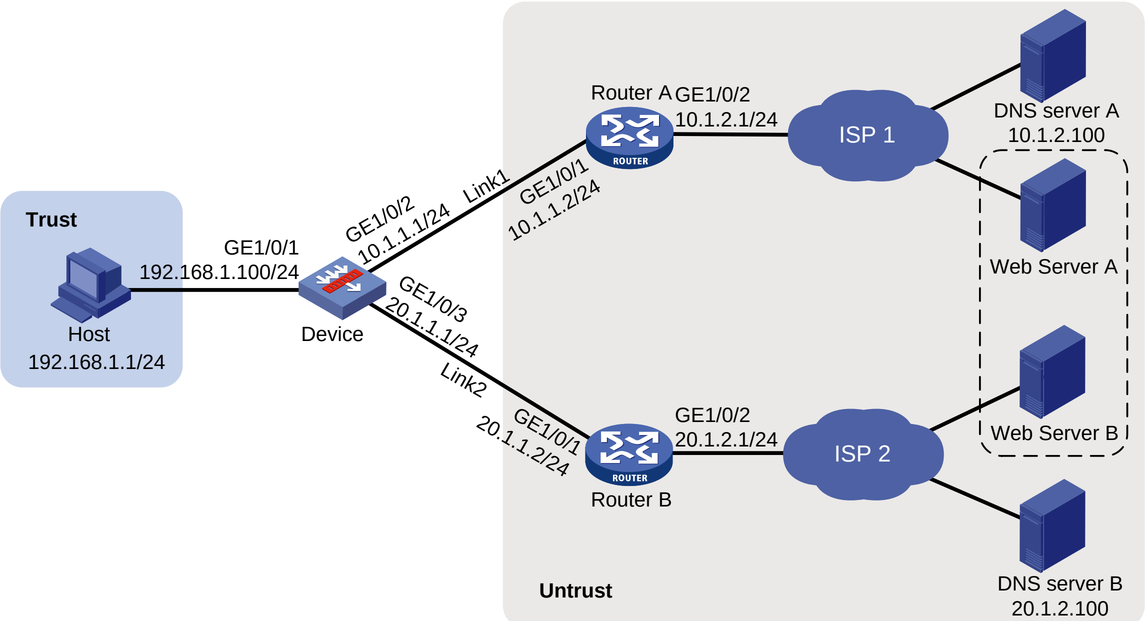
Example: Configuring transparent DNS proxy

Network configuration

In Figure 8, ISP 1 and ISP 2 provide two links with the same bandwidth: Link 1 and Link 2. The IP address of the DNS server of ISP 1 is 10.1.2.100. The IP address of the DNS server of ISP 2 is 20.1.2.100. Intranet users use domain name **www.abc.com** to access Web server A and Web server B.

Configure a transparent DNS proxy on the device to evenly distribute user traffic to Link 1 and Link 2.

Figure 8 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.100 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/1
   [Device-security-zone-Trust] quit
   [Device] security-zone name untrust
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/3
   [Device-security-zone-Untrust] quit
   ```

3. Configure a security policy:

Configure rules to permit traffic from the **Trust** security zone to the **Untrust** security zone and traffic from the **Local** security zone to the **Untrust** security zone, so the users can access the server:

# Configure a rule named **lbrule1** to allow the users to access the server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name lbrule1
[Device-security-policy-ip-1-lbrule1] source-zone trust
[Device-security-policy-ip-1-lbrule1] destination-zone untrust
[Device-security-policy-ip-1-lbrule1] source-ip-subnet 192.168.1.0 255.255.255.0
[Device-security-policy-ip-1-lbrule1] action pass
[Device-security-policy-ip-1-lbrule1] quit
```

# Configure a rule named **lblocalout** to allow the device to send probe packets to the next hop.

```
[Device-security-policy-ip] rule 2 name lblocalout
[Device-security-policy-ip-2-lblocalout] source-zone local
[Device-security-policy-ip-2-lblocalout] destination-zone untrust
[Device-security-policy-ip-2-lblocalout] destination-ip-subnet 10.1.1.0
255.255.255.0
[Device-security-policy-ip-2-lblocalout] destination-ip-subnet 20.1.1.0
255.255.255.0
[Device-security-policy-ip-2-lblocalout] action pass
[Device-security-policy-ip-2-lblocalout] quit
[Device-security-policy-ip] quit
```

4. Configure links:

# Create the link **link1** with next hop address 10.1.1.2.

```
[Device] loadbalance link link1
[Device-lb-link-link1] router ip 10.1.1.2
[Device-lb-link-link1] quit
```

# Create the link **link2** with next hop address 20.1.1.2.

```
[Device] loadbalance link link2
[Device-lb-link-link2] router ip 20.1.1.2
[Device-lb-link-link2] quit
```

5. Create a DNS server pool named **dsp**.

```
[Device] loadbalance dns-server-pool dsp
[Device-lb-dspool-dsp] quit
```

6. Configure DNS servers:

# Create a DNS server named **ds1**, configure its IP address as 10.1.2.100, assign it to DNS server pool **dsp**, and associate it with link **link1**.

```
[Device] loadbalance dns-server ds1
[Device-lb-ds-ds1] ip address 10.1.2.100
[Device-lb-ds-ds1] dns-server-pool dsp
[Device-lb-ds-ds1] link link1
[Device-lb-ds-ds1] quit
```

# Create a DNS server named **ds2**, configure its IP address as 20.1.2.100, assign it to DNS server pool **dsp**, and associate it with link **link2**.

```
[Device] loadbalance dns-server ds2
[Device-lb-ds-ds2] ip address 20.1.2.100
[Device-lb-ds-ds2] dns-server-pool dsp
[Device-lb-ds-ds2] link link2
[Device-lb-ds-ds2] quit
```

7. Configure a transparent DNS proxy:

   # Create a UDP transparent DNS proxy named **dns-proxy1**, configure its IP address as 0.0.0.0, specify DNS server pool **dsp** as its default DNS server pool, and enable the transparent DNS proxy.

```
[Device] loadbalance dns-proxy dns-proxy1 type udp
[Device-lb-dp-udp-dp] ip address 0.0.0.0 0
[Device-lb-dp-udp-dp] default dns-server-pool dsp
[Device-lb-dp-udp-dp] service enable
[Device-lb-dp-udp-dp] quit
```

Verifying the configuration

# Display brief information about all DNS servers.

```
[Device] display loadbalance dns-server brief
DNS server  Address         Port   Link       State      DNS server pool
ds1         10.1.2.100      0      link1      Active     dsp
ds2         20.1.2.100      0      link2      Active     dsp
```

# Display detailed information about all DNS server pools.

```
[Device] display loadbalance dns-server-pool
DNS server pool: dsp
  Description:
  Predictor: Round robin
  Selected server: Disabled
  Probe information:
    Probe success criteria: All
    Probe method:
  Total DNS servers: 2
  Active DNS servers: 2
  DNS server list:
  Name        State         Address         port   Link      Weight   Priority
  ds1         Active        10.1.2.100      0      link1     100      4
  ds2         Active        20.1.2.100      0      link2     100      4
```

# Display detailed information about all transparent DNS proxies.

```
[Device] display loadbalance dns-proxy
DNS proxy: dns-proxy1
  Type: UDP
  State: Active
  Service state: Enabled
  VPN instance:
  IPv4 address: 1.1.1.0/24
  IPv6 address: --
  Port: 53
  DNS server pool: dsp
  Sticky:
  LB policy:
  Connection synchronization: Enabled
  Sticky synchronization: Enabled
  Bandwidth busy protection: Disabled
```

After you complete the previous configuration, the LB device can evenly distribute DNS requests to DNS server A and DNS server B. Then, intranet user traffic is evenly distributed to Link 1 and Link 2.

Configuring inbound link load balancing

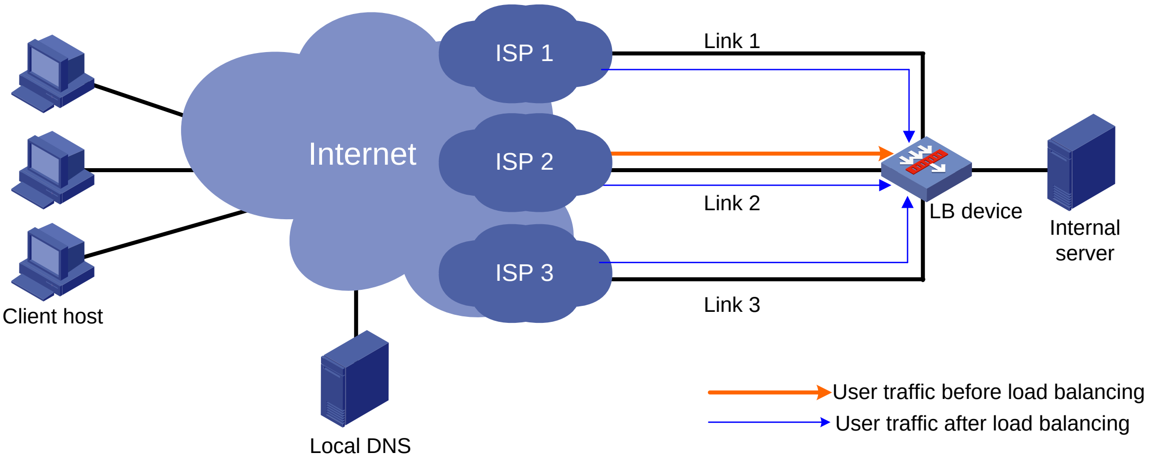
About inbound link load balancing

Inbound link load balancing load balances traffic among the links from the external network to the internal network.

Application scenario

As shown in Figure 9, an enterprise provides services for extranet users through link 1 of ISP 1, link 2 of ISP 2, and link 3 of ISP 3. Inbound link load balancing evenly distributes traffic from extranet users to the internal server on multiple links. This feature can prevent link congestion and implement link switchover upon a link failure.

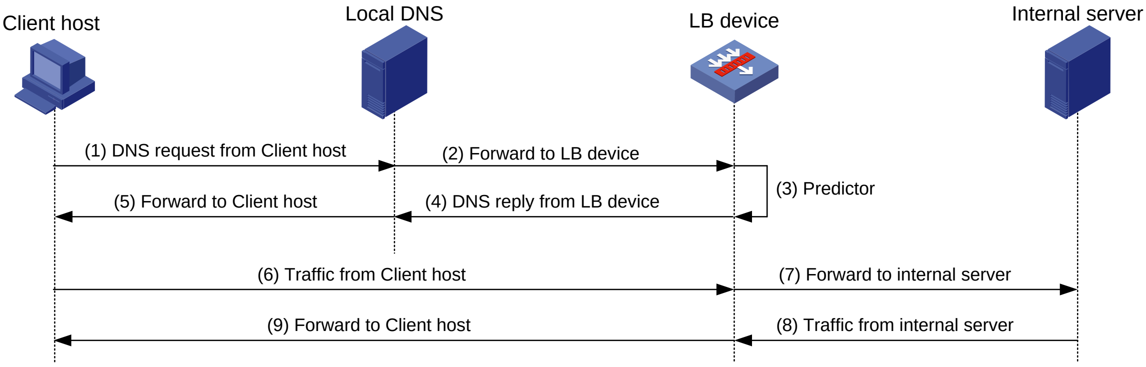
Figure 9 Network diagram



Workflow

Inbound link load balancing is implemented based on DNS resolution. The LB device acts as the authoritative DNS server to process DNS requests from extranet users and select the best link for extranet users. Figure 10 shows the inbound link load balancing workflow.

Figure 10 Inbound link load balancing workflow



Client host
Local DNS
LB device
Internal server
(1) DNS request from Client host
(2) Forward to LB device
(3) Predictor
(5) Forward to Client host
(4) DNS reply from LB device
(6) Traffic from Client host
(7) Forward to internal server
(9) Forward to Client host
(8) Traffic from internal server

Inbound link load balancing uses the following procedure:

1. The client host sends a DNS request to the local DNS server.
2. The local DNS server forwards the DNS request to the LB device.
3. Inbound link load balancing selects a virtual server on the optimal link by using scheduling algorithms, bandwidth limit, and health monitoring method.
4. The LB device sends the virtual server address to the local DNS server in a DNS response.
5. The local DNS server sends the virtual server address to the client host.
6. The client host initiates a connection request to the virtual server address. (The request is forwarded to the LB device.)
7. The LB device initiates a connection request to the internal server.
8. The internal server responds to the LB device.
9. The LB device responds to the client host.

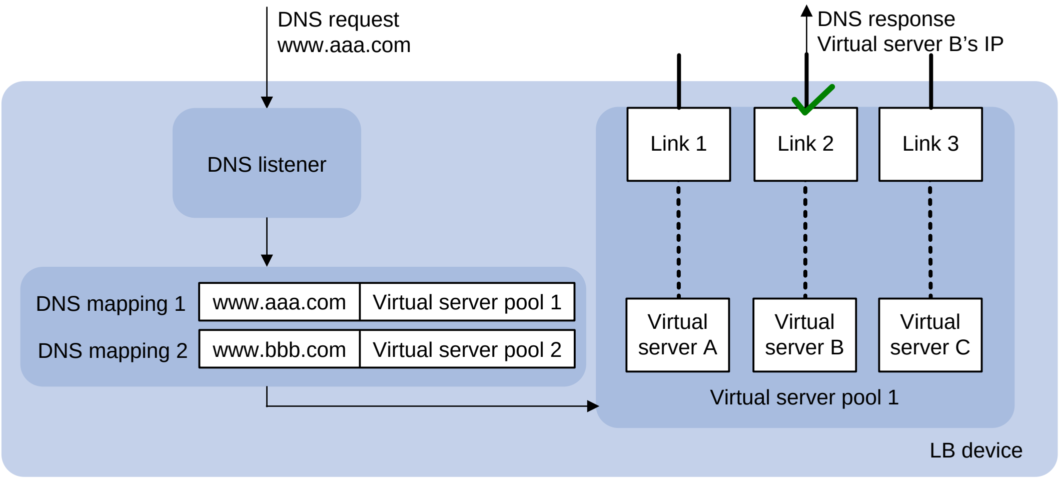
Inbound link load balancing on the LB device

The LB device implements inbound link load balancing by receiving DNS requests and replying with DNS responses that carry IP addresses of virtual severs.

As shown in Figure 11, the LB device contains the following elements:

- **DNS listener**—Listens to DNS requests. When the destination IP address of a DNS request matches that of the DNS listener, the DNS request is processed by inbound link load balancing.
- **DNS mapping**—Associates a domain name with a virtual server pool. The LB device looks up the DNS mappings for the virtual server pool associated with a domain name.
- **Link**—Physical link provided by an ISP.
- **Virtual server pool**—Associates virtual servers with links. The availability of a virtual server and its associated link determines whether the virtual server participates in scheduling.
- **Virtual server**—A virtual entity for processing user services.

Figure 11 Inbound link load balancing on the LB device



If the destination IP address of an incoming DNS request matches that of a DNS listener, the LB device processes the DNS request as follows:

1. The LB device looks up the DNS mappings for the virtual server pool associated with the domain name in the DNS request.
2. The LB device selects the virtual server associated with the best link according to the scheduling algorithm configured for the virtual server pool.

3. The LB device sends the IP address of the selected virtual server in a DNS response to the extranet user.

   The extranet user uses the IP address of the virtual server as the destination IP address and accesses the internal server through the link associated with the virtual server.

Restrictions and guidelines: Inbound link load balancing configuration

You must contact the ISP to configure a delegating domain on the local DNS server to specify the LB device as the authoritative DNS server.

Inbound link load balancing tasks at a glance

To configure inbound link load balancing, perform the following tasks:

1. Configuring a DNS listener
2. Configuring a DNS mapping
3. Configuring a virtual server
4. Configuring a virtual server pool
5. Configuring an LB link
6. (Optional.) Configuring a DNS zone
   - Configuring a DNS forward zone
   - Configuring a DNS reverse zone
7. (Optional.) Configuring a topology
8. (Optional.) Configuring a region
9. (Optional.) Configuring ISP information
10. (Optional.) Enabling load balancing link busy state logging
11. (Optional.) Performing a load balancing test
12. (Optional.) Configuring DNS request parse failure settings
    - Setting the maximum number of DNS request parse failures to be recorded
    - Configuring the types of DNS request parse failures to be recorded

Configuring a DNS listener

DNS listener tasks at a glance

To configure a DNS listener, perform the following tasks:

1. Creating a DNS listener
2. Specifying an IP address and a port number for a DNS listener
3. (Optional.) Specifying a VPN instance
4. Enabling the DNS listening feature
5. (Optional.) Specifying the processing method for DNS mapping search failure

Creating a DNS listener

1. Enter system view.

   system-view

2. Create a DNS listener and enter DNS listener view.

   loadbalance dns-listener *dns-listener-name*

Specifying an IP address and a port number for a DNS listener

About this task

Perform this task to specify an IP address and a port number for the LB device to provide DNS services.

Procedure

1. Enter system view.

   system-view

2. Enter DNS listener view.

   loadbalance dns-listener *dns-listener-name*

3. Specify an IP address and a port number for the DNS listener.

   IPv4:

   ip address *ipv4-address* [**port** *port-number*]

   IPv6:

   ipv6 address *ipv6-address* [**port** *port-number*]

   By default, a DNS listener does not have an IP address or port number.

Specifying a VPN instance

1. Enter system view.

   system-view

2. Enter DNS listener view.

   loadbalance dns-listener *dns-listener-name*

3. Specify a VPN instance for the DNS listener.

   vpn-instance *vpn-instance-name*

   By default, a DNS listener belongs to the public network.

Enabling the DNS listening feature

1. Enter system view.

   system-view

2. Enter DNS listener view.

   loadbalance dns-listener *dns-listener-name*

3. Enable the DNS listening feature.

   service enable

   By default, the DNS listening feature is disabled.

Specifying the processing method for DNS mapping search failure

1. Enter system view.
   system-view
2. Enter DNS listener view.
   loadbalance dns-listener *dns-listener-name*
3. Specify the processing method for DNS mapping search failure.
   fallback { **dns-proxy** | **no-response** | **reject** }
   By default, the processing method is **reject**.

Configuring a DNS mapping

By configuring a DNS mapping, you can associate a domain name with a virtual server pool.

DNS mapping tasks at a glance

To configure a DNS mapping, perform the following tasks:

1. Creating a DNS mapping
2. Specifying a domain name for a DNS mapping
3. Specifying a virtual server pool for a DNS mapping
4. (Optional.) Setting the TTL for DNS records
5. Enabling the DNS mapping feature

Creating a DNS mapping

1. Enter system view.
   system-view
2. Create a DNS mapping and enter DNS mapping view.
   loadbalance dns-map *dns-map-name*

Specifying a domain name for a DNS mapping

Restrictions and guidelines

You can specify multiple domains names for a DNS mapping.

Procedure

1. Enter system view.
   system-view
2. Enter DNS mapping view.
   loadbalance dns-map *dns-map-name*
3. Specify a domain name for the DNS mapping.
   domain-name *domain-name*
   By default, a DNS mapping does not contain domain names.

Specifying a virtual server pool for a DNS mapping

1. Enter system view.
   `system-view`
2. Enter DNS mapping view.
   `loadbalance dns-map` *`dns-map-name`*
3. Specify a virtual server pool for the DNS mapping.
   `virtual-server-pool` *`pool-name`*
   By default, no virtual server pool is specified for a DNS mapping.

Setting the TTL for DNS records

About this task

Perform this task to set a proper TTL to cache DNS records for DNS responses.

- For the DNS client to get the updated DNS record when the LB policy or virtual server configuration changes, set a smaller TTL value, for example, 60 seconds.
- For stable, fast domain name resolution when the network is stable, set a larger TTL value, for example, 86400 seconds.

Procedure

1. Enter system view.
   `system-view`
2. Enter DNS mapping view.
   `loadbalance dns-map` *`dns-map-name`*
3. Set the TTL for DNS records.
   `ttl` *`ttl-value`*
   By default, the TTL for DNS records is 3600 seconds.

Enabling the DNS mapping feature

1. Enter system view.
   `system-view`
2. Enter DNS mapping view.
   `loadbalance dns-map` *`dns-map-name`*
3. Enable the DNS mapping feature.
   `slow-shutdown enable`
   By default, the DNS mapping feature is disabled.

Configuring a virtual server

About this task

Perform this task to specify the IP address and port number that the internal server uses to provide services. Configure inbound link load balancing virtual servers in the same way server load balancing virtual servers are configured. For more information about virtual server configuration

Restrictions and guidelines

- To ensure correct operation of inbound link load balancing when server load balancing is also enabled, do not specify the virtual server's IP address as the DNS listener's IP address. For more information about specifying an IP address for a DNS listener, see "Specifying an IP address and a port number for a DNS listener."
- The virtual server's IPv4 address for inbound link load balancing must be a unicast address with a 32-bit mask length. The IPv4 address cannot be an all-zero address.
- The virtual server's IPv6 address for inbound link load balancing must be a unicast address with a 128-bit prefix length. The IPv6 address cannot be an all-zero address.

Configuring a virtual server pool

Perform this task to facilitate management of virtual servers with similar functions.

Virtual server pool tasks at a glance

To configure a virtual server pool, perform the following tasks:

1. Creating a virtual server pool
2. Adding a virtual server or virtual IP address. Choose the options to configure as needed:
   - Adding a virtual server
   - Adding a virtual IP address
3. (Optional.) Specifying scheduling algorithms for a virtual server pool
4. (Optional.) Enabling the link protection feature

Creating a virtual server pool

1. Enter system view.
   system-view
2. Create a virtual server pool enter virtual server pool view.
   loadbalance virtual-server-pool *name*

Adding a virtual server

1. Enter system view.
   system-view
2. Enter virtual server pool view.
   loadbalance virtual-server-pool *name*
3. Add a virtual server to the virtual server pool.
   virtual-server *virtual-server-name* **link** *link-name* [**weight** *weight-name*]
   By default, no virtual servers are added to a virtual server pool.

Adding a virtual IP address

1. Enter system view.
   system-view

2. Enter virtual server pool view.

   loadbalance virtual-server-pool *name*

3. Add a virtual IP address to the virtual server pool.

   IPv4:

   virtual-ip *ipv4-address* **link** *link-name* [**weight** *weight-value*]

   IPv6:

   virtual-ipv6 *ipv6-address* **link** *link-name* [**weight** *weight-value*]

   By default, no virtual IP addresses are added to a virtual server pool.

Specifying scheduling algorithms for a virtual server pool

About this task

The device provides the following scheduling algorithms for a virtual server pool:

- **Weighted least connection algorithm (least-connection)**—Always assigns DNS requests to the virtual server with the fewest number of weighted active connections (the number of active connections divided by weight).
- **Random algorithm (random)**—Randomly assigns DNS requests to virtual servers.
- **Round robin algorithm (round-robin)**—Assigns DNS requests to virtual servers based on the weights of virtual servers. A higher weight indicates more DNS requests will be assigned.
- **Static proximity algorithm (topology)**—Assigns DNS requests to virtual servers based on static proximity entries.
- **Dynamic proximity algorithm (proximity)**—Assigns DNS requests to virtual servers based on dynamic proximity entries.
- **Bandwidth algorithm (bandwidth)**—Distributes DNS requests to DNS servers according to the weights and remaining bandwidth of DNS servers.
- **Maximum bandwidth algorithm (max-bandwidth)**—Distributes DNS requests always to an idle DNS server that has the largest remaining bandwidth.
- **Source IP address hash algorithm (hash address source)**—Hashes the source IP address of DNS requests and distributes DNS requests to different DNS servers according to the hash values.
- **Source IP address and port hash algorithm (hash address source-ip-port)**—Hashes the source IP address and port number of DNS requests and distributes DNS requests to different DNS servers according to the hash values.
- **Destination IP address hash algorithm (hash address destination)**—Hashes the destination IP address of DNS requests and distributes DNS requests to different DNS servers according to the hash values.

You can specify one preferred scheduling algorithm, one alternative scheduling algorithm, and one backup scheduling algorithm for a virtual server pool. If no virtual server can be selected by using the preferred scheduling algorithm, the alternative scheduling algorithm is used. If no virtual server can be selected by using the alternative scheduling algorithm, the backup scheduling algorithm is used.

Procedure

1. Enter system view.

   system-view

2. Enter virtual server pool view.

   loadbalance virtual-server-pool *name*

3. Specify a scheduling algorithm for the virtual server pool.

predictor { **alternate** | **fallback** | **preferred** } { **least-connection** | **proximity** | **random** | **round-robin** | **topology** **|** { **bandwidth** | **max-bandwidth** } [**inbound** | **outbound**] | **hash address** { **source** | **source-ip-port** | **destination** } [**mask** *mask-length* **|** **prefix** *prefix-length*] }

By default, the preferred scheduling algorithm for the virtual server pool is **round robin**. No alternative or backup scheduling algorithm is specified.

Enabling the link protection feature

About this task

This feature enables a virtual server pool to select a virtual server based on the link bandwidth ratio. If the bandwidth ratio of a link is exceeded, the virtual server is not selected. For more information about configuring the bandwidth ratio, see "Setting the bandwidth ratio and maximum expected bandwidth."

Procedure

1. Enter system view.

   system-view

2. Enter virtual server pool view.

   loadbalance virtual-server-pool *name*

3. Enable the link protection feature.

   bandwidth busy-protection enable

   By default, the link protection feature is disabled.

Configuring an LB link

Link availability is one of the factors that determines whether a virtual server can participate in scheduling. Link availability depends on health monitoring, maximum expected bandwidth, and bandwidth ratio.

LB link tasks at a glance

To configure an LB link, perform the following tasks:

1. Creating an LB link
2. Specifying the outbound next hop for the LB link
3. (Optional.) Configuring health monitoring
4. (Optional.) Setting the bandwidth ratio and maximum expected bandwidth

Creating an LB link

1. Enter system view.

   system-view

2. Create an LB link and enter LB link view.

   loadbalance link *link-name*

Specifying the outbound next hop for the LB link

About this task

The outbound next hop is the IP address of the peer device on the link. You can perform health monitoring and bandwidth limiting on a link specified by the outbound next hop.

Procedure

1. Enter system view.

   `system-view`

2. Enter LB link view.

   `loadbalance link` *`link-name`*

3. Specify the outbound next hop for the LB link.

   `router ip` *`ipv4-address`*

   By default, the outbound next hop is not specified for the LB link.

Configuring health monitoring

About this task

Perform this task to enable health monitoring to detect link quality and status and to ensure link availability. The health monitoring configuration uses NQA templates. For more information about NQA template configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

You can configure multiple health monitoring methods for an LB link.

Procedure

1. Enter system view.

   `system-view`

2. Enter LB link view.

   `loadbalance link` *`link-name`*

3. Specify a health monitoring method for the LB link.

   `probe` *`template-name`*

   By default, no health monitoring method is specified for an LB link.

4. Specify the health monitoring success criteria for the LB link.

   `success-criteria` { **`all`** | **`at-least`** *`min-number`* }

   By default, the health monitoring succeeds only when all the specified health monitoring methods succeed.

Setting the bandwidth ratio and maximum expected bandwidth

About this task

When the traffic exceeds the maximum expected bandwidth multiplied by the bandwidth ratio of a link, new traffic is not distributed to the link. When the traffic drops below the maximum expected bandwidth multiplied by the bandwidth recovery ratio of the link, the link participates in scheduling again.

In addition to being used for link protection, the maximum expected bandwidth is used for remaining bandwidth calculation in the bandwidth algorithm and maximum bandwidth algorithm.

Procedure

1. Enter system view.

   system-view

2. Enter LB link view.

   loadbalance link *name*

3. Set the bandwidth ratio.

   bandwidth [**inbound** | **outbound**] *busy-rate-number* [**recovery** *recovery-rate-number*]

   By default, the total bandwidth ratio is 70.

4. Set the maximum expected bandwidth.

   max-bandwidth [**inbound** | **outbound**] *bandwidth-value* **kbps**

   By default, the maximum expected bandwidth, maximum inbound expected bandwidth, and maximum outbound expected bandwidth are 0. The bandwidths are not limited.

Configuring a DNS forward zone

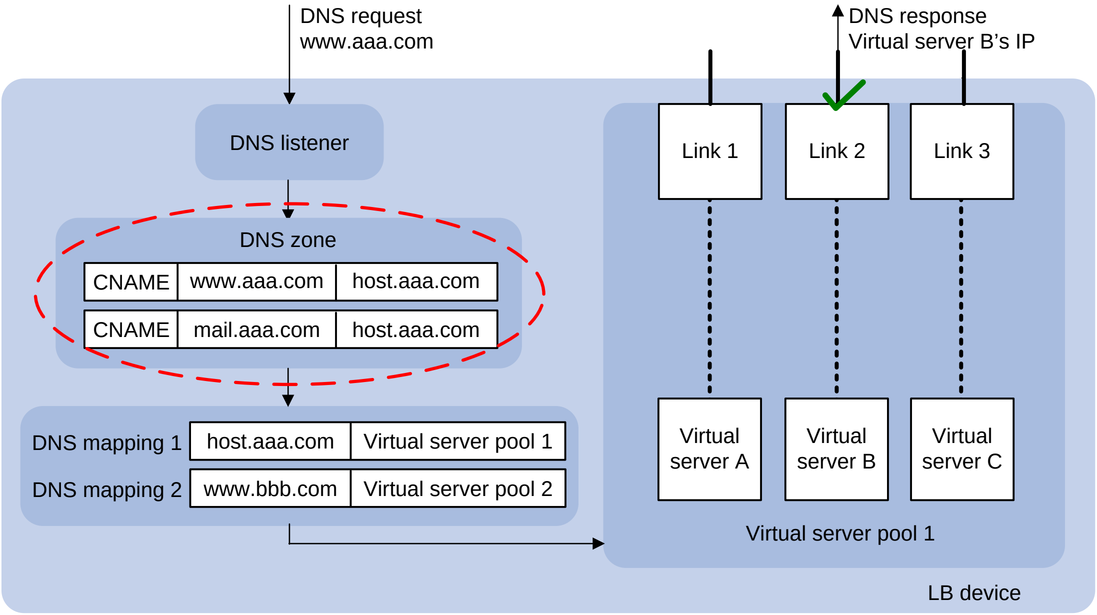
About DNS resource records

During DNS resolution, an LB device looks up the resource records configured in a DNS forward zone for the host name corresponding to the target domain name. DNS resource records are used by an LB device to resolve DNS requests and have the following types:

- **Canonical name (CNAME)**—Maps multiple aliases to one host name (server). For example, an enterprise intranet has a server with host name **host.aaa.com**. The server provides both Web service and mail service. You can configure two aliases (**www.aaa.com** and **mail.aaa.com**) in a CNAME resource record for this server. When a user requests Web service, the user accesses **www.aaa.com**. When a user requests mail service, the user accesses **mail.aaa.com**. Actually, the user accesses **host.aaa.com** in both cases.
- **Mail exchanger (MX)**—Specifies the mail server for a DNS forward zone.
- **Name server (NS)**—Specifies the authoritative DNS server for a DNS forward zone.
- **Start of authority (SOA)**—Specifies authoritative information about a DNS forward zone, including the primary DNS server and administrator mailbox.
- **Service (SRV)**—Specifies the services for a DNS forward zone and the servers that provide these services.
- **Text (TXT)**—Specifies a description for a DNS forward zone.

As shown in Figure 12, the LB device is configured with a DNS forward zone. After receiving a DNS request, the LB device first looks up the resource records in the DNS forward zone for the host name corresponding to the target domain name. Then the LB device looks up the DNS mappings for the IP address of the virtual server associated with the host name.

Figure 12 DNS forward zone workflow on the LB device



DNS forward zone tasks at a glance

To configure a DNS forward zone, perform the following tasks:

1. Creating a DNS forward zone
2. (Optional.) Configuring resource records
   - Configuring a resource record of the specified type

     This task allows you to configure CNAME, MX, NS, SRV, and TXT resource records.
   - (Optional.) Configuring an SOA resource record
3. (Optional.) Setting the TTL for resource records

Creating a DNS forward zone

1. Enter system view.

   `system-view`
2. Create a DNS forward zone and enter DNS forward zone view.

   `loadbalance zone` *`domain-name`*

Configuring a resource record of the specified type

1. Enter system view.

   `system-view`
2. Enter DNS forward zone view.

   `loadbalance zone` *`domain-name`*
3. Configure a resource record of the specified type.

   `record` { **`cname alias`** *`alias-name`* **`canonical`** *`canonical-name`* | **`mx`** [**`host`** *`hostname`*] **`exchanger`** *`exchanger-name`* **`preference`** *`preference`* | **`ns`** [**`sub`** *`subname`*] **`authority`** *`ns-name`* | **`srv`** [**`service`** *`service-name`*]

host-offering-service *hostname* **priority** *priority* **weight** *weight* **port** *port-number* | **txt** [**sub** *subname*] **describe-txt** *description* } [**ttl** *ttl-value*]

By default, a DNS forward zone does not contain resource records.

Configuring an SOA resource record

1. Enter system view.
   system-view
2. Enter DNS forward zone view.
   loadbalance zone *domain-name*
3. Create an SOA resource record and enter SOA view.
   soa
4. Configure the host name for the primary DNS server.
   primary-nameserver *host-name*

   By default, no host name is configured for the primary DNS server.
5. Specify the email address of the administrator.
   responsible-mail *mail-address*

   By default, the email address of the administrator is not specified.
6. Configure the serial number for the DNS forward zone.
   serial *number*

   By default, the serial number for a DNS forward zone is 1.
7. Set the refresh interval.
   refresh *refresh-interval*

   By default, the refresh interval is 3600 seconds.
8. Set the retry interval.
   retry *retry-interval*

   By default, the retry interval is 600 seconds.
9. Set the expiration time.
   expire *expire-time*

   By default, the expiration time is 86400 seconds.
10. Set the minimum TTL.
    min-ttl *ttl-value*

    By default, the minimum TTL is 3600 seconds.

Setting the TTL for resource records

1. Enter system view.
   system-view
2. Enter DNS forward zone view.
   loadbalance zone *domain-name*
3. Set the TTL for resource records.
   ttl *ttl-value*

   By default, the TTL for resource records is 3600 seconds.

Configuring a DNS reverse zone

About this task

The LB device performs reverse DNS resolution according to the DNS reverse zone configuration. Reverse DNS resolution searches for a domain name according to an IP address. The pointer record (PTR) resource records configured in a DNS reverse zone record mappings between domain names and IP addresses.

Reverse DNS resolution is used to address spam attacks by verifying the validity of the email sender. When a mail server receives an email from an external user, it sends a reverse DNS resolution request to the LB device. The LB device resolves the source IP address of the sender into a domain name according to PTR resource records and sends the domain name to the mail server. The mail server compares the received domain name with the actual domain name of the sender. If the two domain names match, the mail server accepts the email. If not, the mail server considers the email as a spam email and discards it.

Procedure

1. Enter system view.

   system-view

2. Create a DNS reverse zone and enter DNS reverse zone view.

   loadbalance reverse-zone { **ip** *ipv4-address mask-length* | **ipv6** *ipv6-address prefix-length* }

3. Configure a PTR resource record.

   record ptr { **ip** *ipv4-address* | **ipv6** *ipv6-address* } *domain-name* [**ttl** *ttl-value*]

   By default, a DNS reverse zone does not contain PTR resource records.

Configuring a topology

About this task

A topology associates the region where the local DNS server resides with the IP address of a virtual server.

When the static proximity algorithm (**topology**) is specified for the virtual server pool, you must configure a topology. For more information about specifying a scheduling algorithm for a virtual server pool, see "Adding a virtual IP address"

When a DNS request matches multiple topology records, the topology record with the highest priority is selected.

Procedure

1. Enter system view.

   system-view

2. Configure a topology.

   topology region *region-name* { **ip** *ipv4-address* { *mask-length* | *mask* } | **ipv6** *ipv6-address prefix-length* } [**priority** *priority*]

Configuring a region

About this task

A region contains network segments corresponding to different ISPs.

Procedure

1. Enter system view.

   system-view

2. Create a region and enter region view.

   loadbalance region *region-name*

3. Add an ISP to the region.

   isp *isp-name*

   By default, a region does not contain any ISPs.

Configuring ISP information

Configure inbound link load balancing ISP information in the same way outbound link load balancing ISP information is configured. For more information about ISP information configuration, see "Configuring outbound link load balancing."

Enabling load balancing link busy state logging

About this task

Perform this task to record busy states for all links.

Procedure

1. Enter system view.

   system-view

2. Enable load balancing link busy state logging.

   loadbalance log enable bandwidth-busy

   By default, load balancing link busy state logging is disabled.

Performing a load balancing test

About performing a load balancing test

Perform this task in any view to test the load balancing result.

Performing an IPv4 load balancing test

To perform an IPv4 load balancing test, execute the following command in any view:

loadbalance local-dns-server schedule-test ip [**vpn-instance** *vpn-instance-name*] **destination** *destination-address* [**destination-port** *destination-port*] **source** *source-address* **source-port** *source-port* **type** { { **a** | **aaaa** | **cname** | **mx** | **ns** | **soa** | **srv** | **txt** } **domain** *domain-name* | **ptr ip address** { *ipv4-address* | *ipv6-address* } } [**slot** *slot-number*]

Performing an IPv6 load balancing test

To perform an IPv6 load balancing test, execute the following command in any view:

loadbalance local-dns-server schedule-test ipv6 [**vpn-instance** *vpn-instance-name*] **destination** *destination-address* [**destination-port** *destination-port*] **source** *source-address* **source-port** *source-port* **type** { { **a** | **aaaa** | **cname** | **mx** | **ns** | **soa** | **srv** | **txt** } **domain** *domain-name* | **ptr ip address** *ipv4-address* } [**slot** *slot-number*]

Setting the maximum number of DNS request parse failures to be recorded

1. Enter system view.

   system-view

2. Set the maximum number of DNS request parse failures that can be recorded.

   loadbalance local-dns-server parse-fail-record max-number *max-number*

   The default setting is 10000.

Configuring the types of DNS request parse failures to be recorded

1. Enter system view.

   system-view

2. Configure the types of DNS request parse failures that can be recorded.

   loadbalance local-dns-server parse-fail-record type { **a** | **aaaa** | **all-disable** | **all-enable** | **cname** | **mx** | **ns** | **ptr** | **soa** | **srv** | **txt** }

   By default, all types of DNS request parse failures are recorded.

Displaying and maintaining inbound link load balancing

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display DNS listener information.	**display loadbalance dns-listener** [**name** *listener-name*]
Display DNS listener statistics.	**display loadbalance dns-listener statistics** [**name** *dns-listener-name*] [**slot** *slot-number*]
Display DNS mapping information.	**display loadbalance dns-map** [**name** *dns-map-name*]
Display DNS mapping statistics.	**display loadbalance dns-map statistics** [**name** *dns-map-name*] [**slot** *slot-number*]
Display virtual server pool information.	**display loadbalance virtual-server-pool** [**brief** | **name** *pool-name*]

Task	Command
Display LB link information.	**display loadbalance link** [**brief** | **name** *link-name*]
Display DNS forward zone information.	**display loadbalance zone** [**name** *domain-name*]
Display DNS reverse zone information.	**display loadbalance reverse-zone** { **ip** [*ipv4-address mask-length*] | **ipv6** [*ipv6-address prefix-length*] }
Display ISP information.	**display loadbalance isp** [**ip** *ipv4-address* | **ipv6** *ipv6-address* | **name** *isp-name*]
Display DNS request parse failures.	**display loadbalance local-dns-server parse-fail-record** [**type** { **a** | **aaaa** | **cname** | **mx** | **ns** | **soa** | **srv** | **txt** }] [**domain** *domain-name*] | **ptr** [**ip address** { *ipv4-address* | *ipv6-address* }]] [**vpn-instance** *vpn-instance-name*] [**slot** *slot-number*]
Clear DNS listener statistics.	**reset loadbalance dns-listener statistics** [*dns-listener-name*]
Clear DNS mapping statistics.	**reset loadbalance dns-map statistics** [*dns-map-name*]
Clear DNS request parse failures.	**reset loadbalance local-dns-server parse-fail-record**

Inbound link load balancing configuration examples

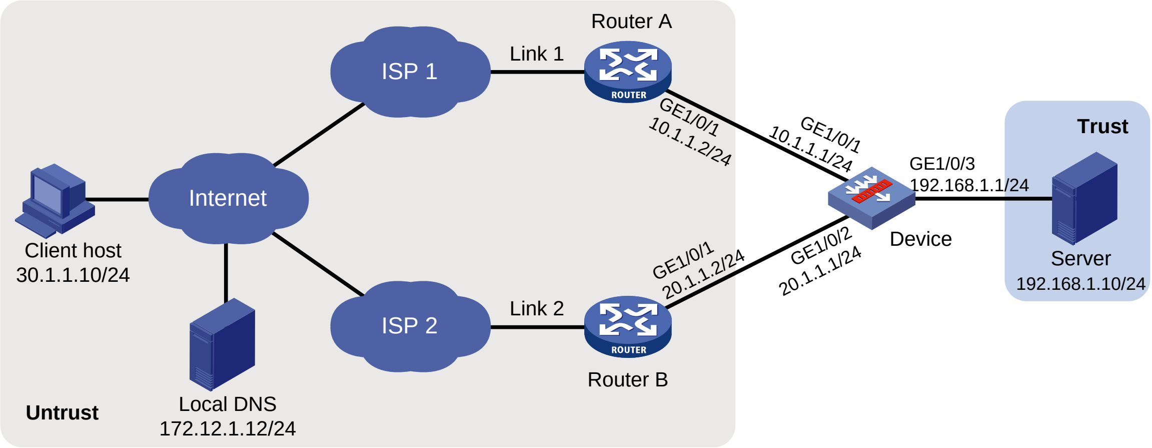
Example: Configuring inbound link load balancing

Network configuration

In Figure 13, ISP 1 and ISP 2 provide two links, Link 1 and Link 2, with the same router hop count, bandwidth, and cost. The internal server uses domain name **l.abc.com** to provide services. The actual host name of the internal server is **www.abc.com**.

Configure inbound link load balancing for the device to select an available link for traffic from the client host to the internal server when a link fails.

Figure 13 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 10.1.1.1 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/1
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
[Device-security-zone-Untrust] quit
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/2
[Device-security-zone-Trust] quit
```

3. Configure a security policy:

   Configure rules to permit traffic from the **Untrust** security zone to the **Trust** security zone and traffic between the **Untrust** and **Local** security zones, so the users can access the server:

   # Configure a rule named **lbrule1** to allow the users to access the server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name lbrule1
[Device-security-policy-ip-1-lbrule1] source-zone untrust
[Device-security-policy-ip-1-lbrule1] destination-zone trust
[Device-security-policy-ip-1-lbrule1] destination-ip-subnet 192.168.1.0
255.255.255.0
[Device-security-policy-ip-1-lbrule1] action pass
[Device-security-policy-ip-1-lbrule1] quit
```

   # Configure a rule named **lblocalin** to allow the users to access the DNS listener.

```
[Device-security-policy-ip] rule name lblocalin
[Device-security-policy-ip-2-lblocalout] source-zone untrust
[Device-security-policy-ip-2-lblocalout] destination-zone local
```

```
[Device-security-policy-ip-2-lblocalout] destination-ip-subnet 10.1.1.1
255.255.255.255
[Device-security-policy-ip-2-lblocalout] destination-ip-subnet 20.1.1.1
255.255.255.255
[Device-security-policy-ip-2-lblocalout] action pass
[Device-security-policy-ip-2-lblocalout] quit
[Device-security-policy-ip] quit
```

# Configure a rule named **lblocalout** to allow the device to send probe packets to the next hop.

```
[Device-security-policy-ip] rule name lblocalout
[Device-security-policy-ip-3-lblocalout] source-zone local
[Device-security-policy-ip-3-lblocalout] destination-zone untrust
[Device-security-policy-ip-3-lblocalout] destination-ip-subnet 10.1.1.0
255.255.255.0
[Device-security-policy-ip-3-lblocalout] destination-ip-subnet 20.1.1.0
255.255.255.0
[Device-security-policy-ip-3-lblocalout] action pass
[Device-security-policy-ip-3-lblocalout] quit
[Device-security-policy-ip] quit
```

4. Configure LB links:

# Create the ICMP-type NQA template **t1**.

```
[Device] nqa template icmp t1
[Device-nqatplt-icmp-t1] quit
```

# Create the LB link **link1**, and specify the outbound next hop as 10.1.1.2 and health monitoring method as **t1** for the LB link.

```
[Device] loadbalance link link1
[Device-lb-link-link1] router ip 10.1.1.2
[Device-lb-link-link1] probe t1
[Device-lb-link-link1] quit
```

# Create the LB link **link2**, and specify the outbound next hop as 20.1.1.2 and health monitoring method as **t1** for the LB link.

```
[Device] loadbalance link link2
[Device-lb-link-link2] router ip 20.1.1.2
[Device-lb-link-link2] probe t1
[Device-lb-link-link2] quit
```

5. Create the server farm **sf**.

```
[Device] server-farm sf
[Device-sfarm-sf] quit
```

6. Create the real server **rs** with the IPv4 address 192.168.1.10, and add it to the server farm **sf**.

```
[Device] real-server rs
[Device-rserver-rs] ip address 192.168.1.10
[Device-rserver-rs] server-farm sf
[Device-rserver-rs] quit
```

7. Configure virtual servers:

# Create the HTTP virtual server **vs1** with the VSIP 10.1.1.3 and port number 80, specify its default master server farm **sf**, and enable the virtual server.

```
[Device] virtual-server vs1 type http
[Device-vs-http-vs1] virtual ip address 10.1.1.3
[Device-vs-http-vs1] port 80
[Device-vs-http-vs1] default server-farm sf
```

```
[Device-vs-http-vs1] service enable
[Device-vs-http-vs1] quit
```

# Create the HTTP virtual server **vs2** with the VSIP 20.1.1.3 and port number 80, specify its default master server farm **sf**, and enable the virtual server.

```
[Device] virtual-server vs2 type http
[Device-vs-http-vs2] virtual ip address 20.1.1.3
[Device-vs-http-vs2] port 80
[Device-vs-http-vs2] default server-farm sf
[Device-vs-http-vs2] service enable
[Device-vs-http-vs2] quit
```

8. Create the virtual server pool **vsp**, and add the virtual servers **vs1** and **vs2** associated with the LB links **link1** and **link2** to the virtual server pool.

```
[Device] loadbalance virtual-server-pool vsp
[Device-lb-vspool-vsp] virtual-server vs1 link link1
[Device-lb-vspool-vsp] virtual-server vs2 link link2
```

9. Configure DNS listeners:

# Create the DNS listener **dl1** with the IP address 10.1.1.1, and enable the DNS listener feature.

```
[Device] loadbalance dns-listener dl1
[Device-lb-dl-dl1] ip address 10.1.1.1
[Device-lb-dl-dl1] service enable
[Device-lb-dl-dl1] quit
```

# Create the DNS listener **dl2** with the IP address 20.1.1.1, and enable the DNS listener feature.

```
[Device] loadbalance dns-listener dl2
[Device-lb-dl-dl2] ip address 20.1.1.1
[Device-lb-dl-dl2] service enable
[Device-lb-dl-dl2] quit
```

10. Create the DNS mapping **dm**, specify the domain name **www.aaa.com** and virtual server pool **vsp** for the DNS mapping, and enable the DNS mapping feature.

```
[Device] loadbalance dns-map dm
[Device-lb-dm-dm] domain-name www.aaa.com
[Device-lb-dm-dm] service enable
[Device-lb-dm-dm] virtual-server-pool vsp
[Device-lb-dm-dm] quit
```

11. Configure a DNS forward zone:

# Create a DNS forward zone with domain name **aaa.com**.

```
[Device] loadbalance zone aaa.com
```

# Configure a CNAME resource record by specifying alias **l.aaa.com** for host name **www.aaa.com**.

```
[Device-lb-zone-abc.com] record cname alias l.aaa.com. canonical www.aaa.com. ttl 600
[Device-lb-zone-abc.com] quit
```

Verifying the configuration

# Display information about all DNS listeners.

```
[Device] display loadbalance dns-listener
DNS listener name: dl1
Service state: Enabled
IPv4 address: 10.1.1.1
```

```
Port: 53
IPv6 address: --
IPv6 Port: 53
Fallback: Reject
VPN instance:
```

# Display information about all DNS mappings.

```
[Device] display loadbalance dns-map
DNS mapping name: dm
  Service state: Enabled
TTL: 3600
  Domain name list: www.aaa.com
  Virtual server pool: vsp
```

# Display information about all DNS forward zones.

```
[Device] display loadbalance zone
  Zone name: aaa.com
    TTL: 3600s
    SOA:
   Record list:
     Type    TTL     RDATA
     CNAME   600s    l.aaa.com. www.aaa.com.
```

# Display brief information about all virtual server pools.

```
[Device] display loadbalance virtual-server-pool brief
Predictor: RR - Round robin, RD - Random, LC - Least connection,
           TOP - Topology, PRO - Proximity
           BW - Bandwidth, MBW - Max bandwidth,
           IBW - Inbound bandwidth, OBW - Outbound bandwidth,
           MIBW - Max inbound bandwidth, MOBW - Max outbound bandwidth,
           HASH(SIP) - Hash address source IP,
           HASH(DIP) - Hash address destination IP,
           HASH(SIP-PORT) - Hash address source IP-port
VSpool           Pre    Alt    Fbk    BWP     Total    Active

NSFOCUS Firewall Series

NF High Availability Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for high availability features.
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
ⓘ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Configuring hot backup

About hot backup

Hot backup is a device-level HA solution. It enables two devices to back up each other dynamically to ensure user service continuity upon failure of one of the devices.

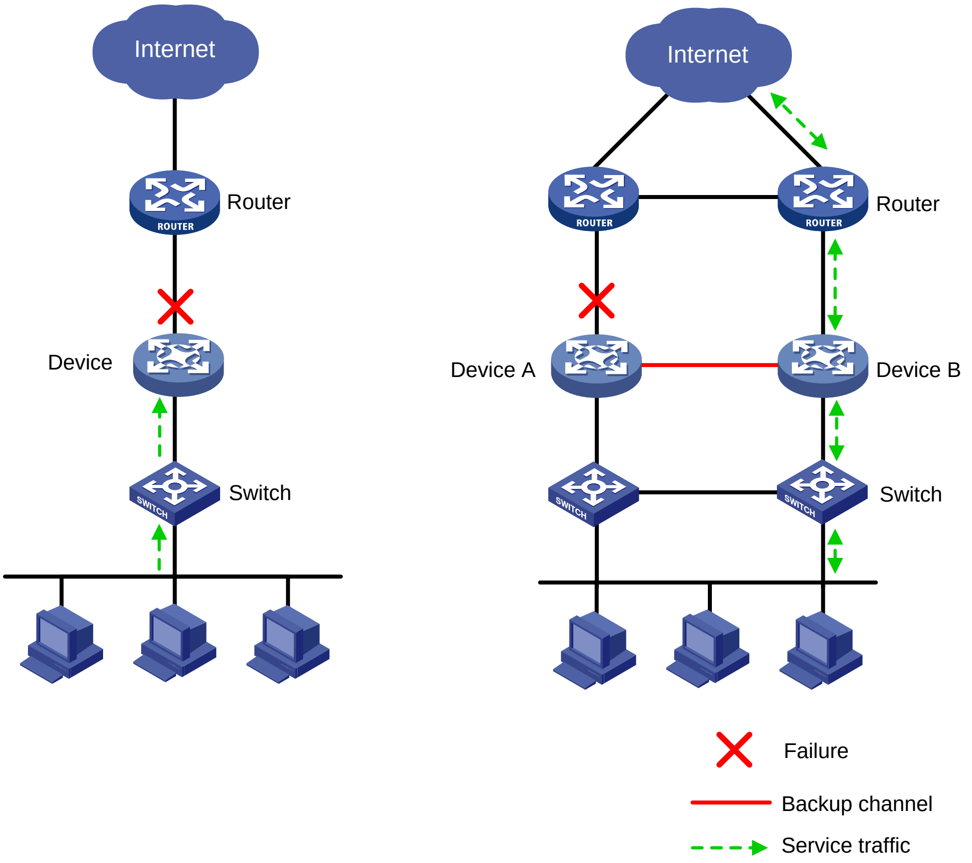
Hot backup works with NSFOCUS proprietary Remote Backup Management (RBM) to manage multiple VRRP groups or adjust the link costs for routing protocols on two member devices to ensure that the devices have consistent roles and states. The hot backup system can synchronize important configuration and service entries between the devices to ensure service continuity. Two devices must have the same software and hardware environments to join a hot backup system.

Application scenario

As shown in Figure 1, typically redundant egress devices are deployed at the border between the external and internal networks to prevent a single point of failure from interrupting traffic forwarding. When one egress device fails, traffic is switched to a different path.

The hot backup system is not used on traditional network devices such as switches and routers as they require only Layer 2 redundancy and route backup to ensure service continuity. It is used on security devices that perform status check and policy-based processing on packets, such as firewalls, IPSs, and network access behavior auditors. These devices check the validity of the first packet of each flow and create a session entry to record the traffic pattern, including the source and destination IP addresses, source and destination ports, and protocol. A security device forwards the subsequent packets of a flow only when the packets match a session entry. To ensure service continuity after traffic is switched between redundant security devices, hot backup is used to synchronize service entries and configuration between the devices through a dedicated channel.

Figure 1 Hot backup network model



Basic hot backup concepts

Basic hot backup concepts are as follows:

- **Primary and secondary roles**—In the control plane, the primary and secondary roles are assigned to the two devices in a hot backup system to control the configuration synchronization between the devices.

  Each hot backup member device adds a prefix to the view prompt to identify its hot backup role. The primary device adds the **RBM_P** prefix, **RBM_P<Sysname>** for example. The secondary device adds the **RBM_S** prefix, **RBM_S<Sysname>** for example.
- **Active and standby states**—Determine which device forwards and processes traffic in the data plane. The active device forwards traffic of services and backs up service entries to the standby device in real time. When the active device fails, the standby device takes over the active role to ensure service continuity.
- **Hot backup channels**—Transmit status information, important configuration, and service entries between the hot backup members.
- **Hot backup modes**—Include active/standby mode and dual-active mode. In active/standby mode, the active device processes all services. In dual-active mode, both devices process services to increase the capability of the hot backup system and load share traffic.
- **Hot backup packets**—RBM packets transmitted through TCP over the hot backup channels between the hot backup members.

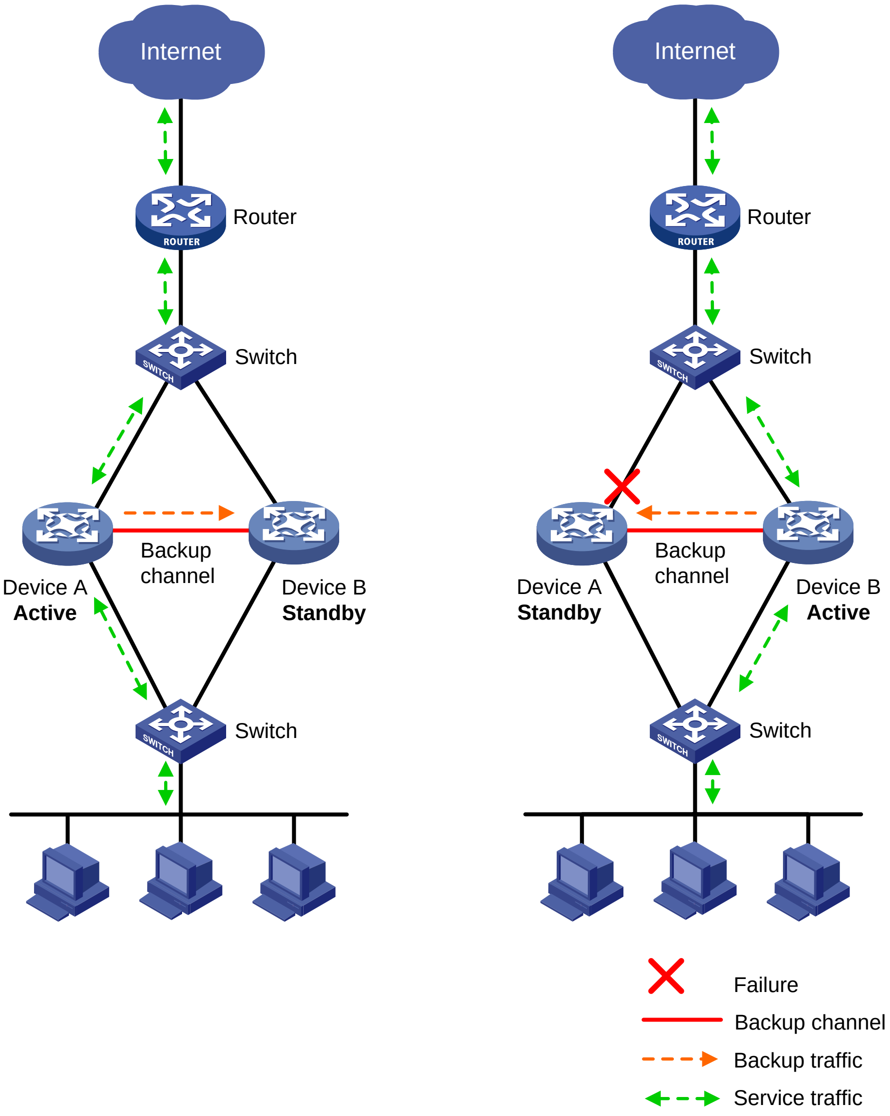
Operating modes of hot backup

Hot backup supports the active/standby and dual-active modes.

Active/standby mode

In active/standby mode, one device is active to process services, and the other device stands by, as shown in Figure 2. When an interface or link on the active device fails or when the active device fails, the standby device becomes active to process services.

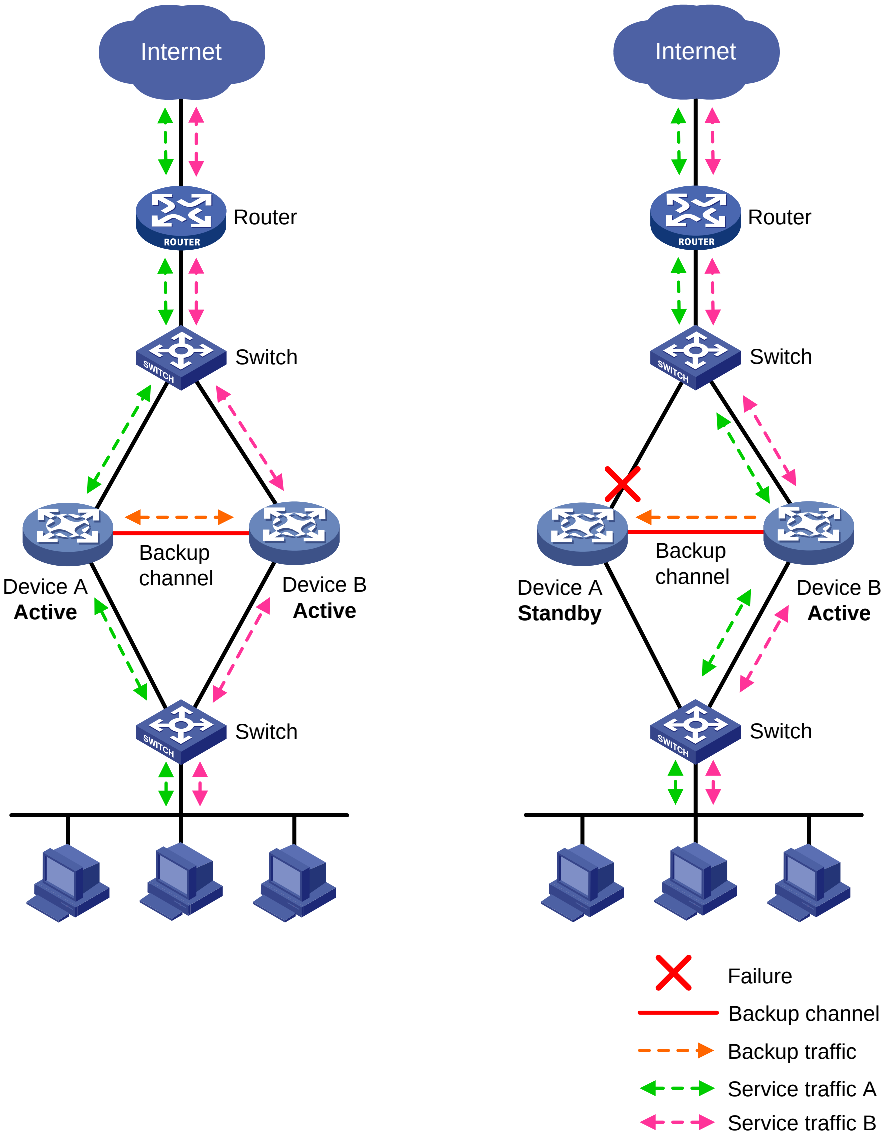
Figure 2 Active/standby mode of hot backup



Dual-active mode

In dual-active mode, both devices process services to increase capability of the hot backup system, as shown in Figure 3. When one device fails, its traffic is switched to the other device for forwarding.

Figure 3 Dual-active mode of hot backup



Hot backup data synchronization

Hot backup packets

Hot backup packets include the following:

- **Keepalive packets**—Transmitted periodically between the hot backup members for peer availability detection.
- **Control packets**—Control active/standby switchovers based on the running status.
- **Backup packets**—Back up configuration and service entries between the hot backup members.
- **Configuration consistency check packets**—Check whether the hot backup members have consistent configuration.
- **Transparent transmission packets**—Transmit or replicate asymmetric-path traffic between the hot backup members.

Hot backup channels

Hot backup transmits hot backup status, important configuration, and service entries between the hot backup members through the following channels:

- **Control channel**—Transmits data by using packets, including hot backup status packets, configuration consistency check packets, and packets used for configuration synchronization.
- **Data channel**—Transmits backup packets and packets that require transparent transmission. The data channel uses the hardware driver for data transmission and supports only Layer 2 forwarding.

The control channel uses the keepalive mechanism of TCP for reachability detection. Each member device periodically sends hot backup keepalive packets to the hot backup peer over the hot backup control channel. If a device has not received any responses from the peer when the maximum number of hot backup keepalive attempts is reached, the hot backup control channel is disconnected.

Service entry backup

Hot backup backs up the service entries generated on the active device to the standby device to prevent service interruption when an active/standby switchover occurs.

Security devices generate a session entry for each dynamic connection. In the hot backup system, only the active device processes traffic and generates session entries. To ensure service continuity, the active device backs up its session entries to the standby device in real time. After an active/standby switchover, the new active device can forward the packets of the existing services based on the session entries without interruption.

Hot backup can perform hot backup for the following service entries:

- NAT port blocks.
- AFT port blocks.
- Session entries.
- Session relation entries.
- Entries generated by security service modules.

Configuration backup

Hot backup backs up important configuration from the primary device to the secondary device to prevent service interruption when an active/standby switchover occurs.

- When both devices are operating correctly, the primary device synchronizes configuration to the secondary device. The configuration on the secondary device is overwritten. As a best practice to ensure correct operation of hot backup, enable configuration backup on the primary device.
- When one of the devices reboots, the device that completes reboot obtains configuration from the device that is not rebooted. The configuration on the rebooted device is overwritten.

Hot backup supports both automatic backup and manual backup.

Hot backup can perform configuration backup for the following services:

- **Resources**—VPN instance, ACL (excluding the **`acl copy`** command), object group, time range, security zone, session management, APR, and AAA (excluding the commands for local users and local guests).
- **DPI**—Application layer inspection engine, IPS, URL filter, data filter, file filter, anti-virus, data analysis center.
- **Polices**—Security policy, ASPF, attack detection and prevention (excluding the **`blacklist ip`** command), connection limit, NAT, AFT, load balancing, bandwidth management, application auditing and management, shared network access management, and proxy policy.
- **Logs**—Fast log output (excluding the **`customlog host source`** command) and flow log (excluding the **`userlog flow export source-ip`** command).

- **VPN**—SSL VPN.
- **Any other services**—VLAN and cloud connection.

Configuration consistency check

Hot backup verifies configuration consistency between the hot backup members by using configuration consistency check packets. If a device detects configuration inconsistency, it generates a log for you to manually synchronize configuration.

Configuration consistency check operates as follows:

1. The primary device sends configuration consistency check packets to the secondary device and collects configuration digests of related modules at the same time.
2. The secondary device receives the packets, encapsulates its configuration digests into configuration consistency check packets, and sends these packets to the primary device.
3. The primary device compares its configuration digests with those of the secondary device. If inconsistency is detected, the primary device generates a log.

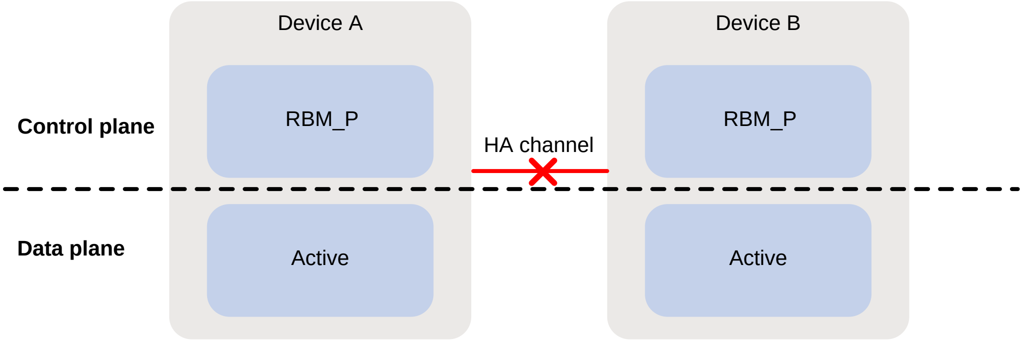
Running status switchover

The hot backup role is determined based on configuration. The running status is determined based on hot backup role election and can be switched over.

Running status switchover process

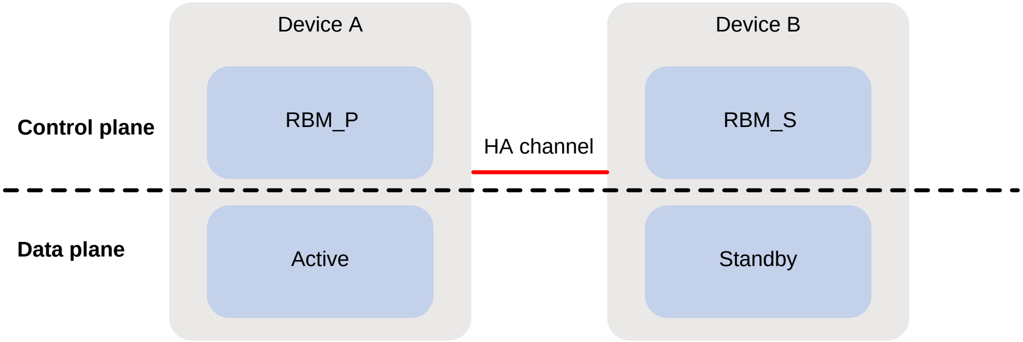
As shown in Figure 4, both devices are primary in the control plane and active in the data plane when the hot backup channels are not established. This is not a correct condition because the hot backup system has not set up.

Figure 4 Hot backup channels not established



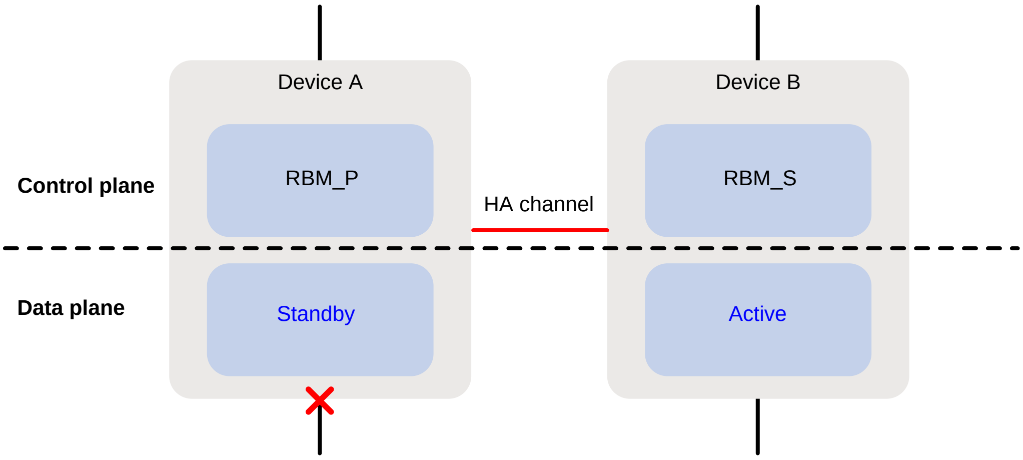
As shown Figure 5, when the hot backup channels are established and both devices are operating correctly, the hot backup roles of the devices are determined based on configuration and do not change in any condition. In the data plane, the running status of the devices is consistent with their hot backup roles. In active/standby mode, the primary device is the active device, and the secondary device is the standby device. In dual-active mode, both devices are active.

Figure 5 Hot backup in active/standby mode



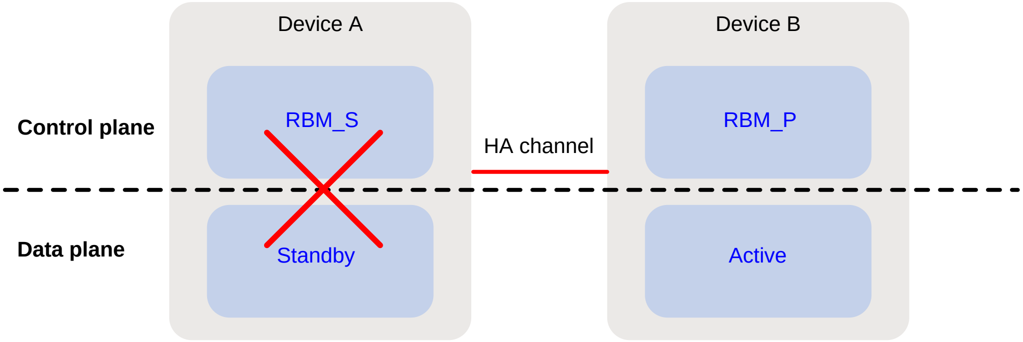
As shown in Figure 6, when the uplink or downlink fails on a device, the status of the devices changes in the data plane. The device that operates correctly processes all traffic. In the control plane, the hot backup roles of the devices do not change.

Figure 6 Uplink or downlink failure



As shown in Figure 7, the hot backup role changes in the control plane only when the primary device fails or restarts, and the running status in the data plane will change accordingly. The secondary device will take over the primary role. When the original primary device recovers, it takes over the primary role.

Figure 7 Device failure or restart



Running status switchover triggers

In the hot backup system, an active/standby switchover occurs if one device fails or its links fail. The other device that operates correctly will take over to process all traffic that traverse the hot backup system to ensure service continuity. The following events can trigger an active/standby switchover.

- Disconnection of the hot backup control channel.

  If the hot backup control channel is disconnected when both member devices are operating correctly, both devices become active devices. However, the devices will leave the hot backup system in this situation, and forwarding of asymmetric-path traffic will be interrupted.
- Failure of the active device.
- Failure of the interface monitored by hot backup on the active device.
- State change to Negative of any track entry monitored by hot backup on the active device.

  This event triggers an active device election. If both member devices have track entries in Negative state, the following rules apply:
  - In active/standby mode, the primary device is the active device, and the secondary device is the standby device.
  - In dual-active mode, both member devices are active.

When an active/standby switchover occurs, hot backup collaborates with other modules to direct traffic to the new active device.

- When working with VRRP, hot backup places all VRRP groups on the failed device to backup state.
- When working with a routing protocol, hot backup increases the link costs of routes on the failed device.

Associating hot backup with VRRP

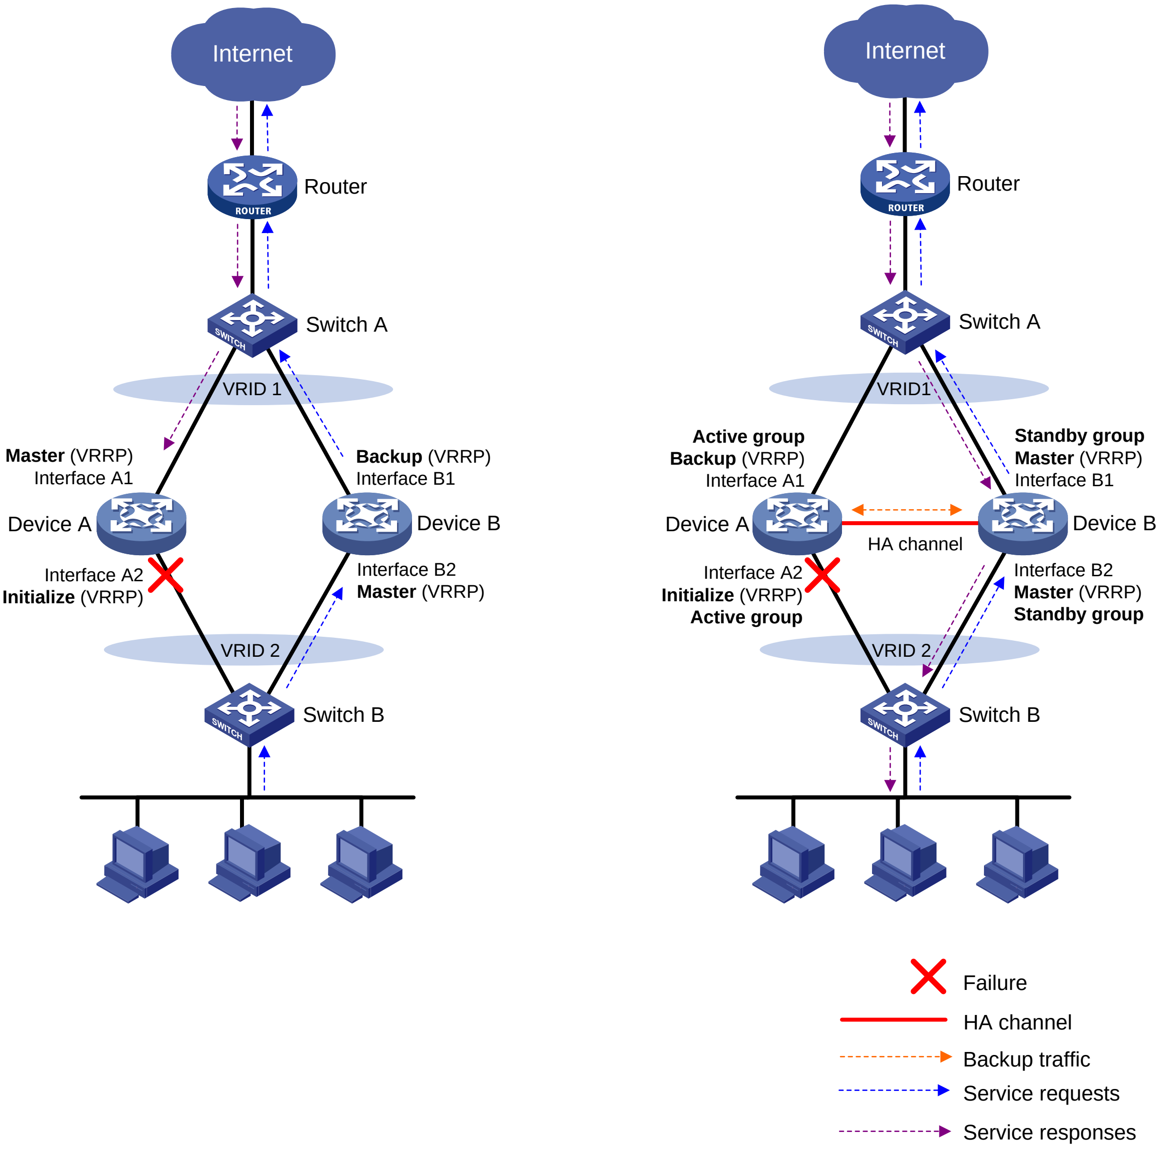
About hot backup and VRRP association

You can use hot backup and VRRP in combination to control master/backup switchover for device role consistency (master or backup) in multiple VRRP groups. This ensures that both inbound and outbound traffic can be switched to the new master for symmetric forwarding upon device failure.

Figure 8 illustrates VRRP association with hot backup in active/standby mode.

- As shown in the left, VRRP cannot ensure symmetric forwarding upon failure on a device, which causes traffic interruption.
- As shown in the right, after the hot backup control channel is established, hot backup determines the roles of the devices in all VRRP groups. The master election mechanism of VRRP no longer takes effect. If the hot backup control channel is disconnected, the master election mechanism of VRRP takes effect again.

Figure 8 VRRP and hot backup association



VRRP active/standby group

Hot backup is associated with VRRP by VRRP active and standby groups.

A VRRP active/standby group can be in master or backup state, which determines the state of devices in the associated VRRP groups. For example, if a VRRP active group is in master state, all devices in the associated VRRP groups are masters.

The initial state of a VRRP active/standby group is depends on the hot backup mode.

- **Active/Standby mode**—On the primary device, the initial state is master for the VRRP active and standby groups. On the secondary device, the initial state is backup for the VRRP active and standby groups.
- **Dual-active mode**—The state of a VRRP active/standby group is not affected by the hot backup roles. The initial state is master for the VRRP active group and is backup for the VRRP standby group.

VRRP master election in the hot backup environment

After hot backup is associated with VRRP, hot backup determines the roles of the devices in the VRRP groups. As shown in Figure 8, Device A is the master in VRRP group 1 and VRRP group 2, and Device B is the backup in VRRP group 1 and VRRP group 2. When Interface A2 on Device A fails, the following events occur:

1. Hot backup receives an interface failure event and sends the status change information of the VRRP active and standby groups to Device B.
2. Device B sets its role to master in the VRRP standby group and then becomes the master in VRRP group 1 and VRRP group 2.
3. Device B sends a response to Device A after the master/backup switchover.
4. Device A sets its role to backup in the VRRP active group and then becomes the backup in VRRP group 1 and VRRP group 2.

When Interface A2 recovers, hot backup performs another master/backup switchover following the same procedure. Traffic is switched back to Device A after the switchover.

ARP and MAC learning in VRRP

When the members of a VRRP group receive an ARP request for the group's virtual IP address, the master replies with the group's virtual MAC address. This allows the upstream and downstream Layer 2 devices and hosts to learn the virtual MAC address.

Associating hot backup with routing protocols

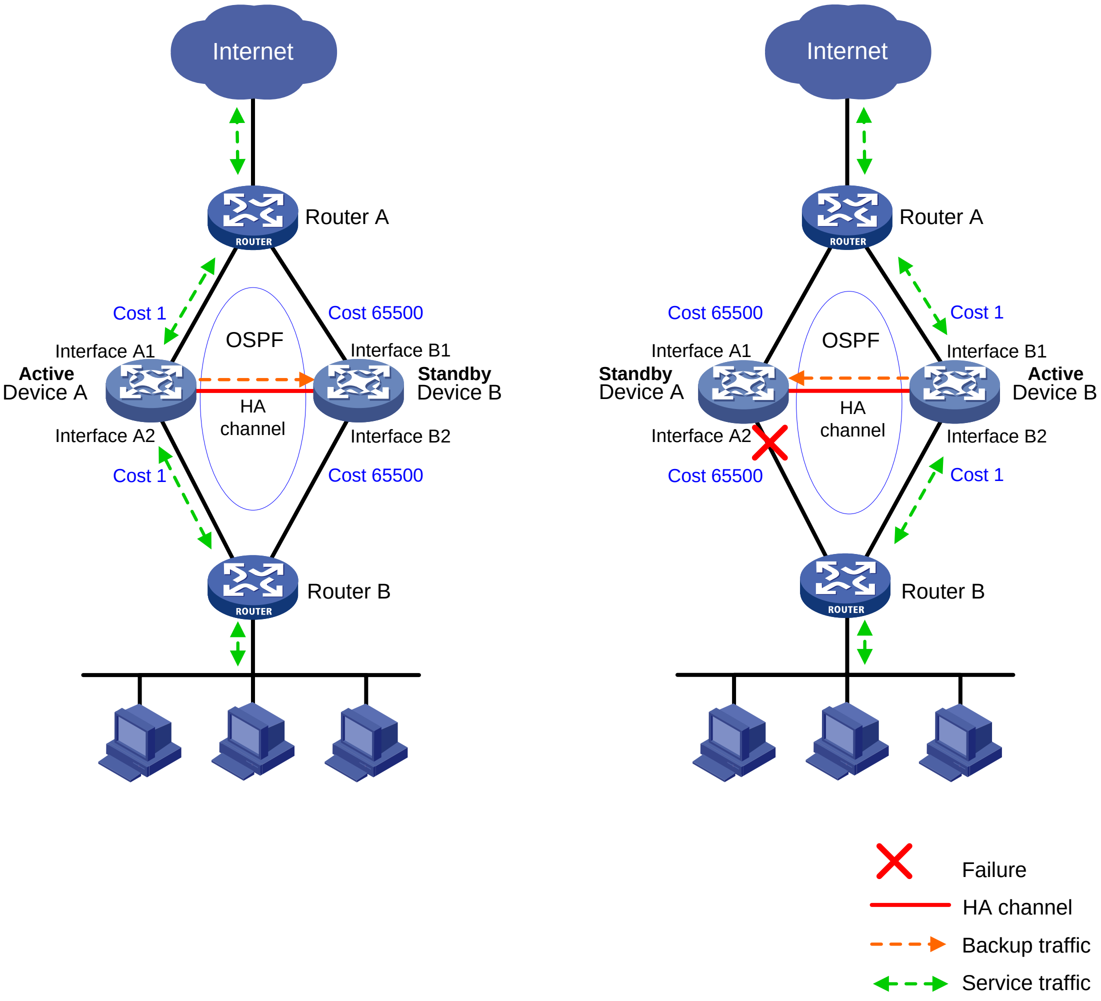
You can use hot backup to enable the routing protocols on the standby device to advertise modified link cost. The feature ensures that both inbound and outbound traffic can be switched to the new active device for symmetric forwarding.

This feature requires associating hot backup with Track to perform active/standby switchover upon link or interface failures.

Figure 9 illustrates OSPF association with hot backup in active/standby mode.

- As shown in the left, Device A (active device) advertises link cost 1 based on OSPF configuration. Device B (standby device) advertises link cost 65500 modified by hot backup. Both inbound and outbound traffic are forwarded through Device A.
- As shown in the right, when interface A2 fails, Device A and Device B perform an active/standby switchover. After the switchover is complete, Device B (active device) advertises link cost 1 based on OSPF configuration. Device A (standby device) advertises link cost 65500 modified by hot backup. Both inbound and outbound traffic are forwarded through Device B.

Figure 9 OSPF and hot backup association



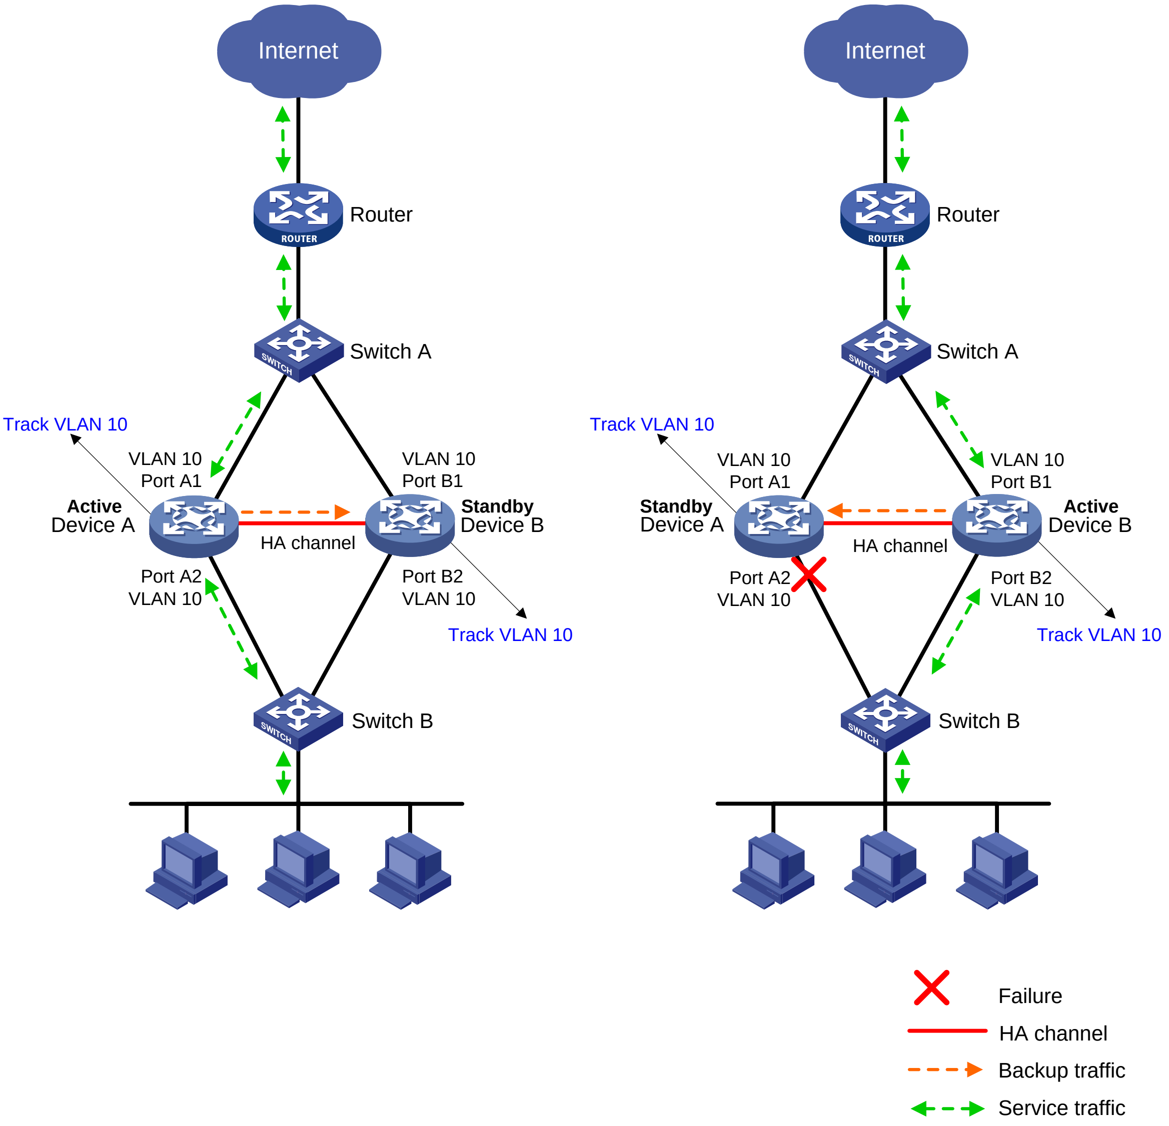
Transparent in-path deployment of hot backup

When you use this networking scheme, you can use the **track vlan** or **track interface** command to enable collaboration between uplink and downlink interfaces. The Track configuration ensures that a group of interfaces have the same status, and uplink and downlink traffic can be switched simultaneously between the member devices.

The following information uses the **track vlan** setting as an example to describe how interfaces collaborate:

- As shown in Figure 10, when both Device A (active) and Device B (standby) are operating correctly, tracked VLAN 10 is in active state on Device A and in inactive state on Device B. As a result, Device A forwards all traffic that traverses the hot backup system.
- As shown in Figure 10, when downlink Port A2 of Device A fails, Device A and Device B switch their roles. Then, hot backup places VLAN 10 in inactive state on Device A (standby) and in active state on Device B (active). As a result, Device B forwards all traffic that traverses the hot backup system.

Figure 10 Transparent in-path deployment of hot backup



Restrictions and guidelines: Hot backup configuration

Member device restrictions and guidelines

A hot backup system can contain a maximum of two devices.

To ensure that the traffic size is within the processing capability of one device upon failure of the other device, make sure the throughput of each device does not exceed 50% of its capability.

Configuration synchronization restrictions and guidelines

For the service modules for which hot backup supports configuration synchronization, you need to configure relevant settings only on the primary device. For the service modules that do not support configuration synchronization, you need to configure relevant settings on all devices in the hot backup system. For support of hot backup for configuration synchronization of service modules, see "Configuration backup."

For resource file associated functions or files (such as public key information, ISP address library file, and signature file), you need import the file with the same content to all devices in the hot backup system.

For the features or signature libraries that require licenses, purchase separate licenses and activate them on the hot backup member devices.

Interface restrictions and guidelines

On each member device, you must assign all interfaces that transmit service traffic to security zones and configure security policies to enable inter-zone communication.

Do not use hot backup in combination with the features that obtain IP addresses automatically, DHCP client for example. The interfaces on the hot backup system must use static IP addresses.

If service interfaces work in Layer 2 mode, assign uplink and downlink service interfaces to the same VLAN.

Hot backup channel restrictions and guidelines

The hot backup channels are set up over the keepalive link that is a direct link or traverses only Layer 2 switches.

When you select interfaces for hot backup channel setup, follow these restrictions and guidelines:

- Use physical interfaces or aggregate interfaces. Do not use subinterfaces or aggregation member ports.
- As a best practice, use the same physical or logical link to convey the hot backup data and control channels. Use the default MTU on the interfaces used for setting up the link.

When configuration backup is in progress, do not perform active/standby switchovers, remove or install service modules, or change the configuration. To view the backup progress, execute the **display remote-backup-group status** command.

If the hot backup system performs asymmetric forwarding, use the **session aging-time state fin** command to set the aging time for TCP sessions in FIN_WAIT state to 15 seconds. This configuration speeds up session entry aging when TCP connections disconnect and thus saves system resources. For more information about the **session aging-time state** command, see session management commands in *Security Command Reference*.

Hot backup deployment restrictions and guidelines

When you deploy hot backup, follow the restrictions and guidelines for the network scheme you have chosen.

Routed in-path hot backup deployment between upstream and downstream routers

You can use either active/standby or dual-active mode.

If you use hot backup with a routing protocol, use the **adjust-cost enable** command to enable hot backup to adjust the link costs for the routing protocol. In addition, associate hot backup with track entries to monitor the status of uplink and downlink interfaces.

If you use hot backup with static routes, use the **track interface** command to monitor uplink and downlink Layer 3 Ethernet interfaces.

Routed in-path hot backup deployment between upstream and downstream switches

You can use either active/standby or dual-active mode.

You must use hot backup with VRRP and configure hot backup to work with track entries to monitor the status of uplink and downlink interfaces.

Transparent in-path hot backup deployment between upstream and downstream routers

You can use either active/standby or dual-active mode.

You must use the **`track interface`** command to enable hot backup to monitor the status of uplink and downlink Layer 2 Ethernet interfaces.

Transparent in-path hot backup deployment between upstream and downstream switches

You can use only active/standby mode.

You must use the **`track vlan`** command to enable hot backup to monitor the status of uplink and downlink VLANs.

Feature compatibility restrictions

Compatibility with contexts

You can configure hot backup only on the default context. The configuration will be issued to all non-default contexts.

When an active/standby switchover occurs on any context, the other contexts will perform an active/standby switchover accordingly. As a best practice, place the active member devices of all contexts on the same device.

If you use hot backup on a non-default context, you must assign service interfaces to the non-default context in shared mode.

Compatibility with NAT

When you use NAT on a hot backup system, follow these restrictions:

- Hot backup does not support detecting reachability of NAT address group members or Easy IP.
- NAT address groups cannot contain the IP addresses of any interfaces on the hot backup member devices. If you violate this restriction, both hot backup member devices will respond to the ARP packets that an upstream device sends to request the IP addresses in the NAT address groups. As a result, ARP conflicts occur.
- The source or destination IP address in a NAT policy does not belong to the interface used for setting up the hot backup channels. Violation of this restriction causes keepalive link faults.
- If you cannot ensure that a flow identified by a five-tuple is processed by the same device in one direction, you must use the **`nat remote-backup port-alloc`** { **`primary`** | **`secondary`** } command to specify NAT port ranges for both hot backup member devices.

When you use NAT on a hot backup system operating in dual-active mode, follow these restrictions:

- NAT address groups do not support EIM.
- If NAT operates in PAT mode, you must execute the following commands on the NAT group members, one command on one device:
  - **`nat remote-backup port-alloc primary`**
  - **`nat remote-backup port-alloc secondary`**

  These commands divide an address group into two halves to avoid conflicts.
- If NAT operates in NO-PAT mode, you must configure two address groups to avoid resource assignment conflicts.

Compatibility with other protocols

Make sure the control and data packets of a multi-channel protocol such as FTP or SIP are processed by the same hot backup member device.

In the hot backup environment, to process traffic based on the SCTP protocol, make sure both the outbound and inbound packets of the same flow are processed by the same device.

Hardware environment consistency

Before you configure hot backup, verify that the following hardware settings are the same on the devices to be assigned to a hot backup system:

- Device model.
- Number and type of management interfaces, service interfaces, and interfaces for setting up the hot backup channels. Do not use one interface for multiple purposes.
- Location, number, and type of disks. A device not with disks installed has small log storage and do not support some types of logs or reports.

Software environment consistency

Before you configure hot backup, verify that the following software settings are the same on the devices to be assigned to a hot backup system:

- Software environment and version, including boot packages, system packages, feature packages, and patches.
- Licensed signature libraries and features, such as signature library types, signature library version, validation time, and number of licensed resources.
- Interface numbers.
- Type, speed, and number of the interfaces for setting up the hot backup channels. As a best practice, use aggregate interfaces.
- Aggregate interface numbers and aggregation member port numbers.
- Security zone configuration on the interfaces at the same location.
- Multi-CPU packet distribution policy (configurable with the **`forwarding policy`** command).

Network interconnection restrictions

Configure security policies for the hot backup members to correctly exchange the packets required in forwarding over the hot backup channels, routing protocol packets for example. As a best practice, make sure only those packets are transmitted between the security zone that accommodates service interfaces and the **Local** security zone.

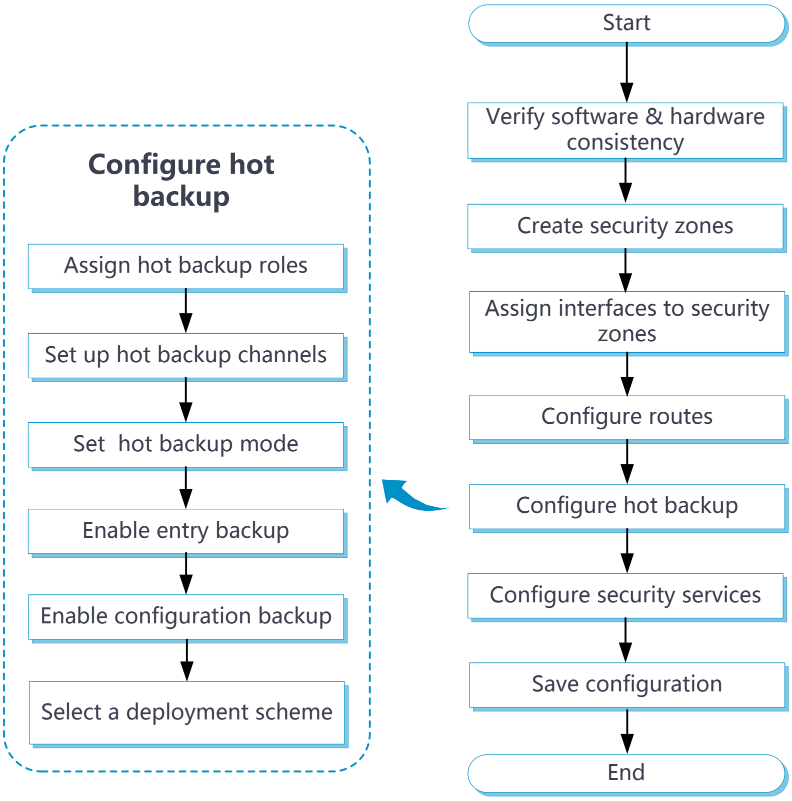
The device by default permits the hot backup packets transmitted over the hot backup channels. You do not need to configure security policies for the hot backup packets.

Configure a feature prior to hot backup deployment if hot backup cannot back up configuration of the feature. For more information about the features that can be backed up by hot backup, see "Configuration backup."

Hot backup configuration flow

Figure 11 shows the configuration flow for hot backup.

Figure 11 Hot backup configuration flow chart



Start
Verify software & hardware consistency
Create security zones

Hot backup tasks at a glance

To configure hot backup, perform the following tasks:

1. Configuring the hot backup role
2. Configuring hot backup data synchronization settings
    a. Configuring the hot backup control channel
    b. Configuring the hot backup data channel
    c. Enabling service entry hot backup
    d. Configuring hot backup configuration synchronization
3. Enabling traffic switchover upon failure recovery
4. Setting the hot backup mode

    Choose one of the following tasks:
    - Configuring the active/standby mode
    - Configuring the dual-active mode
5. Configuring hot backup associations

    Choose one of the following tasks:
    - Associating hot backup with VRRP
    - Associating hot backup with routing protocols
    - Configuring hot backup transparent in-path deployment
6. (Optional.) Associating hot backup with Track
7. (Optional.) Performing an active/standby switchover

8. (Optional.) Enabling transparent service traffic transmission between the hot backup members
9. (Optional.) Configuring service features on the hot backup system

Configuring the hot backup role

About this task

Hot backup backs up important configuration from the primary device to the secondary device to prevent service interruption when an active/standby switchover occurs. The configuration on the secondary device is overwritten. The unidirectional backup mechanism avoids configuration conflicts, especially in dual-active mode. The hot backup roles can only be manually assigned to devices.

Each hot backup member device adds a prefix to the view prompt to identify its hot backup role.

- The primary device adds the **RBM_P** prefix, **RBM_P<Sysname>** for example.
- The secondary device adds the **RBM_S** prefix, **RBM_S<Sysname>** for example.

After you assign hot backup roles to the hot backup member devices, both devices add the **RBM_P** prefix to their view prompts. The devices display view prompt prefixes according to their hot backup roles after they set up the hot backup control channel.

Restrictions and guidelines

You must assign the primary and secondary roles to the two member devices in the hot backup system, respectively.

As a best practice to ensure correct operation of the hot backup system, enable configuration backup on the primary device.

Procedure

1. Enter system view.

   system-view

2. Enter RBM view.

   remote-backup group

3. Configure the hot backup role.

   device-role { **primary** | **secondary** }

   By default, the hot backup role is not configured.

Configuring the hot backup control channel

About this task

Hot backup compares the specified local and peer IP address to determine the device role for setting up the control channel. The device with higher IP address acts as the server, and the other device acts as the client to initiate the TCP connection.

If the port number is configured on the server, the port provides services for the client. If the port number is configured on the client, the port serves as the destination port to establish TCP connection to the server. The source port is randomly generated on the client.

Restrictions and guidelines

You can specify only one peer IP address with the same port number on the hot backup member devices. The specified port cannot be the same as the TCP listening port in use.

The local and peer IP addresses used for setting up the control channel cannot be identical.

You can set up an IPv4 control channel or IPv6 control channel, but not both.

Procedure

1. Enter system view.

   system-view

2. Enter RBM view.

   remote-backup group

3. Set up a hot backup control channel. Choose one of the following options:
   - Set up an IPv4 control channel.
     - Configure the peer IPv4 address for setting up the hot backup control channel.

       remote-ip *ipv4-address* [**port** *port-number*]

       By default, the peer IPv4 address is not configured.
     - Configure the local IPv4 address for setting up the hot backup control channel.

       local-ip *ipv4-address*

       By default, the local IPv4 address is not configured.
   - Set up an IPv6 control channel.
     - Configure the peer IPv6 address for setting up the hot backup control channel.

       remote-ipv6 *ipv6-address* [**port** *port-number*]

       By default, the peer IPv6 address is not configured.
     - Configure the local IPv6 address for setting up the hot backup control channel.

       local-ipv6 *ipv6-address*

       By default, the local IPv6 address is not configured.
4. Set the interval for sending hot backup keepalive packets.

   keepalive interval *interval*

   By default, the device sends hot backup keepalive packets at one-second intervals.
5. Set the maximum number of hot backup keepalive attempts.

   keepalive count *counts*

   By default, the maximum number of hot backup keepalive attempts is 10.

Configuring the hot backup data channel

1. Enter system view.

   system-view
2. Enter RBM view.

   remote-backup group
3. Configure a hot backup data channel.

   data-channel interface *interface-type interface-number*

   By default, no hot backup data channel is configured.

Enabling service entry hot backup

About this task

Service entry hot backup enables the active device to back up service entries to the standby device in real time.

Enable HTTP and DNS backup if asymmetric-path traffic traverses the hot backup system. HTTP and DNS backup ensures that a flow and its return traffic are processed correctly on the hot backup members.

If hot backup active/standby mode is used or only symmetric-path traffic traverses the hot backup system, disabling HTTP and DNS backup can improve performance of the hot backup members at the expense of delayed data synchronization. When you disable HTTP and DNS backup, make sure you are fully aware of the impact on the network. A device removes a DNS or HTTP connection if packet exchange is inactive. When a switchover interrupts a connection, the DNS or HTTP client re-initiates the connection immediately, which has little impact on user services.

Restrictions and guidelines

When the hot backup system is operating stably and is processing traffic, do not execute the **`reset session table`** command. If you execute the command, traffic might be interrupted, and the session entries might become inconsistent on the primary and backup devices. For more information about session management, see *Security Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Enter RBM view.
   `remote-backup group`
3. Enable service entry hot backup.
   `hot-backup enable`

   By default, service entry hot backup is enabled.
4. Enable hot backup for the session entries of application layer protocols.
   `hot-backup protocol { dns | http } * enable`

   By default, the hot backup system performs hot backup for the session entries of application layer protocols.

   The **`hot-backup protocol enable`** command takes effect only on DNS and HTTP. The device automatically backs up the session entries of other application layer protocols after you enable service entry hot backup.

Configuring hot backup configuration synchronization

About this task

The hot backup member devices can synchronize configuration changes in real time and synchronize all configuration in bulk.

- **Real-time synchronization**—The primary device copies added, deleted, or modified configuration to the secondary device in real time to maintain configuration consistency.
- **Bulk synchronization**—The primary device backs up important configuration in bulk to the secondary device. The secondary device will delete the settings that are inconsistent with those on the primary device.

Hot backup can perform hot backup configuration synchronization only when automatic configuration synchronization is enabled and the hot backup control channel is set up.

A bulk synchronization is triggered by the following events:

- The hot backup control channel is set up and automatic configuration synchronization is enabled (including the default status) for the first time. The primary device will send all its key configuration in bulk to overwrite the configuration on the secondary device. Hot backup does not perform bulk synchronization afterwards, even if automatic configuration synchronization is enabled again or the hot backup control channel is set up again.

- An hot backup member device reboots, or the hot backup process restarts, and automatic configuration synchronization is enabled on the other device. After the reboot or restart and the hot backup control channel is set up again, the device that does not reboot will send all its key configuration in bulk to overwrite the configuration on the rebooted device.

Restrictions and guidelines

After the hot backup control channel is set up and automatic configuration synchronization is enabled for the first time, do not disable automatic configuration synchronization. If you fail to do so, the devices will not perform bulk configuration, and configuration inconsistency will affect services.

If the amount of configuration to be synchronized is large, bulk synchronization might take one to two hours. To avoid the issue, you can perform one of the following operations:

- Enable automatic configuration synchronization first when you configure the hot backup system.
- Copy the configuration file to the secondary device during initial network deployment and then enable configuration consistency check.

Procedure

1. Enter system view.

   `system-view`

2. Enter RBM view.

   `remote-backup group`

3. Enable automatic configuration synchronization.

   `configuration auto-sync enable`

   By default, automatic configuration synchronization is enabled.

4. Enable configuration consistency check.

   `configuration sync-check` `[` **`interval`** *`interval`* `]`

   By default, configuration consistency check is enabled.

5. (Optional.) Perform a one-off configuration consistency check.

   `configuration manual-sync-check`

   This command applies only to the primary device.

6. (Optional.) Manually synchronize the configuration of the primary device to the secondary device.

   `configuration manual-sync`

   This command applies only to the primary device.

Enabling traffic switchover upon failure recovery

About this task

After an active/standby switchover occurs, if the original active device recovers, traffic will not be switched back by default. Perform this task to enable traffic switchover to the original active device upon failure recovery. You can set a delay timer to ensure smooth service switchover.

Restrictions and guidelines

In dual-active mode, you must enable this feature to ensure that both devices can operate after the failure is recovered.

This feature does not take effect on ongoing traffic switchovers. It applies only to subsequent traffic switchovers.

Procedure

1. Enter system view.
   system-view
2. Enter RBM view.
   remote-backup group
3. Enable traffic switchover upon failure recovery.
   delay-time *delay-time*
   By default, traffic switchover upon failure recovery is disabled.

Configuring the active/standby mode

1. Enter system view.
   system-view
2. Enter RBM view.
   remote-backup group
3. Configure the active/standby mode.
   undo backup-mode dual-active
   By default, the hot backup mode is active/standby.

Configuring the dual-active mode

1. Enter system view.
   system-view
2. Enter RBM view.
   remote-backup group
3. Configure the dual-active mode.
   backup-mode dual-active
   By default, the hot backup mode is active/standby.

Associating hot backup with VRRP

Restrictions and guidelines

You can associate only VRRP groups operating in standard mode with hot backup.

Use hot backup in combination with VRRP groups only for in-path hot backup deployment between upstream and downstream switches. As a best practice, assign the primary device to the VRRP active group, and assign the secondary device to the VRRP standby group.

You can assign multiple virtual IP addresses to a VRRP group associated with hot backup. Make sure the interfaces in the VRRP group do not own the virtual IP addresses.

You cannot associate a VRRP group with both hot backup and Track.

You cannot use the **track vlan** command in conjunction with the **track interface** command.

For an IPv6 VRRP group to work correctly, you must assign it a link-local address and a global unicast address as virtual IPv6 addresses.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Associate hot backup with VRRP. Choose one of the following options:
   - Create an IPv4 VRRP group and associate it with hot backup.

     vrrp vrid *virtual-router-id* **virtual-ip** *virtual-address* [*mask* | *mask-length*] { **active** | **standby** }

     By default, no IPv4 VRRP groups exist.
   - Create an IPv6 VRRP group and associate it with hot backup. Assign a link-local address and a global unicast address as virtual IPv6 addresses to the VRRP group.

     vrrp ipv6 vrid *virtual-router-id* **virtual-ip** *virtual-address* [*prefix-length*] **link-local** { **active** | **standby** }

     vrrp ipv6 vrid *virtual-router-id* **virtual-ip** *virtual-address*

     By default, no IPv6 VRRP groups exist.

Associating hot backup with routing protocols

Enabling hot backup to adjust the link cost for a routing protocol

About this task

When you use hot backup together with a routing protocol, you can enable hot backup to adjust the link cost for a routing protocol on the standby device. This feature applies to the scenario where the hot backup member devices run the same routing protocol. If you configure this feature, the active device advertises the original link costs for a routing protocol, and the standby device advertises one of the following link costs:

- **Absolute cost**—The device advertises an absolute link cost for the routing protocol.
- **Calculated cost**—The device advertises the original link cost plus the configured increment cost for the specified routing protocol.

The feature takes effect on only the standby device.

Restrictions and guidelines

This feature applies to the scenario where the hot backup member devices run the same routing protocol.

To ensure switchover of both uplink and downlink traffic to the new active device, configure this feature with the same parameters on both hot backup member devices.

Do not use the **silent-backup-interface** and **adjust-cost enable** commands together.

On a hot backup system in dual-active mode and in collaboration with a routing protocol, configure per-flow load sharing for IP forwarding on both the uplink and downlink devices as a best practice.

Procedure

1. Enter system view.

   system-view

2. Enter RBM view.

```
remote-backup group
```

3. Enable hot backup to adjust the link cost for the specified routing protocol on the standby device.

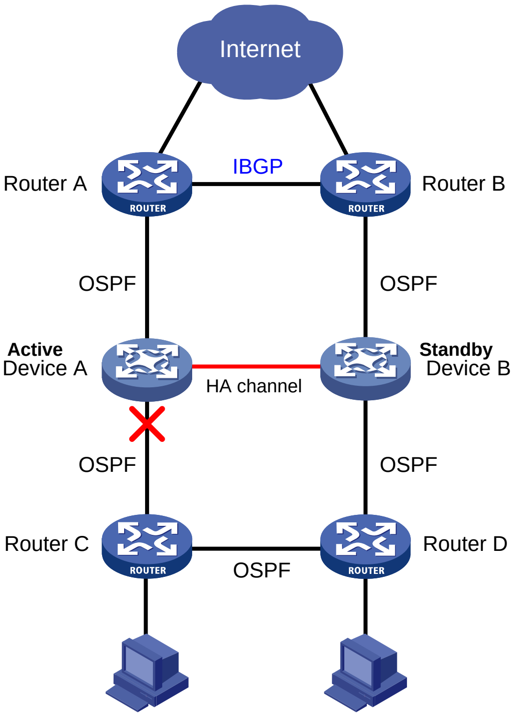
   adjust-cost { **bgp** | **isis** | **ospf** | **ospfv3** } **enable** { **absolute** [*absolute-cost*] | **increment** [*increment-cost*] }

   By default, hot backup does not adjust the link cost for the specified routing protocol on the standby device.

Disabling the standby device from sending or receiving protocol packets of a routing protocol.

This feature applies to the scenario where the hot backup member devices run multiple routing protocols. As shown in Figure 12, IBGP and OSPF have different default priorities. When the link between Device A and Router C fails, traffic destined for the hosts might be forwarded to Device A as OSPF has higher priority than IBGP. To resolve this issue, disable Device A from sending or receiving OSPF protocol packets to disconnect its OSPF neighbors. Then, Device B will forward all uplink and downlink traffic.

Figure 12 hot backup member devices running multiple routing protocols



Restrictions and guidelines

This feature applies to the scenario where the hot backup member devices run multiple routing protocols.

To ensure switchover of both uplink and downlink traffic to the new active device, configure this feature with the same parameters on both hot backup member devices.

Do not use the **silent-backup-interface** and **adjust-cost enable** commands together.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter RBM view.

   remote-backup group

3. Disable the standby device from sending or receiving protocol packets of a dynamic routing protocol.

   silent-backup-interface { **ospf** | **ospfv3** }

   By default, the standby device can send and receive protocol packets of a dynamic routing protocol.

Configuring hot backup transparent in-path deployment

Enabling hot backup to monitor interfaces

About this task

Perform this task to enable hot backup to monitor the interfaces connecting the uplink and downlink devices in hot backup transparent in-path deployment. The monitored interfaces can forward packets only when they are all up. If any of the monitored interfaces goes down, none of them will be able to forward packets.

Restrictions and guidelines

You can use the **track interface** and **track** commands in conjunction, but you cannot use these commands to monitor the same interfaces.

The **track vlan** and **track interface** commands are mutually exclusive. You cannot configure both of them.

Hot backup does not support monitoring member ports of aggregate interfaces.

Procedure

1. Enter system view.

   system-view

2. Enter RBM view.

   remote-backup group

3. Enable hot backup to monitor a Layer 2 or Layer 3 Ethernet interface.

   track interface *interface-type interface-number*

   By default, hot backup does not monitor any interfaces.

Enabling hot backup to monitor VLANs

About this task

Perform this task to enable hot backup to monitor the VLANs of the uplink and downlink devices in hot backup transparent in-path deployment. The monitored VLANs are active and the member ports can forward packets only when the member ports are all up. If any of the member ports goes down, none of them will be able to forward packets, and all the monitored VLANs will become inactive.

In active/standby mode, the state of monitored VLANs is active on the primary device and inactive on the secondary device.

In dual-active mode, the state of monitored VLANs is active on both the primary and secondary devices.

Restrictions and guidelines

The **track vlan** command is mutually exclusive with the **track interface** and **track** commands. You cannot use the **track vlan** command in conjunction with the **track interface** or **track** command.

Do not enable hot backup to monitor VLAN 1 (to which all access ports belong by default). This restriction prevents an unused interface in down state from interrupting operation of other interfaces in VLAN 1.

Procedure

1. Enter system view.

   system-view

2. Enter RBM view.

   remote-backup group

3. Enable hot backup to monitor a VLAN.

   track vlan *vlan-id*

   By default, hot backup does not monitor any VLANs.

Associating hot backup with Track

About this task

Perform this task to associate hot backup with Track to monitor links. If one of the monitored track entries becomes Negative, hot backup performs an active/standby switchover and switches traffic to the new active device to ensure service continuity. For more information about Track, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter RBM view.

   remote-backup group

3. Associate hot backup with Track.

   track *track-entry-number*

   By default, hot backup is not associated with Track.

Performing an active/standby switchover

About this task

If you want to replace components or upgrade software on the current active device, you can perform this task to switch services to the standby device.

Restrictions and guidelines

This feature applies only when hot backup operates in active/standby mode, and it takes effect on only the active device.

In hot backup and VRRP associated network, performing this task might cause temporary virtual IP address conflict in the VRRP group, which is considered a normal condition.

For stable operation of hot backup, do not repeatedly perform this task within one minute.

Procedure

1. Enter system view.

   `system-view`

2. Enter RBM view.

   `remote-backup group`

3. Perform an active/standby switchover.

   `switchover request`

Enabling transparent service traffic transmission between the hot backup members

About this task

Enable transparent service traffic transmission only when asymmetric-path traffic traverses the hot backup system operating in dual-active mode.

If an asymmetric-path flow traverses the hot backup system operating in dual-active mode, the flow and its return traffic are processed by different hot backup members. This will degrade the traffic processing performance of modules such as NBAR, DPI, and load balancing. For example, the packet recognition rate of NBAR might drop. For an asymmetric-path flow and its return traffic to be processed by the same hot backup member, enable transparent service traffic transmission. Transparent service traffic transmission is resource-intensive. Make sure you are fully aware of the impact of this feature when you use it on a live network.

Procedure

1. Enter system view.

   `system-view`

2. Enter RBM view.

   `remote-backup group`

3. Enable transparent service traffic transmission between the hot backup members.

   `transparent-transmit enable`

   By default, transparent service traffic transmission is enabled*.*

Configuring service features on the hot backup system

NAT on the hot backup system

For NAT to operate correctly on the hot backup system, you must associate NAT features with the VRRP groups. For example, when you use dynamic NAT, static NAT, NAT server, or NAT444, you must associate the feature with the VRRP groups. For more information about NAT features, see *NAT Configuration Guide*.

NAT features have similar mechanisms, and the operating mode of hot backup does not change the IP address translation process. This section uses dynamic NAT on the hot backup system in active/standby mode to explain how NAT works on the hot backup system.

About NAT on the hot backup system

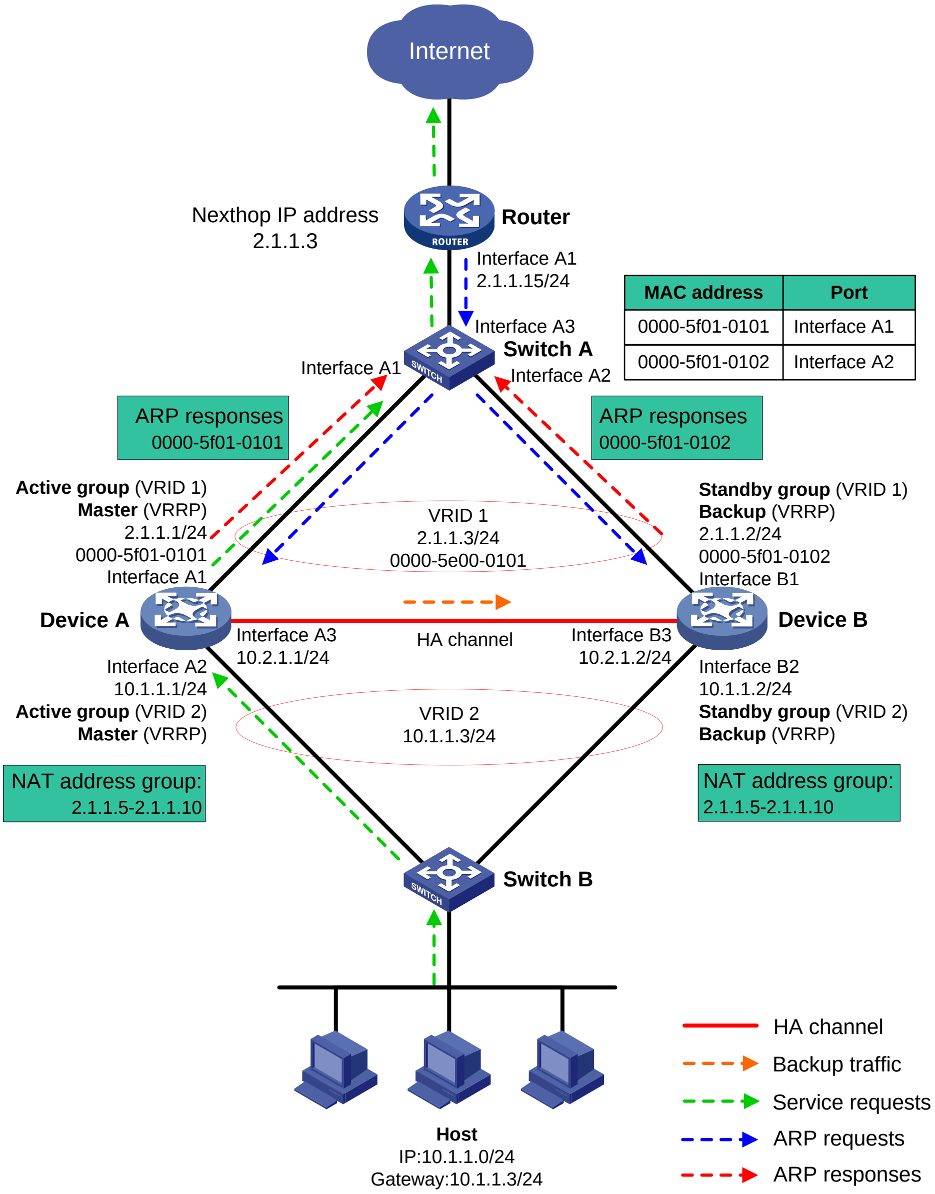
When receiving an ARP request with a target IP address that belongs to the subnet of the IP address of a NAT interface, a NAT device replies with the MAC address of the NAT interface.

As shown in Figure 13, dynamic NAT is configured on the hot backup system that is operating in active/standby mode. If dynamic NAT is not associated with any VRRP group, the devices process the traffic as follows when the host accesses the Internet:

1. When receiving the packets sent by the host, Device A translates the source IP address into a public IP address in the NAT address group and forwards the packets to the router. In this example, the public IP address is in the same subnet as the virtual IP address of uplink VRRP group 1.
2. The router receives the return packets and broadcasts an ARP request for the destination public IP address.
3. Device A and Device B receive the ARP request and reply with the MAC address of their respective uplink interface because they have the same NAT address group configuration.
4. The router might send the return packets to the uplink interface of Device A or Device B, which affects service continuity.

For the router to learn the virtual MAC address of the uplink VRRP group, you must associate NAT features with the VRRP group.

Figure 13 NAT not associated with a VRRP group



MAC address	Port
0000-5f01-0101	Interface A1
0000-5f01-0102	Interface A2

Traffic forwarding process

The master in a VRRP group relies with the virtual MAC address of the VRRP group to an ARP request if the following requirements are met:

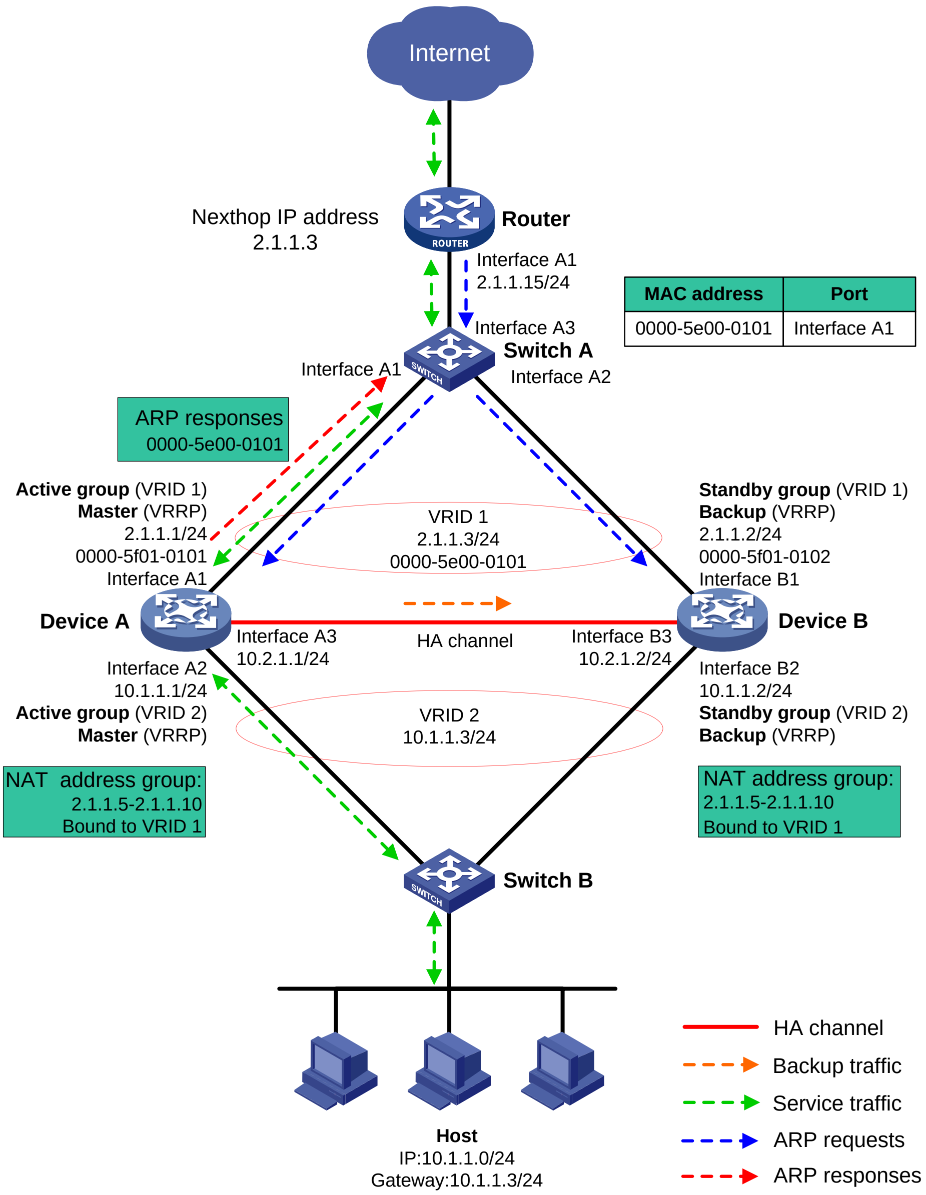
- NAT features are associated with the VRRP group.
- The target IP address belongs to the subnet that contains the IP address of a NAT interface.

As shown in Figure 14, dynamic NAT is configured on the hot backup system that is operating in active/standby mode. If NAT is associated with the uplink VRRP group, the devices process the traffic as follows when the host accesses the Internet:

1. When receiving the packets sent by the host, Device A translates the source IP address into a public IP address in the NAT address group and forwards the packets to the router. In this example, the public IP address is in the same subnet as the virtual IP address of uplink VRRP group 1.
2. The router receives the return packets and broadcasts an ARP request for the destination public IP address.

3. Device A and Device B receive the ARP request, and Device A (master) replies with the virtual MAC addresses of the uplink VRRP group.
4. Router A sends the return packets to Device A.

Figure 14 NAT on the hot backup system



MAC address	Port
0000-5e00-0101	Interface A1

For more information about VRRP group association with dynamic NAT, static NAT, NAT server, and NAT444, see *Layer 3—IP Services Configuration Guide*.

Hot backup support for SSL VPN

The hot backup channels are used to back up SSL VPN data, including user data, entries, and configuration. For more information about SSL VPN configuration, see *VPN Configuration Guide*.

Hot backup supports SSL VPN only when it is operating in active/standby mode and collaborating with VRRP groups.

Hot backup support for DPI services

When you use DPI services on the hot backup system operating in dual-active mode, you must enable DPI support for hot backup if asymmetric-path traffic exists. If you do not enable this feature, DPI services might fail to correctly identify and process packets. For more information about DPI support for hot backup, see DPI engine configuration in *DPI Configuration Guide*.

Hot backup support for contexts

You can configure hot backup only on the default context. The configuration will be issued to all non-default contexts.

To ensure configuration and service entry consistency, all non-default contexts use the hot backup channels created for the default context to back up configuration and service entries and transmit service traffic.

All non-default contexts use the keepalive detection and configuration consistency check mechanisms of the default context. When an active/standby switchover occurs on any context, the other contexts will perform an active/standby switchover accordingly.

Hot backup deployment schemes

Hot backup supports the following deployment schemes:

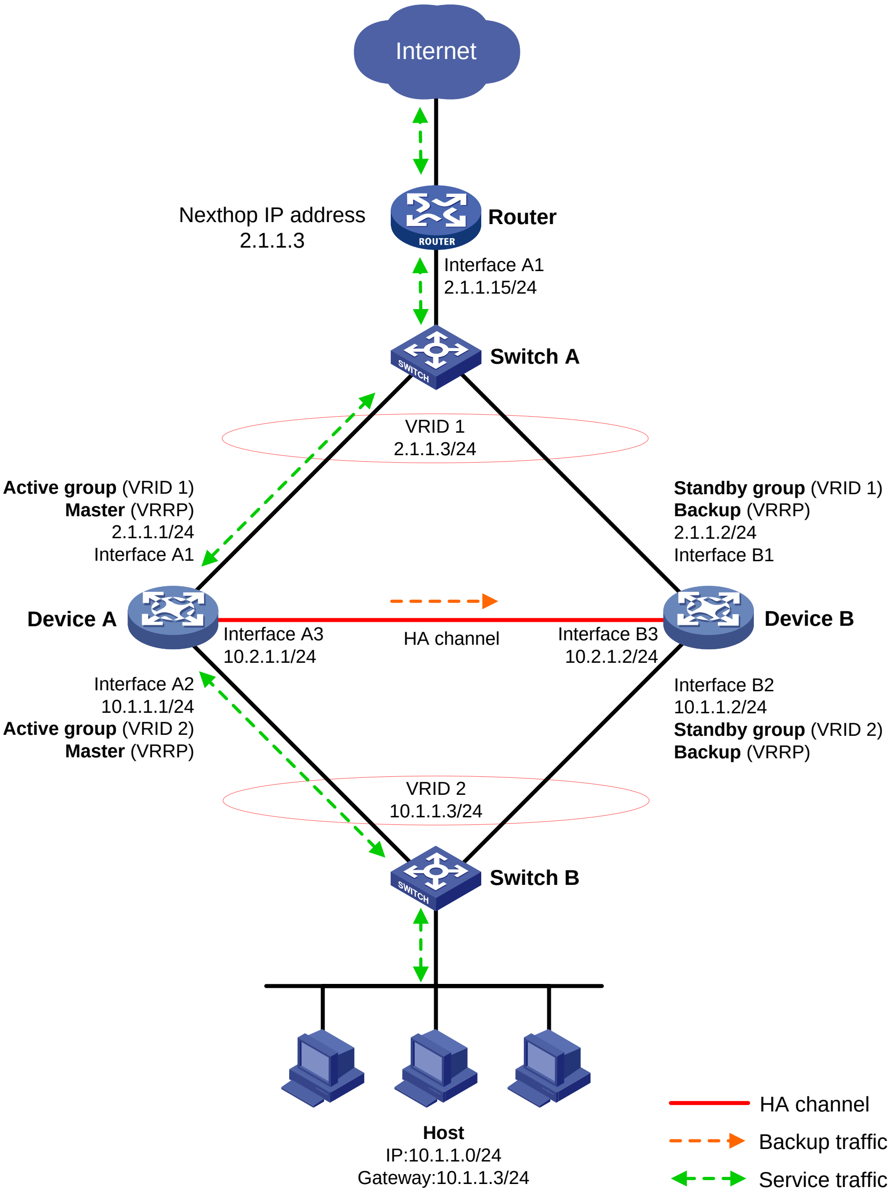
- Routed in-path deployment in active/standby mode.
- Routed in-path deployment in dual-active mode.
- Transparent in-path deployment in active/standby mode.
- Transparent in-path deployment in dual-active mode.

Routed in-path deployment in active/standby mode

Figure 15 shows a typical model of routed in-path deployment in active/standby mode. A hot backup system is directly connected to the upstream and downstream Layer 2 switches by Layer 3 interfaces. To use this scheme in collaboration with VRRP, perform the following tasks:

- Establish hot backup channels between Device A and Device B.
- On Device A and Device B, create uplink VRRP group 1 and downlink VRRP group 2 and associate them with hot backup.
- On Device A, associate VRRP group 1 and VRRP group 2 with the VRRP active group. On Device B, associate VRRP group 1 and VRRP group 2 with the VRRP standby group.
- On Device A and Device B, specify the IP address of Interface A1 on the router (2.1.1.15) as the next hop of the route to the Internet.
- On the router, specify the virtual IP address of VRRP group 1 (2.1.1.3) as the next hop of the route to the host's subnet.
- On the host, specify the virtual IP address of VRRP group 2 (10.1.1.3) as the default gateway.
- On Switch A, assign the interfaces attached to the router, Device A, and Device B to the same VLAN.
- On Switch B, assign the interfaces attached to the host, Device A, and Device B to the same VLAN.

Figure 15 Routed in-path deployment in active/standby mode



The following shows how traffic is forwarded when the host accesses the Internet in Figure 15:

1. The host identifies that the destination IP address is on a different subnet and sends an ARP request to obtain the MAC address of the default gateway. In this example, the host does not have the ARP entry for the default gateway.
2. Switch B broadcasts the ARP request and learns the MAC address of the host.
3. Device A and Device B receives the ARP request, and Device A (master) replies with the virtual MAC address of VRRP group 2.
4. Switch B learns the MAC address entry for the virtual MAC address of VRRP group 2 and forwards the ARP reply to the host.
5. The host learns the virtual MAC address and sends the packets destined for the Internet to the default gateway.
6. Switch B forwards the packets to Device A (master). The traffic of the host will be processed and forwarded by Device A as long as it is the master.

7. Device A does not have the ARP entry for the next hop of the route to the Internet and sends an ARP request to obtain the MAC address of the next hop. In the ARP request, the source MAC address is the virtual MAC address of VRRP group 1.
8. Switch A and the router then perform typical forwarding and ARP and MAC address learning.

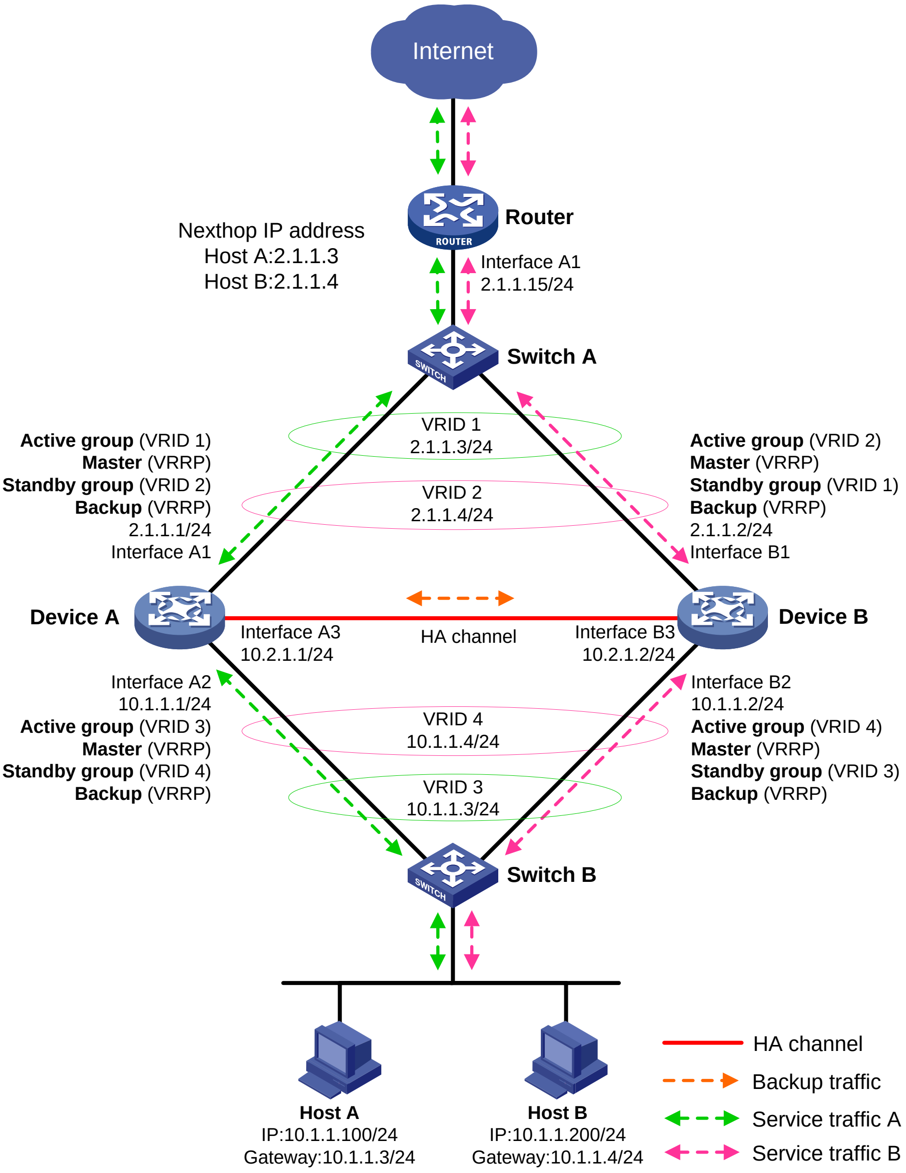
The forwarding process for the traffic sent from the Internet to the host is similar to the above process.

Routed in-path deployment in dual-active mode

Figure 16 shows a typical model of routed in-path deployment in dual-active mode. A hot backup system is directly connected to the upstream and downstream Layer 2 switches by Layer 3 interfaces. To use this scheme in collaboration with VRRP, perform the following tasks:

- Establish hot backup channels between Device A and Device B.
- On Device A and Device B, create two uplink VRRP groups and two downlink VRRP groups.
- Create VRRP group 3 and VRRP group 4 on the downlink interfaces of Device A and Device B.
- On Device A, associate VRRP group 1 and VRRP group 3 with the VRRP active group, and associate VRRP group 2 and VRRP group 4 with the VRRP standby group.
- On Device B, associate VRRP group 1 and VRRP group 3 with the VRRP standby group, and associate VRRP group 2 and VRRP group 4 with the VRRP active group.
- On Device A and Device B, specify the IP address of Interface A1 on the router (2.1.1.15) as the next hop of the route to the Internet.
- On the router, configure routes as follows:
  - Specify the virtual IP address of VRRP group 1 (2.1.1.3) as the next hop of the route to Host A's subnet.
  - Specify the virtual IP address of VRRP group 2 (2.1.1.4) as the next hop of the route to Host B's subnet.
- On Host A, specify the virtual IP address of VRRP group 3 (10.1.1.3) as the default gateway.
- On Host B, specify the virtual IP address of VRRP group 4 (10.1.1.4) as the default gateway.
- On Switch A, assign the interfaces attached to the router, Device A, and Device B to the same VLAN.
- On Switch B, assign the interfaces attached to the hosts, Device A, and Device B to the same VLAN.

Figure 16 Routed in-path deployment in dual-active mode



As shown in Figure 16, the traffic of Host A and Host B is distributed to Device A and Device B, respectively. The traffic forwarding process is similar to that in active/standby mode.

Transparent in-path deployment in active/standby mode

Figure 17 shows a typical model of transparent in-path deployment in active/standby mode. The Layer 2 hot backup system is directly connected to the upstream and downstream Layer 2 switches by Layer 2 interfaces. To use this scheme, perform the following tasks:

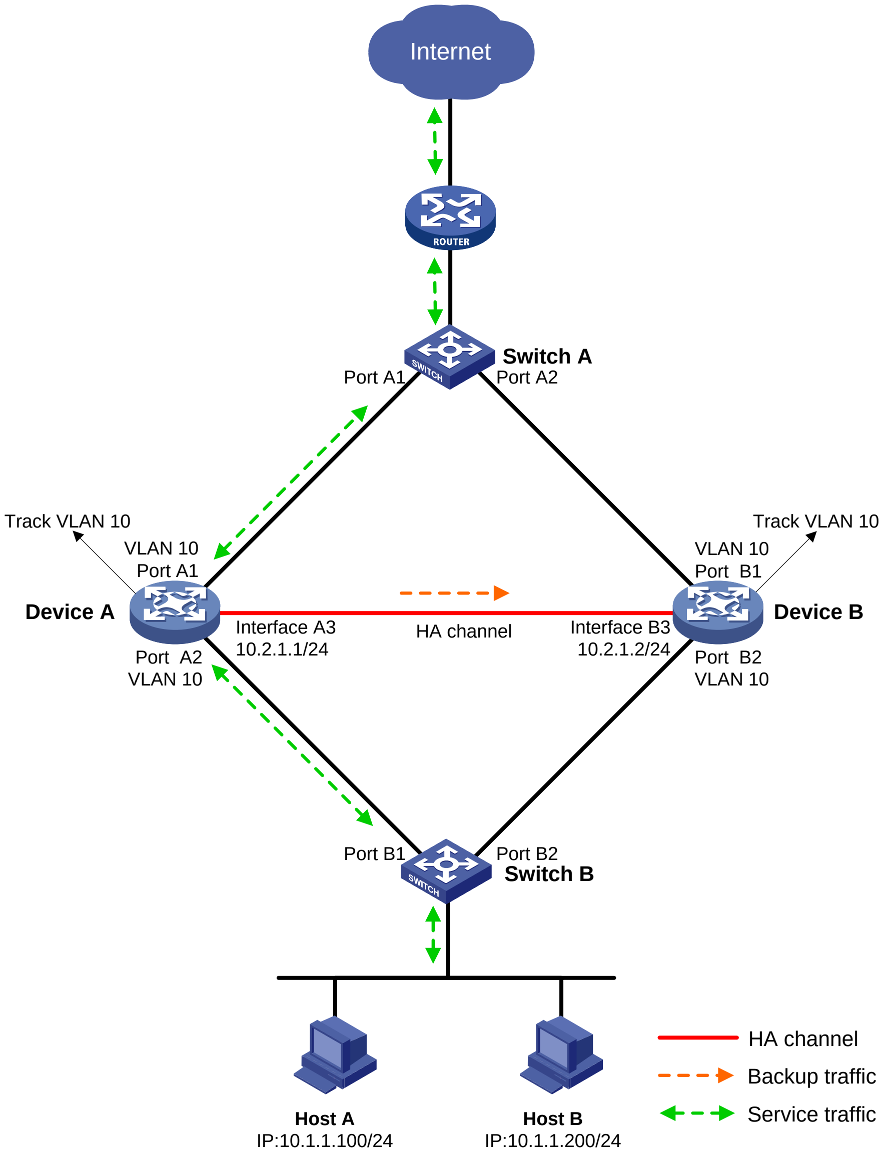
- Establish hot backup channels between Device A and Device B.
- On Device A and Device B, assign uplink and downlink interfaces to the same VLAN.
- Configure hot backup to monitor one of the following objects:
  - The VLAN where Device A and Device B reside.

    You do not need to enable spanning tree on the upstream and downstream switches.
  - Uplink and downlink interfaces of Device A and Device B.

You must enable spanning tree on the upstream and downstream switches.

- On Switch A, assign the interfaces attached to the upstream router, Device A, and Device B to the same VLAN.
- On Switch B, assign the interfaces attached to the hosts, Device A, and Device B to the same VLAN.

Figure 17 Transparent in-path deployment in active/standby mode



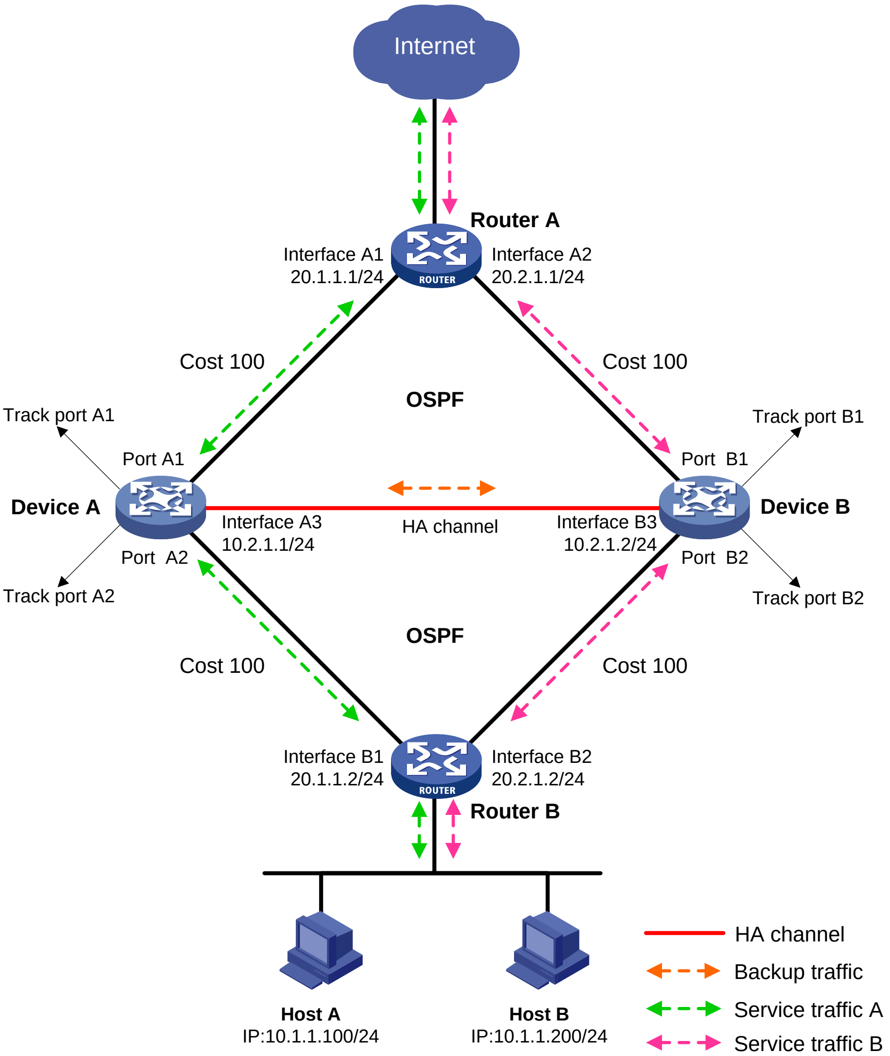
Transparent in-path deployment in dual-active mode

Figure 18 shows a typical model of transparent in-path deployment in dual-active mode. The Layer 2 hot backup system is directly connected to the upstream and downstream routers by Layer 2 interfaces. To use this scheme, perform the following tasks:

- Establish hot backup channels between Device A and Device B.
- On Device A and Device B, assign uplink and downlink interfaces to the same VLAN.
- On Device A and Device B, configure hot backup to monitor the status of the uplink and downlink interfaces.

- On Router A and Router B, configure the same cost for OSPF routes and enable per-flow load sharing among ECMP routes.

Figure 18 Transparent in-path deployment in dual-active mode



Display and maintenance commands for hot backup

Execute **display** commands in any view.

Task	Command
Display hot backup status information.	**display remote-backup-group status**
Display the configuration consistency check result for hot backup.	**display remote-backup-group sync-check**

Hot backup configuration examples (IPv4)

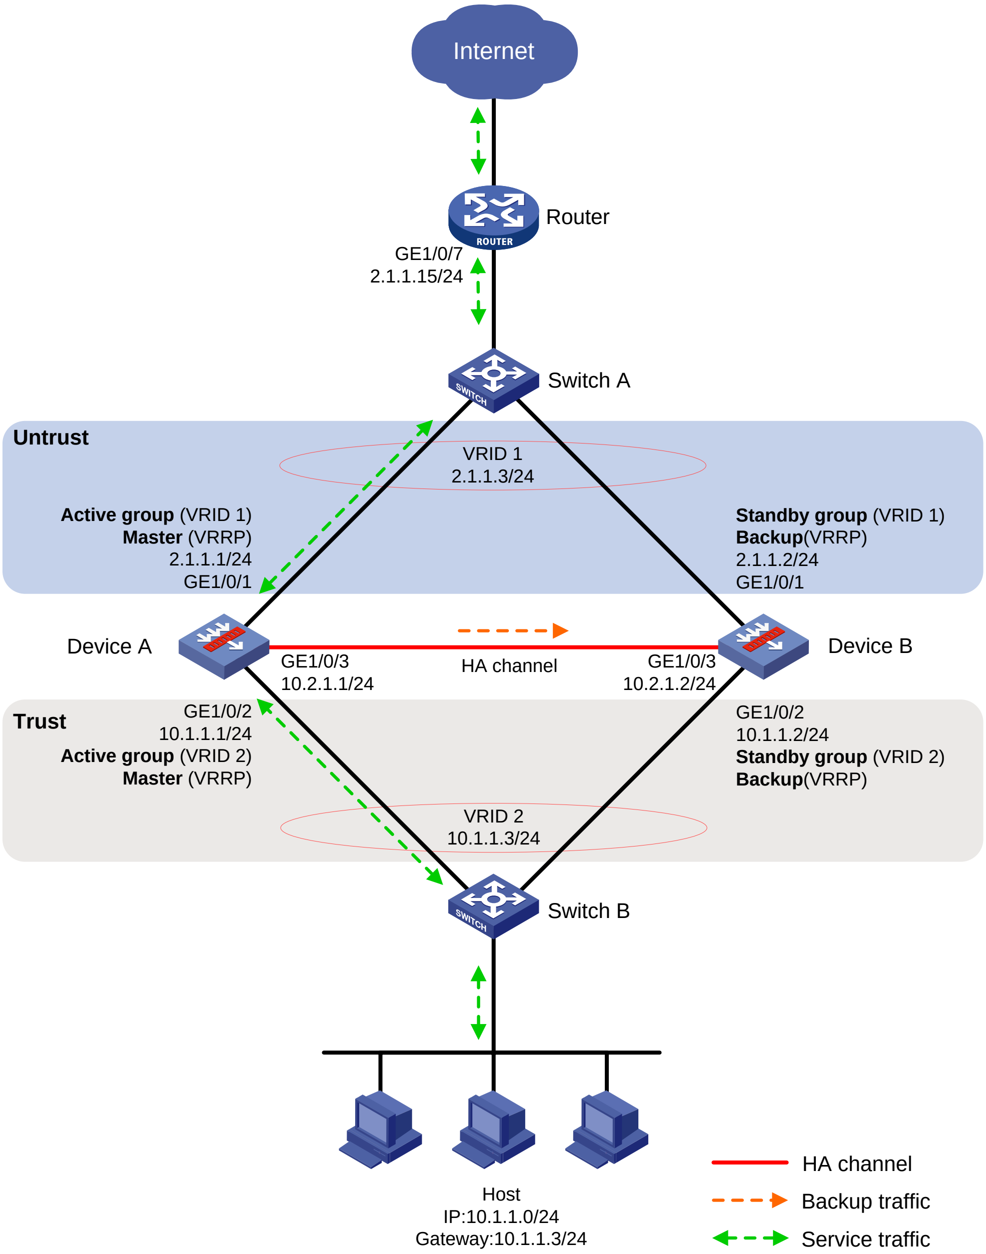
Example: Configuring active/standby hot backup in collaboration with VRRP

Network configuration

As shown in Figure 19, set up a hot backup system at the border between the Internet and the internal network of an enterprise to ensure service continuity.

- Configure the hot backup system to collaborate with VRRP.
- Configure the hot backup system to operate in active/standby mode.
- Configure Device A and Device B as the primary device and the secondary device, respectively.

Figure 19 Network diagram



Procedure

1. Verify that Device A and Device B have software and hardware environment consistency.
2. Configure Switch A:

   NOTE:

   This step only provides the brief configuration procedure.

   # Create VLAN 10.

   # Configure the interfaces attached to the hot backup system and the router to operate at Layer 2. Assign them to VLAN 10 as access interfaces.
3. Configure Switch B:

NOTE:

This step only provides the brief configuration procedure.

# Create VLAN 10.

# Configure the interfaces attached to the hot backup system and the host to operate at Layer 2. Assign them to VLAN 10 as access interfaces.

4. Configure the router:

NOTE:

This step only provides the brief configuration procedure.

# Assign 2.1.1.15/24 to GigabitEthernet 1/0/7.

# Configure routes as follows:

- Specify 2.1.1.3 (virtual IP address of VRRP group 1) as the next hop of the routes to the internal network.
- Specify the IP address of the peer interface attached to the traffic outgoing interface as the next hop of the route to the Internet.

5. Configure Device A:

a. Assign an IP address to GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 2.1.1.1 255.255.255.0
[DeviceA-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

b. Add interfaces to security zones.

```
[DeviceA] security-zone name untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] quit
[DeviceA] security-zone name trust
[DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceA-security-zone-Trust] quit
```

c. Configure settings for routing. This example configures a static route, and the next hop in the route is 2.1.1.15.

```
[DeviceA] ip route-static 0.0.0.0 0.0.0.0 2.1.1.15
```

d. Configure a security policy.

Perform this task only on the primary device. After the hot backup system is set up, the secondary device automatically synchronizes its security policy configuration with the primary device.

# Configure a rule named **trust-untrust** to permit the packets from 10.1.1.0/24 to the Internet.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-3-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-3-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-3-trust-untrust] source-ip-subnet 10.1.1.0 24
[DeviceA-security-policy-ip-3-trust-untrust] action pass
[DeviceA-security-policy-ip-3-trust-untrust] quit
```

# Configure rules to permit VRRP protocol packets. When the hot backup channel is disconnected, Device A and Device B can exchange VRRP protocol packets to elect a VRRP master.

```
[DeviceA-security-policy-ip] rule name vrrp1
[DeviceA-security-policy-ip-4-vrrp1] source-zone trust
[DeviceA-security-policy-ip-4-vrrp1] destination-zone local
[DeviceA-security-policy-ip-4-vrrp1] service vrrp
[DeviceA-security-policy-ip-4-vrrp1] action pass
[DeviceA-security-policy-ip-4-vrrp1] quit
[DeviceA-security-policy-ip] rule name vrrp2
[DeviceA-security-policy-ip-5-vrrp2] source-zone local
[DeviceA-security-policy-ip-5-vrrp2] destination-zone trust
[DeviceA-security-policy-ip-5-vrrp2] service vrrp
[DeviceA-security-policy-ip-5-vrrp2] action pass
[DeviceA-security-policy-ip-5-vrrp2] quit
[DeviceA-security-policy-ip] rule name vrrp3
[DeviceA-security-policy-ip-6-vrrp3] source-zone untrust
[DeviceA-security-policy-ip-6-vrrp3] destination-zone local
[DeviceA-security-policy-ip-6-vrrp3] service vrrp
[DeviceA-security-policy-ip-6-vrrp3] action pass
[DeviceA-security-policy-ip-6-vrrp3] quit
[DeviceA-security-policy-ip] rule name vrrp4
[DeviceA-security-policy-ip-7-vrrp4] source-zone local
[DeviceA-security-policy-ip-7-vrrp4] destination-zone untrust
[DeviceA-security-policy-ip-7-vrrp4] service vrrp
[DeviceA-security-policy-ip-7-vrrp4] action pass
[DeviceA-security-policy-ip-7-vrrp4] quit
[DeviceA-security-policy-ip] quit
```

e. Configure hot backup settings.

# Set up a hot backup system.

```
[DeviceA] remote-backup group
[DeviceA-remote-backup-group] remote-ip 10.2.1.2
[DeviceA-remote-backup-group] local-ip 10.2.1.1
[DeviceA-remote-backup-group] data-channel interface gigabitethernet 1/0/3
[DeviceA-remote-backup-group] device-role primary
RBM_P[DeviceA-remote-backup-group] undo backup-mode
RBM_P[DeviceA-remote-backup-group] hot-backup enable
RBM_P[DeviceA-remote-backup-group] configuration auto-sync enable
RBM_P[DeviceA-remote-backup-group] configuration sync-check interval 12
RBM_P[DeviceA-remote-backup-group] quit
```

# Create VRRP groups and associate them with the hot backup system.

```
RBM_P[DeviceA] interface gigabitethernet 1/0/1
RBM_P[DeviceA-GigabitEthernet1/0/1] vrrp vrid 1 virtual-ip 2.1.1.3 active
RBM_P[DeviceA-GigabitEthernet1/0/1] quit
RBM_P[DeviceA] interface gigabitethernet 1/0/2
RBM_P[DeviceA-GigabitEthernet1/0/2] vrrp vrid 2 virtual-ip 10.1.1.3 active
RBM_P[DeviceA-GigabitEthernet1/0/2] quit
```

f. Configure security services on Device A. (Details not shown.)

6. Configure Device B:

   a. Assign an IP address to GigabitEthernet 1/0/1.

   ```
   <DeviceB> system-view
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] ip address 2.1.1.2 255.255.255.0
   [DeviceB-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

   b. Add interfaces to security zones.

   ```
   [DeviceB] security-zone name untrust
   [DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
   [DeviceB-security-zone-Untrust] quit
   [DeviceB] security-zone name trust
   [DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
   [DeviceB-security-zone-Trust] quit
   ```

   c. Configure settings for routing. This example configures a static route, and the next hop in the route is 2.1.1.15.

   ```
   [DeviceB] ip route-static 0.0.0.0 0.0.0.0 2.1.1.15
   ```

   d. Configure hot backup settings.

   # Set up a hot backup system.

   ```
   [DeviceB] remote-backup group
   [DeviceB-remote-backup-group] remote-ip 10.2.1.1
   [DeviceB-remote-backup-group] local-ip 10.2.1.2
   [DeviceB-remote-backup-group] data-channel interface gigabitethernet 1/0/3
   [DeviceB-remote-backup-group] device-role secondary
   RBM_S[DeviceB-remote-backup-group] undo backup-mode
   RBM_S[DeviceB-remote-backup-group] hot-backup enable
   RBM_S[DeviceB-remote-backup-group] configuration auto-sync enable
   RBM_S[DeviceB-remote-backup-group] configuration sync-check interval 12
   RBM_S[DeviceB-remote-backup-group] quit
   ```

   # Create VRRP groups and associate them with the hot backup system.

   ```
   RBM_S[DeviceB] interface gigabitethernet 1/0/1
   RBM_S[DeviceB-GigabitEthernet1/0/1] vrrp vrid 1 virtual-ip 2.1.1.3 standby
   RBM_S[DeviceB-GigabitEthernet1/0/1] quit
   RBM_S[DeviceB] interface gigabitethernet 1/0/2
   RBM_S[DeviceB-GigabitEthernet1/0/2] vrrp vrid 2 virtual-ip 10.1.1.3 standby
   RBM_S[DeviceB-GigabitEthernet1/0/2] quit
   ```

7. On the host, specify 10.1.1.3 (virtual IP address of VRRP group 2) as the default gateway. (Details not shown.)

Verifying the configuration

1. Verify the configuration on Device A:

   # Verify that the hot backup channels have been set up.

   ```
   RBM_P[DeviceA] display remote-backup-group status
   Remote backup group information:
     Backup mode: Active/standby
     Device management role: Primary
     Device running status: Active
     Data channel interface: GigabitEthernet1/0/3
   ```

```
  Local IP: 10.2.1.1
  Remote IP: 10.2.1.2    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 0 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:
    Time                     Status change        Cause
    2021-06-22 13:33:33      Initial to Active    Interface status changed
```

# Verify that Device A is the master in all VRRP groups.

```
RBM_P[DeviceA] display vrrp
IPv4 Virtual Router Information:
 Running mode      : Standard
 RBM control channel is established
   VRRP active group status : Master
   VRRP standby group status: Master
 Total number of virtual routers : 2
 Interface          VRID  State        Running Adver   Auth     Virtual
                                       Pri     Timer   Type        IP
 ---------------------------------------------------------------------
 GE1/0/1            1     Master       100     100     None     2.1.1.3
 GE1/0/2            2     Master       100     100     None     10.1.1.3
```

# Enable logging for the security policy that permits communication between security zones **Trust** and **Untrust**. Verity that Device A generates log messages when the host communicates with the Internet. (Details not shown.)

2. Verify the configuration on Device B:

# Verify that the hot backup channels have been set up.

```
RBM_S[DeviceB] display remote-backup-group status
Remote backup group information:
  Backup mode: Active/standby
  Device management role: Secondary
  Device running status: Standby
  Data channel interface: GigabitEthernet1/0/3
  Local IP: 10.2.1.2
  Remote IP: 10.2.1.1    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 0 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:
    Time                         Status change        Cause
    2021-06-22 13:33:33          Initial to Active    Interface status changed
```

# Verify that Device A is the backup in all VRRP groups.

```
RBM_S[DeviceB] display vrrp
IPv4 Virtual Router Information:
 Running mode      : Standard
 RBM control channel is established
   VRRP active group status : Backup
   VRRP standby group status: Backup
 Total number of virtual routers : 2
 Interface          VRID  State        Running Adver   Auth     Virtual
                                       Pri     Timer   Type        IP
 ---------------------------------------------------------------------
 GE1/0/1            1     Backup       100     100     None     2.1.1.3
 GE1/0/2            2     Backup       100     100     None     10.1.1.3
```

# Enable logging for the security policy that permits communication between security zones **Trust** and **Untrust**. Verity that Device B does not generate log messages when the host communicates with the Internet. (Details not shown.)

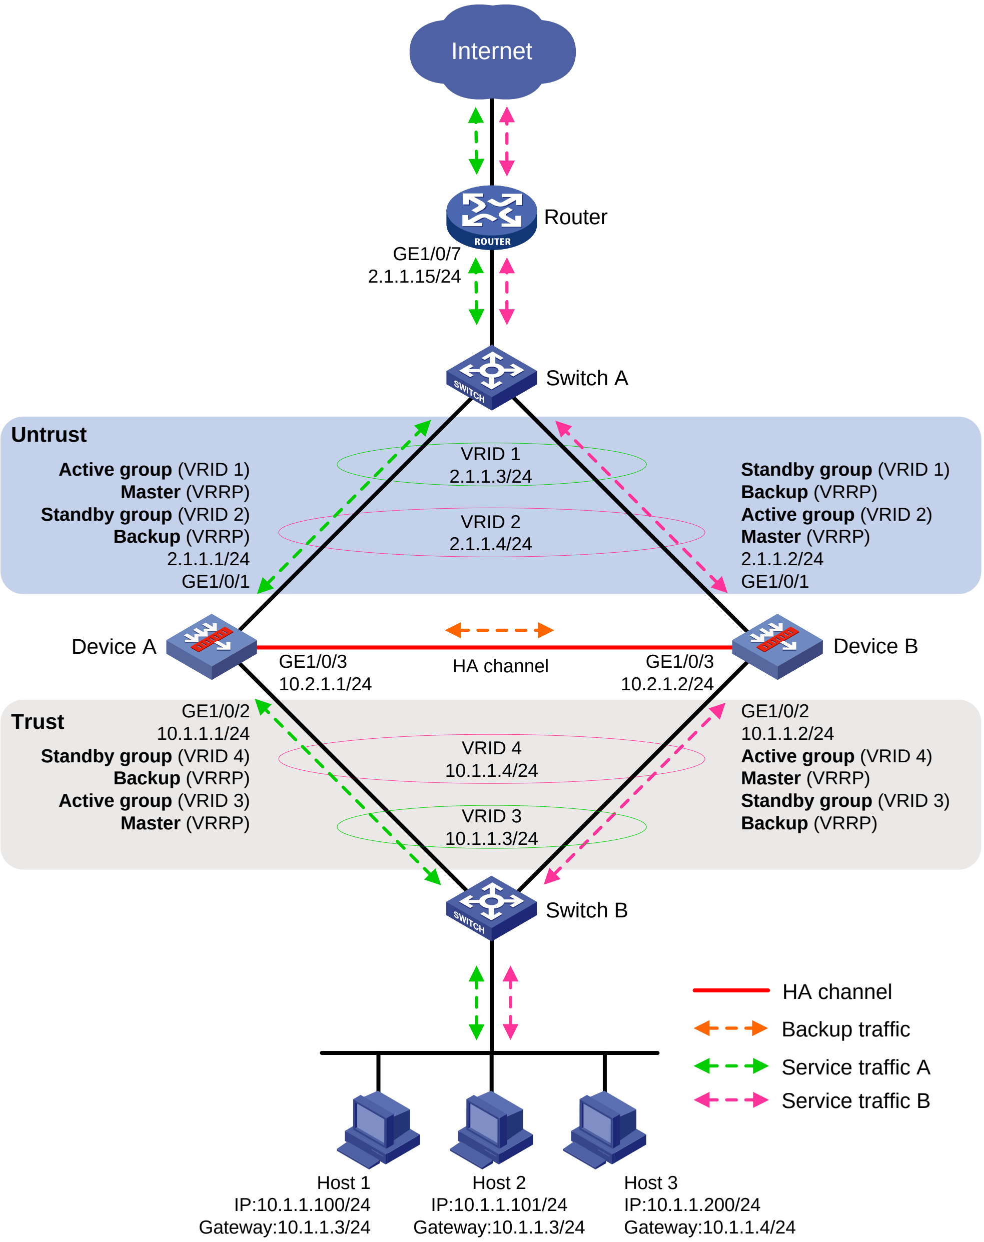
Example: Configuring dual-active hot backup in collaboration with VRRP

Network configuration

As shown in Figure 20, set up a hot backup system at the border between the Internet and the internal network of an enterprise to ensure service continuity.

- Configure the hot backup system to collaborate with VRRP.
- Configure the hot backup system to operate in dual-active mode.
- Configure Device A and Device B to load share traffic.

Figure 20 Network diagram



Procedure

1. Verify that Device A and Device B have software and hardware environment consistency.
2. Configure Switch A:

   NOTE:

   This step only provides the brief configuration procedure.

   # Create VLAN 10.

   # Configure the interfaces attached to the hot backup system and the router to operate at Layer 2. Assign them to VLAN 10 as access interfaces.
3. Configure Switch B:

NOTE:

This step only provides the brief configuration procedure.

# Create VLAN 10.

# Configure the interfaces attached to the hot backup system and the host to operate at Layer 2. Assign them to VLAN 10 as access interfaces.

4. Configure the router:

NOTE:

This step only provides the brief configuration procedure.

# Assign 2.1.1.15/24 to GigabitEthernet 1/0/7.

# Configure routes as follows:

- Specify 2.1.1.3 (virtual IP address of VRRP group 1) as the next hop of the routes to some subnets of the internal network. Specify 2.1.1.4 (virtual IP address of VRRP group 2) as the next hop of the routes to the other subnets of the internal network.
- Specify the IP address of the peer interface attached to the traffic outgoing interface as the next hop of the route to the Internet.

5. Configure Device A:

a. Assign an IP address to GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 2.1.1.1 255.255.255.0
[DeviceA-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

b. Add interfaces to security zones.

```
[DeviceA] security-zone name untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] quit
[DeviceA] security-zone name trust
[DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceA-security-zone-Trust] quit
```

c. Configure settings for routing. This example configures a static route, and the next hop in the route is 2.1.1.15.

```
[DeviceA] ip route-static 0.0.0.0 0.0.0.0 2.1.1.15
```

d. Configure a security policy.

Perform this task only on the primary device. After the hot backup system is set up, the secondary device automatically synchronizes its security policy configuration with the primary device.

# Configure a rule named **trust-untrust** to permit the packets from 10.1.1.0/24 to the Internet.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-3-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-3-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-3-trust-untrust] source-ip-subnet 10.1.1.0 24
[DeviceA-security-policy-ip-3-trust-untrust] action pass
[DeviceA-security-policy-ip-3-trust-untrust] quit
```

# Configure rules to permit VRRP protocol packets. When the hot backup channel is disconnected, Device A and Device B can exchange VRRP protocol packets to elect a VRRP master.

```
[DeviceA-security-policy-ip] rule name vrrp1
[DeviceA-security-policy-ip-4-vrrp1] source-zone trust
[DeviceA-security-policy-ip-4-vrrp1] destination-zone local
[DeviceA-security-policy-ip-4-vrrp1] service vrrp
[DeviceA-security-policy-ip-4-vrrp1] action pass
[DeviceA-security-policy-ip-4-vrrp1] quit
[DeviceA-security-policy-ip] rule name vrrp2
[DeviceA-security-policy-ip-5-vrrp2] source-zone local
[DeviceA-security-policy-ip-5-vrrp2] destination-zone trust
[DeviceA-security-policy-ip-5-vrrp2] service vrrp
[DeviceA-security-policy-ip-5-vrrp2] action pass
[DeviceA-security-policy-ip-5-vrrp2] quit
[DeviceA-security-policy-ip] rule name vrrp3
[DeviceA-security-policy-ip-6-vrrp3] source-zone untrust
[DeviceA-security-policy-ip-6-vrrp3] destination-zone local
[DeviceA-security-policy-ip-6-vrrp3] service vrrp
[DeviceA-security-policy-ip-6-vrrp3] action pass
[DeviceA-security-policy-ip-6-vrrp3] quit
[DeviceA-security-policy-ip] rule name vrrp4
[DeviceA-security-policy-ip-7-vrrp4] source-zone local
[DeviceA-security-policy-ip-7-vrrp4] destination-zone untrust
[DeviceA-security-policy-ip-7-vrrp4] service vrrp
[DeviceA-security-policy-ip-7-vrrp4] action pass
[DeviceA-security-policy-ip-7-vrrp4] quit
[DeviceA-security-policy-ip] quit
```

e. Configure hot backup settings.

# Set up a hot backup system.

```
[DeviceA] remote-backup group
[DeviceA-remote-backup-group] remote-ip 10.2.1.2
[DeviceA-remote-backup-group] local-ip 10.2.1.1
[DeviceA-remote-backup-group] data-channel interface gigabitethernet 1/0/3
[DeviceA-remote-backup-group] device-role primary
RBM_P[DeviceA-remote-backup-group] backup-mode dual-active
RBM_P[DeviceA-remote-backup-group] hot-backup enable
RBM_P[DeviceA-remote-backup-group] configuration auto-sync enable
RBM_P[DeviceA-remote-backup-group] configuration sync-check interval 12
RBM_P[DeviceA-remote-backup-group] delay-time 1
RBM_P[DeviceA-remote-backup-group] quit
```

# Create VRRP groups and associate them with the hot backup system.

```
RBM_P[DeviceA] interface gigabitethernet 1/0/1
RBM_P[DeviceA-GigabitEthernet1/0/1] vrrp vrid 1 virtual-ip 2.1.1.3 active
RBM_P[DeviceA-GigabitEthernet1/0/1] vrrp vrid 2 virtual-ip 2.1.1.4 standby
RBM_P[DeviceA-GigabitEthernet1/0/1] quit
RBM_P[DeviceA] interface gigabitethernet 1/0/2
RBM_P[DeviceA-GigabitEthernet1/0/2] vrrp vrid 3 virtual-ip 10.1.1.3 active
RBM_P[DeviceA-GigabitEthernet1/0/2] vrrp vrid 4 virtual-ip 10.1.1.4 standby
```

```
RBM_P[DeviceA-GigabitEthernet1/0/2] quit
```

   f. Configure security services on Device A. (Details not shown.)

6. Configure Device B:

   a. Assign an IP address to GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 2.1.1.2 255.255.255.0
[DeviceB-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

   b. Add interfaces to security zones.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

   c. Configure settings for routing. This example configures a static route, and the next hop in the route is 2.1.1.15.

```
[DeviceB] ip route-static 0.0.0.0 0.0.0.0 2.1.1.15
```

   d. Configure hot backup settings.

   # Set up a hot backup system.

```
[DeviceB] remote-backup group
[DeviceB-remote-backup-group] remote-ip 10.2.1.1
[DeviceB-remote-backup-group] local-ip 10.2.1.2
[DeviceB-remote-backup-group] data-channel interface gigabitethernet 1/0/3
[DeviceB-remote-backup-group] device-role secondary
RBM_S[DeviceB-remote-backup-group] backup-mode dual-active
RBM_S[DeviceB-remote-backup-group] hot-backup enable
RBM_S[DeviceB-remote-backup-group] configuration auto-sync enable
RBM_S[DeviceB-remote-backup-group] configuration sync-check interval 12
RBM_S[DeviceB-remote-backup-group] delay-time 1
RBM_S[DeviceB-remote-backup-group] quit
```

   # Create VRRP groups and associate them with the hot backup system.

```
RBM_S[DeviceB] interface gigabitethernet 1/0/1
RBM_S[DeviceB-GigabitEthernet1/0/1] vrrp vrid 1 virtual-ip 2.1.1.3 standby
RBM_S[DeviceB-GigabitEthernet1/0/1] vrrp vrid 2 virtual-ip 2.1.1.4 active
RBM_S[DeviceB-GigabitEthernet1/0/1] quit
RBM_S[DeviceB] interface gigabitethernet 1/0/2
RBM_S[DeviceB-GigabitEthernet1/0/2] vrrp vrid 3 virtual-ip 10.1.1.3 standby
RBM_S[DeviceB-GigabitEthernet1/0/2] vrrp vrid 4 virtual-ip 10.1.1.4 active
RBM_S[DeviceB-GigabitEthernet1/0/2] quit
```

7. On some hosts, specify 10.1.1.3 (virtual IP address of VRRP group 3) as the default gateway. On the other hosts, specify 10.1.1.4 (virtual IP address of VRRP group 4) as the default gateway. (Details not shown.)

Verifying the configuration

1. Verify the configuration on Device A:

   # Verify that the hot backup channels have been set up.

```
RBM_P[DeviceA] display remote-backup-group status
Remote backup group information:
  Backup mode: Dual-active
  Device management role: Primary
  Device running status: Active
  Data channel interface: GigabitEthernet1/0/3
  Local IP: 10.2.1.1
  Remote IP: 10.2.1.2    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 1 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:
    Time                     Status change        Cause
    2021-06-22 13:33:33      Initial to Active    Interface status changed
```

# Verify that Device A is the master in VRRP groups 1 and 3 and the backup in VRRP groups 2 and 4.

```
RBM_P[DeviceA] display vrrp
IPv4 Virtual Router Information:
 Running mode      : Standard
 RBM control channel is established
   VRRP active group status : Master
   VRRP standby group status: Backup
 Total number of virtual routers : 4
 Interface          VRID  State        Running Adver   Auth     Virtual
                                       Pri     Timer   Type        IP
 ---------------------------------------------------------------------
 GE1/0/1            1     Master       100     100     None     2.1.1.3
 GE1/0/1            2     Backup       100     100     None     2.1.1.4
 GE1/0/2            3     Master       100     100     None     10.1.1.3
 GE1/0/2            4     Backup       100     100     None     10.1.1.4
```

# Enable logging for the security policy that permits communication between security zones **Trust** and **Untrust**. Verity that Device A generates log messages when a host for which Device A forwards traffic communicates with the Internet. Verity that Device A does not generate log messages when a host for which Device B forwards traffic communicates with the Internet. (Details not shown.)

2. Verify the configuration on Device B:

# Verify that the hot backup channels have been set up.

```
RBM_S[DeviceB] display remote-backup-group status
Remote backup group information:
  Backup mode: Dual-active
  Device management role: Secondary
  Device running status: Active
  Data channel interface: GigabitEthernet1/0/3
  Local IP: 10.2.1.2
  Remote IP: 10.2.1.1    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 1 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:
    Time                     Status change        Cause
    2021-06-22 13:33:33      Initial to Active    Interface status changed
```

# Verify that Device B is the master in VRRP groups 2 and 4 and the backup in VRRP groups 1 and 3.

```
RBM_S[DeviceB] display vrrp

```

# Enable logging for the security policy that permits communication between security zones **Trust** and **Untrust**. Verity that Device B generates log messages when a host for which Device B forwards traffic communicates with the Internet. Verity that Device B does not generate log messages when a host for which Device A forwards traffic communicates with the Internet. (Details not shown.)

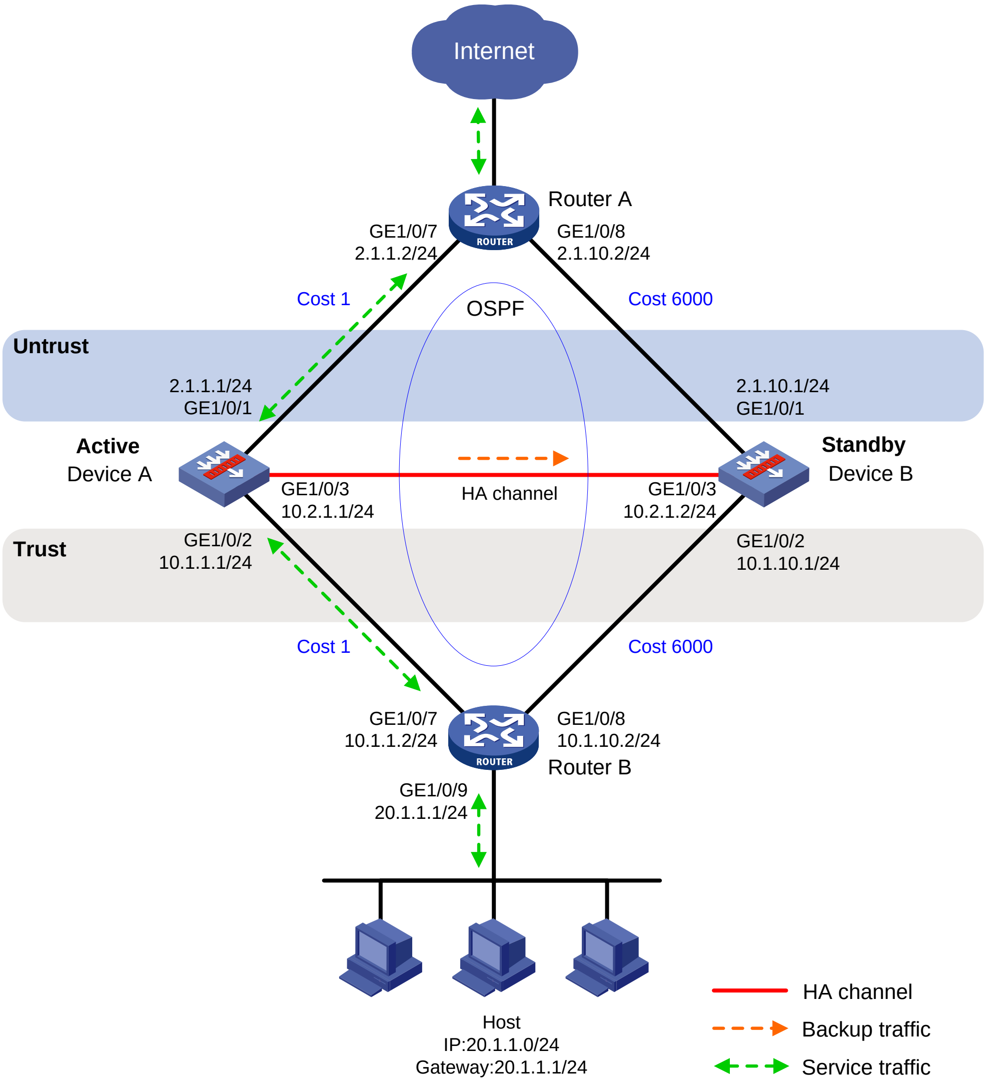
Example: Configuring active/standby hot backup in collaboration with a routing protocol

Network configuration

As shown in Figure 21, set up a hot backup system at the border between the Internet and the internal network of an enterprise to ensure service continuity.

- Configure the hot backup system to collaborate with OSPF.
- Configure the hot backup system to operate in active/standby mode.
- Configure Device A and Device B as the primary device and the secondary device, respectively.

Figure 21 Network diagram



Procedure

1. Verify that Device A and Device B have software and hardware environment consistency.
2. Configure Router A:

   NOTE:

   This step only provides the brief configuration procedure.

   # Assign 2.1.1.2/24 to GigabitEthernet 1/0/7.

   # Assign 2.1.10.2/24 to GigabitEthernet 1/0/8.

   # Configure OSPF for Device A, Device B, and the routers to have Layer 3 reachability.
3. Configure Router B:

   NOTE:

   This step only provides the brief configuration procedure.

   # Assign 10.1.1.2/24 to GigabitEthernet 1/0/7.

   # Assign 10.1.10.2/24 to GigabitEthernet 1/0/8.

# Configure OSPF for Device A, Device B, and the routers to have Layer 3 reachability.

4. Configure Device A:

   a. Assign an IP address to GigabitEthernet 1/0/1.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 2.1.1.1 255.255.255.0
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

   b. Add interfaces to security zones.

   ```
   [DeviceA] security-zone name untrust
   [DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
   [DeviceA-security-zone-Untrust] quit
   [DeviceA] security-zone name trust
   [DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
   [DeviceA-security-zone-Trust] quit
   ```

   c. Configure OSPF. Use the default OSPF link cost configuration.

   ```
   [DeviceA] router id 2.1.1.1
   [DeviceA] ospf
   [DeviceA-ospf-1] area 0
   [DeviceA-ospf-1-area-0.0.0.0] network 2.1.1.0 0.0.0.255
   [DeviceA-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
   [DeviceA-ospf-1-area-0.0.0.0] quit
   [DeviceA-ospf-1] quit
   ```

   d. Configure a security policy.

   Perform this task only on the primary device. After the hot backup system is set up, the secondary device automatically synchronizes its security policy configuration with the primary device.

   # Configure a rule named **trust-untrust** to permit the packets from 20.1.1.0/24 to the Internet.

   ```
   [DeviceA] security-policy ip
   [DeviceA-security-policy-ip] rule name trust-untrust
   [DeviceA-security-policy-ip-3-trust-untrust] source-zone trust
   [DeviceA-security-policy-ip-3-trust-untrust] destination-zone untrust
   [DeviceA-security-policy-ip-3-trust-untrust] source-ip-subnet 20.1.1.0 24
   [DeviceA-security-policy-ip-3-trust-untrust] action pass
   [DeviceA-security-policy-ip-3-trust-untrust] quit
   ```

   # Configure rules to permit OSPF protocol packets.

   ```
   [DeviceA-security-policy-ip] rule name ospf1
   [DeviceA-security-policy-ip-4-ospf1] source-zone trust
   [DeviceA-security-policy-ip-4-ospf1] destination-zone local
   [DeviceA-security-policy-ip-4-ospf1] service ospf
   [DeviceA-security-policy-ip-4-ospf1] action pass
   [DeviceA-security-policy-ip-4-ospf1] quit
   [DeviceA-security-policy-ip] rule name ospf2
   [DeviceA-security-policy-ip-5-ospf2] source-zone local
   [DeviceA-security-policy-ip-5-ospf2] destination-zone trust
   [DeviceA-security-policy-ip-5-ospf2] service ospf
   [DeviceA-security-policy-ip-5-ospf2] action pass
   ```

```
[DeviceA-security-policy-ip-5-ospf2] quit
[DeviceA-security-policy-ip] rule name ospf3
[DeviceA-security-policy-ip-6-ospf3] source-zone untrust
[DeviceA-security-policy-ip-6-ospf3] destination-zone local
[DeviceA-security-policy-ip-6-ospf3] service ospf
[DeviceA-security-policy-ip-6-ospf3] action pass
[DeviceA-security-policy-ip-6-ospf3] quit
[DeviceA-security-policy-ip] rule name ospf4
[DeviceA-security-policy-ip-7-ospf4] source-zone local
[DeviceA-security-policy-ip-7-ospf4] destination-zone untrust
[DeviceA-security-policy-ip-7-ospf4] service ospf
[DeviceA-security-policy-ip-7-ospf4] action pass
[DeviceA-security-policy-ip-7-ospf4] quit
[DeviceA-security-policy-ip] quit
```

e. Configure hot backup settings.

# Associate track entries with interfaces.

```
[DeviceA] track 1 interface gigabitethernet 1/0/1
[DeviceA-track-1] quit
[DeviceA] track 2 interface gigabitethernet 1/0/2
[DeviceA-track-2] quit
```

# Set up a hot backup system.

```
[DeviceA] remote-backup group
[DeviceA-remote-backup-group] remote-ip 10.2.1.2
[DeviceA-remote-backup-group] local-ip 10.2.1.1
[DeviceA-remote-backup-group] data-channel interface gigabitethernet 1/0/3
[DeviceA-remote-backup-group] device-role primary
RBM_P[DeviceA-remote-backup-group] undo backup-mode
RBM_P[DeviceA-remote-backup-group] hot-backup enable
RBM_P[DeviceA-remote-backup-group] configuration auto-sync enable
RBM_P[DeviceA-remote-backup-group] configuration sync-check interval 12
```

# Configure the hot backup system to change the link costs advertised in OSPF routes to 6000.

```
RBM_P[DeviceA-remote-backup-group] adjust-cost ospf enable absolute 6000
```

# Configure the hot backup system to monitor the status of track entry 1 and track entry 2.

```
RBM_P[DeviceA-remote-backup-group] track 1
RBM_P[DeviceA-remote-backup-group] track 2
RBM_P[DeviceA-remote-backup-group] quit
```

f. Configure security services on Device A. (Details not shown.)

5. Configure Device B:

a. Assign an IP address to GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 2.1.10.1 255.255.255.0
[DeviceB-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

b. Add interfaces to security zones.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
```

```
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

c. Configure OSPF. Use the default OSPF link cost configuration.

```
[DeviceB] router id 2.1.10.1
[DeviceB] ospf
[DeviceB-ospf-1] area 0
[DeviceB-ospf-1-area-0.0.0.0] network 2.1.10.0 0.0.0.255
[DeviceB-ospf-1-area-0.0.0.0] network 10.1.10.0 0.0.0.255
[DeviceB-ospf-1-area-0.0.0.0] quit
[DeviceB-ospf-1] quit
```

# Associate track entries with interfaces.

```
[DeviceB] track 1 interface gigabitethernet 1/0/1
[DeviceB-track-1] quit
[DeviceB] track 2 interface gigabitethernet 1/0/2
[DeviceB-track-2] quit
```

# Set up a hot backup system.

```
[DeviceB] remote-backup group
[DeviceB-remote-backup-group] remote-ip 10.2.1.1
[DeviceB-remote-backup-group] local-ip 10.2.1.2
[DeviceB-remote-backup-group] data-channel interface gigabitethernet 1/0/3
[DeviceB-remote-backup-group] device-role secondary
RBM_S[DeviceB-remote-backup-group] undo backup-mode
RBM_S[DeviceB-remote-backup-group] hot-backup enable
RBM_S[DeviceB-remote-backup-group] configuration auto-sync enable
RBM_S[DeviceB-remote-backup-group] configuration sync-check interval 12
```

# Configure the hot backup system to change the link costs advertised in OSPF routes to 6000.

```
RBM_S[DeviceB-remote-backup-group] adjust-cost ospf enable absolute 6000
```

# Configure the hot backup system to monitor the status of track entry 1 and track entry 2.

```
RBM_S[DeviceB-remote-backup-group] track 1
RBM_S[DeviceB-remote-backup-group] track 2
RBM_S[DeviceB-remote-backup-group] quit
```

6. On the host, specify 20.1.1.1 as the default gateway. (Details not shown.)

Verifying the configuration

1. Verify the configuration on Device A:

# Verify that the hot backup channels have been set up.

```
RBM_P[DeviceA] display remote-backup-group status
Remote backup group information:
  Backup mode: Active/standby
  Device management role: Primary
  Device running status: Active
  Data channel interface: GigabitEthernet1/0/3
  Local IP: 10.2.1.1
  Remote IP: 10.2.1.2    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 0 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:
    Time                     Status change        Cause
    2021-06-22 13:33:33      Initial to Active    Interface status changed
```

# Verify that the OSPF routes advertised by Device A include a smaller link cost than that advertised by Device B.

```
RBM_P[DeviceA] display ospf interface

         OSPF Process 1 with Router ID 2.1.1.1
                 Interfaces

 Area: 0.0.0.0

```

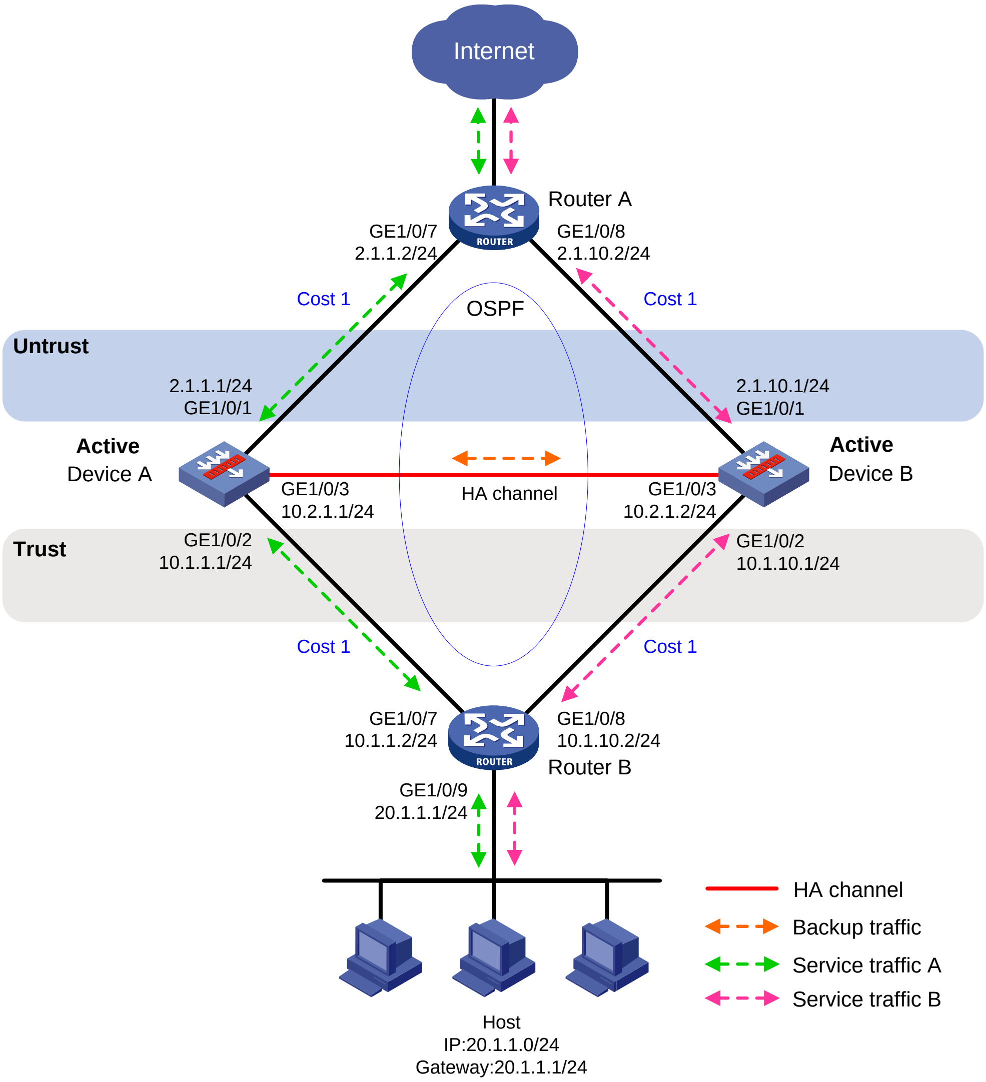
Example: Configuring dual-active hot backup in collaboration with a routing protocol

Network configuration

As shown in Figure 22, set up a hot backup system at the border between the Internet and the internal network of an enterprise to ensure service continuity.

- Configure the hot backup system to collaborate with OSPF.
- Configure the hot backup system to operate in dual-active mode.
- Configure Device A and Device B to load share traffic.

Figure 22 Network diagram



Procedure

1. Verify that Device A and Device B have software and hardware environment consistency.
2. Configure Router A:

NOTE:

This step only provides the brief configuration procedure.

# Assign 2.1.1.2/24 to GigabitEthernet 1/0/7.

# Assign 2.1.10.2/24 to GigabitEthernet 1/0/8.

# Configure OSPF for Device A, Device B, and the routers to have Layer 3 reachability.

# Configure per-flow load sharing for IP forwarding.

3. Configure Router B:

NOTE:

This step only provides the brief configuration procedure.

# Assign 10.1.1.2/24 to GigabitEthernet 1/0/7.

# Assign 10.1.10.2/24 to GigabitEthernet 1/0/8.

# Configure OSPF for Device A, Device B, and the routers to have Layer 3 reachability.

# Configure per-flow load sharing for IP forwarding.

4. Configure Device A:

   a. Assign an IP address to GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 2.1.1.1 255.255.255.0
[DeviceA-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

   b. Add interfaces to security zones.

```
[DeviceA] security-zone name untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] quit
[DeviceA] security-zone name trust
[DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceA-security-zone-Trust] quit
```

   c. Configure OSPF. Use the default OSPF link cost configuration.

```
[DeviceA] router id 2.1.1.1
[DeviceA] ospf
[DeviceA-ospf-1] area 0
[DeviceA-ospf-1-area-0.0.0.0] network 2.1.1.0 0.0.0.255
[DeviceA-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[DeviceA-ospf-1-area-0.0.0.0] quit
[DeviceA-ospf-1] quit
```

   d. Configure a security policy.

   Perform this task only on the primary device. After the hot backup system is set up, the secondary device automatically synchronizes its security policy configuration with the primary device.

   # Configure a rule named **trust-untrust** to permit the packets from 20.1.1.0/24 to the Internet.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-3-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-3-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-3-trust-untrust] source-ip-subnet 20.1.1.0 24
[DeviceA-security-policy-ip-3-trust-untrust] action pass
[DeviceA-security-policy-ip-3-trust-untrust] quit
```

   # Configure rules to permit OSPF protocol packets.

```
[DeviceA-security-policy-ip] rule name ospf1
[DeviceA-security-policy-ip-4-ospf1] source-zone trust
[DeviceA-security-policy-ip-4-ospf1] destination-zone local
[DeviceA-security-policy-ip-4-ospf1] service ospf
[DeviceA-security-policy-ip-4-ospf1] action pass
[DeviceA-security-policy-ip-4-ospf1] quit
[DeviceA-security-policy-ip] rule name ospf2

RBM_P[DeviceA-remote-backup-group] backup-mode dual-active
RBM_P[DeviceA-remote-backup-group] hot-backup enable
RBM_P[DeviceA-remote-backup-group] configuration auto-sync enable
RBM_P[DeviceA-remote-backup-group] configuration sync-check interval 12
RBM_P[DeviceA-remote-backup-group] delay-time 1
```

# Configure the hot backup system to change the link costs advertised in OSPF routes to 1.

```
RBM_P[DeviceA-remote-backup-group] adjust-cost ospf enable absolute 1
```

# Configure the hot backup system to monitor the status of track entry 1 and track entry 2.

```
RBM_P[DeviceA-remote-backup-group] track 1
RBM_P[DeviceA-remote-backup-group] track 2
RBM_P[DeviceA-remote-backup-group] quit
```

f. Configure security services on Device A. (Details not shown.)

5. Configure Device B:

a. Assign an IP address to GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 2.1.10.1 255.255.255.0
[DeviceB-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

b. Add interfaces to security zones.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

c. Configure OSPF. Use the default OSPF link cost configuration.

```
[DeviceB] router id 2.1.10.1
[DeviceB] ospf
[DeviceB-ospf-1] area 0
[DeviceB-ospf-1-area-0.0.0.0] network 2.1.10.0 0.0.0.255
[DeviceB-ospf-1-area-0.0.0.0] network 10.1.10.0 0.0.0.255
[DeviceB-ospf-1-area-0.0.0.0] quit
[DeviceB-ospf-1] quit
```

d. Configure hot backup settings.

# Associate track entries with interfaces.

```
[DeviceB] track 1 interface gigabitethernet 1/0/1
[DeviceB-track-1] quit
[DeviceB] track 2 interface gigabitethernet 1/0/2
[DeviceB-track-2] quit
```

# Set up a hot backup system.

```
[DeviceB] remote-backup group
[DeviceB-remote-backup-group] remote-ip 10.2.1.1
[DeviceB-remote-backup-group] local-ip 10.2.1.2

RBM_S[DeviceB-remote-backup-group] delay-time 1
```

# Configure the hot backup system to change the link costs advertised in OSPF routes to 1.

```
RBM_S[DeviceB-remote-backup-group] adjust-cost ospf enable absolute 1
```

# Configure the hot backup system to monitor the status of track entry 1 and track entry 2.

```
RBM_S[DeviceB-remote-backup-group] track 1
RBM_S[DeviceB-remote-backup-group] track 2
RBM_S[DeviceB-remote-backup-group] quit
```

6. On the hosts, specify 20.1.1.1 as the default gateway. (Details not shown.)

Verifying the configuration

1. Verify the configuration on Device A:

# Verify that the hot backup channels have been set up.

```
RBM_P[DeviceA] display remote-backup-group status
Remote backup group information:
  Backup mode: Dual-active
  Device management role: Primary
  Device running status: Active
  Data channel interface: GigabitEthernet1/0/3
  Local IP: 10.2.1.1
  Remote IP: 10.2.1.2    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 1 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:
    Time                     Status change        Cause
    2021-06-22 13:33:33      Initial to Active    Interface status changed
```

# Verify that the OSPF routes advertised by Device A and Device B include the same link cost.

```
RBM_P[DeviceA] display ospf interface

         OSPF Process 1 with Router ID 2.1.1.1

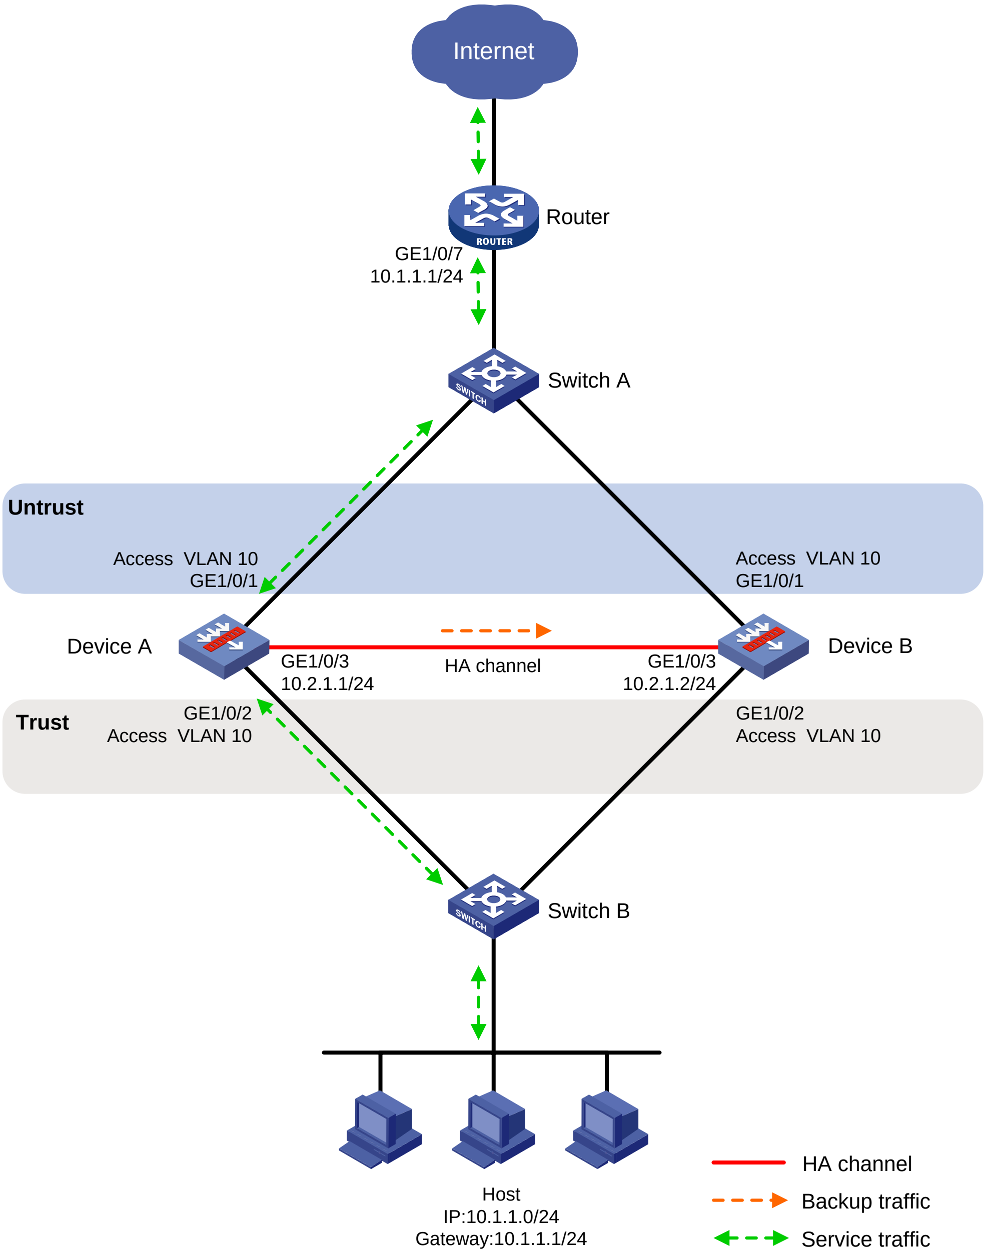
Example: Configuring a transparent in-path hot backup system in active/standby mode

Network configuration

As shown in Figure 23, set up a transparent in-path hot backup system at the border between the Internet and the internal network of an enterprise to ensure service continuity.

- Configure the hot backup system to operate in active/standby mode.
- Connect Switch A and Switch B to Layer 2 interfaces of the hot backup system.
- Configure Device A and Device B as the primary device and the secondary device, respectively.

Figure 23 Network diagram



Procedure

1. Verify that Device A and Device B have software and hardware environment consistency.
2. Configure Switch A:

   NOTE:

   This step only provides the brief configuration procedure.

   # Create VLAN 10.

   # Configure the interfaces attached to the hot backup system and the router to operate at Layer 2. Assign them to VLAN 10 as access interfaces.
3. Configure Switch B:

NOTE:

This step only provides the brief configuration procedure.

# Create VLAN 10.

# Configure the interfaces attached to the hot backup system and the host to operate at Layer 2. Assign them to VLAN 10 as access interfaces.

4. Configure Device A:

   a. Configure VLANs.

      # Configure the uplink and downlink interfaces to operate at Layer 2.

      ```
      <DeviceA> system-view
      [DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/2
      [DeviceA-if-range] port link-mode bridge
      [DeviceA-if-range] quit
      ```

      # Assign the uplink and downlink interfaces to VLAN 10.

      ```
      [DeviceA] vlan 10
      [DeviceA-vlan10] port gigabitethernet 1/0/1
      [DeviceA-vlan10] port gigabitethernet 1/0/2
      [DeviceA-vlan10] quit
      ```

   b. Assign an IP address to GigabitEthernet 1/0/3.

      ```
      [DeviceA] interface gigabitethernet 1/0/3
      [DeviceA-GigabitEthernet1/0/3] ip address 10.2.1.1 255.255.255.0
      [DeviceA-GigabitEthernet1/0/3] quit
      ```

      # Assign IP addresses to other interfaces in the same way. (Details not shown.)

   c. Add interfaces to security zones.

      ```
      [DeviceA] security-zone name untrust
      [DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1 vlan 10
      [DeviceA-security-zone-Untrust] quit
      [DeviceA] security-zone name trust
      [DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2 vlan 10
      [DeviceA-security-zone-Trust] quit
      ```

   d. Configure a rule named **trust-untrust** to permit the packets from 10.1.1.0/24 to the Internet.

      Perform this task only on the primary device. After the hot backup system is set up, the secondary device automatically synchronizes its security policy configuration with the primary device.

      ```
      [DeviceA] security-policy ip
      [DeviceA-security-policy-ip] rule name trust-untrust
      [DeviceA-security-policy-ip-3-trust-untrust] source-zone trust
      [DeviceA-security-policy-ip-3-trust-untrust] destination-zone untrust
      [DeviceA-security-policy-ip-3-trust-untrust] source-ip-subnet 10.1.1.0 24
      [DeviceA-security-policy-ip-3-trust-untrust] action pass
      [DeviceA-security-policy-ip-3-trust-untrust] quit
      [DeviceA-security-policy-ip] quit
      ```

   e. Configure hot backup settings.

      # Set up a hot backup system.

      ```
      [DeviceA] remote-backup group
      [DeviceA-remote-backup-group] remote-ip 10.2.1.2
      [DeviceA-remote-backup-group] local-ip 10.2.1.1
      [DeviceA-remote-backup-group] data-channel interface gigabitethernet 1/0/3
      ```

```
[DeviceA-remote-backup-group] device-role primary
RBM_P[DeviceA-remote-backup-group] undo backup-mode
RBM_P[DeviceA-remote-backup-group] hot-backup enable
RBM_P[DeviceA-remote-backup-group] configuration auto-sync enable
RBM_P[DeviceA-remote-backup-group] configuration sync-check interval 12
```

# Configure the hot backup system to monitor the status of VLAN 10.

```
RBM_P[DeviceA-remote-backup-group] track vlan 10
RBM_P[DeviceA-remote-backup-group] quit
```

f. Configure security services on Device A. (Details not shown.)

5. Configure Device B:

a. Configure VLANs.

# Configure the uplink and downlink interfaces to operate at Layer 2.

```
<DeviceB> system-view
[DeviceB] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/2
[DeviceB-if-range] port link-mode bridge
[DeviceB-if-range] quit
```

# Assign the uplink and downlink interfaces to VLAN 10.

```
[DeviceB] vlan 10
[DeviceB-vlan10] port gigabitethernet 1/0/1
[DeviceB-vlan10] port gigabitethernet 1/0/2
[DeviceB-vlan10] quit
```

b. Assign an IP address to GigabitEthernet 1/0/3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] ip address 10.2.1.2 255.255.255.0
[DeviceB-GigabitEthernet1/0/3] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

c. Add interfaces to security zones.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1 vlan 10
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2 vlan 10
[DeviceB-security-zone-Trust] quit
```

d. Configure hot backup settings.

# Set up a hot backup system.

```
[DeviceB] remote-backup group
[DeviceB-remote-backup-group] remote-ip 10.2.1.1
[DeviceB-remote-backup-group] local-ip 10.2.1.2
[DeviceB-remote-backup-group] data-channel interface gigabitethernet 1/0/3
[DeviceB-remote-backup-group] device-role secondary
RBM_S[DeviceB-remote-backup-group] undo backup-mode
RBM_S[DeviceB-remote-backup-group] hot-backup enable
RBM_S[DeviceB-remote-backup-group] configuration auto-sync enable
RBM_S[DeviceB-remote-backup-group] configuration sync-check interval 12
```

# Configure the hot backup system to monitor the state of VLAN 10.

```
RBM_S[DeviceB-remote-backup-group] track vlan 10
RBM_S[DeviceB-remote-backup-group] quit
```

6. On the host, specify 10.1.1.1 as the default gateway. (Details not shown.)

Verifying the configuration

1. Verify that the hot backup channels have been set up on Device A.

```
RBM_P[DeviceA] display remote-backup-group status
Remote backup group information:
  Backup mode: Active/standby
  Device management role: Primary
  Device running status: Active
  Data channel interface: GigabitEthernet1/0/3
  Local IP: 10.2.1.1
  Remote IP: 10.2.1.2    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 0 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:
    Time                     Status change        Cause
    2021-06-22 13:33:33      Initial to Active    Interface status changed
```

2. Verify that the hot backup channels have been set up on Device B.

```
RBM_S[DeviceB] display remote-backup-group status
Remote backup group information:
  Backup mode: Active/standby
  Device management role: Secondary
  Device running status: Standby
  Data channel interface: GigabitEthernet1/0/3
  Local IP: 10.2.1.2
  Remote IP: 10.2.1.1    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 0 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:
    Time                     Status change        Cause
    2021-06-22 13:33:33      Initial to Active    Interface status changed
```

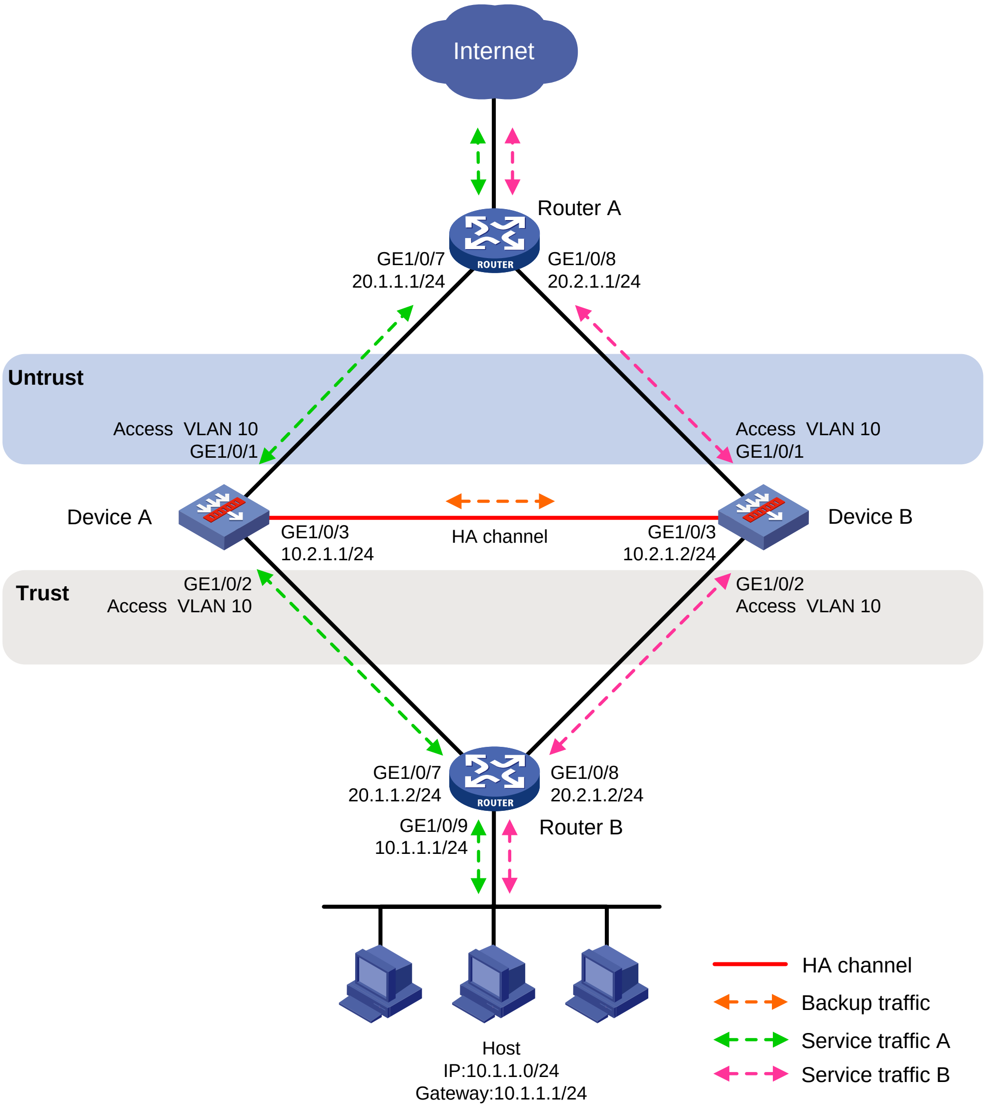
Example: Configuring a transparent in-path hot backup system in dual-active mode

Network configuration

As shown in Figure 24, set up a transparent in-path hot backup system at the border between the Internet and the internal network of an enterprise to ensure service continuity.

- Configure the hot backup system to operate in dual-active mode.
- Connect Router A and Router B to Layer 2 interfaces of the hot backup system.
- Configure Device A and Device B to load share traffic.

Figure 24 Network diagram



Procedure

1. Verify that Device A and Device B have software and hardware environment consistency.
2. Configure OSPF on Router A for the host to access the Internet and for Device A and Device B to load share the traffic sent to the host.

3. Configure OSPF on Router B for the host to access the Internet and for Device A and Device B to load share the traffic sent to the Internet.

4. Configure Device A:

   a. Configure VLANs.

      # Configure the uplink and downlink interfaces to operate at Layer 2.

      ```
      <DeviceA> system-view
      [DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/2
      [DeviceA-if-range] port link-mode bridge
      [DeviceA-if-range] quit
      ```

      # Assign the uplink and downlink interfaces to VLAN 10.

      ```
      [DeviceA] vlan 10
      [DeviceA-vlan10] port gigabitethernet 1/0/1
      [DeviceA-vlan10] port gigabitethernet 1/0/2
      [DeviceA-vlan10] quit
      ```

   b. Assign an IP address to GigabitEthernet 1/0/3.

      ```
      [DeviceA] interface GigabitEthernet 1/0/3
      [DeviceA-GigabitEthernet1/0/3] ip address 10.2.1.1 255.255.255.0
      [DeviceA-GigabitEthernet1/0/3] quit
      ```

      # Assign IP addresses to other interfaces in the same way. (Details not shown.)

   c. Add interfaces to security zones.

      ```
      [DeviceA] security-zone name untrust
      [DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1 vlan 10
      [DeviceA-security-zone-Untrust] quit
      [DeviceA] security-zone name trust
      [DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2 vlan 10
      [DeviceA-security-zone-Trust] quit
      ```

   d. Configure a security policy.

      Perform this task only on the primary device. After the hot backup system is set up, the secondary device automatically synchronizes its security policy configuration with the primary device.

      # Configure a rule named **trust-untrust** to permit the packets from 10.1.1.0/24 to the Internet.

      ```
      [DeviceA] security-policy ip
      [DeviceA-security-policy-ip] rule name trust-untrust
      [DeviceA-security-policy-ip-3-trust-untrust] source-zone trust
      [DeviceA-security-policy-ip-3-trust-untrust] destination-zone untrust
      [DeviceA-security-policy-ip-3-trust-untrust] source-ip-subnet 10.1.1.0 24
      [DeviceA-security-policy-ip-3-trust-untrust] action pass
      [DeviceA-security-policy-ip-3-trust-untrust] quit
      ```

      # Configure rules to permit OSPF protocol packets.

      ```
      [DeviceA-security-policy-ip] rule name ospf1
      [DeviceA-security-policy-ip-4-ospf1] source-zone trust
      [DeviceA-security-policy-ip-4-ospf1] destination-zone untrust
      [DeviceA-security-policy-ip-4-ospf1] service ospf
      [DeviceA-security-policy-ip-4-ospf1] action pass
      [DeviceA-security-policy-ip-4-ospf1] quit
      [DeviceA-security-policy-ip] rule name ospf2
      [DeviceA-security-policy-ip-5-ospf2] source-zone untrust
      ```

```
[DeviceA-security-policy-ip-5-ospf2] destination-zone trust
[DeviceA-security-policy-ip-5-ospf2] service ospf
[DeviceA-security-policy-ip-5-ospf2] action pass
[DeviceA-security-policy-ip-5-ospf2] quit
[DeviceA-security-policy-ip] quit
```

e. Configure hot backup settings.

# Set up a hot backup system.

```
[DeviceA] remote-backup group
[DeviceA-remote-backup-group] remote-ip 10.2.1.2
[DeviceA-remote-backup-group] local-ip 10.2.1.1
[DeviceA-remote-backup-group] data-channel interface gigabitethernet 1/0/3
[DeviceA-remote-backup-group] device-role primary
RBM_P[DeviceA-remote-backup-group] backup-mode dual-active
RBM_P[DeviceA-remote-backup-group] hot-backup enable
RBM_P[DeviceA-remote-backup-group] configuration auto-sync enable
RBM_P[DeviceA-remote-backup-group] configuration sync-check interval 12
RBM_P[DeviceA-remote-backup-group] delay-time 1
```

# Configure the hot backup system to monitor the status of GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
RBM_P[DeviceA-remote-backup-group] track interface gigabitethernet 1/0/1
RBM_P[DeviceA-remote-backup-group] track interface gigabitethernet 1/0/2
RBM_P[DeviceA-remote-backup-group] quit
```

f. Configure security services on Device A. (Details not shown.)

5. Configure Device B:

a. Configure VLANs.

# Configure the uplink and downlink interfaces to operate at Layer 2.

```
<DeviceB> system-view
[DeviceB] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/2
[DeviceB-if-range] port link-mode bridge
[DeviceB-if-range] quit
```

# Assign the uplink and downlink interfaces to VLAN 10.

```
[DeviceB] vlan 10
[DeviceB-vlan10] port gigabitethernet 1/0/1
[DeviceB-vlan10] port gigabitethernet 1/0/2
[DeviceB-vlan10] quit
```

b. Assign an IP address to GigabitEthernet 1/0/3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] ip address 10.2.1.2 255.255.255.0
[DeviceB-GigabitEthernet1/0/3] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

c. Add interfaces to security zones.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1 vlan 10
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2 vlan 10
[DeviceB-security-zone-Trust] quit
```

d. Configure hot backup settings.

# Set up a hot backup system.

```
[DeviceB] remote-backup group
[DeviceB-remote-backup-group] remote-ip 10.2.1.1
[DeviceB-remote-backup-group] local-ip 10.2.1.2

[DeviceB-remote-backup-group] device-role secondary
RBM_S[DeviceB-remote-backup-group] backup-mode dual-active
RBM_S[DeviceB-remote-backup-group] hot-backup enable
RBM_S[DeviceB-remote-backup-group] configuration auto-sync enable
RBM_S[DeviceB-remote-backup-group] delay-time 1
RBM_S[DeviceB-remote-backup-group] configuration sync-check interval 12
```

# Configure the hot backup system to monitor the status of GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
RBM_S[DeviceB-remote-backup-group] track interface gigabitethernet 1/0/1
RBM_S[DeviceB-remote-backup-group] track interface gigabitethernet 1/0/2
RBM_S[DeviceB-remote-backup-group] quit
```

6. On the host, specify 10.1.1.1 as the default gateway. (Details not shown.)

Verifying the configuration

1. Verify that the hot backup channels have been set up on Device A.

```
RBM_P[DeviceA] display remote-backup-group status
Remote backup group information:
  Backup mode: Dual-active
  Device management role: Primary
  Device running status: Active
  Data channel interface: GigabitEthernet1/0/3
  Local IP: 10.2.1.1
  Remote IP: 10.2.1.2    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 1 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:

    2021-06-22 13:33:33      Initial to Active    Interface status changed
```

2. Verify that the hot backup channels have been set up on Device B.

```
RBM_S[DeviceB] display remote-backup-group status
Remote backup group information:
  Backup mode: Dual-active
  Device management role: Secondary
  Device running status: Active
  Data channel interface: GigabitEthernet1/0/3
  Local IP: 10.2.1.2
  Remote IP: 10.2.1.1    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 1 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:
    Time                         Status change        Cause
    2021-06-22 13:33:33      Initial to Active    Interface status changed
```

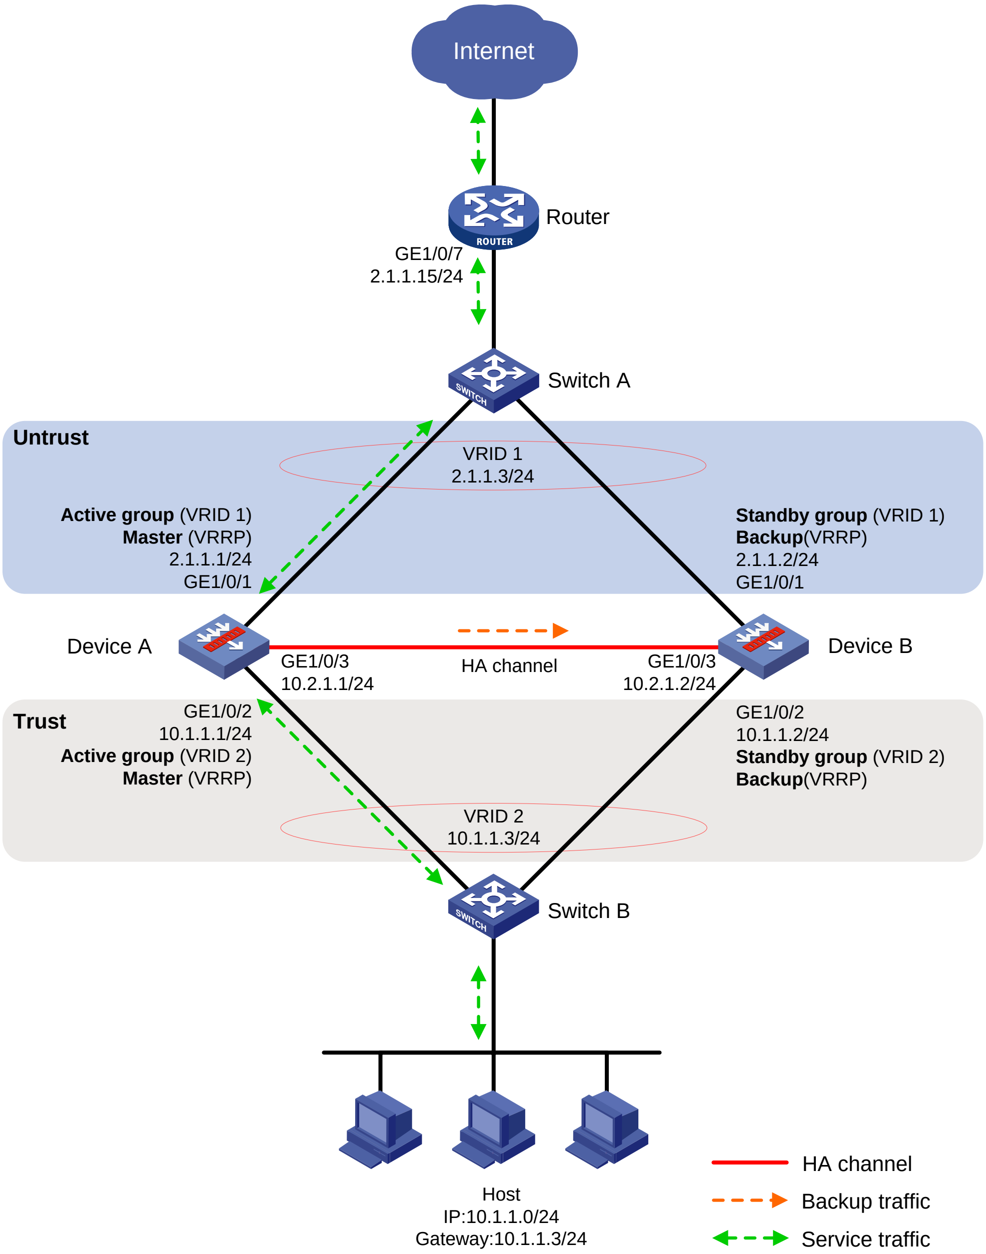
Example: Configuring interface-based NAT on an active/standby hot backup system in collaboration with VRRP

Network configuration

As shown in Figure 25, set up a hot backup system at the border between the Internet and the internal network of an enterprise to ensure service continuity.

- Configure the hot backup system to collaborate with VRRP.
- Configure the hot backup system to operate in active/standby mode.
- Configure Device A and Device B as the primary device and the secondary device, respectively.
- Configure dynamic NAT to translate the private IP addresses in the internal network into public IP addresses 2.1.1.1 through 2.1.1.10.

Figure 25 Network diagram



Procedure

1. Set up the hot backup system as described in "Example: Configuring active/standby hot backup in collaboration with VRRP."
2. Configure dynamic NAT on Device A (primary):

   # Create NAT address group 1 and add address range 2.1.1.5 to 2.1.1.10. Associate NAT address group 1 with VRRP group 1.

   ```
   RBM_P<DeviceA> system-view
   RBM_P[DeviceA] nat address-group 1
   RBM_P[DeviceA-address-group-1] address 2.1.1.5 2.1.1.10
   RBM_P[DeviceA-address-group-1] vrrp vrid 1
   RBM_P[DeviceA-address-group-1] quit
   ```

# Configure outbound dynamic NAT to use NAT address group 1 for address translation on GigabitEthernet 1/0/1.

```
RBM_P[DeviceA] interface gigabitethernet 1/0/1
RBM_P[DeviceA-GigabitEthernet1/0/1] nat outbound address-group 1
RBM_P[DeviceA-GigabitEthernet1/0/1] quit
```

Verifying the configuration

# Verify that the host can communicate with the Internet. (Details not shown.)

# Verify that Device A has generated a NAT session entry.

```
RBM_P[DeviceA] display nat session verbose

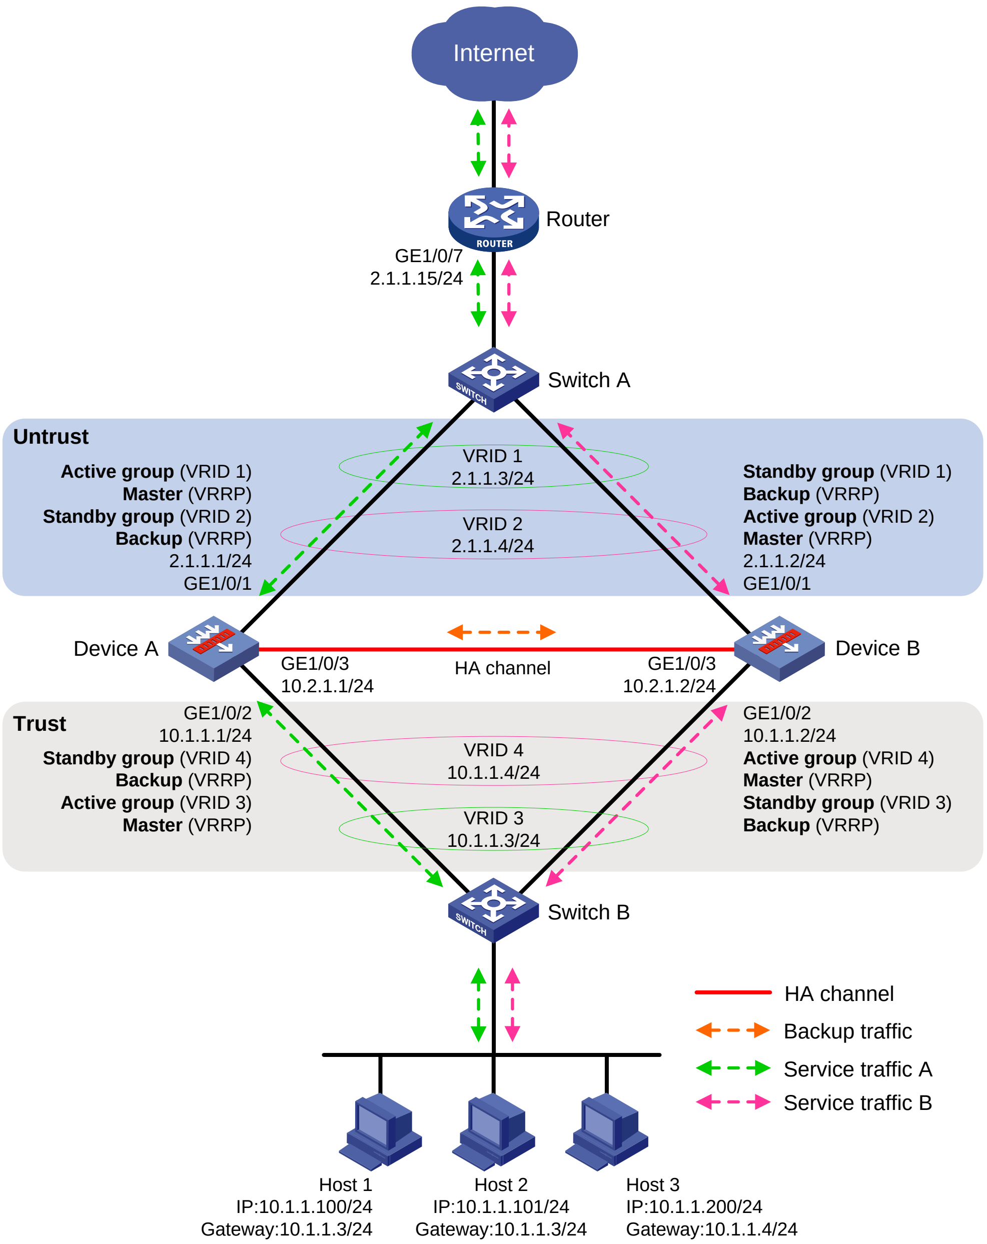
Example: Configuring interface-based NAT on a dual-active hot backup system in collaboration with VRRP

Network configuration

As shown in Figure 26, set up a hot backup system at the border between the Internet and the internal network of an enterprise to ensure service continuity.

- Configure the hot backup system to collaborate with VRRP.
- Configure the hot backup system to operate in dual-active mode.
- Configure Device A and Device B to load share traffic.
- Configure dynamic NAT to translate the private IP addresses in the internal network into public IP addresses 2.1.1.1 through 2.1.1.10.

Figure 26 Network diagram



Procedure

1. Set up the hot backup system as described in "Example: Configuring dual-active hot backup in collaboration with VRRP".
2. Configure dynamic NAT on Device A (primary):

   # Create NAT address group 1 and add address range 2.1.1.5 to 2.1.1.7. Associate NAT address group 1 with VRRP group 1.

   ```
   RBM_P<DeviceA> system-view
   RBM_P[DeviceA] nat address-group 1
   RBM_P[DeviceA-address-group-1] address 2.1.1.5 2.1.1.7
   RBM_P[DeviceA-address-group-1] vrrp vrid 1
   RBM_P[DeviceA-address-group-1] quit
   ```

   # Create NAT address group 2 and add address range 2.1.1.8 to 2.1.1.10. Associate NAT address group 2 with VRRP group 2.

```
RBM_P[DeviceA] nat address-group 2
RBM_P[DeviceA-address-group-2] address 2.1.1.8 2.1.1.10
RBM_P[DeviceA-address-group-2] vrrp vrid 2
RBM_P[DeviceA-address-group-2] quit
```

# Configure ACL 3000 to permit packets from 10.1.1.1/25. Configure ACL 3001 to permit packets from 10.1.1.129/25.

```

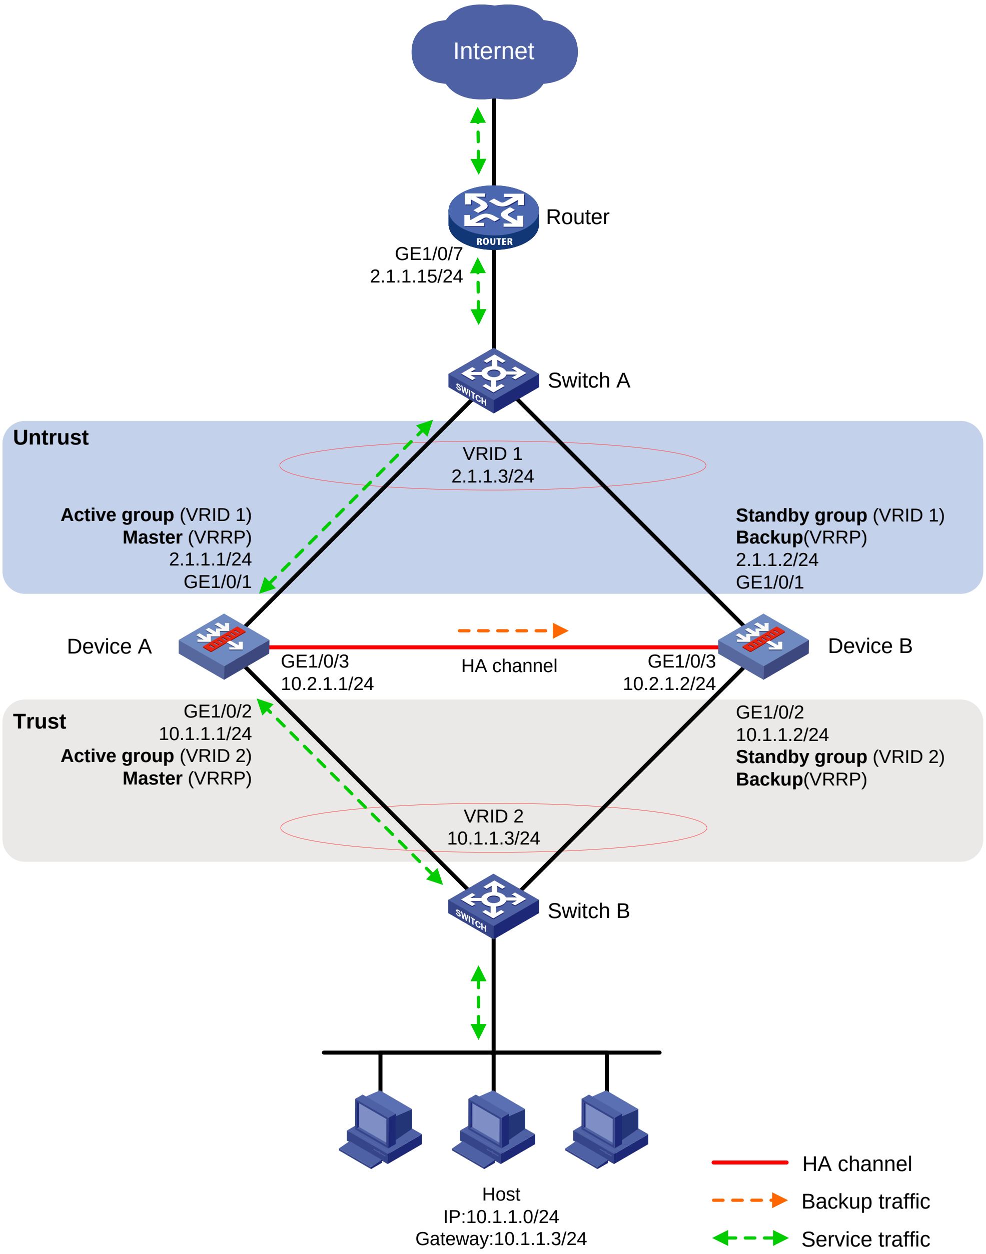
Example: Configuring global NAT on an active/standby hot backup system in collaboration with VRRP

Network configuration

As shown in Figure 27, set up a hot backup system at the border between the Internet and the internal network of an enterprise to ensure service continuity.

- Configure the hot backup system to collaborate with VRRP.
- Configure the hot backup system to operate in active/standby mode.
- Configure Device A and Device B as the primary device and the secondary device, respectively.
- Configure dynamic NAT to translate the private IP addresses in the internal network into public IP addresses 2.1.1.1 through 2.1.1.10.

Figure 27 Network diagram



Procedure

1. Set up the hot backup system as described in "Example: Configuring active/standby hot backup in collaboration with VRRP."
2. Configure dynamic NAT globally on Device A (primary):

   # Create NAT address group 1 and add address range 2.1.1.5 to 2.1.1.10. Associate NAT address group 1 with VRRP group 1.

```
RBM_P<DeviceA> system-view
RBM_P[DeviceA] nat address-group 1
RBM_P[DeviceA-address-group-1] address 2.1.1.5 2.1.1.10
RBM_P[DeviceA-address-group-1] vrrp vrid 1
RBM_P[DeviceA-address-group-1] quit
```

# Configure a global NAT policy to use NAT address group 1 for address translation of the traffic sent from the internal network to the Internet.

```
RBM_P[DeviceA] nat global-policy
RBM_P[DeviceA-nat-global-policy] rule name rule1
RBM_P[DeviceA-nat-global-policy-rule1] source-zone Trust
RBM_P[DeviceA-nat-global-policy-rule1] destination-zone Untrust
RBM_P[DeviceA-nat-global-policy-rule1] source-ip subnet 10.1.1.0 24
RBM_P[DeviceA-nat-global-policy-rule1] action snat address-group 1 vrrp 1
RBM_P[DeviceA-nat-global-policy-rule1] quit
RBM_P[DeviceA-nat-global-policy] quit
```

Verifying the configuration

# Verify that the host can communicate with the Internet. (Details not shown.)

# Verify that Device A has generated a NAT session entry.

```

Example: Configuring global NAT on a dual-active hot backup system in collaboration with VRRP

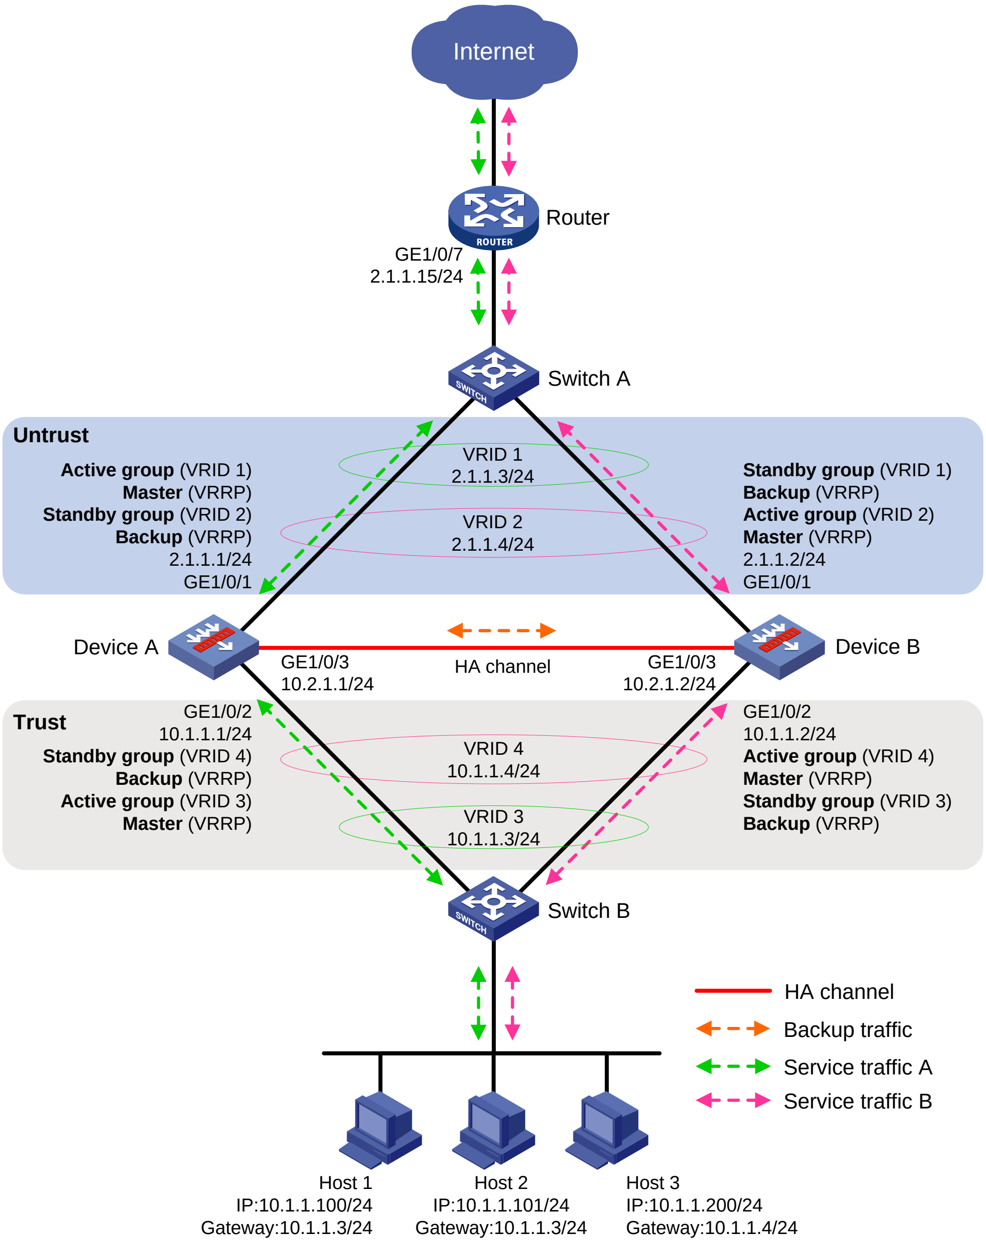
Network configuration

As shown in Figure 28, set up a hot backup system at the border between the Internet and the internal network of an enterprise to ensure service continuity.

- Configure the hot backup system to collaborate with VRRP.

- Configure the hot backup system to operate in dual-active mode.
- Configure Device A and Device B to load share traffic.
- Configure dynamic NAT to translate the private IP addresses in the internal network into public IP addresses 2.1.1.1 through 2.1.1.10.

Figure 28 Network diagram



Procedure

1. Set up the hot backup system as described in "Example: Configuring dual-active hot backup in collaboration with VRRP".
2. Configure dynamic NAT on Device A (primary):

   # Create NAT address group 1 and add address range 2.1.1.5 to 2.1.1.7. Associate NAT address group 1 with VRRP group 1.

   ```
   RBM_P<DeviceA> system-view
   RBM_P[DeviceA] nat address-group 1
   ```

```
RBM_P[DeviceA-address-group-1] address 2.1.1.5 2.1.1.7
RBM_P[DeviceA-address-group-1] vrrp vrid 1
RBM_P[DeviceA-address-group-1] quit
```

# Create NAT address group 2 and add address range 2.1.1.8 to 2.1.1.10. Associate NAT address group 2 with VRRP group 2.

```
RBM_P[DeviceA] nat address-group 2
RBM_P[DeviceA-address-group-2] address 2.1.1.8 2.1.1.10
RBM_P[DeviceA-address-group-2] vrrp vrid 2
RBM_P[DeviceA-address-group-2] quit
```

# Configure global NAT rule 1 to use NAT address group 1 for address translation of the traffic sent from the 10.1.1.1/25 network to the Internet.

Hot backup configuration examples (IPv6)

Example: Configuring active/standby hot backup in collaboration with VRRP

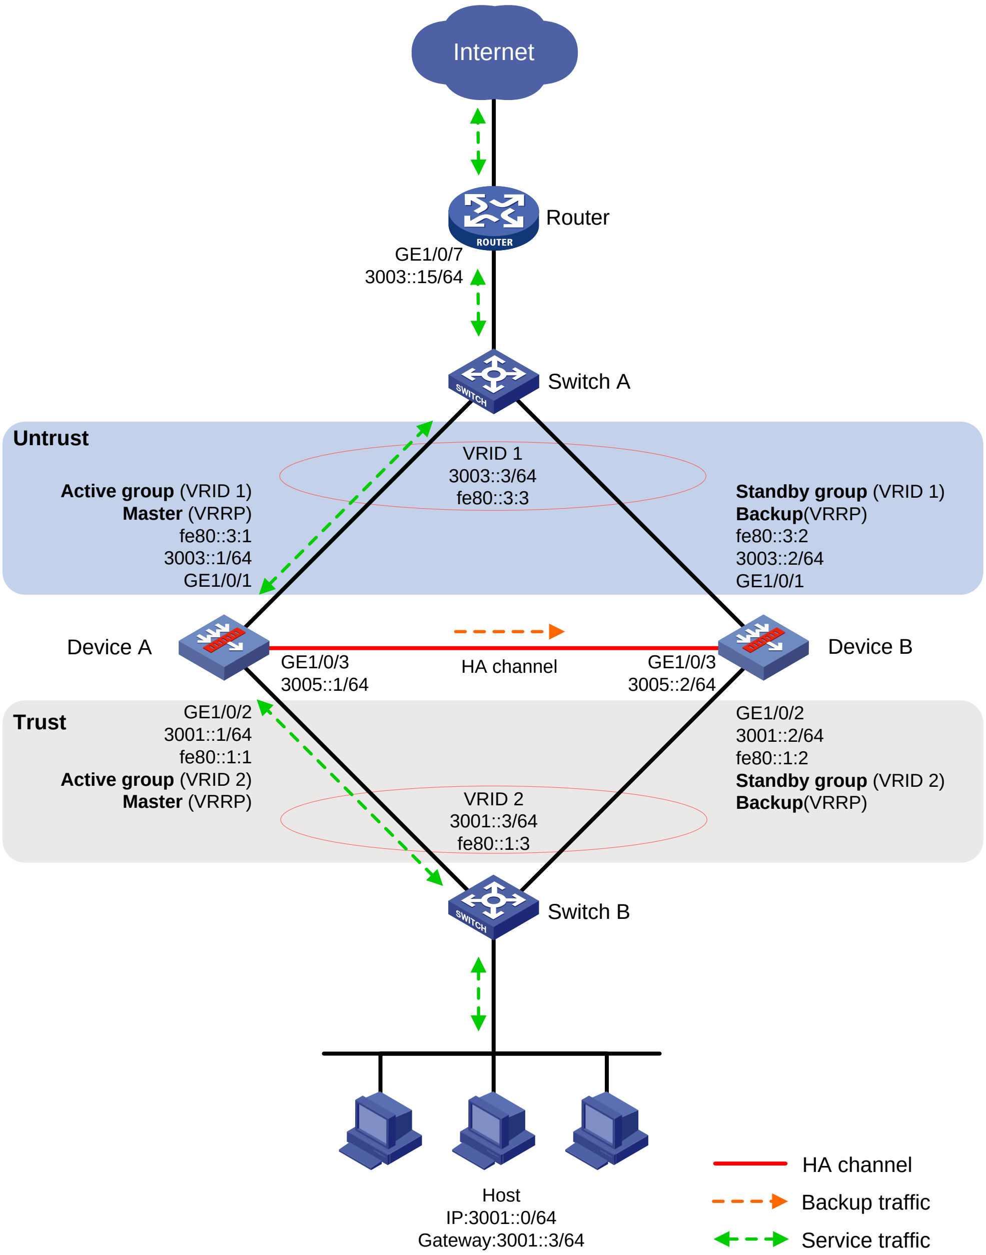
Network configuration

As shown in Figure 19, set up a hot backup system at the border between the Internet and the internal network of an enterprise to ensure service continuity.

- Configure the hot backup system to collaborate with VRRP.

- Configure the hot backup system to operate in active/standby mode.
- Configure Device A and Device B as the primary device and the secondary device, respectively.

Figure 29 Network diagram



Procedure

1. Verify that Device A and Device B have software and hardware environment consistency.
2. Configure Switch A:

NOTE:

This step only provides the brief configuration procedure.

# Create VLAN 10.

# Configure the interfaces attached to the hot backup system and the router to operate at Layer 2. Assign them to VLAN 10 as access interfaces.

3. Configure Switch B:

NOTE:

This step only provides the brief configuration procedure.

# Create VLAN 10.

# Configure the interfaces attached to the hot backup system and the host to operate at Layer 2. Assign them to VLAN 10 as access interfaces.

4. Configure the router:

NOTE:

This step only provides the brief configuration procedure.

# Assign 3003::15/64 to GigabitEthernet 1/0/7.

# Configure routes as follows:

- Specify 3003::3/64 (virtual IP address of VRRP group 1) as the next hop of the routes to the internal network.
- Specify the IP address of the peer interface attached to the traffic outgoing interface as the next hop of the route to the Internet.

5. Configure Device A:

   a. Assign IP addresses to interfaces.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ipv6 address 3003::1/64
[DeviceA-GigabitEthernet1/0/1] ipv6 address fe80::3:1 link-local
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] ipv6 address 3001::1/64
[DeviceA-GigabitEthernet1/0/2] ipv6 address fe80::1:1 link-local
[DeviceA-GigabitEthernet1/0/2] undo ipv6 nd ra halt
[DeviceA-GigabitEthernet1/0/2] quit
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] ipv6 address 3005::1/64
[DeviceA-GigabitEthernet1/0/3] ipv6 address auto link-local
[DeviceA-GigabitEthernet1/0/3] quit
```

   b. Add interfaces to security zones.

```
[DeviceA] security-zone name untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] quit
[DeviceA] security-zone name trust
[DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceA-security-zone-Trust] quit
```

   c. Configure settings for routing. This example configures a static route, and the next hop in the route is 3003::15.

```
[DeviceA] ipv6 route-static 0::0 0 3003::15
```

   d. Configure a security policy.

   Perform this task only on the primary device. After the hot backup system is set up, the secondary device automatically synchronizes its security policy configuration with the primary device.

# Configure security policy rule named **trust-untrust** to permit the packets from 3001::0/64 to the Internet.

```
[DeviceA] security-policy ipv6
[DeviceA-security-policy-ipv6] rule name trust-untrust
[DeviceA-security-policy-ipv6-3-trust-untrust] source-zone trust
[DeviceA-security-policy-ipv6-3-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ipv6-3-trust-untrust] source-ip-subnet 3001::0 64
[DeviceA-security-policy-ipv6-3-trust-untrust] action pass
[DeviceA-security-policy-ipv6-3-trust-untrust] quit
```

# Configure rules to permit VRRP protocol packets. When the hot backup channel is disconnected, Device A and Device B can exchange VRRP protocol packets to elect a VRRP master.

```
[DeviceA-security-policy-ipv6] rule name vrrp1
[DeviceA-security-policy-ipv6-4-vrrp1] source-zone trust
[DeviceA-security-policy-ipv6-4-vrrp1] destination-zone local
[DeviceA-security-policy-ipv6-4-vrrp1] service vrrp
[DeviceA-security-policy-ipv6-4-vrrp1] action pass
[DeviceA-security-policy-ipv6-4-vrrp1] quit
[DeviceA-security-policy-ipv6] rule name vrrp2
[DeviceA-security-policy-ipv6-5-vrrp2] source-zone local
[DeviceA-security-policy-ipv6-5-vrrp2] destination-zone trust
[DeviceA-security-policy-ipv6-5-vrrp2] service vrrp
[DeviceA-security-policy-ipv6-5-vrrp2] action pass
[DeviceA-security-policy-ipv6-5-vrrp2] quit
[DeviceA-security-policy-ipv6] rule name vrrp3
[DeviceA-security-policy-ipv6-6-vrrp3] source-zone untrust
[DeviceA-security-policy-ipv6-6-vrrp3] destination-zone local
[DeviceA-security-policy-ipv6-6-vrrp3] service vrrp
[DeviceA-security-policy-ipv6-6-vrrp3] action pass
[DeviceA-security-policy-ipv6-6-vrrp3] quit
[DeviceA-security-policy-ipv6] rule name vrrp4
[DeviceA-security-policy-ipv6-7-vrrp4] source-zone local
[DeviceA-security-policy-ipv6-7-vrrp4] destination-zone untrust
[DeviceA-security-policy-ipv6-7-vrrp4] service vrrp
[DeviceA-security-policy-ipv6-7-vrrp4] action pass
[DeviceA-security-policy-ipv6-7-vrrp4] quit
[DeviceA-security-policy-ipv6] quit
```

e. Configure hot backup settings.

# Set up a hot backup system.

```
[DeviceA] remote-backup group
[DeviceA-remote-backup-group] remote-ipv6 3005::2
[DeviceA-remote-backup-group] local-ipv6 3005::1
[DeviceA-remote-backup-group] data-channel interface gigabitethernet 1/0/3
[DeviceA-remote-backup-group] device-role primary
RBM_P[DeviceA-remote-backup-group] undo backup-mode
RBM_P[DeviceA-remote-backup-group] hot-backup enable
RBM_P[DeviceA-remote-backup-group] configuration auto-sync enable
RBM_P[DeviceA-remote-backup-group] configuration sync-check interval 12
RBM_P[DeviceA-remote-backup-group] quit
```

# Create VRRP groups and associate them with the hot backup system.

```
RBM_P[DeviceA] interface gigabitethernet 1/0/1
RBM_P[DeviceA-GigabitEthernet1/0/1] vrrp ipv6 vrid 1 virtual-ip fe80::3:3
link-local active
RBM_P[DeviceA-GigabitEthernet1/0/1] vrrp ipv6 vrid 1 virtual-ip 3003::3
RBM_P[DeviceA-GigabitEthernet1/0/1] quit
RBM_P[DeviceA] interface gigabitethernet 1/0/2
RBM_P[DeviceA-GigabitEthernet1/0/2] vrrp ipv6 vrid 1 virtual-ip fe80::1:3
link-local active
RBM_P[DeviceA-GigabitEthernet1/0/2] vrrp ipv6 vrid 1 virtual-ip 3001::3
RBM_P[DeviceA-GigabitEthernet1/0/2] quit
```

f. Configure security services on Device A. (Details not shown.)

6. Configure Device B:

a. Assign IP addresses to interfaces.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ipv6 address 3003::2/64
[DeviceB-GigabitEthernet1/0/1] ipv6 address fe80::3:2 link-local
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] ipv6 address 3001::2/64
[DeviceB-GigabitEthernet1/0/2] ipv6 address fe80::1:2 link-local
[DeviceB-GigabitEthernet1/0/2] undo ipv6 nd ra halt
[DeviceB-GigabitEthernet1/0/2] quit
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] ipv6 address 3005::2/64
[DeviceB-GigabitEthernet1/0/3] ipv6 address auto link-local
[DeviceB-GigabitEthernet1/0/3] quit
```

b. Add interfaces to security zones.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

c. Configure settings for routing. This example configures a static route, and the next hop in the route is 3003::15.

```
[DeviceB] ipv6 route-static 0::0 0 3003::15
```

d. Configure hot backup settings.

# Set up a hot backup system.

```
[DeviceB] remote-backup group
[DeviceB-remote-backup-group] remote-ipv6 3005::1
[DeviceB-remote-backup-group] local-ipv6 3005::2
[DeviceB-remote-backup-group] data-channel interface gigabitethernet 1/0/3
[DeviceB-remote-backup-group] device-role secondary
RBM_S[DeviceB-remote-backup-group] undo backup-mode
RBM_S[DeviceB-remote-backup-group] hot-backup enable
RBM_S[DeviceB-remote-backup-group] configuration auto-sync enable
```

```
RBM_S[DeviceB-remote-backup-group] configuration sync-check interval 12
RBM_S[DeviceB-remote-backup-group] quit
```

# Create VRRP groups and associate them with the hot backup system.

```
RBM_S[DeviceB] interface gigabitethernet 1/0/1
RBM_S[DeviceB-GigabitEthernet1/0/1] vrrp ipv6 vrid 1 virtual-ip fe80::3:3
link-local standby
RBM_S[DeviceB-GigabitEthernet1/0/1] vrrp ipv6 vrid 1 virtual-ip 3003::3
RBM_S[DeviceB-GigabitEthernet1/0/1] quit
RBM_S[DeviceB] interface gigabitethernet 1/0/2
RBM_S[DeviceB-GigabitEthernet1/0/2] vrrp ipv6 vrid 1 virtual-ip fe80::1:3
link-local standby
RBM_S[DeviceB-GigabitEthernet1/0/2] vrrp ipv6 vrid 1 virtual-ip 3001::3
RBM_S[DeviceB-GigabitEthernet1/0/2] quit
```

7. On the host, specify 3001::3 (virtual IP address of VRRP group 2) as the default gateway. (Details not shown.)

Verifying the configuration

1. Verify the configuration on Device A:

# Verify that the hot backup channels have been set up.

```
RBM_P[DeviceA] display remote-backup-group status
Remote backup group information:
  Backup mode: Active/standby
  Device management role: Primary
  Device running status: Active
  Data channel interface: GigabitEthernet1/0/3
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 0 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:
    Time                     Status change        Cause
    2021-06-22 13:33:33      Initial to Active    Interface status changed
```

# Verify that Device A is the master in all VRRP groups.

```
RBM_P[DeviceA] display vrrp ipv6
IPv6 Virtual Router Information:
 Running mode      : Standard
 RBM control channel is established
   IPv6 VRRP active group status : Master
   IPv6 VRRP standby group status: Master
 Total number of virtual routers : 2
 Interface          VRID  State        Running Adver   Auth     Virtual
                                       Pri     Timer   Type        IP
 ---------------------------------------------------------------------
 GE1/0/1            1     Master       100     100     None     FE80::3:3
 GE1/0/2            1     Master       100     100     None     FE80::1:3
```

# Enable logging for the security policy that permits communication between security zones **Trust** and **Untrust**. Verity that Device A generates log messages when the host communicates with the Internet. (Details not shown.)

2. Verify the configuration on Device B:

# Verify that the hot backup channels have been set up.

```
RBM_S[DeviceB] display remote-backup-group status
Remote backup group information:
  Backup mode: Active/standby
  Device management role: Secondary
  Device running status: Standby
  Data channel interface: GigabitEthernet1/0/3
  Local IPv6: 3005::2
  Remote IPv6: 3005::1    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 0 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:

```

# Enable logging for the security policy that permits communication between security zones **Trust** and **Untrust**. Verity that Device B does not generate log messages when the host communicates with the Internet. (Details not shown.)

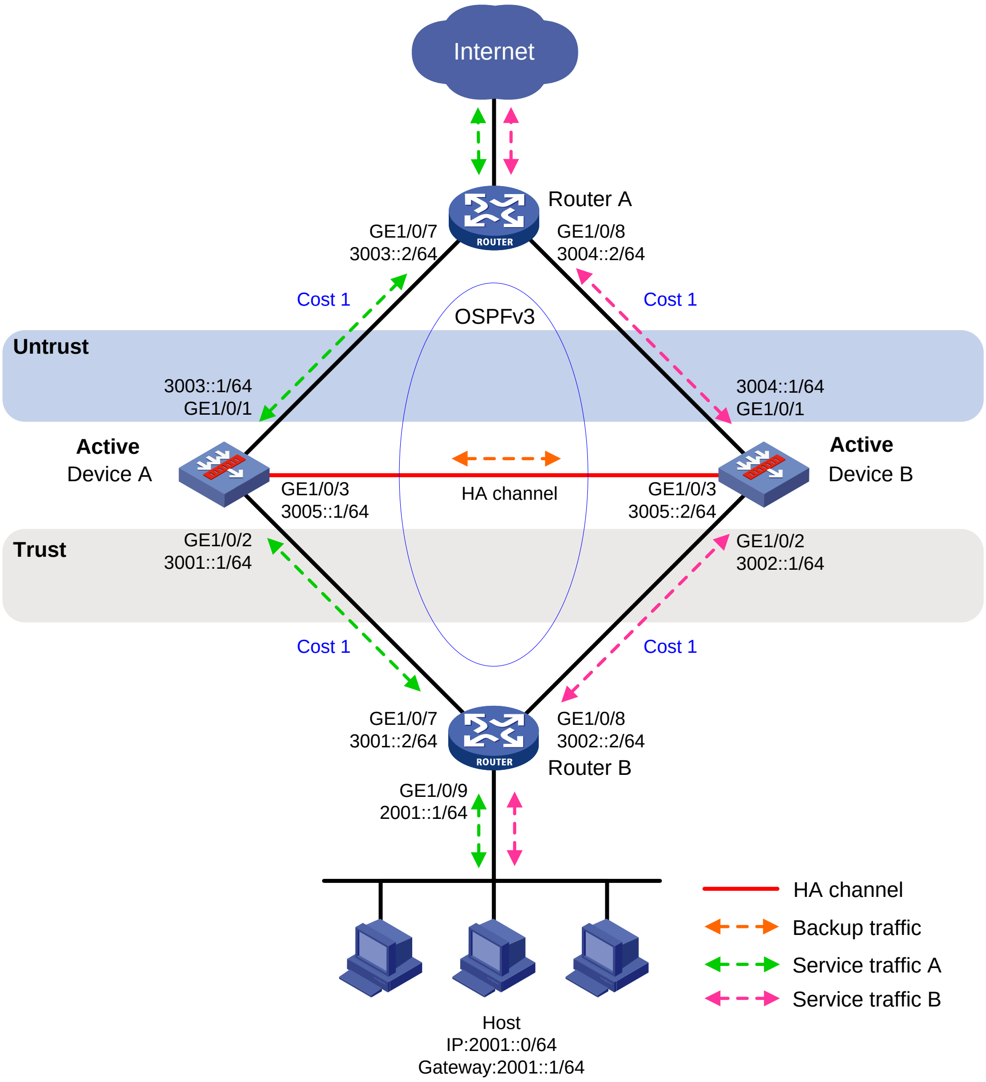
Example: Configuring dual-active hot backup in collaboration with a routing protocol

Network configuration

As shown in Figure 22, set up a hot backup system at the border between the Internet and the internal network of an enterprise to ensure service continuity.

- Configure the hot backup system to collaborate with OSPFv3.
- Configure the hot backup system to operate in dual-active mode.
- Configure Device A and Device B to load share traffic.

Figure 30 Network diagram



Procedure

1. Verify that Device A and Device B have software and hardware environment consistency.
2. Configure Router A:

NOTE:

This step only provides the brief configuration procedure.

# Assign 3003::2/64 to GigabitEthernet 1/0/7.

# Assign 3004::2/64 to GigabitEthernet 1/0/8.

# Configure OSPFv3 for Device A, Device B, and the routers to have Layer 3 reachability.

# Configure per-flow load sharing for IP forwarding.

3. Configure Router B:

NOTE:

This step only provides the brief configuration procedure.

# Assign 3001::2/64 to GigabitEthernet 1/0/7.

# Assign 3002::2/64 to GigabitEthernet 1/0/8.

# Configure OSPFv3 for Device A, Device B, and the routers to have Layer 3 reachability.

# Configure per-flow load sharing for IP forwarding.

4. Configure Device A:
   a. Assign an IP address to GigabitEthernet 1/0/1.
      ```
      <DeviceA> system-view
      [DeviceA] interface gigabitethernet 1/0/1
      [DeviceA-GigabitEthernet1/0/1] ipv6 address 3003::1/64
      [DeviceA-GigabitEthernet1/0/1] ipv6 address auto link-local
      [DeviceA-GigabitEthernet1/0/1] quit
      ```
      # Assign IP addresses to other interfaces in the same way. (Details not shown.)
   b. Add interfaces to security zones.
      ```
      [DeviceA] security-zone name untrust
      [DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
      [DeviceA-security-zone-Untrust] quit
      [DeviceA] security-zone name trust
      [DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
      [DeviceA-security-zone-Trust] quit
      ```
   c. Configure OSPFv3. Use the default OSPFv3 link cost configuration.
      ```
      [DeviceA] ospfv3 1
      [DeviceA-ospfv3-1] router-id 2.1.1.1
      [DeviceA-ospfv3-1] quit
      [DeviceA] interface gigabitethernet 1/0/1
      [DeviceA-GigabitEthernet1/0/1] ospfv3 1 area 0
      [DeviceA-GigabitEthernet1/0/1] quit
      [DeviceA] interface GigabitEthernet1/0/2
      [DeviceA-GigabitEthernet1/0/2] ospfv3 1 area 0
      [DeviceA-GigabitEthernet1/0/2] quit
      ```
   d. Configure a security policy.

      Perform this task only on the primary device. After the hot backup system is set up, the secondary device automatically synchronizes its security policy configuration with the primary device.

      # Configure security policy rule named **trust-untrust** to permit the packets from 2001::0/64 to the Internet.
      ```
      [DeviceA] security-policy ipv6
      [DeviceA-security-policy-ipv6] rule name trust-untrust
      [DeviceA-security-policy-ipv6-3-trust-untrust] source-zone trust
      [DeviceA-security-policy-ipv6-3-trust-untrust] destination-zone untrust
      [DeviceA-security-policy-ipv6-3-trust-untrust] source-ip-subnet 2001::0 64
      [DeviceA-security-policy-ipv6-3-trust-untrust] action pass
      [DeviceA-security-policy-ipv6-3-trust-untrust] quit
      ```
      # Configure rules to permit OSPFv3 protocol packets.
      ```
      [DeviceA-security-policy-ipv6] rule name ospf1
      [DeviceA-security-policy-ipv6-4-ospf1] source-zone trust
      ```

```
[DeviceA-security-policy-ipv6-4-ospf1] destination-zone local
[DeviceA-security-policy-ipv6-4-ospf1] service ospf
[DeviceA-security-policy-ipv6-4-ospf1] action pass
[DeviceA-security-policy-ipv6-4-ospf1] quit
[DeviceA-security-policy-ipv6] rule name ospf2
[DeviceA-security-policy-ipv6-5-ospf2] source-zone local
[DeviceA-security-policy-ipv6-5-ospf2] destination-zone trust
[DeviceA-security-policy-ipv6-5-ospf2] service ospf
[DeviceA-security-policy-ipv6-5-ospf2] action pass
[DeviceA-security-policy-ipv6-5-ospf2] quit
[DeviceA-security-policy-ipv6] rule name ospf3
[DeviceA-security-policy-ipv6-6-ospf3] source-zone untrust
[DeviceA-security-policy-ipv6-6-ospf3] destination-zone local
[DeviceA-security-policy-ipv6-6-ospf3] service ospf
[DeviceA-security-policy-ipv6-6-ospf3] action pass
[DeviceA-security-policy-ipv6-6-ospf3] quit
[DeviceA-security-policy-ipv6] rule name ospf4
[DeviceA-security-policy-ipv6-7-ospf4] source-zone local
[DeviceA-security-policy-ipv6-7-ospf4] destination-zone untrust
[DeviceA-security-policy-ipv6-7-ospf4] service ospf
[DeviceA-security-policy-ipv6-7-ospf4] action pass
[DeviceA-security-policy-ipv6-7-ospf4] quit
[DeviceA-security-policy-ipv6] quit
```

e. Configure hot backup settings.

# Associate track entries with interfaces.

```
[DeviceA] track 1 interface gigabitethernet 1/0/1
[DeviceA-track-1] quit
[DeviceA] track 2 interface gigabitethernet 1/0/2
[DeviceA-track-2] quit
```

# Set up a hot backup system.

```
[DeviceA] remote-backup group
[DeviceA-remote-backup-group] remote-ipv6 3005::2
[DeviceA-remote-backup-group] local-ipv6 3005::1
[DeviceA-remote-backup-group] data-channel interface gigabitethernet 1/0/3
[DeviceA-remote-backup-group] device-role primary
RBM_P[DeviceA-remote-backup-group] backup-mode dual-active
RBM_P[DeviceA-remote-backup-group] hot-backup enable
RBM_P[DeviceA-remote-backup-group] configuration auto-sync enable
RBM_P[DeviceA-remote-backup-group] configuration sync-check interval 12
RBM_P[DeviceA-remote-backup-group] delay-time 1
```

# Configure the hot backup system to change the link costs advertised in OSPFv3 routes to 1.

```
RBM_P[DeviceA-remote-backup-group] adjust-cost ospfv3 enable absolute 1
```

# Configure the hot backup system to monitor the status of track entry 1 and track entry 2.

```
RBM_P[DeviceA-remote-backup-group] track 1
RBM_P[DeviceA-remote-backup-group] track 2
RBM_P[DeviceA-remote-backup-group] quit
```

f. Configure security services on Device A. (Details not shown.)

5. Configure Device B:

   a. Assign IP addresses to interfaces.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ipv6 address 3004::1/64
[DeviceB-GigabitEthernet1/0/1] ipv6 address auto link-local
[DeviceB-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

   b. Add interfaces to security zones.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

   c. Configure OSPFv3. Use the default OSPFv3 link cost configuration.

```
[DeviceB] ospfv3 1
[DeviceB-ospfv3-1] router-id 3.1.1.1
[DeviceB-ospfv3-1] quit
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ospfv3 1 area 0
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface GigabitEthernet1/0/2
[DeviceB-GigabitEthernet1/0/2] ospfv3 1 area 0
[DeviceB-GigabitEthernet1/0/2] quit
```

   d. Configure hot backup settings.

   # Associate track entries with interfaces.

```
[DeviceB] track 1 interface gigabitethernet 1/0/1
[DeviceB-track-1] quit
[DeviceB] track 2 interface gigabitethernet 1/0/2
[DeviceB-track-2] quit
```

   # Set up a hot backup system.

```
[DeviceB] remote-backup group
[DeviceB-remote-backup-group] remote-ipv6 3005::1
[DeviceB-remote-backup-group] local-ipv6 3005::2
[DeviceB-remote-backup-group] data-channel interface gigabitethernet 1/0/3
[DeviceB-remote-backup-group] device-role secondary
RBM_S[DeviceB-remote-backup-group] backup-mode dual-active
RBM_S[DeviceB-remote-backup-group] hot-backup enable
RBM_S[DeviceB-remote-backup-group] configuration auto-sync enable
RBM_S[DeviceB-remote-backup-group] configuration sync-check interval 12
RBM_S[DeviceB-remote-backup-group] delay-time 1
```

   # Configure the hot backup system to change the link costs advertised in OSPFv3 routes to 1.

```
RBM_S[DeviceB-remote-backup-group] adjust-cost ospfv3 enable absolute 1
```

   # Configure the hot backup system to monitor the status of track entry 1 and track entry 2.

```
RBM_S[DeviceB-remote-backup-group] track 1
RBM_S[DeviceB-remote-backup-group] track 2
```

```
RBM_S[DeviceB-remote-backup-group] quit
```

6. On the hosts, specify 2002::1 as the default gateway. (Details not shown.)

Verifying the configuration

1. Verify the configuration on Device A:

   # Verify that the hot backup channels have been set up.

```
RBM_P[DeviceA] display remote-backup-group status
Remote backup group information:
  Backup mode: Dual-active
  Device management role: Primary
  Device running status: Active
  Data channel interface: GigabitEthernet1/0/3
  Local IPv6: 3005::1
  Remote IPv6: 3005::2    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 1 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:
    Time                     Status change        Cause
    2021-06-22 13:33:33      Initial to Active    Interface status changed
```

   # Verify that the OSPFv3 routes advertised by Device A and Device B include the same link cost.

```
RBM_P[DeviceA] display ospfv3 interface

               OSPFv3 Process 1 with Router ID 2.1.1.1

 Area: 0.0.0.0
-------------------------------------------------------------------------
 ID      State    Cost  Pri DR              BDR             Ins Name
 2       DR       1     1   2.1.1.1         1.1.1.1         0   GE1/0/1
 3       BDR      1     1   4.1.1.1         2.1.1.1         0   GE1/0/2
```

2. Verify the configuration on Device B:

   # Verify that the hot backup channels have been set up.

```
RBM_S[DeviceB] display remote-backup-group status
Remote backup group information:
  Backup mode: Dual-active
  Device management role: Secondary
  Device running status: Active
  Data channel interface: GigabitEthernet1/0/3
  Local IPv6: 3005::2
  Remote IPv6: 3005::1    Destination port: 60064
  Control channel status: Connected
  Keepalive interval: 1s
  Keepalive count: 10
  Configuration consistency check interval: 12 hour
  Configuration consistency check result: Not Performed
  Configuration backup status: Auto sync enabled
  Session backup status: Hot backup enabled
  Delay-time: 1 min
  Uptime since last switchover: 0 days, 3 hours, 11 minutes
  Switchover records:
    Time                     Status change        Cause
    2021-06-22 13:33:33      Initial to Active    Interface status changed
```

# Verify that the OSPFv3 routes advertised by Device A and Device B include the same link cost.

```
RBM_S[DeviceB] display ospfv3 interface

               OSPFv3 Process 1 with Router ID 3.1.1.1

 Area: 0.0.0.0
-------------------------------------------------------------------------

NSFOCUS Firewall Series

NF Interface Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for configuring interfaces in bulk, Ethernet interfaces, loopback interfaces, null interfaces, and inloopback interfaces.
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
ⓘ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Bulk configuring interfaces

About interface bulk configuration

You can enter interface range view to bulk configure multiple interfaces with the same feature instead of configuring them one by one. For example, you can execute the **`shutdown`** command in interface range view to shut down a range of interfaces.

To configure interfaces in bulk, you must configure an interface range and enter its view by using the **`interface range`** or **`interface range name`** command.

The interface range created by using the **`interface range`** command is not saved to the running configuration. You cannot use the interface range repeatedly. To create an interface range that can be used repeatedly, use the **`interface range name`** command.

Restrictions and guidelines: Bulk interface configuration

When you bulk configure interfaces in interface range view, follow these restrictions and guidelines:

- In interface range view, only the commands supported by the first interface in the specified interface list are available for configuration.
- Before you configure an interface as the first interface in an interface range, make sure you can enter the view of the interface by using the **`interface`** *`interface-type`* { *`interface-number`* | *`interface-number.subnumber`* } command.
- Do not assign both an aggregate interface and any of its member interfaces to an interface range. Some commands, after being executed on both an aggregate interface and its member interfaces, can break up the aggregation.
- Understand that the more interfaces you specify, the longer the command execution time.
- To guarantee bulk interface configuration performance, configure fewer than 1000 interface range names.
- After a command is executed in interface range view, one of the following situations might occur:
  - The system displays an error message and stays in interface range view. This means that the execution failed on one or multiple member interfaces.
    - If the execution failed on the first member interface, the command is not executed on any member interfaces.
    - If the execution failed on a non-first member interface, the command takes effect on the remaining member interfaces.
  - The system returns to system view. This means that:
    - The command is supported in both system view and interface view.
    - The execution failed on a member interface in interface range view and succeeded in system view.
    - The command is not executed on the subsequent member interfaces.

    You can use the **`display this`** command to verify the configuration in interface view of each member interface. In addition, if the configuration in system view is not needed, use the **`undo`** form of the command to remove the configuration.

Procedure

1. Enter system view.

   system-view

2. Create an interface range and enter interface range view.

   ○ Create an interface range without specifying a name.

     interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

   ○ Create a named interface range.

     interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

3. (Optional.) Display commands available for the first interface in the interface range.

   Enter a question mark (?) at the interface range prompt.

4. Use available commands to configure the interfaces.

   Available commands depend on the interface.

5. (Optional.) Verify the configuration.

   display this

Display and maintenance commands for bulk interface configuration

Execute the **display** command in any view.

Task	Command
Display information about the interface ranges created by using the **interface range name** command.	**display interface range** [**name** *name*]

Contents

Configuring Ethernet interfaces

About Ethernet interface

IMPORTANT:

Physical interfaces on firewall modules can only be used as IRF physical interfaces.

This series devices support Ethernet interfaces, Console interfaces, and USB interfaces. For the interface types and the number of interfaces supported by a device model, see the installation guide.

Configuring a management Ethernet interface

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

About this task

A management interface uses an RJ-45/LC connector. You can connect the interface to a PC for software loading and system debugging, or connect it to a remote NMS for remote system management.

Each member device in an IRF system has a management Ethernet interface. For management link backup, perform the following tasks:

1. Connect your PC to the management Ethernet interface on the master device.
2. Connect the PC to a management Ethernet interface with the same interface number on a subordinate device.

The two management Ethernet interfaces operate as follows:

- When the IRF system has multiple management Ethernet interfaces, only the management Ethernet interface on the master device processes management traffic.
- When the management Ethernet interface on the master device fails, the management Ethernet interface on the subordinate device takes over to process management traffic.
- When the management Ethernet interface on the master device recovers, it takes over to process management traffic again.

Procedure

1. Enter system view.
   system-view
2. Enter management Ethernet interface view.
   interface M-GigabitEthernet *interface-number*
3. (Optional.) Set the interface description.
   description *text*

The default setting is M-GigabitEthernet0/0/0 Interface.

4. (Optional.) Set the duplex mode for the management Ethernet interface.

   duplex { **auto** | **full** | **half** }

   By default, the duplex mode is **auto** for a management Ethernet interface.

5. (Optional.)_Set the speed for the management Ethernet interface.

   speed { **10** | **100** | **1000** | **auto** }

   By default, the speed is **auto** for a management Ethernet interface.

6. (Optional.) Shut down the interface.

   shutdown

   By default, the management Ethernet interface is up.

CAUTION:

Executing the **shutdown** command on an interface will disconnect the link of the interface and interrupt communication. Use this command with caution.

Ethernet interface naming conventions

The Ethernet interfaces are named in the format of **interface type A/B/C**. The letters that follow the interface type represent the following elements:

- **A**—IRF member ID. If the device is not in an IRF fabric, A is 1 by default.
- **B**—Card slot number. **0** indicates the interface is a fixed interface of the device. **1** indicates the interface is on expansion interface card 1. **2** indicates the interface is on expansion interface card 2.
- **C**—Port index.

Configuring common Ethernet interface settings

This section describes the settings common to Layer 2 Ethernet interfaces, Layer 3 Ethernet interfaces, and Layer 3 Ethernet subinterfaces. For more information about the settings specific to Layer 2 Ethernet interfaces, see "Configuring a Layer 2 Ethernet interface." For more information about the settings specific to Layer 3 Ethernet interfaces or subinterfaces, see "Configuring a Layer 3 Ethernet interface or subinterface."

Configuring the physical type for a combo interface (single combo interface)

About this task

A combo interface is a logical interface that physically comprises one fiber combo port and one copper combo port. The two ports share one forwarding channel and one interface view. As a result, they cannot work simultaneously. When you activate one port, the other port is automatically disabled. In the interface view, you can activate the fiber or copper combo port, and configure other port attributes such as the interface rate and duplex mode.

Hardware and feature compatibility

△ **CAUTION:**

- In the BootWare menu, fiber combo ports are not available.
- When the fiber combo port is active, it supports only the speeds autonegotiation and 1000 Mbps, and supports only duplex modes full and autonegotiation. If the copper combo port is configured with any other speed or duplex settings, the settings do not take effect after it is switched to the fiber combo port.

Models	**Feature compatibility**
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Prerequisites

Before you configure combo interfaces, complete the following tasks:

- Determine the combo interfaces on your device. Identify the two physical interfaces that belong to each combo interface according to the marks on the device panel.
- Use the **`display interface`** command to determine which port (fiber or copper) of each combo interface is active:
  - If the copper port is active, the output includes "Media type is twisted pair, Port hardware type is 1000_BASE_T."
  - If the fiber port is active, the output does not include this information.

  Also, you can use the **`display this`** command in the view of each combo interface to display the combo interface configuration:
  - If the fiber port is active, the **`combo enable fiber`** command exists in the output.
  - If the copper port is active, the **`combo enable fiber`** command does not exist in the output.

Procedure

1. Enter system view.
   `system-view`
2. Enter Ethernet interface view.
   `interface` *`interface-type interface-number`*
3. Activate the copper combo port or fiber combo port.
   `combo enable` `{` **`copper`** `|` **`fiber`** `}`
   By default, the copper combo port is active.

Configuring basic settings of an Ethernet interface

About this task

You can configure an Ethernet interface to operate in one of the following duplex modes:

- **Full-duplex mode**—The interface can send and receive packets simultaneously.
- **Half-duplex mode**—The interface can only send or receive packets at a given time.
- **Autonegotiation mode**—The interface negotiates a duplex mode with its peer.

You can set the speed of an Ethernet interface or enable it to automatically negotiate a speed with its peer.

Restrictions and guidelines

The **shutdown** and **loopback** commands are mutually exclusive.

Procedure

1. Enter system view.

   system-view

2. Enter Ethernet interface view.

   interface *interface-type interface-number*

3. Set the description for the Ethernet interface.

   description *text*

   The default setting is *interface-name* **Interface**. For example, **GigabitEthernet1/0/1 Interface**.

4. Set the duplex mode for the Ethernet interface.

   duplex { **auto** | **full** | **half** }

   By default, the duplex mode is **auto** for Ethernet interfaces.

   Fiber ports do not support the **half** keyword.

5. Set the speed for the Ethernet interface.

   speed { **10** | **100** | **1000** | **auto** }

   By default, an interface autonegotiates its speed.

6. Set the expected bandwidth for the Ethernet interface.

   bandwidth *bandwidth-value*

   By default, the expected bandwidth (in kbps) is the interface baud rate divided by 1000.

7. Bring up the Ethernet interface.

   undo shutdown

   By default, an Ethernet interface is up.

Configuring basic settings of an Ethernet subinterface

About this task

By default, a Layer 3 Ethernet subinterface processes packets for only the VLAN whose ID is the same as the subinterface number.

Restrictions and guidelines for Ethernet subinterface basic settings

- To transmit and receive packets through an Ethernet subinterface, you must associate it with a VLAN. For more information, see VLAN termination configuration in *Layer 2—LAN Switching Configuration Guide*.
- To transmit packets between a local Ethernet subinterface and a remote Ethernet subinterface, configure them with the same subinterface number and VLAN ID.
- Before creating a Layer 3 Ethernet subinterface, do not reserve a resource for the VLAN interface whose interface number is the subinterface number. After you reserve a VLAN interface resource, do not create a Layer 3 Ethernet subinterface whose subinterface number is the VLAN interface number. A Layer 3 Ethernet subinterface uses the VLAN interface resource in processing tagged packets whose VLAN ID matches the subinterface number. For more information about reserving resources for VLAN interfaces, see *Layer 2—LAN Switching Configuration Guide*.
- The **shutdown** command cannot be configured on an Ethernet interface in a loopback test.

Procedure

1. Enter system view.

   `system-view`

2. Create an Ethernet subinterface.

   `interface` *`interface-type interface-number.subnumber`*

3. Set the description for the Ethernet subinterface.

   `description` *`text`*

   The default setting is *interface-name* **Interface**. For example, **GigabitEthernet1/0/1.1 Interface**.

4. Set the expected bandwidth for the Ethernet subinterface.

   `bandwidth` *`bandwidth-value`*

   By default, the expected bandwidth (in kbps) is the interface baud rate divided by 1000.

5. Bring up the Ethernet subinterface.

   `undo shutdown`

   By default, an Ethernet subinterface is up.

Configuring the link mode of an Ethernet interface

About this task

Ethernet interfaces operate differently depending on the hardware structure of interface cards:

- Some Ethernet interfaces can operate only as Layer 2 Ethernet interfaces (in bridge mode).
- Some Ethernet interfaces can operate only as Layer 3 Ethernet interfaces (in route mode).
- Some Ethernet interfaces can operate either as Layer 2 or Layer 3 Ethernet interfaces. You can set the link mode to bridge or route for these Ethernet interfaces.

Procedure

1. Enter system view.

   `system-view`

2. Enter Ethernet interface view.

   `interface` *`interface-type interface-number`*

3. Configure the link mode of the Ethernet interface.

   `port link-mode` { **`bridge`** | **`route`** }

   By default, an Ethernet interface operates in Layer 3 mode.

> △ **CAUTION:**
>
> Changing the link mode of an Ethernet interface also restores all commands (except **`shutdown`** and **`combo enable`**) on the Ethernet interface to their defaults in the new link mode.

Configuring jumbo frame support

About this task

Jumbo frames are frames larger than a device-specific size and are typically received by an Ethernet interface during high-throughput data exchanges, such as file transfers. For more information, see *Interface Command Reference*.

The Ethernet interface processes jumbo frames in the following ways:

- When the Ethernet interface is configured to deny jumbo frames (by using the **`undo jumboframe enable`** command), the Ethernet interface discards jumbo frames.
- When the Ethernet interface is configured with jumbo frame support, the Ethernet interface performs the following operations:
    - Processes jumbo frames within the specified length.
    - Discards jumbo frames that exceed the specified length.

Procedure

1. Enter system view.

   `system-view`

2. Enter Ethernet interface view.

   `interface` *`interface-type interface-number`*

3. Configure jumbo frame support.

   `jumboframe enable` [*`size`*]

   By default, the device allows jumbo frames within the specified length to pass through. For the maximum length of jumbo frames, see *Interface Command Reference*.

   If you set the *`size`* argument multiple times, the most recent configuration takes effect.

Configuring dampening on an Ethernet interface

About this task

The interface dampening feature uses an exponential decay mechanism to prevent excessive interface flapping events from adversely affecting routing protocols and routing tables in the network. Suppressing interface state change events protects the system resources.

If an interface is not dampened, its state changes are reported. For each state change, the system also generates an SNMP trap and log message.

After a flapping interface is dampened, it does not report its state changes to the CPU. For state change events, the interface only generates SNMP trap and log messages.

Parameters

- **Penalty**—The interface has an initial penalty of 0. When the interface flaps, the penalty increases by 1000 for each down event until the ceiling is reached. It does not increase for up events. When the interface stops flapping, the penalty decreases by half each time the half-life timer expires until the penalty drops to the reuse threshold.
- **Ceiling**—The penalty stops increasing when it reaches the ceiling.
- **Suppress-limit**—The accumulated penalty that triggers the device to dampen the interface. In dampened state, the interface does not report its state changes to the CPU. For state change events, the interface only generates SNMP traps and log messages.
- **Reuse-limit**—When the accumulated penalty decreases to this reuse threshold, the interface is not dampened. Interface state changes are reported to the upper layers. For each state change, the system also generates an SNMP trap and log message.
- **Decay**—The amount of time (in seconds) after which a penalty is decreased.
- **Max-suppress-time**—The maximum amount of time the interface can be dampened. If the penalty is still higher than the reuse threshold when this timer expires, the penalty stops increasing for down events. The penalty starts to decrease until it drops below the reuse threshold.

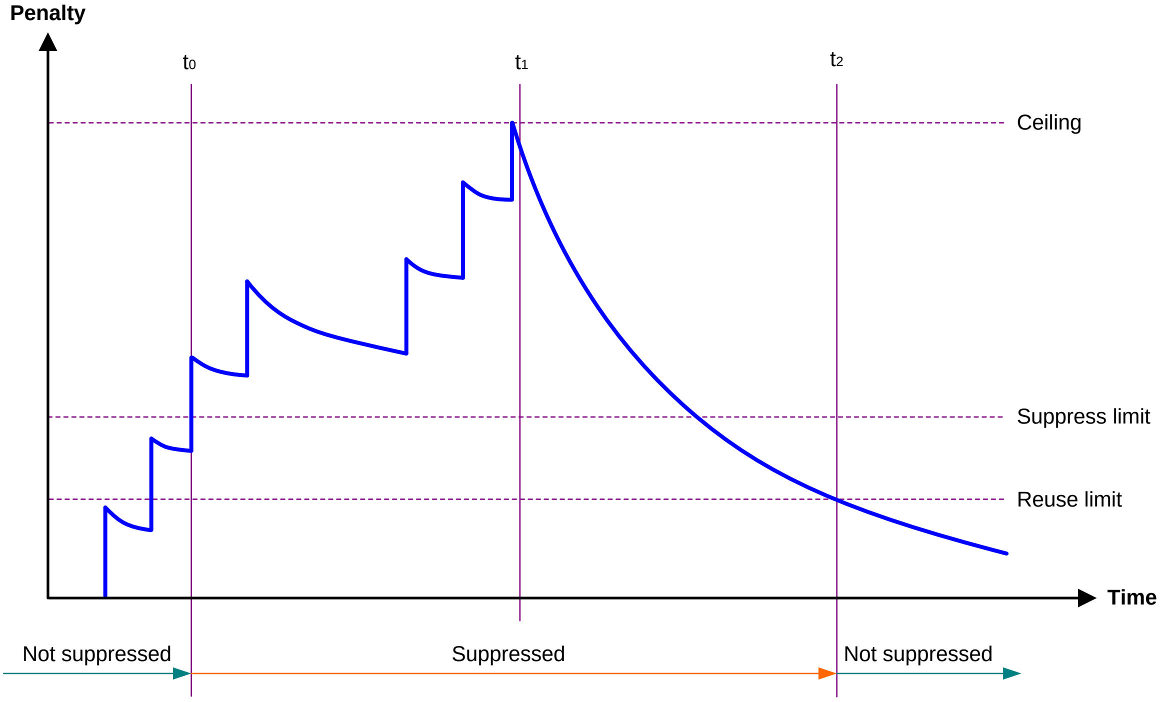
When configuring the **`dampening`** command, follow these rules to set the values mentioned above:

- The ceiling is equal to $2^{(\text{Max-suppress-time/Decay})}$ × reuse-limit. It is not user configurable.

- The configured suppress limit is lower than or equal to the ceiling.
- The ceiling is lower than or equal to the maximum suppress limit supported.

Figure 1 shows the change rule of the penalty value. The lines t_0 and t_2 indicate the start time and end time of the suppression, respectively. The period from t_0 to t_2 indicates the suppression period, t_0 to t_1 indicates the max-suppress-time, and t_1 to t_2 indicates the complete decay period.

Figure 1 Change rule of the penalty value



Restrictions and guidelines

- The **`dampening`** command does not take effect on the administratively down events. When you execute the **`shutdown`** command, the penalty restores to 0, and the interface reports the down event to the upper-layer protocols.

Do not enable this feature on an interface that has spanning tree protocols or Smart Link enabled.

Procedure

1. Enter system view.
   `system-view`
2. Enter Ethernet interface view.
   `interface` *`interface-type interface-number`*
3. Enable dampening on the interface.
   `dampening` `[` *`half-life reuse suppress max-suppress-time`* `]`
   By default, interface dampening is disabled on Ethernet interfaces.

Configuring storm suppression

About this task

The storm suppression feature ensures that the size of a particular type of traffic (broadcast, multicast, or unknown unicast traffic) does not exceed the threshold on an interface. When the broadcast, multicast, or unknown unicast traffic on the interface exceeds this threshold, the system discards packets until the traffic drops below this threshold.

Both storm suppression and storm control can suppress storms on an interface. Storm suppression uses the chip to suppress traffic. Storm suppression has less impact on the device performance than storm control, which uses software to suppress traffic.

Restrictions and guidelines

- For the traffic suppression result to be determined, do not configure storm control together with storm suppression for the same type of traffic. For more information about storm control, see "Configuring storm control on an Ethernet interface."
- The configured suppression threshold value in pps or kbps might be converted into a multiple of the step value supported by the chip. As a result, the effective suppression threshold might be different from the configured one. For information about the suppression threshold that takes effect, see the prompt on the device.

Procedure

1. Enter system view.

   `system-view`

2. Enter Ethernet interface view.

   `interface` *`interface-type interface-number`*

3. Enable broadcast suppression and set the broadcast suppression threshold.

   `broadcast-suppression` { *`ratio`* | **`pps`** *`max-pps`* | **`kbps`** *`max-kbps`* }

   By default, broadcast suppression is disabled.

4. Enable multicast suppression and set the multicast suppression threshold.

   `multicast-suppression` { *`ratio`* | **`pps`** *`max-pps`* | **`kbps`** *`max-kbps`* }

   By default, multicast suppression is disabled.

5. Enable unknown unicast suppression and set the unknown unicast suppression threshold.

   `unicast-suppression` { *`ratio`* | **`pps`** *`max-pps`* | **`kbps`** *`max-kbps`* }

   By default, unknown unicast suppression is disabled.

Configuring generic flow control on an Ethernet interface

About this task

To avoid dropping packets on a link, you can enable generic flow control at both ends of the link. When traffic congestion occurs at the receiving end, the receiving end sends a flow control (Pause) frame to ask the sending end to suspend sending packets. Generic flow control includes the following types:

- **TxRx-mode generic flow control**—Enabled by using the **`flow-control`** command. With TxRx-mode generic flow control enabled, an interface can both send and receive flow control frames:
  - When congestion occurs, the interface sends a flow control frame to its peer.
  - When the interface receives a flow control frame from its peer, it suspends sending packets to its peer.

Procedure

1. Enter system view.

   `system-view`

2. Enter Ethernet interface view.

   `interface` *`interface-type interface-number`*

3. Enable generic flow control.

```
flow-control
```

By default, generic flow control is disabled on an Ethernet interface.

By default, generic flow control is disabled on an Ethernet interface.

Setting the statistics polling interval

About this task

By setting the statistics polling interval, you can collect statistics of packets and analyze packets at the specified interval. Based on the interface traffic statistics, you can take traffic control measures promptly to avoid network congestion and service interruption.

- When network congestion is detected, you can set the statistics polling interval to be smaller than 300 seconds (30 seconds when congestion deteriorates). Then, check traffic distribution on interfaces within a short period of time. For data packets that cause congestion, take traffic control measures.
- When the network bandwidth is sufficient and services are operating normally, you can set the statistics polling interval to be greater than 300 seconds. Once traffic parameter anomalies occur, modify the statistics polling interval promptly so that you can observe the traffic parameter trend in real time.

To display the interface statistics collected in the last statistics polling interval, use the **display interface** command. To clear the interface statistics, use the **reset counters interface** command.

A device supports either the system view settings or the Ethernet interface view settings.

- The statistics polling interval configured in system view takes effect on all Ethernet interface.
- The statistics polling interval configured in Ethernet interface view takes effect only on the current interface.
- For an interface, the configuration in its Ethernet interface view takes priority. The configuration in system view is used when the configuration in Ethernet interface view is the default.

Restrictions and guidelines for setting the statistics polling interval

- This feature is not applicable to interfaces assigned to contexts in shared mode.
- As a best practice, use the default setting when you set the statistics polling interval in system view. A short statistics polling interval might decrease the system performance and result in inaccurate statistics.

Setting the statistics polling interval in system view

1. Enter system view.

```
system-view
```

2. Set the statistics polling interval.

```
flow-interval interval
```

By default, the statistics polling interval is 300 seconds.

Setting the statistics polling interval in Ethernet interface view

1. Enter system view.

```
system-view
```

2. Enter Ethernet interface view.

```
interface interface-type interface-number
```

3. Set the statistics polling interval for the Ethernet interface.

```
flow-interval interval
```

By default, the statistics polling interval is 300 seconds.

Enabling subinterface rate statistics collection on an Ethernet interface

Restrictions and guidelines

This feature is resource intensive. When you use this feature, make sure you fully understand its impact on system performance.

After you enable subinterface rate statistics collection on an Ethernet interface, the device periodically refreshes the rate statistics on the subinterfaces of this Ethernet interface.

Procedure

1. Enter system view.
   `system-view`
2. Enter Ethernet interface view.
   `interface` *`interface-type interface-number`*
3. Enable subinterface rate statistics collection on the Ethernet interface.
   `sub-interface rate-statistic`
   By default, subinterface rate statistics collection is disabled on an Ethernet interface.
4. (Optional.) View the subinterface rate statistics.
   `display interface`

Enabling loopback testing on an Ethernet interface

About this task

Perform this task to determine whether an Ethernet link works correctly.

Loopback testing includes the following types:

- **Internal loopback testing**—Tests the device where the Ethernet interface resides. The Ethernet interface sends outgoing packets back to the local device. If the device fails to receive the packets, the device fails.
- **External loopback testing**—Tests the inter-device link. The Ethernet interface sends incoming packets back to the remote device. If the remote device fails to receive the packets, the inter-device link fails.

Restrictions and guidelines

- After you enable this feature on an Ethernet interface, the interface does not forward data traffic.
- The **`shutdown`** and **`loopback`** commands are mutually exclusive.
- After you enable this feature on an Ethernet interface, the Ethernet interface switches to full duplex mode. After you disable this feature, the Ethernet interface restores to its duplex setting.

Procedure

1. Enter system view.
   `system-view`
2. Enter Ethernet interface view.
   `interface` *`interface-type interface-number`*
3. Enable loopback testing.

```
loopback { external | internal }
```

Restoring the default settings for an interface

Restrictions and guidelines

△ **CAUTION:**

This feature might interrupt ongoing network services. Make sure you are fully aware of the impacts of this feature when you use it in a live network.

This feature might fail to restore the default settings for some commands because of command dependencies or system restrictions. You can use the **display this** command in interface view to check for these commands and perform their **undo** forms or follow the command reference to restore their default settings. If your restoration attempt still fails, follow the error message to resolve the problem.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter Ethernet interface view or Ethernet subinterface view.

   ```
   interface interface-type { interface-number |
   interface-number.subnumber }
   ```

3. Restore the default settings for the interface.

   ```
   default
   ```

Configuring a Layer 2 Ethernet interface

Setting the MDIX mode of an Ethernet interface

IMPORTANT:

Fiber ports do not support the MDIX mode setting.

About this task

A physical Ethernet interface has eight pins, each of which plays a dedicated role. For example, pins 1 and 2 transmit signals, and pins 3 and 6 receive signals. You can use both crossover and straight-through Ethernet cables to connect copper Ethernet interfaces. To accommodate these types of cables, a copper Ethernet interface can operate in one of the following Medium Dependent Interface-Crossover (MDIX) modes:

- **MDIX mode**—Pins 1 and 2 are receive pins and pins 3 and 6 are transmit pins.
- **MDI mode**—Pins 1 and 2 are transmit pins and pins 3 and 6 are receive pins.
- **AutoMDIX mode**—The interface negotiates pin roles with its peer.

NOTE:

This feature does not take effect on pins 4, 5, 7, and 8 of physical Ethernet interfaces.

- Pins 4, 5, 7, and 8 of interfaces operating at 10 Mbps or 100 Mbps do not receive or transmit signals.
- Pins 4, 5, 7, and 8 of interfaces operating at 1000 Mbps or higher rates receive and transmit signals.

Restrictions and guidelines

To enable a copper Ethernet interface to communicate with its peer, set the MDIX mode of the interface by following these guidelines:

- Typically, set the MDIX mode of the interface to AutoMDIX. Set the MDIX mode of the interface to MDI or MDIX only when the device cannot determine the cable type.
- When a straight-through cable is used, configure the interface to operate in an MDIX mode different than its peer.
- When a crossover cable is used, perform one of the following tasks:
    - Configure the interface to operate in the same MDIX mode as its peer.
    - Configure either end to operate in AutoMDIX mode.

Procedure

1. Enter system view.

   `system-view`

2. Enter Ethernet interface view.

   `interface` *`interface-type interface-number`*

3. Set the MDIX mode of the Ethernet interface.

   `mdix-mode` `{` **`automdix`** `|` **`mdi`** `|` **`mdix`** `}`

   By default, a copper Ethernet interface operates in auto mode to negotiate pin roles with its peer.

Configuring storm control on an Ethernet interface

About this task

Storm control compares multicast and broadcast traffic regularly with their respective traffic thresholds on an Ethernet interface. For each type of traffic, storm control provides a lower threshold and an upper threshold.

Depending on your configuration, when a particular type of traffic exceeds its upper threshold, the interface performs either of the following operations:

- **Blocks this type of traffic and forwards other types of traffic**—Even though the interface does not forward the blocked type of traffic, it still counts the type of traffic. When the blocked type of traffic drops below the lower threshold, the interface begins to forward the traffic.
- **Goes down automatically**—The interface goes down automatically and stops forwarding any traffic. When the type of traffic exceeding the upper threshold drops below the lower threshold, the interface does not automatically come up. To bring up the interface, use the **`undo shutdown`** command or disable the storm control feature.

You can configure an Ethernet interface to output threshold event traps and log messages when monitored traffic meets one of the following conditions:

- Exceeds the upper threshold.
- Drops below the lower threshold.

Both storm suppression and storm control can suppress storms on an interface. Storm suppression uses the chip to suppress traffic. Storm suppression has less impact on the device performance than storm control, which uses software to suppress traffic. For more information about storm suppression, see "Configuring storm suppression."

Storm control uses a complete polling cycle to collect traffic data, and analyzes the data in the next cycle. An interface takes one to two polling intervals to take a storm control action.

Restrictions and guidelines

For the traffic suppression result to be determined, do not configure storm control together with storm suppression for the same type of traffic.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Set the statistics polling interval of the storm control module.

   storm-constrain interval *interval*

   The default setting is 10 seconds.

   For network stability, use the default or set a longer statistics polling interval.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Enable storm control, and set the lower and upper thresholds for broadcast, multicast, or unknown unicast traffic.

   storm-constrain { **broadcast** | **multicast** } **pps** *upperlimit lowerlimit*

   By default, storm control is disabled.

5. Set the control action to take when monitored traffic exceeds the upper threshold.

   storm-constrain control { **block** | **shutdown** }

   By default, storm control is disabled.

6. Enable the Ethernet interface to output log messages when it detects storm control threshold events.

   storm-constrain enable log

   By default, the Ethernet interface outputs log messages when monitored traffic exceeds the upper threshold or drops below the lower threshold from a value above the upper threshold.

7. Enable the Ethernet interface to send storm control threshold event traps.

   storm-constrain enable trap

   By default, the Ethernet interface sends traps when monitored traffic exceeds the upper threshold or drops below the lower threshold from the upper threshold from a value above the upper threshold.

Configuring an interface to operate in promiscuous mode

About this task

By default, a Layer 3 Ethernet interface does not operate in promiscuous mode. In this case, the interface accepts and processes only packets destined to the MAC address of the interface, and drops packets destined to any other MAC address.

For an interface to snoop all packets received, use this command to configure the interface to operate in promiscuous mode. In this mode, a Layer 3 Ethernet interface does not perform MAC address filtering, and accepts and processes all packets regardless whether they are destined to the MAC address of the interface.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 3 Ethernet interface view.

   interface *interface-type interface-number*

3. Configure the interface to operate in promiscuous mode.

port promiscuous-mode

By default, an interface does not operate in promiscuous mode.

Configuring a Layer 3 Ethernet interface or subinterface

Setting the MTU for an Ethernet interface or subinterface

About this task

The maximum transmission unit (MTU) determines the maximum number of bytes in a single IP packet that can be sent. The length of an IP packet refers to the number of bytes starting from the IP header to the payload.

When the IP layer receives an IP data packet to be sent, the IP layer determines the local destination interface of the packet and obtains the MTU of the interface. The IP layer compares the MTU with the length of the data packet to be sent. If the length is greater than the MTU, the IP layer fragments the packet. The length of a fragment can be smaller than or equal to the MTU to ensure that big packets are not lost on the network.

As a best practice, use the default MTU. When the packet length or the packet receiver changes, you can adjust the MTU as needed. When configuring the MTU, follow these restrictions and guidelines:

- If the configured MTU is small but the packet length is large, the following events might occur:
  - Packets will be dropped when they are forwarded by hardware.
  - Packets will be fragmented into too many fragments when packets are forwarded through the CPUs, which affects normal data transmission.
- If the configured MTU is too large, the MTU will exceed the receiving capabilities of the receiver or a device along the transmission path. As a result, packets will be fragmented or even dropped, which increases the network transmission load and affects data transmission.

Restrictions and guidelines

The MTU of an Ethernet interface affects the fragmentation and reassembly of IP packets on the interface. Typically, you do not need to modify the MTU of an interface.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type* { *interface-number* | *interface-number.subnumber* }

3. Set the interface MTU.

   mtu *size*

   The default setting is 1500 bytes.

Setting the MAC address of an Ethernet interface

About this task

In a network, when the Layer 3 Ethernet interfaces of different devices have the same MAC address, the devices might fail to communicate correctly. To eliminate the MAC address conflicts, use the **mac-address** command to modify the MAC addresses of Layer 3 Ethernet interfaces.

Additionally, a Layer 3 Ethernet subinterface uses the MAC address of its main interface by default. The MAC address of a Layer 3 Ethernet subinterface must be the same as that of its main interface. To modify the MAC address of a Layer 3 Ethernet subinterface, first use the **`mac-address`** command to modify the MAC address of the main interface, and then modify the MAC address of the Layer 3 Ethernet subinterface.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Set the interface MAC address.

   `mac-address` *`mac-address`*

   By default, no MAC address is set for a Layer 3 Ethernet interface.

Enabling destination MAC filtering

About this task

Typically, use the default settings.

With this feature enabled, when an interface receives a packet, the interface operates as follows:

- If the destination MAC address of the packet is the MAC address of the interface, the interface accepts and processes the packet.
- If the destination MAC address of the packet is not the MAC address of the interface, the interface drops the packet.

With this feature disabled, an interface accepts and processes a packet, without checking the destination MAC address of the packet.

Restrictions and guidelines

This feature takes effect only on Layer 3 Ethernet interfaces/subinterfaces, Layer 3 aggregate interfaces, and Layer 3 Reth interfaces. These interfaces are referred to as interfaces in this feature.

Procedure

1. Enter system view.

   `system-view`

2. Enable destination MAC filtering.

   `mac-address-filter enable`

   By default, destination MAC filtering is enabled.

Enabling statistics collection on a Layer 3 Ethernet subinterface

About this task

This feature is resource intensive. When you use this feature, make sure you fully understand its impact on system performance.

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 3 Ethernet subinterface view.
   interface *interface-type interface-number.subnumber*
3. Enable statistics collection on the Layer 3 Ethernet subinterface.
   traffic-statistic enable

   By default, statistics collection is disabled on a Layer 3 Ethernet subinterface.
4. (Optional.) Display the subinterface traffic statistics.
   display interface

   display counters

   The **Input** and **Output** fields in the **display interface** command output display the subinterface traffic statistics.

Display and maintenance commands

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display interface traffic statistics.	**display counters** { **inbound** | **outbound** } **interface** [*interface-type* [*interface-number* | *interface-number.subnumber*]]
Display traffic rate statistics of interfaces in up state over the last statistics polling interval.	**display counters rate** { **inbound** | **outbound** } **interface** [*interface-type* [*interface-number* | *interface-number.subnumber*]]
Display the Ethernet module statistics.	**display ethernet statistics slot** *slot-number*
Display the operational and status information of the specified interfaces.	**display interface** [*interface-type* [*interface-number* | *interface-number.subnumber*]] [**brief** [**description** | **down**]]
Display the status and packet statistics of interfaces.	**display interface link-info** [**main**]
Display operating status and information of all interfaces except subinterfaces.	**display interface** [*interface-type*] [**brief** [**description** | **down**]] **main**
Display information about dropped packets on the specified interfaces.	**display packet-drop** { **interface** [*interface-type* [*interface-number*]] | **summary** }
Display information about storm control on the specified interfaces.	**display storm-constrain** [**broadcast** | **multicast**] [**interface** *interface-type interface-number*]
Clear interface statistics.	**reset counters interface** [*interface-type* [*interface-number* | *interface-number.subnumber*]]
Clear the Ethernet module statistics.	**reset ethernet statistics** [**slot** *slot-number*]
Clear the statistics of dropped packets	**reset packet-drop interface**

Task	Command
on the specified interfaces.	[*interface-type* [*interface-number*]]

Contents

Configuring loopback, null, and inloopback interfaces

This chapter describes how to configure a loopback interface, a null interface, and an inloopback interface.

About loopback, null, and inloopback interfaces

About loopback interfaces

A loopback interface is a virtual interface. The physical layer state of a loopback interface is always up unless the loopback interface is manually shut down. Because of this benefit, loopback interfaces are widely used in the following scenarios:

- **Configuring a loopback interface address as the source address of the IP packets that the device generates**—Because loopback interface addresses are stable unicast addresses, they are usually used as device identifications.

  When you configure a rule on an authentication or security server, you can configure it to permit or deny packets carrying the loopback interface address of a device. This simplifies your configuration and achieves the effect of permitting or denying packets that the device generates. To use a loopback interface address as the source address of IP packets, make sure the loopback interface is reachable from the peer by performing routing configuration. All data packets sent to the loopback interface are considered packets sent to the device itself, so the device does not forward these packets.
- **Using a loopback interface in dynamic routing protocols**—With no router ID configured for a dynamic routing protocol, the system selects the highest loopback interface IP address as the router ID. In BGP, to avoid interruption of BGP sessions due to physical port failure, you can use a loopback interface as the source interface of BGP packets.

About null interfaces

A null interface is a virtual interface and is always up, but you cannot use it to forward data packets or configure it with an IP address or link layer protocol. The null interface provides a simpler way to filter packets than ACL. You can filter undesired traffic by transmitting it to a null interface instead of applying an ACL. For example, if you specify a null interface as the next hop of a static route to a network segment, any packets routed to the network segment are dropped.

About inloopback interfaces

An inloopback interface is a virtual interface created by the system, which cannot be configured or deleted. The physical layer and link layer protocol states of an inloopback interface are always up. All IP packets sent to an inloopback interface are considered packets sent to the device itself and are not forwarded.

Configuring a loopback interface

1. Enter system view.

   ```
   system-view
   ```
2. Create a loopback interface and enter loopback interface view.

```
interface loopback interface-number
```

3. Configure the interface description.

```
description text
```

The default setting is *interface name* **Interface** (for example, **LoopBack1 Interface**).

4. Configure the expected bandwidth of the loopback interface.

```
bandwidth bandwidth-value
```

By default, the expected bandwidth of a loopback interface is 0 kbps.

5. Bring up the loopback interface.

```
undo shutdown
```

By default, a loopback interface is up.

Configuring a null interface

1. Enter system view.

```
system-view
```

2. Enter null interface view.

```
interface null 0
```

Interface Null 0 is the default null interface on the device and cannot be manually created or removed.

Only one null interface, Null 0, is supported on the device. The null interface number is always 0.

3. Configure the interface description.

```
description text
```

The default setting is NULL0 Interface.

Restoring the default settings for an interface

Restrictions and guidelines

△ **CAUTION:**

This feature might interrupt ongoing network services. Make sure you are fully aware of the impact of this feature when you use it on a live network.

This feature might fail to restore the default settings for some commands because of command dependencies or system restrictions. You can use the **display this** command in interface view to check for these commands and perform their **undo** forms or follow the command reference to restore their default settings. If your restoration attempt still fails, follow the error message to resolve the problem.

Procedure

1. Enter system view.

```
system-view
```

2. Enter loopback interface view or null interface view.

   ○ `interface loopback interface-number`

   ○ `interface null 0`

3. Restore the default settings for the interface.

```
default
```

Display and maintenance commands for loopback, null, and inloopback interfaces

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about the inloopback interface.	**display interface** [**inloopback** [**0**]] [**brief** [**description** | **down**]]
Display information about the specified or all loopback interfaces.	**display interface** [**loopback** [*interface-number*]] [**brief** [**description** | **down**]]
Display information about the null interface.	**display interface** [**null** [**0**]] [**brief** [**description** | **down**]]
Clear the statistics on the specified or all loopback interfaces.	**reset counters interface** [**loopback** [*interface-number*]]
Clear the statistics on the null interface.	**reset counters interface** [**null** [**0**]]

NSFOCUS Firewall Series

NF Layer 2—LAN Switching

Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for LAN switching features, including MAC address table, Ethernet link aggregation, VLANs, VLAN termination, spanning tree, LLDP, and Layer 2 forwarding.
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
ⓘ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Configuring the MAC address table

About the MAC address table

An Ethernet device uses a MAC address table to forward frames. A MAC address entry includes a destination MAC address, an outgoing interface, and a VLAN ID. When the device receives a frame, it uses the destination MAC address of the frame to look for a match in the MAC address table.

- The device forwards the frame out of the outgoing interface in the matching entry if a match is found.
- The device floods the frame in the VLAN of the frame if no match is found.

How a MAC address entry is created

The entries in the MAC address table include entries automatically learned by the device and entries manually added.

MAC address learning

The device can automatically populate its MAC address table by learning the source MAC addresses of incoming frames on each interface.

The device performs the following operations to learn the source MAC address of incoming packets:

1. Checks the source MAC address (for example, MAC-SOURCE) of the frame.
2. Looks up the source MAC address in the MAC address table.
   - The device updates the entry if an entry is found.
   - The device adds an entry for MAC-SOURCE and the incoming port if no entry is found.

When the device receives a frame destined for MAC-SOURCE after learning this source MAC address, the device performs the following operations:

1. Finds the MAC-SOURCE entry in the MAC address table.
2. Forwards the frame out of the port in the entry.

The device performs the learning process for each incoming frame with an unknown source MAC address until the table is fully populated.

Manually configuring MAC address entries

Dynamic MAC address learning does not distinguish between illegitimate and legitimate frames, which can invite security hazards. When Host A is connected to Port A, a MAC address entry will be learned for the MAC address of Host A (for example, MAC A). When an illegal user sends frames with MAC A as the source MAC address to Port B, the device performs the following operations:

1. Learns a new MAC address entry with Port B as the outgoing interface and overwrites the old entry for MAC A.
2. Forwards frames destined for MAC A out of Port B to the illegal user.

As a result, the illegal user obtains the data of Host A. To improve the security for Host A, manually configure a static entry to bind Host A to Port A. Then, the frames destined for Host A are always sent out of Port A. Other hosts using the forged MAC address of Host A cannot obtain the frames destined for Host A.

Types of MAC address entries

A MAC address table can contain the following types of entries:

- **Static entries**—A static entry is manually added to forward frames with a specific destination MAC address out of the associated interface, and it never ages out. A static entry has higher priority than a dynamically learned one.
- **Dynamic entries**—A dynamic entry can be manually configured or dynamically learned to forward frames with a specific destination MAC address out of the associated interface. A dynamic entry might age out. A manually configured dynamic entry has the same priority as a dynamically learned one.
- **Blackhole entries**—A blackhole entry is manually configured and never ages out. A blackhole entry is configured for filtering out frames with a specific source or destination MAC address. For example, to block all frames destined for or sourced from a user, you can configure the MAC address of the user as a blackhole MAC address entry. A blackhole entry has higher priority than a dynamically learned one.

A static or blackhole MAC address entry can overwrite a dynamic MAC address entry, but not vice versa. A static entry and a blackhole entry cannot overwrite each other.

MAC address table tasks at a glance

All MAC address table configuration tasks are optional.

To configure the MAC address table, perform the following tasks:

- Configuring MAC address entries
  - Adding or modifying a static or dynamic MAC address entry
  - Adding or modifying a blackhole MAC address entry
- Setting the aging timer for dynamic MAC address entries
- Configuring MAC address learning
  - Disabling MAC address learning
  - Setting the MAC learning limit
  - Configuring the unknown frame forwarding rule after the MAC learning limit is reached
  - Assigning MAC learning priority to interfaces
- Enabling SNMP notifications for the MAC address table

Configuring MAC address entries

About MAC address entry-based frame forwarding

A frame whose source MAC address matches different types of MAC address entries is processed differently.

Type	Description
Static MAC address entry	Forwards the frame according to the destination MAC address regardless of whether the frame's ingress interface is the same as that in the entry.
Blackhole MAC address entry	Drops the frame.
Dynamic MAC address entry	• Learns the MAC address of the frames received on a different interface from that in the entry and overwrites the original entry. • Forwards the frame received on the same interface as that in the entry and updates the aging timer for the entry.

Restrictions and guidelines for MAC address entry configuration

You cannot add a dynamic MAC address entry if a learned entry already exists with a different outgoing interface for the MAC address.

The manually configured static and blackhole MAC address entries cannot survive a reboot if you do not save the configuration. The manually configured dynamic MAC address entries are lost upon reboot whether or not you save the configuration.

Do not configure the following MAC addresses as static, dynamic, or blackhole MAC addresses:

- Reserved MAC addresses of the device.
- MAC addresses of Layer 3 Ethernet interfaces or subinterfaces.
- MAC addresses of Layer 3 aggregate interfaces or subinterfaces.

For information about bridge MAC addresses, see IRF in *Virtual Technologies Configuration Guide*.

Prerequisites for MAC address entry configuration

Before manually configuring a MAC address entry for an interface, make sure the VLAN in the entry has been created.

Adding or modifying a static or dynamic MAC address entry

Adding or modifying a static or dynamic MAC address entry globally

1. Enter system view.

   system-view

2. Add or modify a static or dynamic MAC address entry.

   mac-address { **dynamic** | **static** } *mac-address* **interface** *interface-type interface-number* **vlan** *vlan-id*

   By default, no MAC address entry is configured globally.

   Make sure you have assigned the interface to the VLAN.

Adding or modifying a static or dynamic MAC address entry on an interface

1. Enter system view.

   system-view

2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.

     interface bridge-aggregation *interface-number*

3. Add or modify a static or dynamic MAC address entry.

   mac-address { **dynamic** | **static** } *mac-address* **vlan** *vlan-id*

   By default, no MAC address entry is configured on an interface.

   Make sure you have assigned the interface to the VLAN.

Adding or modifying a blackhole MAC address entry

1. Enter system view.

   system-view

2. Add or modify a blackhole MAC address entry.

   mac-address blackhole *mac-address* **vlan** *vlan-id*

   By default, no blackhole MAC address entry is configured.

Setting the aging timer for dynamic MAC address entries

About this task

For security and efficient use of table space, the MAC address table uses an aging timer for each dynamic MAC address entry. If a dynamic MAC address entry is not updated before the aging timer expires, the device deletes the entry. This aging mechanism ensures that the MAC address table can promptly update to accommodate latest network topology changes.

A stable network requires a longer aging interval, and an unstable network requires a shorter aging interval.

An aging interval that is too long might cause the MAC address table to retain outdated entries. As a result, the MAC address table resources might be exhausted, and the MAC address table might fail to update its entries to accommodate the latest network changes.

An interval that is too short might result in removal of valid entries, which would cause unnecessary floods and possibly affect the device performance.

To reduce floods on a stable network, set a long aging timer or disable the timer to prevent dynamic entries from unnecessarily aging out. Reducing floods improves the network performance. Reducing flooding also improves the security because it reduces the chances for a data frame to reach unintended destinations.

Procedure

1. Enter system view.

   system-view

2. Set the aging timer for dynamic MAC address entries.

   mac-address timer { **aging** *seconds* | **no-aging** }

   The default setting is 300 seconds.

Disabling MAC address learning

About disabling MAC address learning

MAC address learning is enabled by default. To prevent the MAC address table from being saturated when the device is experiencing attacks, disable MAC address learning. For example, you can disable MAC address learning to prevent the device from being attacked by a large amount of frames with different source MAC addresses.

After MAC address learning is disabled, existing dynamic MAC address entries can age out.

Disabling global MAC address learning

Restrictions and guidelines

After you disable global MAC address learning, the device cannot learn MAC addresses on any interfaces.

Procedure

1. Enter system view.
   system-view
2. Disable global MAC address learning.
   undo mac-address mac-learning enable
   By default, global MAC address learning is enabled.

Disabling MAC address learning on an interface

About this task

When global MAC address learning is enabled, you can disable MAC address learning on a single interface.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
3. Disable MAC address learning on the interface.
   undo mac-address mac-learning enable
   By default, MAC address learning is enabled on an interface.

Setting the MAC learning limit

Setting the MAC learning limit on interfaces

About this task

This feature limits the MAC address table size. A large MAC address table will degrade forwarding performance.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.

```
interface bridge-aggregation interface-number
```

3. Set the MAC learning limit on the interface.

   ```
   mac-address max-mac-count count
   ```

   By default, the maximum number of MAC addresses that an interface can learn is restricted by hardware capability of the device.

Configuring the unknown frame forwarding rule after the MAC learning limit is reached

In this document, unknown frames refer to frames whose source MAC addresses are not in the MAC address table.

About unknown frame forwarding rule configuration

You can enable or disable forwarding of unknown frames after the MAC learning limit is reached.

Configuring the device to forward unknown frames after the MAC learning limit on an interface is reached

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

     ```
     interface interface-type interface-number
     ```

   - Enter Layer 2 aggregate interface view.

     ```
     interface bridge-aggregation interface-number
     ```

3. Configure the device to forward unknown frames received on the interface after the MAC learning limit on the interface is reached.

   ```
   mac-address max-mac-count enable-forwarding
   ```

   By default, the device can forward unknown frames received on an interface after the MAC learning limit on the interface is reached.

Assigning MAC learning priority to interfaces

About this task

The MAC learning priority mechanism assigns either low priority or high priority to an interface. An interface with high priority can learn MAC addresses as usual. However, an interface with low priority is not allowed to learn MAC addresses already learned on a high-priority interface.

The MAC learning priority mechanism can help defend your network against MAC address spoofing attacks. In a network that performs MAC-based forwarding, an upper layer device MAC address might be learned by a downlink interface because of a loop or attack to the downlink interface. To avoid this issue, perform the following tasks:

- Assign high MAC learning priority to an uplink interface.
- Assign low MAC learning priority to a downlink interface.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   - Enter Layer 2 Ethernet interface view.

     interface *interface-type interface-number*

   - Enter Layer 2 aggregate interface view.

     interface bridge-aggregation *interface-number*

3. Assign MAC learning priority to the interface.

   mac-address mac-learning priority { **high** | **low** }

   By default, low MAC learning priority is used.

Enabling SNMP notifications for the MAC address table

About this task

To report critical MAC address move events to an NMS, enable SNMP notifications for the MAC address table. For MAC address move event notifications to be sent correctly, you must also configure SNMP on the device.

When SNMP notifications are disabled for the MAC address table, the device sends the generated logs to the information center. To display the logs, configure the log destination and output rule configuration in the information center.

For more information about SNMP and information center configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for the MAC address table.

   snmp-agent trap enable mac-address

   By default, SNMP notifications are enabled for the MAC address table.

   When SNMP notifications are disabled for the MAC address table, syslog messages are sent to notify important events on the MAC address table module.

Display and maintenance commands for MAC address table

Execute **display** commands in any view.

Task	Command
Display MAC address table information.	**display mac-address** [*mac-address* [**vlan** *vlan-id*] | [[**dynamic** | **static**] [**interface** *interface-type interface-number*] | **blackhole**] [**vlan** *vlan-id*] [**count**]]

Task	Command
Display the aging timer for dynamic MAC address entries.	**display mac-address aging-time**
Display the system or interface MAC address learning state.	**display mac-address mac-learning** [**interface** *interface-type interface-number*]

Contents

Configuring Ethernet link aggregation

About Ethernet link aggregation

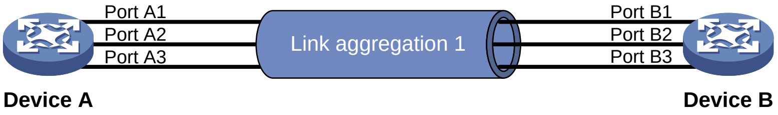
Ethernet link aggregation bundles multiple physical Ethernet links into one logical link (called an aggregate link). Link aggregation provides the following benefits:

- Increased bandwidth beyond the limits of a single individual link. In an aggregate link, traffic is distributed across the member ports.
- Improved link reliability. The member ports dynamically back up one another. When a member port fails, its traffic is automatically switched to other member ports.

Ethernet link aggregation application scenario

As shown in Figure 1, Device A and Device B are connected by three physical Ethernet links. These physical Ethernet links are combined into an aggregate link called link aggregation 1. The bandwidth of this aggregate link can reach up to the total bandwidth of the three physical Ethernet links. At the same time, the three Ethernet links back up one another. When a physical Ethernet link fails, the traffic transmitted on the failed link is switched to the other two links.

Figure 1 Ethernet link aggregation diagram



Aggregate interface, aggregation group, and member port

Each link aggregation is represented by a logical aggregate interface. Each aggregate interface has an automatically created aggregation group, which contains member ports to be used for aggregation. The type and number of an aggregation group are the same as its aggregate interface.

Supported aggregate interface types

An aggregate interface can be one of the following types:

- **Layer 2**—A Layer 2 aggregate interface is created manually. The member ports in a Layer 2 aggregation group can only be Layer 2 Ethernet interfaces.
- **Layer 3**—A Layer 3 aggregate interface is created manually. The member ports in its Layer 3 aggregation group can only be Layer 3 Ethernet interfaces.

  On a Layer 3 aggregate interface, you can create subinterfaces. A Layer 3 aggregate subinterface processes traffic only for the VLAN numbered with the same ID as the subinterface number.

The port rate of an aggregate interface equals the total rate of its Selected member ports. Its duplex mode is the same as that of the Selected member ports. For more information about Selected member ports, see "Aggregation states of member ports in an aggregation group."

Aggregation states of member ports in an aggregation group

A member port in an aggregation group can be in any of the following aggregation states:

- **Selected**—A Selected port can forward traffic.
- **Unselected**—An Unselected port cannot forward traffic.

- **Individual**—An Individual port can forward traffic as a normal physical port. This state is peculiar to the member ports of edge aggregate interfaces. A Selected or Unselected member port of an edge aggregate interface is placed in Individual state if the following events occur in sequence:
  - **a.** The member port goes down and then comes up.
  - **b.** The LACP timeout timer expires because it has not received LACPDUs.

  For more information about edge aggregate interfaces, see "Edge aggregate interface."

Operational key

When aggregating ports, the system automatically assigns each port an operational key based on port information, such as port rate and duplex mode. Any change to this information triggers a recalculation of the operational key.

In an aggregation group, all Selected ports have the same operational key.

Configuration types

Port configuration includes the attribute configuration and protocol configuration. Attribute configuration affects the aggregation state of the port but the protocol configuration does not.

Attribute configuration

To become a Selected port, a member port must have the same attribute configuration as the aggregate interface. Table 1 describes the attribute configuration.

Table 1 Attribute configuration

Feature	Attribute configuration
VLAN	VLAN attribute settings: • Permitted VLAN IDs. • PVID. • Link type (trunk, hybrid, or access). For information about VLANs, see "Configuring VLANs."

Protocol configuration

Protocol configuration of a member port does not affect the aggregation state of the member port. MAC address learning and spanning tree settings are examples of the protocol configuration.

Link aggregation modes

An aggregation group operates in one of the following modes:

- **Static**—Static aggregation is stable. An aggregation group in static mode is called a static aggregation group. The aggregation states of the member ports in a static aggregation group are not affected by the peer ports.
- **Dynamic**—An aggregation group in dynamic mode is called a dynamic aggregation group. Dynamic aggregation is implemented through IEEE 802.3ad Link Aggregation Control Protocol (LACP). The local system and the peer system automatically maintain the aggregation states of the member ports. Dynamic link aggregation reduces the administrators' workload.

How static link aggregation works

Reference port selection process

When setting the aggregation states of the ports in an aggregation group, the system automatically chooses a member port as the reference port. A Selected port must have the same operational key and attribute configurations as the reference port.

The system chooses a reference port from the member ports in up state.

The candidate reference ports are organized into different priority levels following these rules:

1. In descending order of port priority.
2. Full duplex.
3. In descending order of speed.
4. Half duplex.
5. In descending order of speed.

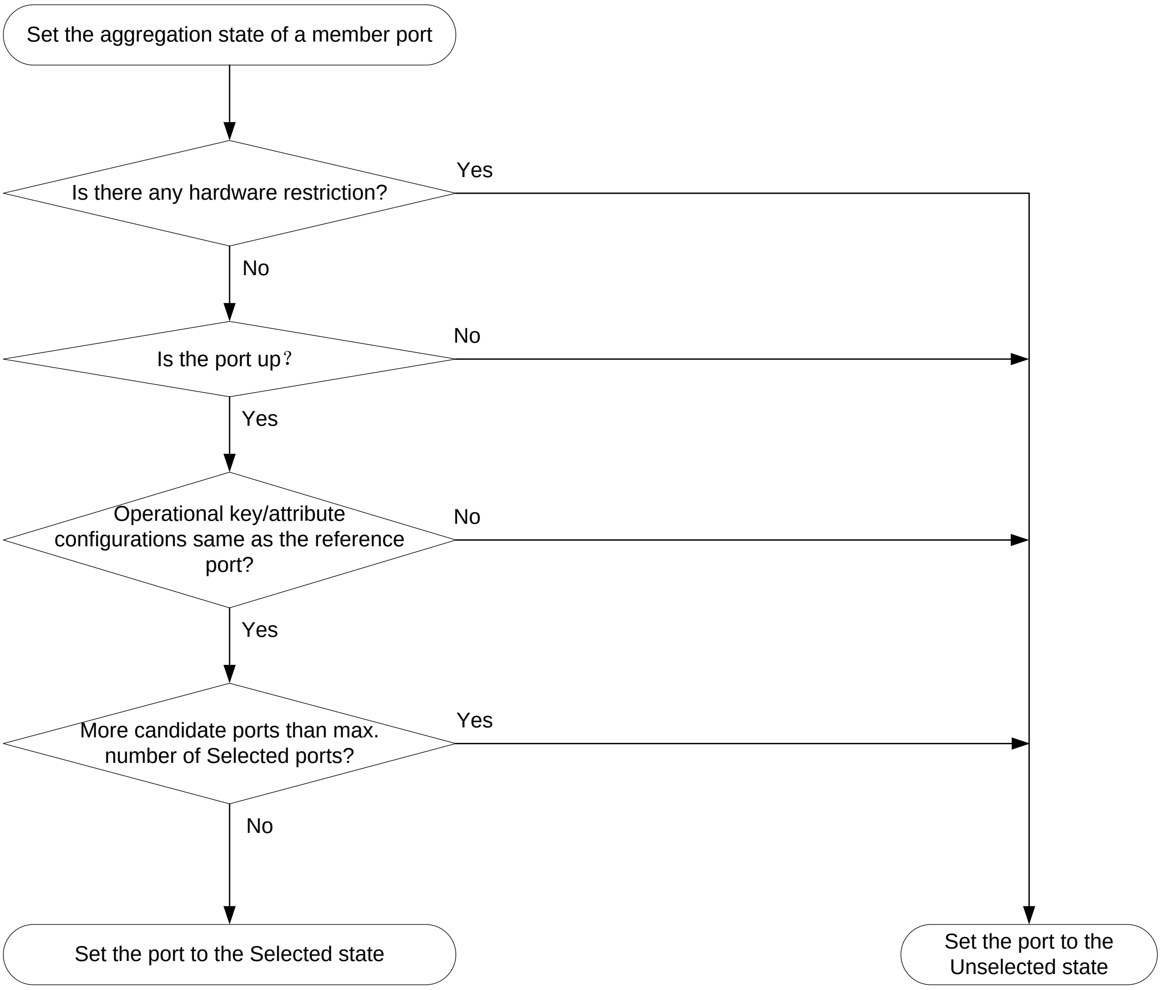
From the candidate ports with the same attribute configurations as the aggregate interface, the one with the highest priority level is chosen as the reference port.

- If multiple ports have the same priority level, the port that has been Selected (if any) is chosen. If multiple ports with the same priority level have been Selected, the one with the smallest port number is chosen.
- If multiple ports have the same priority level and none of them has been Selected, the port with the smallest port number is chosen.

Setting the aggregation state of each member port

After the reference port is chosen, the system sets the aggregation state of each member port in the static aggregation group.

Figure 2 Setting the aggregation state of a member port in a static aggregation group



Set the aggregation state of a member port
Is there any hardware restriction?
Yes
No
Is the port up？
No
Yes
Operational key/attribute configurations same as the reference port?
No
Yes
More candidate ports than max. number of Selected ports?
Yes
No
Set the port to the Selected state
Set the port to the Unselected state

After the limit on Selected ports is reached, the aggregation state of a new member port varies by following conditions:

- The port is placed in Unselected state if the port and the Selected ports have the same port priority. This mechanism prevents traffic interruption on the existing Selected ports. A device reboot can cause the device to recalculate the aggregation states of member ports.
- The port is placed in Selected state when the following conditions are met:
    - The port and the Selected ports have different port priorities, and the port has a higher port priority than a minimum of one Selected port.
    - The port has the same attribute configurations as the aggregate interface.

Any operational key or attribute configuration change might affect the aggregation states of link aggregation member ports.

Dynamic link aggregation

About LACP

Dynamic aggregation is implemented through IEEE 802.3ad Link Aggregation Control Protocol (LACP).

LACP uses LACPDUs to exchange aggregation information between LACP-enabled devices. Each member port in a dynamic aggregation group can exchange information with its peer. When a member port receives an LACPDU, it compares the received information with information received on the other member ports. In this way, the two systems reach an agreement on which ports are placed in Selected state.

LACP functions

LACP offers basic LACP functions and extended LACP functions, as described in Table 2.

Table 2 LACP functions

Category	Description
Basic LACP functions	Implemented through the basic LACPDU fields, including the system LACP priority, system MAC address, port priority, port number, and operational key.
Extended LACP functions	Implemented by extending the LACPDU with new TLV fields. Extended LACP can implement LACP MAD for the IRF feature. • If a device supports both extended LACP and IRF, it can participate in LACP MAD as either an IRF member device or an intermediate device. • If a device supports extended LACP but not IRF, it can participate in LACP MAD only as an intermediate device. For more information about IRF and the LACP MAD mechanism, see *Virtual Technologies Configuration Guide*.

LACP operating modes

LACP can operate in active or passive mode.

When LACP is operating in passive mode on a local member port and its peer port, both ports cannot send LACPDUs. When LACP is operating in active mode on either end of a link, both ports can send LACPDUs.

LACP priorities

LACP priorities include system LACP priority and port priority, as described in Table 3. The smaller the priority value, the higher the priority.

Table 3 LACP priorities

Type	Description
System LACP priority	Used by two peer devices (or systems) to determine which one is superior in link aggregation. In dynamic link aggregation, the system that has higher system LACP priority sets the Selected state of member ports on its side. The system that has lower priority sets the aggregation state of local member ports the same as their respective peer ports.
Port priority	Determines the likelihood of a member port to be a Selected port on a system. A port with a higher port priority is more likely to become Selected.

LACP timeout interval

The LACP timeout interval specifies how long a member port waits to receive LACPDUs from the peer port. If a local member port has not received LACPDUs from the peer within the LACP timeout interval plus 3 seconds, the member port considers the peer as failed.

The LACP timeout interval also determines the LACPDU sending rate of the peer. LACP timeout intervals include the following types:

- **Short timeout interval**—3 seconds. If you use the short timeout interval, the peer sends one LACPDU per second.
- **Long timeout interval**—90 seconds. If you use the long timeout interval, the peer sends one LACPDU every 30 seconds.

How dynamic link aggregation works

Choosing a reference port

The system chooses a reference port from the member ports in up state. A Selected port must have the same operational key and attribute configurations as the reference port.

The local system (the actor) and the peer system (the partner) negotiate a reference port by using the following workflow:

1. The two systems determine the system with the smaller system ID.

   A system ID contains the system LACP priority and the system MAC address.

   a. The two systems compare their LACP priority values.

      The lower the LACP priority, the smaller the system ID. If the LACP priority values are the same, the two systems proceed to step b.

   b. The two systems compare their MAC addresses.

      The lower the MAC address, the smaller the system ID.

2. The system with the smaller system ID chooses the port with the smallest port ID as the reference port.

   A port ID contains a port priority and a port number. The lower the port priority, the smaller the port ID.

   a. The system chooses the port with the lowest priority value as the reference port.

      If the ports have the same priority, the system proceeds to step b.

   b. The system compares their port numbers.

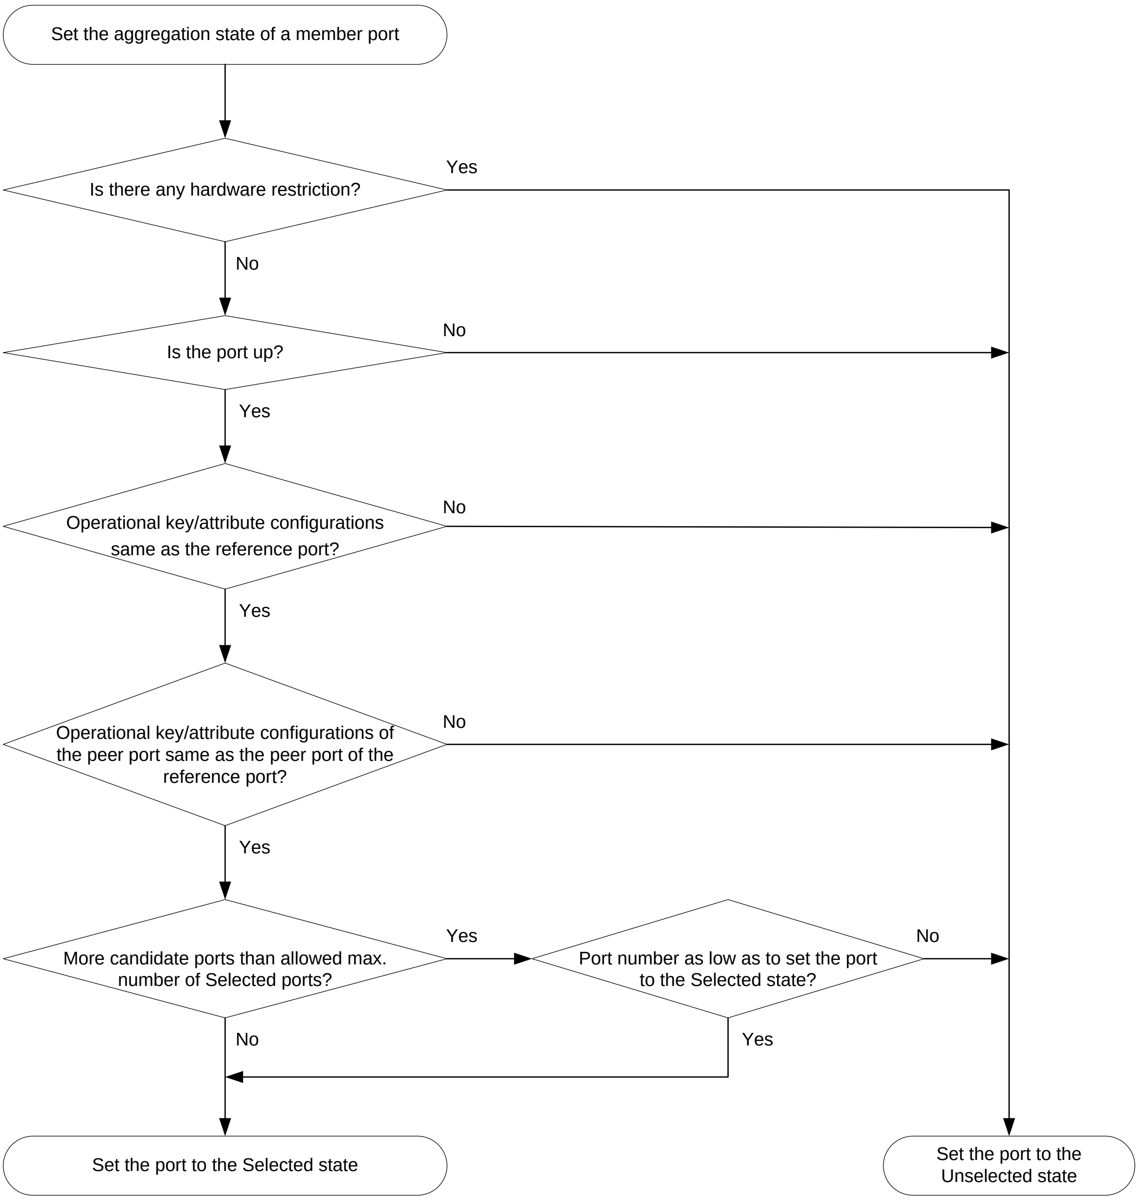
      The smaller the port number, the smaller the port ID.

      The port with the smallest port number and the same attribute configurations as the aggregate interface is chosen as the reference port.

Setting the aggregation state of each member port

After the reference port is chosen, the system with the smaller system ID sets the state of each member port on its side.

Figure 3 Setting the state of a member port in a dynamic aggregation group



Set the aggregation state of a member port
Is there any hardware restriction?
Yes
No
Is the port up?
No
Yes
Operational key/attribute configurations same as the reference port?
No
Yes
Operational key/attribute configurations of the peer port same as the peer port of the reference port?
No
Yes
More candidate ports than allowed max. number of Selected ports?
Yes
Port number as low as to set the port to the Selected state?
No
No
Yes
Set the port to the Selected state
Set the port to the Unselected state

The system with the greater system ID can detect the aggregation state changes on the peer system. The system with the greater system ID sets the aggregation state of local member ports the same as their peer ports.

When you aggregate interfaces in dynamic mode, follow these guidelines:

- A dynamic link aggregation group chooses only full-duplex ports as the Selected ports.
- For stable aggregation and service continuity, do not change the operational key or attribute configurations on any member port.
- When a member port changes to the Selected or Unselected state, its peer port changes to the same aggregation state.
- After the Selected port limit is reached, a newly joining port becomes a Selected port if it is more eligible than a current Selected port.

Edge aggregate interface

Dynamic link aggregation fails on a server-facing aggregate interface if dynamic link aggregation is configured only on the device. The device forwards traffic by using only one of the physical ports that are connected to the server.

To improve link reliability, configure the aggregate interface as an edge aggregate interface. This feature enables all member ports of the aggregation group to forward traffic. When a member port fails, its traffic is automatically switched to other member ports.

After dynamic link aggregation is configured on the server, the device can receive LACPDUs from the server. Then, link aggregation between the device and the server operates correctly.

An edge aggregate interface takes effect only when it is configured on an aggregate interface corresponding to a dynamic aggregation group.

Load sharing modes for link aggregation groups

In a link aggregation group, traffic can be load shared across the Selected ports based on any of the following modes:

- **Per-flow load sharing**—Distributes traffic on a per-flow basis. The load sharing mode classifies packets into flows and forwards packets of the same flow on the same link. This mode can be one of or a combination of the following traffic classification criteria:
    - Ingress port.
    - Source or destination IP.
    - Source or destination MAC.
    - Source or destination port number.
- **Bandwidth usage-based load sharing**—Distributes a data flow to the Selected port that had the lowest bandwidth usage when the first packet of that data flow arrived. In this mode, each flow is identified by an IP five-tuple (source and destination IP addresses, source and destination ports, and protocol). For packets that do not contain the IP five-tuple, the default load sharing mode applies.
- **Packet type-based load sharing**—Automatically selects a load sharing mode depending on the packet type. For example, the load sharing mode differs between IPv4 packets and Layer 2 packets. This mode is also called the flexible mode.

Restrictions and guidelines: Mixed use of manual and automatic link aggregation configuration

To avoid unexpected aggregation issues, do not use manual assignment and automatic link aggregation together. If you use these features together, an automatically assigned member port might move between aggregation groups or undesirably change from Selected to Unselected in some situations.

Ethernet link aggregation tasks at a glance

To configure Ethernet link aggregation, perform the following tasks:

1. Configuring link aggregations
    - Configuring a manual link aggregation
2. (Optional.) Configuring an aggregate interface
    - Setting the minimum and maximum numbers of Selected ports for an aggregation group

    - Configuring the description of an aggregate interface
    - Configuring jumbo frame support
    - Disabling the default action of selecting a Selected port for dynamic aggregation groups that have not received LACPDUs
    - Specifying ignored VLANs for a Layer 2 aggregate interface

      To have the system ignore the permit state and tagging mode of a VLAN when it decides Selected ports, perform this task.
    - Setting the MTU of a Layer 3 aggregate interface
    - Setting the expected bandwidth for an aggregate interface
    - Configuring an edge aggregate interface

      An edge aggregate interface uses all member ports to forward traffic when the aggregation peer is not enabled with dynamic link aggregation.
    - Configuring physical state change suppression on an aggregate interface
    - Shutting down an aggregate interface
    - Restoring the default settings for an aggregate interface
3. (Optional.) Configuring load sharing for link aggregation groups
    - Setting load sharing modes for link aggregation groups
    - Enabling local-first load sharing for link aggregation
4. (Optional.) Enabling forwarding acceleration for link aggregation
5. (Optional.) Enabling link-aggregation traffic redirection

   This feature redirects traffic on an unavailable Selected port to the remaining available Selected ports of an aggregation group to avoid traffic interruption.

Configuring a manual link aggregation

Restrictions and guidelines for aggregation group configuration

Layer 2 aggregation group restrictions

You cannot assign an interface to a Layer 2 aggregation group if the redundancy group node feature or MAC authentication is configured on that interface. For more information about redundancy groups, see *Virtual Technologies Configuration Guide*. For more information about MAC authentication, see *Security Configuration Guide*.

Layer 3 aggregation group restrictions

You cannot assign an interface to a Layer 3 aggregation group if any features in Table 4 are configured on that interface.

Table 4 Features incompatible with Layer 3 aggregation member interfaces

Feature on the interface	Reference
Reth interface	Reth interfaces in *Virtual Technologies Configuration Guide*
Redundancy group node	Redundancy groups in *Virtual Technologies Configuration Guide*

Aggregation member port restrictions

Deleting an aggregate interface also deletes its aggregation group and causes all member ports to leave the aggregation group.

The following restrictions apply if you have not enabled multi-VLAN termination on an aggregate interface by using the **`link-aggregation multivlan-termination`** command:

- You cannot assign both Ethernet interfaces and Ethernet subinterfaces to the aggregation group.
- You cannot create subinterfaces on an Ethernet interface that is in the aggregation group.
- You cannot assign an Ethernet interface that has subinterfaces to the aggregation group.

You cannot create aggregate subinterfaces on an aggregate interface if its aggregation group contains Ethernet subinterfaces. You cannot assign Ethernet subinterfaces to an aggregation group if its aggregate interface has aggregate subinterfaces.

Before you assign an Ethernet subinterface to an aggregation group, perform the following tasks:

- If multi-VLAN termination is not enabled on the aggregate interface, configure VLAN termination on the Ethernet subinterface. You will be unable to modify the VLAN termination configuration after you assign the subinterface to the aggregation group. To configure VLAN termination, use the following commands:
    - **`vlan-type dot1q default`**.
    - **`vlan-type dot1q untagged`**.
    - **`vlan-type dot1q vid`**.
- To assign Ethernet subinterfaces that terminate different VLANs to the same aggregation group, enable multi-VLAN termination on the aggregate interface. If multi-VLAN termination is not enabled on the aggregate interface, you must make sure the Ethernet subinterfaces to be assigned to its aggregation group terminate the same VLAN.
- If you are assigning the Ethernet subinterface to a dynamic aggregation group, specify only one VLAN ID when you execute the **`vlan-type dot1q vid`** *`vlan-id-list`* [**`loose`**] command.

Attribute and protocol configuration restrictions

For a link aggregation, attribute configuration changes on the aggregate interface are automatically synchronized to all member ports. If an attribute setting on the aggregate interface fails to be synchronized to a Selected member port, the port might change to the Unselected state. To have the port become Selected again, you can change the attribute configurations on the aggregate interface or the member port. The configurations that have been synchronized from the aggregate interface are retained on the member ports even after the aggregate interface is deleted.

Any attribute configuration change on a member port might affect the aggregation states and running services of the member ports. The system displays a warning message every time you try to change an attribute configuration setting on a member port.

The protocol configurations for an aggregate interface take effect only on the current aggregate interface. The protocol configurations for a member port take effect only when the port leaves its aggregation group.

Configuration consistency requirements

You must configure the same aggregation mode at the two ends of an aggregate link.

- For a successful static aggregation, make sure the ports at both ends of each link are in the same aggregation state.
- For a successful dynamic aggregation, make sure the ports at both ends of a link are assigned to the correct aggregation group. The two ends can automatically negotiate the aggregation state of each member port.

Configuring a Layer 2 aggregation group

Configuring a Layer 2 static aggregation group

1. Enter system view.

   system-view

2. Create a Layer 2 aggregate interface and enter Layer 2 aggregate interface view.

   interface bridge-aggregation *interface-number*

   When you create a Layer 2 aggregate interface, the system automatically creates a Layer 2 static aggregation group numbered the same as that interface.

3. Return to system view.

   quit

4. Assign an interface to the Layer 2 aggregation group:

   a. Enter Layer 2 Ethernet interface view.

      interface *interface-type interface-number*

   b. Assign the interface to the Layer 2 aggregation group.

      port link-aggregation group *group-id*

   Repeat the substeps to assign more interfaces to the aggregation group.

5. (Optional.) Set the port priority of the interface.

   link-aggregation port-priority *priority*

   The default port priority of an interface is 32768.

Configuring a Layer 2 dynamic aggregation group

1. Enter system view.

   system-view

2. Set the system LACP priority.

   lacp system-priority *priority*

   By default, the system LACP priority is 32768.

   Changing the system LACP priority might affect the aggregation states of the ports in a dynamic aggregation group.

3. Create a Layer 2 aggregate interface and enter Layer 2 aggregate interface view.

   interface bridge-aggregation *interface-number*

   When you create a Layer 2 aggregate interface, the system automatically creates a Layer 2 static aggregation group numbered the same as that interface.

4. Configure the aggregation group to operate in dynamic mode.

   link-aggregation mode dynamic

   By default, an aggregation group operates in static mode.

5. Return to system view.

   quit

6. Assign an interface to the Layer 2 aggregation group:

   a. Enter Layer 2 Ethernet interface view.

      interface *interface-type interface-number*

   b. Assign the interface to the Layer 2 aggregation group.

      port link-aggregation group *group-id*

   Repeat these substeps to assign more Layer 2 Ethernet interfaces to the aggregation group.

7. Set the LACP operating mode for the interface.
   - Set the LACP operating mode to passive.

     lacp mode passive
   - Set the LACP operating mode to active.

     undo lacp mode

   By default, LACP is operating in active mode.
8. (Optional.) Set the port priority for the interface.

   link-aggregation port-priority *priority*

   The default setting is 32768.
9. (Optional.) Set the short LACP timeout interval (3 seconds) for the interface.

   lacp period short

   By default, the long LACP timeout interval (90 seconds) is used by the interface.

   To avoid traffic interruption during an ISSU, do not set the short LACP timeout interval before performing the ISSU. For more information about ISSU, see *Fundamentals Configuration Guide*.

Configuring a Layer 3 aggregation group

Configuring a Layer 3 static aggregation group

1. Enter system view.

   system-view
2. Create a Layer 3 aggregate interface and enter Layer 3 aggregate interface view.

   interface route-aggregation *interface-number*

   When you create a Layer 3 aggregate interface, the system automatically creates a Layer 3 static aggregation group numbered the same as that interface.
3. Return to system view.

   quit
4. Assign an interface to the Layer 3 aggregation group:
   a. Enter Layer 3 Ethernet interface view.

      interface *interface-type interface-number*

   b. Assign the interface to the Layer 3 aggregation group.

      port link-aggregation group *group-id*

   Repeat the substeps to assign more interfaces to the aggregation group.
5. (Optional.) Set the port priority of the interface.

   link-aggregation port-priority *priority*

   The default port priority of an interface is 32768.

Configuring a Layer 3 dynamic aggregation group

1. Enter system view.

   system-view
2. Set the system LACP priority.

   lacp system-priority *priority*

   By default, the system LACP priority is 32768.

   Changing the system LACP priority might affect the aggregation states of the ports in the dynamic aggregation group.

3. Create a Layer 3 aggregate interface and enter Layer 3 aggregate interface view.

   `interface route-aggregation` *`interface-number`*

   When you create a Layer 3 aggregate interface, the system automatically creates a Layer 3 static aggregation group numbered the same as that interface.

4. Configure the aggregation group to operate in dynamic mode.

   `link-aggregation mode dynamic`

   By default, an aggregation group operates in static mode.

5. Return to system view.

   `quit`

6. Assign an interface to the Layer 3 aggregation group:

   a. Enter Layer 3 Ethernet interface view.

      `interface` *`interface-type interface-number`*

   b. Assign the interface to the Layer 3 aggregation group.

      `port link-aggregation group` *`group-id`*

   Repeat these two substeps to assign more Layer 3 Ethernet interfaces to the aggregation group.

7. Set the LACP operating mode for the interface.

   - Set the LACP operating mode to passive.

     `lacp mode passive`

   - Set the LACP operating mode to active.

     `undo lacp mode`

   By default, LACP is operating in active mode.

8. (Optional.) Set the port priority of the interface.

   `link-aggregation port-priority` *`priority`*

   The default setting is 32768.

9. (Optional.) Set the short LACP timeout interval (3 seconds) for the interface.

   `lacp period short`

   By default, the long LACP timeout interval (90 seconds) is used by the interface.

   To avoid traffic interruption during an ISSU, do not set the short LACP timeout interval before performing the ISSU. For more information about ISSU, see *Fundamentals Configuration Guide*.

Configuring an aggregate interface

Most settings that can be made on Layer 2 or Layer 3 Ethernet interfaces can also be made on Layer 2 or Layer 3 aggregate interfaces.

Setting the minimum and maximum numbers of Selected ports for an aggregation group

About this task

The bandwidth of an aggregate link increases as the number of Selected member ports increases. To avoid congestion, you can set the minimum number of Selected ports required for bringing up an aggregate interface.

This minimum threshold setting affects the aggregation states of aggregation member ports and the state of the aggregate interface.

- When the number of member ports eligible to be Selected ports is smaller than the minimum threshold, the following events occur:
  - The eligible member ports are placed in Unselected state.
  - The link layer state of the aggregate interface becomes down.
- When the number of member ports eligible to be Selected ports reaches or exceeds the minimum threshold, the following events occur:
  - The eligible member ports are placed in Selected state.
  - The link layer state of the aggregate interface becomes up.

The maximum number of Selected ports allowed in an aggregation group is limited by either manual configuration or hardware limitation, whichever value is smaller.

You can implement backup between two ports by performing the following tasks:

- Assigning two ports to an aggregation group.
- Setting the maximum number of Selected ports to 1 for the aggregation group.

Then, only one Selected port is allowed in the aggregation group, and the Unselected port acts as a backup port.

Restrictions and guidelines

The minimum and maximum numbers of Selected ports must be the same between the local and peer aggregation groups.

For an aggregation group, the maximum number of Selected ports must be equal to or higher than the minimum number of Selected ports.

Procedure

1. Enter system view.
   `system-view`
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     `interface bridge-aggregation` *`interface-number`*
   - Enter Layer 3 aggregate interface view.
     `interface route-aggregation` *`interface-number`*
3. Set the minimum number of Selected ports for the aggregation group.
   `link-aggregation selected-port minimum` *`min-number`*
   By default, the minimum number of Selected ports is not specified for an aggregation group.
4. Set the maximum number of Selected ports for the aggregation group.
   `link-aggregation selected-port maximum` *`max-number`*
   The maximum number of Selected ports for an aggregation group is in the range of 1 to 16.

Configuring the description of an aggregate interface

About this task

You can configure the description of an aggregate interface for administration purposes, for example, describing the purpose of the interface.

Procedure

1. Enter system view.

system-view

2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
   - Enter Layer 3 aggregate subinterface view.
     interface route-aggregation *interface-number.subnumber* }
3. Configure the interface description.
   description *text*

   By default, the description of an interface is *interface-name* **Interface**.

Configuring jumbo frame support

About this task

An aggregate interface might receive frames larger than the maximum frame size allowed by an interface during high-throughput data exchanges, such as file transfers. These frames are called jumbo frames.

How an aggregate interface processes jumbo frames depends on whether jumbo frame support is enabled on the interface.

- If configured to deny jumbo frames, the aggregate interface discards jumbo frames.
- If enabled with jumbo frame support, the aggregate interface performs the following operations:
  - Processes jumbo frames within the allowed length.
  - Discards jumbo frames that exceed the allowed length.

Procedure

1. Enter system view.
   system-view
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
3. Allow jumbo frames.
   jumboframe enable [*size*]

   The default setting varies by device model. For more information, see the command reference.

   If you execute this command multiple times, the most recent configuration takes effect.

Disabling the default action of selecting a Selected port for dynamic aggregation groups that have not received LACPDUs

About this task

The default port selection action applies to dynamic aggregation groups.

This action automatically chooses the port with the lowest ID from among all up member ports as a Selected port if none of them has received LACPDUs before the LACP timeout interval expires.

After this action is disabled, a dynamic aggregation group will not have any Selected ports to forward traffic if it has not received LACPDUs before the LACP timeout interval expires.

Procedure

1. Enter system view.

   `system-view`

2. Disable the default port selection action.

   `lacp default-selected-port disable`

   By default, the default port selection action is enabled for dynamic aggregation groups.

Specifying ignored VLANs for a Layer 2 aggregate interface

About this task

By default, to become Selected, the member ports must have the same VLAN permit state and tagging mode as the corresponding Layer 2 aggregate interface. To have the system ignore the permit state and tagging mode of a VLAN when choosing Selected ports, specify the VLAN as an ignored VLAN.

Restrictions and guidelines

This feature takes effect only when the link type of a Layer 2 aggregate interface is hybrid or trunk.

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 2 aggregate interface view.

   `interface bridge-aggregation` *`interface-number`*

3. Specify ignored VLANs.

   `link-aggregation ignore vlan` *`vlan-id-list`*

   By default, a Layer 2 aggregate interface does not ignore any VLANs.

Setting the MTU of a Layer 3 aggregate interface

About this task

The MTU of an interface affects IP packets fragmentation and reassembly on the interface.

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 3 aggregate interface or subinterface view.

   `interface route-aggregation` { *`interface-number`* | *`interface-number.subnumber`* }

3. Set the MTU.

   `mtu` *`size`*

   The default setting is 1500 bytes.

Setting the expected bandwidth for an aggregate interface

About this task

Expected bandwidth is an informational parameter used only by higher-layer protocols for calculation. You cannot adjust the actual bandwidth of an interface by performing this task.

Procedure

1. Enter system view.

   `system-view`

2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.

     `interface bridge-aggregation` *`interface-number`*
   - Enter Layer 3 aggregate interface view.

     `interface route-aggregation` *`interface-number`*
   - Enter Layer 3 aggregate subinterface view.

     `interface route-aggregation` *`interface-number.subnumber`* }

3. Set the expected bandwidth for the interface.

   `bandwidth` *`bandwidth-value`*

   By default, the expected bandwidth (in kbps) is the interface baud rate divided by 1000.

Configuring an edge aggregate interface

Restrictions and guidelines

This configuration takes effect only on aggregate interface in dynamic mode.

Link-aggregation traffic redirection cannot operate correctly on an edge aggregate interface. For more information about link-aggregation traffic redirection, see "Enabling link-aggregation traffic redirection."

Procedure

1. Enter system view.

   `system-view`

2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.

     `interface bridge-aggregation` *`interface-number`*
   - Enter Layer 3 aggregate interface view.

     `interface route-aggregation` *`interface-number`*

3. Configure the aggregate interface as an edge aggregate interface.

   `lacp edge-port`

   By default, an aggregate interface does not operate as an edge aggregate interface.

Configuring physical state change suppression on an aggregate interface

About this task

The physical link state of an aggregate interface is either up or down. Each time the physical link of an interface comes up or goes down, the system immediately reports the change to the CPU. The CPU then performs the following operations:

- Notifies the upper-layer protocol modules (such as routing and forwarding modules) of the change for guiding packet forwarding.
- Automatically generates traps and logs to inform users to take the correct actions.

To prevent frequent physical link flapping from affecting system performance, configure physical state change suppression. You can configure this feature to suppress link-down events, link-up events, or both. If an event of the specified type persists when the suppression interval expires, the system reports the event to the CPU.

Restrictions and guidelines

On an interface, you can configure different suppression intervals for link-up and link-down events. If you execute the **link-delay** command multiple times for an event type, the most recent configuration takes effect on that event type.

Procedure

1. Enter system view.

   system-view

2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.

     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.

     interface route-aggregation *interface-number*

3. Configure physical state change suppression.

   link-delay [**msec**] *delay-time* [**mode** { **up** | **updown** }]

   By default, each time the physical link of an aggregate interface goes up or comes down, the system immediately reports the change to the CPU.

   To suppress only link-down events, do not specify the **mode** keyword. To suppress only link-up events, specify the **mode up** keywords. To suppress both link-down and link-up events, specify the **mode updown** keywords.

Shutting down an aggregate interface

Restrictions and guidelines

△ **CAUTION:**

The **shutdown** command will disconnect all links established on an interface. Make sure you are fully aware of the impacts of this command when you use it on a live network.

Shutting down or bringing up an aggregate interface affects the aggregation states and link states of member ports in the corresponding aggregation group as follows:

- When an aggregate interface is shut down, all its Selected ports become Unselected and all member ports go down.

- When an aggregate interface is brought up, the aggregation states of all its member ports are recalculated.

Procedure

1. Enter system view.
   system-view
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
   - Enter Layer 3 aggregate subinterface view.
     interface route-aggregation *interface-number.subnumber* }
3. Shut down the interface.
   shutdown

   By default, an interface is not manually shut down.

Restoring the default settings for an aggregate interface

Restrictions and guidelines

CAUTION:

The **default** command might interrupt ongoing network services. Make sure you are fully aware of the impacts of this command when you execute it on a live network.

The **default** command might fail to restore the default settings for some commands for reasons such as command dependencies and system restrictions.

To resolve this issue:

1. Use the **display this** command in interface view to identify these commands.
2. Use their **undo** forms or follow the command reference to restore their default settings.
3. If the restoration attempt still fails, follow the error message instructions to resolve the issue.

Procedure

1. Enter system view.
   system-view
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
   - Enter Layer 3 aggregate subinterface view.
     interface route-aggregation *interface-number.subnumber* }
3. Restore the default settings for the aggregate interface.
   default

Configuring load sharing for link aggregation groups

Setting load sharing modes for link aggregation groups

About this task

You can set the global or group-specific load sharing mode. A link aggregation group preferentially uses the group-specific load sharing mode. If the group-specific load sharing mode is not available, the group uses the global load sharing mode.

Setting the global link-aggregation load sharing mode

1. Enter system view.

   `system-view`

2. Set the global link-aggregation load sharing mode.

   `link-aggregation global load-sharing mode` { **`destination-ip`** | **`destination-mac`** | **`destination-port`** | **`ingress-port`** | **`source-ip`** | **`source-mac`** | **`source-port`** } *

   By default, the system automatically chooses a load sharing mode depending on the packet type.

Setting the group-specific load sharing mode

1. Enter system view.

   `system-view`

2. Enter aggregate interface view.

   - Enter Layer 2 aggregate interface view.

     `interface bridge-aggregation` *`interface-number`*

   - Enter Layer 3 aggregate interface view.

     `interface route-aggregation` *`interface-number`*

3. Set the load sharing mode for the aggregation group.

   `link-aggregation load-sharing mode` { **`destination-ip`** | **`destination-mac`** | **`destination-port`** | **`source-ip`** | **`source-mac`** | **`source-port`** } *

   By default, an aggregation group uses the global link-aggregation load sharing mode.

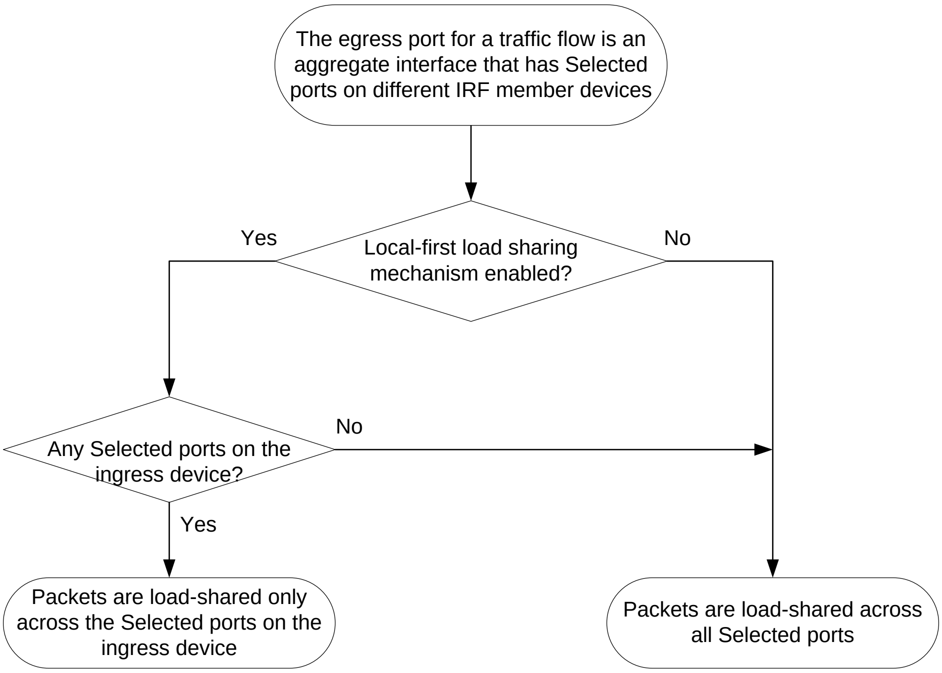
Enabling local-first load sharing for link aggregation

About this task

Use local-first load sharing in a multichassis link aggregation scenario to distribute traffic preferentially across member ports on the ingress device.

When you aggregate ports on different member devices in an IRF fabric, you can use local-first load sharing to reduce traffic on IRF links, as shown in Figure 4. For more information about IRF, see *Virtual Technologies Configuration Guide*.

Figure 4 Load sharing for multichassis link aggregation in an IRF fabric



The egress port for a traffic flow is an aggregate interface that has Selected ports on different IRF member devices
Yes
Local-first load sharing mechanism enabled?
No
Any Selected ports on the ingress device?
No
Yes
Packets are load-shared only across the Selected ports on the ingress device
Packets are load-shared across all Selected ports

Enabling local-first load sharing for link aggregation globally

1. Enter system view.

   `system-view`

2. Enable local-first load sharing for link aggregation globally.

   `link-aggregation load-sharing mode local-first`

   By default, local-first load sharing is enabled globally.

Enabling forwarding acceleration for link aggregation

About this task

This feature accelerates traffic forwarding on an aggregate interface whose member ports are located on multiple slots.

Restrictions and guidelines

Forwarding acceleration takes effect on an aggregate interface only when it is enabled both globally and on the aggregate interface.

Procedure

1. Enter system view.

   `system-view`

2. Enable forwarding acceleration globally.

   `link-aggregation global forwarding-acceleration enable`

   By default, forwarding acceleration is disabled globally.

3. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.

```
interface bridge-aggregation interface-number
```

- Enter Layer 3 aggregate interface view.

```
interface route-aggregation interface-number
```

4. Enable forwarding acceleration on the interface.

```
link-aggregation forwarding-acceleration enable
```

By default, forwarding acceleration is enabled on aggregate interfaces.

Enabling link-aggregation traffic redirection

About link-aggregation traffic redirection

This feature operates on dynamic link aggregation groups. It redirects traffic on a Selected port to the remaining available Selected ports of an aggregation group if the port is shut down by using the **shutdown** command or the slot that hosts the port reboots.

NOTE:

The device does not redirect traffic to member ports that become Selected during the traffic redirection process.

This feature ensures zero packet loss for known unicast traffic, but does not protect unknown unicast traffic.

Restrictions and guidelines for link-aggregation traffic redirection

Link-aggregation traffic redirection applies only to dynamic link aggregation groups.

As a best practice, enable link-aggregation traffic redirection on a per-interface basis. If you enable this feature globally, communication with a third-party peer device might be affected if the peer is not compatible with this feature.

To prevent traffic interruption, enable link-aggregation traffic redirection at both ends of the aggregate link.

To prevent packet loss that might occur at a reboot, do not enable the spanning tree feature together with link-aggregation traffic redirection.

Link-aggregation traffic redirection does not operate correctly on an edge aggregate interface.

Enabling link-aggregation traffic redirection globally

1. Enter system view.

```
system-view
```

2. Enable link-aggregation traffic redirection globally.

```
link-aggregation lacp traffic-redirect-notification enable
```

By default, link-aggregation traffic redirection is disabled globally.

Display and maintenance commands for Ethernet link aggregation

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about aggregate interfaces.	**display interface** [{ **bridge-aggregation** | **route-aggregation** } [*interface-number*]] [**brief** [**description** | **down**]]
Display the local system ID.	**display lacp system-id**
Display the global or group-specific link-aggregation load sharing modes.	**display link-aggregation load-sharing mode** [**interface** [{ **bridge-aggregation** | **route-aggregation** } *interface-number*]]
Display forwarding information for the specified traffic flow.	**display link-aggregation load-sharing path interface** { **bridge-aggregation** | **route-aggregation** } *interface-number* **ingress-port** *interface-type* *interface-number* [**route**] { { **destination-ip** *ip-address* | **destination-ipv6** *ipv6-address* } | { **source-ip** *ip-address* | **source-ipv6** *ipv6-address* } | **destination-mac** *mac-address* | **destination-port** *port-id* | **ethernet-type** *type-number* | **ip-protocol** *protocol-id* | **source-mac** *mac-address* | **source-port** *port-id* | **vlan** *vlan-id* } * **slot** *slot-number*
Display detailed link aggregation information about link aggregation member ports.	**display link-aggregation member-port** [*interface-list* | **auto**]
Display summary information about all aggregation groups.	**display link-aggregation summary**
Display detailed information about the specified aggregation groups.	**display link-aggregation verbose** [{ **bridge-aggregation** | **route-aggregation** } [*interface-number*]]
Clear statistics about the specified aggregate interfaces.	**reset counters interface** [{ **bridge-aggregation** | **route-aggregation** } [*interface-number*]]
Clear LACP statistics about the specified link aggregation member ports.	**reset lacp statistics** [**interface** *interface-list*]

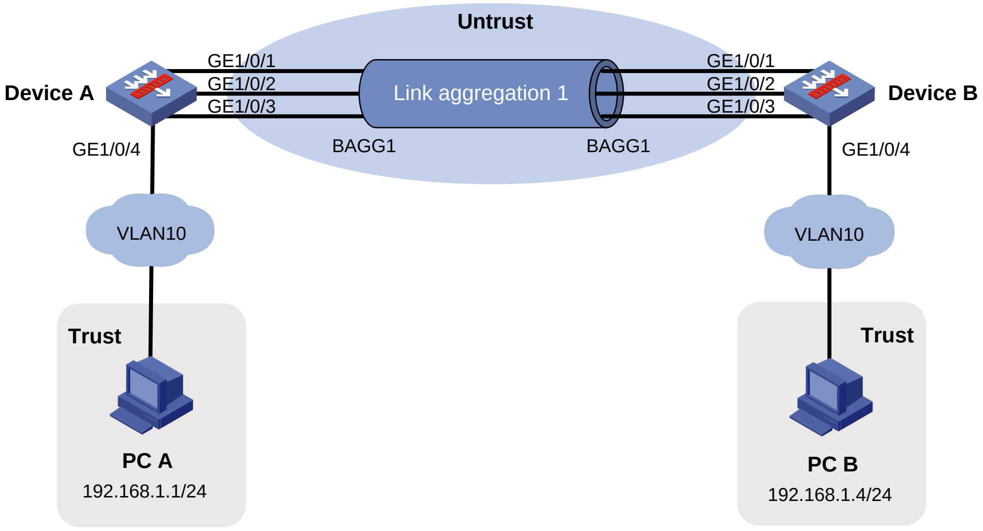
Ethernet link aggregation configuration examples

Example: Configuring a Layer 2 static aggregation group

Network configuration

As shown in Figure 5, configure a Layer 2 static aggregation group on both Device A and Device B to aggregate the links between them.

Figure 5 Network diagram



Procedure

1. Configure interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to operate in Layer 2 mode.

```
<DeviceA> system-view
[DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[DeviceA-if-range] port link-mode bridge
[DeviceA-if-range] quit
```

2. Create VLAN 10, and assign interface GigabitEthernet 1/0/4 to VLAN 10.

```
[DeviceA] vlan 10
[DeviceA-vlan10] port gigabitethernet 1/0/4
[DeviceA-vlan10] quit
```

3. Configure a Layer 2 static aggregation group:

# Configure Layer 2 aggregate interface Bridge-Aggregation 1 as a trunk port and assign it to VLANs 1 and 10.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] port link-type trunk
[DeviceA-Bridge-Aggregation1] port trunk permit vlan 1 10
[DeviceA-Bridge-Aggregation1] quit
```

# Assign interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to link aggregation group 1.

```
[DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/3
[DeviceA-if-range] port link-aggregation group 1
[DeviceA-if-range] quit
```

4. Configure interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 as trunk ports and assign them to VLANs 1 and 10.

```
[DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/3
[DeviceA-if-range] port link-type trunk
[DeviceA-if-range] port trunk permit vlan 1 10
[DeviceA-if-range] quit
```

5. Add interfaces to security zones.

```
[DeviceA] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/4 vlan 10
[Device-security-zone-Trust] quit
[DeviceA] security-zone name untrust
[Device-security-zone-Untrust] import interface bridge-aggregation 1 vlan 1 10
[Device-security-zone-Untrust] quit
```

6. Configure a security policy:

Configure rules to permit traffic between the **Trust** and **Untrust** security zones, so the devices can communicate with each other:

# Configure a rule named **trust-untrust** to permit the packets sent from the **Trust** security zone to the **Untrust** security zone.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-0-trust-untrust] action pass
[DeviceA-security-policy-ip-0-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-0-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-0-trust-untrust] quit
[DeviceA-security-policy-ip] quit
```

# Configure a rule named **untrust-trust** to permit the packets sent from the **Untrust** security zone to the **Trust** security zone.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name untrust-trust
[DeviceA-security-policy-ip-1-untrust-trust] action pass
[DeviceA-security-policy-ip-1-untrust-trust] source-zone untrust
[DeviceA-security-policy-ip-1-untrust-trust] destination-zone trust
[DeviceA-security-policy-ip-1-untrust-trust] quit
[DeviceA-security-policy-ip] quit
```

7. Configure Device B in the same way Device A is configured. (Details not shown.)

Verifying the configuration

# Display detailed information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation verbose
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Port Status: S -- Selected, U -- Unselected, I -- Individual
Port: A -- Auto port
Flags:  A -- LACP_Activity, B -- LACP_Timeout, C -- Aggregation,
        D -- Synchronization, E -- Collecting, F -- Distributing,
        G -- Defaulted, H -- Expired
Aggregate Interface: Bridge-Aggregation1
Aggregation Mode: Static
Loadsharing Type: Shar
  Port             Status  Priority Oper-Key
```

```
--------------------------------------------------------------------------------
  GE1/0/1          S       32768    1
  GE1/0/2          S       32768    1
  GE1/0/3          S       32768    1
```

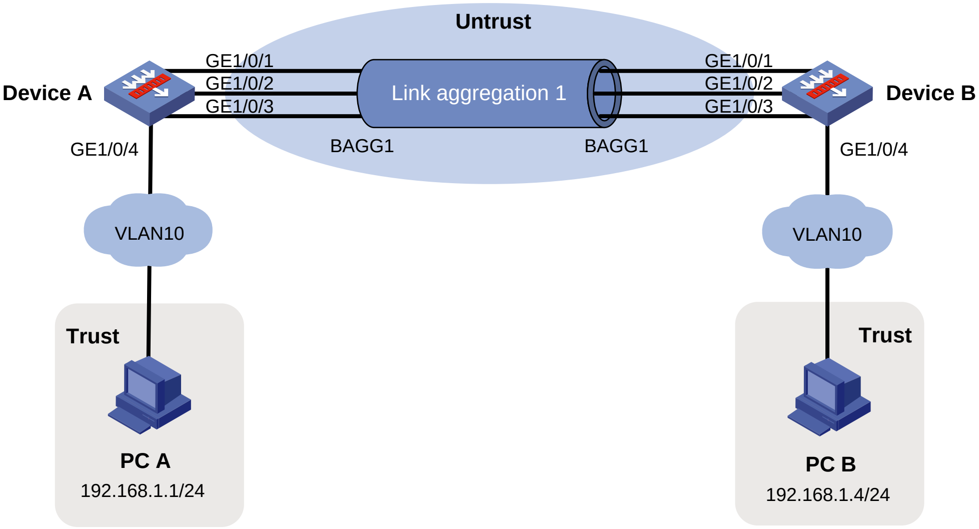
The output shows that link aggregation group 1 is a Layer 2 static aggregation group that contains three Selected ports.

Example: Configuring a Layer 2 dynamic aggregation group

Network configuration

As shown in Figure 6, configure a Layer 2 dynamic aggregation group on both Device A and Device B to aggregate the links between them.

Figure 6 Network diagram



Procedure

1. Configure interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to operate in Layer 2 mode.

```
<DeviceA> system-view
[DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[DeviceA-if-range] port link-mode bridge
[DeviceA-if-range] quit
```

2. Create VLAN 10, and assign interface GigabitEthernet 1/0/4 to VLAN 10.

```
[DeviceA] vlan 10
[DeviceA-vlan10] port gigabitethernet 1/0/4
[DeviceA-vlan10] quit
```

3. Configure a Layer 2 dynamic aggregation group:

# Configure Layer 2 aggregate interface Bridge-Aggregation 1 as a trunk port, assign it to VLANs 1 and 10, and set the link aggregation mode to dynamic.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] port link-type trunk
[DeviceA-Bridge-Aggregation1] port trunk permit vlan 1 10
[DeviceA-Bridge-Aggregation1] link-aggregation mode dynamic
```

```
[DeviceA-Bridge-Aggregation1] quit
```

# Assign interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to link aggregation group 1.

```
[DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/3
[DeviceA-if-range] port link-aggregation group 1
[DeviceA-if-range] quit
```

4. Configure interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 as trunk ports and assign them to VLANs 1 and 10.

```
[DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/3
[DeviceA-if-range] port link-type trunk
[DeviceA-if-range] port trunk permit vlan 1 10
[DeviceA-if-range] quit
```

5. Add interfaces to security zones.

```
[DeviceA] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/4 vlan 10
[Device-security-zone-Trust] quit
[DeviceA] security-zone name untrust
[Device-security-zone-Untrust] import interface bridge-aggregation 1 vlan 1 10
[Device-security-zone-Untrust] quit
```

6. Configure a security policy:

Configure rules to permit traffic between the **Trust** and **Untrust** security zones, so the devices can communicate with each other:

# Configure a rule named **trust-untrust** to permit the packets sent from the **Trust** security zone to the **Untrust** security zone.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-0-trust-untrust] action pass
[DeviceA-security-policy-ip-0-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-0-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-0-trust-untrust] quit
[DeviceA-security-policy-ip] quit
```

# Configure a rule named **untrust-trust** to permit the packets sent from the **Untrust** security zone to the **Trust** security zone.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name untrust-trust
[DeviceA-security-policy-ip-1-untrust-trust] action pass
[DeviceA-security-policy-ip-1-untrust-trust] source-zone untrust
[DeviceA-security-policy-ip-1-untrust-trust] destination-zone trust
[DeviceA-security-policy-ip-1-untrust-trust] quit
[DeviceA-security-policy-ip] quit
```

7. Configure Device B in the same way Device A is configured. (Details not shown.)

Verifying the configuration

# Display detailed information about all aggregation groups on Device A.

```
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Port Status: S -- Selected, U -- Unselected, I -- Individual
Port: A -- Auto port
Flags:  A -- LACP_Activity, B -- LACP_Timeout, C -- Aggregation,
        D -- Synchronization, E -- Collecting, F -- Distributing,
        G -- Defaulted, H -- Expired
Aggregate Interface: Bridge-Aggregation1
Creation Mode: Manual
Aggregation Mode: Dynamic
Loadsharing Type: Shar
System ID: 0x8000, 000f-e267-6c6a
Local:
  Port             Status  Priority Oper-Key  Flag
--------------------------------------------------------------------------------
  GE1/0/1          S       32768    1         {ACDEF}
  GE1/0/2          S       32768    1         {ACDEF}
  GE1/0/3          S       32768    1         {ACDEF}
Remote:
  Actor            Partner Priority Oper-Key  SystemID               Flag
--------------------------------------------------------------------------------
  GE1/0/1          1       32768    1         0x8000, 000f-e267-57ad {ACDEF}
  GE1/0/2          2       32768    1         0x8000, 000f-e267-57ad {ACDEF}
  GE1/0/3          3       32768    1         0x8000, 000f-e267-57ad {ACDEF}
```

The output shows that link aggregation group 1 is a Layer 2 dynamic aggregation group that contains three Selected ports.

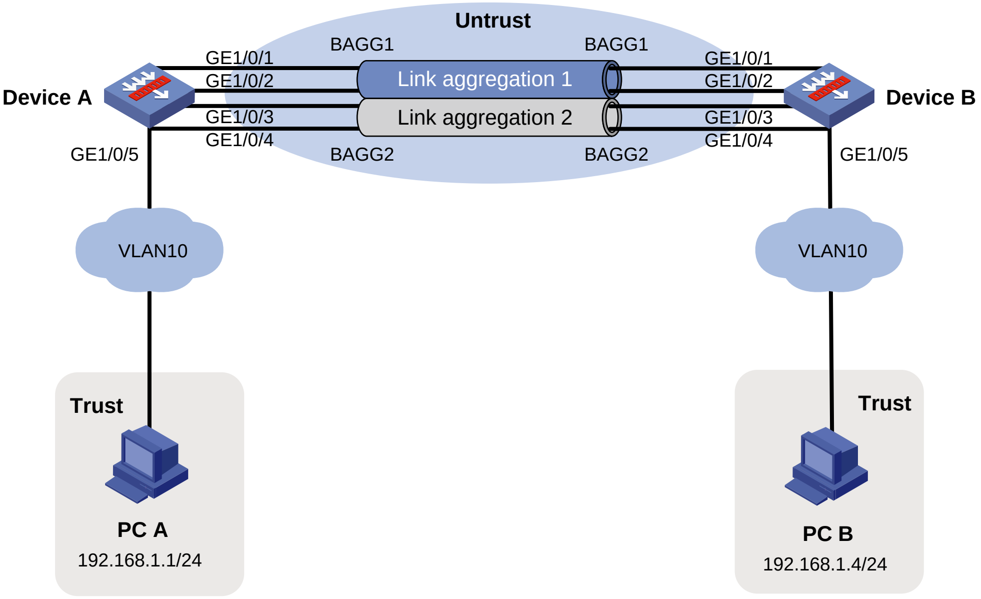
Example: Configuring Layer 2 aggregation load sharing

Network configuration

As shown in Figure 7, perform the following tasks:

- Configure Layer 2 static aggregation groups 1 and 2 on Device A and Device B, respectively.
- Configure link aggregation groups 1 and 2 to load share traffic across aggregation group member ports.
    - Configure link aggregation group 1 to load share packets based on source MAC addresses.
    - Configure link aggregation group 2 to load share packets based on destination MAC addresses.

Figure 7 Network diagram



Procedure

1. Configure interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/5 to operate in Layer 2 mode.

```
<DeviceA> system-view
[DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/5
[DeviceA-if-range] port link-mode bridge
[DeviceA-if-range] quit
```

2. Create VLAN 10, and assign interface GigabitEthernet 1/0/5 to VLAN 10.

```
[DeviceA] vlan 10
[DeviceA-vlan10] port gigabitethernet 1/0/5
[DeviceA-vlan10] quit
```

3. Configure Layer 2 aggregation groups:

# Configure Layer 2 aggregate interface Bridge-Aggregation 1 as a trunk port and assign it to VLANs 1 and 10, and configure it to load share packets based on source MAC addresses..

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] port link-type trunk
[DeviceA-Bridge-Aggregation1] port trunk permit vlan 1 10
[DeviceA-Bridge-Aggregation1] link-aggregation load-sharing mode source-mac
[DeviceA-Bridge-Aggregation1] quit
```

# Assign interfaces GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to link aggregation group 1.

```
[DeviceA] interface range GigabitEthernet1/0/1 to GigabitEthernet1/0/2
[DeviceA-if-range] port link-aggregation group 1
[DeviceA-if-range] quit
```

# Configure Layer 2 aggregate interface Bridge-Aggregation 2 as a trunk port and assign it to VLANs 1 and 10, and configure it to load share packets based on destination MAC addresses..

```
[DeviceA] interface bridge-aggregation 2
[DeviceA-Bridge-Aggregation1] port link-type trunk
[DeviceA-Bridge-Aggregation1] port trunk permit vlan 1 10
```

```
[DeviceA-Bridge-Aggregation1] link-aggregation load-sharing mode destination-mac
[DeviceA-Bridge-Aggregation1] quit
```

# Assign interfaces GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to link aggregation group 2.

```
[DeviceA] interface range gigabitethernet 1/0/3 to gigabitethernet 1/0/4
[DeviceA-if-range] port link-aggregation group 2
[DeviceA-if-range] quit
```

4. Configure interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 as trunk ports and assign them to VLANs 1 and 10.

```
[DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[DeviceA-if-range] port link-type trunk
[DeviceA-if-range] port trunk permit vlan 1 10
[DeviceA-if-range] quit
```

5. Add interfaces to security zones.

```
[DeviceA] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/5 vlan 10
[Device-security-zone-Trust] quit
[DeviceA] security-zone name untrust
[Device-security-zone-Untrust] import interface bridge-aggregation 1 vlan 1 10
[Device-security-zone-Untrust] import interface bridge-aggregation 2 vlan 1 10
[Device-security-zone-Untrust] quit
```

6. Configure a security policy:

Configure rules to permit traffic between the **Trust** and **Untrust** security zones, so the devices can communicate with each other:

# Configure a rule named **trust-untrust** to permit the packets sent from the **Trust** security zone to the **Untrust** security zone

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-0-trust-untrust] action pass
[DeviceA-security-policy-ip-0-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-0-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-0-trust-untrust] quit
[DeviceA-security-policy-ip] quit
```

# Configure a rule named **untrust-trust** to permit the packets sent from the **Untrust** security zone to the **Trust** security zone

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name untrust-trust
[DeviceA-security-policy-ip-1-untrust-trust] action pass
[DeviceA-security-policy-ip-1-untrust-trust] source-zone untrust
[DeviceA-security-policy-ip-1-untrust-trust] destination-zone trust
[DeviceA-security-policy-ip-1-untrust-trust] quit
[DeviceA-security-policy-ip] quit
```

7. Configure Device B in the same way Device A is configured. (Details not shown.)

Verifying the configuration

# Display detailed information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation verbose
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Port Status: S -- Selected, U -- Unselected, I -- Individual
```

```
Port: A -- Auto port
Flags:  A -- LACP_Activity, B -- LACP_Timeout, C -- Aggregation,
        D -- Synchronization, E -- Collecting, F -- Distributing,
        G -- Defaulted, H -- Expired

Aggregate Interface: Bridge-Aggregation1
Aggregation Mode: Static
Loadsharing Type: Shar
  Port             Status  Priority Oper-Key
--------------------------------------------------------------------------------
  GE1/0/1          S       32768    1
  GE1/0/2          S       32768    1

Aggregate Interface: Bridge-Aggregation2
Aggregation Mode: Static
Loadsharing Type: Shar
  Port             Status  Priority Oper-Key
--------------------------------------------------------------------------------
  GE1/0/3          S       32768    2
  GE1/0/4          S       32768    2
```

The output shows that:

- Link aggregation groups 1 and 2 are both load-shared Layer 2 static aggregation groups.
- Each aggregation group contains two Selected ports.

# Display all the group-specific load sharing modes on Device A.

```
[DeviceA] display link-aggregation load-sharing mode interface
Bridge-Aggregation1 Load-Sharing Mode:
source-mac address

Bridge-Aggregation2 Load-Sharing Mode:
destination-mac address
```

The output shows that:

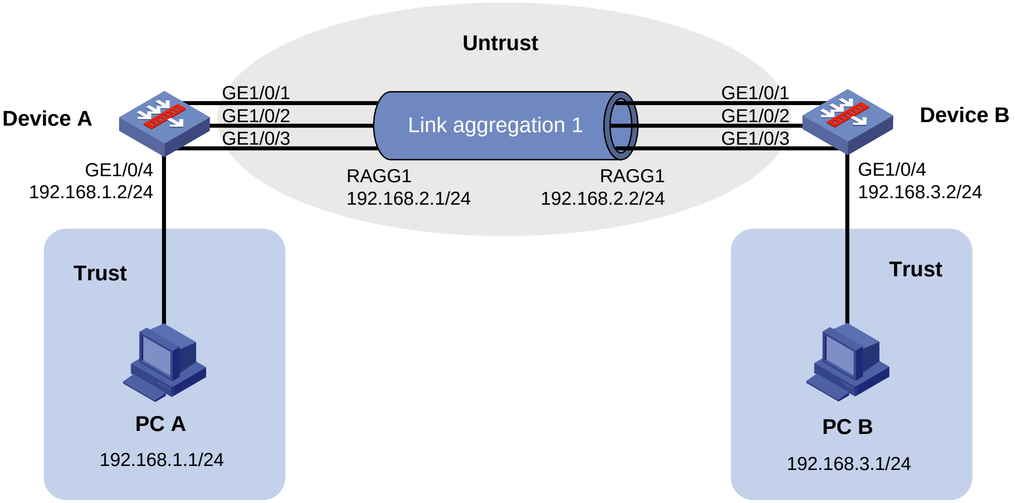
- Link aggregation group 1 distributes packets based on source MAC addresses.
- Link aggregation group 2 distributes packets based on destination MAC addresses.

Example: Configuring a Layer 3 static aggregation group

Network configuration

As shown in Figure 8, configure a Layer 3 static aggregation group on both Device A and Device B to aggregate the links between them.

Figure 8 Network diagram



Procedure

1. Configure a Layer 3 static aggregation group:

   # Create Layer 3 aggregate interface Route-Aggregation 1, and assign an IP address to the aggregate interface.

```
<DeviceA> system-view
[DeviceA] interface route-aggregation 1
[DeviceA-Route-Aggregation1] ip address 192.168.2.1 24
[DeviceA-Route-Aggregation1] quit
```

   # Assign Layer 3 Ethernet interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to aggregation group 1.

```
[DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/3
[DeviceA-if-range] port link-aggregation group 1
[DeviceA-if-range] quit
```

2. Assign an IP address to interface GigabitEthernet 1/0/4.

```
[DeviceA] interface GigabitEthernet 1/0/4
[DeviceA-GigabitEthernet1/0/4] ip address 192.168.1.2 24
[DeviceA-GigabitEthernet1/0/4] quit
```

3. Configure settings for routing.

   This example configure a static route for PC B, and the next hop is 192.168.2.2.

```
[DeviceA] ip route-static 192.168.3.1 24 192.168.2.2
```

4. Add interfaces to security zones.

```
[DeviceA] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/4
[Device-security-zone-Trust] quit
[DeviceA] security-zone name untrust
[Device-security-zone-Untrust] import interface route-aggregation 1
[Device-security-zone-Untrust] quit
```

5. Configure a security policy:

   Configure rules to permit traffic between PC A and PC B:

   # Configure a rule named **trust-untrust** to permit the packets sent from the **Trust** security zone to the **Untrust** security zone.

```
[DeviceA] security-policy ip
```

```
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-0-trust-untrust] action pass
[DeviceA-security-policy-ip-0-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-0-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-0-trust-untrust] source-ip-subnet 192.168.1.0 24
[DeviceA-security-policy-ip-0-trust-untrust] destination-ip-subnet 192.168.3.0 24
[DeviceA-security-policy-ip-0-trust-untrust] quit
[DeviceA-security-policy-ip] quit
```

# Configure a rule named **untrust-trust** to permit the packets sent from the **Untrust** security zone to the **Trust** security zone

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name untrust-trust
[DeviceA-security-policy-ip-1-untrust-trust] action pass
[DeviceA-security-policy-ip-1-untrust-trust] source-zone untrust
[DeviceA-security-policy-ip-1-untrust-trust] destination-zone trust
[DeviceA-security-policy-ip-1-untrust-trust] source-ip-subnet 192.168.3.0 24
[DeviceA-security-policy-ip-1-untrust-trust] destination-ip-subnet 192.168.1.0 24
[DeviceA-security-policy-ip-1-untrust-trust] quit
[DeviceA-security-policy-ip] quit
```

6. Configure Device B in the same way Device A is configured. (Details not shown.)

Verifying the configuration

# Display detailed information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation verbose
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Port Status: S -- Selected, U -- Unselected, I -- Individual
Port: A -- Auto port
Flags:  A -- LACP_Activity, B -- LACP_Timeout, C -- Aggregation,
        D -- Synchronization, E -- Collecting, F -- Distributing,
        G -- Defaulted, H -- Expired

Aggregate Interface: Route-Aggregation1
Aggregation Mode: Static
Loadsharing Type: Shar
  Port             Status  Priority Oper-Key
--------------------------------------------------------------------------------
  GE1/0/1          S       32768    1
  GE1/0/2          S       32768    1
  GE1/0/3          S       32768    1
```

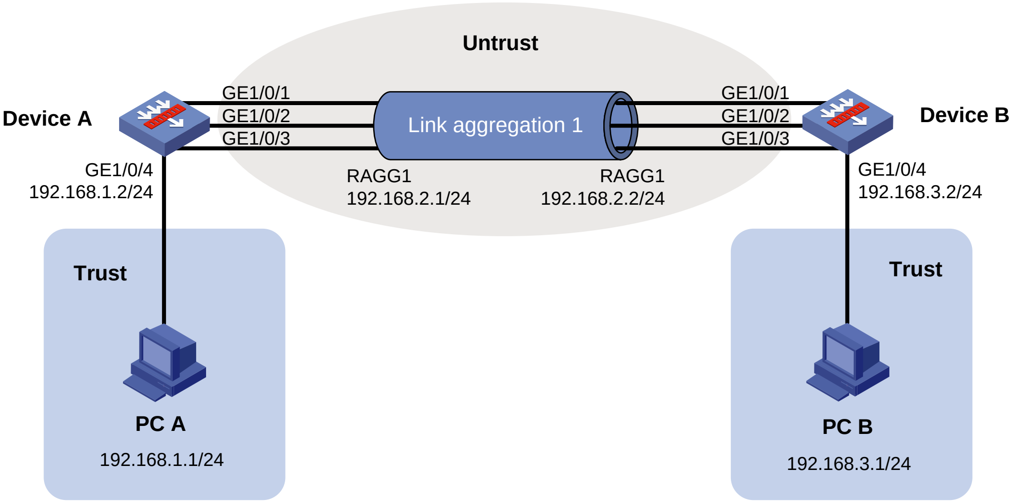
The output shows that link aggregation group 1 is a Layer 3 static aggregation group that contains three Selected ports.

Example: Configuring a Layer 3 dynamic aggregation group

Network configuration

As shown in Figure 9, configure a Layer 3 dynamic aggregation group on both Device A and Device B to aggregate the links between them.

Figure 9 Network diagram



Procedure

1. Configure a dynamic aggregation group:

   # Create Layer 3 aggregate interface Route-Aggregation 1.

   ```
   <DeviceA> system-view
   [DeviceA] interface route-aggregation 1
   ```

   # Assign an IP address to Route-Aggregation 1.

   ```
   [DeviceA-Route-Aggregation1] ip address 192.168.2.1 24
   ```

   # Set the link aggregation mode to dynamic.

   ```
   [DeviceA-Route-Aggregation1] link-aggregation mode dynamic
   [DeviceA-Route-Aggregation1] quit
   ```

   # Assign Layer 3 Ethernet interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to aggregation group 1.

   ```
   [DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/3
   [DeviceA-if-range] port link-aggregation group 1
   [DeviceA-if-range] quit
   ```

2. Assign an IP address to interface GigabitEthernet 1/0/4.

   ```
   [DeviceA] interface GigabitEthernet 1/0/4
   [DeviceA-GigabitEthernet1/0/4] ip address 192.168.1.2 24
   [DeviceA-GigabitEthernet1/0/4] quit
   ```

3. Configure settings for routing.

   This example configure a static route for PC B, and the next hop in the routes is 192.168.2.2.

   ```
   [DeviceA] ip route-static 192.168.3.1 24 192.168.2.2
   ```

4. Add interfaces to security zones.

   ```
   [DeviceA] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/4
   [Device-security-zone-Trust] quit
   [DeviceA] security-zone name untrust
   [Device-security-zone-Untrust] import interface route-aggregation 1
   [Device-security-zone-Untrust] quit
   ```

5. Configure a security policy:

   Configure rules to permit traffic between PC A and PC B:

# Configure a rule named **trust-untrust** to permit the packets sent from the **Trust** security zone to the **Untrust** security zone.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-0-trust-untrust] action pass
[DeviceA-security-policy-ip-0-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-0-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-0-trust-untrust] source-ip-subnet 192.168.1.0 24
[DeviceA-security-policy-ip-0-trust-untrust] destination-ip-subnet 192.168.3.0 24
[DeviceA-security-policy-ip-0-trust-untrust] quit
[DeviceA-security-policy-ip] quit
```

# Configure a rule named **untrust-trust** to permit the packets sent from the **Untrust** security zone to the **Trust** security zone

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name untrust-trust
[DeviceA-security-policy-ip-1-untrust-trust] action pass
[DeviceA-security-policy-ip-1-untrust-trust] source-zone untrust
[DeviceA-security-policy-ip-1-untrust-trust] destination-zone trust
[DeviceA-security-policy-ip-1-untrust-trust] source-ip-subnet 192.168.3.0 24
[DeviceA-security-policy-ip-1-untrust-trust] destination-ip-subnet 192.168.1.0 24
[DeviceA-security-policy-ip-1-untrust-trust] quit
[DeviceA-security-policy-ip] quit
```

6. Configure Device B in the same way Device A is configured. (Details not shown.)

Verifying the configuration

# Display detailed information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation verbose
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Port Status: S -- Selected, U -- Unselected, I -- Individual
Port: A -- Auto port
Flags:  A -- LACP_Activity, B -- LACP_Timeout, C -- Aggregation,
        D -- Synchronization, E -- Collecting, F -- Distributing,
        G -- Defaulted, H -- Expired

Aggregate Interface: Route-Aggregation1
Creation Mode: Manual
Aggregation Mode: Dynamic
Loadsharing Type: Shar
System ID: 0x8000, 000f-e267-6c6a
Local:

  GE1/0/3          S       32768    1         {ACDEF}
Remote:
  Actor            Partner Priority Oper-Key  SystemID               Flag
--------------------------------------------------------------------------------
  GE1/0/1          1       32768    1         0x8000, 000f-e267-57ad {ACDEF}
```

```
GE1/0/2          2        32768     1          0x8000, 000f-e267-57ad {ACDEF}
GE1/0/3          3        32768     1          0x8000, 000f-e267-57ad {ACDEF}
```

The output shows that link aggregation group 1 is a Layer 3 dynamic aggregation group that contains three Selected ports.

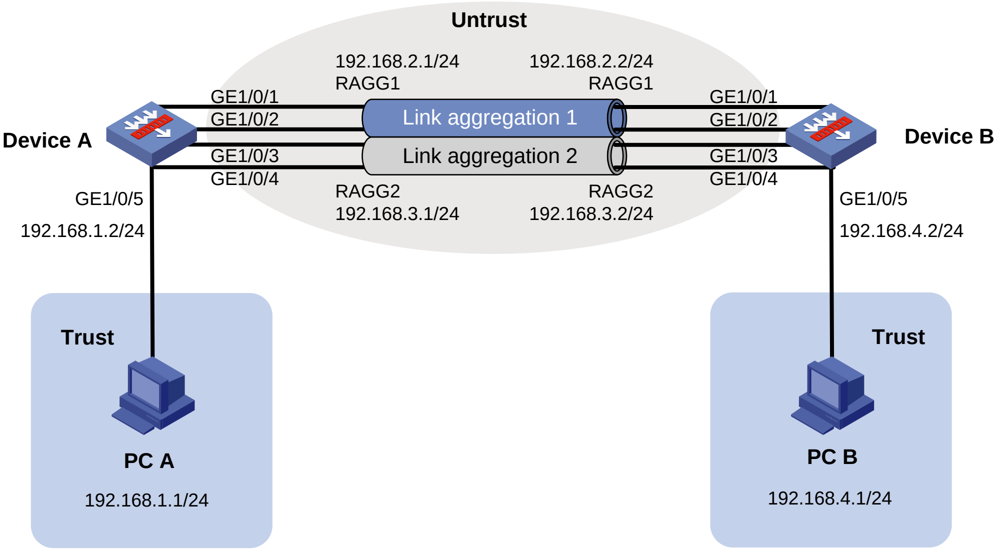
Example: Configuring Layer 3 aggregation load sharing

Network configuration

As shown in Figure 10, perform the following tasks:

- Configure Layer 3 static aggregation groups 1 and 2 on Device A and Device B, respectively.
- Configure link aggregation groups 1 and 2 to load share traffic across aggregation group member ports.
    - Configure link aggregation group 1 to load share packets based on source IP addresses.
    - Configure link aggregation group 2 to load share packets based on destination IP addresses.

Figure 10 Network diagram



Procedure

1. Configure Layer 3 aggregation groups:

# Create Layer 3 aggregate interface Route-Aggregation 1.

```
<DeviceA> system-view
[DeviceA] interface route-aggregation 1
```

# Configure Layer 3 aggregation group 1 to load share packets based on source IP addresses.

```
[DeviceA-Route-Aggregation1] link-aggregation load-sharing mode source-ip
```

# Assign an IP address to Layer 3 aggregate interface Route-Aggregation 1.

```
[DeviceA-Route-Aggregation1] ip address 192.168.2.1 24
[DeviceA-Route-Aggregation1] quit
```

# Assign Layer 3 Ethernet interfaces GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 1.

```
[DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/2
[DeviceA-if-range] port link-aggregation group 1
[DeviceA-if-range] quit
```

# Create Layer 3 aggregate interface Route-Aggregation 2.

```
[DeviceA] interface route-aggregation 2
```

# Configure Layer 3 aggregation group 2 to load share packets based on destination IP addresses.

```
[DeviceA-Route-Aggregation2] link-aggregation load-sharing mode destination-ip
```

# Assign an IP address to Layer 3 aggregate interface Route-Aggregation 2.

```
[DeviceA-Route-Aggregation2] ip address 192.168.3.1 24
[DeviceA-Route-Aggregation2] quit
```

# Assign Layer 3 Ethernet interfaces GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to aggregation group 2.

```
[DeviceA] interface range gigabitethernet 1/0/3 to gigabitethernet 1/0/4
[DeviceA-if-range] port link-aggregation group 2
[DeviceA-if-range] quit
```

2. Assign an IP address to interface GigabitEthernet 1/0/5.

```
[DeviceA] interface gigabitethernet 1/0/5
[DeviceA-GigabitEthernet1/0/5] ip address 192.168.1.2 24
[DeviceA-GigabitEthernet1/0/5] quit
```

3. Configure settings for routing.

This example configure static routes for PC B, and the next hops in the routes are 192.168.2.2 and 192.168.3.2.

```
[DeviceA] ip route-static 192.168.4.1 24 192.168.2.2
[DeviceA] ip route-static 192.168.4.1 24 192.168.3.2
```

4. Add interfaces to security zones.

```
[DeviceA] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/5
[Device-security-zone-Trust] quit
[DeviceA] security-zone name untrust
[Device-security-zone-Untrust] import interface route-aggregation 1
[Device-security-zone-Untrust] import interface route-aggregation 2
[Device-security-zone-Untrust] quit
```

5. Configure a security policy:

Configure rules to permit traffic between PC A and PC B:

# Configure a rule named **trust-untrust** to permit the packets sent from the **Trust** security zone to the **Untrust** security zone.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-0-trust-untrust] action pass
[DeviceA-security-policy-ip-0-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-0-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-0-trust-untrust] source-ip-subnet 192.168.1.0 24
[DeviceA-security-policy-ip-0-trust-untrust] destination-ip-subnet 192.168.4.0 24
[DeviceA-security-policy-ip-0-trust-untrust] quit
[DeviceA-security-policy-ip] quit
```

# Configure a rule named **untrust-trust** to permit the packets sent from the **Untrust** security zone to the **Trust** security zone.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name untrust-trust
[DeviceA-security-policy-ip-1-untrust-trust] action pass
```

```
[DeviceA-security-policy-ip-1-untrust-trust] source-zone untrust
[DeviceA-security-policy-ip-1-untrust-trust] destination-zone trust
[DeviceA-security-policy-ip-1-untrust-trust] source-ip-subnet 192.168.4.0 24
[DeviceA-security-policy-ip-1-untrust-trust] destination-ip-subnet 192.168.1.0 24
[DeviceA-security-policy-ip-1-untrust-trust] quit
[DeviceA-security-policy-ip] quit
```

6. Configure Device B in the same way Device A is configured. (Details not shown.)

Verifying the configuration

# Display detailed information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation verbose
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Port Status: S -- Selected, U -- Unselected, I -- Individual
Port: A -- Auto port
Flags:  A -- LACP_Activity, B -- LACP_Timeout, C -- Aggregation,
        D -- Synchronization, E -- Collecting, F -- Distributing,
        G -- Defaulted, H -- Expired

Aggregate Interface: Route-Aggregation1
Aggregation Mode: Static
Loadsharing Type: Shar
  Port             Status  Priority Oper-Key
--------------------------------------------------------------------------------
  GE1/0/1          S       32768    1
  GE1/0/2          S       32768    1

Aggregate Interface: Route-Aggregation2
Aggregation Mode: Static
Loadsharing Type: Shar
  Port             Status  Priority Oper-Key
--------------------------------------------------------------------------------
  GE1/0/3          S       32768    2
  GE1/0/4          S       32768    2
```

The output shows that:

- Link aggregation groups 1 and 2 are both load-shared Layer 3 static aggregation groups.
- Each aggregation group contains two Selected ports.

# Display all the group-specific load sharing modes on Device A.

```
[DeviceA] display link-aggregation load-sharing mode interface
Route-Aggregation1 Load-Sharing Mode:
source-ip address

Route-Aggregation2 Load-Sharing Mode:
destination-ip address
```

The output shows that:

- Link aggregation group 1 distributes packets based on source IP addresses.
- Link aggregation group 2 distributes packets based on destination IP addresses.

Configuring VLANs

About VLANs

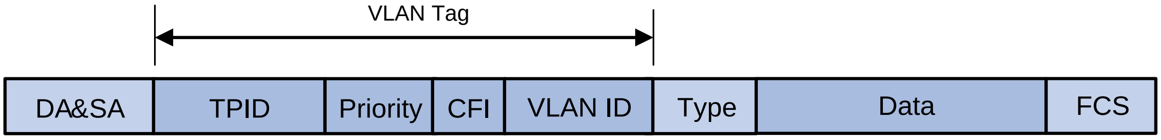
The Virtual Local Area Network (VLAN) technology divides a physical LAN into multiple logical LANs. It has the following benefits:

- **Security**—Hosts in the same VLAN can communicate with one another at Layer 2, but they are isolated from hosts in other VLANs at Layer 2.
- **Broadcast traffic isolation**—Each VLAN is a broadcast domain that limits the transmission of broadcast packets.
- **Flexibility**—A VLAN can be logically divided on a workgroup basis. Hosts in the same workgroup can be assigned to the same VLAN, regardless of their physical locations.

VLAN frame encapsulation

To identify Ethernet frames from different VLANs, IEEE 802.1Q inserts a four-byte VLAN tag between the destination and source MAC address (DA&SA) field and the Type field.

Figure 1 VLAN tag placement and format



A VLAN tag includes the following fields:

- **TPID**—16-bit tag protocol identifier that indicates whether a frame is VLAN-tagged. By default, the hexadecimal TPID value 8100 identifies a VLAN-tagged frame. A device vendor can set the TPID to a different value. For compatibility with a neighbor device, set the TPID value on the device to be the same as the neighbor device. For more information about setting the TPID value, see "Configuring VLAN termination.".
- **Priority**—3-bit long, identifies the 802.1p priority of the frame. For more information, see *ACL and QoS Configuration Guide*.
- **CFI**—1-bit long canonical format indicator that indicates whether the MAC addresses are encapsulated in the standard format when packets are transmitted across different media. Available values include:
    - **0 (default)**—The MAC addresses are encapsulated in the standard format.
    - **1**—The MAC addresses are encapsulated in a non-standard format.

  This field is always set to 0 for Ethernet.
- **VLAN ID**—12-bit long, identifies the VLAN to which the frame belongs. The VLAN ID range is 0 to 4095. VLAN IDs 0 and 4095 are reserved, and VLAN IDs 1 to 4094 are user configurable.

The way a network device handles an incoming frame depends on whether the frame has a VLAN tag and the value of the VLAN tag (if any).

Ethernet supports encapsulation formats Ethernet II, 802.3/802.2 LLC, 802.3/802.2 SNAP, and 802.3 raw. The Ethernet II encapsulation format is used here. For information about the VLAN tag fields in other frame encapsulation formats, see related protocols and standards.

For a frame that has multiple VLAN tags, the device handles it according to its outermost VLAN tag and transmits its inner VLAN tags as the payload.

Port-based VLANs

Port-based VLANs group VLAN members by port. A port forwards packets from a VLAN only after it is assigned to the VLAN.

Port link type

You can set the link type of a port to access, trunk, or hybrid. The port link type determines whether the port can be assigned to multiple VLANs. The link types use the following VLAN tag handling methods:

- **Access**—An access port can forward packets only from one VLAN and send these packets untagged. An access port is typically used in the following conditions:
  - Connecting to a terminal device that does not support VLAN packets.
  - In scenarios that do not distinguish VLANs.
- **Trunk**—A trunk port can forward packets from multiple VLANs. Except packets from the port VLAN ID (PVID), packets sent out of a trunk port are VLAN-tagged. Ports connecting network devices are typically configured as trunk ports.
- **Hybrid**—A hybrid port can forward packets from multiple VLANs. The tagging status of the packets forwarded by a hybrid port depends on the port configuration.

PVID

The PVID identifies the default VLAN of a port. Untagged packets received on a port are considered as the packets from the port PVID.

An access port can join only one VLAN. The VLAN to which the access port belongs is the PVID of the port. A trunk or hybrid port supports multiple VLANs and the PVID configuration.

How ports of different link types handle frames

<table>
<tr><th>Actions</th><th>Access</th><th>Trunk</th><th>Hybrid</th></tr>
<tr><td>In the inbound direction for an untagged frame</td><td>Tags the frame with the PVID tag.</td><td colspan="2">• If the PVID is permitted on the port, tags the frame with the PVID tag.
• If not, drops the frame.</td></tr>
<tr><td>In the inbound direction for a tagged frame</td><td>• Receives the frame if its VLAN ID is the same as the PVID.
• Drops the frame if its VLAN ID is different from the PVID.</td><td colspan="2">• Receives the frame if its VLAN is permitted on the port.
• Drops the frame if its VLAN is not permitted on the port.</td></tr>
<tr><td>In the outbound direction</td><td>Removes the VLAN tag and sends the frame.</td><td>• Removes the tag and sends the frame if the frame carries the PVID tag and the port belongs to the PVID.
• Sends the frame without removing the tag if its VLAN is carried on the port but is different from the PVID.</td><td>Sends the frame if its VLAN is permitted on the port. The tagging status of the frame depends on the <b>port hybrid vlan</b> command configuration.</td></tr>
</table>

Layer 3 communication between VLANs

Hosts of different VLANs use VLAN interfaces to communicate at Layer 3. VLAN interfaces are virtual interfaces that do not exist as physical entities on devices. For each VLAN, you can create one VLAN interface and assign an IP address to it. The VLAN interface acts as the gateway of the VLAN to forward packets destined for another IP subnet at Layer 3.

Protocols and standards

IEEE 802.1Q, *IEEE Standard for Local and Metropolitan Area Networks: Virtual Bridged Local Area Networks*

Configuring a VLAN

Restrictions and guidelines

- As the system default VLAN, VLAN 1 cannot be created or deleted.
- Before you delete a dynamic VLAN or a VLAN locked by an application, you must first remove the configuration from the VLAN.

Creating VLANs

1. Enter system view.

   `system-view`

2. Create one or multiple VLANs.
   - Create a VLAN and enter its view.

     `vlan` *`vlan-id`*
   - Create multiple VLANs and enter VLAN view.

     Create VLANs.

     `vlan` { *`vlan-id1`* **`to`** *`vlan-id2`* | **`all`** }

     Enter VLAN view.

     `vlan` *`vlan-id`*

   By default, only the system default VLAN (VLAN 1) exists.

3. (Optional.) Set a name for the VLAN.

   `name` *`text`*

   By default, the name of a VLAN is **VLAN** *vlan-id.* The *vlan-id* argument specifies the VLAN ID in a four-digit format. If the VLAN ID has fewer than four digits, leading zeros are added. For example, the name of VLAN 100 is **VLAN 0100**.

4. (Optional.) Configure the description for the VLAN.

   `description` *`text`*

   By default, the description of a VLAN is **VLAN** *vlan-id.* The *vlan-id* argument specifies the VLAN ID in a four-digit format. If the VLAN ID has fewer than four digits, leading zeros are added. For example, the default description of VLAN 100 is **VLAN 0100**.

Configuring port-based VLANs

Restrictions and guidelines for port-based VLANs

- When you use the **undo vlan** command to delete the PVID of a port, either of the following events occurs depending on the port link type:
  - For an access port, the PVID of the port changes to VLAN 1.
  - For a hybrid or trunk port, the PVID setting of the port does not change.

  You can use a nonexistent VLAN as the PVID for a hybrid or trunk port, but not for an access port.
- As a best practice, set the same PVID for a local port and its peer.
- To prevent a port from dropping untagged packets or PVID-tagged packets, assign the port to its PVID.

Assigning an access port to a VLAN

About this task

You can assign an access port to a VLAN in VLAN view or interface view.

Assigning one or multiple access ports to a VLAN in VLAN view

1. Enter system view.

   system-view
2. Enter VLAN view.

   vlan *vlan-id*
3. Assign one or multiple access ports to the VLAN.

   port *interface-list*

   By default, all ports belong to VLAN 1.

Assigning an access port to a VLAN in interface view

1. Enter system view.

   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.

     interface bridge-aggregation *interface-number*
3. Set the port link type to access.

   port link-type access

   By default, all ports are access ports.
4. Assign the access port to a VLAN.

   port access vlan *vlan-id*

   By default, all access ports belong to VLAN 1.

Assigning a trunk port to a VLAN

About this task

A trunk port supports multiple VLANs. You can assign it to a VLAN in interface view.

Restrictions and guidelines

To change the link type of a port from trunk to hybrid, set the link type to access first.

To enable a trunk port to transmit packets from its PVID, you must assign the trunk port to the PVID by using the **`port trunk permit vlan`** command.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

     `interface` *`interface-type interface-number`*
   - Enter Layer 2 aggregate interface view.

     `interface bridge-aggregation` *`interface-number`*

3. Set the port link type to trunk.

   `port link-type trunk`

   By default, all ports are access ports.

4. Assign the trunk port to the specified VLANs.

   `port trunk permit vlan` { *`vlan-id-list`* | **`all`** }

   By default, a trunk port permits only VLAN 1.

5. (Optional.) Set the PVID for the trunk port.

   `port trunk pvid vlan` *`vlan-id`*

   The default setting is VLAN 1.

Assigning a hybrid port to a VLAN

About this task

A hybrid port supports multiple VLANs. You can assign it to the specified VLANs in interface view. Make sure the VLANs have been created.

Restrictions and guidelines

To change the link type of a port from trunk to hybrid, set the link type to access first.

To enable a hybrid port to transmit packets from its PVID, you must assign the hybrid port to the PVID by using the **`port hybrid vlan`** command.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

     `interface` *`interface-type interface-number`*
   - Enter Layer 2 aggregate interface view.

     `interface bridge-aggregation` *`interface-number`*

3. Set the port link type to hybrid.

   port link-type hybrid

   By default, all ports are access ports.

4. Assign the hybrid port to the specified VLANs.

   port hybrid vlan *vlan-id-list* { **tagged** | **untagged** }

   By default, the hybrid port is an untagged member of the VLAN to which the port belongs when its link type is **access**.

5. (Optional.) Set the PVID for the hybrid port.

   port hybrid pvid vlan *vlan-id*

   By default, the PVID of a hybrid port is the ID of the VLAN to which the port belongs when its link type is **access**.

Configuring a VLAN group

About this task

A VLAN group includes a set of VLANs.

Procedure

1. Enter system view.

   system-view

2. Create a VLAN group and enter its view.

   vlan-group *group-name*

3. Add VLANs to the VLAN group.

   vlan-list *vlan-id-list*

   By default, no VLANs exist in a VLAN group.

   You can add multiple VLAN lists to a VLAN group.

Configuring VLAN interfaces

VLAN interfaces configuration tasks at a glance

To configure VLAN interfaces, perform the following tasks:

1. Creating a VLAN interface
2. (Optional.) Restoring the default settings for the VLAN interface

Prerequisites

Before you create a VLAN interface for a VLAN, create the VLAN first.

Creating a VLAN interface

1. Enter system view.

   system-view

2. Create a VLAN interface and enter its view.

   interface vlan-interface *interface-number*

3. Assign an IP address to the VLAN interface.

   ip address *ip-address* { *mask* | *mask-length* } [**sub**]

   By default, no IP address is assigned to a VLAN interface.

4. (Optional.) Configure the description for the VLAN interface.

   description *text*

   The default setting is the VLAN interface name. For example, **Vlan-interface1 Interface**.

5. (Optional.) Set the MTU for the VLAN interface.

   mtu *size*

   By default, the MTU is 1500 for a VLAN interface.

6. (Optional.) Set the expected bandwidth for the interface.

   bandwidth *bandwidth-value*

   By default, the expected bandwidth (in kbps) is the interface baud rate divided by 1000.

7. Bring up the VLAN interface.

   undo shutdown

   By default, a VLAN interface is not manually shut down.

Restoring the default settings for the VLAN interface

Restrictions and guidelines

This feature might fail to restore the default settings for some commands for reasons such as command dependencies or system restrictions. Use the **display this** command in interface view to identify these commands, and then use their **undo** forms or follow the command reference to restore their default settings. If your restoration attempt still fails, follow the error message instructions to resolve the problem.

Procedure

1. Enter system view.

   system-view

2. Enter a VLAN interface view.

   interface vlan-interface *interface-number*

3. Restore the default settings for the VLAN interface.

   default

△ **CAUTION:**

This feature might interrupt ongoing network services. Make sure you are fully aware of the impact of this feature when you use it on a live network.

Display and maintenance commands for VLANs

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display VLAN interface information.	**display interface** [**vlan-interface** [*interface-number*]] [**brief**]
Display hybrid ports or trunk ports on the	**display port** { **hybrid** | **trunk** }

Task	Command
device.	
Display VLAN information.	**display vlan** [*vlan-id1* [**to** *vlan-id2*] | **all** | **dynamic** | **static**]
Display brief VLAN information.	**display vlan brief**
Display VLAN group information.	**display vlan-group** [*group-name*]
Clear statistics on a port.	**reset counters interface** [**vlan-interface** [*interface-number*]]

Contents

Configuring VLAN termination

About VLAN termination

VLAN termination typically processes packets that include VLAN tags. A VLAN termination-enabled interface performs the following tasks when receiving a VLAN-tagged packet:

1. Assigns the packet to an interface according to its VLAN tags.
2. Removes the VLAN tags of the packet.
3. Delivers the packet to Layer 3 forwarding or other processing pipelines.

Before sending the packet, the VLAN termination-enabled interface determines whether to add new VLAN tags to the packet, based on the VLAN termination type.

VLAN termination can also process packets that do not include any VLAN tags.

This document uses the following VLAN tag concepts for a packet that has two or more layers of VLAN tags:

- **Layer 1 VLAN tag**—Specifies the outermost layer of VLAN tags.
- **Layer 2 VLAN tag**—Specifies the second outermost layer of VLAN tags.

The VLAN IDs of the packets are numbered in the same manner as the VLAN tags.

VLAN termination types

VLAN termination types	Types of packets to be terminated on the interface	Tags of outgoing packets on the interface
Dot1q termination	The packets must meet both of the following requirements: • The packets include one or more layers of VLAN tags. • The outermost VLAN ID matches the configured value.	Single-tagged
Untagged termination	Untagged packets.	Untagged
Default termination	Packets that cannot be processed on any other subinterfaces of the same main interface.	Untagged

VLAN termination mechanism

VLAN interfaces and subinterfaces, such as Layer 3 Ethernet subinterfaces and Layer 3 aggregate subinterfaces, can terminate the following packets:

- Packets whose outermost VLAN IDs match the configured values.
- Packets whose outermost two layers of VLAN IDs match the configured values.

A VLAN interface terminates only the packets whose outermost VLAN ID is the same as the VLAN interface number. For example, VLAN-interface 10 terminates only the packets with the outermost VLAN tag 10.

A main interface does not terminate VLAN-tagged packets (for example, Layer 3 Ethernet interface or Layer 3 aggregate interface). To terminate VLAN-tagged packets, create subinterfaces for the main interface.

Subinterfaces of the same main interface can use different types of VLAN termination. To process received packets, the system selects a subinterface based on the following VLAN termination types in descending order of priority:

- Dot1q termination or support for Dot1q termination by default.
- Untagged termination.
- Default termination.

If none of these VLAN termination types applies, the main interface processes the packets.

If untagged termination is enabled on a subinterface of an interface, untagged packets are processed by the subinterface instead of the main interface.

If default termination is enabled on a subinterface of an interface, packets are processed by the subinterface instead of the main interface.

When a main interface is bound to a VLAN interface, the main interface processes VLAN-tagged packets according to the VLAN termination configuration of the VLAN interface.

VLAN termination application scenarios

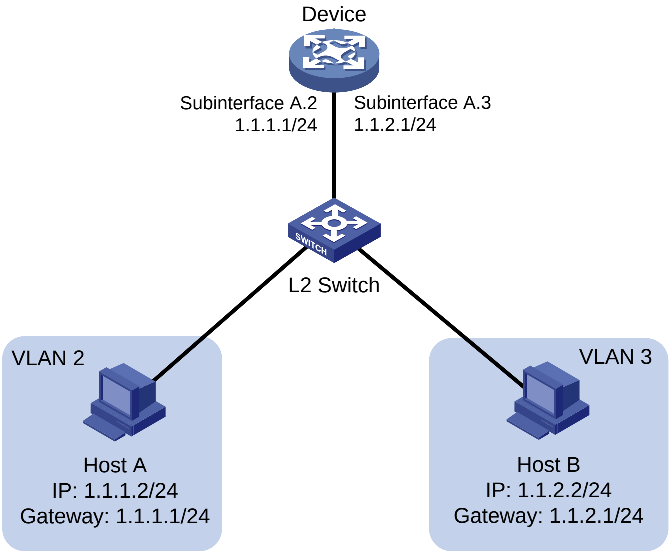
Inter-VLAN communication

Hosts in different VLANs cannot directly communicate with each other. You can use Layer 3 routing to allow all VLANs to communicate. To restrict communication to the specified VLANs, configure VLAN termination on subinterfaces or VLAN interfaces.

As shown in Figure 1, Host A and Host B are in different VLANs. For the two hosts to communicate with each other, perform the following tasks:

1. Specify 1.1.1.1/24 and 1.1.2.1/24 as the gateway IP address for Host A and Host B, respectively.
2. On the device, configure Dot1q termination on Layer 3 Ethernet subinterfaces Subinterface A.2 and Subinterface A.3.

Figure 1 Inter-VLAN communication through Layer 3 subinterfaces



As shown in Figure 2, Host A is in VLAN 2, Host B is in VLAN 3, and Host C is in VLAN 4. For Host A and Host B to communicate with each other, perform the following tasks:

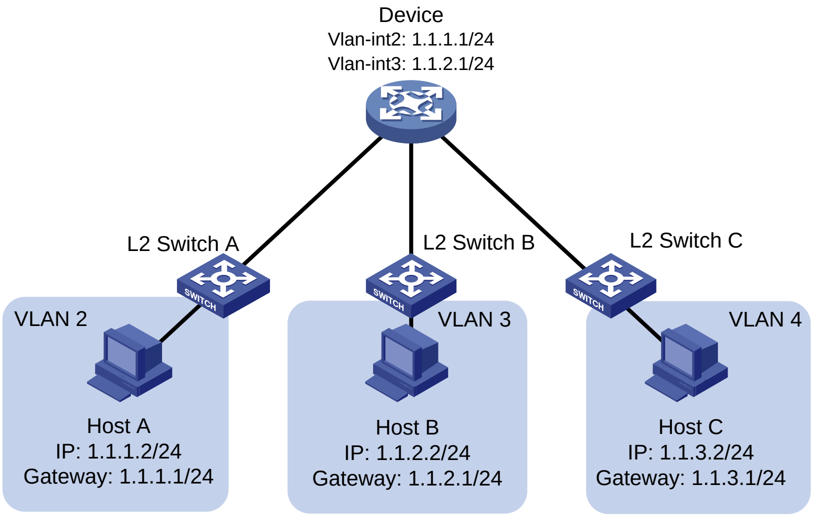
1. Specify 1.1.1.1/24 and 1.1.2.1/24 as the gateway IP address for Host A and Host B, respectively.

2. On the device, create VLAN-interface 2 and configure the IP address as 1.1.1.1/24, which is the same as the gateway address of Host A. Create VLAN-interface 3 and configure the IP address as 1.1.2.1/24, which is the same as the gateway address of Host B.

VLAN termination by the outermost VLAN ID of packets is automatically performed on VLAN interfaces. For example, when Host A sends a packet to Host B, VLAN-interface 2 removes the VLAN tag from the packet and forwards it to VLAN-interface 3. Then, VLAN-interface 3 tags the packet with VLAN 3 and Host B can receive the packet.

Because the device does not have a VLAN interface to terminate packets from VLAN 4, Host C cannot communicate with Host A or Host B.

Figure 2 Inter-VLAN communication through VLAN interfaces



Restrictions and guidelines: VLAN termination configuration

When you configure VLAN termination, follow these restrictions and guidelines:

- On a portal-enabled interface, log off all portal users before you change the VLAN termination type. Any portal users who remain online after the change cannot be logged off or reauthenticated. For more information about portal authentication, see *Security Configuration Guide*.
- After you modify the VLAN termination configuration for a subinterface, the subinterface automatically restarts. All dynamic ARP table entries for the subinterface are deleted.

VLAN termination tasks at a glance

To configure VLAN termination, perform the following tasks:

1. (Required.) Configuring VLAN termination

   Choose one of the following tasks:

   - Configuring ambiguous Dot1q termination
   - Configuring unambiguous Dot1q termination
   - Configuring untagged termination
   - Configuring default termination

2. (Optional.) Enabling a VLAN termination-enabled interface to transmit broadcasts and multicasts

   Perform this task to enable VLAN termination-enabled interfaces to transmit broadcasts and multicasts.
3. (Optional.) Configuring the TPID for VLAN-tagged packets

Configuring ambiguous Dot1q termination

About this task

Use this feature to terminate VLAN-tagged packets whose outermost VLAN IDs are in the specified range. Other VLAN-tagged packets are not allowed to pass.

When an interface receives a packet, it removes the outermost VLAN ID from the packet. When the interface sends a packet, it tags the packet with a VLAN ID as follows:

- For a PPPoE packet, the VLAN ID is from the matching PPPoE session entry.
- For a DHCP relay packet, the VLAN ID is from the matching DHCP session entry.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.
   - Enter Layer 3 Ethernet subinterface view.

     interface *interface-type interface-number.subnumber*
   - Enter Layer 3 aggregate subinterface view.

     interface route-aggregation *interface-number.subnumber*
   - Enter Reth subinterface view.

     interface reth *interface-number.subnumber*
3. Configure ambiguous Dot1q termination.

   vlan-type dot1q vid *vlan-id-list*

   By default, Dot1q termination is disabled on a subinterface.

Configuring unambiguous Dot1q termination

About this task

Use this feature to terminate only VLAN-tagged packets whose outermost VLAN ID matches the specified VLAN ID. Other VLAN-tagged packets are not allowed to pass.

When an interface receives a packet, it removes the outermost VLAN ID from the packet. When the interface sends a packet, it tags the packet with the specified VLAN ID.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.
   - Enter Layer 3 Ethernet subinterface view.

     interface *interface-type interface-number.subnumber*
   - Enter Layer 3 aggregate subinterface view.

     interface route-aggregation *interface-number.subnumber*

    - Enter Reth subinterface view.

      interface reth *interface-number.subnumber*

3. Configure unambiguous Dot1q termination.

   vlan-type dot1q vid *vlan-id*

   By default, Dot1q termination is disabled on a subinterface.

Configuring untagged termination

1. Enter system view.

   system-view

2. Enter interface view.
    - Enter Layer 3 Ethernet subinterface view.

      interface *interface-type interface-number.subnumber*
    - Enter Layer 3 aggregate subinterface view.

      interface route-aggregation *interface-number.subnumber*
    - Enter Reth subinterface view.

      interface reth *interface-number.subnumber*
3. Configure untagged termination.

   vlan-type dot1q untagged

   By default, untagged termination is disabled on a subinterface.

Configuring default termination

1. Enter system view.

   system-view

2. Enter interface view.
    - Enter Layer 3 Ethernet subinterface view.

      interface *interface-type interface-number.subnumber*
    - Enter Layer 3 aggregate subinterface view.

      interface route-aggregation *interface-number.subnumber*
    - Enter Reth subinterface view.

      interface reth *interface-number.subnumber*
3. Configure default termination.

   vlan-type dot1q default

   By default, default termination is disabled on a subinterface.

Enabling a VLAN termination-enabled interface to transmit broadcasts and multicasts

About this task

This function enables ambiguous Dot1q termination-enabled interfaces to transmit broadcasts and multicasts.

To transmit a broadcast or multicast packet, the interface starts a traversal over the VLAN IDs specified for ambiguous termination. It copies the packet and tags each copy with a VLAN ID, until all VLAN IDs in the specified range are traversed.

Restrictions and guidelines

As a best practice, use the **vlan-termination broadcast ra** command to enable an ambiguous Dot1q termination-enabled interface to transmit RA multicast packets on an IPv6 network. This command prohibits transmission of broadcast packets and other types of multicast packets, and consumes less CPU resources than the **vlan-termination broadcast enable** command.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 3 Ethernet subinterface view.
     interface *interface-type interface-number.subnumber*
   - Enter Layer 3 aggregate subinterface view.
     interface route-aggregation *interface-number.subnumber*
   - Enter Reth subinterface view.
     interface reth *interface-number.subnumber*
3. Enable the interface to transmit broadcasts and multicasts.
   - Enable the interface to transmit broadcasts and multicasts.
     vlan-termination broadcast enable
   - Enable the interface to transmit only RA multicasts on an IPv6 network.
     vlan-termination broadcast ra

   By default, an ambiguous Dot1q termination-enabled interface does not transmit broadcasts and multicasts.

Configuring the TPID for VLAN-tagged packets

About this task

TPID identifies whether or not a frame contains VLAN tags. By default, the value of 0x8100 identifies an IEEE 802.1Q-tagged frame. You can set another TPID value to identify VLAN-tagged packets.

To work with VLAN termination on a subinterface, set the TPID value in the outermost VLAN tag of packets on the main interface of the subinterface. If VLAN termination is enabled on a VLAN interface, set the TPID value in the outermost VLAN tag of packets on the same VLAN interface.

The interface processes packets as untagged packets if their outermost VLAN tag is not 0x8100 or the configured value.

When sending a packet, the interface sets the TPID value in the outermost VLAN tag to the configured value. If the packet includes two or more layers of VLAN tags, the interface sets the TPID values to 0x8100 in all VLAN tags except the outermost VLAN tag.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 3 Ethernet interface view.

    interface interface-*type* *interface-number*

    - Enter Layer 3 aggregate interface view.

      interface route-aggregation *interface-number*

    - Enter Reth subinterface view.

      interface reth *interface-number.subnumber*

3. Set the TPID value in the outermost VLAN tag of packets received and sent by the interface.

   dot1q ethernet-type *hex-value*

   The default setting is 0x8100.

Spanning tree protocol overview

Spanning tree protocols eliminate loops in a physical link-redundant network by selectively blocking redundant links and putting them in a standby state.

The recent versions of STP include the Rapid Spanning Tree Protocol (RSTP), the Per-VLAN Spanning Tree (PVST), and the Multiple Spanning Tree Protocol (MSTP).

About STP

STP was developed based on the 802.1d standard of IEEE to eliminate loops at the data link layer in a LAN. Networks often have redundant links as backups in case of failures, but loops are a very serious problem. Devices running STP detect loops in the network by exchanging information with one another. They eliminate loops by selectively blocking certain ports to prune the loop structure into a loop-free tree structure. This avoids proliferation and infinite cycling of packets that would occur in a loop network.

In a narrow sense, STP refers to IEEE 802.1d STP. In a broad sense, STP refers to the IEEE 802.1d STP and various enhanced spanning tree protocols derived from that protocol.

STP protocol frames

STP uses bridge protocol data units (BPDUs), also known as configuration messages, as its protocol frames. This chapter uses BPDUs to represent all types of spanning tree protocol frames.

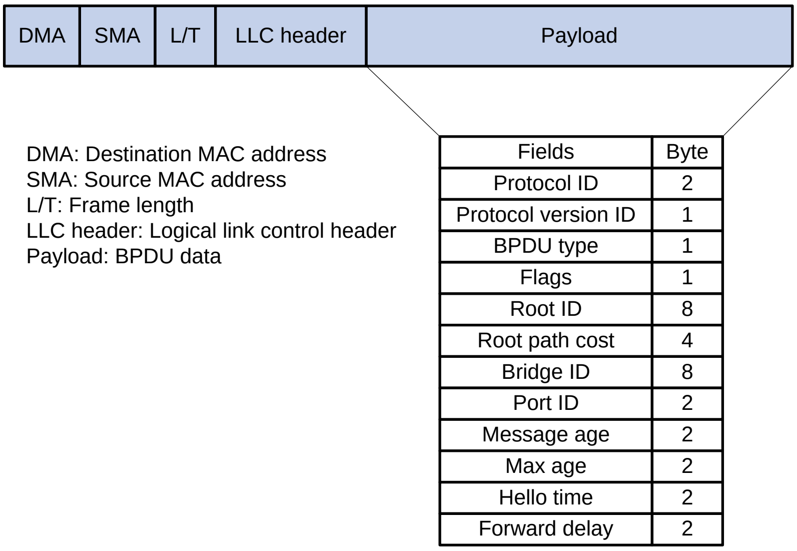
STP-enabled devices exchange BPDUs to establish a spanning tree. BPDUs contain sufficient information for the devices to complete spanning tree calculation.

STP uses two types of BPDUs, configuration BPDUs and topology change notification (TCN) BPDUs.

Configuration BPDUs

Devices exchange configuration BPDUs to elect the root bridge and determine port roles. Figure 1 shows the configuration BPDU format.

Figure 1 Configuration BPDU format



DMA: Destination MAC address
SMA: Source MAC address
L/T: Frame length
LLC header: Logical link control header
Payload: BPDU data

Fields	Byte
Protocol ID	2
Protocol version ID	1
BPDU type	1
Flags	1
Root ID	8
Root path cost	4
Bridge ID	8
Port ID	2
Message age	2
Max age	2
Hello time	2
Forward delay	2

The payload of a configuration BPDU includes the following fields:

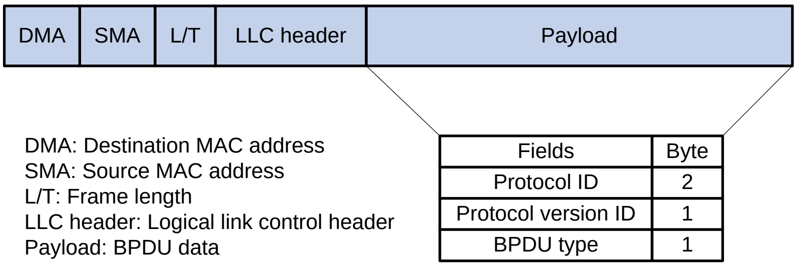
- **Protocol ID**—Fixed at 0x0000, which represents IEEE 802.1d.
- **Protocol version ID**—Spanning tree protocol version ID. The protocol version ID for STP is 0x00.
- **BPDU type**—Type of the BPDU. The value is 0x00 for a configuration BPDU.
- **Flags**—An 8-bit field indicates the purpose of the BPDU. The lowest bit is the Topology Change (TC) flag. The highest bit is the Topology Change Acknowledge (TCA) flag. All other bits are reserved.
- **Root ID**—Root bridge ID formed by the priority and MAC address of the root bridge.
- **Root path cost**—Cost of the path to the root bridge.
- **Bridge ID**—Designated bridge ID formed by the priority and MAC address of the designated bridge.
- **Port ID**—Designated port ID formed by the priority and global port number of the designated port.
- **Message age**—Age of the configuration BPDU while it propagates in the network.
- **Max age**—Maximum age of the configuration BPDU stored on the switch.
- **Hello time**—Configuration BPDU transmission interval.
- **Forward delay**—Delay for STP bridges to transit port state.

Devices use the root bridge ID, root path cost, designated bridge ID, designated port ID, message age, max age, hello time, and forward delay for spanning tree calculation.

TCN BPDUs

Devices use TCN BPDUs to announce changes in the network topology. Figure 2 shows the TCN BPDU format.

Figure 2 TCN BPDU format



DMA: Destination MAC address
SMA: Source MAC address
L/T: Frame length
LLC header: Logical link control header
Payload: BPDU data

Fields	Byte
Protocol ID	2
Protocol version ID	1
BPDU type	1

The payload of a TCN BPDU includes the following fields:

- **Protocol ID**—Fixed at 0x0000, which represents IEEE 802.1d.
- **Protocol version ID**—Spanning tree protocol version ID. The protocol version ID for STP is 0x00.
- **BPDU type**—Type of the BPDU. The value is 0x80 for a TCN BPDU.

A non-root bridge sends TCN BPDUs when one of the following events occurs on the bridge:

- A port transits to the forwarding state, and the bridge has a minimum of one designated port.
- A port transits from the forwarding or learning state to the blocking state.

The non-root bridge uses TCN BPDUs to notify the root bridge once the network topology changes. The root bridge then sets the TC flag in its configuration BPDU and propagates it to other bridges.

Basic concepts in STP

Root bridge

A tree network must have a root bridge. The entire network contains only one root bridge, and all the other bridges in the network are called leaf nodes. The root bridge is not permanent, but can change with changes of the network topology.

Upon initialization of a network, each device generates and periodically sends configuration BPDUs, with itself as the root bridge. After network convergence, only the root bridge generates and periodically sends configuration BPDUs. The other devices only forward the BPDUs.

Root port

On a non-root bridge, the port nearest to the root bridge is the root port. The root port communicates with the root bridge. Each non-root bridge has only one root port. The root bridge has no root port.

Designated bridge and designated port

Classification	Designated bridge	Designated port
For a device	Device directly connected to the local device and responsible for forwarding BPDUs to the local device.	Port through which the designated bridge forwards BPDUs to this device.
For a LAN	Device responsible for forwarding BPDUs to this LAN segment.	Port through which the designated bridge forwards BPDUs to this LAN segment.

As shown in Figure 3, Device B and Device C are directly connected to a LAN.

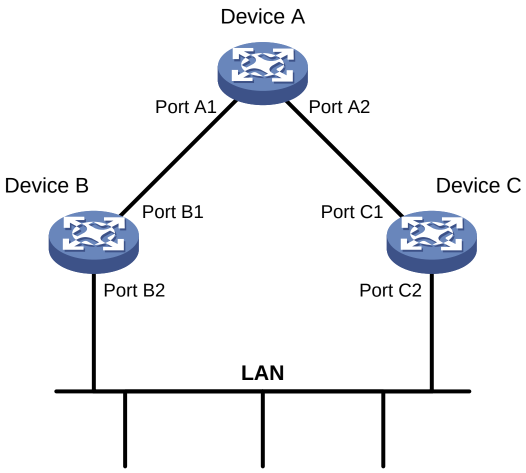
If Device A forwards BPDUs to Device B through port A1, the designated bridge and designated port are as follows:

- The designated bridge for Device B is Device A.
- The designated port for Device B is port A1 on Device A.

If Device B forwards BPDUs to the LAN, the designated bridge and designated port are as follows:

- The designated bridge for the LAN is Device B.
- The designated port for the LAN is port B2 on Device B.

Figure 3 Designated bridges and designated ports



Port states

Table 1 lists the port states in STP.

Table 1 STP port states

State	Receives/sends BPDUs	Learns MAC addresses	Forwards user data
Disabled	No	No	No
Listening	Yes	No	No
Learning	Yes	Yes	No
Forwarding	Yes	Yes	Yes
Blocking	Receive	No	No

Path cost

Path cost is a reference value used for link selection in STP. To prune the network into a loop-free tree, STP calculates path costs to select the most robust links and block redundant links that are less robust.

Calculation process of the STP algorithm

In STP calculation, a device compares the priorities of the received configuration BPDUs from different ports, and elects the root bridge, root ports and designated ports. When the spanning tree calculation is completed, a tree-shape topology forms.

The spanning tree calculation process described in the following sections is an example of a simplified process.

Network initialization

Upon initialization of a device, each port generates a BPDU with the following contents:

- The port as the designated port.
- The device as the root bridge.
- 0 as the root path cost.
- The device ID as the designated bridge ID.

Root bridge selection

The root bridge can be selected in the following methods:

- **Automatic election**—Initially, each STP-enabled device on the network assumes itself to be the root bridge, with its own device ID as the root bridge ID. By exchanging configuration BPDUs, the devices compare their root bridge IDs to elect the device with the smallest root bridge ID as the root bridge.
- **Manual assignment**—You can configure a device as the root bridge or a secondary root bridge of a spanning tree.
    - A spanning tree can have only one root bridge. If you configure multiple devices as the root bridge for a spanning tree, the device with the lowest MAC address is selected.
    - You can configure one or multiple secondary root bridges for a spanning tree. When the root bridge fails or is shut down, a secondary root bridge can take over. If multiple secondary root bridges are configured, the one with the lowest MAC address is selected. However, if a new root bridge is configured, the secondary root bridge is not selected.

Root port and designated ports selection on the non-root bridges

Step	Description
1	A non-root-bridge device regards the port on which it received the optimum configuration BPDU as the root port. Table 2 describes how the optimum configuration BPDU is selected.

Step	Description
2	Based on the configuration BPDU and the path cost of the root port, the device calculates a designated port configuration BPDU for each of the other ports. • The root bridge ID is replaced with that of the configuration BPDU of the root port. • The root path cost is replaced with that of the configuration BPDU of the root port plus the path cost of the root port. • The designated bridge ID is replaced with the ID of this device. • The designated port ID is replaced with the ID of this port.
3	The device compares the calculated configuration BPDU with the configuration BPDU on the port whose port role will be determined. Then, the device acts depending on the result of the comparison: • If the calculated configuration BPDU is superior, the device performs the following operations: ○ Considers this port as the designated port. ○ Replaces the configuration BPDU on the port with the calculated configuration BPDU. ○ Periodically sends the calculated configuration BPDU. • If the configuration BPDU on the port is superior, the device blocks this port without updating its configuration BPDU. The blocked port can receive BPDUs, but cannot send BPDUs or forward data traffic.

When the network topology is stable, only the root port and designated ports forward user traffic. Other ports are all in the blocking state to receive BPDUs but not to forward BPDUs or user traffic.

Table 2 Selecting the optimum configuration BPDU

Step	Actions
1	Upon receiving a configuration BPDU on a port, the device compares the priority of the received configuration BPDU with that of the configuration BPDU generated by the port. • If the former priority is lower, the device discards the received configuration BPDU and keeps the configuration BPDU the port generated. • If the former priority is higher, the device replaces the content of the configuration BPDU generated by the port with the content of the received configuration BPDU.
2	The device compares the configuration BPDUs of all the ports and chooses the optimum configuration BPDU.

The following are the principles of configuration BPDU comparison:

1. The configuration BPDU with the lowest root bridge ID has the highest priority.
2. If configuration BPDUs have the same root bridge ID, their root path costs are compared. For example, the root path cost in a configuration BPDU plus the path cost of a receiving port is S. The configuration BPDU with the smallest S value has the highest priority.
3. If all configuration BPDUs have the same root bridge ID and S value, the following attributes are compared in sequence:
    a. Designated bridge IDs.
    b. Designated port IDs.
    c. IDs of the receiving ports.

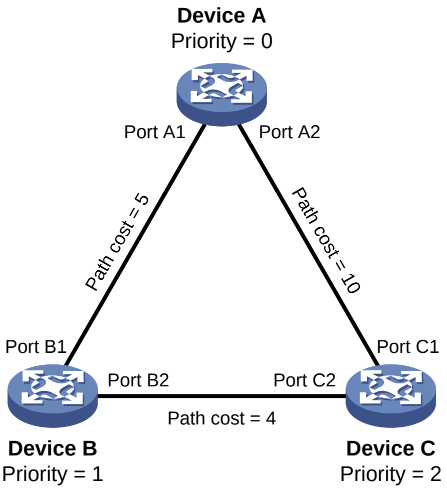
    The configuration BPDU that contains a smaller designated bridge ID, designated port ID, or receiving port ID is selected.

A tree-shape topology forms when the root bridge, root ports, and designated ports are selected.

Example of STP calculation

Figure 4 provides an example showing how the STP algorithm works.

Figure 4 The STP algorithm



As shown in Figure 4, the priority values of Device A, Device B, and Device C are 0, 1, and 2, respectively. The path costs of links among the three devices are 5, 10, and 4.

Device state initialization

In Table 3, each configuration BPDU contains the following fields: root bridge ID, root path cost, designated bridge ID, and designated port ID.

Table 3 Initial state of each device

Device	Port name	Configuration BPDU on the port
Device A	Port A1	{0, 0, 0, Port A1}
	Port A2	{0, 0, 0, Port A2}
Device B	Port B1	{1, 0, 1, Port B1}
	Port B2	{1, 0, 1, Port B2}
Device C	Port C1	{2, 0, 2, Port C1}
	Port C2	{2, 0, 2, Port C2}

Configuration BPDUs comparison on each device

In Table 4, each configuration BPDU contains the following fields: root bridge ID, root path cost, designated bridge ID, and designated port ID.

Table 4 Comparison process and result on each device

Device	Comparison process	Configuration BPDU on ports after comparison
Device A	Port A1 performs the following operations: **1.** Receives the configuration BPDU of Port B1 {1, 0, 1, Port B1}. **2.** Determines that its existing configuration BPDU {0, 0, 0, Port A1} is superior to the received configuration BPDU. **3.** Discards the received one. Port A2 performs the following operations: **1.** Receives the configuration BPDU of Port C1 {2, 0, 2, Port C1}. **2.** Determines that its existing configuration BPDU {0, 0, 0, Port A2} is superior to the received configuration BPDU. **3.** Discards the received one. Device A determines that it is both the root bridge and designated bridge in the configuration BPDUs of all its ports. It considers itself as the root bridge. It does not change the configuration BPDU of any port and starts to periodically send configuration BPDUs.	• Port A1: {0, 0, 0, Port A1} • Port A2: {0, 0, 0, Port A2}
Device B	Port B1 performs the following operations: **4.** Receives the configuration BPDU of Port A1 {0, 0, 0, Port A1}. **5.** Determines that the received configuration BPDU is superior to its existing configuration BPDU {1, 0, 1, Port B1}. **6.** Updates its configuration BPDU. Port B2 performs the following operations: **1.** Receives the configuration BPDU of Port C2 {2, 0, 2, Port C2}. **2.** Determines that its existing configuration BPDU {1, 0, 1, Port B2} is superior to the received configuration BPDU. **3.** Discards the received BPDU.	• Port B1: {0, 0, 0, Port A1} • Port B2: {1, 0, 1, Port B2}
	Device B performs the following operations: **1.** Compares the configuration BPDUs of all its ports. **2.** Decides that the configuration BPDU of Port B1 is the optimum. **3.** Selects Port B1 as the root port with the configuration BPDU unchanged. Based on the configuration BPDU and path cost of the root port, Device B calculates a designated port configuration BPDU for Port B2 {0, 5, 1, Port B2}. Device B compares it with the existing configuration BPDU of Port B2 {1, 0, 1, Port B2}. Device B determines that the calculated one is superior, and determines that Port B2 is the designated port. It replaces the configuration BPDU on Port B2 with the calculated one, and periodically sends the calculated configuration BPDU.	• Root port (Port B1): {0, 0, 0, Port A1} • Designated port (Port B2): {0, 5, 1, Port B2}
Device C	Port C1 performs the following operations: **1.** Receives the configuration BPDU of Port A2 {0, 0, 0, Port A2}. **2.** Determines that the received configuration BPDU is superior to its existing configuration BPDU {2, 0, 2,	• Port C1: {0, 0, 0, Port A2} • Port C2: {1, 0, 1, Port B2}

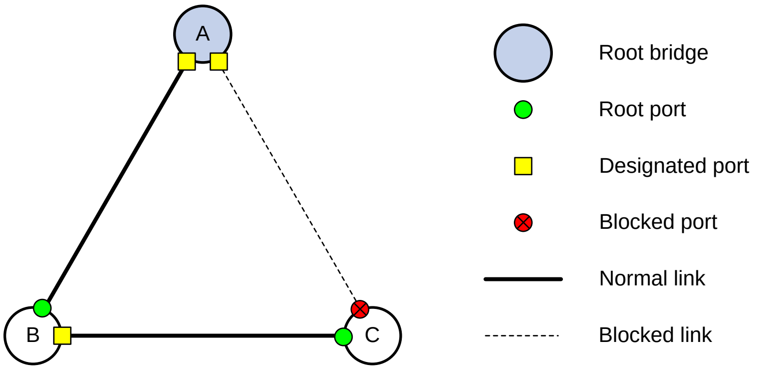
Device	Comparison process	Configuration BPDU on ports after comparison
	Port C1}. **3.** Updates its configuration BPDU. Port C2 performs the following operations: **1.** Receives the original configuration BPDU of Port B2 {1, 0, 1, Port B2}. **2.** Determines that the received configuration BPDU is superior to the existing configuration BPDU {2, 0, 2, Port C2}. **3.** Updates its configuration BPDU.	
	Device C performs the following operations: **1.** Compares the configuration BPDUs of all its ports. **2.** Decides that the configuration BPDU of Port C1 is the optimum. **3.** Selects Port C1 as the root port with the configuration BPDU unchanged. Based on the configuration BPDU and path cost of the root port, Device C calculates the configuration BPDU of Port C2 {0, 10, 2, Port C2}. Device C compares it with the existing configuration BPDU of Port C2 {1, 0, 1, Port B2}. Device C determines that the calculated configuration BPDU is superior to the existing one, selects Port C2 as the designated port, and replaces the configuration BPDU of Port C2 with the calculated one.	• Root port (Port C1): {0, 0, 0, Port A2} • Designated port (Port C2): {0, 10, 2, Port C2}
	Port C2 performs the following operations: **1.** Receives the updated configuration BPDU of Port B2 {0, 5, 1, Port B2}. **2.** Determines that the received configuration BPDU is superior to its existing configuration BPDU {0, 10, 2, Port C2}. **3.** Updates its configuration BPDU. Port C1 performs the following operations: **1.** Receives a periodic configuration BPDU {0, 0, 0, Port A2} from Port A2. **2.** Determines that it is the same as the existing configuration BPDU. **3.** Discards the received BPDU.	• Port C1: {0, 0, 0, Port A2} • Port C2: {0, 5, 1, Port B2}
	Device C determines that the root path cost of Port C1 is larger than that of Port C2. The root path cost of Port C1 is 10, root path cost of the received configuration BPDU (0) plus path cost of Port C1 (10). The root path cost of Port C2 is 9, root path cost of the received configuration BPDU (5) plus path cost of Port C2 (4). Device C determines that the configuration BPDU of Port C2 is the optimum, and selects Port C2 as the root port with the configuration BPDU unchanged. Based on the configuration BPDU and path cost of the root port, Device C performs the following operations: **1.** Calculates a designated port configuration BPDU for Port C1 {0, 9, 2, Port C1}. **2.** Compares it with the existing configuration BPDU of Port C1 {0, 0, 0, Port A2}. **3.** Determines that the existing configuration BPDU is superior to the calculated one and blocks Port C1 with the configuration BPDU unchanged. Port C1 does not forward data until a new event triggers a	• Blocked port (Port C1): {0, 0, 0, Port A2} • Root port (Port C2): {0, 5, 1, Port B2}

Device	Comparison process	Configuration BPDU on ports after comparison
	spanning tree calculation process: for example, the link between Device B and Device C is down.	

Final calculated spanning tree

After the comparison processes described in Table 4, a spanning tree with Device A as the root bridge is established, as shown in Figure 5.

Figure 5 The final calculated spanning tree



The configuration BPDU forwarding mechanism of STP

The configuration BPDUs of STP are forwarded according to these guidelines:

- Upon network initiation, every device regards itself as the root bridge and generates configuration BPDUs with itself as the root. Then it sends the configuration BPDUs at a regular hello interval.
- If the root port receives a configuration BPDU superior to the configuration BPDU of the port, the device performs the following operations:
  - Increases the message age carried in the configuration BPDU.
  - Starts a timer to time the configuration BPDU.
  - Sends this configuration BPDU through the designated port.
- If a designated port receives a configuration BPDU with a lower priority than its configuration BPDU, the port immediately responds with its configuration BPDU.
- If a path fails, the root port on this path no longer receives new configuration BPDUs and the old configuration BPDUs will be discarded due to timeout. The device generates a configuration BPDU with itself as the root and sends the BPDUs and TCN BPDUs. This triggers a new spanning tree calculation process to establish a new path to restore the network connectivity.

However, the newly calculated configuration BPDU cannot be propagated throughout the network immediately. As a result, the old root ports and designated ports that have not detected the topology change continue forwarding data along the old path. If the new root ports and designated ports begin to forward data as soon as they are elected, a temporary loop might occur.

STP timers

The most important timing parameters in STP calculation are forward delay, hello time, and max age.

- Forward delay

  Forward delay is the delay time for port state transition. By default, the forward delay is 15 seconds.

  A path failure can cause spanning tree re-calculation to adapt the spanning tree structure to the change. However, the resulting new configuration BPDU cannot propagate throughout the network immediately. If the newly elected root ports and designated ports start to forward data immediately, a temporary loop will likely occur.

  The newly elected root ports or designated ports must go through the listening and learning states before they transit to the forwarding state. This requires twice the forward delay time and allows the new configuration BPDU to propagate throughout the network.

- Hello time

  The device sends configuration BPDUs at the hello time interval to the neighboring devices to ensure that the paths are fault-free. By default, the hello time is 2 seconds. If the device does not receive configuration BPDUs within the timeout period, it recalculates the spanning tree. The formula for calculating the timeout period is timeout period = timeout factor × 3 × hello time.

- Max age

  The device uses the max age to determine whether a stored configuration BPDU has expired and discards it if the max age is exceeded. By default, the max age is 20 seconds. In the CIST of an MSTP network, the device uses the max age timer to determine whether a configuration BPDU received by a port has expired. If it is expired, a new spanning tree calculation process starts. The max age timer does not take effect on MSTIs.

If a port does not receive any configuration BPDUs within the timeout period, the port transits to the listening state. The device will recalculate the spanning tree. It takes the port 50 seconds to transit back to the forwarding state. This period includes 20 seconds for the max age, 15 seconds for the listening state, and 15 seconds for the learning state.

To ensure a fast topology convergence, make sure the timer settings meet the following formulas:

- 2 × (forward delay – 1 second) ≥ max age
- Max age ≥ 2 × (hello time + 1 second)

About RSTP

RSTP achieves rapid network convergence by allowing a newly elected root port or designated port to enter the forwarding state much faster than STP.

RSTP protocol frames

An RSTP BPDU uses the same format as an STP BPDU except that a Version1 length field is added to the payload of RSTP BPDUs. The differences between an RSTP BPDU and an STP BPDU are as follows:

- **Protocol version ID**—The value is 0x02 for RSTP.
- **BPDU type**—The value is 0x02 for RSTP BPDUs.
- **Flags**—All 8 bits are used.
- **Version1 length**—The value is 0x00, which means no version 1 protocol information is present.

RSTP does not use TCN BPDUs to advertise topology changes. RSTP floods BPDUs with the TC flag set in the network to advertise topology changes.

Basic concepts in RSTP

Port roles

In addition to root port and designated port, RSTP also uses the following port roles:

- **Alternate port**—Acts as the backup port for a root port. When the root port is blocked, the alternate port takes over.
- **Backup port**—Acts as the backup port of a designated port. When the designated port is invalid, the backup port becomes the new designated port. A loop occurs when two ports of the same spanning tree device are connected, so the device blocks one of the ports. The blocked port is the backup port.
- **Edge port**—Directly connects to a user host rather than a network device or network segment.

Port states

RSTP uses the discarding state to replace the disabled, blocking, and listening states in STP. Table 5 shows the differences between the port states in RSTP and STP.

Table 5 Port state differences between RSTP and STP

STP port state	RSTP port state	Sends BPDU	Learns MAC addresses	Forwards user data
Disabled	Discarding	No	No	No
Blocking	Discarding	No	No	No
Listening	Discarding	Yes	No	No
Learning	Learning	Yes	Yes	No
Forwarding	Forwarding	Yes	Yes	Yes

How RSTP works

During RSTP calculation, the following events occur:

- If a port in discarding state becomes an alternate port, it retains its state.
- If a port in discarding state is elected as the root port or designated port, it enters the learning state after the forward delay. The port learns MAC addresses, and enters the forwarding state after another forward delay.
    - A newly elected RSTP root port rapidly enters the forwarding state if the following requirements are met:
        - The old root port on the device has stopped forwarding data.
        - The upstream designated port has started forwarding data.
    - A newly elected RSTP designated port rapidly enters the forwarding state if one of the following requirements is met:
        - The designated port is configured as an edge port which directly connects to a user terminal.
        - The designated port connects to a point-to-point link and receives a handshake response from the directly connected device.

RSTP BPDU processing

In RSTP, a non-root bridge actively sends RSTP BPDUs at the hello time through designated ports without waiting for the root bridge to send RSTP BPDUs. This enables RSTP to quickly detect link failures. If a device fails to receive any RSTP BPDUs on a port within triple the hello time, the device considers that a link failure has occurred. After the stored configuration BPDU expires, the device floods RSTP BPDUs with the TC flag set to initiate a new RSTP calculation.

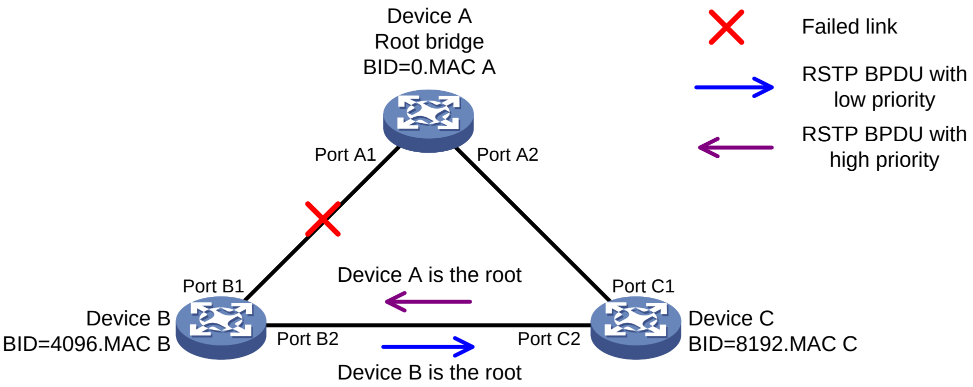
In RSTP, a port in blocking state can immediately respond to an RSTP BPDU with a lower priority than its own BPDU.

As shown in Figure 6, Device A is the root bridge. The priority of Device B is higher than the priority of Device C. Port C2 on Device C is blocked.

When the link between Device A and Device B fails, the following events occur:

1. Device B sends an RSTP BPDU with itself as the root bridge to Device C.
2. Device C compares the RSTP BPDU with its own BPDU.
3. Because the RSTP BPDU from Device B has a lower priority, Device C sends its own BPDU to Device B.
4. Device B considers that Port B2 is the root port and stops sending RSTP BPDUs to Device C.

Figure 6 BPDU processing in RSTP



About PVST

In an STP- or RSTP-enabled LAN, all bridges share one spanning tree. Traffic from all VLANs is forwarded along the spanning tree, and ports cannot be blocked on a per-VLAN basis to prune loops.

PVST allows every VLAN to have its own spanning tree, which increases usage of links and bandwidth. Because each VLAN runs RSTP independently, a spanning tree only serves its VLAN.

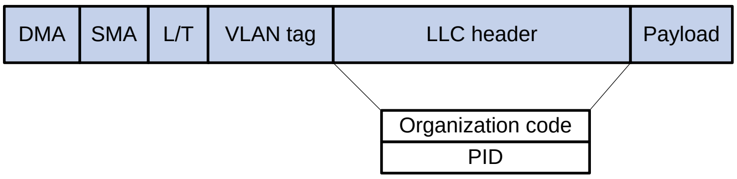
A PVST-enabled NSFOCUS device can communicate with a third-party device that is running Rapid PVST or PVST. The PVST-enabled NSFOCUS device supports fast network convergence like RSTP when connected to PVST-enabled NSFOCUS devices or third-party devices enabled with Rapid PVST.

PVST protocol frames

As shown in Figure 7, a PVST BPDU uses the same format as an RSTP BPDU except the following differences:

- The destination MAC address of a PVST BPDU is 01-00-0c-cc-cc-cd, which is a private MAC address.
- Each PVST BPDU carries a VLAN tag. The VLAN tag identifies the VLAN to which the PVST BPDU belongs.
- The organization code and PID fields are added to the LLC header of the PVST BPDU.

Figure 7 PVST BPDU format



A port's link type determines the type of BPDUs the port sends.

- An access port sends RSTP BPDUs.
- A trunk or hybrid port sends RSTP BPDUs in the default VLAN and sends PVST BPDUs in other VLANs.

How PVST works

PVST implements per-VLAN spanning tree calculation by mapping each VLAN to an MSTI. In PVST, each VLAN runs RSTP independently to maintain its own spanning tree without affecting the spanning trees of other VLANs. In this way, loops in each VLAN are eliminated and traffic of different VLANs is load shared over links. PVST uses RSTP BPDUs in the default VLAN and PVST BPDUs in other VLANs for spanning tree calculation.

PVST uses the same port roles and port states as RSTP for rapid transition. For more information, see "Basic concepts in RSTP."

About MSTP

MSTP features

Developed based on IEEE 802.1s, MSTP overcomes the limitations of STP, RSTP, and PVST. In addition to supporting rapid network convergence, it allows data flows of different VLANs to be forwarded along separate paths. This provides a better load sharing mechanism for redundant links.

MSTP provides the following features:

- MSTP divides a switched network into multiple regions, each of which contains multiple spanning trees that are independent of one another.
- MSTP supports mapping VLANs to spanning tree instances by means of a VLAN-to-instance mapping table. MSTP can reduce communication overheads and resource usage by mapping multiple VLANs to one instance.
- MSTP prunes a loop network into a loop-free tree, which avoids proliferation and endless cycling of frames in a loop network. In addition, it supports load balancing of VLAN data by providing multiple redundant paths for data forwarding.
- MSTP is compatible with STP and RSTP, and partially compatible with PVST.

MSTP protocol frames

Figure 8 shows the format of an MSTP BPDU.

Figure 8 MSTP BPDU format

Fields	Byte
Protocol ID	2
Protocol version ID	1
BPDU type	1
Flags	1
Root ID	8
Root path cost	4
Bridge ID	8
Port ID	2
Message age	2
Max age	2
Hello time	2
Forward delay	2
Version1 length=0	1
Version3 length	2
MST configuration ID	51
CIST IRPC	4
CIST bridge ID	8
CIST remaining ID	1
MSTI configuration messages	LEN

MSTP-specific fields

The first 13 fields of an MSTP BPDU are the same as an RSTP BPDU. The other six fields are unique to MSTP.

- **Protocol version ID**—The value is 0x03 for MSTP.
- **BPDU type**—The value is 0x02 for RSTP/MSTP BPDUs.
- **Root ID**—ID of the common root bridge.
- **Root path cost**—CIST external path cost.
- **Bridge ID**—ID of the regional root for the IST or an MSTI.
- **Port ID**—ID of the designated port in the CIST.
- **Version3 length**—Length of the MSTP-specific fields. Devices use this field for verification upon receiving an MSTP BPDU.
- **MST configuration ID**—Includes the format selector, configuration name, revision level, and configuration digest. The value for format selector is fixed at 0x00. The other parameters are used to identify the MST region for the originating bridge.
- **CIST IRPC**—Internal root path cost (IRPC) from the originating bridge to the root of the MST region.
- **CIST bridge ID**—ID of the bridge that sends the MSTP BPDU.
- **CIST remaining ID**—Remaining hop count. This field limits the scale of the MST region. The regional root sends a BPDU with the remaining hop count set to the maximum value. Each device that receives the BPDU decrements the hop count by one. When the hop count reaches zero, the BPDU is discarded. Devices beyond the maximum hops of the MST region cannot participate in spanning tree calculation. The default remaining hop count is 20.
- **MSTI configuration messages**—Contains MSTI configuration messages. Each MSTI configuration message is 16 bytes. This field can contain 0 to 64 MSTI configuration messages. The number of the MSTI configuration messages is determined by the number of MSTIs in the MST region.

Basic concepts in MSTP

Figure 9 shows a switched network that contains four MST regions, each MST region containing four MSTP devices. Figure 10 shows the networking topology of MST region 3.

Figure 9 Basic concepts in MSTP

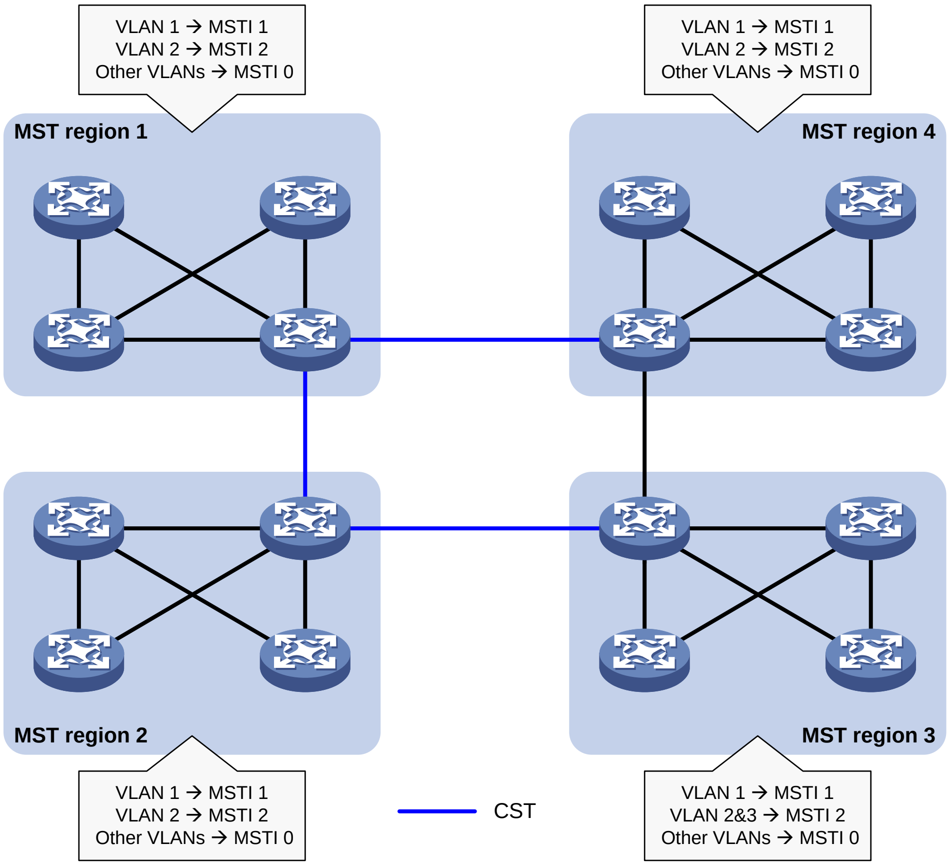


Figure 10 Network diagram and topology of MST region 3

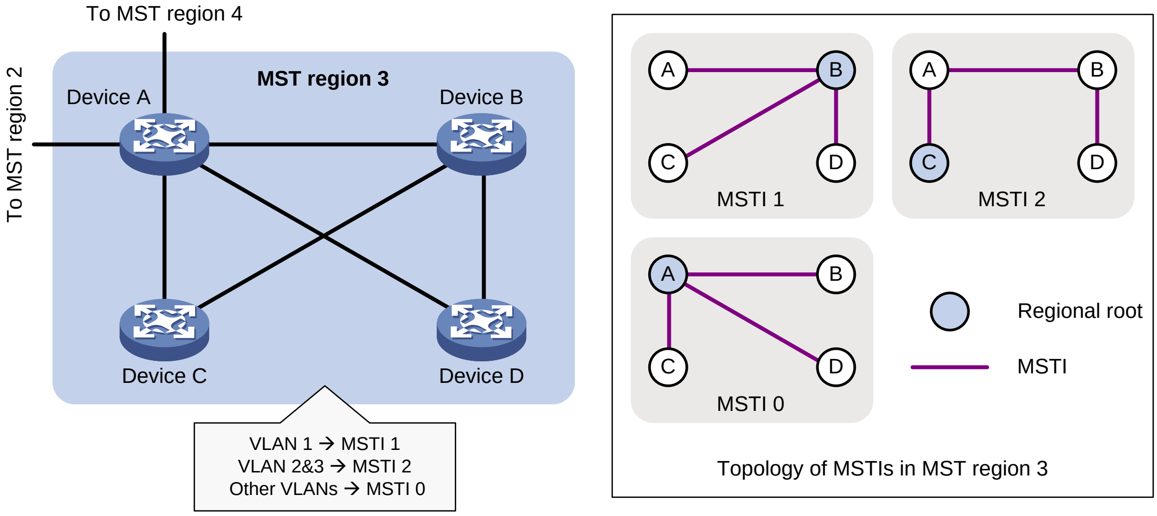


MST region

A multiple spanning tree region (MST region) consists of multiple devices in a switched network and the network segments among them. All these devices have the following characteristics:

- A spanning tree protocol enabled
- Same region name
- Same VLAN-to-instance mapping configuration
- Same MSTP revision level
- Physically linked together

Multiple MST regions can exist in a switched network. You can assign multiple devices to the same MST region, as shown in Figure 9.

- The switched network contains four MST regions, MST region 1 through MST region 4.
- All devices in each MST region have the same MST region configuration.

MSTI

MSTP can generate multiple independent spanning trees in an MST region, and each spanning tree is mapped to the specific VLANs. Each spanning tree is referred to as a multiple spanning tree instance (MSTI).

In Figure 10, MST region 3 contains three MSTIs, MSTI 1, MSTI 2, and MSTI 0.

VLAN-to-instance mapping table

As an attribute of an MST region, the VLAN-to-instance mapping table describes the mapping relationships between VLANs and MSTIs.

In Figure 10, the VLAN-to-instance mapping table of MST region 3 is as follows:

- VLAN 1 to MSTI 1.
- VLAN 2 and VLAN 3 to MSTI 2.
- Other VLANs to MSTI 0.

MSTP achieves load balancing by means of the VLAN-to-instance mapping table.

CST

The common spanning tree (CST) is a single spanning tree that connects all MST regions in a switched network. If you regard each MST region as a device, the CST is a spanning tree calculated by these devices through STP or RSTP.

The blue lines in Figure 9 represent the CST.

IST

An internal spanning tree (IST) is a spanning tree that runs in an MST region. It is also called MSTI 0, a special MSTI to which all VLANs are mapped by default.

In Figure 9, MSTI 0 is the IST in MST region 3.

CIST

The common and internal spanning tree (CIST) is a single spanning tree that connects all devices in a switched network. It consists of the ISTs in all MST regions and the CST.

In Figure 9, the ISTs (MSTI 0) in all MST regions plus the inter-region CST constitute the CIST of the entire network.

Regional root

The root bridge of the IST or an MSTI within an MST region is the regional root of the IST or MSTI. Based on the topology, different spanning trees in an MST region might have different regional roots, as shown in MST region 3 in Figure 10.

- The regional root of MSTI 1 is Device B.
- The regional root of MSTI 2 is Device C.
- The regional root of MSTI 0 (also known as the IST) is Device A.

Common root bridge

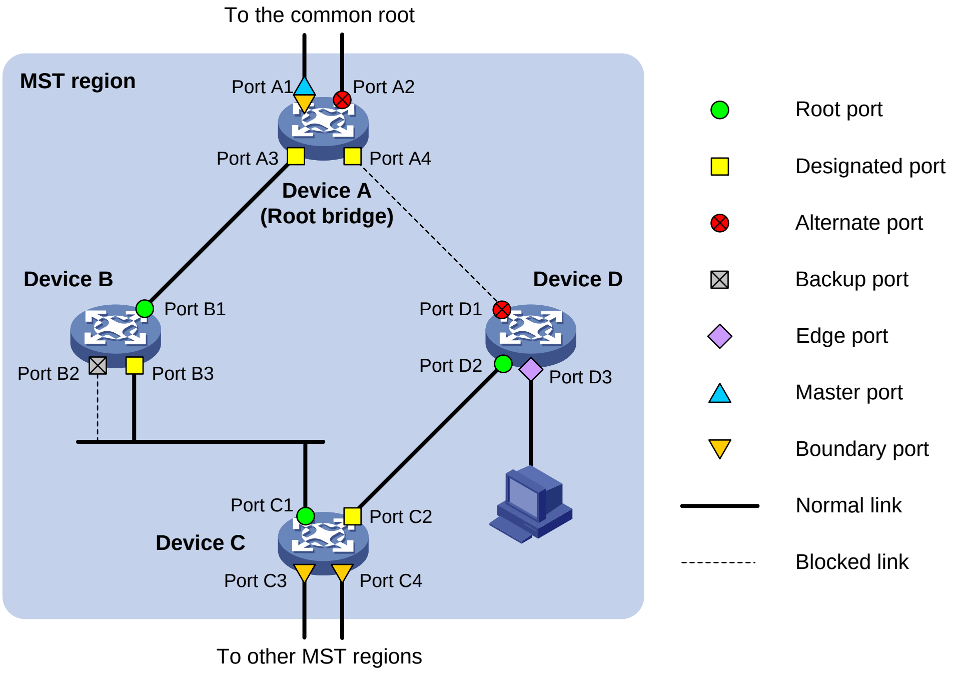
The common root bridge is the root bridge of the CIST.

In Figure 9, the common root bridge is a device in MST region 1.

Port roles

A port can play different roles in different MSTIs. As shown in Figure 11, an MST region contains Device A, Device B, Device C, and Device D. Port A1 and port A2 of Device A connect to the common root bridge. Port B2 and Port B3 of Device B form a loop. Port C3 and Port C4 of Device C connect to other MST regions. Port D3 of Device D directly connects to a host.

Figure 11 Port roles



MSTP calculation involves the following port roles:

- **Root port**—Forwards data for a non-root bridge to the root bridge. The root bridge does not have any root port.
- **Designated port**—Forwards data to the downstream network segment or device.
- **Alternate port**—Acts as the backup port for a root port or master port. When the root port or master port is blocked, the alternate port takes over.
- **Backup port**—Acts as the backup port of a designated port. When the designated port is invalid, the backup port becomes the new designated port. A loop occurs when two ports of the same spanning tree device are connected, so the device blocks one of the ports. The blocked port acts as the backup.
- **Edge port**—Directly connects to a user host rather than a network device or network segment.
- **Master port**—Acts as a port on the shortest path from the local MST region to the common root bridge. The master port is not always located on the regional root. It is a root port on the IST or CIST and still a master port on the other MSTIs.
- **Boundary port**—Connects an MST region to another MST region or to an STP/RSTP-running device. In MSTP calculation, a boundary port's role on an MSTI is consistent with its role on the

CIST. However, that is not true with master ports. A master port on MSTIs is a root port on the CIST.

Port states

In MSTP, a port can be in one of the following states:

- **Forwarding**—The port receives and sends BPDUs, learns MAC addresses, and forwards user traffic.
- **Learning**—The port receives and sends BPDUs, learns MAC addresses, but does not forward user traffic. Learning is an intermediate port state.
- **Discarding**—The port receives and sends BPDUs, but does not learn MAC addresses or forward user traffic.

NOTE:

When in different MSTIs, a port can be in different states.

A port state is not exclusively associated with a port role. Table 6 lists the port states that each port role supports. (A check mark [√] indicates that the port supports this state, while a dash [—] indicates that the port does not support this state.)

Table 6 Port states that different port roles support

Port role (right) Port state (below)	Root port/master port	Designated port	Alternate port	Backup port
Forwarding	√	√	—	—
Learning	√	√	—	—
Discarding	√	√	√	√

How MSTP works

MSTP divides an entire Layer 2 network into multiple MST regions, which are connected by a calculated CST. Inside an MST region, multiple spanning trees, called MSTIs, are calculated. Among these MSTIs, MSTI 0 is the IST.

Like STP, MSTP uses configuration BPDUs to calculate spanning trees. An important difference is that an MSTP BPDU carries the MSTP configuration of the bridge from which the BPDU is sent.

CIST calculation

During the CIST calculation, the following process takes place:

- The device with the highest priority is elected as the root bridge of the CIST.
- MSTP generates an IST within each MST region through calculation.
- MSTP regards each MST region as a single device and generates a CST among these MST regions through calculation.

The CST and ISTs constitute the CIST of the entire network.

MSTI calculation

Within an MST region, MSTP generates different MSTIs for different VLANs based on the VLAN-to-instance mappings. For each spanning tree, MSTP performs a separate calculation process similar to spanning tree calculation in STP. For more information, see "Calculation process of the STP algorithm."

In MSTP, a VLAN frame is forwarded along the following paths:

- Within an MST region, the frame is forwarded along the corresponding MSTI.
- Between two MST regions, the frame is forwarded along the CST.

MSTP implementation on devices

MSTP is compatible with STP and RSTP. Devices that are running MSTP and that are used for spanning tree calculation can identify STP and RSTP protocol frames.

In addition to basic MSTP features, the following features are provided for ease of management:

- Root bridge hold.
- Root bridge backup.
- Root guard.
- BPDU guard.
- Loop guard.
- TC-BPDU guard.
- Port role restriction.
- TC-BPDU transmission restriction.

Rapid transition mechanism

In STP, a port must wait twice the forward delay (30 seconds by default) before it transits from the blocking state to the forwarding state. The forward delay is related to the hello time and network diameter. If the forward delay is too short, loops might occur. This affects the stability of the network.

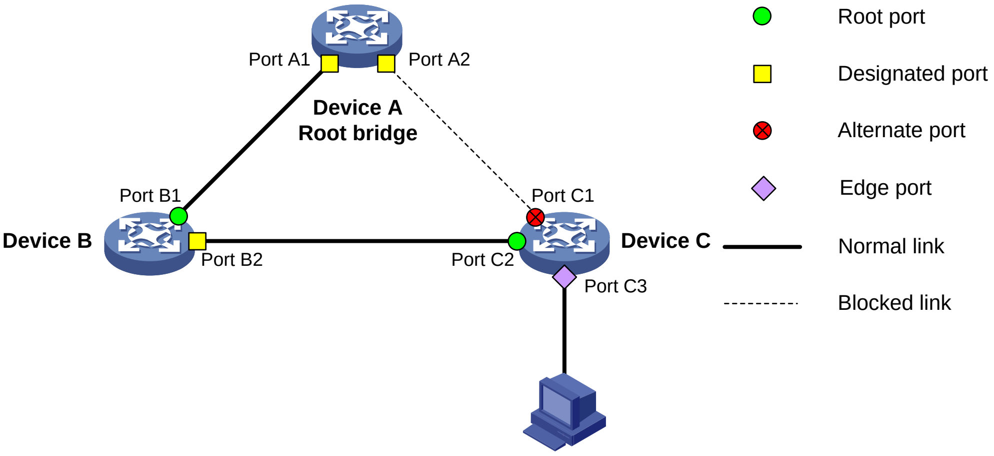
RSTP, PVST, and MSTP all use the rapid transition mechanism to speed up port state transition for edge ports, root ports, and designated ports. The rapid transition mechanism for designated ports is also known as the proposal/agreement (P/A)_transition.

Edge port rapid transition

As shown in Figure 12, Port C3 is an edge port connected to a host. When a network topology change occurs, the port can immediately transit from the blocking state to the forwarding state because no loop will be caused.

Because a device cannot determine whether a port is directly connected to a terminal, you must manually configure the port as an edge port.

Figure 12 Edge port rapid transition

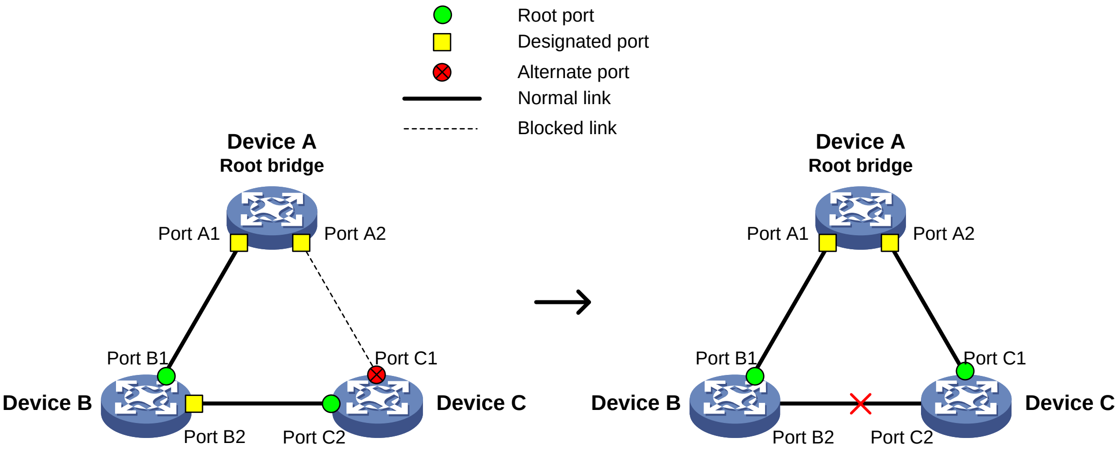


Root port rapid transition

When a root port is blocked, the bridge will elect the alternate port with the highest priority as the new root port. If the new root port's peer is in the forwarding state, the new root port immediately transits to the forwarding state.

As shown in Figure 13, Port C2 on Device C is a root port and Port C1 is an alternate port. When Port C2 transits to the blocking state, Port C1 is elected as the root port and immediately transits to the forwarding state.

Figure 13 Root port rapid transition



P/A transition

The P/A transition enables a designated port to rapidly transit to the forwarding state after a handshake with its peer. The P/A transition applies only to point-to-point links.

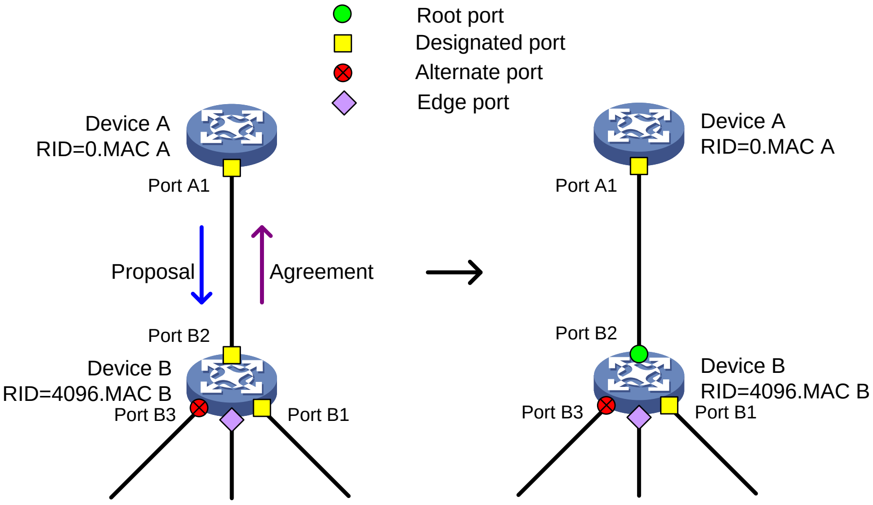
P/A transition for RSTP and PVST

In RSTP or PVST, the ports on a new link or recovered link are designated ports in blocking state. When one of the designated ports transits to the discarding or learning state, it sets the proposal flag in its BPDU. Its peer bridge receives the BPDU and determines whether the receiving port is the root port. If it is the root port, the bridge blocks the other ports except edge ports. The bridge then replies an agreement BPDU to the designated port. The designated port immediately transits to the forwarding state upon receiving the agreement BPDU. If the designated port does not receive the agreement BPDU, it waits for twice the forward delay to transit to the forwarding state.

As shown in Figure 14, the P/A transition operates as follows:

1. Device A sends a proposal BPDU to Device B through Port A1.
2. Device B receives the proposal BPDU on Port B2. Port B2 is elected as the root port.
3. Device B blocks its designated port Port B1 and alternate port Port B3 to eliminate loops.
4. The root port Port B2 transits to the forwarding state and sends an agreement BPDU to Device A.
5. The designated port Port A1 on Device A immediately transits to the forwarding state after receiving the agreement BPDU.

Figure 14 P/A transition for RSTP and PVST



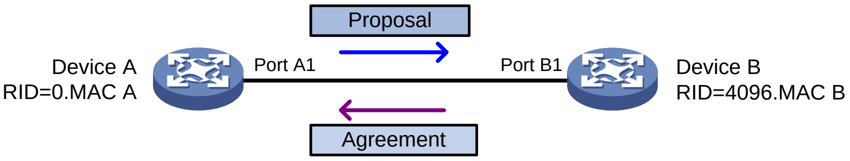
P/A transition for MSTP.

In MSTP, an upstream bridge sets both the proposal and agreement flags in its BPDU. If a downstream bridge receives the BPDU and its receiving port is elected as the root port, the bridge blocks all the other ports except edge ports. The downstream bridge then replies an agreement BPDU to the upstream bridge. The upstream port immediately transits to the forwarding state upon receiving the agreement BPDU. If the upstream port does not receive the agreement BPDU, it waits for twice the forward delay to transit to the forwarding state.

As shown in Figure 15, the P/A transition operates as follows:

1. Device A sets the proposal and agreement flags in its BPDU and sends it to Device B through Port A1.
2. Device B receives the BPDU. Port B1 of Device B is elected as the root port.
3. Device B then blocks all its ports except the edge ports.
4. The root port Port B1 of Device B transits to the forwarding state and sends an agreement BPDU to Device A.
5. Port A1 of Device A immediately transits to the forwarding state upon receiving the agreement BPDU.

Figure 15 P/A transition for MSTP



Protocols and standards

MSTP is documented in the following protocols and standards:

- IEEE 802.1d, *Media Access Control (MAC) Bridges*
- IEEE 802.1w, *Part 3: Media Access Control (MAC) Bridges—Amendment 2: Rapid Reconfiguration*
- IEEE 802.1s, *Virtual Bridged Local Area Networks—Amendment 3: Multiple Spanning Trees*

- IEEE 802.1Q-REV/D1.3, *Media Access Control (MAC) Bridges and Virtual Bridged Local Area Networks —Clause 13: Spanning tree Protocols*

Configuring spanning tree protocols

Restrictions and guidelines: spanning tree protocol configuration

Restrictions: Interface configuration

- Some spanning tree features are supported in Layer 2 Ethernet interface view and Layer 2 aggregate interface view. Unless otherwise stated, these views are collectively referred to as interface view in this document. .
- Configurations made in system view take effect globally. Configurations made in Layer 2 Ethernet interface view take effect only on the interface. Configurations made in Layer 2 aggregate interface view take effect only on the aggregate interface. Configurations made on an aggregation member port can take effect only after the port is removed from the aggregation group.
- After you enable a spanning tree protocol on a Layer 2 aggregate interface, the system performs spanning tree calculation on the Layer 2 aggregate interface. It does not perform spanning tree calculation on the aggregation member ports. The spanning tree protocol enable state and forwarding state of each selected member port are consistent with those of the corresponding Layer 2 aggregate interface.
- The member ports of an aggregation group do not participate in spanning tree calculation. However, the ports still reserve their spanning tree configurations for participating in spanning tree calculation after leaving the aggregation group.

Spanning tree protocol tasks at a glance

STP tasks at a glance

Configuring the root bridge

To configure the root bridge in STP mode, perform the following tasks:

1. Setting the spanning tree mode

   Set the spanning tree mode to STP.
2. (Optional.) Configuring the root bridge or a secondary root bridge
3. (Optional.) Configuring the device priority
4. (Optional.) Configuring parameters that affects STP topology convergence
   - Configuring the network diameter of a switched network
   - Setting spanning tree timers
   - Setting the timeout factor
   - Configuring the BPDU transmission rate
5. (Optional.) Enabling outputting port state transition information
6. Enabling the spanning tree feature
7. (Optional.) Configuring advanced spanning tree features
   - Configuring TC Snooping

  - Configuring protection features
  - Enabling SNMP notifications for new-root election and topology change events

Configuring the leaf nodes

To configure the leaf nodes in STP mode, perform the following tasks:

1. Setting the spanning tree mode
   Set the spanning tree mode to STP.
2. (Optional.) Configuring the device priority
3. (Optional.) Configuring parameters that affects STP topology convergence
   - Setting the timeout factor
   - Configuring the BPDU transmission rate
   - Configuring path costs of ports
   - Configuring the port priority
4. (Optional.) Enabling outputting port state transition information
5. Enabling the spanning tree feature
6. (Optional.) Configuring advanced spanning tree features
   - Configuring TC Snooping
   - Configuring protection features
   - Enabling SNMP notifications for new-root election and topology change events

RSTP tasks at a glance

Configuring the root bridge

To configure the root bridge in RSTP mode, perform the following tasks:

1. Setting the spanning tree mode
   Set the spanning tree mode to RSTP.
2. (Optional.) Configuring the root bridge or a secondary root bridge
3. (Optional.) Configuring the device priority
4. (Optional.) Configuring parameters that affects RSTP topology convergence
   - Configuring the network diameter of a switched network
   - Setting spanning tree timers
   - Setting the timeout factor
   - Configuring the BPDU transmission rate
   - Configuring edge ports
   - Configuring the port link type
5. (Optional.) Enabling outputting port state transition information
6. Enabling the spanning tree feature
7. (Optional.) Configuring advanced spanning tree features
   - Performing mCheck
   - Configuring TC Snooping
   - Configuring protection features
   - Enabling SNMP notifications for new-root election and topology change events

Configuring the leaf nodes

To configure the leaf nodes in RSTP mode, perform the following tasks:

1. Setting the spanning tree mode

   Set the spanning tree mode to RSTP.
2. (Optional.) Configuring the device priority
3. (Optional.) Configuring parameters that affects RSTP topology convergence
   - Setting the timeout factor
   - Configuring the BPDU transmission rate
   - Configuring edge ports
   - Configuring path costs of ports
   - Configuring the port priority
   - Configuring the port link type
4. (Optional.) Enabling outputting port state transition information
5. Enabling the spanning tree feature
6. (Optional.) Configuring advanced spanning tree features
   - Performing mCheck
   - Configuring TC Snooping
   - Configuring protection features
   - Enabling SNMP notifications for new-root election and topology change events

PVST tasks at a glance

Configuring the root bridge

To configure the root bridge in PVST mode, perform the following tasks:

1. Setting the spanning tree mode

   Set the spanning tree mode to PVST.
2. (Optional.) Configuring the root bridge or a secondary root bridge
3. (Optional.) Configuring the device priority
4. (Optional.) Configuring parameters that affects PVST topology convergence
   - Configuring the network diameter of a switched network
   - Setting spanning tree timers
   - Setting the timeout factor
   - Configuring the BPDU transmission rate
   - Configuring edge ports
   - Configuring the port link type
5. (Optional.) Enabling outputting port state transition information
6. Enabling the spanning tree feature
7. (Optional.) Configuring advanced spanning tree features
   - Performing mCheck
   - Disabling inconsistent PVID protection
   - Configuring protection features
   - Enabling SNMP notifications for new-root election and topology change events

Configuring the leaf nodes

To configure the leaf nodes in PVST mode, perform the following tasks:

1. Setting the spanning tree mode

   Set the spanning tree mode to PVST.

2. (Optional.) Configuring the device priority
3. (Optional.) Configuring parameters that affects PVST topology convergence
    - Setting the timeout factor
    - Configuring the BPDU transmission rate
    - Configuring edge ports
    - Configuring path costs of ports
    - Configuring the port priority
    - Configuring the port link type
4. (Optional.) Enabling outputting port state transition information
5. Enabling the spanning tree feature
6. (Optional.) Configuring advanced spanning tree features
    - Performing mCheck
    - Disabling inconsistent PVID protection
    - Configuring protection features
    - Enabling SNMP notifications for new-root election and topology change events

MSTP tasks at a glance

Configuring the root bridge

To configure the root bridge in MSTP mode, perform the following tasks:

1. Setting the spanning tree mode

    Set the spanning tree mode to MSTP.
2. Configuring an MST region
3. (Optional.) Configuring the root bridge or a secondary root bridge
4. (Optional.) Configuring the device priority
5. (Optional.) Configuring parameters that affects MSTP topology convergence
    - Configuring the maximum hops of an MST region
    - Configuring the network diameter of a switched network
    - Setting spanning tree timers
    - Setting the timeout factor
    - Configuring the BPDU transmission rate
    - Configuring edge ports
    - Configuring the port link type
6. (Optional.) Configuring the mode a port uses to recognize and send MSTP frames
7. (Optional.) Enabling outputting port state transition information
8. Enabling the spanning tree feature
9. (Optional.) Configuring advanced spanning tree features
    - Performing mCheck
    - Configuring Digest Snooping
    - Configuring No Agreement Check
    - Configuring TC Snooping
    - Configuring protection features
    - Enabling SNMP notifications for new-root election and topology change events

Configuring the leaf nodes

To configure the leaf nodes in MSTP mode, perform the following tasks:

1. Setting the spanning tree mode
   Set the spanning tree mode to MSTP.
2. Configuring an MST region
3. (Optional.) Configuring the device priority
4. (Optional.) Configuring parameters that affects MSTP topology convergence
   - Setting the timeout factor
   - Configuring the BPDU transmission rate
   - Configuring edge ports
   - Configuring path costs of ports
   - Configuring the port priority
   - Configuring the port link type
5. (Optional.) Configuring the mode a port uses to recognize and send MSTP frames
6. (Optional.) Enabling outputting port state transition information
7. Enabling the spanning tree feature
8. (Optional.) Configuring advanced spanning tree features
   - Performing mCheck
   - Configuring Digest Snooping
   - Configuring No Agreement Check
   - Configuring TC Snooping
   - Configuring protection features
   - Enabling SNMP notifications for new-root election and topology change events

Setting the spanning tree mode

About this task

The spanning tree modes include:

- **STP mode**—All ports of the device send STP BPDUs. Select this mode when the peer device of a port supports only STP.
- **RSTP mode**—All ports of the device send RSTP BPDUs. A port in this mode automatically transits to the STP mode when it receives STP BPDUs from the peer device. A port in this mode does not transit to the MSTP mode when it receives MSTP BPDUs from the peer device.
- **PVST mode**—All ports of the device send PVST BPDUs. Each VLAN maintains a spanning tree. In a network, the amount of spanning trees maintained by all devices equals the number of PVST-enabled VLANs multiplied by the number of PVST-enabled ports. If the amount of spanning trees exceeds the capacity of the network, device CPUs will be overloaded. Packet forwarding is interrupted, and the network becomes unstable.
- **MSTP mode**—All ports of the device send MSTP BPDUs. A port in this mode automatically transits to the STP mode when receiving STP BPDUs from the peer device. A port in this mode does not transit to the RSTP mode when receiving RSTP BPDUs from the peer device.

Restrictions and guidelines

The MSTP mode is compatible with the RSTP mode, and the RSTP mode is compatible with the STP mode.

Compatibility of the PVST mode depends on the link type of a port.

- On an access port, the PVST mode is compatible with other spanning tree modes in all VLANs.
- On a trunk port or hybrid port, the PVST mode is compatible with other spanning tree modes only in the default VLAN.

Procedure

1. Enter system view.

   system-view
2. Set the spanning tree mode.

   stp mode { **mstp** | **pvst** | **rstp** | **stp** }

   The default setting is the MSTP mode.

Configuring an MST region

About this task

Spanning tree devices belong to the same MST region if they are both connected through a physical link and configured with the following details:

- Format selector (0 by default, not configurable).
- MST region name.
- MST region revision level.
- VLAN-to-instance mapping entries in the MST region.

The configuration of MST region-related parameters (especially the VLAN-to-instance mapping table) might cause MSTP to begin a new spanning tree calculation. To reduce the possibility of topology instability, the MST region configuration takes effect only after you activate it by doing one of the following:

- Use the **active region-configuration** command.
- Enable a spanning tree protocol by using the **stp global enable** command if the spanning tree protocol is disabled.

Restrictions and guidelines

In STP, PVST, or RSTP mode, MST region configurations do not take effect.

Procedure

1. Enter system view.

   system-view
2. Enter MST region view.

   stp region-configuration
3. Configure the MST region name.

   region-name *name*

   The default setting is the MAC address.
4. Configure the VLAN-to-instance mapping table. Choose one option as needed:
   - Map a list of VLANs to an MSTI.

     instance *instance-id* **vlan** *vlan-id-list*
   - Quickly create a VLAN-to-instance mapping table.

     vlan-mapping modulo *modulo*

   By default, all VLANs in an MST region are mapped to the CIST (or MSTI 0).
5. Configure the MSTP revision level of the MST region.

revision-level *level*

The default setting is 0.

6. (Optional.) Display the MST region configurations that are not activated yet.

   check region-configuration

7. Manually activate MST region configuration.

   active region-configuration

Configuring the root bridge or a secondary root bridge

Restrictions and guidelines

You can have the spanning tree protocol determine the root bridge of a spanning tree through calculation. You can also specify a device as the root bridge or as a secondary root bridge.

When you specify a device as the root bridge or as a secondary root bridge, follow these restrictions and guidelines:

- A device has independent roles in different spanning trees. It can act as the root bridge in one spanning tree and as a secondary root bridge in another. However, one device cannot be the root bridge and a secondary root bridge in the same spanning tree.
- If you specify the root bridge for a spanning tree, no new root bridge is elected according to the device priority settings. Once you specify a device as the root bridge or a secondary root bridge, you cannot change the priority of the device.
- You can configure a device as the root bridge by setting the device priority to 0. For the device priority configuration, see "Configuring the device priority."

Configuring the device as the root bridge of a spanning tree

1. Enter system view.

   system-view

2. Configure the device as the root bridge.
   - In STP/RSTP mode:

     stp root primary
   - In PVST mode:

     stp vlan *vlan-id-list* **root primary**
   - In MSTP mode:

     stp [**instance** *instance-list*] **root primary**

   By default, the device is not a root bridge.

Configuring the device as a secondary root bridge of a spanning tree

1. Enter system view.

   system-view

2. Configure the device as a secondary root bridge.
   - In STP/RSTP mode:

stp root secondary

- In PVST mode:

  stp vlan *vlan-id-list* **root secondary**
- In MSTP mode:

  stp [**instance** *instance-list*] **root secondary**

By default, the device is not a secondary root bridge.

Configuring the device priority

About this task

Device priority is a factor in calculating the spanning tree. The priority of a device determines whether the device can be elected as the root bridge of a spanning tree. A lower value indicates a higher priority. You can set the priority of a device to a low value to specify the device as the root bridge of the spanning tree. A spanning tree device can have different priorities in different spanning trees.

During root bridge selection, if all devices in a spanning tree have the same priority, the one with the lowest MAC address is selected. You cannot change the priority of a device after it is configured as the root bridge or as a secondary root bridge.

Procedure

1. Enter system view.

   system-view
2. Configure the priority of the device.
   - In STP/RSTP mode:

     stp priority *priority*
   - In PVST mode:

     stp vlan *vlan-id-list* **priority** *priority*
   - In MSTP mode:

     stp [**instance** *instance-list*] **priority** *priority*

   The default setting is 32768.

Configuring the maximum hops of an MST region

About this task

Restrict the region size by setting the maximum hops of an MST region. The hop limit configured on the regional root bridge is used as the hop limit for the MST region.

Configuration BPDUs sent by the regional root bridge always have a hop count set to the maximum value. When a device receives this configuration BPDU, it decrements the hop count by one, and uses the new hop count in the BPDUs that it propagates. When the hop count of a BPDU reaches zero, it is discarded by the device that received it. Devices beyond the reach of the maximum hops can no longer participate in spanning tree calculations, so the size of the MST region is limited.

Restrictions and guidelines

Make this configuration only on the root bridge. All other devices in the MST region use the maximum hop value set for the root bridge.

You can configure the maximum hops of an MST region based on the STP network size. As a best practice, set the maximum hops to a value that is greater than the maximum hops of each edge device to the root bridge.

Procedure

1. Enter system view.

   system-view

2. Configure the maximum hops of the MST region.

   stp max-hops *hops*

   The default setting is 20.

Configuring the network diameter of a switched network

About this task

Any two terminal devices in a switched network can reach each other through a specific path, and there are a series of devices on the path. The switched network diameter is the maximum number of devices on the path for an edge device to reach another one in the switched network through the root bridge. The network diameter indicates the network size. The bigger the diameter, the larger the network size.

Based on the network diameter you configured, the system automatically sets an optimal hello time, forward delay, and max age for the device.

In STP, RSTP, or MSTP mode, each MST region is considered a device. The configured network diameter takes effect only on the CIST (or the common root bridge) but not on other MSTIs.

In PVST mode, the configured network diameter takes effect only on the root bridges of the specified VLANs.

Procedure

1. Enter system view.

   system-view

2. Configure the network diameter of the switched network.

   - In STP/RSTP/MSTP mode:

     stp bridge-diameter *diameter*

   - In PVST mode:

     stp vlan *vlan-id-list* **bridge-diameter** *diameter*

   The default setting is 7.

Setting spanning tree timers

About this task

The following timers are used for spanning tree calculation:

- **Forward delay**—Delay time for port state transition. To prevent temporary loops on a network, the spanning tree feature sets an intermediate port state (the learning state) before it transits from the discarding state to the forwarding state. The feature also requires that the port transit its state after a forward delay timer. This ensures that the state transition of the local port stays synchronized with the peer.
- **Hello time**—Interval at which the device sends configuration BPDUs to detect link failures. If the device does not receive configuration BPDUs within the timeout period, it recalculates the spanning tree. The formula for calculating the timeout period is timeout period = timeout factor × 3 × hello time.

- **Max age**—In the CIST of an MSTP network, the device uses the max age timer to determine whether a configuration BPDU received by a port has expired. If it is expired, a new spanning tree calculation process starts. The max age timer does not take effect on MSTIs.

To ensure a fast topology convergence, make sure the timer settings meet the following formulas:

- 2 × (forward delay – 1 second) ≥ max age
- Max age ≥ 2 × (hello time + 1 second)

As a best practice, specify the network diameter and letting spanning tree protocols automatically calculate the timers based on the network diameter instead of manually setting the spanning tree timers. If the network diameter uses the default value, the timers also use their default values.

Set the timers only on the root bridge. The timer settings on the root bridge apply to all devices on the entire switched network.

Restrictions and guidelines

- The length of the forward delay is related to the network diameter of the switched network. The larger the network diameter is, the longer the forward delay time should be. As a best practice, use the automatically calculated value because inappropriate forward delay setting might cause temporary redundant paths or increase the network convergence time.
- An appropriate hello time setting enables the device to promptly detect link failures on the network without using excessive network resources. If the hello time is too long, the device mistakes packet loss for a link failure and triggers a new spanning tree calculation process. If the hello time is too short, the device frequently sends the same configuration BPDUs, which wastes device and network resources. As a best practice, use the automatically calculated value.
- If the max age timer is too short, the device frequently begins spanning tree calculations and might mistake network congestion as a link failure. If the max age timer is too long, the device might fail to promptly detect link failures and quickly launch spanning tree calculations, reducing the auto-sensing capability of the network. As a best practice, use the automatically calculated value.

Procedure

1. Enter system view.

   `system-view`

2. Set the forward delay timer.
   - In STP/RSTP/MSTP mode:

     stp timer forward-delay *time*
   - In PVST mode:

     stp vlan *vlan-id-list* **timer forward-delay** *time*

   The default setting is 15 seconds.

3. Set the hello timer.
   - In STP/RSTP/MSTP mode:

     stp timer hello *time*
   - In PVST mode:

     stp vlan *vlan-id-list* **timer hello** *time*

   The default setting is 2 seconds.

4. Set the max age timer.
   - In STP/RSTP/MSTP mode:

     stp timer max-age *time*
   - In PVST mode:

     stp vlan *vlan-id-list* **timer max-age** *time*

The default setting is 20 seconds.

Setting the timeout factor

About this task

The timeout factor is a parameter used to decide the timeout period. The formula for calculating the timeout period is: *timeout period* = *timeout factor* × 3 × *hello time*.

In a stable network, each non-root-bridge device forwards configuration BPDUs to the downstream devices at the hello time interval to detect link failures. If a device does not receive a BPDU from the upstream device within nine times the hello time, it assumes that the upstream device has failed. Then, it starts a new spanning tree calculation process.

Restrictions and guidelines

As a best practice, set the timeout factor to 5, 6, or 7 in the following situations:

- To prevent undesired spanning tree calculations. An upstream device might be too busy to forward configuration BPDUs in time, for example, many Layer 2 interfaces are configured on the upstream device. In this case, the downstream device fails to receive a BPDU within the timeout period and then starts an undesired spanning tree calculation.
- To save network resources on a stable network.

Procedure

1. Enter system view.

```
system-view
```

2. Set the timeout factor of the device.

```
stp timer-factor factor
```

The default setting is 3.

Configuring the BPDU transmission rate

About this task

The maximum number of BPDUs a port can send within each hello time equals the BPDU transmission rate plus the hello timer value.

The higher the BPDU transmission rate, the more BPDUs are sent within each hello time, and the more system resources are used. By setting an appropriate BPDU transmission rate, you can limit the rate at which the port sends BPDUs. Setting an appropriate rate also prevents spanning tree protocols from using excessive network resources when the network topology changes.

Restrictions and guidelines

The BPDU transmission rate depends on the physical status of the port and the network structure. As a best practice, use the default setting.

Procedure

1. Enter system view.

```
system-view
```

2. Enter interface view.

```
interface interface-type interface-number
```

3. Configure the BPDU transmission rate of the ports.

```
stp transmit-limit limit
```

The default setting is 10.

Configuring edge ports

About this task

If a port directly connects to a user terminal rather than another device or a shared LAN segment, this port is regarded as an edge port. When network topology change occurs, an edge port will not cause a temporary loop. Because a device does not determine whether a port is directly connected to a terminal, you must manually configure the port as an edge port. After that, the port can rapidly transit from the blocking state to the forwarding state.

Restrictions and guidelines

- If BPDU guard is disabled on a port configured as an edge port, the port becomes a non-edge port again if it receives a BPDU from another port. To restore the edge port, re-enable it.
- If a port directly connects to a user terminal, configure it as an edge port and enable BPDU guard for it. This enables the port to quickly transit to the forwarding state when ensuring network security.
- On a port, the loop guard feature and the edge port setting are mutually exclusive.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure the port as an edge port.

   `stp edged-port`

   By default, all ports are non-edge ports.

Configuring path costs of ports

About path cost

Path cost is a parameter related to the link speed of a port. On a spanning tree device, a port can have different path costs in different MSTIs. Setting appropriate path costs allows VLAN traffic flows to be forwarded along different physical links, achieving VLAN-based load balancing.

You can have the device automatically calculate the default path cost, or you can configure the path cost for ports.

Specifying a standard for the default path cost calculation

About this task

You can specify a standard for the device to use in automatic calculation for the default path cost. The device supports the following standards:

- **dot1d-1998**—The device calculates the default path cost for ports based on IEEE 802.1d-1998.
- **dot1t**—The device calculates the default path cost for ports based on IEEE 802.1t.
- **legacy**—The device calculates the default path cost for ports based on a private standard.

Table 7 Mappings between the link speed (100M and below) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
0	N/A	65535	200000000	200000
10 Mbps	Single port	100	2000000	2000
	Aggregate interface containing two Selected ports		1000000	1800
	Aggregate interface containing three Selected ports		666666	1600
	Aggregate interface containing four Selected ports		500000	1400
100 Mbps	Single port	19	200000	200
	Aggregate interface containing two Selected ports		100000	180
	Aggregate interface containing three Selected ports		66666	160
	Aggregate interface containing four Selected ports		50000	140

Table 8 Mappings between the link speed (1000M) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
1000 Mbps	Single port	4	20000	20
	Aggregate interface containing two Selected ports		10000	18
	Aggregate interface containing three Selected ports		6666	16
	Aggregate interface containing four Selected ports		5000	14

Table 9 Mappings between the link speed (10G) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
10 Gbps	Single port	2	2000	2
	Aggregate interface		1000	1

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
	containing two Selected ports			
	Aggregate interface containing three Selected ports		666	1
	Aggregate interface containing four Selected ports		500	1

Table 10 Mappings between the link speed (20G) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
20 Gbps	Single port	1	1000	1
	Aggregate interface containing two Selected ports		500	1
	Aggregate interface containing three Selected ports		333	1
	Aggregate interface containing four Selected ports		250	1

Table 11 Mappings between the link speed (40G) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
40 Gbps	Single port	1	500	1
	Aggregate interface containing two Selected ports		250	1
	Aggregate interface containing three Selected ports		166	1
	Aggregate interface containing four Selected ports		125	1

Table 12 Mappings between the link speed (100G) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
100 Gbps	Single port	1	200	1

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
	Aggregate interface containing two Selected ports		100	1
	Aggregate interface containing three Selected ports		66	1
	Aggregate interface containing four Selected ports		50	1

Restrictions and guidelines

If you change the standard for the default path cost calculation, you restore the path costs to the default.

When the device calculates the path cost for an aggregate interface, IEEE 802.1t takes into account the number of Selected ports in its aggregation group. However, IEEE 802.1d-1998 does not take into account the number of Selected ports. The calculation formula of IEEE 802.1t is: Path cost = 200,000,000/link speed (in 100 kbps). The link speed is the sum of the link speed values of the Selected ports in the aggregation group.

IEEE 802.1d-1998 or the private standard always assigns the smallest possible value to a single port or aggregate interface with a speed exceeding 10 Gbps. The forwarding path selected based on this criterion might not be the best one. To solve this problem, perform one of the following tasks:

- Use **dot1t** as the standard for default path cost calculation.
- Manually set the path cost for the port (see "Configuring path costs of ports").

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Specify a standard for the default path costs calculation.

   ```
   stp pathcost-standard { dot1d-1998 | dot1t | legacy }
   ```

   The default standard is **legacy**.

Configuring path costs of ports

Restrictions and guidelines

When the path cost of a port changes, the system recalculates the port role and initiates a state transition.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Configure the path cost of the ports.

   - In STP/RSTP mode:

     ```
     stp cost cost-value
     ```

- In PVST mode:

  stp vlan *vlan-id-list* **cost** *cost-value*
- In MSTP mode:

  stp [**instance** *instance-list*] **cost** *cost-value*

By default, the system automatically calculates the path cost of each port.

Configuring the port priority

About this task

The priority of a port is a factor that determines whether the port can be elected as the root port of a device. If all other conditions are the same, the port with the highest priority is elected as the root port.

On a spanning tree device, a port can have different priorities and play different roles in different spanning trees. As a result, data of different VLANs can be propagated along different physical paths, implementing per-VLAN load balancing. You can set port priority values based on the actual networking requirements.

Restrictions and guidelines

When the priority of a port changes, the system recalculates the port role and initiates a state transition. Prepare for the network topology change before configuring the port priority.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure the port priority.
   - In STP/RSTP mode:

     stp port priority *priority*
   - In PVST mode:

     stp vlan *vlan-id-list* **port priority** *priority*
   - In MSTP mode:

     stp [**instance** *instance-list*] **port priority** *priority*

   The default setting is 128 for all ports.

Configuring the port link type

About this task

A point-to-point link directly connects two devices. If two root ports or designated ports are connected over a point-to-point link, they can rapidly transit to the forwarding state after a proposal-agreement handshake process.

Restrictions and guidelines

- You can configure the link type as point-to-point for a Layer 2 aggregate interface or a port that operates in full duplex mode. As a best practice, use the default setting and let the device automatically detect the port link type.

- In PVST or MSTP mode, the **`stp point-to-point force-false`** or **`stp point-to-point force-true`** command configured on a port takes effect on all VLANs or all MSTIs.
- Before you set the link type of a port to point-to-point, make sure the port is connected to a point-to-point link. Otherwise, a temporary loop might occur.

Procedure

1. Enter system view.

`system-view`

2. Enter interface view.

`interface` *`interface-type interface-number`*

3. Configure the port link type.

`stp point-to-point { auto | force-false | force-true }`

By default, the link type is **auto** where the port automatically detects the link type.

Configuring the mode a port uses to recognize and send MSTP frames

About this task

A port can receive and send MSTP frames in the following formats:

- **dot1s**—802.1s-compliant standard format
- **legacy**—Compatible format

By default, the frame format recognition mode of a port is **auto**. The port automatically distinguishes the two MSTP frame formats, and determines the format of frames that it will send based on the recognized format.

You can configure the MSTP frame format on a port. Then, the port sends only MSTP frames of the configured format to communicate with devices that send frames of the same format.

By default, a port in **auto** mode sends 802.1s MSTP frames. When the port receives an MSTP frame of a legacy format, the port starts to send frames only of the legacy format. This prevents the port from frequently changing the format of sent frames. To configure the port to send 802.1s MSTP frames, shut down and then bring up the port.

Restrictions and guidelines

When the number of existing MSTIs exceeds 48, the port can send only 802.1s MSTP frames.

Procedure

1. Enter system view.

`system-view`

2. Enter interface view.

`interface` *`interface-type interface-number`*

3. Configure the mode that the port uses to recognize/send MSTP frames.

`stp compliance { auto | dot1s | legacy }`

The default setting is **auto**.

Enabling outputting port state transition information

About this task

In a large-scale spanning tree network, you can enable devices to output the port state transition information. Then, you can monitor the port states in real time.

Procedure

1. Enter system view.

   `system-view`

2. Enable outputting port state transition information.
   - In STP/RSTP mode:

     stp port-log instance 0
   - In PVST mode:

     stp port-log vlan *vlan-id-list*
   - In MSTP mode:

     stp port-log { **all** | **instance** *instance-list* }

   By default, outputting port state transition information is disabled.

Enabling the spanning tree feature

Restrictions and guidelines

You must enable the spanning tree feature for the device before any other spanning tree related configurations can take effect. In STP, RSTP, or MSTP mode, make sure the spanning tree feature is enabled globally and on the desired ports. In PVST mode, make sure the spanning tree feature is enabled globally, in the desired VLANs, and on the desired ports.

To exclude specific ports from spanning tree calculation and save CPU resources, disable the spanning tree feature for these ports with the **undo stp enable** command. Make sure no loops occur in the network after you disable the spanning tree feature on these ports.

Enabling the spanning tree feature in STP/RSTP/MSTP mode

1. Enter system view.

   system-view

2. Enable the spanning tree feature.

   stp global enable

   By default, the spanning tree feature is disabled globally.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable the spanning tree feature for the port.

   stp enable

   By default, the spanning tree feature is enabled on all ports.

Enabling the spanning tree feature in PVST mode

1. Enter system view.

   system-view

2. Enable the spanning tree feature.

   stp global enable

   By default, the spanning tree feature is disabled globally.

3. Enable the spanning tree feature in VLANs.

   stp vlan *vlan-id-list* **enable**

   By default, the spanning tree feature is enabled in VLANs.

4. Enter interface view.

   interface *interface-type interface-number*

5. Enable the spanning tree feature on the port.

   stp enable

   By default, the spanning tree feature is enabled on all ports.

Performing mCheck

About mCheck

The mCheck feature enables user intervention in the port state transition process.

When a port on an MSTP, PVST, or RSTP device connects to an STP device and receives STP BPDUs, the port automatically transits to the STP mode. However, the port cannot automatically transit back to the original mode when the following conditions exist:

- The peer STP device is shut down or removed.
- The port cannot detect the change.

To forcibly transit the port to operate in the original mode, you can perform an mCheck operation.

For example, Device A, Device B, and Device C are connected in sequence. Device A runs STP, Device B does not run any spanning tree protocol, and Device C runs RSTP, PVST, or MSTP. In this case, when Device C receives an STP BPDU transparently transmitted by Device B, the receiving port transits to the STP mode. If you configure Device B to run RSTP, PVST, or MSTP with Device C, you must perform mCheck operations on the ports interconnecting Device B and Device C.

Restrictions and guidelines

The mCheck operation takes effect on devices operating in MSTP, PVST, or RSTP mode.

Performing mCheck globally

1. Enter system view.

   system-view

2. Perform mCheck.

   stp global mcheck

Performing mCheck in interface view

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Perform mCheck.
   `stp mcheck`

Disabling inconsistent PVID protection

About this task

In PVST, if two connected ports use different PVIDs, PVST calculation errors might occur. By default, inconsistent PVID protection is enabled to avoid PVST calculation errors. If PVID inconsistency is detected on a port, the system blocks the port.

Restrictions and guidelines

If different PVIDs are required on two connected ports, disable inconsistent PVID protection on the devices that host the ports. To avoid PVST calculation errors, make sure the following requirements are met:

- Make sure the VLANs on one device do not use the same ID as the PVID of its peer port (except the default VLAN) on another device.
- If the local port or its peer is a hybrid port, do not configure the local and peer ports as untagged members of the same VLAN.
- Disable inconsistent PVID protection on both the local device and the peer device.

This feature takes effect only when the device is operating in PVST mode.

Procedure

1. Enter system view.
   `system-view`
2. Disable the inconsistent PVID protection feature.
   `stp ignore-pvid-inconsistency`
   By default, the inconsistent PVID protection feature is enabled.

Configuring Digest Snooping

About this task

As defined in IEEE 802.1s, connected devices are in the same region only when they have the same MST region-related configurations, including:

- Region name.
- Revision level.
- VLAN-to-instance mappings.

A spanning tree device identifies devices in the same MST region by determining the configuration ID in BPDUs. The configuration ID includes the region name, revision level, and configuration digest. It is 16-byte long and is the result calculated through the HMAC-MD5 algorithm based on VLAN-to-instance mappings.

Because spanning tree implementations vary by vendor, the configuration digests calculated through private keys are different. The devices of different vendors in the same MST region cannot communicate with each other.

To enable communication between an NSFOCUS device and a third-party device in the same MST region, enable Digest Snooping on the NSFOCUS device port connecting them.

Restrictions and guidelines

△ **CAUTION:**

Use caution with global Digest Snooping in the following situations:

- When you modify the VLAN-to-instance mappings.
- When you restore the default MST region configuration.

If the local device has different VLAN-to-instance mappings than its neighboring devices, loops or traffic interruption will occur.

- Before you enable Digest Snooping, make sure associated devices of different vendors are connected and run spanning tree protocols.
- With Digest Snooping enabled, in-the-same-region verification does not require comparison of configuration digest. The VLAN-to-instance mappings must be the same on associated ports.
- To make Digest Snooping take effect, you must enable Digest Snooping both globally and on associated ports. As a best practice, enable Digest Snooping on all associated ports first and then enable it globally. This will make the configuration take effect on all configured ports and reduce impact on the network.
- To prevent loops, do not enable Digest Snooping on MST region edge ports.
- As a best practice, enable Digest Snooping first and then enable the spanning tree feature. To avoid traffic interruption, do not configure Digest Snooping when the network is already working well.

Prerequisites

Before configuring Digest Snooping, you need to make sure your NSFOCUS device and the third-party device both run spanning tree protocols properly.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Enable Digest Snooping on the interface.

   `stp config-digest-snooping`

   By default, Digest Snooping is disabled on ports.

4. Return to system view.

   `quit`

5. Enable Digest Snooping globally.

   `stp global config-digest-snooping`

   By default, Digest Snooping is disabled globally.

Configuring No Agreement Check

About this task

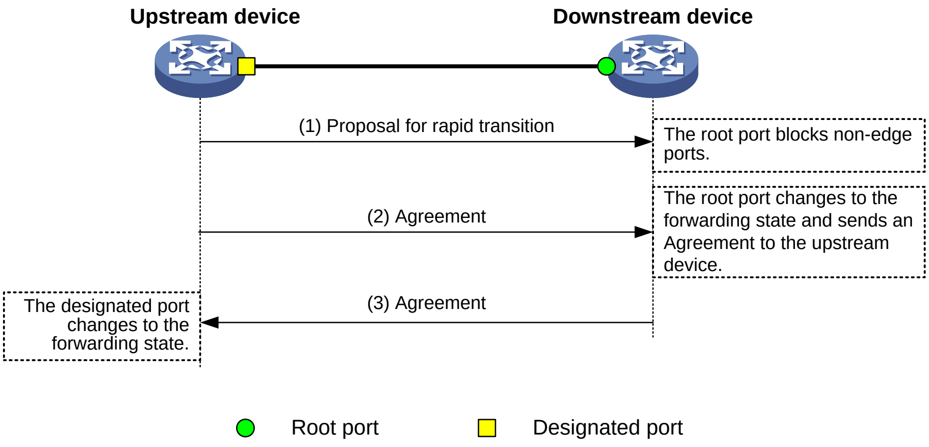
In RSTP and MSTP, the following types of messages are used for rapid state transition on designated ports:

- **Proposal**—Sent by designated ports to request rapid transition
- **Agreement**—Used to acknowledge rapid transition requests

Both RSTP and MSTP devices can perform rapid transition on a designated port only when the port receives an agreement packet from the downstream device. RSTP and MSTP devices have the following differences:

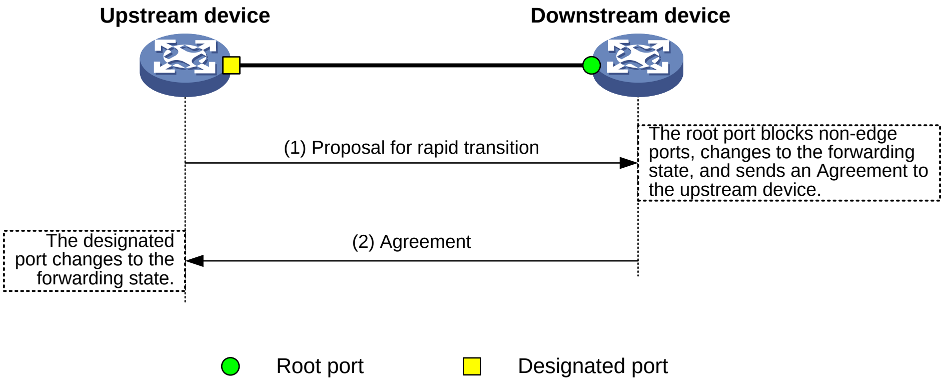
- For MSTP, the root port of the downstream device sends an agreement packet only after it receives an agreement packet from the upstream device.
- For RSTP, the downstream device sends an agreement packet whether or not an agreement packet from the upstream device is received.

Figure 16 Rapid state transition of an MSTP designated port



Upstream device
Downstream device
(1) Proposal for rapid transition
The root port blocks non-edge ports.
(2) Agreement
The root port changes to the forwarding state and sends an Agreement to the upstream device.
The designated port changes to the forwarding state.
(3) Agreement
Root port
Designated port

Figure 17 Rapid state transition of an RSTP designated port



Upstream device
Downstream device
(1) Proposal for rapid transition
The root port blocks non-edge ports, changes to the forwarding state, and sends an Agreement to the upstream device.
The designated port changes to the forwarding state.
(2) Agreement
Root port
Designated port

If the upstream device is a third-party device, the rapid state transition implementation might be limited as follows:

- The upstream device uses a rapid transition mechanism similar to that of RSTP.
- The downstream device runs MSTP and does not operate in RSTP mode.

In this case, the following occurs:

1. The root port on the downstream device receives no agreement from the upstream device.
2. It sends no agreement to the upstream device.

As a result, the designated port of the upstream device can transit to the forwarding state only after a period twice the forward delay.

To enable the designated port of the upstream device to transit its state rapidly, enable No Agreement Check on the downstream device's port.

Restrictions and guidelines

Configure No Agreement Check on the root port of your device, because this feature takes effect only if it's configured on root ports.

Prerequisites

Before you configure the No Agreement Check feature, complete the following tasks:

- Connect a device to a third-party upstream device that supports spanning tree protocols through a point-to-point link.
- Configure the same region name, revision level, and VLAN-to-instance mappings on the two devices.

Procedure

Enable the No Agreement Check feature on the root port.

1. Enter system view.
   ```
   system-view
   ```
2. Enter interface view.
   ```
   interface interface-type interface-number
   ```
3. Enable No Agreement Check.
   ```
   stp no-agreement-check
   ```
   By default, No Agreement Check is disabled.

Configuring TC Snooping

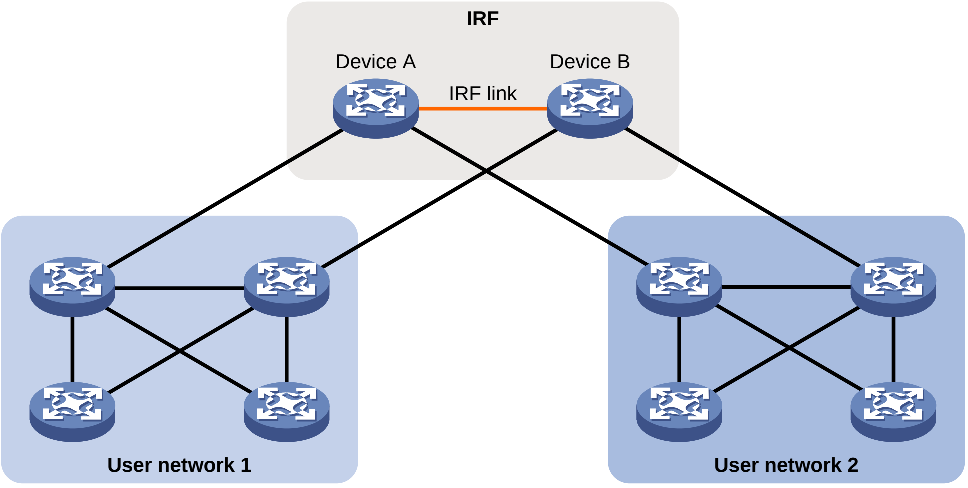
About this task

As shown in Figure 18, Device A and Device B connect to two user networks through double links.

- The spanning tree feature is disabled on Device A and Device B and enabled on all devices in user network 1 and user network 2.
- Device A and Device B transparently transmit BPDUs for both user networks and are not involved in the calculation of spanning trees.

When the network topology changes, it takes time for the IRF fabric to update its MAC address table and ARP table. During this period, traffic in the network might be interrupted.

Figure 18 TC Snooping application scenario



To avoid traffic interruption, you can enable TC Snooping on Device A and Device B. After receiving a TC-BPDU through a port, Device A or Device B updates MAC address table and ARP table entries associated with the port's VLAN. In this way, TC Snooping prevents topology change from interrupting traffic forwarding in the network. For more information about the MAC address table and the ARP table, see "Configuring the MAC address table" and *Layer 3—IP Services Configuration Guide*.

Restrictions and guidelines

- TC Snooping and the spanning tree feature are mutually exclusive. You must globally disable the spanning tree feature before enabling TC Snooping.
- TC Snooping does not support the PVST mode.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Globally disable the spanning tree feature.

   ```
   undo stp global enable
   ```

   By default, the spanning tree feature is disabled globally.

3. Enable TC Snooping.

   ```
   stp tc-snooping
   ```

   By default, TC Snooping is disabled.

Configuring protection features

Spanning tree protection tasks at a glance

All spanning tree protection tasks are optional.

- Configuring BPDU guard
- Enabling root guard
- Enabling loop guard
- Configuring port role restriction
- Configuring TC-BPDU transmission restriction

Configuring BPDU guard

About this task

For access layer devices, the access ports can directly connect to the user terminals (such as PCs) or file servers. The access ports are configured as edge ports to allow rapid transition. When these ports receive configuration BPDUs, the system automatically sets the ports as non-edge ports and starts a new spanning tree calculation process. This causes a change of network topology. Under normal conditions, these ports should not receive configuration BPDUs. However, if someone uses configuration BPDUs maliciously to attack the devices, the network will become unstable.

The spanning tree protocol provides the BPDU guard feature to protect the system against such attacks. When edge ports receive configuration BPDUs on a device with BPDU guard enabled, the device performs the following operations:

- Shuts down these ports.
- Notifies the NMS that these ports have been shut down by the spanning tree protocol.

The device reactivates the ports that have been shut down when the port status detection timer expires. You can set this timer by using the **`shutdown-interval`** command. For more information about this command, see device management commands in *Fundamentals Command Reference*.

Restrictions and guidelines

Configure BPDU guard on edge ports which directly connect to a user terminal rather than other device or shared LAN segment.

BPDU guard takes effect only on the edge ports configured by using the **`stp edged-port`** command.

BPDU guard does not take effect on loopback-testing-enabled ports. For more information about loopback testing, see Ethernet interface configuration in *Interface Configuration Guide*.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable BPDU guard globally.

   ```
   stp bpdu-protection
   ```

   By default, BPDU guard is globally disabled.

Enabling root guard

About this task

Configure root guard on a designated port.

The root bridge and secondary root bridge of a spanning tree should be located in the same MST region. Especially for the CIST, the root bridge and secondary root bridge are put in a high-bandwidth core region during network design. However, due to possible configuration errors or malicious attacks in the network, the legal root bridge might receive a configuration BPDU with a higher priority. Another device supersedes the current legal root bridge, causing an undesired change of the network topology. The traffic that should go over high-speed links is switched to low-speed links, resulting in network congestion.

To prevent this situation, MSTP provides the root guard feature. If root guard is enabled on a port of a root bridge, this port plays the role of designated port on all MSTIs. After this port receives a configuration BPDU with a higher priority from an MSTI, it performs the following operations:

- Immediately sets that port to the listening state in the MSTI.
- Does not forward the received configuration BPDU.

This is equivalent to disconnecting the link connected to this port in the MSTI. If the port receives no BPDUs with a higher priority within twice the forwarding delay, it reverts to its original state.

Restrictions and guidelines

On a port, the loop guard feature and the root guard feature are mutually exclusive.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Enable the root guard feature.

   ```
   stp root-protection
   ```

   By default, root guard is disabled.

Enabling loop guard

About this task

Configure loop guard on the root port and alternate ports of a device.

By continuing to receive BPDUs from the upstream device, a device can maintain the state of the root port and blocked ports. However, link congestion or unidirectional link failures might cause these ports to fail to receive BPDUs from the upstream devices. In this situation, the device reselects the following port roles:

- Those ports in forwarding state that failed to receive upstream BPDUs become designated ports.
- The blocked ports transit to the forwarding state.

As a result, loops occur in the switched network. The loop guard feature can suppress the occurrence of such loops.

The initial state of a loop guard-enabled port is **discarding** in every MSTI. When the port receives BPDUs, it transits its state. Otherwise, it stays in the discarding state to prevent temporary loops.

Restrictions and guidelines

Do not enable loop guard on a port that connects user terminals. Otherwise, the port stays in the discarding state in all MSTIs because it cannot receive BPDUs.

On a port, the loop guard feature is mutually exclusive with the root guard feature or the edge port setting.

A loop guard-enabled interface can receive BPDUs and transit from the discarding state to the forwarding state after two forward delays if one of the following events occurs:

- The state of the interface changes from down to up.
- The spanning tree feature is enabled on the up interface.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the loop guard feature.

   stp loop-protection

   By default, loop guard is disabled.

Configuring port role restriction

About this task

Make this configuration on the port that connects to the user access network.

The bridge ID change of a device in the user access network might cause a change to the spanning tree topology in the core network. To avoid this problem, you can enable port role restriction on a port. With this feature enabled, when the port receives a superior BPDU, it becomes an alternate port rather than a root port.

Restrictions and guidelines

Use this feature with caution, because enabling port role restriction on a port might affect the connectivity of the spanning tree topology.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable port role restriction.

   stp role-restriction

   By default, port role restriction is disabled.

Configuring TC-BPDU transmission restriction

About this task

Make this configuration on the port that connects to the user access network.

The topology change to the user access network might cause the forwarding address changes to the core network. When the user access network topology is unstable, the user access network might affect the core network. To avoid this problem, you can enable TC-BPDU transmission restriction on a port. With this feature enabled, when the port receives a TC-BPDU, it does not forward the TC-BPDU to other ports.

Restrictions and guidelines

Enabling TC-BPDU transmission restriction on a port might cause the previous forwarding address table to fail to be updated when the topology changes.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable TC-BPDU transmission restriction.

   stp tc-restriction

By default, TC-BPDU transmission restriction is disabled.

Enabling TC-BPDU guard

About this task

When a device receives topology change (TC) BPDUs (the BPDUs that notify devices of topology changes), it flushes its forwarding address entries. If someone uses TC-BPDUs to attack the device, the device will receive a large number of TC-BPDUs within a short time. Then, the device is busy with forwarding address entry flushing. This affects network stability.

TC-BPDU guard allows you to set the maximum number of immediate forwarding address entry flushes performed within 10 seconds after the device receives the first TC-BPDU. For TC-BPDUs received in excess of the limit, the device performs a forwarding address entry flush when the time period expires. This prevents frequent flushing of forwarding address entries.

Restrictions and guidelines

As a best practice, enable TC-BPDU guard.

Procedure

1. Enter system view.
   `system-view`
2. Enable the TC-BPDU guard feature.
   `stp tc-protection`
   By default, TC-BPDU guard is enabled.
3. (Optional.) Configure the maximum number of forwarding address entry flushes that the device can perform every 10 seconds.
   `stp tc-protection threshold` *`number`*
   The default setting is 6.

Enabling PVST BPDU guard

About this task

This feature takes effect only when the device is operating in MSTP mode.

An MSTP-enabled device forwards PVST BPDUs as data traffic because it cannot recognize PVST BPDUs. If a PVST-enabled device in another independent network receives the PVST BPDUs, a PVST calculation error might occur. To avoid PVST calculation errors, enable PVST BPDU guard on the MSTP-enabled device. The device shuts down a port if the port receives PVST BPDUs.

Procedure

1. Enter system view.
   `system-view`
2. Enable PVST BPDU guard.
   `stp pvst-bpdu-protection`
   By default, PVST BPDU guard is disabled.

About dispute guard

Dispute guard is enabled by default. You do not need to manually configure this feature.

Dispute guard can be triggered by unidirectional link failures. If an upstream port receives inferior BPDUs from a downstream designated port in forwarding or learning state because of a unidirectional link failure, a loop appears. Dispute guard blocks the upstream designated port to prevent the loop.

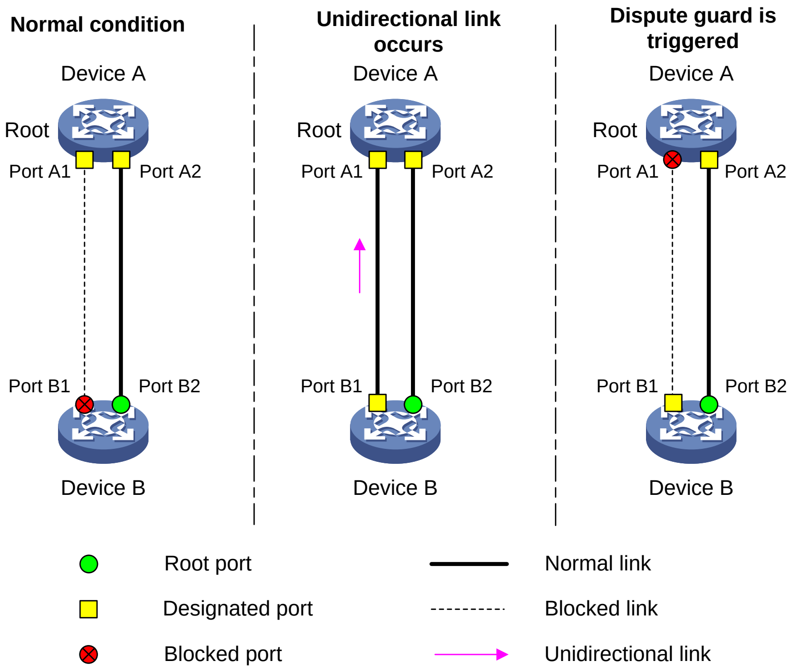
As shown in Figure 19, in normal conditions, the spanning tree calculation result is as follows:

- Device A is the root bridge, and Port A1 is a designated port.
- Port B1 is blocked.

When the link between Port A1 and Port B1 fails in the direction of Port A1 to Port B1 and becomes unidirectional, the following events occur:

1. Port A1 can only receive BPDUs and cannot send BPDUs to Port B1.
2. Port B1 does not receive BPDUs from Port A1 for a certain period of time.
3. Device B determines itself as the root bridge.
4. Port B1 sends its BPDUs to Port A1.
5. Port A1 determines the received BPDUs are inferior to its own BPDUs. A dispute is detected.
6. Dispute guard is triggered and blocks Port A1 to prevent a loop.

Figure 19 Dispute guard triggering scenario



Enabling SNMP notifications for new-root election and topology change events

About this task

This task enables the device to generate logs and report new-root election events or spanning tree topology changes to SNMP. For the event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.

```
system-view
```

2. Enable SNMP notifications for new-root election and topology change events.

   snmp-agent trap enable stp [**new-root** | **tc**]

   The default settings are as follows:

   - SNMP notifications are disabled for new-root election events.
   - In MSTP mode, SNMP notifications are enabled in MSTI 0 and disabled in other MSTIs for spanning tree topology changes.
   - In PVST mode, SNMP notifications are disabled for spanning tree topology changes in all VLANs.

Display and maintenance commands for the spanning tree protocols

Execute **display** commands in any view and **reset** command in user view.

Task	Command
Display the spanning tree status and statistics.	**display stp** [**instance** *instance-list* | **vlan** *vlan-id-list*] [**interface** *interface-list* | **slot** *slot-number*] [**brief**]
Display the port role calculation history for the specified MSTI or all MSTIs.	**display stp** [**instance** *instance-list* | **vlan** *vlan-id-list*] **history** [**slot** *slot-number*]
Display the incoming and outgoing TC/TCN BPDU statistics by all ports in the specified MSTI or all MSTIs.	**display stp** [**instance** *instance-list* | **vlan** *vlan-id-list*] **tc** [**slot** *slot-number*]
Display information about ports blocked by spanning tree protection features.	**display stp abnormal-port**
Display BPDU statistics on ports.	**display stp bpdu-statistics** [**interface** *interface-type interface-number* [**instance** *instance-list*]]
Display information about ports shut down by spanning tree protection features.	**display stp down-port**
Display the MST region configuration information that has taken effect.	**display stp region-configuration**
Display the root bridge information of all MSTIs.	**display stp root**
Clear the spanning tree statistics.	**reset stp** [**interface** *interface-list*]

Contents

Configuring LLDP

About LLDP

The Link Layer Discovery Protocol (LLDP) is a standard link layer protocol that allows network devices from different vendors to discover neighbors and exchange system and configuration information.

In an LLDP-enabled network, a device advertises local device information in LLDP Data Units (LLDPDUs) to the directly connected devices. The information distributed through LLDP is stored by its recipients in standard MIBs, making it possible for the information to be accessed by a Network Management System (NMS) through SNMP.

Information that can be distributed through LLDP includes (but is not limited to):

- Major capabilities of the system.
- Management IP address of the system.
- Device ID.
- Port ID.

LLDP agents and bridge modes

An LLDP agent is a mapping of a protocol entity that implements LLDP. Multiple LLDP agents can run on the same interface.

LLDP agents are classified into the following types:

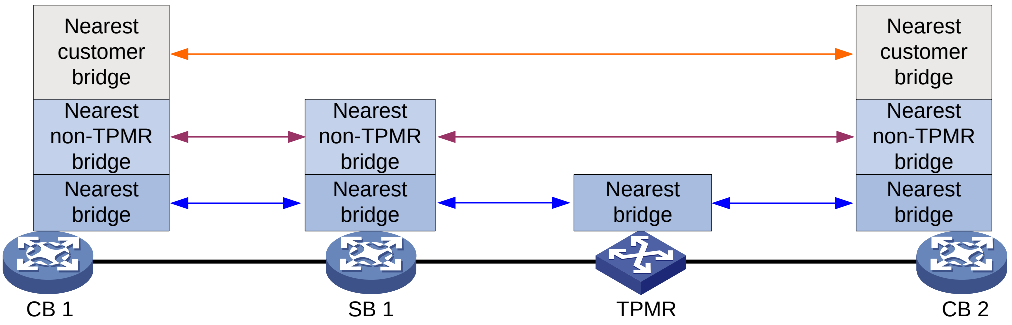
- Nearest bridge agent.
- Nearest customer bridge agent.
- Nearest non-TPMR bridge agent.

  A Two-port MAC Relay (TPMR) is a type of bridge that has only two externally-accessible bridge ports. It supports a subset of the features of a MAC bridge. A TPMR is transparent to all frame-based media-independent protocols except for the following protocols:

  - Protocols destined for the TPMR.
  - Protocols destined for reserved MAC addresses that the relay feature of the TPMR is configured not to forward.

LLDP exchanges packets between neighbor agents and creates and maintains neighbor information for them. Figure 1 shows the neighbor relationships for these LLDP agents.

Figure 1 LLDP neighbor relationships



The types of supported LLDP agents vary with the bridge mode in which LLDP operates. LLDP supports the following bridge modes: customer bridge (CB) and service bridge (SB).

- **Customer bridge mode**—LLDP supports nearest bridge agent, nearest non-TPMR bridge agent, and nearest customer bridge agent. LLDP processes the LLDP frames with destination MAC addresses for these agents and transparently transmits the LLDP frames with other destination MAC addresses in VLANs.
- **Service bridge mode**—LLDP supports nearest bridge agent and nearest non-TPMR bridge agent. LLDP processes the LLDP frames with destination MAC addresses for these agents and transparently transmits the LLDP frames with other destination MAC addresses in VLANs.

LLDP frame formats

LLDP sends device information in LLDP frames. LLDP frames are encapsulated in Ethernet II or Subnetwork Access Protocol (SNAP) format.

LLDP frame encapsulated in Ethernet II

Figure 2 Ethernet II-encapsulated LLDP frame

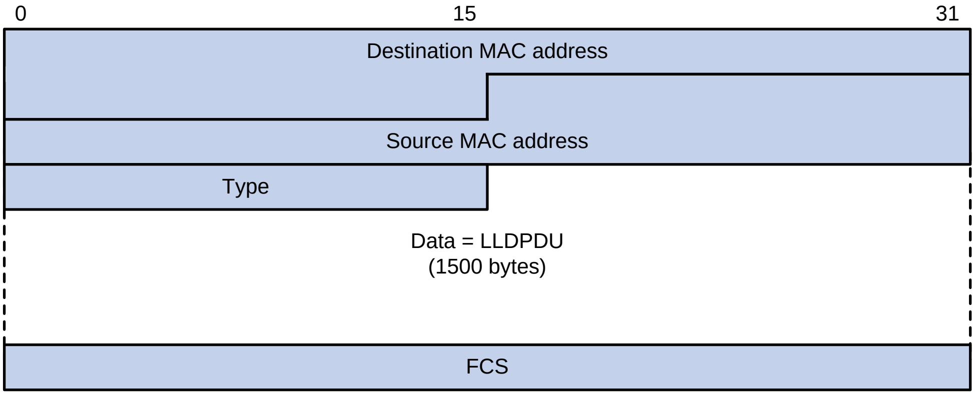


Table 1 Fields in an Ethernet II-encapsulated LLDP frame

Field	Description
Destination MAC address	MAC address to which the LLDP frame is advertised. LLDP specifies different multicast MAC addresses as destination MAC addresses for LLDP frames destined for agents of different types. This helps distinguish between LLDP frames sent and received by different agent types on the same interface. The destination MAC address is fixed to one of the following multicast MAC addresses: • 0x0180-c200-000E for LLDP frames destined for nearest bridge agents. • 0x0180-c200-0000 for LLDP frames destined for nearest customer bridge agents. • 0x0180-c200-0003 for LLDP frames destined for nearest non-TPMR bridge agents.
Source MAC address	MAC address of the sending port.
Type	Ethernet type for the upper-layer protocol. This field is 0x88CC for LLDP.
Data	LLDPDU.
FCS	Frame check sequence, a 32-bit CRC value used to determine the validity of the received Ethernet frame.

LLDP frame encapsulated in SNAP

Figure 3 SNAP-encapsulated LLDP frame

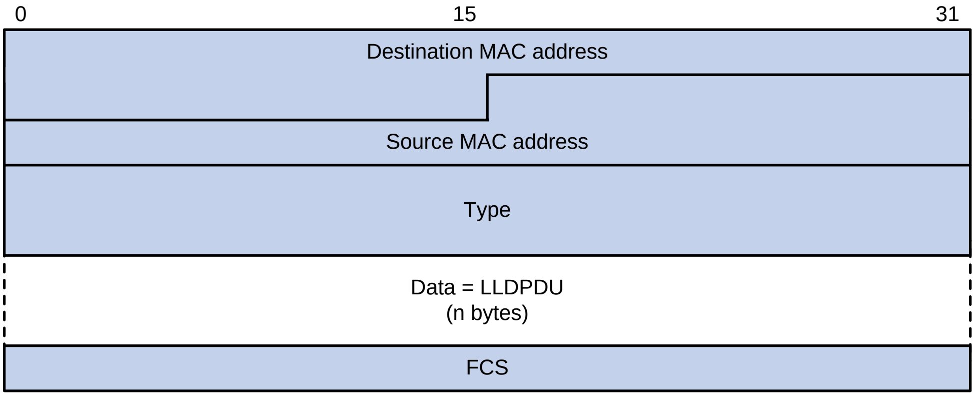

Table 2 Fields in a SNAP-encapsulated LLDP frame

Field	Description
Destination MAC address	MAC address to which the LLDP frame is advertised. It is the same as that for Ethernet II-encapsulated LLDP frames.
Source MAC address	MAC address of the sending port.
Type	SNAP type for the upper-layer protocol. This field is 0xAAAA-0300-0000-88CC for LLDP.
Data	LLDPDU.
FCS	Frame check sequence, a 32-bit CRC value used to determine the validity of the received Ethernet frame.

LLDPDUs

Each LLDP frame contains one LLDPDU. Each LLDPDU is a sequence of type-length-value (TLV) structures.

Figure 4 LLDPDU encapsulation format

As shown in Figure 4, each LLDPDU starts with the following mandatory TLVs: Chassis ID TLV, Port ID TLV, and Time to Live TLV. The mandatory TLVs are followed by a maximum of 29 optional TLVs.

TLVs

A TLV is an information element that contains the type, length, and value fields.

LLDPDU TLVs include the following categories:

- Basic management TLVs.
- Organizationally (IEEE 802.1 and IEEE 802.3) specific TLVs.
- LLDP-MED (media endpoint discovery) TLVs.

Basic management TLVs are essential to device management.

Organizationally specific TLVs and LLDP-MED TLVs are used for enhanced device management. They are defined by standardization or other organizations and are optional for LLDPDUs.

Basic management TLVs

Table 3 lists the basic management TLV types. Some of them are mandatory for LLDPDUs.

Table 3 Basic management TLVs

Type	Description	Remarks
Chassis ID	Specifies the bridge MAC address of the sending device.	Mandatory.
Port ID	Specifies the ID of the sending port: • If the LLDPDU carries LLDP-MED TLVs, the port ID TLV carries the MAC address of the sending port. • Otherwise, the port ID TLV carries the port name.	
Time to Live	Specifies the life of the transmitted information on the receiving device.	
End of LLDPDU	Marks the end of the TLV sequence in the LLDPDU.	
Port Description	Specifies the description for the sending port.	Optional.
System Name	Specifies the assigned name of the sending device.	
System Description	Specifies the description for the sending device.	
System Capabilities	Identifies the primary features of the sending device and the enabled primary features.	
Management Address	Specifies the following elements: • The management address of the local device. • The interface number and object identifier (OID) associated with the address.	

IEEE 802.1 organizationally specific TLVs

Table 4 lists the IEEE 802.1 organizationally specific TLVs.

The device can receive protocol identity TLVs and VID usage digest TLVs, but it cannot send these TLVs.

Layer 3 Ethernet ports support only link aggregation TLVs.

Table 4 IEEE 802.1 organizationally specific TLVs

Type	Description
Port VLAN ID (PVID)	Specifies the port PVID.
Port And Protocol VLAN ID (PPVID)	Indicates whether the device supports protocol VLANs and, if so, what VLAN IDs these protocols will be associated with.
VLAN Name	Specifies the textual name of any VLAN to which the port belongs.
Protocol Identity	Indicates protocols supported on the port.
DCBX	Data center bridging exchange protocol. DCBX TLVs are not supported in the current software version.

Type	Description
EVB module	Edge Virtual Bridging module, including EVB TLV and CDCP TLV. EVB module TLVs are not supported in the current software version.
Link Aggregation	Indicates whether the port supports link aggregation, and if yes, whether link aggregation is enabled.
Management VID	Management VLAN ID.
VID Usage Digest	VLAN ID usage digest.
ETS Configuration	Enhanced Transmission Selection configuration. ETS configuration TLVs are not supported in the current software version.
ETS Recommendation	ETS recommendation. ETS recommendation TLVs are not supported in the current software version.
PFC	Priority-based Flow Control. PFC TLVs are not supported in the current software version.
APP	Application protocol. APP TLVs are not supported in the current software version.
QCN	Quantized Congestion Notification. QCN TLVs are not supported in the current software version.

IEEE 802.3 organizationally specific TLVs

Table 5 shows the IEEE 802.3 organizationally specific TLVs.

The Power Stateful Control TLV is defined in IEEE P802.3at D1.0 and is not supported in later versions. The device sends this type of TLVs only after receiving them.

Table 5 IEEE 802.3 organizationally specific TLVs

Type	Description
MAC/PHY Configuration/Status	Contains the bit-rate and duplex capabilities of the port, support for autonegotiation, enabling status of autonegotiation, and the current rate and duplex mode.
Power Via MDI	Contains the power supply capabilities of the port: • Port class (PSE or PD). • Power supply mode. • Whether PSE power supply is supported. • Whether PSE power supply is enabled. • Whether pair selection can be controlled. • Power supply type. • Power source. • Power priority. • PD requested power. • PSE allocated power.
Maximum Frame Size	Indicates the supported maximum frame size.
Power Stateful Control	Indicates the power state control configured on the sending port, including the following: • Power supply mode of the PSE/PD. • PSE/PD priority. • PSE/PD power.
Energy-Efficient Ethernet	Indicates Energy Efficient Ethernet (EEE). EEE TLVs are not supported in the current software version.

LLDP-MED TLVs

LLDP-MED TLVs provide multiple advanced applications for voice over IP (VoIP), such as basic configuration, network policy configuration, and address and directory management. LLDP-MED TLVs provide a cost-effective and easy-to-use solution for deploying voice devices in Ethernet. LLDP-MED TLVs are shown in Table 6.

If the MAC/PHY configuration/status TLV is not advertisable, none of the LLDP-MED TLVs will be advertised even if they are advertisable.

If the LLDP-MED capabilities TLV is not advertisable, the other LLDP-MED TLVs will not be advertised even if they are advertisable.

Table 6 LLDP-MED TLVs

Type	Description
LLDP-MED Capabilities	Allows a network device to advertise the LLDP-MED TLVs that it supports.
Network Policy	Allows a network device or terminal device to advertise the VLAN ID of a port, the VLAN type, and the Layer 2 and Layer 3 priorities for specific applications.
Extended Power-via-MDI	Allows a network device or terminal device to advertise power supply capability. This TLV is an extension of the Power Via MDI TLV.
Hardware Revision	Allows a terminal device to advertise its hardware version.
Firmware Revision	Allows a terminal device to advertise its firmware version.
Software Revision	Allows a terminal device to advertise its software version.
Serial Number	Allows a terminal device to advertise its serial number.
Manufacturer Name	Allows a terminal device to advertise its vendor name.
Model Name	Allows a terminal device to advertise its model name.
Asset ID	Allows a terminal device to advertise its asset ID. The typical case is that the user specifies the asset ID for the endpoint to facilitate directory management and asset tracking.
Location Identification	Allows a network device to advertise the appropriate location identifier information for a terminal device to use in the context of location-based applications.

Management address

The network management system uses the management address of a device to identify and manage the device for topology maintenance and network management. The management address is encapsulated in the management address TLV.

LLDP operating modes

An LLDP agent can operate in one of the following modes:

- **TxRx mode**—An LLDP agent in this mode can send and receive LLDP frames.
- **Tx mode**—An LLDP agent in this mode can only send LLDP frames.
- **Rx mode**—An LLDP agent in this mode can only receive LLDP frames.

- **Disable mode**—An LLDP agent in this mode cannot send or receive LLDP frames.

Each time the operating mode of an LLDP agent changes, its LLDP protocol state machine reinitializes. A configurable reinitialization delay prevents frequent initializations caused by frequent changes to the operating mode. If you configure the reinitialization delay, an LLDP agent must wait the specified amount of time to initialize LLDP after the LLDP operating mode changes.

Transmitting and receiving LLDP frames

Transmitting LLDP frames

An LLDP agent operating in TxRx mode or Tx mode sends LLDP frames to its directly connected devices both periodically and when the local configuration changes. To prevent LLDP frames from overwhelming the network during times of frequent changes to local device information, LLDP uses the token bucket mechanism to rate limit LLDP frames. For more information about the token bucket mechanism, see *ACL and QoS Configuration Guide*.

LLDP automatically enables the fast LLDP frame transmission mechanism in either of the following cases:

- A new LLDP frame is received and carries device information new to the local device.
- The LLDP operating mode of the LLDP agent changes from Disable or Rx to TxRx or Tx.

The fast LLDP frame transmission mechanism successively sends the specified number of LLDP frames at a configurable fast LLDP frame transmission interval. The mechanism helps LLDP neighbors discover the local device as soon as possible. Then, the normal LLDP frame transmission interval resumes.

Receiving LLDP frames

An LLDP agent operating in TxRx mode or Rx mode confirms the validity of TLVs carried in every received LLDP frame. If the TLVs are valid, the LLDP agent saves the information and starts an aging timer. The initial value of the aging timer is equal to the TTL value in the Time To Live TLV carried in the LLDP frame. When the LLDP agent receives a new LLDP frame, the aging timer restarts. When the aging timer decreases to zero, all saved information ages out.

Protocols and standards

- IEEE 802.1AB-2005, *Station and Media Access Control Connectivity Discovery*
- IEEE 802.1AB-2009, *Station and Media Access Control Connectivity Discovery*

Restrictions and guidelines: LLDP configuration

When you configure LLDP, follow these restrictions and guidelines:

- Some of the LLDP configuration tasks are available in different interface views (see Table 7).

Table 7 Support of LLDP configuration tasks in different views

Tasks	Supported views
Enabling LLDP	Layer 2 Ethernet interface view Layer 3 Ethernet interface view
Setting the LLDP operating mode	

Tasks	Supported views
Configuring the advertisable TLVs	Layer 2 aggregate interface view Layer 3 aggregate interface view
Configuring advertisement of the management address TLV	
Setting the encapsulation format for LLDP frames	
Enabling LLDP polling	
Configuring LLDP trapping and LLDP-MED trapping	

LLDP tasks at a glance

To configure LLDP, perform the following tasks:

1. Enabling LLDP
2. Setting the LLDP bridge mode
3. Setting the LLDP operating mode
4. (Optional.) Setting the LLDP reinitialization delay
5. (Optional.) Configuring LLDP packet-related settings
    - Configuring the advertisable TLVs
    - Configuring advertisement of the management address TLV
    - Setting the encapsulation format for LLDP frames
    - Setting LLDP frame transmission parameters
    - Setting the timeout for receiving LLDP frames
6. (Optional.) Enabling LLDP polling
7. (Optional.) Disabling LLDP PVID inconsistency check
8. (Optional.) Configuring LLDP trapping and LLDP-MED trapping
9. (Optional.) Setting the source MAC address of LLDP frames
10. (Optional.) Enabling generation of ARP or ND entries for received management address TLVs

Enabling LLDP

Restrictions and guidelines

For LLDP to take effect on specific ports, you must enable LLDP both globally and on these ports.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable LLDP globally.
   ```
   lldp global enable
   ```
   By default, LLDP is disabled globally.
3. Enter interface view.
   ```
   interface interface-type interface-number
   ```
4. Enable LLDP.
   ```
   lldp enable
   ```
   By default, LLDP is enabled on a port.

Setting the LLDP bridge mode

1. Enter system view.

   system-view

2. Set the LLDP bridge mode.

   - Set the LLDP bridge mode to service bridge.

     lldp mode service-bridge

     By default, LLDP operates in customer bridge mode.

   - Set the LLDP bridge mode to customer bridge.

     undo lldp mode service-bridge

   By default, LLDP operates in customer bridge mode.

Setting the LLDP operating mode

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the LLDP operating mode.

   - In Layer 2 or Layer 3 Ethernet interface view:

     lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **admin-status** { **disable** | **rx** | **tx** | **txrx** }

     In Ethernet interface view, if you do not specify an agent type, the command sets the operating mode for the nearest bridge agent.

   - In Layer 2/Layer 3 aggregate interface view:

     lldp agent { **nearest-customer** | **nearest-nontpmr** } **admin-status** { **disable**| **rx**| **tx**| **txrx** }

     In aggregate interface view, you can set the operating mode only for the nearest customer bridge agent and nearest non-TPMR bridge agent.

   By default:

   - The nearest bridge agent operates in TxRx mode.
   - The nearest customer bridge agent and nearest non-TPMR bridge agent operate in Disable mode.

Setting the LLDP reinitialization delay

About this task

When the LLDP operating mode changes on a port, the port initializes the protocol state machines after an LLDP reinitialization delay. By adjusting the delay, you can avoid frequent initializations caused by frequent changes to the LLDP operating mode on a port.

Procedure

1. Enter system view.

   system-view

2. Set the LLDP reinitialization delay.

```
lldp timer reinit-delay delay
```

The default LLDP reinitialization delay is 2 seconds.

Configuring the advertisable TLVs

1. Enter system view.

```
system-view
```

2. Enter interface view.

```
interface interface-type interface-number
```

3. Configure the advertisable TLVs.

   - In Layer 2 Ethernet interface view:

```
lldp tlv-enable { basic-tlv { all | port-description |
system-capability | system-description | system-name |
management-address-tlv [ ipv6 ] [ ip-address ] } | dot1-tlv { all |
port-vlan-id | link-aggregation | protocol-vlan-id [ vlan-id ] |
vlan-name [ vlan-id ] | management-vid [ mvlan-id ] } | dot3-tlv { all |
mac-physic | max-frame-size | power } | med-tlv { all | capability |
inventory | network-policy [ vlan-id ] | power-over-ethernet |
location-id { civic-address device-type country-code { ca-type
ca-value }&<1-10> | elin-address tel-number } } }
```

     By default, the nearest bridge agent advertises all supported TLVs except the following TLVs:

     – Location identification TLVs.

     – Port and protocol VLAN ID TLVs.

     – VLAN name TLVs.

     – Management VLAN ID TLVs.

```
lldp agent nearest-nontpmr tlv-enable { basic-tlv { all |
port-description | system-capability | system-description |
system-name | management-address-tlv [ ipv6 ] [ ip-address ] } |
dot1-tlv { all | port-vlan-id | link-aggregation } }
```

```
lldp tlv-enable dot1-tlv { protocol-vlan-id [ vlan-id ] | vlan-name
[ vlan-id ] | management-vid [ mvlan-id ] }
```

     By default, the nearest non-TPMR bridge agent does not advertise any TLVs.

```
lldp agent nearest-customer tlv-enable { basic-tlv { all |
port-description | system-capability | system-description |
system-name | management-address-tlv [ ipv6 ] [ ip-address ] } |
dot1-tlv { all | port-vlan-id | link-aggregation } }
```

```
lldp tlv-enable dot1-tlv { protocol-vlan-id [ vlan-id ] | vlan-name
[ vlan-id ] | management-vid [ mvlan-id ] }
```

     By default, the nearest customer bridge agent advertises all the supported basic management TLVs and IEEE 802.1 organizationally specific TLVs.

   - In Layer 3 Ethernet interface view:

```
lldp tlv-enable { basic-tlv { all | port-description |
system-capability | system-description | system-name |
management-address-tlv [ ipv6 ] [ ip-address | interface loopback
interface-number ] } | dot1-tlv { all | link-aggregation } | dot3-tlv
{ all | mac-physic | max-frame-size | power } | med-tlv { all |
capability | inventory | power-over-ethernet | location-id
```

{ **civic-address** *device-type country-code* { *ca-type ca-value* }&<1-10> | **elin-address** *tel-number* } } }

By default, the nearest bridge agent advertises the following TLVs:

- Link aggregation TLVs in the 802.1 organizationally specific TLV set.
- All supported 802.3 organizationally specific TLVs.
- All supported LLDP-MED TLVs except the network policy TLVs.

lldp agent { **nearest-nontpmr** | **nearest-customer** } **tlv-enable** { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **link-aggregation** } }

By default:

- The nearest non-TPMR bridge agent does not advertise any TLVs.
- The nearest customer bridge agent advertises all supported basic management TLVs and link aggregation TLVs in the IEEE 802.1 organizationally specific TLV set.

- In Layer 2 aggregate interface view:

  lldp tlv-enable dot1-tlv { **protocol-vlan-id** [*vlan-id*] | **vlan-name** [*vlan-id*] | **management-vid** [*mvlan-id*]

  lldp agent nearest-nontpmr tlv-enable { **basic-tlv** { **all** | **management-address-tlv** [**ipv6**] [*ip-address*] | **port-description** | **system-capability** | **system-description** | **system-name** } | **dot1-tlv** { **all** | **port-vlan-id** } }

  By default, the nearest non-TPMR bridge agent does not advertise any TLVs.

  lldp agent nearest-customer tlv-enable { **basic-tlv** { **all** | **management-address-tlv** [**ipv6**] [*ip-address*] | **port-description** | **system-capability** | **system-description** | **system-name** } | **dot1-tlv** { **all** | **port-vlan-id** } }

  By default, the nearest customer bridge agent advertises all supported basic management TLVs and the following IEEE 802.1 organizationally specific TLVs:

  - Port and protocol VLAN ID TLVs.
  - VLAN name TLVs.
  - Management VLAN ID TLVs.

  The nearest bridge agent is not supported.

- In Layer 3 aggregate interface view:

  lldp agent { **nearest-customer** | **nearest-nontpmr** } **tlv-enable basic-tlv** { **all** | **management-address-tlv** [**ipv6**] [*ip-address*] | **port-description** | **system-capability** | **system-description** | **system-name** }

  By default:

  - The nearest non-TPMR bridge agent does not advertise any TLVs.
  - The nearest customer bridge agent advertises all supported basic management TLVs.

  The nearest bridge agent is not supported.

Configuring advertisement of the management address TLV

About this task

LLDP encodes management addresses in numeric or string format in management address TLVs.

If a neighbor encodes its management address in string format, set the encoding format of the management address to **string** on the connecting port. This guarantees normal communication with the neighbor.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable advertisement of the management address TLV on the interface and set the management address to be advertised.

   - In Layer 2 Ethernet interface view:

     lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **tlv-enable basic-tlv management-address-tlv** [**ipv6**] [*ip-address*]

   - In Layer 3 Ethernet interface view:

     lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **tlv-enable basic-tlv management-address-tlv** [**ipv6**] [*ip-address*] | **interface loopback** *interface-number*]

   - In Layer 2/Layer 3 aggregate interface view:

     lldp agent { **nearest-customer** | **nearest-nontpmr** } **tlv-enable basic-tlv management-address-tlv** [**ipv6**] [*ip-address*]

4. Set the encoding format of the management address to string.

   - In Layer 2 or Layer 3 Ethernet interface view:

     lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **management-address-format string**

   - In Layer 2/Layer 3 aggregate interface view:

     lldp agent { **nearest-customer** | **nearest-nontpmr** } **management-address-format string**

   The default management address encoding format is numeric.

Setting the encapsulation format for LLDP frames

About this task

Earlier versions of LLDP require the same encapsulation format on both ends to process LLDP frames. To successfully communicate with a neighboring device running an earlier version of LLDP, the local device must be set with the same encapsulation format.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

interface *interface-type interface-number*

3. Set the encapsulation format for LLDP frames to SNAP.
   - In Layer 2 or Layer 3 Ethernet interface view:

     lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **encapsulation snap**
   - In Layer 2/Layer 3 aggregate interface view:

     lldp agent { **nearest-customer** | **nearest-nontpmr** } **encapsulation snap**

   By default, the Ethernet II encapsulation format is used.

Setting LLDP frame transmission parameters

About this task

The Time to Live TLV carried in an LLDPDU determines how long the device information carried in the LLDPDU can be saved on a recipient device.

By setting the TTL multiplier, you can configure the TTL of locally sent LLDPDUs. The TTL is expressed by using the following formula:

TTL = Min (65535, (TTL multiplier × LLDP frame transmission interval + 1))

As the expression shows, the TTL can be up to 65535 seconds. TTLs greater than 65535 will be rounded down to 65535 seconds.

Procedure

1. Enter system view.

   system-view
2. Set the TTL multiplier.

   lldp hold-multiplier *value*

   The default setting is 4.
3. Set the LLDP frame transmission interval.

   lldp timer tx-interval *interval*

   The default setting is 30 seconds.
4. Set the token bucket size for sending LLDP frames.

   lldp max-credit *credit-value*

   The default setting is 5.
5. Set the number of LLDP frames sent each time fast LLDP frame transmission is triggered.

   lldp fast-count *count*

   The default setting is 4.
6. Set the fast LLDP frame transmission interval.

   lldp timer fast-interval *interval*

   The default setting is 1 second.

Setting the timeout for receiving LLDP frames

About this task

This feature allows the device to detect the presence of directly connected neighbors by setting the timeout timer for receiving LLDP frames. If an interface has not received any frames when the timeout timer expires, the device reports a no LLDP neighbor event to the NETCONF module.

Restrictions and guidelines

To avoid misdetection, make sure the timeout for receiving LLDP frames is greater than the LLDP frame transmission interval.

Procedure

1. Enter system view.

   system-view

2. Set the timeout for receiving LLDP frames.

   lldp timer rx-timeout *timeout*

   By default, no timeout is set for receiving LLDP frames, and the device does not report no LLDP neighbor events.

Enabling LLDP polling

About this task

With LLDP polling enabled, a device periodically searches for local configuration changes. When the device detects a configuration change, it sends LLDP frames to inform neighboring devices of the change.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable LLDP polling and set the polling interval.
   - In Layer 2 or Layer 3 Ethernet interface view:

     lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **check-change-interval** *interval*

   - In Layer 2/Layer 3 aggregate interface view:

     lldp agent { **nearest-customer** | **nearest-nontpmr** } **check-change-interval** *interval*

   By default, LLDP polling is disabled.

Disabling LLDP PVID inconsistency check

About this task

By default, when the system receives an LLDP packet, it compares the PVID value contained in the packet with the PVID configured on the receiving interface. If the two PVIDs do not match, a log message will be printed to notify the user.

You can disable PVID inconsistency check if different PVIDs are required on a link.

Procedure

1. Enter system view.

   `system-view`

2. Disable LLDP PVID inconsistency check.

   `lldp ignore-pvid-inconsistency`

   By default, LLDP PVID inconsistency check is enabled.

Configuring CDP compatibility

About this task

To enable your device to exchange information with a directly connected Cisco device that supports only CDP, you must enable CDP compatibility.

CDP compatibility enables your device to receive and recognize CDP packets from the neighboring CDP device and send CDP packets to the neighboring device. The CDP packets sent to the neighboring CDP device carry the following information:

- Device ID.
- ID of the port connecting to the neighboring device.
- Port IP address.
- TTL.

The port IP address is the primary IP address of a VLAN interface in up state. The VLAN ID of the VLAN interface must be the lowest among the VLANs permitted on the port. If no VLAN interfaces of the permitted VLANs are assigned an IP address or all VLAN interfaces are down, no port IP address will be advertised.

You can view the neighboring CDP device information that can be recognized by the device in the output of the **`display lldp neighbor-information`** command. For more information about the **`display lldp neighbor-information`** command, see LLDP commands in *Layer 2—LAN Switching Command Reference*.

CDP-compatible LLDP operates in one of the following modes:

- **TxRx**—CDP packets can be transmitted and received.
- **Disable**—CDP packets cannot be transmitted or received.

Restrictions and guidelines

When you configure CDP compatibility for LLDP, follow these restrictions and guidelines:

- To make CDP-compatible LLDP take effect on a port, follow these steps:
  - **a.** Enable CDP-compatible LLDP globally.
  - **b.** Configure CDP-compatible LLDP to operate in TxRx mode on the port.
- The maximum TTL value that CDP allows is 255 seconds. To make CDP-compatible LLDP work correctly with Cisco IP phones, configure the LLDP frame transmission interval to be no more than 1/3 of the TTL value.

Prerequisites

Before you configure CDP compatibility, complete the following tasks:

- Globally enable LLDP.
- Enable LLDP on the port connecting to a CDP device.
- Configure LLDP to operate in TxRx mode on the port.

Procedure

1. Enter system view.

   system-view

2. Enable CDP compatibility globally.

   lldp compliance cdp

   By default, CDP compatibility is disabled globally.

3. Enter Layer 2/Layer 3 Ethernet interface view or management Ethernet interface view.

   interface *interface-type interface-number*

4. Configure CDP-compatible LLDP to operate in TxRx mode.

   lldp compliance admin-status cdp txrx

   By default, CDP-compatible LLDP operates in **disable** mode.

Configuring LLDP trapping and LLDP-MED trapping

About this task

LLDP trapping or LLDP-MED trapping notifies the network management system of events such as newly detected neighboring devices and link failures.

To prevent excessive LLDP traps from being sent when the topology is unstable, set a trap transmission interval for LLDP.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable LLDP trapping.

   - In Layer 2 or Layer 3 Ethernet interface view:

     lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **notification remote-change enable**

   - In Layer 2/Layer 3 aggregate interface view:

     lldp agent { **nearest-customer** | **nearest-nontpmr** } **notification remote-change enable**

   By default, LLDP trapping is disabled.

4. (In Layer 2 or Layer 3 Ethernet interface view.) Enable LLDP-MED trapping.

   lldp notification med-topology-change enable

   By default, LLDP-MED trapping is disabled.

5. Return to system view.

   quit

6. (Optional.) Set the LLDP trap transmission interval.

   lldp timer notification-interval *interval*

   The default setting is 30 seconds.

Setting the source MAC address of LLDP frames

About this task

Use this feature together with generation of ARP or ND entries for received management address TLVs for the device to use the MAC address of a Layer 3 Ethernet subinterface as the source MAC address of LLDP frames. This ensures that the LLDP neighbor can learn correct ARP or ND entries.

This feature allows you to set the source MAC address of LLDP frames to the MAC address of a Layer 3 Ethernet subinterface that terminates a specified VLAN. If the VLAN is not terminated by any Layer 3 Ethernet subinterface, the MAC address of the Layer 3 Ethernet interface is used as the source MAC address of outgoing LLDP frames. For more information about VLAN termination, see "Configuring VLAN termination."

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 3 Ethernet interface view.

   `interface` *`interface-type interface-number`*

3. Set the source MAC address of LLDP frames to the MAC address of the Layer 3 Ethernet subinterface that terminates a specified VLAN.

   `lldp source-mac vlan` *`vlan-id`*

   By default, the source MAC address of LLDP frames is the MAC address of the egress interface.

Enabling generation of ARP or ND entries for received management address TLVs

About this task

This feature enables the device to generate an ARP or ND entry after receiving an LLDP frame containing a management address TLV on an interface. The ARP or ND entry maps the advertised management address to the source MAC address of the frame.

You can enable generation of both ARP and ND entries on an interface. If the management address TLV contains an IPv4 address, the device generates an ARP entry. If the management address TLV contains an IPv6 address, the device generates an ND entry.

Use this feature together with the source MAC address configuration for LLDP frames for the device to use the MAC address of a Layer 3 Ethernet subinterface as the source MAC address of LLDP frames. This ensures that the LLDP neighbor can learn correct ARP or ND entries.

If you specify a VLAN ID, the Layer 3 Ethernet subinterface that terminates the VLAN is recorded as the output interface in the generated ARP or ND entries. If the VLAN is not terminated by any Layer 3 Ethernet subinterface or no VLAN is specified, the Layer 3 Ethernet interface is recorded as the output interface. For more information about VLAN termination, see "Configuring VLAN termination."

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 3 Ethernet interface view.

   `interface` *`interface-type interface-number`*

3. Enable generation of ARP or ND entries for management address TLVs received on the interface.

lldp management-address { **arp-learning** | **nd-learning** } [**vlan** *vlan-id*]

By default, generation of ARP or ND entries for received management address TLVs is disabled on an interface.

You can enable generation of both ARP and ND entries on an interface.

Display and maintenance commands for LLDP

Execute **display** commands in any view.

Task	Command
Display local LLDP information.	**display lldp local-information** [**global** | **interface** *interface-type interface-number*]
Display the information contained in the LLDP TLVs sent from neighboring devices.	**display lldp neighbor-information** [[[**interface** *interface-type interface-number*] [**agent** { **nearest-bridge** | **nearest-customer** | **nearest-nontpmr** }] [**verbose**]] | **list** [**system-name** *system-name*]]
Display LLDP statistics.	**display lldp statistics** [**global** | [**interface** *interface-type interface-number*] [**agent** { **nearest-bridge** | **nearest-customer** | **nearest-nontpmr** }]]
Display LLDP status of a port.	**display lldp status** [**interface** *interface-type interface-number*] [**agent** { **nearest-bridge** | **nearest-customer** | **nearest-nontpmr** }]
Display types of advertisable optional LLDP TLVs.	**display lldp tlv-config** [**interface** *interface-type interface-number*] [**agent** { **nearest-bridge** | **nearest-customer** | **nearest-nontpmr** }]

Contents

Configuring normal Layer 2 forwarding

About normal Layer 2 forwarding

When an incoming frame's destination MAC address does not match any Layer 3 interface's MAC address, normal Layer 2 forwarding forwards the frame through a Layer 2 interface.

The device uses the destination MAC address of the frame to look for a match in the MAC address table.

- The device forwards the frame out of the outgoing interface in the matching entry if a match is found.
- The device floods the frame to all interfaces in the VLAN of the frame if no match is found.

Normal Layer 2 forwarding is enabled by default.

Display and maintenance commands for Layer 2 forwarding

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display Layer 2 forwarding statistics.	**display mac-forwarding statistics** [**interface** *interface-type interface-number*]
Clear Layer 2 forwarding statistics.	**reset mac-forwarding statistics**

Configuring fast Layer 2 forwarding

About fast Layer 2 forwarding

Fast Layer 2 forwarding improves packet forwarding efficiency by using a high-speed cache and flow-based technology. It identifies a flow by using the following items:

- Source IP address.
- Source port number.
- Destination IP address.
- Destination port number.
- Protocol number.
- Input interface.
- Output interface.
- VLAN ID.

Fast Layer 2 forwarding creates an entry in a high-speed cache by obtaining the forwarding information of a flow's first packet. Subsequent packets of the flow are forwarded based on the entry.

Fast Layer 2 forwarding is enabled by default.

Disabling VLAN ID check for fast Layer 2 forwarding

About this task

The VLAN ID of a packet helps the device to determine the TCP session to which the packet belongs. On a hot backup system formed by two firewalls, you must disable VLAN ID check if the traffic incoming interfaces on the primary and secondary devices belong to different VLANs. If you enable VLAN ID check, traffic cannot match session entries correctly when asymmetric-path traffic exists.

Procedure

1. Enter system view.
   system-view
2. Disable VLAN ID check for fast Layer 2 forwarding.
   undo mac fast-forwarding check-vlan-id
   By default, VLAN ID check is enabled for fast Layer 2 forwarding.

Display and maintenance commands for fast Layer 2 forwarding

Execute **display** commands in any view.

Task	Command
Display IPv4 fast forwarding entries.	**display mac-forwarding cache ip** [*ip-address*] [**slot** *slot-number*]

Display IPv4 fast forwarding entries for fragments.	**display mac-forwarding cache ip fragment** [*ip-address*] [**slot** *slot-number*]
Display IPv6 fast forwarding entries.	**display mac-forwarding cache ipv6** [*ipv6-address*] [**slot** *slot-number*]

Configuring bridge forwarding

About bridge forwarding

Bridge forwarding allows users to customize bridge instances to implement VLAN or port based secure packet forwarding.

Bridge forwarding types

Bridge forwarding has the following types:

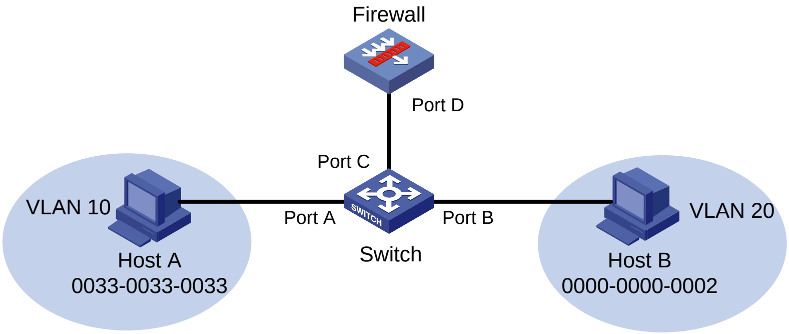
- **Inter-VLAN bridge forwarding**—Forwards a packet between different VLANs.
- **Inline forwarding**—Inline forwarding has the following types:
  - **Reflect-type bridge forwarding**—Forwards a packet through the receiving port of the packet.
  - **Forward-type bridge forwarding**—Forwards a packet through a port that is different from the receiving port of the packet.
  - **Blackhole-type bridge forwarding**—Drops the received packets.

Inter-VLAN bridge forwarding

Inter-VLAN bridge forwarding enables communication between different VLANs at the data link layer. It is typically used on firewall products. A firewall connected to a switch filters Layer 2 traffic before passing the traffic to the switch for further forwarding.

As shown in Figure 1, bridge forwarding enables communication between VLANs 10 and 20. VLANs 10 and 20 are in bridge instance 1 on the firewall. The interface that connects the switch to the firewall is Port C.

Figure 1 Bridge forwarding



The following process uses ARP to describe the MAC address learning and packet forwarding in bridge forwarding. Host A requires the MAC address of Host B and sends out an ARP request. When receiving the request from Host A, bridge forwarding processes the request as follows:

1. The switch performs the following operations:
   a. Learns a new entry to the MAC address table of the switch. The entry contains the MAC address of Host A (0033-0033-0033), the output interface Port A, and VLAN 10.
   b. Broadcasts the request in VLAN 10. Because VLAN 10 is in bridge instance 1, the request enters the firewall through Port C.
2. The firewall performs the following operations:

   a. Learns a new entry to the MAC address table of bridge instance 1. The entry contains the MAC address of Host A (0033-0033-0033), the output interface Port D, and VLAN 10.
   b. Replaces the VLAN tag of the request with VLAN 20 and broadcasts the request in VLAN 20. No matching MAC address entry exists in VLAN 20.
   c. Sends the request to the switch through Port D.
3. The switch performs the following operations:
   a. Learns a new entry to the MAC address table of the switch. The entry contains the MAC address of Host A (0033-0033-0033), interface Port C, and VLAN 20.
   b. Broadcasts the request in VLAN 20.

Host B in VLAN 20 receives the request, places its MAC address in the reply, and sends the reply to Host A. Bridge forwarding processes the reply as follows:

1. The switch performs the following operations:
   a. Learns a new entry to the MAC address table of the switch. The entry contains the MAC address of Host B (0000-0000-0002), the output interface Port B, and VLAN 20.
   b. Uses the destination MAC address 0033-0033-0033 and VLAN ID 20 to search the MAC address table for a match. An entry with interface Port C is found.
   c. Sends the reply to the firewall through Port C.
2. The firewall performs the following operations:
   a. Learns a new entry to the MAC address table of bridge instance 1. The entry contains the MAC address of Host B (0000-0000-0002), the output interface Port D, and VLAN 20.
   b. Uses the destination MAC address 0033-0033-0033 to search the MAC address table of bridge instance 1 for a match. An entry with the output interface Port D and VLAN 10 is found.
   c. Replaces the VLAN ID of the reply (VLAN 20) with the VLAN ID in the entry (VLAN 10).
   d. Sends the reply to the switch through Port D.
3. The switch performs the following operations:
   a. Uses the destination MAC address 0033-0033-0033 and VLAN ID 10 to search the MAC address table for a match. An entry with the output interface Port A exists.
   b. Forwards the reply through Port A.

Inline forwarding

Inline forwarding monitors traffic at the data link layer. It is typically used on security devices. Layer 2 traffic arriving at a device is redirected to a security device based on QoS policies, filtered, and then forwarded toward the destination.

Inline forwarding can be further classified into the following forwarding types:

- Reflect-type bridge forwarding.
- Blackhole-type bridge forwarding.
- Forward-type bridge forwarding.

Reflect-type/blackhole-type bridge forwarding

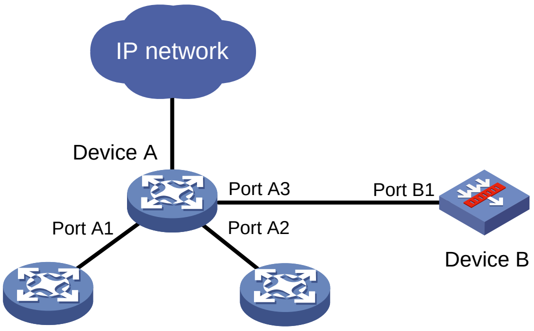
Reflect-type bridge forwarding and blackhole-type bridge forwarding are applicable to the scenario where a device directly accesses the network and is directly connected to a security device.

As shown in Figure 2, Device A is connected to the security device (Device B) through a physical port.

- In reflect-type bridge forwarding mode, packets arriving at Device A are forwarded to Device B for security service processing and then sent back to Device A for forwarding.

- In blackhole-type bridge forwarding mode, packets arriving at Device A are forwarded to Device B. Device B processes the packets and then drops the packets.

Figure 2 Reflect-type/blackhole-type bridge forwarding network

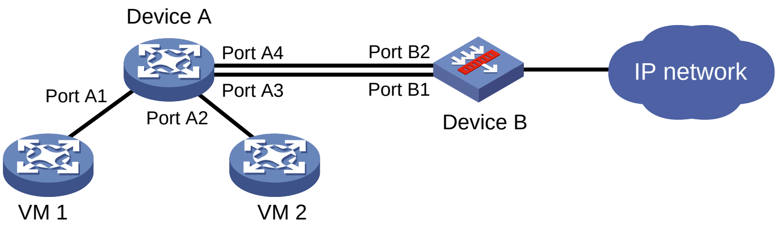


Forward-type bridge forwarding

Forward-type bridge forwarding is applicable to the scenario where a device accesses the network through a security device.

As shown in Figure 3, Device A is connected to Device B through two physical ports. Device B uses one port to receive packets from Device A, and it uses the other port to send packets back to Device A.

Figure 3 Forward-type bridge forwarding network



Packet processing example in inline forwarding

As shown in Figure 2 and Figure 3, when VMs 1 and 2 communicate through Device A, inline forwarding processes packets between them as follows:

- Device A forwards the received packets to Device B.
- Device B passes the IP packets to the security modules for processing and sends other types of packets back to Device A.
- Device B creates forwarding entries for IP packets that meet the security requirements and forwards them to Device A. IP packets that do not meet the security requirements are dropped.

Configuring bridging forwarding

Configuring inter-VLAN bridge forwarding

1. Enter system view.

   system-view

2. (Optional.) Set the aging timer for dynamic MAC address entries.

   bridge mac-address timer aging *seconds*

   The default setting is 300 seconds.

3. Create an inter-VLAN bridge instance, and enter bridge view.

bridge *bridge-index* **inter-vlan**

4. Add a list of VLANs to the bridge instance.

   add vlan *vlan-id-list*

5. (Optional.) Set the MAC learning limit on the bridge instance.

   mac-address max-mac-count *count*

   By default, a maximum of 4096 MAC addresses can be learned on a bridge instance.

Configuring inline forwarding

Restrictions and guidelines

You can manually create reflect-type, forward-type, and blackhole-type bridge instances for inline forwarding and add interfaces to the instances.

The device will automatically create a forward-type bridge instance upon insertion of a hardware bypass subcard. For a forward-type bridge instance to be automatically created, make sure the device does not have an inter-VLAN bridge instance before you insert a hardware bypass subcard.

If you configure inline forwarding on a security device connected to a switch, disable MAC address learning on the switch's interface that is connected to the security device to avoid frequent MAC moves.

Only one interface can be added to a reflect-type or blackhole-type bridge instance.

Only two interfaces can be added to a manually created forward-type bridge instance. The two interfaces must be the same type.

An automatically created forward-type bridge instance uses the pair of interfaces on the bypass subcard by default and you cannot edit the interfaces in the instance.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Configure the device to ignore the tunnel encapsulation when forwarding tunneled packets in inline mode.

   bridge tunnel-encapsulation skip

   In inline forwarding mode, tunneled packets are forwarded based on information in the tunnel encapsulation by default.

3. Create a bridge instance and enter its view.

   - Create a reflect-type bridge instance.

     bridge *bridge-index* **reflect**

   - Create a forward-type bridge instance.

     bridge *bridge-index* **forward**

   - Create a blackhole-type bridge instance.

     bridge *bridge-index* **blackhole**

4. Add an interface to the bridge instance.

   add interface *interface-type interface-number*

   By default, no interfaces exist in a manually created bridge instance.

Configuring security service bypass

About this task

By default, packets are processed by the security service first before being forwarded according to the configured bridge forwarding mode.

The security service bypass feature enables user traffic to bypass security service processing of a security device and be forwarded directly according to the configured bridge forwarding mode.

The device supports only the internal bypass mode. In internal bypass mode, user traffic is sent to the security device but is not processed by it. The security device directly forwards or drops the traffic according to the configured bridge forwarding mode.

Restrictions and guidelines for security service bypass

If you configure the **bypass enable** command for the same bridge instance multiple times, the most recent configuration takes effect.

Enabling internal security service bypass

1. Enter system view.
   system-view
2. Enter bridge instance view.
   - Enter the view of a reflect-type bridge instance.
     bridge *bridge-index* **reflect**
   - Enter the view of an automatically created forward-type bridge instance.
     bridge *bridge-index* **forward**
   - Enter the view of a manually created forward-type bridge instance.
     bridge *bridge-index* **forward**
   - Enter the view of a blackhole-type bridge instance.
     bridge *bridge-index* **blackhole**
3. Enable internal security service bypass.
   bypass enable
   Security service bypass is disabled by default.

Display and maintenance commands for bridge forwarding

Execute **display** commands in any view.

Task	Command
Display MAC address entries in bridge instances.	**display bridge mac-address** [*bridge-index* [**vlan** *vlan-id*]] [**count**] [**slot** *slot-number*]

Configuring fast bridge forwarding

About fast bridge forwarding

Fast bridge forwarding improves packet forwarding efficiency by using a high-speed cache and flow-based technology. It identifies a flow by using the following items:

- Source IP address.
- Source port number.
- Destination IP address.
- Destination port number.
- Protocol number.
- Input interface.
- Output interface.
- VLAN ID.

Fast bridge forwarding creates an entry in a high-speed cache by obtaining the forwarding information of a flow's first packet. Subsequent packets of the flow are forwarded based on the entry.

Fast bridge forwarding is enabled by default.

Disabling VLAN ID check for fast bridge forwarding

About this task

The VLAN ID of a packet helps the device to determine the TCP session to which the packet belongs. On a hot backup system formed by two firewalls, you must disable VLAN ID check if the traffic incoming interfaces on the primary and secondary devices belong to different VLANs. If you enable VLAN ID check, traffic cannot match session entries correctly when asymmetric-path traffic exists.

Restrictions and guidelines

Only inline forwarding supports VLAN ID check. You do not need to configure this feature for inter-VLAN fast bridge forwarding because the device does not check VLAN IDs for inter-VLAN fast bridge forwarding. That is, this feature does not take effect on inter-VLAN fast bridge forwarding.

On a hot backup system formed by two firewalls, inter-VLAN fast bridge forwarding enables a packet to match the same session after being transmitted between the primary and secondary devices.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Disable VLAN ID check for fast bridge forwarding.
   ```
   undo bridge fast-forwarding check-vlan-id
   ```
   By default, VLAN ID check is enabled for fast bridge forwarding.

Display and maintenance commands for fast bridge forwarding

Execute **display** commands in any view.

Task	Command
Display IPv4 fast bridge forwarding entries.	**display bridge cache ip** { **inline** | **inter-vlan** } [*ip-address*] [**slot** *slot-number*]
Display IPv4 fast bridge forwarding entries for fragments.	**display bridge cache ip fragment** { **inline** | **inter-vlan** } [*ip-address*] [**slot** *slot-number*]
Display IPv6 fast bridge forwarding entries.	**display bridge cache ipv6** { **inline** | **inter-vlan** } [*ipv6-address*] [**slot** *slot-number*]

NSFOCUS Firewall Series

NF Layer 2—WAN Access

Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for Layer 2 WAN access features, including PPP and Mobile communication modem.
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
ⓘ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Configuring PPP

About PPP

Point-to-Point Protocol (PPP) is a point-to-point link layer protocol. It provides user authentication, supports synchronous/asynchronous communication, and allows for easy extension.

PPP protocols

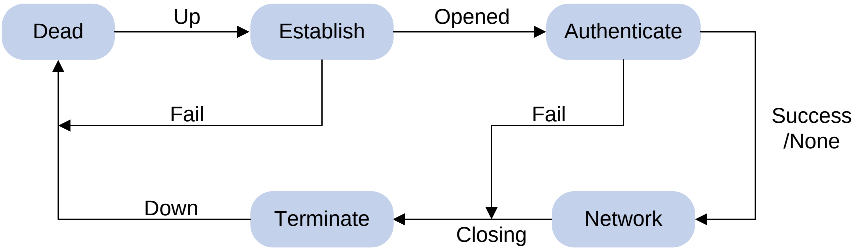
PPP includes the following protocols:

- **Link control protocol (LCP)**—Establishes, tears down, and monitors data links.
- **Network control protocol (NCP)**—Negotiates the packet format and type for data links.
- **Authentication protocols**—Authenticate users. Protocols include the following:
  - Password Authentication Protocol (PAP).
  - Challenge Handshake Authentication Protocol (CHAP).
  - Microsoft CHAP (MS-CHAP).
  - Microsoft CHAP Version 2 (MS-CHAP-V2).

PPP link establishment process

Figure 1 shows the PPP link establishment process.

Figure 1 PPP link establishment process



1. Initially, PPP is in Link Dead phase. After the physical layer goes up, PPP enters the Link Establishment phase (Establish).
2. In the Link Establishment phase, the LCP negotiation is performed. The LCP configuration options include Authentication-Protocol, Maximum-Receive-Unit (MRU), Magic-Number, Protocol-Field-Compression (PFC), Address-and-Control-Field-Compression (ACFC).
   - If the negotiation fails, LCP reports a Fail event, and PPP returns to the Dead phase.
   - If the negotiation succeeds, LCP enters the Opened state and reports an Up event, indicating that the underlying layer link has been established. At this time, the PPP link is not established for the network layer, and network layer packets cannot be transmitted over the link.
3. If authentication is configured, the PPP link enters the Authentication phase, where PAP, CHAP, MS-CHAP, or MS-CHAP-V2 authentication is performed.
   - If the client fails to pass the authentication, LCP reports a Fail event and enters the Link Termination phase. In this phase, the link is torn down and LCP goes down.
   - If the client passes the authentication, LCP reports a Success event.

4. If a network layer protocol is configured, the PPP link enters the Network-Layer Protocol phase for NCP negotiation, such as IPCP negotiation and IPv6CP negotiation.
   - If the NCP negotiation succeeds, the link goes up and becomes ready to carry negotiated network-layer protocol packets.
   - If the NCP negotiation fails, NCP reports a Down event and enters the Link Termination phase.

   If the interface is configured with an IP address, the IPCP negotiation is performed. IPCP configuration options include IP addresses and DNS server IP addresses. After the IPCP negotiation succeeds, the link can carry IP packets.
5. After the NCP negotiation is performed, the PPP link remains active until either of the following events occurs:
   - Explicit LCP or NCP frames close the link.
   - Some external events take place (for example, the intervention of a user).

PPP authentication

PPP supports the following authentication methods:

PAP

PAP is a two-way handshake authentication protocol using the username and password.

PAP sends username/password pairs in plain text over the network. If authentication packets are intercepted in transit, network security might be threatened. For this reason, it is suitable only for low-security environments.

CHAP

CHAP is a three-way handshake authentication protocol.

CHAP transmits usernames but not passwords over the network. It transmits the result calculated from the password and random packet ID by using the MD5 algorithm. It is more secure than PAP. The authenticator may or may not be configured with a username. As a best practice, configure a username for the authenticator, which makes it easier for the peer to verify the identity of the authenticator.

MS-CHAP

MS-CHAP is a three-way handshake authentication protocol. MS-CHAP differs from CHAP as follows:

- MS-CHAP uses CHAP Algorithm 0x80.
- MS-CHAP provides authentication retry. If the peer fails authentication, it is allowed to retransmit authentication information to the authenticator for reauthentication. The authenticator allows a peer to retransmit a maximum of three times.

MS-CHAP-V2

MS-CHAP-V2 is a three-way handshake authentication protocol. MS-CHAP-V2 differs from CHAP as follows:

- MS-CHAP-V2 uses CHAP Algorithm 0x81.
- MS-CHAP-V2 provides two-way authentication by piggybacking a peer challenge on the Response packet and an authenticator response on the Acknowledge packet.
- MS-CHAP-V2 supports authentication retry. If the peer fails authentication, it is allowed to retransmit authentication information to the authenticator for reauthentication. The authenticator allows a peer to retransmit a maximum of three times.
- MS-CHAP-V2 supports password change. If the peer fails authentication because of an expired password, it will send the new password entered by the user to the authenticator for reauthentication.

PPP for IPv4

On IPv4 networks, PPP negotiates the IP address and DNS server address during IPCP negotiation.

IP address negotiation

IP address negotiation enables one end to assign an IP address to the other.

An interface can act as a client or a server during IP address negotiation:

- **Client**—Obtains an IP address from the server. Use the client mode when the device accesses the Internet through an ISP.
- **Server**—Assigns an IP address to the client. Before you configure the IP address of the server, you must perform one of the following tasks:
  - Configure a local address pool and associate the pool with the ISP domain.
  - Specify an IP address or an address pool for the client on the interface.

When IP address negotiation is enabled on a client, the server selects an IP address for the client in the following sequence:

1. If the AAA server configures an IP address or address pool for the client, the server selects that IP address or an IP address from the pool. The IP address or address pool is configured on the AAA server instead of the PPP server. For information about AAA, see *Security Configuration Guide*.
2. If an address pool is associated with the ISP domain used during client authentication, the server selects an IP address from the pool.
3. If an IP address or address pool is specified for the client on the interface of the server, the server selects that IP address or an IP address from that pool.

DNS server address negotiation

IPCP negotiation can determine the DNS server IP address.

When the device is connected to a host, configure the device as the server to assign the DNS server IP address to the host.

When the device is connected to an ISP access server, configure the device as the client. Then, the device can obtain the DNS server IP address from the ISP access server.

PPP for IPv6

On IPv6 networks, PPP negotiates only the IPv6 interface identifier instead of the IPv6 address and IPv6 DNS server address during IPv6CP negotiation.

IPv6 address assignment

PPP cannot negotiate the IPv6 address.

The client can get an IPv6 global unicast address through the following methods:

- **Method 1**—The client obtains an IPv6 prefix in an RA message. The client then generates an IPv6 global unicast address by combining the IPv6 prefix and the negotiated IPv6 interface identifier. The IPv6 prefix in the RA message is determined in the following sequence:
  - IPv6 prefix authorized by AAA.
  - RA prefix configured on the interface.
  - Prefix of the IPv6 global unicast address configured on the interface.

  For information about the ND protocol, see *Layer 3—IP Services Configuration Guide*.
- **Method 2**—The client requests an IPv6 global unicast address through DHCPv6. The server assigns an IPv6 address to the client from the address pool authorized by AAA. If no AAA-authorized address pool exists, DHCPv6 uses the address pool that matches the server's

IPv6 address to assign an IPv6 address to the client. For information about DHCPv6, see *Layer 3—IP Services Configuration Guide*.

- **Method 3**—The client requests prefixes through DHCPv6 and assigns them to downstream hosts. The hosts then uses the prefixes to generate global IPv6 addresses. This method uses the same principle of selecting address pools as method 2.

The device can assign a host an IPv6 address in either of the following ways:

- When the host connects to the device directly or through a bridge device, the device can use method 1 or method 2.
- When the host accesses the device through a router, the device can use method 3 to assign an IPv6 prefix to the router. The router assigns the prefix to the host to generate an IPv6 global unicast address.

IPv6 DNS server address assignment

On IPv6 networks, two methods are available for the IPv6 DNS address assignment:

- AAA authorizes the IPv6 DNS address and assigns this address to the host through RA messages.
- The DHCPv6 client requests an IPv6 DNS address from the DHCPv6 server.

PPP tasks at a glance

To configure PPP, perform the following tasks:

1. Configuring a VT interface
   - Creating a VT interface

   Perform this task in PPPoE and L2TP networks.
   - (Optional.) Restoring the default settings for the VT interface
2. Configuring PPP authentication

   Choose one of the following tasks:
   - Configuring PAP authentication
   - Configuring CHAP authentication (authenticator name is configured)
   - Configuring CHAP authentication (authenticator name is not configured)
   - Configuring MS-CHAP or MS-CHAP-V2 authentication

   Configure PPP authentication for high-security environments.
3. (Optional.) Configuring the polling feature
4. (Optional.) Configuring PPP negotiation
   - Configuring the PPP negotiation timeout time
   - Configuring IP address negotiation on the client
   - Configuring IP address negotiation on the server
   - Enabling IP segment match
   - Configuring DNS server IP address negotiation on the client
   - Configuring DNS server IP address negotiation on the server
   - Configuring ACFC negotiation
   - Configuring PFC negotiation
5. (Optional.) Enabling IP header compression

   IPHC is often used for voice communications over low-speed links.
6. (Optional.) Configuring the NAS-Port-Type attribute
7. (Optional.) Enabling PPP accounting

8. (Optional.) Enabling PPP user logging

Configuring a VT interface

Creating a VT interface

About this task

A virtual-template (VT) interface is a template for creating VA interfaces. In PPPoE, L2TP, and MP networks, VA interfaces are needed for exchanging data with peers. In this case, the system will select a VT interface and dynamically create VA interfaces based on the VT interface.

In PPPoE and L2TP applications, you can use VT interfaces to implement related functions of PPP. For more information about PPPoE and L2TP, see "Configuring PPPoE" and L2TP configuration in *VPN Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create a VT interface and enter its view.

   interface virtual-template *number*

3. (Optional.) Set the interface description.

   description *text*

   By default, the description of a VT interface is *interface name* **Interface**, for example, **Virtual-Template1 Interface**.

4. (Optional.) Set the MTU size of the interface.

   mtu *size*

   By default, the MTU size of an interface is 1500 bytes.

5. (Optional.) Set the expected bandwidth of the VT interface.

   bandwidth *bandwidth-value*

   By default, the expected bandwidth (in kbps) is the interface baud rate divided by 1000.

Restoring the default settings for the VT interface

Restrictions and guidelines

The **default** command might interrupt ongoing network services. Make sure you are fully aware of the impact of this command when you execute it on a live network.

The **default** command might fail to restore the default settings for some commands for reasons such as command dependencies or system restrictions. Use the **display this** command in interface view to identify these commands. Use the **undo** forms of these commands or follow the command reference to individually restore their default settings. If your restoration attempt still fails, follow the error message instructions to resolve the problem.

Procedure

1. Enter system view.

   system-view

2. Enter VT interface view.

   interface virtual-template *number*

3. Restore the default settings for the interface.

default

Configuring PPP authentication

About PPP authentication

PPP supports authentication methods PAP, CHAP, MS-CHAP, and MS-CHAP-V2. You can configure several authentication modes simultaneously. In LCP negotiation, the authenticator negotiates with the peer in the sequence of configured authentication modes until the LCP negotiation succeeds. If the response packet from the peer carries a recommended authentication mode, the authenticator directly uses the authentication mode if it finds the mode configured.

Configuring PAP authentication

Restrictions and guidelines for PAP authentication

For local AAA authentication, the username and password of the peer must be configured on the authenticator.

For remote AAA authentication, the username and password of the peer must be configured on the remote AAA server.

The username and password configured for the peer must be the same as those configured on the peer by using the **ppp pap local-user** command.

Configuring the authenticator

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the authenticator to authenticate the peer by using PAP.

   ppp authentication-mode pap [[**call-in**] **domain** { *isp-name* | **default enable** *isp-name* }]

   By default, PPP authentication is disabled.

4. Configure local or remote AAA authentication.

   For more information about AAA authentication, see *Security Configuration Guide*.

Configuring the peer

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the PAP username and password sent from the peer to the authenticator when the peer is authenticated by the authenticator by using PAP.

   ppp pap local-user *username* **password** { **cipher** | **simple** } *string*

   By default, when being authenticated by the authenticator by using PAP, the peer sends null username and password to the authenticator.

   For security purposes, the password specified in plaintext form and ciphertext form will be stored in encrypted form.

Configuring CHAP authentication (authenticator name is configured)

Restrictions and guidelines for CHAP authentication (authenticator name is configured)

When you configure the authenticator, follow these guidelines:

- For local AAA authentication, the username and password of the peer must be configured on the authenticator.
- For remote AAA authentication, the username and password of the peer must be configured on the remote AAA server.
- The username and password configured for the peer must meet the following requirements:
  - The username configured for the peer must be the same as that configured on the peer by using the **`ppp chap user`** command.
  - The passwords configured for the authenticator and peer must be the same.

When you configure the peer, follow these guidelines:

- For local AAA authentication, the username and password of the authenticator must be configured on the peer.
- For remote AAA authentication, the username and password of the authenticator must be configured on the remote AAA server.
- The username and password configured for the authenticator must meet the following requirements:
  - The username configured for the authenticator must be the same as that configured on the authenticator by using the **`ppp chap user`** command.
  - The passwords configured for the authenticator and peer must be the same.
- The peer does not support the CHAP authentication password configured by using the **`ppp chap password`** command. CHAP authentication (authenticator name is configured) will apply even if the authentication name is configured.

Configuring the authenticator

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure the authenticator to authenticate the peer by using CHAP.

   `ppp authentication-mode chap` [[**`call-in`**] **`domain`** { *`isp-name`* | **`default enable`** *`isp-name`* }]

   By default, PPP authentication is disabled.

4. Configure a username for the CHAP authenticator.

   `ppp chap user` *`username`*

   The default setting is null.

5. Configure local or remote AAA authentication.

   For more information about AAA authentication, see *Security Configuration Guide*.

Configuring the peer

1. Enter system view.

   `system-view`

2. Enter interface view.

interface *interface-type interface-number*

3. Configure a username for the CHAP peer.

   ppp chap user *username*

   The default setting is null.

4. Configure local or remote AAA authentication.

   For more information about AAA authentication, see *Security Configuration Guide*.

Configuring CHAP authentication (authenticator name is not configured)

Restrictions and guidelines for CHAP authentication (authenticator name is not configured)

For local AAA authentication, the username and password of the peer must be configured on the authenticator.

For remote AAA authentication, the username and password of the peer must be configured on the remote AAA server.

The username and password configured for the peer must meet the following requirements:

- The username configured for the peer must be the same as that configured on the peer by using the **ppp chap user** command.
- The password configured for the peer must be the same as that configured on the peer by using the **ppp chap password** command.

Configuring the authenticator

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the authenticator to authenticate the peer by using CHAP.

   ppp authentication-mode chap [[**call-in**] **domain** { *isp-name* | **default enable** *isp-name* }]

   By default, PPP authentication is disabled.

4. Configure local or remote AAA authentication.

   For more information about AAA authentication, see *Security Configuration Guide*.

Configuring the peer

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure a username for the CHAP peer.

   ppp chap user *username*

   The default setting is null.

4. Set the CHAP authentication password.

   ppp chap password { **cipher** | **simple** } *string*

   The default setting is null.

   For security purposes, the password specified in plaintext form and ciphertext form will be stored in encrypted form.

Configuring MS-CHAP or MS-CHAP-V2 authentication

Restrictions and guidelines for MS-CHAP or MS-CHAP-V2 authentication

The device can only act as an authenticator for MS-CHAP or MS-CHAP-V2 authentication.

MS-CHAP-V2 authentication supports password change only when using RADIUS.

As a best practice, do not set the authentication method for PPP users to **none** when MS-CHAP-V2 authentication is used.

For local AAA authentication, the username and password of the peer must be configured on the authenticator. For remote AAA authentication, the username and password of the peer must be configured on the remote AAA server. The username and password of the peer configured on the authenticator or remote AAA server must be the same as those configured on the peer.

If authentication name is configured, the username configured for the authenticator on the peer must be the same as that configured on the authenticator by using the **ppp chap user** command.

Configuring MS-CHAP or MS-CHAP-V2 authentication (authenticator name is configured)

1. Enter system view.

   system-view

2. Enter interface view.

   interface interface-type interface-number

3. Configure the authenticator to authenticate the peer by using MS-CHAP or MS-CHAP-V2.

   ppp authentication-mode { **ms-chap** | **ms-chap-v2** } [[**call-in**] **domain** { *isp-name* | **default enable** *isp-name* }]

   By default, PPP authentication is disabled.

4. Configure a username for the MS-CHAP or MS-CHAP-V2 authenticator.

   ppp chap user *username*

5. Configure local or remote AAA authentication.

   For more information about AAA authentication, see *Security Configuration Guide*.

Configuring MS-CHAP or MS-CHAP-V2 authentication (authenticator name is not configured)

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the authenticator to authenticate the peer by using MS-CHAP or MS-CHAP-V2.

   ppp authentication-mode { **ms-chap** | **ms-chap-v2** } [[**call-in**] **domain** { *isp-name* | **default enable** *isp-name* }]

   By default, PPP authentication is disabled.

4. Configure local or remote AAA authentication.

   For more information about AAA authentication, see *Security Configuration Guide*.

Configuring the polling feature

About this task

The polling feature checks PPP link state.

On an interface that uses PPP encapsulation, the link layer sends keepalive packets at keepalive intervals to detect the availability of the peer. If the interface receives no response to keepalive packets when the keepalive retry limit is reached, it determines that the link fails and reports a link layer down event.

To set the keepalive retry limit, use the **timer-hold retry** command.

The value 0 disables an interface from sending keepalive packets. In this case, the interface can respond to keepalive packets from the peer.

Restrictions and guidelines

On a slow link, increase the keepalive interval to prevent false shutdown of the interface. This situation might occur when keepalive packets are delayed because a large packet is being transmitted on the link.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the keepalive interval.

   timer-hold *seconds*

   The default setting is 10 seconds.

4. Set the keepalive retry limit.

   timer-hold retry *retries*

   The default setting is 5.

Configuring PPP negotiation

Configuring the PPP negotiation timeout time

About this task

The device starts the PPP negotiation timeout timer after sending a packet. If no response is received before the timer expires, the device sends the packet again.

If two ends of a PPP link vary greatly in the LCP negotiation packet processing rate, configure this command on the end with a higher processing rate. The LCP negotiation delay timer prevents frequent LCP negotiation packet retransmission. After the physical layer comes up, PPP starts LCP negotiation when the delay timer expires. If PPP receives LCP negotiation packets before the delay timer expires, it starts LCP negotiation immediately.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the negotiation timeout time.

   ppp timer negotiate *seconds*

   The default setting is 3 seconds.

4. (Optional.) Set the LCP negotiation delay timer.

   ppp lcp delay *milliseconds*

   By default, PPP starts LCP negotiation immediately after the physical layer comes up.

Configuring IP address negotiation on the client

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Enable IP address negotiation.

   ```
   ip address ppp-negotiate
   ```

   By default, IP address negotiation is not enabled.

   If you execute this command and the **ip address** command multiple times, the most recent configuration takes effect. For more information about the **ip address** command, see *Layer 3—IP Services Command Reference*.

Configuring IP address negotiation on the server

About this task

Configure the server to assign an IP address to a client by using the following methods:

- Method 1: Specify an IP address for the client on the server interface.
- Method 2: Specify a PPP or DHCP address pool on the server interface.
- Method 3: Associate a PPP or DHCP address pool with an ISP domain.

Restrictions and guidelines for IP address negotiation on the server

For clients requiring no authentication, you can use either method 1 or method 2. When both method 1 and method 2 are configured, the most recent configuration takes effect.

For clients requiring authentication, you can use one or more of the three methods. When multiple methods are configured, method 3 takes precedence over method 1 or method 2. When both method 1 and method 2 are configured, the most recent configuration takes effect.

PPP supports IP address assignment from a PPP or DHCP address pool. If you use a pool name that identifies both a PPP address pool and a DHCP address pool, the system uses the PPP address pool.

When assigning IP address to users through a PPP address pool, make sure the PPP address pool excludes the gateway IP address of the PPP address pool.

Specifying an IP address for the client on the server interface

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Configure the interface to assign an IP address to the peer.

   ```
   remote address ip-address
   ```

   By default, an interface does not assign an IP address to the peer.

4. Configure an IP address for the interface.

   ```
   ip address ip-address
   ```

   By default, no IP address is configured on an interface.

Specifying a PPP address pool on the server interface

1. Enter system view.

system-view

2. Configure a PPP address pool.

   ip pool *pool-name start-ip-address* [*end-ip-address*] [**group** *group-name*]

3. (Optional.) Configure a gateway address for the PPP address pool.

   ip pool *pool-name* **gateway** *ip-address* [**vpn-instance** *vpn-instance-name*]

   By default, the PPP address pool is not configured with a gateway address.

4. (Optional.) Configure a PPP address pool route.

   ppp ip-pool route *ip-address* { *mask-length* | *mask* } [**vpn-instance** *vpn-instance-name*]

   By default, no PPP address pool route exists.

   The destination network of the PPP address pool route must include the PPP address pool.

5. Enter interface view.

   interface *interface-type interface-number*

6. Configure the interface to assign an IP address from the configured PPP address pool to the peer.

   remote address pool *pool-name*

   By default, an interface does not assign an IP address to the peer.

7. Configure an IP address for the interface.

   ip address *ip-address*

   By default, no IP address is configured on an interface.

Specifying a DHCP address pool on the server interface

1. Enter system view.

   system-view

2. Configure DHCP.
   - If the server acts as a DHCP server, perform the following tasks:
     - Configure the DHCP server.
     - Configure a DHCP address pool on the server.
   - If the server acts as a DHCP relay agent, perform the following tasks:
     - Configure the DHCP relay agent on the server.
     - Configure a DHCP address pool on the remote DHCP server.
     - Enable the DHCP relay agent to record relay entries.
     - Configure a DHCP relay address pool.

   For information about configuring a DHCP server and a DHCP relay agent, see *Layer 3—IP Services Configuration Guide*.

3. Enter interface view.

   interface *interface-type interface-number*

4. Configure the interface to assign an IP address from the configured DHCP address pool to the peer.

   remote address pool *pool-name*

   By default, an interface does not assign an IP address to the peer.

5. (Optional.) Configure the DHCP client IDs for PPP users acting as DHCP clients.

   remote address dhcp client-identifier { **callingnum** | **username** }

By default, no DHCP client IDs are configured for PPP users acting as DHCP clients.

When PPP usernames are used as DHCP client IDs, make sure different users use different PPP usernames to come online.

6. Configure an IP address for the interface.

   ip address *ip-address*

   By default, no IP address is configured on an interface.

Associating a PPP address pool with an ISP domain

1. Enter system view.

   system-view

2. Configure a PPP address pool.

   ip pool *pool-name start-ip-address* [*end-ip-address*] [**group** *group-name*]

   By default, no PPP address pool is configured.

3. (Optional.) Configure a gateway address for the PPP address pool.

   ip pool *pool-name* **gateway** *ip-address* [**vpn-instance** *vpn-instance-name*]

   By default, the PPP address pool is not configured with a gateway address.

4. (Optional.) Configure a PPP address pool route.

   ppp ip-pool route *ip-address* { *mask-length* | *mask* } [**vpn-instance** *vpn-instance-name*]

   By default, no PPP address pool route exists.

   The destination network of the PPP address pool route must include the PPP address pool.

5. Enter ISP domain view.

   domain *isp-name*

6. Associate the ISP domain with the configured PPP address pool for address assignment.

   authorization-attribute ip-pool *pool-name*

   By default, no PPP address pool is associated.

   For more information about this command, see *Security Command Reference.*

7. Return to system view.

   quit

8. Enter interface view.

   interface *interface-type interface-number*

9. Configure an IP address for the interface.

   ip address *ip-address*

   By default, no IP address is configured on an interface.

Associating a DHCP address pool with an ISP domain

1. Enter system view.

   system-view

2. Configure DHCP.

   - If the server acts as a DHCP server, perform the following tasks:
     - Configure the DHCP server.
     - Configure a DHCP address pool on the server.
   - If the server acts as a DHCP relay agent, perform the following tasks:
     - Configure the DHCP relay agent on the server.

- Configure a DHCP address pool on the remote DHCP server.
- Enable the DHCP relay agent to record relay entries.
- Configure a DHCP relay address pool.

For information about configuring a DHCP server and a DHCP relay agent, see *Layer 3—IP Services Configuration Guide*.

3. Enter ISP domain view.

   domain *isp-name*

4. Associate the ISP domain with the configured DHCP address pool or DHCP relay address pool for address assignment.

   authorization-attribute ip-pool *pool-name*

   By default, no DHCP address pool or DHCP relay address pool is associated.

   For more information about this command, see *Security Command Reference*.

5. Return to system view.

   quit

6. Enter interface view.

   interface *interface-type interface-number*

7. (Optional.) Configure the DHCP client IDs for PPP users acting as DHCP clients.

   remote address dhcp client-identifier { **callingnum** | **username** }

   By default, no DHCP client IDs are configured for PPP users acting as DHCP clients.

   When PPP usernames are used as DHCP client IDs, make sure different users use different PPP usernames to come online.

8. Configure an IP address for the interface.

   ip address *ip-address*

   By default, no IP address is configured on an interface.

Enabling IP segment match

About this task

This feature enables the local interface to check whether its IP address and the IP address of the remote interface are in the same network segment. If they are not, IPCP negotiation fails.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable IP segment match.

   ppp ipcp remote-address match

   By default, this feature is disabled.

Configuring DNS server IP address negotiation on the client

About this task

During PPP negotiation, the server will assign a DNS server IP address only for a client configured with the **ppp ipcp dns request** command. For some special devices to forcibly assign DNS server IP addresses to clients that do not initiate requests, configure the **ppp ipcp dns admit-any** command on these devices.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the device to request the peer for a DNS server IP address.

   ppp ipcp dns request

   By default, a client does not request its peer for a DNS server IP address.

4. Configure the device to accept the DNS server IP addresses assigned by the peer even though it does not request the peer for the DNS server IP addresses.

   ppp ipcp dns admit-any

   By default, a device does not accept the DNS server IP addresses assigned by the peer if it does not request the peer for the DNS server IP addresses.

   This command is not necessary if the **ppp ipcp dns request** command is configured.

Configuring DNS server IP address negotiation on the server

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify the primary and secondary DNS server IP addresses to be allocated to the peer in PPP negotiation.

   ppp ipcp dns *primary-dns-address* [*secondary-dns-address*]

   By default, a device does not allocate DNS server IP addresses to its peer if the peer does not request them.

   After this command is configured, the server allocate DNS server IP addresses to a client that initiates requests.

Configuring ACFC negotiation

About this task

PPP can compress the address and control fields of PPP packets to increase the payload size.

ACFC negotiation notifies the peer that the local end can receive packets carrying compressed address and control fields.

ACFC negotiation is implemented at the LCP negotiation stage. After the ACFC negotiation succeeds, PPP does not include the address and control fields in non-LCP packets. To ensure successful LCP negotiation, PPP does not apply the compression to LCP packets.

Restrictions and guidelines for ACFC negotiation

As a best practice, use the ACFC configuration option on low-speed links.

Configuring the local end to send ACFC requests

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the local end to send ACFC requests by including the ACFC option in outbound LCP negotiation requests.

   ppp acfc local request

   By default, the local end does not include the ACFC option in outbound LCP negotiation requests.

Configuring local end to reject ACFC requests received from the peer

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the local end to reject ACFC requests received from the peer.

   ppp acfc remote-reject

   By default, the local end accepts the ACFC requests from the remote peer, and performs ACFC on frames sent to the peer.

Configuring PFC negotiation

About this task

PPP can compress the protocol field of PPP packets from 2 bytes to 1 byte to increase the payload size.

PFC negotiation notifies the peer that the local end can receive packets with a single-byte protocol field.

PFC negotiation is implemented at the LCP negotiation stage. After PFC negotiation is completed, the device compresses the protocol field of sent non-LCP packets. If the first eight bits of the protocol field are all zeros, the device does not add those bits into the packet. To ensure successful LCP negotiation, PPP does not apply the compression to LCP packets.

Restrictions and guidelines for PFC negotiation

As a best practice, use this configuration option on low-speed links.

Configuring the local end to send PFC requests

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the local end to send PFC requests by including the PFC option in outbound LCP negotiation requests.

   ppp pfc local request

   By default, the local end does not include the PFC option in outbound LCP negotiation requests.

Configuring the local end to reject PFC requests received from the peer

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the local end to reject PFC requests received from the peer.

   ppp pfc remote-reject

   By default, the device accepts PFC requests received from the peer, and performs PFC on frames sent to the peer.

Enabling IP header compression

About this task

IP header compression (IPHC) compresses packet headers to speed up packet transmission. IPHC is often used for voice communications over low-speed links.

IPHC provides the following compression features:

- **RTP header compression**—Compresses the IP header, UDP header, and RTP header of an RTP packet, which have a total length of 40 bytes.
- **TCP header compression**—Compresses the IP header and TCP header of a TCP packet, which have a total length of 40 bytes.

Restrictions and guidelines

To use IPHC, you must enable it on both sides of a PPP link.

Enabling or disabling IPHC on a VT or dialer interface does not immediately take effect. You must execute the **shutdown** and **undo shutdown** commands on the interface or the bound physical interface to apply the new setting.

After you enable IPHC, you can configure the maximum number of connections for RTP or TCP header compression. The configuration takes effect after you execute the **shutdown** and **undo shutdown** command on the interface. The configuration is removed after IPHC is disabled.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable IP header compression.

   ppp compression iphc enable [**nonstandard**]

   By default, IP header compression is disabled.

   The **nonstandard** option must be specified when the device communicates with a non-NSFOCUS device.

   When the **nonstandard** keyword is specified, only RTP header compression is supported and TCP header compression is not supported.

4. Set the maximum number of connections for which an interface can perform RTP header compression.

   ppp compression iphc rtp-connections *number*

   The default setting is 16.

5. Set the maximum number of connections for which an interface can perform TCP header compression.

   ppp compression iphc tcp-connections *number*

   The default setting is 16.

Configuring the NAS-Port-Type attribute

About this task

The NAS-Port-Type attribute is used for RADIUS authentication and accounting. For information about the NAS-Port-Type attribute, see RFC 2865.

Restrictions and guidelines

The configuration of this feature does not affect existing users.

Procedure

1. Enter system view.

   `system-view`

2. Enter VT interface view.

   `interface virtual-template` *`number`*

3. Configure the NAS-Port-Type attribute.

   `nas-port-type` { **`ethernet`** | **`virtual`** }

   By default, the NAS-Port-Type attribute is determined by the service type and link type of the PPP user as follows:

   - When the service type is PPPoE, the NAS-Port-Type attribute is **`ethernet`**.
   - When the service type is L2TP, the NAS-Port-Type attribute is **`virtual`**.

Enabling PPP accounting

About this task

PPP accounting collects PPP statistics, including the numbers of received and sent PPP packets and bytes. AAA can use the PPP statistics for accounting. For more information about AAA, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Enable PPP accounting.

   `ppp account-statistics enable` [**`acl`** { *`acl-number`* | **`name`** *`acl-name`* }]

   By default, PPP accounting is disabled.

Enabling PPP user logging

About this task

The PPP user logging feature enables the device to generate PPP logs and send them to the information center. Logs are generated after a user comes online, goes offline, or fails to come online. A log entry contains information such as the username, IP address, interface name, inner VLAN, outer VLAN, MAC address, and failure causes. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

Typically, disable this feature to prevent excessive PPP log output.

Procedure

1. Enter system view.
   `system-view`
2. Enable PPP user logging.
   `ppp access-user log enable` [**`successful-login`** | **`failed-login`** | **`normal-logout`** | **`abnormal-logout`**] *
   By default, PPP user logging is disabled.

Display and maintenance commands for PPP

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display information about VA interfaces.	**display interface** [**virtual-access** [*interface-number*]] [**brief** [**description** | **down**]]
Display information about VT interfaces.	**display interface** [**virtual-template** [*interface-number*]] [**brief** [**description** | **down**]]
Display PPP address pools.	**display ip pool** [*pool-name* | **group** *group-name*]
Display information about PPP access users.	**display ppp access-user** { **domain** *domain-name* | **interface** *interface-type interface-number* [**count**] | **ip-address** *ipv4-address* | **ipv6-address** *ipv6-address* | **username** *user-name* | **user-type** { **lac** | **lns** | **pppoe** } [**count**] }
Display PPP negotiation packet statistics.	**display ppp packet statistics** [**slot** *slot-number*]
Display IPHC statistics.	**display ppp compression iphc** { **rtp** | **tcp** } [**interface** *interface-type interface-number*]
Clear statistics on VA interfaces.	**reset counters interface** [**virtual-access** [*interface-number*]]
Log off a PPP user.	**reset ppp access-user** { **ip-address** *ipv4-address* [**vpn-instance** *ipv4-vpn-instance-name*] | **ipv6-address** *ipv6-address* [**vpn-instance** *ipv6-vpn-instance-name*] | **username** *user-name* }
Clear IPHC statistics.	**reset ppp compression iphc** [**rtp** | **tcp**] [**interface** *interface-type interface-number*]
Clear PPP negotiation packet statistics.	**reset ppp packet statistics** [**slot**

Task	Command
	slot-number]

Configuring PPPoE

About PPPoE

Point-to-Point Protocol over Ethernet (PPPoE) extends PPP by transporting PPP frames encapsulated in Ethernet over point-to-point links.

PPPoE specifies the methods for establishing PPPoE sessions and encapsulating PPP frames over Ethernet. PPPoE requires a point-to-point relationship between peers instead of a point-to-multipoint relationship as in multi-access environments such as Ethernet. PPPoE provides Internet access for the hosts in an Ethernet through a remote access device and implement access control, authentication, and accounting on a per-host basis. Integrating the low cost of Ethernet and scalability and management functions of PPP, PPPoE gained popularity in various application environments, such as residential access networks.

For more information about PPPoE, see RFC 2516.

PPPoE network structure

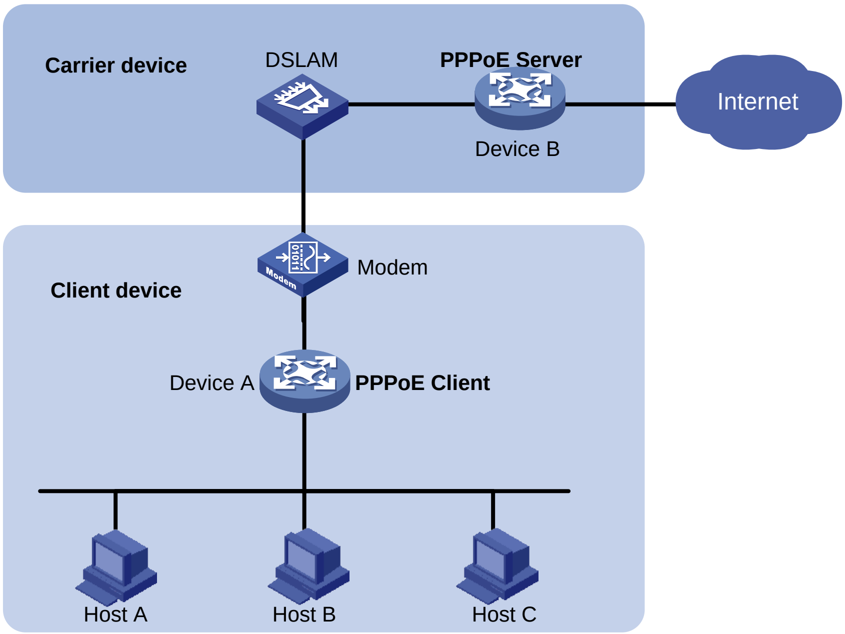
PPPoE uses the client/server model. The PPPoE client initiates a connection request to the PPPoE server. After session negotiation between them is complete, a session is established between them, and the PPPoE server provides access control, authentication, and accounting to the PPPoE client.

PPPoE network structures are classified into router-initiated and host-initiated network structures depending on the starting point of the PPPoE session.

Router-initiated network structure

As shown in Figure 2, the PPPoE session is established between devices (Device A and Device B). All hosts share one PPPoE session for data transmission without being installed with PPPoE client software. This network structure is typically used by enterprises.

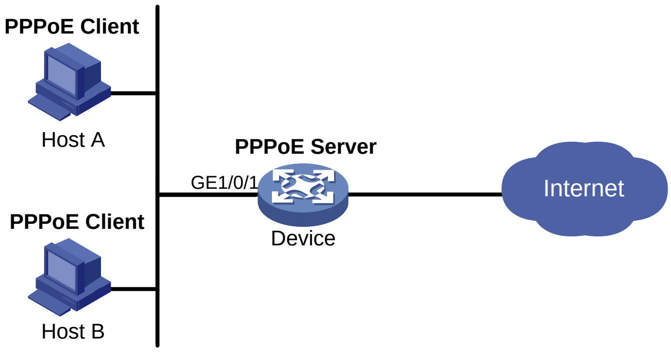
Figure 2 Router-initiated network structure



Host-initiated network structure

As shown in Figure 3, a PPPoE session is established between each host (PPPoE client) and the carrier device (PPPoE server). The service provider assigns an account to each host for billing and control. The host must be installed with PPPoE client software.

Figure 3 Host-initiated network structure



Configuring a PPPoE client

Operation mode

A PPPoE session can operate in one of the following modes:

- **Permanent mode**—A PPPoE session is established immediately when the line is physically up. This type of session remains until the physical link comes down or until the session is disconnected.
- **On-demand mode**—A PPPoE session is established when there is a demand for data transmission instead of when the line is physically up. It is terminated when idled for a specific period of time.
- **Diagnostic mode**—A PPPoE session is established immediately after the device configurations finish. The device automatically terminates the PPPoE session and then tries to re-establish a PPPoE session at a pre-configured interval. By establishing and terminating PPPoE sessions periodically, you can monitor the operating status of the PPPoE link.

The PPPoE session operating mode is determined by your configuration on the dialer interface:

- **Permanent mode**—Used when you set the link idle time to 0 by using the **`dialer timer idle`** command and do not configure the **`dialer diagnose`** command.
- **On-demand mode**—Used when you set the link idle time to a non-zero value by using the **`dialer timer idle`** command and do not configure the **`dialer diagnose`** command.
- **Diagnostic mode**—Used when you configure the **`dialer diagnose`** command.

PPPoE client tasks at a glance

To configure a PPPoE client, perform the following tasks:

1. Configuring a dialer interface
2. Configuring a PPPoE session
3. (Optional.) Resetting a PPPoE session

Configuring a dialer interface

About this task

Before establishing a PPPoE session, you must first create a dialer interface and configure bundle DDR on the interface. Each PPPoE session uniquely corresponds to a dialer bundle, and each dialer bundle uniquely corresponds to a dialer interface. A PPPoE session uniquely corresponds to a dialer interface.

Procedure

1. Enter system view.

   system-view

2. Create a dialer group and configure a dial rule.

   dialer-group *group-number* **rule** { **ip** | **ipv6** } { **deny** | **permit** | **acl** { *acl-number* | **name** *acl-name* } }

   Configure this command only when the PPPoE session operates in on-demand mode.

3. Create a dialer interface and enter its view.

   interface dialer *number*

4. Assign an IP address to the interface.

   ip address { *address mask* | **ppp-negotiate** }

   By default, no IP address is configured.

5. Enable bundle DDR on the interface.

   dialer bundle enable

   By default, bundle DDR is disabled.

6. Associate the interface with the dial rule by associating the interface with the corresponding dialer group.

   dialer-group *group-number*

   By default, a dialer interface is not assigned to any dialer group.

   Configure this command only when the PPPoE session operates in on-demand mode.

7. Configure the link-idle timeout timer.

   dialer timer idle *idle* [**in** | **in-out**]

   The default setting is 120 seconds.

   When this timer is set to 0 seconds, the PPPoE session operates in permanent mode. Otherwise, the PPPoE session operates in on-demand mode.

8. Configure the DDR application to operate in diagnostic mode.

   dialer diagnose [**interval** *interval*]

   By default, the DDR application operates in non-diagnostic mode.

   Execute this command only when the PPPoE session operates in diagnostic mode.

9. (Optional.) Set the auto-dial interval.

   dialer timer autodial *autodial-interval*

   The default setting is 300 seconds.

   DDR starts the auto-dial timer after the link is disconnected and originates a new call when the auto-dial timer expires.

   As a best practice, set a shorter auto-dial interval for DDR to soon originate a new call.

10. (Optional.) Set the MTU for the dialer interface

    mtu *size*

    By default, the MTU on a dialer interface is 1500 bytes.

The dialer interface fragments a packet that exceeds the configured MTU, and adds a 2-byte PPP header and a 6-byte PPPoE header to each fragment. You should modify the MTU of a dialer interface to make sure the total length of any fragment packet is less than the MTU of the physical interface.

Configuring a PPPoE session

About this task

After a PPPoE session is successfully established, the system automatically creates a VA interface for exchanging packets with the peer. To display information about VA interfaces, execute the **display interface virtual-access** command. VA interfaces cannot be manually configured.

After the PPPoE session is terminated, the corresponding VA interface is automatically deleted.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Create a PPPoE session and specify a dialer bundle for the session.
   pppoe-client dial-bundle-number *number* [**no-hostuniq**]
   The *number* argument in this command must take the same value as the configured dialer interface number.

Resetting a PPPoE session

About this task

After you reset a PPPoE session in permanent mode, the device establishes a new PPPoE session when the autodial timer expires.

After you reset a PPPoE session in on-demand mode, the device establishes a new PPPoE session when there is a demand for data transmission.

Procedure

To reset a PPPoE session, execute the following command in user view:

reset pppoe-client { **all** | **dial-bundle-number** *number* }

Display and maintenance commands for PPPoE

Display and maintenance commands for PPPoE client

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display summary information for a PPPoE session.	**display pppoe-client session summary** [**dial-bundle-number** *number*]
Display the protocol packet statistics for a PPPoE session.	**display pppoe-client session packet** [**dial-bundle-number** *number*]

Task	Command
Clear the protocol packet statistics for a PPPoE session.	**reset pppoe-client session packet** [**dial-bundle-number** *number*]

Contents

Managing a mobile communication modem

About managing a mobile communication modem

A mobile communication modem connects a device to a mobile communication network.

USB 3G/4G modems and built-in modems are available for the device.

The device uses a fixed cellular interface to configure and manage a USB 3G/4G modem or a built-in modem. A USB 3G/4G modem is hot swappable. The configuration for a USB 3G/4G modem remains after the modem is removed from the device.

A cellular interface can be channelized into an Eth-channel interface. The data link layer protocol of the Eth-channel interface is Ethernet. The interface supports IP at the network layer.

The cellular interface of a 4G modem can only be channelized into an Eth-channel interface.

Restrictions: Hardware compatibility with mobile communication modem management

Model	Mobile communication modem management compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No
NFNX3-HDB680, NFNX3-HDB1080	Yes

Restrictions and guidelines: Mobile communication modem management

Follow these restrictions and guidelines when you configure mobile communication modem management:

- Do not remove a USB 3G/4G modem while it is transmitting data. As a best practice, execute the **shutdown** command to shut down the USB 3G/4G modem before removing it.
- A USB 3G/4G modem is not usable when the USB interface to which the modem is attached is shut down. For more information about shutting down a USB interface, see *Fundamentals Configuration Guide*.
- Unless otherwise noted, the mobile communication modem configuration in this document is saved in the NVM of the mobile communication modem. To verify the configuration, use the **display cellular** command.

Mobile communication modem management tasks at a glance

To management a mobile communication modem, perform the following tasks:

1. Configuring the mobile communication modem cellular interface
   - Configuring the 4G modem cellular interface
2. Configuring an Eth-channel interface for a 4G modem
3. Configuring a mobile communication network
4. Configuring parameter profiles
5. (Optional.) Specifying the primary or secondary SIM card
6. (Optional.) Associating mobile communication link backup with a track entry
7. (Optional.) Configuring PIN verification
8. (Optional.) Configuring DM
9. (Optional.) Setting the RSSI thresholds
10. (Optional.) Issuing a configuration directive to a mobile communication modem
11. (Optional.) Configuring mobile communication modem reboot
    - Configuring automatic reboot
    - Configuring manual reboot

Configuring the 4G modem cellular interface

1. Enter system view.

   `system-view`

2. Enter cellular interface view.

   `controller cellular` *`cellular-number`*

3. Configure a description for the cellular interface.

   `description` *`text`*

   By default, the description for a cellular interface is *interface name* **Interface**, for example, Cellular 1/0/1 Interface.

4. Channelize the cellular interface into an Eth-channel interface.

   `eth-channel` *`channel-number`*

   This command names the Eth-channel interface as eth-channel *cellular-number*:*channel-number*.

   Specify an IP address for the Eth-channel interface channelized from the cellular interface of a 4G modem as needed.

5. Bring up the cellular interface.

   `undo shutdown`

   By default, a cellular interface is up.

Configuring an Eth-channel interface for a 4G modem

Configuring basic parameters for an Eth-channel interface

1. Enter system view.

   system-view

2. Enter Eth-channel interface view.

   interface eth-channel *interface-number*

3. Configure a description of the Eth-channel interface.

   description *text*

   By default, the description for an Eth-channel interface is *interface name* **Interface**, for example, Echannel1/0/1:0 Interface.

4. Set the MTU for the Eth-channel interface.

   mtu *size*

   By default, the MTU for an Eth-channel interface is 1500 bytes.

5. Set the expected bandwidth of the Eth-channel interface.

   bandwidth *bandwidth-value*

   By default, the expected bandwidth (in kbps) of an Eth-channel is the interface baud rate divided by 1000.

   The baud rate of an Eth-channel interface is 100 Mbps.

6. Bring up the Eth-channel interface.

   undo shutdown

   By default, an Eth-channel interface is up.

Restoring the default settings for an Eth-channel interface

Restrictions and guidelines

△ **CAUTION:**

Restoring the default interface settings might interrupt ongoing network services. Make sure you are fully aware of the impact of this command when you use it on a live network.

The **default** command might fail to restore the default settings for some commands for reasons such as command dependencies and system restrictions. Use the **display this** command in interface view to identify these commands. Then use their **undo** forms or follow the command reference to individually restore their default settings. If your restoration attempt still fails, follow the error message instructions to resolve the problem.

Procedure

1. Enter system view.

   system-view

2. Enter Eth-channel interface view.

   interface eth-channel *interface-number*

3. Restore the default configurations.

   default

Configuring an IP address for an Eth-channel interface of a 4G modem

About this task

An Eth-channel interface can communicate with other devices only after it obtains an IP address. You can configure an IP address for an Eth-channel interface in the following ways:

- **DHCP**—The Eth-channel interface obtains the modem's IP address as its own IP address through DHCP. The modem's IP address is automatically allocated by the service provider.
- **Modem manufacturer's proprietary protocol**—The Eth-channel interface obtains the modem's IP address as its own IP address through the modem manufacturer's proprietary protocol. The modem's IP address is automatically allocated by the service provider.
- **Manual configuration**.

The ways for the Eth-channel interface to obtain an IP address are mutually exclusive. The most recent configuration overrides the previous one.

Restrictions and guidelines

Changing the IP address will result in dialup interruption. Immediate re-dialup upon interruption might not be supported by service providers.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter Eth-channel interface view.

   ```
   interface eth-channel interface-number
   ```

3. Configure an IP address for the Eth-channel interface in one of the three ways.

   - Obtain an IP address by using DHCP.

     ```
     ip address dhcp-alloc
     ```

     For more information about the command, see DHCP commands in *Layer 3–IP Service Command Reference*.

     By default, an Eth-channel interface does not obtain an IP address through the modem-manufacturer's proprietary protocol.

     For the support of hardware platforms for this command, see 3G and 4G modem commands in *Network Management and Monitoring Command Reference*.

   - Obtain an IP address by using the modem-manufacturer's proprietary protocol.

     IPv4:

     ```
     ip address cellular-alloc
     ```

     IPv6:

     ```
     ipv6 address cellular-alloc
     ```

     By default, an Eth-channel interface does not obtain an IP address through the modem-manufacturer's proprietary protocol.

   - Configure an IP address manually.

     ```
     ip address ip-address { mask-length | mask } [ sub ]
     ```

     By default, no IP address is specified for an Eth-channel interface.

Configuring a mobile communication network

Restrictions and guidelines

A 3G modem can access GSM, CDMA2000, TD-SCDMA, and WCDMA networks. A 4G modem can access GSM, CDMA2000, TD-SCDMA, WCDMA, and LTE networks.

A mobile communication modem is used to search a public land mobile network (PLMN) for accessible mobile networks. A PLMN is uniquely identified by the mobile country code (MCC) and the mobile network code (MNC). Some mobile communication modems can automatically access a mobile network. To manually specify a mobile network for a mobile communication modem, first search for available mobile networks.

Procedure

1. Enter system view.

   system-view

2. Enter cellular interface view.

   controller cellular *interface-number*

3. (Optional.) Search for PLMNs.

   plmn search

4. Configure a PLMN searching mode.

   plmn select { **auto** | **manual** *mcc mnc* }

   The default setting depends on the modem model.

5. Specify the network service to which the modem connects.

   mode { **1xrtt** | **auto** | **evdo** | **gsm** | **gsm-precedence** | **hybrid** | **lte** | **td** | **td-precedence** | **wcdma** | **wcdma-precedence** }

   The default setting for this command and support for the arguments depend on the modem model.

6. (Optional.) Specify a GSM frequency band.

   gsm band { **egsm900** | **gsm450** | **gsm480** | **gsm750** | **gsm850** | **gsm1800** | **gsm1900** | **pgsm900** | **rsgm900** }

   By default, no GSM frequency band is specified.

   This command is supported only by Sierra MC7354 (ATT version) and MC7304 4G modules.

7. (Optional.) Specify a WCDMA frequency band.

   wcdma band { **wcdma800** | **wcdma850** | **wcdma900** | **wcdma1700ip** | **wcdma1700us** | **wcdma1800** | **wcdma1900** | **wcdma2100** | **wcdma2600** }

   By default, no WCDMA frequency band is specified.

   This command is supported only by Sierra MC7354 (ATT version) and MC7304 4G modules.

8. (Optional.) Specify an LTE frequency band.

   lte band *band-number*

   The default setting for this command and support for the *band-number* argument depend on the 4G modem model.

Configuring parameter profiles

About parameter profiles

A parameter profile defines the following items:

- The access point with which a mobile communication modem is associated.
- The authentication mode in which the service provider authenticates the mobile communication modem.

Creating a parameter profile for a 3G modem

1. Enter system view.

   system-view

2. Enter cellular interface view.

   controller cellular *interface-number*

3. Create a parameter profile.

   profile create *profile-number* { **dynamic** | **static** *apn* } **authentication-mode** { **none** | { **chap** | **pap** } **user** *username* [**password** *password*] }

   The default setting depends on the modem model.

Creating a parameter profile for a 4G modem

1. Enter system view.

   system-view

2. Create a parameter profile and enter its view.

   apn-profile *profile-name*

3. Specify the PDP data carrying protocol.

   pdp-type { **ipv4** | **ipv6** | **ipv4v6** }

   By default, the data carrying protocol is IPv4 and IPv6.

4. Specify an APN for accessing a 4G network.

   apn { **dynamic** | **static** *apn* }

   By default, no APN is specified for accessing a 4G network.

5. Specify an authentication mode for accessing a 4G network.

   authentication-mode { **pap** | **chap** | **pap-chap** } **user** *user-name* **password** { **cipher** | **simple** } *string*

   By default, no authentication is performed for accessing a 4G network.

6. Specify a separator for the IMSI/SN binding authentication information.

   attach-format imsi-sn split *splitchart*

   By default, no separator is specified for the IMSI/SN binding authentication information.

Specifying the primary and backup profiles

About this task

By default, profile 1 is used for mobile communication modem dialup. The dialup fails if profile 1 does not exist.

You can also specify the primary and backup profiles for mobile communication modem dialup. The primary profile always has priority over the backup profile. For each dialup connection establishment, the mobile communication modem uses the backup profile only when it has failed to dial up using the primary profile.

Restrictions and guidelines

You must configure the same username and password for the primary and backup profiles.

Specifying the primary and backup profiles for a 3G modem

1. Enter system view.
   system-view
2. Enter cellular interface view.
   controller cellular *interface-number*
3. Specify the primary and backup profiles for the 3G modem.
   profile main *main-profile-number* **backup** *backup-profile-number*
   By default, profile 1 is used for 3G modem dialup.

Specifying the primary and backup profiles for a 4G modem

1. Enter system view.
   system-view
2. Enter Eth-channel interface view.
   interface eth-channel *interface-number*
3. Specify the primary and backup profiles for the 4G modem.
   apn-profile apply *profile-name* [**backup** *profile-name*]
   By default, no profiles are specified for 4G modem dialup.

Specifying the primary or secondary SIM card

About this task

On a device that uses dual SIM card, you can specify the use of the secondary SIM card when one of the following problems occurs:

- The mobile communication link signals of the primary SIM card are weak.
- The service provider network that the primary SIM card connects to is unavailable.
- The primary SIM card has failed.

If the problems of the primary SIM card are resolved, you can specify the use of the primary SIM card or enable the mobile communication modem to automatically switch back to the primary SIM card.

Procedure

1. Enter system view.
   system-view
2. Enter cellular interface view.
   controller cellular *interface-number*
3. Specify the primary or secondary SIM card.
   sim switch-to *card-number*
   By default, a mobile communication modem uses the primary SIM card.

Associating mobile communication link backup with a track entry

About this task

This configuration allows the system to use a track entry to monitor the status of the primary mobile communication link. When the track entry state changes from Positive to Negative, the secondary mobile communication link takes over.

Procedure

1. Enter system view.

   `system-view`

2. Enter cellular interface view.

   `controller cellular` *`interface-number`*

3. Associate mobile communication link backup with a track entry

   `sim backup enable track` *`entry-number`*

   By default, mobile communication link backup is not associated with a track entry.

Configuring PIN verification

About this task

A UIM card is used in the CDMA network and a SIM card is used in other mobile networks. Each SIM/UIM card has a Personal Identification Number (PIN). PIN verification prevents unauthorized access to the SIM/UIM card.

To perform PIN verification, you need to save the PIN of the SIM/UIM card on the device by using the **`pin verify`** command and enable PIN verification. The **`pin verify`** command can be executed before and after you enable PIN verification. After the PIN is saved on the device, the PIN is used for verification automatically when required.

When PIN verification is enabled, PIN verification is performed after you perform any of the following tasks:

- Install a mobile communication modem.
- Reboot the device where a USB mobile communication modem is attached.
- Execute the **`modem reboot`** command to reboot a mobile communication modem.
- Hot swap a USB mobile communication modem.

If PIN verification fails after a maximum number of attempts, the SIM/UIM card is locked, and a PIN Unlocking Key (PUK) is required to unlock the card. The maximum number of attempts depends on the mobile communication modem model.

Procedure

1. Enter system view.

   `system-view`

2. Enter cellular interface view.

   `controller cellular` *`interface-number`*

3. Enable PIN verification.

   `pin verification enable` [*`pin`*]

   The default setting depends on the modem model.

Whether you are required to enter the PIN when enabling PIN verification depends on the modem model.

4. Specify the PIN for verification.

   pin verify { **cipher** | **simple** } *string*

   By default, no PIN is configured on a device for mobile communication modem verification.

   This command saves the PIN on the device.

5. (Optional.) Specify a PUK to unlock the SIM/UIM card.

   pin unlock *puk new-pin*

   After the SIM/UIM card is unlocked, execute the **pin verify** command to save the new PIN on the device.

6. (Optional.) Modify the PIN of the SIM/UIM card.

   pin modify *current-pin new-pin*

   The new PIN is saved in the SIM/UIM card.

   After the PIN is modified, execute the **pin verify** command to save the new PIN on the device.

Configuring DM

NOTE:

Support for DM depends on the modem model.

About this task

Diagnostic and monitoring (DM) allows third-party debugging tools to diagnose and monitor the mobile communication modem through cellular interface debugging output. For more information about DM, see related mobile communication modem user manuals.

Procedure

1. Enter system view.

   system-view

2. Enter cellular interface view.

   controller cellular *interface-number*

3. Enable DM.

   dm-port open

   The default setting for this command depends on the modem model.

Setting the RSSI thresholds

About this task

After setting the RSSI thresholds, you will stay informed about the RSSI changes.

Procedure

1. Enter system view.

   system-view

2. Enter cellular interface view.

   controller cellular *interface-number*

3. Set the RSSI thresholds.

rssi { **gsm** | **1xrtt** | **evdo** | **lte** } { **low** *lowthreshold* | **medium** *mediumthreshold* }

By default, the lower and upper RSSI thresholds for a mobile communication modem are –150 dBm and 0 dBm, respectively.

The value of *lowthreshold* cannot be smaller than the value of *mediumthreshold* because the system automatically adds a negative sign to the RSSI thresholds.

Issuing a configuration directive to a mobile communication modem

Restrictions and guidelines

Configuration directives might cause malfunction of a mobile communication modem. When you issue a configuration directive to the modem, make sure you understand the impact on the mobile communication modem.

Procedure

1. Enter system view.

   system-view

2. Enter cellular interface view.

   controller cellular *interface-number*

3. Issue a configuration directive to the mobile communication modem.

   sendat *at-string*

Configuring mobile communication modem reboot

Configuring automatic reboot

About this task

A mobile communication modem might malfunction in an unstable mobile communication network or when the application environment changes. During a malfunction, the modem cannot respond to the device's requests or configuration commands. If the device does not receive any responses from the mobile communication modem within the timeout interval, a response failure occurs. When the number of consecutive response failures reaches the threshold, the device restarts the mobile communication modem automatically.

The device does not restart the mobile communication modem when the mobile communication modem has not made a successful dialup since the last restart. This restriction avoids repeated restarts of the mobile communication modem when there are configuration errors.

Procedure

1. Enter system view.

   system-view

2. Enter cellular interface view.

   controller cellular *interface-number*

3. Configure the response timeout and the threshold for the number of consecutive timeouts to enable automatic reboot of the mobile communication modem.

   modem response timer *time* **auto-recovery** *threshold*

   By default, the response timeout is 10 seconds and the consecutive timeout threshold is 3.

The configuration is saved on the device rather than the mobile communication modem.

Configuring manual reboot

About this task

A mobile communication modem can automatically detect running errors and reboot. If the mobile communication modem fails to reboot by itself, you can use this command to manually reboot it.

Procedure

1. Enter system view.
   `system-view`
2. Enter cellular interface view.
   `controller cellular` *`interface-number`*
3. Manually reboot the mobile communication modem.
   `modem reboot`

△ **CAUTION:**

Execute this command with caution. This command will disconnect the established 3G/4G modem connections.

Display and maintenance commands for mobile communication modem management

Execute **`display`** commands in any view and the **`reset`** command in user view.

Task	Command
Display the call connection information for the mobile communication modem.	**display cellular** [*interface-number*]
Display information about a cellular interface.	**display controller** [**cellular** [*interface-number*]]
Display information about an Eth-channel interface.	**display interface** [**eth-channel** [*channel-id*]] [**brief** [**description** | **down**]]
Clear the statistics for a cellular interface.	**reset counters controller** [**cellular** [*interface-number*]]
Clear the statistics for an Eth-channel interface.	**reset counters interface** [**eth-channel** [*channel-id*]]

Troubleshooting

Symptom

A mobile communication modem fails to function correctly. For example, the mobile communication modem receives no signals or fails to connect to service providers' networks.

Solution

To resolve the issue:

1. Execute the **shutdown** command and the **undo shutdown** command on the cellular interface.
2. If the mobile communication modem still fails to function, execute the **modem reboot** command on the cellular interface.
3. If the issue persists, contact NSFOCUS Support.

NSFOCUS Firewall Series

NF Layer 3—IP Services

Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for IP services features, including ARP, IP addressing, DHCP, DNS, IP forwarding basics, fast forwarding, adjacency table, IP performance optimization, IPv6 basics, DHCPv6, IPv6 fast forwarding, and multi-CPU packet distribution.
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
ⓘ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Configuring IP addressing

About IP addressing

The IP addresses in this chapter refer to IPv4 addresses unless otherwise specified.

IP address representation and classes

IP addressing uses a 32-bit address to identify each host on an IPv4 network. To make addresses easier to read, they are written in dotted decimal notation, each address being four octets in length. For example, address 00001010000000010000000100000001 in binary is written as 10.1.1.1.

Each IP address breaks down into the following sections:

- **Net ID**—Identifies a network. The first several bits of a net ID, known as the class field or class bits, identify the class of the IP address.
- **Host ID**—Identifies a host on a network.

IP addresses are divided into five classes, as shown in Figure 1. The shaded areas represent the address class. The first three classes are most commonly used.

Figure 1 IP address classes

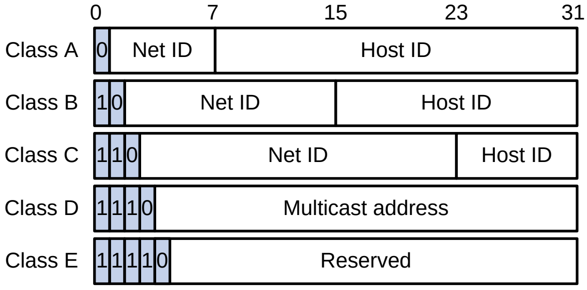


Table 1 IP address classes and ranges

Class	Address range	Remarks
A	0.0.0.0 to 127.255.255.255	The IP address 0.0.0.0 is used by a host at startup for temporary communication. This address is never a valid destination address. Addresses starting with 127 are reserved for loopback test. Packets destined to these addresses are processed locally as input packets rather than sent to the link.
B	128.0.0.0 to 191.255.255.255	N/A
C	192.0.0.0 to 223.255.255.255	N/A
D	224.0.0.0 to 239.255.255.255	Multicast addresses.
E	240.0.0.0 to 255.255.255.255	Reserved for future use, except for the broadcast address 255.255.255.255.

Special IP addresses

The following IP addresses are for special use and cannot be used as host IP addresses:

- **IP address with an all-zero net ID**—Identifies a host on the local network. For example, IP address 0.0.0.16 indicates the host with a host ID of 16 on the local network.
- **IP address with an all-zero host ID**—Identifies a network.
- **IP address with an all-one host ID**—Identifies a directed broadcast address. For example, a packet with the destination address of 192.168.1.255 will be broadcast to all the hosts on the network 192.168.1.0.

Subnetting and masking

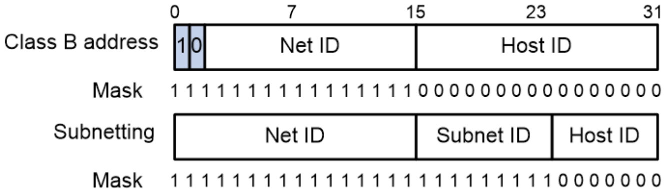
Subnetting divides a network into smaller networks called subnets by using some bits of the host ID to create a subnet ID.

Masking identifies the boundary between the host ID and the combination of net ID and subnet ID.

Each subnet mask comprises 32 bits that correspond to the bits in an IP address. In a subnet mask, consecutive ones represent the net ID and subnet ID, and consecutive zeros represent the host ID.

Before being subnetted, Class A, B, and C networks use these default masks (also called natural masks): 255.0.0.0, 255.255.0.0, and 255.255.255.0, respectively.

Figure 2 Subnetting a Class B network



Subnetting increases the number of addresses that cannot be assigned to hosts. Therefore, using subnets means accommodating fewer hosts.

For example, a Class B network without subnetting can accommodate 1022 more hosts than the same network subnetted into 512 subnets.

- **Without subnetting**—65534 (2^{16} – 2) hosts. (The two deducted addresses are the broadcast address, which has an all-one host ID, and the network address, which has an all-zero host ID.)
- **With subnetting**—Using the first nine bits of the host-id for subnetting provides 512 (2^9) subnets. However, only seven bits remain available for the host ID. This allows 126 (2^7 – 2) hosts in each subnet, a total of 64512 (512 × 126) hosts.

IP address assignment

The following are methods available for assigning an IP address to an interface:

- Manual assignment. This chapter describes only manual IP address assignment for interfaces.
- BOOTP. For information about BOOTP, see "Configuring the BOOTP client."
- DHCP. For information about DHCP, see "Configuring the DHCP client."
- PPP address negotiation. For information about PPP, see *Layer 2—WAN Access Configuration Guide*.

These methods are mutually exclusive. If you change the IP address assignment method, the new IP address will overwrite the previous address.

Assigning an IP address to an interface

About this task

An interface can have one primary address and multiple secondary addresses.

Typically, you need to configure a primary IP address for an interface. If the interface connects to multiple subnets, configure primary and secondary IP addresses on the interface so the subnets can communicate with each other through the interface.

Restrictions and guidelines

- An interface can have only one primary IP address. If you execute the **`ip address`** command multiple times to specify different primary IP addresses, the most recent configuration takes effect.
- You cannot assign secondary IP addresses to an interface that obtains an IP address through BOOTP, DHCP, PPP address negotiation, or IP unnumbered.
- The primary and secondary IP addresses assigned to the interface can be located on the same network segment. Different interfaces on your device must reside on different network segments.
- You can assign interfaces IP addresses that have different masks but the same network address if ANDed with the shortest mask. For example, 1.1.1.1/16 and 1.1.2.1/24 have the same network address 1.1.0.0 if ANDed with 255.255.0.0. You can assign the IP addresses to two interfaces on the device. By default, users connected to the two interfaces cannot communicate with each other. For the users to communicate, you must configure common proxy ARP on the device. For more information, see "Configuring proxy ARP."

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Assign an IP address to the interface.

   `ip address` *`ip-address`* { *`mask-length`* | *`mask`* } [**`sub`**]

   By default, no IP address is assigned to the interface.

Configuring IP unnumbered

About this task

You can configure an interface to borrow an IP address from other interfaces. This is called IP unnumbered, and the interface borrowing the IP address is called IP unnumbered interface.

You can use IP unnumbered to save IP addresses when available IP addresses are inadequate or when an interface is used only occasionally.

Restrictions and guidelines

- Loopback interfaces cannot borrow IP addresses of other interfaces, but other interfaces can borrow IP addresses of loopback interfaces.
- An interface cannot borrow an IP address from an unnumbered interface.
- Multiple interfaces can use the same unnumbered IP address.
- If an interface has multiple manually configured IP addresses, only the manually configured primary IP address can be borrowed.

- A dynamic routing protocol cannot be enabled on the interface where IP unnumbered is configured. To enable the interface to communicate with other devices, configure a static route to the peer device on the interface.
- A Layer 3 Ethernet subinterface or Layer 3 aggregate subinterface cannot learn the ARP entry for the IP address it borrows. As a best practice, do not configure IP unnumbered on Layer 3 Ethernet subinterfaces or Layer 3 aggregate subinterfaces.

Prerequisites

Assign an IP address to the interface from which you want to borrow the IP address. Alternatively, you can configure the interface to obtain one through BOOTP, DHCP, or PPP address negotiation. .

Do not configure IP unnumbered on an Ethernet subinterface or a Layer-3 aggregate subinterface because they cannot learn the ARP entries for the borrowed IP address.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the interface to borrow the IP address of the specified interface.
   ip address unnumbered interface *interface-type interface-number*
   By default, the interface does not borrow IP addresses from other interfaces.

Display and maintenance commands for IP addressing

Execute **display** commands in any view.

Task	Command
Display brief IP configuration for Layer 3 interfaces.	**display ip interface** [*interface-type* [*interface-number*]] **brief** [**description**]
Display IP configuration and statistics for the specified or all Layer 3 interfaces.	**display ip interface** [*interface-type* [*interface-number*]]

Contents

Configuring IP forwarding basic settings

About FIB table

A device uses the FIB table to make packet forwarding decisions.

A device selects optimal routes from the routing table, and puts them into the FIB table. Each FIB entry specifies the next hop IP address and output interface for packets destined for a specific subnet or host.

For more information about the routing table, see *Layer 3—IP Routing Configuration Guide*.

Use the **display fib** command to display the FIB table. The following example displays the entire FIB table.

```
<Sysname> display fib

Destination count: 4 FIB entry count: 4

Flag:
  U:Useable   G:Gateway   H:Host   B:Blackhole   D:Dynamic   S:Static
  R:Relay     F:FRR

Destination/Mask   Nexthop         Flag     OutInterface/Token       Label
10.2.0.0/16        10.2.1.1        U        GE1/0/1                  Null
10.2.1.1/32        127.0.0.1       UH       InLoop0                  Null
127.0.0.0/8        127.0.0.1       U        InLoop0                  Null
127.0.0.1/32       127.0.0.1       UH       InLoop0                  Null
```

A FIB entry includes the following items:

- **Destination**—Destination IP address.
- **Mask**—Network mask. The mask and the destination address identify the destination network. A logical AND operation between the destination address and the network mask yields the address of the destination network. For example, if the destination address is 192.168.1.40 and the mask 255.255.255.0, the address of the destination network is 192.168.1.0. A network mask includes a certain number of consecutive 1s. It can be expressed in dotted decimal format or by the number of the 1s.
- **Nexthop**—IP address of the next hop.
- **Flag**—Route flag.
- **OutInterface**—Output interface.
- **Token**—MPLS Label Switched Path index number.
- **Label**—Inner label.

Enabling last hop holding

About this task

Last hop holding implements symmetric routing.

When the interface enabled with this feature receives the first IP packet of a forward flow, this feature implements the following operations:

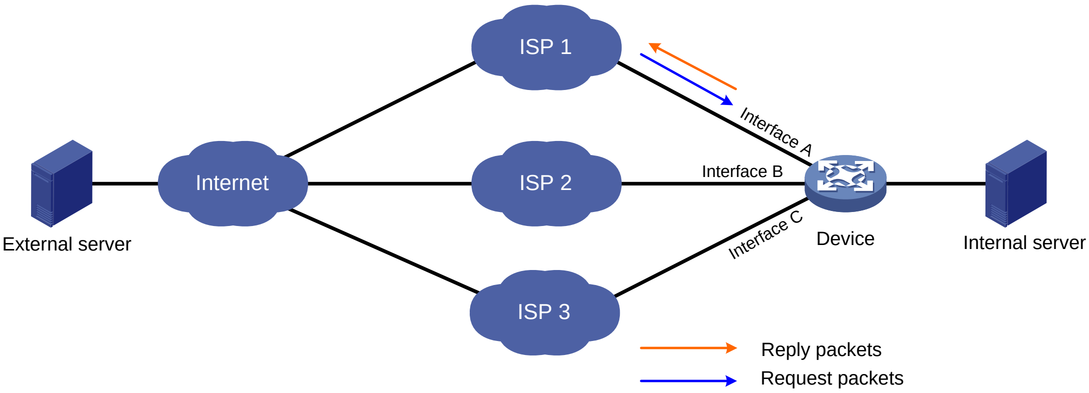
- Obtains the forward flow information and last hop information of the packet.

- Based on the obtained information, creates a fast forwarding entry for the return flow.

When packets of the return flow arrive at the device, the device forwards those packets according to the entry.

As is shown in Figure 1, when the external server sends a request to the internal server, the packet travels through ISP 1 to Interface A on the device. The last hop holding feature on the device ensures that the reply packet follows the same route as the request packet back to ISP 1. If last hop holding is disabled, the reply packet might be sent out of Interface B or Interface C to the external network.

Figure 1 Last hop holding application



Restrictions and guidelines

This feature relies on fast forwarding entries. If the MAC address of a last hop changes on an Ethernet link, this feature can function correctly only after the fast forwarding entry is updated for the MAC address.

In an IRF fabric, this feature is not supported for those packets that are forwarded between member devices.

This feature is not applicable to asymmetric-path traffic forwarding in an RBM-based hot backup system. For more information about RBM-based hot backup, see high availability group configuration in *High Availability Configuration Guide*.

On a device that supports deployment of multiple security service modules, this feature does not take effect on the external traffic destined for that device

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type`* { *`interface-number`* | *`interface-number.subnumber`* }

3. Enable last hop holding.

   `ip last-hop hold`

   By default, last hop holding is disabled.

Enabling last hop backup

About this task

This feature enables the system to transmit the forward flow and reverse flow between the local node and a peer node over the same path.

In an IRF fabric enabled with this feature, the IRF master device performs the following operations when receiving the first IP packet of a forward flow on an interface enabled with last hop holding:

1. Saves the last hop information of the packet.
2. Synchronizes the last hop information to subordinate devices in the IRF fabric.

The last hop information can be used for guiding the backward flow when the flow arrives at the master device or is forwarded through a subordinate device.

For this feature to take effect in an IRF fabric, you must also enable session synchronization by using the **session synchronization enable** command. For more information about the **session synchronization enable** command, see *Security Command Reference*.

This feature is also applicable to multi-module devices enabled with service backup. If this feature is enabled on such a device, a device module performs the following operations when receiving the first IP packet of a forward flow on an interface enabled with last hop holding:

1. Saves the last hop information of the packet.
2. Synchronizes the last hop information to other modules in the device.

The last hop information can be used for guiding the backward flow when the flow arrives at one of these modules.

For this feature to take effect on a multi-module device, you must also enable session flow redirection by using the **session flow-redirect enable** command. For more information about the **session flow-redirect enable** command, see *Security Command Reference*.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable last hop backup.
   ```
   last-hop backup enable
   ```
   By default, last hop backup is enabled.

Display and maintenance commands for FIB table

Execute **display** commands in any view.

Task	Command
Display FIB entries.	**display fib** [**vpn-instance** *vpn-instance-name*] [*ip-address* [*mask* | *mask-length*]]

Configuring load sharing

About load sharing

If a routing protocol finds multiple equal-cost best routes to the same destination, the device forwards packets over the equal-cost routes to implement load sharing.

Configuring load sharing mode

About this task

In the per-flow load sharing mode, the device forwards flows over equal-cost routes. Packets of one flow travel along the same routes. You can configure the device to identify a flow based on the following criteria: source IP address, destination IP address, source port number, destination port number, and IP protocol number.

In the per-packet load sharing mode, the device forwards packets over equal-cost routes.

Hardware and feature compatibility

Models	Command compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB1180, NFNX3-HDB1480	No

Restrictions and guidelines

Per-packet load sharing does not take effect on packets that are fast forwarded. It takes effect only on those packets that are delivered to the CPU. For more information about configuring load balancing for fast forwarding, see fast forwarding configuration in *Layer 3—IP Services Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Configure load sharing.

   ip load-sharing mode { **per-flow** [**dest-ip** | **dest-port** | **ip-pro** | **src-ip** | **src-port**] * | **per-packet** } { **global** | **slot** *slot-number* }

   By default, the device performs per-flow load sharing.

Enabling local-first load sharing

About this task

Local-first load sharing distributes traffic preferentially across the output interfaces on the receiving IRF member device if output interfaces for multiple equal-cost routes are on different members. This feature enhances packets forwarding efficiency.

Procedure

1. Enter system view.

```
system-view
```

2. Enable local-first load sharing.

```
ip load-sharing local-first enable
```

By default, local-first load sharing is disabled.

Contents

Configuring fast forwarding

About fast forwarding

Fast forwarding reduces route lookup time and improves packet forwarding efficiency by using a high-speed cache and data-flow-based technology. It identifies a data flow by using the following fields: source IP address, source port number, destination IP address, destination port number, and protocol number. After a flow's first packet is forwarded through the routing table, fast forwarding creates an entry and uses the entry to forward subsequent packets of the flow.

Restrictions and guidelines: Fast forwarding configuration

Fast forwarding can process fragmented IP packets, but it does not fragment IP packets.

Fast forwarding can be implemented by software or hardware. Unless otherwise noted, fast forwarding in this chapter refers to software fast forwarding.

Configuring the aging time for fast forwarding entries

About this task

The fast forwarding table uses an aging timer for each forwarding entry. If an entry is not updated before the timer expires, the device deletes the entry. If an entry has a hit within the aging time, the aging timer restarts.

Procedure

1. Enter system view.

   `system-view`

2. Configure the aging time for fast forwarding entries.

   `ip fast-forwarding aging-time` *`aging-time`*

   By default, the aging time is 30 seconds.

Configuring fast forwarding load sharing

About this task

Fast forwarding load sharing enables the device to identify a data flow by using the packet information.

If fast forwarding load sharing is disabled, the device identifies a data flow by the packet information and the input interface.

Procedure

1. Enter system view.

   `system-view`

2. Configure fast forwarding load sharing. Choose one option as needed:
   - Enable fast forwarding load sharing.
     ip fast-forwarding load-sharing
   - Disable fast forwarding load sharing.
     undo ip fast-forwarding load-sharing

   By default, fast forwarding load sharing is enabled.

Enabling DSCP-based fast forwarding for GRE packets

About this task

This feature uses the DSCP value in the outer header instead of the source port number among the identification criteria to identify GRE traffic flows.

Procedure

1. Enter system view.
   system-view
2. Enable DSCP-based fast forwarding for GRE packets.
   ip fast-forwarding dscp

   By default, DSCP-based fast forwarding for GRE packet is disabled.

Display and maintenance commands for fast forwarding

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the aging time of fast forwarding entries.	**display ip fast-forwarding aging-time**
Display fast forwarding entries.	**display ip fast-forwarding cache** [*ip-address*] [**slot** *slot-number*]
Display fast forwarding entries about fragmented packets.	**display ip fast-forwarding fragcache** [*ip-address*] [**slot** *slot-number*]
Clear the fast forwarding table.	**reset ip fast-forwarding cache** [**slot** *slot-number*]

Contents

Configuring ARP

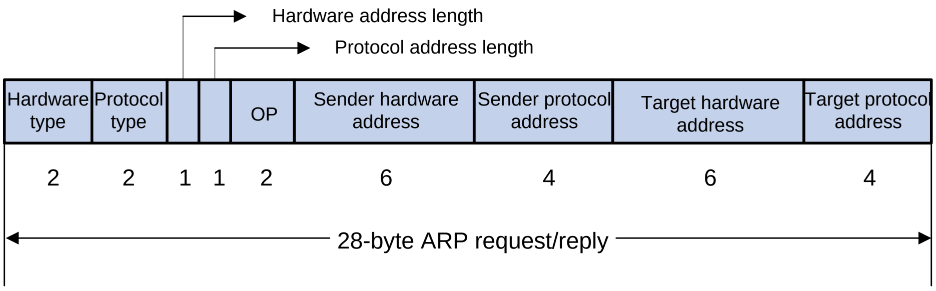
About ARP

ARP resolves IP addresses into MAC addresses on Ethernet networks.

ARP message format

ARP uses two types of messages: ARP request and ARP reply. Figure 1 shows the format of ARP request/reply messages. Numbers in the figure refer to field lengths.

Figure 1 ARP message format



- **Hardware type**—Hardware address type. The value 1 represents Ethernet.
- **Protocol type**—Type of the protocol address to be mapped. The hexadecimal value 0x0800 represents IP.
- **Hardware address length and protocol address length**—Length, in bytes, of a hardware address and a protocol address. For an Ethernet address, the value of the hardware address length field is 6. For an IPv4 address, the value of the protocol address length field is 4.
- **OP**—Operation code, which describes the type of ARP message. The value 1 represents an ARP request, and the value 2 represents an ARP reply.
- **Sender hardware address**—Hardware address of the device sending the message.
- **Sender protocol address**—Protocol address of the device sending the message.
- **Target hardware address**—Hardware address of the device to which the message is being sent.
- **Target protocol address**—Protocol address of the device to which the message is being sent.

ARP operating mechanism

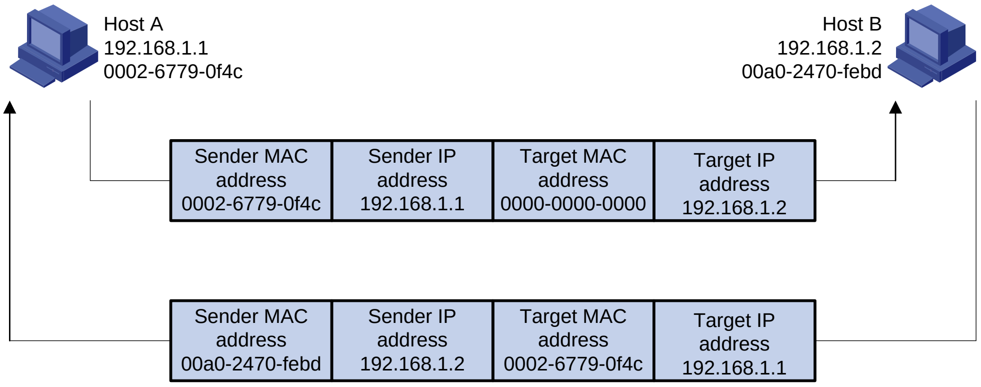
As shown in Figure 2, Host A and Host B are on the same subnet. Host A sends a packet to Host B as follows:

1. Host A looks through the ARP table for an ARP entry for Host B. If one entry is found, Host A uses the MAC address in the entry to encapsulate the IP packet into a data link layer frame. Then Host A sends the frame to Host B.
2. If Host A finds no entry for Host B, Host A buffers the packet and broadcasts an ARP request. The payload of the ARP request contains the following information:
   - **Sender IP address and sender MAC address**—Host A's IP address and MAC address.
   - **Target IP address**—Host B's IP address.
   - **Target MAC address**—An all-zero MAC address.

All hosts on this subnet can receive the broadcast request, but only the requested host (Host B) processes the request.

3. Host B compares its own IP address with the target IP address in the ARP request. If they are the same, Host B operates as follows:
   a. Adds the sender IP address and sender MAC address into its ARP table.
   b. Encapsulates its MAC address into an ARP reply.
   c. Unicasts the ARP reply to Host A.
4. After receiving the ARP reply, Host A operates as follows:
   a. Adds the MAC address of Host B into its ARP table.
   b. Encapsulates the MAC address into the packet and sends the packet to Host B.

Figure 2 ARP address resolution process



Sender MAC address	Sender IP address	Target MAC address	Target IP address
0002-6779-0f4c	192.168.1.1	0000-0000-0000	192.168.1.2

Sender MAC address	Sender IP address	Target MAC address	Target IP address
00a0-2470-febd	192.168.1.2	0002-6779-0f4c	192.168.1.1

If Host A and Host B are on different subnets, Host A sends a packet to Host B as follows:

1. Host A broadcasts an ARP request where the target IP address is the IP address of the gateway.
2. The gateway responds with its MAC address in an ARP reply to Host A.
3. Host A uses the gateway's MAC address to encapsulate the packet, and then sends the packet to the gateway.
4. If the gateway has an ARP entry for Host B, it forwards the packet to Host B directly. If not, the gateway broadcasts an ARP request, in which the target IP address is the IP address of Host B.
5. After the gateway gets the MAC address of Host B, it sends the packet to Host B.

ARP entry types

An ARP table stores dynamic ARP entries Rule ARP entries, and static ARP entries.

Dynamic ARP entry

ARP automatically creates and updates dynamic entries. A dynamic ARP entry is removed when its aging timer expires or the output interface goes down. In addition, a dynamic ARP entry can be overwritten by a static ARP entry.

Static ARP entry

A static ARP entry is manually configured and maintained. It does not age out and cannot be overwritten by any dynamic ARP entry.

Static ARP entries protect communication between devices because attack packets cannot modify the IP-to-MAC mapping in a static ARP entry.

The device supports the following types of static ARP entries:

- **Long static ARP entry**—It is directly used for forwarding packets. A long static ARP entry contains the IP address, MAC address, and one of the following combinations:
  - VLAN and output interface.
  - Input and output interfaces.
- **Short static ARP entry**—It contains only the IP address and MAC address.

  If the output interface is a Layer 3 Ethernet interface, the short ARP entry can be directly used to forward packets.

  If the output interface is a VLAN interface, the device sends an ARP request whose target IP address is the IP address in the short entry. If the sender IP and MAC addresses in the received ARP reply match the short static ARP entry, the device performs the following operations:
  - Adds the interface that received the ARP reply to the short static ARP entry.
  - Uses the resolved short static ARP entry to forward IP packets.

To communicate with a host by using a fixed IP-to-MAC mapping, configure a short static ARP entry on the device. To communicate with a host by using a fixed IP-to-MAC mapping through an interface in a VLAN, configure a long static ARP entry on the device.

Rule ARP entry

Rule ARP entries can be directly used for packet forwarding. A Rule ARP entry does not age out, and it cannot be updated. It can be overwritten by a static ARP entry.

ARP creates Rule ARP entries by learning from the Portal module. For more information about portal, see *Security Configuration Guide*.

- IPoE. For more information about IPoE, see *Security Configuration Guide*.
- Portal. For more information about portal, see *Security Configuration Guide*.

ARP tasks at a glance

All ARP tasks are optional.

- Configuring a static ARP entry
  - Configuring a short static ARP entry
  - Configuring a long static ARP entry
- Configuring features for dynamic ARP entries
  - Setting the dynamic ARP learning limit for a device
  - Setting the dynamic ARP learning limit for an interface
  - Setting the aging timer for dynamic ARP entries
  - Enabling dynamic ARP entry check
- Enabling an IP unnumbered interface to learn ARP entries for different subnets
- Enabling ARP logging

Configuring a static ARP entry

Static ARP entries are effective when the device functions correctly.

Configuring a short static ARP entry

Restrictions and guidelines

A resolved short static ARP entry becomes unresolved upon certain events, for example, when the resolved output interface goes down, or the corresponding VLAN or VLAN interface is deleted.

Procedure

1. Enter system view.

   system-view

2. Configure a short static ARP entry.

   arp static *ip-address mac-address* [**vpn-instance** *vpn-instance-name*] [**description** *text*]

Configuring a long static ARP entry

About this task

Long static ARP entries can be effective or ineffective. Ineffective long static ARP entries cannot be used for packet forwarding. A long static ARP entry is ineffective when any of the following conditions exists:

- The IP address in the entry conflicts with a local IP address.
- No local interface has an IP address in the same subnet as the IP address in the ARP entry.

A long static ARP entry in a VLAN is deleted if the VLAN or VLAN interface is deleted.

Procedure

1. Enter system view.

   system-view

2. Configure a long static ARP entry.

   arp static *ip-address mac-address* [*vlan-id interface-type interface-number*] [**vpn-instance** *vpn-instance-name*] [**description** *text*]

Configuring features for dynamic ARP entries

Setting the dynamic ARP learning limit for a device

About this task

A device can dynamically learn ARP entries. To prevent a device from holding too many ARP entries, you can set the maximum number of dynamic ARP entries that the device can learn. When the limit is reached, the device stops ARP learning.

If you set a value lower than the number of existing dynamic ARP entries, the device does not delete the existing entries unless they age out. You can use the **reset arp dynamic** command to clear dynamic ARP entries.

Procedure

1. Enter system view.

   system-view

2. Set the dynamic ARP learning limit for the device.

   arp max-learning-number *max-number* **slot** *slot-number*

   By default, the device can learn a maximum of 16384 dynamic ARP entries.

   To disable the device from dynamic ARP learning, set the value to 0.

Setting the dynamic ARP learning limit for an interface

About this task

An interface can dynamically learn ARP entries. To prevent an interface from holding too many ARP entries, you can set the maximum number of dynamic ARP entries that the interface can learn. When the limit is reached, the interface stops ARP learning.

You can set limits for both a Layer 2 interface and the VLAN interface for a permitted VLAN on the Layer 2 interface. The Layer 2 interface learns an ARP entry only when neither limit is reached.

The total dynamic ARP learning limit for all interfaces will not be higher than the dynamic ARP learning limit for the device.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Set the dynamic ARP learning limit for the interface.

   `arp max-learning-num` *`max-number`*

   By default, an interface can learn a maximum of 16384 dynamic ARP entries.

   To disable the interface from dynamic ARP learning, set the value to 0.

Setting the aging timer for dynamic ARP entries

About this task

Each dynamic ARP entry in the ARP table has a limited lifetime, called an aging timer. The aging timer of a dynamic ARP entry is reset each time the dynamic ARP entry is updated. A dynamic ARP entry that is not updated before its aging timer expires is deleted from the ARP table.

Procedure

1. Enter system view.

   `system-view`

2. Set the aging timer for dynamic ARP entries.

   `arp timer aging` *`aging-time`*

   The default setting is 20 minutes.

Enabling dynamic ARP entry check

About this task

The dynamic ARP entry check feature disables the device from supporting dynamic ARP entries that contain multicast MAC addresses. The device cannot learn dynamic ARP entries containing multicast MAC addresses. You cannot manually add static ARP entries containing multicast MAC addresses.

When dynamic ARP entry check is disabled, ARP entries containing multicast MAC addresses are supported. The device can learn dynamic ARP entries containing multicast MAC addresses obtained from the ARP packets sourced from a unicast MAC address. You can also manually add static ARP entries containing multicast MAC addresses.

Procedure

1. Enter system view.

   `system-view`

2. Enable dynamic ARP entry check.

   `arp check enable`

   By default, dynamic ARP entry check is enabled.

Enabling an IP unnumbered interface to learn ARP entries for different subnets

About this task

An IP unnumbered interface cannot learn the ARP entry of the peer device if the unnumbered interface and the peer device are on different subnets. To ensure communication between them, you can enable this feature on the IP unnumbered interface.

If an IP unnumbered interface is disabled from learning ARP entries for different subnets, existing ARP entries learned for different subnets are deleted after they age out.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure the interface to borrow the IP address of the specified interface.

   `ip address unnumbered interface` *`interface-type interface-number`*

   By default, the interface does not borrow IP addresses from other interfaces.

4. Enable the IP unnumbered interface to learn ARP entries for different subnets.

   `arp ip-unnumbered learning enable`

   By default, an IP unnumbered interface cannot learn ARP entries for different subnets.

Enabling ARP logging

About this task

This feature enables a device to log ARP events when ARP cannot resolve IP addresses correctly. The log information helps administrators locate and solve problems. The device can log the following ARP events:

- On a proxy ARP-disabled interface, the target IP address of a received ARP packet is not one of the following IP addresses:
  - The IP address of the receiving interface.
  - The virtual IP address of the VRRP group.
  - The public IP address after NAT.
- The sender IP address of a received ARP reply conflicts with one of the following IP addresses:
  - The IP address of the receiving interface.
  - The virtual IP address of the VRRP group.
  - The public IP address after NAT.

The device sends ARP log messages to the information center. You can use the **info-center source** command to specify the log output rules for the information center. For more information about information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable ARP logging.

   arp check log enable

   By default, ARP logging is disabled.

Display and maintenance commands for ARP

△ **CAUTION:**

Clearing ARP entries from the ARP table might cause communication failures. Make sure the entries to be cleared do not affect current communications.

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display ARP entries.	**display arp** [[**all** | **dynamic** | **static**] [**slot** *slot-number*] | **vlan** *vlan-id* | **interface** *interface-type interface-number*] [**count** | **verbose**]
Display the ARP entry for an IP address.	**display arp** *ip-address* [**slot** *slot-number*] [**verbose**]
Display the aging timer of dynamic ARP entries.	**display arp timer aging**
Display the ARP entries for a VPN instance.	**display arp vpn-instance** *vpn-instance-name* [**count** | **verbose**]
Clear ARP entries from the ARP table.	**reset arp** { **all** | **dynamic** | **interface** *interface-type interface-number* | **slot** *slot-number* | **static** }

Configuring gratuitous ARP

About gratuitous ARP

In a gratuitous ARP packet, the sender IP address and the target IP address are the IP address of the sending device.

A device sends a gratuitous ARP packet for either of the following purposes:

- Determine whether its IP address is already used by another device. If the IP address is already used, the device is informed of the conflict by an ARP reply.
- Inform other devices of a MAC address change.

IP conflict detection

When an interface obtains an IP address, the device broadcasts gratuitous ARP packets in the LAN where the interface resides. If the device receives an ARP reply, its IP address conflicts with the IP address of another device in the LAN. The device displays a log message about the conflict and informs the administrator to change the IP address. The device will not use the conflicting IP address. If no ARP reply is received, the device uses the IP address.

Gratuitous ARP packet learning

This feature enables a device to create or update ARP entries by using the sender IP and MAC addresses in received gratuitous ARP packets.

When this feature is disabled, the device uses received gratuitous ARP packets to update existing ARP entries only. ARP entries are not created based on the received gratuitous ARP packets, which saves ARP table space.

Periodic sending of gratuitous ARP packets

Periodic sending of gratuitous ARP packets helps downstream devices update ARP entries or MAC entries in a timely manner.

This feature can implement the following functions:

- Prevent gateway spoofing.

  Gateway spoofing occurs when an attacker uses the gateway address to send gratuitous ARP packets to the hosts on a network. The traffic destined for the gateway from the hosts is sent to the attacker instead. As a result, the hosts cannot access the external network.

  To prevent such gateway spoofing attacks, you can enable the gateway to send gratuitous ARP packets at intervals. Gratuitous ARP packets contain the primary IP address and manually configured secondary IP addresses of the gateway, so hosts can learn correct gateway information.

- Prevent ARP entries from aging out.

  If network traffic is heavy or if the host CPU usage is high, received ARP packets can be discarded or are not promptly processed. Eventually, the dynamic ARP entries on the receiving host age out. The traffic between the host and the corresponding devices is interrupted until the host re-creates the ARP entries.

  To prevent this problem, you can enable the gateway to send gratuitous ARP packets periodically. Gratuitous ARP packets contain the primary IP address and manually configured secondary IP addresses of the gateway, so the receiving hosts can update ARP entries in a timely manner.

- Prevent the virtual IP address of a VRRP group from being used by a host.

  The master router of a VRRP group can periodically send gratuitous ARP packets to the hosts on the local network. The hosts can then update local ARP entries and avoid using the virtual IP address of the VRRP group. The sender MAC address in the gratuitous ARP packet is the virtual MAC address of the virtual router.

Gratuitous ARP tasks at a glance

All gratuitous ARP tasks are optional. If all of the following features are disabled, gratuitous ARP still provides the IP conflict detection function.

- Enabling IP conflict notification
- Enabling gratuitous ARP packet learning
- Enabling periodic sending of gratuitous ARP packets
- Enabling sending gratuitous ARP packets for ARP requests with sender IP address on a different subnet
- Configuring gratuitous ARP packet retransmission for the device MAC address change

Enabling IP conflict notification

About this task

Upon detecting an IP conflict, the device will sends a gratuitous ARP request. By default, the device displays an error message only after it receives an ARP reply. You can enable this feature to allow the device to display an error message immediately upon detecting an IP conflict.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable IP conflict notification.

   ```
   arp ip-conflict log prompt
   ```

   If the system starts up with the factory defaults, IP conflict notification is enabled. If the system starts up with the initial configuration, IP conflict notification is disabled. For more information about factory defaults and initial configuration, see configuration file management in *Fundamentals Configuration Guide*.

Enabling gratuitous ARP packet learning

1. Enter system view.

   ```
   system-view
   ```

2. Enable gratuitous ARP packet learning.

   ```
   gratuitous-arp-learning enable
   ```

   By default, gratuitous ARP packet learning is enabled.

Enabling periodic sending of gratuitous ARP packets

Restrictions and guidelines

- You can enable periodic sending of gratuitous ARP packets on a maximum of 1024 interfaces.
- Periodic sending of gratuitous ARP packets takes effect on an interface only when the following conditions are met:
  - The data link layer state of the interface is up.
  - The interface has an IP address.
- If you change the sending interval for gratuitous ARP packets, the configuration takes effect at the next sending interval.
- The sending interval for gratuitous ARP packets might be much longer than the specified sending interval in any of the following circumstances:
  - This feature is enabled on multiple interfaces.
  - Each interface is configured with multiple secondary IP addresses.
  - A small sending interval is configured when the previous two conditions exist.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable periodic sending of gratuitous ARP packets.

   arp send-gratuitous-arp [**interval** *interval*]

   By default, periodic sending of gratuitous ARP packets is disabled.

Enabling sending gratuitous ARP packets for ARP requests with sender IP address on a different subnet

1. Enter system view.

   system-view

2. Enable the device to send gratuitous ARP packets upon receiving ARP requests whose sender IP address belongs to a different subnet.

   gratuitous-arp-sending enable

   By default, a device does not send gratuitous ARP packets upon receiving ARP requests whose sender IP address belongs to a different subnet.

Configuring gratuitous ARP packet retransmission for the device MAC address change

About this task

The device sends a gratuitous ARP packet to inform other devices of its MAC address change. However, the other devices might fail to receive the packet because the device sends the gratuitous ARP packet once only by default. Configure the gratuitous ARP packet retransmission feature to ensure that the other devices can receive the packet.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Set the times and the interval for retransmitting a gratuitous ARP packet for the device MAC address change.

   ```
   gratuitous-arp mac-change retransmit times interval seconds
   ```

   By default, the device sends a gratuitous packet to inform its MAC address change once only.

Configuring proxy ARP

About proxy ARP

Proxy ARP enables a device on one network to answer ARP requests for an IP address on another network. With proxy ARP, hosts on different broadcast domains can communicate with each other as they would on the same broadcast domain.

Proxy ARP includes common proxy ARP and local proxy ARP.

- **Common proxy ARP**—Allows communication between hosts that connect to different Layer 3 interfaces and reside in different broadcast domains.
- **Local proxy ARP**—Allows communication between hosts that connect to the same Layer 3 interface and reside in different broadcast domains.

Enabling common proxy ARP

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

   The following interface types are supported:

   - VLAN interface.
   - Layer 3 Ethernet interface.
   - Layer 3 Ethernet subinterface.
   - Layer 3 aggregate interface.
   - Layer 3 aggregate subinterface.

3. Enable common proxy ARP.

   `proxy-arp enable`

   By default, common proxy ARP is disabled.

Enabling local proxy ARP

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

   The following interface types are supported:

   - VLAN interface.
   - Layer 3 Ethernet interface.
   - Layer 3 Ethernet subinterface.
   - Layer 3 aggregate interface.
   - Layer 3 aggregate subinterface.

3. Enable local proxy ARP.

   `local-proxy-arp enable` [**`ip-range`** *`start-ip-address`* **`to`** *`end-ip-address`*]

By default, local proxy ARP is disabled.

Display and maintenance commands for proxy ARP

Execute **display** commands in any view.

Task	Command
Display common proxy ARP status.	**display proxy-arp** [**interface** *interface-type interface-number*]
Display local proxy ARP status.	**display local-proxy-arp** [**interface** *interface-type interface-number*]

Configuring ARP snooping

About ARP snooping

ARP snooping is used in Layer 2 switching networks. It creates ARP snooping entries by using information in ARP packets.

Creation of ARP snooping entries

If you enable ARP snooping for a VLAN, ARP packets received in the VLAN are redirected to the CPU. The CPU uses the sender IP and MAC addresses of the ARP packets, and receiving VLAN and port to create ARP snooping entries.

Aging of ARP snooping entries

The aging timer and valid period of an ARP snooping entry are 25 minutes and 15 minutes. If an ARP snooping entry is not updated in 12 minutes, the device sends an ARP request. The ARP request uses the IP address of the entry as the target IP address. If an ARP snooping entry is not updated in 15 minutes, it becomes invalid and cannot be used. After that, if an ARP packet matching the entry is received, the entry becomes valid, and its aging timer restarts.

If the aging timer of an ARP snooping entry expires, the entry is removed.

Protection for ARP snooping

An attack occurs if an ARP packet has the same sender IP address as a valid ARP snooping entry but a different sender MAC address. The ARP snooping entry becomes invalid, and it is removed in 1 minute.

Enabling ARP snooping

1. Enter system view.
   `system-view`
2. Enter VLAN view.
   `vlan` *`vlan-id`*
3. Enable ARP snooping
   `arp snooping enable`
   By default, ARP snooping is disabled.

Display and maintenance commands for ARP snooping

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display ARP snooping entries.	**display arp snooping** [**vlan** *vlan-id*] [**slot** *slot-number*] [**count**] **display arp snooping ip** *ip-address* [**slot** *slot-number*]
Delete ARP snooping entries.	**reset arp snooping** [**ip** *ip-address* | **vlan** *vlan-id*]

Configuring ARP fast-reply

About ARP fast-reply

ARP fast-reply enables a device to directly answer ARP requests according to IPSG bindings or ARP snooping entries. ARP fast-reply functions in a VLAN.

The device processes a received ARP request as follows:

1. Checks the target IP address of the ARP request.
   - If the target IP address is the IP address of the VLAN interface, the device delivers the request to the ARP module.
   - If the target IP address is not the IP address of the VLAN interface, the process goes to step 2.
2. Searches IPSG bindings by using the target IP address.
   - If a match is found and the interface in the matching entry is a wireless interface, the device returns a reply according to the matching entry.
   - If a match is found and the interface in the matching entry is the Ethernet interface that received the ARP request, the device does not return any reply.
   - If a match is found and the interface in the matching entry is an Ethernet interface other than the receiving interface, the device returns a reply according to the matching entry.
   - If no match is found, the process goes to step 3.

   For information about IPSG, see IP source guard configuration in *Security Configuration Guide*.
3. Searches the ARP snooping table if ARP snooping is enabled on the device. If ARP snooping is disabled on the device, the process goes to step 4.
   - If a match is found and the interface in the matching entry is a wireless interface, the device returns a reply according to the ARP snooping entry.
   - If a match is found and the interface in the matching entry is the Ethernet interface that received the ARP request, the device does not return any reply.
   - If a match is found and the interface in the matching entry is an Ethernet interface other than the receiving interface, the device returns a reply according to the ARP snooping entry.
   - If no match is found, the process goes to step 4.
4. Forwards the ARP request to other interfaces except the receiving interface in the VLAN, or delivers the ARP request to other modules.

Enabling ARP fast-reply

Restrictions and guidelines

To improve the availability of ARP fast-reply, enable ARP snooping at the same time.

Procedure

1. Enter system view.

   system-view
2. Enter VLAN view.

   vlan *vlan-id*
3. Enable ARP fast-reply.

   arp fast-reply enable

By default, ARP fast-reply is disabled.

Configuring ARP direct route advertisement

About ARP direct route advertisement

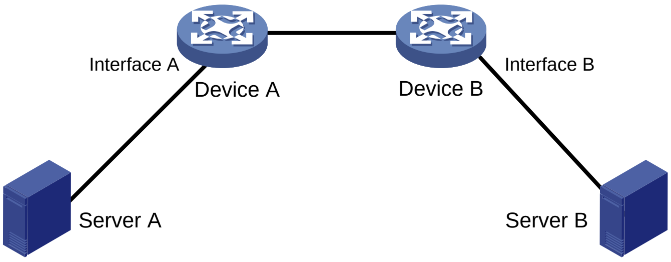
Mechanism of ARP direct route advertisement

The ARP direct route advertisement feature generates host routes based on ARP entries for packet forwarding and route advertisement.

Application in Layer 3 networks

As shown in Figure 3, ARP direct route advertisement is enabled on Interface A and Interface B. This feature advertises a host route to Server A and a host route to Device B, respectively. The routing protocol advertises these host routes rather than the network routes, reducing unexpected traffic caused by network route advertisements.

Figure 3 Application in a Layer 3 network



Enabling ARP direct route advertisement

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Enable the ARP direct route advertisement feature.

   `arp route-direct advertise`

   By default, the ARP direct route advertisement feature is disabled.

Contents

Configuring basic IPv6 settings

About IPv6

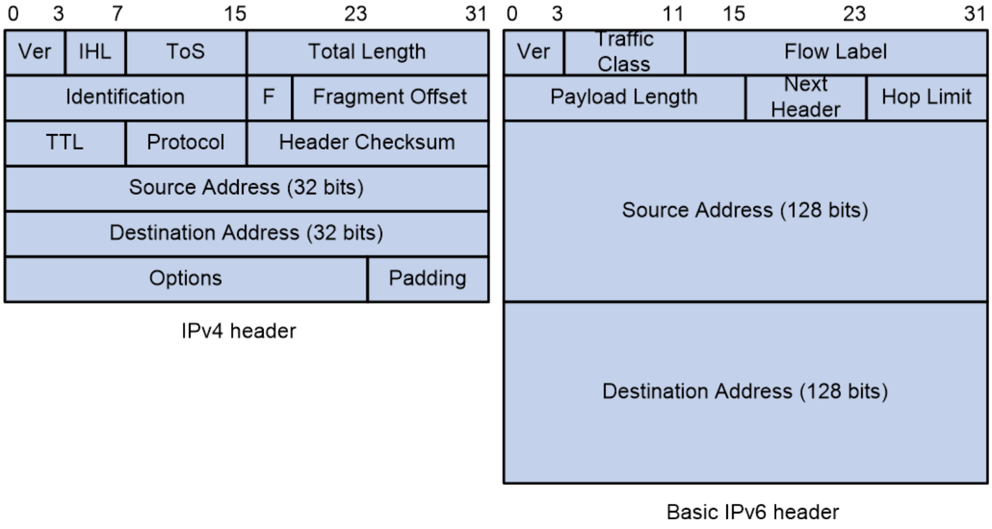
IPv6, also called IP next generation (IPng), was designed by the IETF as the successor to IPv4. One significant difference between IPv6 and IPv4 is that IPv6 increases the IP address size from 32 bits to 128 bits.

IPv6 features

Simplified header format

IPv6 removes several IPv4 header fields or moves them to the IPv6 extension headers to reduce the length of the basic IPv6 packet header. The basic IPv6 packet header has a fixed length of 40 bytes to simplify IPv6 packet handling and improve forwarding efficiency. Although the IPv6 address size is four times the IPv4 address size, the basic IPv6 packet header size is only twice the size of the option-less IPv4 packet header.

Figure 1 IPv4 packet header format and basic IPv6 packet header format



Larger address space

IPv6 can provide 3.4 x 10^{38} addresses to meet the requirements of hierarchical address assignment for both public and private networks.

Hierarchical address structure

IPv6 uses a hierarchical address structure to speed up route lookup and reduce the IPv6 routing table size through route aggregation.

Address autoconfiguration

To simplify host configuration, IPv6 supports stateful and stateless address autoconfiguration.

- Stateful address autoconfiguration enables a host to acquire an IPv6 address and other configuration information from a server (for example, a DHCPv6 server). For more information about DHCPv6 server, see "Configuring the DHCPv6 server."

- Stateless address autoconfiguration enables a host to automatically generate an IPv6 address and other configuration information by using its link-layer address and the prefix information advertised by a router.

To communicate with other hosts on the same link, a host automatically generates a link-local address based on its link-layer address and the link-local address prefix (FE80::/10).

Built-in security

IPv6 defines extension headers to support IPsec. IPsec provides end-to-end security and enhances interoperability among different IPv6 applications.

QoS support

The Flow Label field in the IPv6 header allows the device to label the packets of a specific flow for special handling.

Enhanced neighbor discovery mechanism

The IPv6 neighbor discovery protocol uses a group of ICMPv6 messages to manage information exchange among neighboring nodes on the same link. The group of ICMPv6 messages replaces ARP messages, ICMPv4 router discovery messages, and ICMPv4 redirect messages and provides a series of other functions.

Flexible extension headers

IPv6 eliminates the Options field in the header and introduces optional extension headers to provide scalability and improve efficiency. The Options field in the IPv4 packet header contains a maximum of 40 bytes, whereas the IPv6 extension headers are restricted to the maximum size of IPv6 packets.

IPv6 addresses

IPv6 address format

An IPv6 address is represented as a set of 16-bit hexadecimals separated by colons (:). An IPv6 address is divided into eight groups, and each 16-bit group is represented by four hexadecimal numbers, for example, 2001:0000:130F:0000:0000:09C0:876A:130B.

To simplify the representation of IPv6 addresses, you can handle zeros in IPv6 addresses by using the following methods:

- The leading zeros in each group can be removed. For example, the above address can be represented in a shorter format as 2001:0:130F:0:0:9C0:876A:130B.
- If an IPv6 address contains one or more consecutive groups of zeros, they can be replaced by a double colon (::). For example, the above address can be represented in the shortest format as 2001:0:130F::9C0:876A:130B.

IMPORTANT:

A double colon can appear once or not at all in an IPv6 address. This limit allows the device to determine how many zeros the double colon represents and correctly convert it to zeros to restore a 128-bit IPv6 address.

An IPv6 address consists of an address prefix and an interface ID, which are equivalent to the network ID and the host ID of an IPv4 address.

An IPv6 address prefix is written in IPv6-address/prefix-length notation. The prefix-length is a decimal number indicating how many leftmost bits of the IPv6 address are in the address prefix.

IPv6 address types

IPv6 addresses include the following types:

- **Unicast address**—An identifier for a single interface, similar to an IPv4 unicast address. A packet sent to a unicast address is delivered to the interface identified by that address.

- **Multicast address**—An identifier for a set of interfaces (typically belonging to different nodes), similar to an IPv4 multicast address. A packet sent to a multicast address is delivered to all interfaces identified by that address.

  Broadcast addresses are replaced by multicast addresses in IPv6.
- **Anycast address**—An identifier for a set of interfaces (typically belonging to different nodes). A packet sent to an anycast address is delivered to the nearest interface among the interfaces identified by that address. The nearest interface is chosen according to the routing protocol's measure of distance.

The type of an IPv6 address is designated by the first several bits, called the format prefix.

Table 1 Mappings between address types and format prefixes

Type		Format prefix (binary)	IPv6 prefix ID
Unicast address	Unspecified address	00...0 (128 bits)	::/128
	Loopback address	00...1 (128 bits)	::1/128
	Link-local address	1111111010	FE80::/10
	Global unicast address	Other forms	N/A
Multicast address		11111111	FF00::/8
Anycast address		Anycast addresses use the unicast address space and have the identical structure of unicast addresses.	

Unicast addresses

Unicast addresses include global unicast addresses, link-local unicast addresses, the loopback address, and the unspecified address.

- **Global unicast addresses**—Equivalent to public IPv4 addresses, global unicast addresses are provided for Internet service providers. This type of address allows for prefix aggregation to restrict the number of global routing entries.
- **Link-local addresses**—Used for communication among link-local nodes for neighbor discovery and stateless autoconfiguration. Packets with link-local source or destination addresses are not forwarded to other links.
- **A loopback address**—0:0:0:0:0:0:0:1 (or ::1). It has the same function as the loopback address in IPv4. It cannot be assigned to any physical interface. A node uses this address to send an IPv6 packet to itself.
- **An unspecified address**—0:0:0:0:0:0:0:0 (or ::). It cannot be assigned to any node. Before acquiring a valid IPv6 address, a node fills this address in the source address field of IPv6 packets. The unspecified address cannot be used as a destination IPv6 address.

Multicast addresses

IPv6 multicast addresses listed in Table 2 are reserved for special purposes.

Table 2 Reserved IPv6 multicast addresses

Address	Application
FF01::1	Node-local scope all-nodes multicast address.
FF02::1	Link-local scope all-nodes multicast address.
FF01::2	Node-local scope all-routers multicast address.
FF02::2	Link-local scope all-routers multicast address.

Multicast addresses also include solicited-node addresses. A node uses a solicited-node multicast address to acquire the link-layer address of a neighboring node on the same link and to detect duplicate addresses. Each IPv6 unicast or anycast address has a corresponding solicited-node address. The format of a solicited-node multicast address is FF02:0:0:0:0:1:FFXX:XXXX. FF02:0:0:0:0:1:FF is fixed and consists of 104 bits, and XX:XXXX is the last 24 bits of an IPv6 unicast address or anycast address.

EUI-64 address-based interface identifiers

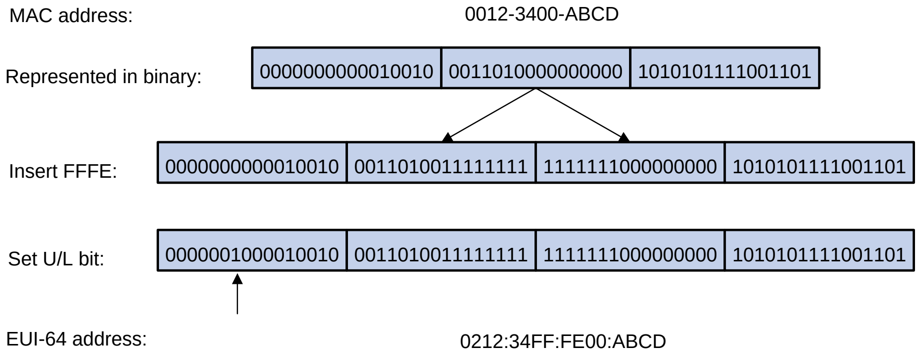
An interface identifier is 64 bits long and uniquely identifies an interface on a link.

On an IEEE 802 interface (such as a VLAN interface), the interface identifier is derived from the link-layer address (typically a MAC address) of the interface. The MAC address is 48 bits long.

To obtain an EUI-64 address-based interface identifier, follow these steps:

1. Insert the 16-bit binary number 1111111111111110 (hexadecimal value of FFFE) behind the 24th high-order bit of the MAC address.
2. Invert the universal/local (U/L) bit (the seventh high-order bit). This operation makes the interface identifier have the same local or global significance as the MAC address.

Figure 2 Converting a MAC address into an EUI-64 address-based interface identifier



On a tunnel interface, the lower 32 bits of the EUI-64 address-based interface identifier are the source IPv4 address of the tunnel interface. The higher 32 bits of the EUI-64 address-based interface identifier of an ISATAP tunnel interface are 0000:5EFE, whereas those of other tunnel interfaces are all zeros. For more information about tunnels, see *VPN Configuration Guide*.

On an interface of another type the EUI-64 address-based interface identifier is generated randomly by the device.

IPv6 path MTU discovery

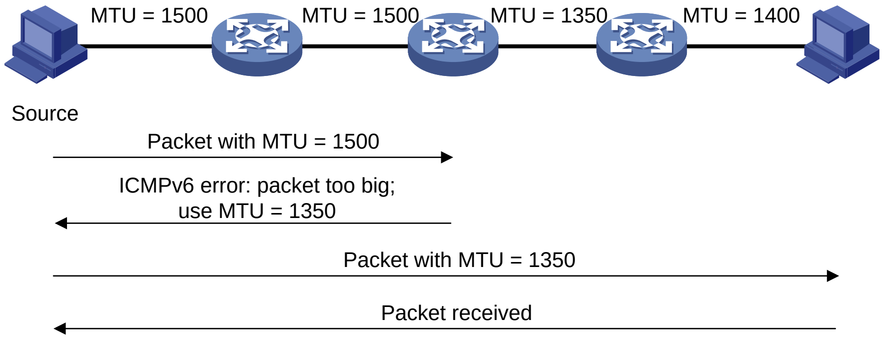
The links that a packet passes from a source to a destination can have different MTUs, among which the minimum MTU is the path MTU. If a packet exceeds the path MTU, the source end fragments the packet to reduce the processing pressure on intermediate devices and to use network resources effectively.

A source end uses path MTU discovery to find the path MTU to a destination, as shown in Figure 3.

1. The source host sends a packet no larger than its MTU to the destination host.
2. If the MTU of an intermediate device's output interface is smaller than the packet, the device performs the following operations:
   - Discards the packet.
   - Returns an ICMPv6 error message containing the interface MTU to the source host.
3. Upon receiving the ICMPv6 error message, the source host performs the following operations:
   - Uses the returned MTU to limit the packet size.
   - Performs fragmentation.
   - Sends the fragments to the destination host.

4. Step 2 and step 3 are repeated until the destination host receives the packet. In this way, the source host finds the minimum MTU of all links in the path to the destination host.

Figure 3 Path MTU discovery process



IPv6 transition technologies

IPv6 transition technologies enable communication between IPv4 and IPv6 networks.

Dual stack

Dual stack is the most direct transition approach. A network node that supports both IPv4 and IPv6 is a dual-stack node. A dual-stack node configured with an IPv4 address and an IPv6 address can forward both IPv4 and IPv6 packets. An application that supports both IPv4 and IPv6 prefers IPv6 at the network layer.

Dual stack is suitable for communication between IPv4 nodes or between IPv6 nodes. It is the basis of all transition technologies. However, it does not solve the IPv4 address depletion issue because each dual-stack node must have a globally unique IPv4 address.

Tunneling

Tunneling uses one network protocol to encapsulate the packets of another network protocol and transfers them over the network. For more information about tunneling, see *VPN Configuration Guide*.

AFT

Address Family Translation (AFT) translates an IP address of one address family into an IP address of the other address family, enabling an IPv4 network and an IPv6 network to communicate with each other. Configured on the edge devices of the IPv4 and IPv6 networks, AFT is transparent to users and does not require configuration changes on IPv4 hosts and IPv6 hosts. For more information about AFT, see *NAT Configuration Guide*.

IPv6 basics tasks at a glance

To configure basic IPv6 settings, perform the following tasks:

1. Configuring an IPv6 address

   Choose the following tasks as needed:
   - Configuring an IPv6 global unicast address
   - Configuring an IPv6 link-local address
   - Configuring an IPv6 anycast address
2. (Optional.) Configuring path MTU discovery
   - Setting the interface MTU
   - Setting a static path MTU for an IPv6 address
   - Setting the aging time for dynamic path MTUs
3. (Optional.) Controlling sending ICMPv6 messages
   - Configuring the rate limit for ICMPv6 error messages
   - Enabling replying to multicast echo requests
   - Enabling sending ICMPv6 destination unreachable messages
   - Enabling sending ICMPv6 time exceeded messages
   - Enabling sending ICMPv6 redirect messages
   - Specifying the source address for ICMPv6 packets
4. (Optional.) Enabling IPv6 local fragment reassembly
5. (Optional.) Enabling discarding IPv6 packets that contain extension headers
6. (Optional.) Configuring IPv6 last hop holding

Configuring an IPv6 global unicast address

About IPv6 global unicast address

Use one of the following methods to configure an IPv6 global unicast address for an interface:

- **EUI-64 IPv6 address**—The IPv6 address prefix of the interface is manually configured, and the interface ID is generated automatically by the interface.
- **Manual configuration**—The IPv6 global unicast address is manually configured.
- **Prefix-specific address autoconfiguration**—The IPv6 global unicast address is generated automatically based on the prefix specified by its ID. The prefix can be manually configured or obtained through DHCPv6.
- **Stateless address autoconfiguration**—The IPv6 global unicast address is generated automatically based on the address prefix information contained in the RA message.

You can configure multiple IPv6 global unicast addresses on an interface.

Manually configured global unicast addresses (including EUI-64 IPv6 addresses) take precedence over automatically generated ones. If you manually configure a global unicast address with the same address prefix as an existing global unicast address on an interface, the manually configured one takes effect. However, it does not overwrite the automatically generated address. If you delete the manually configured global unicast address, the device uses the automatically generated one.

Generating an EUI-64 IPv6 address

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure an EUI-64 IPv6 address on the interface.

   ipv6 address { *ipv6-address prefix-length* | *ipv6-address/prefix-length* } **eui-64**

   By default, no EUI-64 IPv6 address is configured on an interface.

Manually assigning an IPv6 global unicast address

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Assign an IPv6 global unicast address to the interface.

   ipv6 address { *ipv6-address prefix-length* | *ipv6-address/prefix-length* }

   By default, no IPv6 global unicast address is configured on an interface.

Stateless address autoconfiguration

About this task

Stateless address autoconfiguration enables an interface to automatically generate an IPv6 global unicast address by using the address prefix in the received RA message and the interface ID. On an IEEE 802 interface (such as an Ethernet interface or a VLAN interface), the interface ID is generated based on the interface's MAC address and is globally unique. An attacker can exploit this rule to identify the sending device easily.

To fix the vulnerability, you can configure the temporary address feature. With this feature, an IEEE 802 interface generates the following addresses:

- **Public IPv6 address**—Includes the address prefix in the RA message and a fixed interface ID generated based on the MAC address of the interface.
- **Temporary IPv6 address**—Includes the address prefix in the RA message and a random interface ID generated through MD5.

You can also configure the interface to preferentially use the temporary IPv6 address as the source address of sent packets. When the valid lifetime of the temporary IPv6 address expires, the interface deletes the address and generates a new one. This feature enables the system to send packets with different source addresses through the same interface. If the temporary IPv6 address cannot be used because of a DAD conflict, the public IPv6 address is used.

The preferred lifetime and valid lifetime for a temporary IPv6 address are determined as follows:

- The preferred lifetime of a temporary IPv6 address takes the smaller of the following values:
  - The preferred lifetime of the address prefix in the RA message.

    - The preferred lifetime configured for temporary IPv6 addresses minus DESYNC_FACTOR (a random number in the range of 0 to 600 seconds).
- The valid lifetime of a temporary IPv6 address takes the smaller of the following values:
    - The valid lifetime of the address prefix.
    - The valid lifetime configured for temporary IPv6 addresses.

Restrictions and guidelines

If the IPv6 prefix in the RA message is not 64 bits long, stateless address autoconfiguration fails to generate an IPv6 global unicast address.

To generate a temporary address, an interface must be enabled with stateless address autoconfiguration. Temporary IPv6 addresses do not overwrite public IPv6 addresses, so an interface can have multiple IPv6 addresses with the same address prefix but different interface IDs.

If an interface fails to generate a public IPv6 address because of a prefix conflict or other reasons, it does not generate any temporary IPv6 address.

Executing the **undo ipv6 address auto** command on an interface deletes all IPv6 global unicast addresses and link-local addresses that are automatically generated on the interface.

Enabling stateless address autoconfiguration

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable stateless address autoconfiguration on an interface, so that the interface can automatically generate a global unicast address.
   ipv6 address auto
   By default, the stateless address autoconfiguration feature is disabled on an interface.

Configuring the temporary address feature and preferentially using the temporary IPv6 address as the source address of outgoing packets

1. Enter system view.
   system-view
2. Enable the temporary IPv6 address feature.
   ipv6 temporary-address [*valid-lifetime preferred-lifetime*]
   By default, the temporary IPv6 address feature is disabled.
3. Enable the system to preferentially use the temporary IPv6 address as the source address of the outgoing packets.
   ipv6 prefer temporary-address
   By default, the system does not preferentially use the temporary IPv6 address as the source address of the outgoing packets.

Configuring prefix-specific address autoconfiguration

1. Enter system view.
   system-view
2. Configure an IPv6 prefix.
   Choose one option as needed:
    - Configure a static IPv6 prefix.
      ipv6 prefix *prefix-number ipv6-prefix*/*prefix-length*

By default, no static IPv6 prefixes exist.

  - Use DHCPv6 to obtain a dynamic IPv6 prefix.

    For more information about IPv6 prefix acquisition, see "Configuring the DHCPv6 client."

3. Enter interface view.

   `interface` *`interface-type interface-number`*

4. Specify an IPv6 prefix for an interface to automatically generate an IPv6 global unicast address and advertise the prefix.

   `ipv6 address` *`prefix-number sub-prefix/prefix-length`*

   By default, no IPv6 prefix is specified for the interface to automatically generate an IPv6 global unicast address.

Configuring an IPv6 link-local address

About IPv6 link-local address

Configure IPv6 link-local addresses using one of the following methods:

- **Automatic generation**—The device automatically generates a link-local address for an interface according to the link-local address prefix (FE80::/10) and the link-layer address of the interface.
- **Manual assignment**—Manually configure an IPv6 link-local address for an interface.

Restrictions and guidelines

After you configure an IPv6 global unicast address for an interface, the interface automatically generates a link-local address. This link-local address is the same as the one generated by using the **`ipv6 address auto link-local`** command. If a link-local address is manually assigned to an interface, this manual assigned link-local address takes effect. If the manually assigned link-local address is deleted, the automatically generated link-local address takes effect.

Using the **`undo ipv6 address auto link-local`** command on an interface deletes only the link-local address generated by the **`ipv6 address auto link-local`** command. If the interface has an IPv6 global unicast address, it still has a link-local address. If the interface has no IPv6 global unicast address, it has no link-local address.

An interface can have only one link-local address. As a best practice, use the automatic generation method to avoid link-local address conflicts. If both the automatic generation and manual assignment methods are used, the manual assignment takes precedence.

- If you first use automatic generation and then manual assignment, the manually assigned link-local address overwrites the automatically generated one.
- If you first use manual assignment and then automatic generation, both of the following occur:
  - The link-local address is still the manually assigned one.
  - The automatically generated link-local address does not take effect. If you delete the manually assigned address, the automatically generated link-local address takes effect.

Configuring automatic generation of an IPv6 link-local address for an interface

1. Enter system view.

   `system-view`

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the interface to automatically generate an IPv6 link-local address.

   ipv6 address auto link-local

   By default, no link-local address is configured on an interface.

   After an IPv6 global unicast address is configured on the interface, a link-local address is generated automatically.

Manually assigning an IPv6 link-local address to an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Manually assign an IPv6 link-local address to the interface.

   ipv6 address *ipv6-address* **link-local**

   By default, no link-local address is configured on an interface.

Configuring an IPv6 anycast address

4. Enter system view.

   system-view

5. Enter interface view.

   interface *interface-type interface-number*

6. Configure an IPv6 anycast address.

   ipv6 address { *ipv6-address prefix-length* | *ipv6-address/prefix-length* } **anycast**

   By default, no IPv6 anycast address is configured on an interface.

Configuring path MTU discovery

Setting the interface MTU

About this task

IPv6 routers do not support packet fragmentation. If a packet exceeds the MTU of the output interface, the router discards the packet and sends a packet too big message to the source host. This message contains the interface MTU. The source host fragments the packet according to the returned MTU. To avoid traffic overload due to packet dropping, set a proper interface MTU.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the interface MTU.

   ipv6 mtu *size*

By default, no interface MTU is set.

Setting a static path MTU for an IPv6 address

About this task

You can set a static path MTU for an IPv6 address. Before sending a packet to the IPv6 address, the device compares the output interface MTU with the static path MTU. If the packet size exceeds the smaller one of the two values, the device fragments the packet according to the smaller value. After sending the fragmented packets, the device dynamically finds the path MTU to a destination host (see "IPv6 path MTU discovery").

Procedure

1. Enter system view.

   system-view

2. Set a static path MTU for an IPv6 address.

   ipv6 pathmtu [**vpn-instance** *vpn-instance-name*] *ipv6-address value*

   By default, no path MTU is set for any IPv6 address.

Setting the aging time for dynamic path MTUs

About this task

After the device dynamically discovers the path MTU to a destination host (see "IPv6 path MTU discovery"), it performs the following operations:

- Sends packets to the destination host based on this path MTU.
- Starts the aging timer for this path MTU.

When the aging timer expires, the device removes the dynamic path MTU and discovers the path MTU again.

Restrictions and guidelines

The aging time is invalid for a static path MTU.

Procedure

1. Enter system view.

   system-view

2. Set the aging time for dynamic path MTUs.

   ipv6 pathmtu age *age-time*

   The default setting is 10 minutes.

Controlling sending ICMPv6 messages

Configuring the rate limit for ICMPv6 error messages

About this task

To avoid sending excessive ICMPv6 error messages within a short period that might cause network congestion, you can limit the rate at which ICMPv6 error messages are sent. A token bucket algorithm is used with one token representing one ICMPv6 error message.

A token is placed in the bucket at intervals until the maximum number of tokens that the bucket can hold is reached.

A token is removed from the bucket when an ICMPv6 error message is sent. When the bucket is empty, ICMPv6 error messages are not sent until a new token is placed in the bucket.

Procedure

1. Enter system view.
   `system-view`
2. Set the bucket size and the interval for tokens to arrive in the bucket for ICMPv6 error messages.
   `ipv6 icmpv6 error-interval` *`interval`* `[` *`bucketsize`* `]`
   By default, the bucket allows a maximum of 10 tokens. A token is placed in the bucket at an interval of 100 milliseconds.
   To disable the ICMPv6 rate limit, set the interval to 0 milliseconds.

Enabling replying to multicast echo requests

1. Enter system view.
   `system-view`
2. Enable replying to multicast echo requests.
   `ipv6 icmpv6 multicast-echo-reply enable`
   By default, this feature is disabled.

Enabling sending ICMPv6 destination unreachable messages

About this task

The device sends the source the following ICMPv6 destination unreachable messages:

- **ICMPv6 No Route to Destination message**—A packet to be forwarded does not match any route.
- **ICMPv6 Communication with Destination Administratively Prohibited message**—An administrative prohibition is preventing successful communication with the destination. This is typically caused by a firewall or an ACL on the device.
- **ICMPv6 Beyond Scope of Source Address message**—The destination is beyond the scope of the source IPv6 address. For example, a packet's source IPv6 address is a link-local address, and its destination IPv6 address is a global unicast address.
- **ICMPv6 Address Unreachable message**—The device fails to resolve the link layer address for the destination IPv6 address of a packet.
- **ICMPv6 Port Unreachable message**—No port process on the destination device exists for a received UDP packet.

Restrictions and guidelines

An ICMPv6 destination unreachable message indicates that the destination is not reachable from the source device. Attackers can launch malicious attacks to make the device generate incorrect ICMPv6 destination unreachable messages, which will affect the function of the network. To protect the network from malicious attacks and decrease unnecessary network traffic, you can disable the sending of ICMPv6 destination unreachable messages.

Procedure

1. Enter system view.
   `system-view`

2. Enable sending ICMPv6 destination unreachable messages.

   `ipv6 unreachables enable`

   By default, this feature is disabled.

Enabling sending ICMPv6 time exceeded messages

About this task

The device sends the source ICMPv6 time exceeded messages as follows:

- If a received packet is not destined for the device and its hop limit is 1, the device sends an ICMPv6 hop limit exceeded in transit message to the source.
- Upon receiving the first fragment of an IPv6 datagram destined for the device, the device starts a timer. If the timer expires before all fragments arrive, the device sends an ICMPv6 fragment reassembly time exceeded message to the source.

Restrictions and guidelines

If the device receives large numbers of malicious packets, its performance degrades greatly because it must send back ICMP time exceeded messages. To prevent such attacks, disable sending ICMPv6 time exceeded messages.

Procedure

1. Enter system view.

   `system-view`

2. Enable sending ICMPv6 time exceeded messages.

   `ipv6 hoplimit-expires enable`

   The default setting is disabled.

Enabling sending ICMPv6 redirect messages

About this task

Upon receiving a packet from a host, the device sends an ICMPv6 redirect message to inform the host of a better next hop when the following conditions are met:

- The interface receiving the packet is the interface forwarding the packet.
- The selected route is not created or modified by any ICMPv6 redirect messages.
- The selected route is not a default route.
- The forwarded packet does not contain the routing extension header.

The ICMPv6 redirect feature simplifies host management by enabling hosts that hold few routes to optimize their routing table gradually. However, to avoid adding too many routes on hosts, this feature is disabled by default.

Procedure

1. Enter system view.

   `system-view`

2. Enable sending ICMPv6 redirect messages.

   `ipv6 redirects enable`

   By default, sending ICMPv6 redirect messages is disabled.

Specifying the source address for ICMPv6 packets

About this task

Perform this task to specify the source IPv6 address for outgoing ping echo requests and ICMPv6 error messages. It is a good practice to specify the IPv6 address of the loopback interface as the source IPv6 address. This feature helps users to easily locate the sending device.

Restrictions and guidelines

If you specify an IPv6 address in the **ping** command, ping echo requests use the specified address as the source IPv6 address. If you do not specify an IPv6 address in the **ping** command, ping echo requests use the IPv6 address specified by the **ipv6 icmpv6 source** command.

Procedure

1. Enter system view.

   system-view

2. Specify an IPv6 address as the source address for outgoing ICMPv6 packets.

   ipv6 icmpv6 source [**vpn-instance** *vpn-instance-name*] *ipv6-address*

   By default, the device uses the IPv6 address of the sending interface as the source IPv6 address for outgoing ICMPv6 packets.

Enabling IPv6 local fragment reassembly

About this task

Use this feature on a multichassis IRF fabric to improve fragment reassembly efficiency. This feature enables a subordinate to reassemble the IPv6 fragments of a packet if all the fragments arrive at it. If this feature is disabled, all IPv6 fragments are delivered to the master device for reassembly.

Restrictions and guidelines

The IPv6 local fragment reassembly feature applies only to fragments destined for the same subordinate.

Procedure

1. Enter system view.

   system-view

2. Enable IPv6 local fragment reassembly.

   ipv6 reassemble local enable

   By default, IPv6 local fragment reassembly is disabled.

Enabling discarding IPv6 packets that contain extension headers

About this task

This feature enables a device to discard a received IPv6 packet in which the extension headers cannot be processed by the device.

Procedure

1. Enter system view

   system-view

2. Enable the device to discard IPv6 packets that contain extension headers.

   ipv6 extension-header drop enable

   By default, the device does not discard IPv6 packets that contain extension headers.

Configuring IPv6 last hop holding

About this task

Last hop holding implements symmetric routing.

When the interface enabled with this feature receives the first IPv6 packet of a forward flow, this feature implements the following operations:

- Obtains the forward flow information and last hop information of the packet.
- Based on the information, creates an IPv6 fast forwarding entry for the reverse flow.

When packets of the reverse flow arrive at the device, the device forwards those packets based on the entry.

Restrictions and guidelines

Last hop holding is based on IPv6 fast forwarding entries. If the MAC address of a last hop changes on an Ethernet link, this feature can function correctly only after the fast forwarding entry is updated for the MAC address.

Procedure

1. Enter system view.

   system-view

2. Enter interface view. Choose one option as needed:
   - Enter Layer 3 Ethernet interface view or Layer 3 Ethernet subinterface view.

     interface *interface-type interface-number*
   - Enter dialer interface view.

     interface dialer *number*

3. Enable IPv6 last hop holding.

   ipv6 last-hop hold

   By default, IPv6 last hop holding is disabled.

Display and maintenance commands for IPv6 basics

Execute **display** commands in any view and **reset** commands in user view.

For information about the **display tcp statistics**, **display udp statistics**, **reset tcp statistics**, and **reset udp statistics** command, see the IP performance commands in *Layer 3—IP Services Command Reference*.

Task	Command
Display IPv6 FIB entries.	**display ipv6 fib** [**vpn-instance** *vpn-instance-name*] [*ipv6-address* [*prefix-length*]]
Display ICMPv6 traffic statistics.	**display ipv6 icmp statistics** [**slot**

Task	Command
	slot-number]
Display IPv6 information about the interface.	**display ipv6 interface** [*interface-type* [*interface-number*]] [**brief**]
Display IPv6 prefix information about the interface.	**display ipv6 interface** *interface-type interface-number* **prefix**
Display the IPv6 path MTU information.	**display ipv6 pathmtu** [**vpn-instance** *vpn-instance-name*] { *ipv6-address* | { **all** | **dynamic** | **static** } [**count**] }
Display the IPv6 prefix information.	**display ipv6 prefix** [*prefix-number*]
Display brief information about IPv6 RawIP connections.	**display ipv6 rawip** [**slot** *slot-number*]
Display detailed information about IPv6 RawIP connections.	**display ipv6 rawip verbose** [**slot** *slot-number* [**pcb** *pcb-index*]]
Display IPv6 and ICMPv6 packet statistics.	**display ipv6 statistics** [**slot** *slot-number*]
Display brief information about IPv6 TCP connections.	**display ipv6 tcp** [**slot** *slot-number*]
Display detailed information about IPv6 TCP connections.	**display ipv6 tcp verbose** [**slot** *slot-number* [**pcb** *pcb-index*]]
Display brief information about IPv6 TCP proxy.	**display ipv6 tcp-proxy slot** *slot-number*
Display the usage of non-well known ports for IPv6 TCP proxy.	**display ipv6 tcp-proxy port-info slot** *slot-number*
Display brief information about IPv6 UDP connections.	**display ipv6 udp** [**slot** *slot-number*]
Display detailed information about IPv6 UDP connections.	**display ipv6 udp verbose** [**slot** *slot-number* [**pcb** *pcb-index*]]
Display IPv6 TCP traffic statistics.	**display tcp statistics** [**slot** *slot-number*]
Display IPv6 UDP traffic statistics.	**display udp statistics** [**slot** *slot-number*]
Clear path MTUs.	**reset ipv6 pathmtu** { **all** | **dynamic** | **static** }
Clear IPv6 and ICMPv6 packet statistics.	**reset ipv6 statistics** [**slot** *slot-number*]
Clear IPv6 TCP traffic statistics.	**reset tcp statistics**
Clear IPv6 UDP traffic statistics.	**reset udp statistics**

Configuring IPv6 neighbor discovery

About IPv6 neighbor discovery

ICMPv6 messages used by IPv6 neighbor discovery

The IPv6 neighbor discovery (ND) process uses ICMP messages for address resolution, neighbor reachability verification, and neighboring device tracking.

Table 3 describes the ICMPv6 messages used by the IPv6 ND protocol.

Table 3 ICMPv6 messages used by ND

ICMPv6 message	Type	Function
Neighbor Solicitation (NS)	135	Acquires the link-layer address of a neighbor on the local link.
		Verifies the reachability of a neighbor.
		Detects duplicate addresses.
Neighbor Advertisement (NA)	136	Responds to an NS message.
		Notifies the neighboring nodes of link layer changes.
Router Solicitation (RS)	133	Requests an address prefix and other configuration information for autoconfiguration after startup.
Router Advertisement (RA)	134	Responds to an RS message.
		Advertises information, such as the Prefix Information options and flag bits.
Redirect	137	Informs the source host of a better next hop on the path to a particular destination when certain conditions are met.

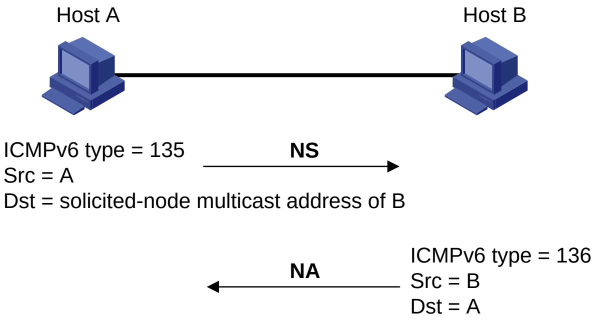
Address resolution

This function is similar to ARP in IPv4. An IPv6 node acquires the link-layer addresses of neighboring nodes on the same link through NS and NA messages.

Figure 4 shows how Host A acquires the link-layer address of Host B on the same link. The address resolution procedure is as follows:

1. Host A multicasts an NS message. The source address of the NS message is the IPv6 address of the sending interface of Host A. The destination address is the solicited-node multicast address of Host B. The NS message body contains the link-layer address of Host A and the target IPv6 address.
2. After receiving the NS message, Host B determines whether the target address of the packet is its IPv6 address. If it is, Host B learns the link-layer address of Host A, and then unicasts an NA message containing its link-layer address.
3. Host A acquires the link-layer address of Host B from the NA message.

Figure 4 Address resolution



Neighbor reachability detection

After Host A acquires the link-layer address of its neighbor Host B, Host A can use NS and NA messages to test the reachability of Host B as follows:

1. Host A sends an NS message whose destination address is the IPv6 address of Host B.
2. If Host A receives an NA message from Host B, Host A decides that Host B is reachable. Otherwise, Host B is unreachable.

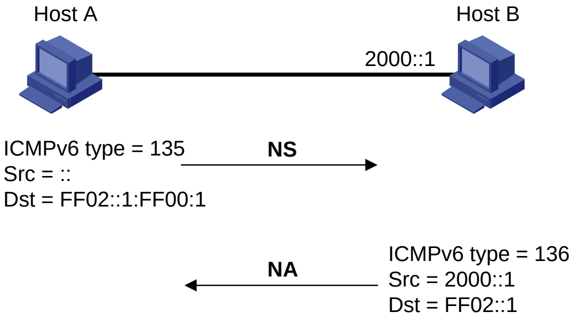
Duplicate address detection

After Host A acquires an IPv6 address, it performs Duplicate Address Detection (DAD) to check whether the address is being used by any other node. This is similar to gratuitous ARP in IPv4. DAD is accomplished through NS and NA messages.

The DAD procedure is as follows:

1. Host A sends an NS message. The source address is the unspecified address and the destination address is the corresponding solicited-node multicast address of the IPv6 address to be detected. The NS message body contains the detected IPv6 address.
2. If Host B uses this IPv6 address, Host B returns an NA message that contains its IPv6 address.
3. Host A knows that the IPv6 address is being used by Host B after receiving the NA message from Host B. If receiving no NA message, Host A decides that the IPv6 address is not in use and uses this address.

Figure 5 Duplicate address detection



Router/prefix discovery and stateless address autoconfiguration

Router/prefix discovery allows an IPv6 node to find the neighboring routers and learn the prefix and network configuration parameters of the network from receiving RA messages.

Stateless address autoconfiguration allows an IPv6 node to automatically generate an IPv6 address based on the information learned through router/prefix discovery.

A node performs router/prefix discovery and stateless address autoconfiguration as follows:

1. At startup, a node sends an RS message to request configuration information from a router.
2. The router returns an RA message containing the Prefix Information option and other configuration information. (The router also periodically sends an RA message.)
3. The node automatically generates an IPv6 address and other configuration parameters according to the configuration information in the RA message.

The Prefix Information option contains an address prefix and the preferred lifetime and valid lifetime of the address prefix. A node updates the preferred lifetime and valid lifetime upon receiving a periodic RA message.

The generated IPv6 address is valid within the valid lifetime and becomes invalid when the valid lifetime expires.

After the preferred lifetime expires, the node cannot use the generated IPv6 address to establish new connections, but can receive packets destined for the IPv6 address. The preferred lifetime cannot be greater than the valid lifetime.

Redirection

Upon receiving a packet from a host, the gateway sends an ICMPv6 redirect message to inform the host of a better next hop when the following conditions are met:

- The interface receiving the packet is the same as the interface forwarding the packet.
- The selected route is not created or modified by an ICMPv6 redirect message.
- The selected route is not a default route on the device.
- The forwarded IPv6 packet does not contain the routing extension header.

Protocols and standards

- RFC 4861, *Neighbor Discovery for IP Version 6 (IPv6)*
- RFC 8106, *IPv6 Router Advertisement Options for DNS Configuration*

IPv6 neighbor discovery tasks at a glance

All IPv6 neighbor discovery tasks are optional.

- Configuring a static neighbor entry
- Setting the dynamic neighbor learning limit on an interface
- Enabling unsolicited NA learning
- Setting the aging timer for ND entries in stale state
- Minimizing link-local ND entries
- Setting the hop limit
- Configuring RA message sending and parameters

Configuring a static neighbor entry

About this task

A neighbor entry stores information about a link-local node. The entry can be created dynamically through NS and NA messages, or configured statically.

The device uniquely identifies a static neighbor entry by using the neighbor's IPv6 address and the number of the Layer 3 interface that connects to the neighbor. You can configure a static neighbor entry by using one of the following methods:

- **Method 1**—Associate a neighbor's IPv6 address and link-layer address with the local Layer 3 interface.
- **Method 2**—Associate a neighbor's IPv6 address and link-layer address with a Layer 2 port in a VLAN.

Restrictions and guidelines

You can use either of the methods to configure a static neighbor entry for a VLAN interface.

- If you use Method 1, the device is required to resolve the Layer 2 port in the related VLAN.
- If you use Method 2, make sure the Layer 2 port belongs to the specified VLAN and the corresponding VLAN interface already exists. After the configuration, the device associates the VLAN interface with the neighbor IPv6 address to identify the static neighbor entry.

Do not specify a Reth interface as the outgoing interface in IPv6 static neighbor entries if its member interfaces contain subinterfaces. For more information about Reth interfaces, see *Virtual Technologies Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Configure a static neighbor entry.

   `ipv6 neighbor` *`ipv6-address mac-address`* `{` *`vlan-id port-type port-number`* `|` **`interface`** *`interface-type interface-number`* `}` `[` **`vpn-instance`** *`vpn-instance-name`* `]`

   By default, no static neighbor entries exist.

Setting the dynamic neighbor learning limit on an interface

About this task

The device can dynamically acquire the link-layer address of a neighboring node through NS and NA messages and add it into the neighbor table. When the number of dynamic neighbor entries reaches the limit, the interface stops learning neighbor information.

This feature limits the neighbor table size. A large neighbor table will degrade the forwarding performance.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the dynamic neighbor learning limit on the interface.

   ipv6 neighbors max-learning-num *max-number*

   By default, an interface can learn a maximum of 65536 dynamic neighbor entries.

Enabling unsolicited NA learning

About this task

On some networks, a server multicasts NA messages to two peer devices for link backup. The peer devices cannot learn ND entry for the server from these NA messages by default. If no ND learning is triggered by data exchange between the server and peer devices, the peer devices learn the entry for the server only when the server unicasts messages to them.

Restrictions and guidelines

This feature enables an interface to learn ND entries from unsolicited NA messages. The ND entries generated by using this method are in stale state. To ensure that the device learns ND entries from trusted NA messages, enable this feature only on a secure network.

This feature might cause the device to learn excessive ND entries that consume too many system resources. As a best practice, execute the **ipv6 neighbor stale-aging** command to set a smaller aging timer before you enable this feature. The smaller aging timer accelerates the aging of ND entries in stale state.

This feature is available only on Layer 3 interfaces.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Enable unsolicited NA learning.

   ipv6 nd unsolicited-na-learning enable

   By default, unsolicited NA learning is disabled.

Setting the aging timer for ND entries in stale state

About this task

ND entries in stale state have an aging timer. If an ND entry in stale state is not refreshed before the timer expires, the ND entry changes to the delay state. If it is still not refreshed in 5 seconds, the ND entry changes to the probe state, and the device sends an NS message three times. If no response is received, the device deletes the ND entry.

Procedure

1. Enter system view.

   system-view

2. Set the aging timer for ND entries in stale state.

```
ipv6 neighbor stale-aging aging-time
```

The default setting is 240 minutes.

Minimizing link-local ND entries

About this task

Perform this task to minimize link-local ND entries assigned to the hardware. Link-local ND entries refer to ND entries that contain link-local addresses.

By default, the device assigns all ND entries to the hardware. With this feature enabled, the newly learned link-local ND entries are not assigned to the hardware if the link-local addresses of the entries are not the next hops of any routes. This feature saves hardware resources.

This feature takes effect only on newly learned link-local ND entries.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Minimize link-local ND entries.

   ```
   ipv6 neighbor link-local minimize
   ```

   By default, the device assigns all ND entries to the hardware.

Setting the hop limit

About this task

You can set the hop limit value to fill in the Hop Limit field for IPv6 packets to be sent.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Set the value for the Hop Limit field in the IP header.

   ```
   ipv6 hop-limit value
   ```

   The default setting is 64.

Configuring RA message sending and parameters

About RA message parameters

You can enable an interface to send RA messages, and configure the interval for sending RA messages and parameters in RA messages. After receiving an RA message, a host can use these parameters to perform corresponding operations. Table 4 describes the configurable parameters in an RA message.

Table 4 Parameters in an RA message and their descriptions

Parameter	Description
Hop Limit	Maximum number of hops in RA messages. A host receiving the RA message fills the value in the Hop Limit field of sent IPv6 packets.
Prefix information	After receiving the prefix information, the hosts on the same link can perform stateless autoconfiguration.

Parameter	Description
MTU	Guarantees that all nodes on the link use the same MTU.
M flag	Determines whether a host uses stateful autoconfiguration to obtain an IPv6 address. If the M flag is set to 1, the host uses stateful autoconfiguration (for example, from a DHCPv6 server) to obtain an IPv6 address. Otherwise, the host uses stateless autoconfiguration to generate an IPv6 address according to its link-layer address and the prefix information in the RA message.
O flag	Determines whether a host uses stateful autoconfiguration to obtain configuration information other than the IPv6 address. If the O flag is set to 1, the host uses stateful autoconfiguration (for example, from a DHCPv6 server) to obtain configuration information other than the IPv6 address. Otherwise, the host uses stateless autoconfiguration.
Router Lifetime	Tells the receiving hosts how long the advertising router can live. If the lifetime of a router is 0, the router cannot be used as the default gateway.
Retrans Timer	If the device does not receive a response message within the specified time after sending an NS message, it retransmits the NS message.
Reachable Time	If the neighbor reachability detection shows that a neighbor is reachable, the device considers the neighbor reachable within the specified reachable time. If the device needs to send a packet to the neighbor after the specified reachable time expires, the device reconfirms whether the neighbor is reachable.
Router Preference	Specifies the router preference in an RA message. A host selects a router as the default gateway according to the router preference. If router preferences are the same, the host selects the router from which the first RA message is received.
DNS server option	DNS server information for IPv6 hosts. Hosts can obtain DNS server information from received RA messages instead of using DHCPv6.
DNS suffix information in DNS Search List (DNSSL) option	DNS suffix information for IPv6 hosts. Hosts can obtain DNS suffix information from received RA messages instead of using DHCPv6.

Restrictions and guidelines

The maximum interval for sending RA messages should be less than (or equal to) the router lifetime in RA messages. In this way, the router can be updated by an RA message before expiration.

The values of the NS retransmission timer and the reachable time configured for an interface are sent in RA messages to hosts. This interface sends NS messages at the interval of the NS retransmission timer and considers a neighbor reachable within the reachable time.

Enabling the sending of RA messages

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the sending of RA messages.
   undo ipv6 nd ra halt
   The default setting is disabled.
4. Set the maximum and minimum intervals for sending RA messages.
   ipv6 nd ra interval *max-interval min-interval*

By default, the maximum interval for sending RA messages is 600 seconds, and the minimum interval is 200 seconds.

The device sends RA messages at random intervals between the maximum interval and the minimum interval.

The minimum interval should be less than or equal to 0.75 times the maximum interval.

Configuring parameters for RA messages

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the prefix information in RA messages.

   ipv6 nd ra prefix { *ipv6-prefix prefix-length* | *ipv6-prefix***/***prefix-length* } [*valid-lifetime preferred-lifetime* [**no-autoconfig** | **off-link**] * | **no-advertise**]

   By default, no prefix information is configured for RA messages, and the IPv6 address of the interface sending RA messages is used as the prefix information. If the IPv6 address is manually configured, the prefix uses a fixed valid lifetime of 2592000 seconds (30 days) and a preferred lifetime of 604800 seconds (7 days). If the IPv6 address is automatically obtained (through DHCP, for example), the prefix uses the valid lifetime and preferred lifetime configured for the IPv6 address.

4. Configure the default settings for prefixes advertised in RA messages.

   ipv6 nd ra prefix default [*valid-lifetime preferred-lifetime* [**no-autoconfig** | **off-link**] * | **no-advertise**]

   By default, no default settings are configured for prefixes advertised in RA messages.

5. Turn off the MTU option in RA messages.

   ipv6 nd ra no-advlinkmtu

   By default, RA messages contain the MTU option.

6. Specify unlimited hops in RA messages.

   ipv6 nd ra hop-limit unspecified

   By default, the maximum number of hops in RA messages is 64.

7. Set the M flag bit to 1.

   ipv6 nd autoconfig managed-address-flag

   By default, the M flag bit is set to 0 in RA advertisements. Hosts receiving the advertisements will obtain IPv6 addresses through stateless autoconfiguration.

8. Set the O flag bit to 1.

   ipv6 nd autoconfig other-flag

   By default, the O flag bit is set to 0 in RA advertisements. Hosts receiving the advertisements will acquire other configuration information through stateless autoconfiguration.

9. Set the router lifetime in RA messages.

   ipv6 nd ra router-lifetime *time*

   By default, the router lifetime is three times as long as the maximum interval for advertising RA messages.

10. Set the NS retransmission timer.

    ipv6 nd ns retrans-timer *value*

By default, an interface sends NS messages every 1000 milliseconds, and the value of the Retrans Timer field in RA messages is 0.

11. Set the router preference in RA messages.

```
ipv6 nd router-preference { high | low | medium }
```

By default, the router preference is medium.

12. Set the reachable time.

```
ipv6 nd nud reachable-time time
```

By default, the neighbor reachable time is 30000 milliseconds, and the value of the Reachable Time field in sent RA messages is 0.

Specifying DNS server information in RA messages

About this task

The DNS server options in RA messages provide DNS server information for IPv6 hosts. The RA messages allow hosts to obtain their IPv6 addresses and the DNS server through stateless autoconfiguration. This method is useful in a network where DHCPv6 infrastructure is not provided.

One DNS server option contains one DNS server. All DNS server options are sorted in ascending order of the DNS server sequence number.

After you execute the **ipv6 nd ra dns server** command, the device immediately sends an RA message with the existing and newly specified DNS server information.

After you execute the **undo ipv6 nd ra dns server** command, the device immediately sends two RA messages.

- The first RA message contains information about all DNS servers, including the DNS servers specified in the **undo** command with their lifetime set to 0 seconds.
- The second RA message contains information about remaining DNS servers.

Each time the device sends an RA message from an interface, it immediately refreshes the RA message advertisement interval for that interface.

Restrictions and guidelines

You can configure a maximum of eight DNS servers on an interface.

The default lifetime of a DNS server is three times the maximum interval for advertising RA messages. To set the maximum interval, use the **ipv6 nd ra interval** command.

In an IPv6 environment, PPP users and IPoE IPv6-ND-RS users can obtain the IPv6 DNS server address through AAA authorization. This AAA-authorized IPv6 DNS server address is also carried in RA messages. If an interface obtains the AAA-authorized and manually specified IPv6 DNS server addresses, the RA messages contain both, with the AAA-authorized address in the front. When the two addresses conflict, the AAA-authorized DNS-related attributes are used.

For more information about the PPP support for IPv6, see PPP configuration in *Layer 2—WAN Access Configuration Guide*.

For more information about IPoE IPv6-ND-RS users, see IPoE configuration in *Security Configuration Guide*.

Procedure

1. Enter system view.

```
system-view
```

2. Enter interface view.

```
interface interface-type interface-number
```

3. Specify DNS server information to be advertised in RA messages.

ipv6 nd ra dns server *ipv6-address* [*seconds* | **infinite**] **sequence** *seqno*

By default, no DNS server information is specified and RA messages do not contain DNS server options.

Specifying DNS suffix information in RA messages

About this task

The DNSSL option in RA messages provides suffix information for IPv6 hosts. The RA messages allow hosts to obtain their IPv6 addresses and the DNS suffix through stateless autoconfiguration. This method is useful in a network where DHCPv6 infrastructure is not provided.

One DNSSL option contains one DNS suffix. All DNSSL options are sorted in ascending order of the sequence number of the DNS suffix.

After you execute the **ipv6 nd ra dns search-list** command, the device immediately sends an RA message with the existing and newly specified DNS suffix information.

After you execute the **undo ipv6 nd ra dns search-list** command, the device immediately sends two RA messages.

- The first RA message contains information about all DNS suffixes, including DNS suffixes specified in the **undo** command with their lifetime set to 0 seconds.
- The second RA message contains information about remaining DNS suffixes.

Each time the device sends an RA message from an interface, it immediately refreshes the RA message advertisement interval for that interface.

Restrictions and guidelines

You can configure a maximum of eight DNS suffixes on an interface.

The default lifetime of a DNS suffix is three times the maximum interval for advertising RA messages. To set the maximum interval, use the **ipv6 nd ra interval** command.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify DNS suffix information to be advertised in RA messages.

   ipv6 nd ra dns search-list *domain-name* [*seconds* | **infinite**] **sequence** *seqno*

   By default, no DNS suffix information is specified and RA messages do not contain DNS suffix options.

Suppressing advertising DNS information in RA messages

About this task

Perform this task to suppress the device from advertising information about DNS server addresses and DNS suffixes in RA messages.

Whether enabling this feature on an interface will trigger sending RA message immediately depends on the interface configuration:

- If the interface has DNS server information configured or has obtained an AAA-authorized DNS server address, the device immediately sends two RA messages. In the first message, the lifetime for DNS server addresses is 0 seconds. The second RA message does not contain any DNS server options.

- If the interface has no DNS server information specified or no AAA-authorized DNS server address assigned, no RA messages are triggered.

If you specify a new DNS server or remove a DNS server on the interface after enabling DNS server suppression, the device immediately sends an RA message without any DNS server options.

Whether disabling this feature on an interface will trigger sending RA message immediately depends on the interface configuration:

- If the interface has DNS server information configured or has obtained an AAA-authorized DNS server address, the device immediately sends an RA message containing the DNS server information.
- If the interface has no DNS server information specified or no AAA-authorized DNS server address assigned, no RA messages are triggered.

Each time the device sends an RA message from an interface, it immediately refreshes the RA message advertisement interval for that interface.

The same suppression mechanism applies when you enable or disable DNS suffix suppression in RA messages.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Enable DNS server suppression in RA messages.

   `ipv6 nd ra dns server suppress`

   By default, DNS server suppression in RA messages is disabled.

4. Enable DNS suffix suppression in RA messages.

   `ipv6 nd ra dns search-list suppress`

   By default, DNS suffix suppression in RA messages is disabled.

Setting the maximum number of attempts to send an NS message for DAD

About this task

An interface sends an NS message for DAD for an obtained IPv6 address. The interface resends the NS message if it does not receive a response within the time specified by the **`ipv6 nd ns retrans-timer`** command. If the interface receives no response after making the maximum attempts specified by the **`ipv6 nd dad attempts`** command, the interface uses the IPv6 address.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Set the number of attempts to send an NS message for DAD.

   `ipv6 nd dad attempts` *`times`*

The default setting is 1. When the *times* argument is set to 0, DAD is disabled.

Enabling ND proxy

About ND proxy

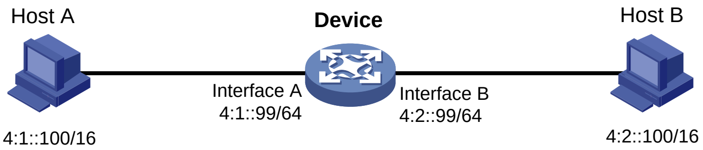
ND proxy enables a device to answer an NS message requesting the hardware address of a host on another network. With ND proxy, hosts in different broadcast domains can communicate with each other as they would on the same network.

ND proxy includes common ND proxy and local ND proxy.

Common ND proxy

As shown in Figure 6, Interface A with IPv6 address 4:1::99/64 and Interface B with IPv6 address 4:2::99/64 belong to different subnets. Host A and Host B reside on the same network but in different broadcast domains.

Figure 6 Application environment of ND proxy



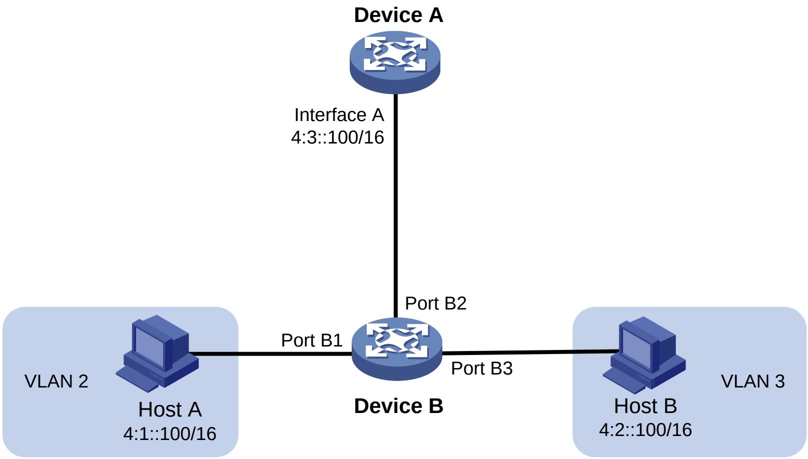
Because Host A's IPv6 address is on the same subnet as Host B's, Host A directly sends an NS message to obtain Host B's MAC address. However, Host B cannot receive the NS message because they belong to different broadcast domains.

To solve this problem, enable common ND proxy on Interface A and Interface B of the device. The device replies to the NS message from Host A, and forwards packets from other hosts to Host B.

Local ND proxy

As shown in Figure 7, Host A belongs to VLAN 2 and Host B belongs to VLAN 3. Host A and Host B connect to Port B1 and Port B3, respectively.

Figure 7 Application environment of local ND proxy



Because Host A's IPv6 address is on the same subnet as Host B's, Host A directly sends an NS message to obtain Host B's MAC address. However, Host B cannot receive the NS message because they belong to different VLANs.

To solve this problem, enable local ND proxy on Interface A of Device A so that Device A can forward messages between Host A and Host B.

Local ND proxy implements Layer 3 communication for two hosts in the following cases:

- The two hosts connect to ports of the same device and the ports must be in different VLANs.
- The two hosts connect to isolated Layer 2 ports in the same isolation group of a VLAN.

Enabling common ND proxy

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Enable common ND proxy.
   `proxy-nd enable`
   By default, common ND proxy is disabled.

Enabling local ND proxy

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Enable local ND proxy.
   `local-proxy-nd enable`
   By default, local ND proxy is disabled.

Display and maintenance commands for IPv6 ND

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the total number of neighbor entries.	**display ipv6 neighbors** { { **all** | **dynamic** | **static** } [**slot** *slot-number*] | **interface** *interface-type interface-number* | **vlan** *vlan-id* } **count**
Display neighbor information.	**display ipv6 neighbors** { { *ipv6-address* | **all** | **dynamic** | **static** } [**slot** *slot-number*] | **interface** *interface-type interface-number* | **vlan** *vlan-id* } [**verbose**]
Display neighbor information for a VPN.	**display ipv6 neighbors vpn-instance** *vpn-instance-name* [**count**]
Clear IPv6 neighbor information.	**reset ipv6 neighbors** { **all** | **dynamic** | **interface** *interface-type interface-number* | **slot** *slot-number* | **static** }

Contents

Configuring IPv6 fast forwarding

About IPv6 fast forwarding

Fast forwarding reduces route lookup time and improves packet forwarding efficiency by using a high-speed cache and data-flow-based technology. It identifies a data flow by using the following fields:

- Source IPv6 address.
- Destination IPv6 address.
- Source port number.
- Destination port number.
- Protocol number.

After a flow's first packet is forwarded through the routing table, fast forwarding creates an entry and uses the entry to forward subsequent packets of the flow.

Configuring IPv6 fast forwarding

About this task

The IPv6 fast forwarding feature will create fast forwarding entries for the device to speed up packet forwarding. When the traffic volume is high, the device will generate a large number of fast forwarding entries. These entries will cause high memory usage, which eventually leads to memory allocation failure for other services. In this case, you can disable this feature temporarily to free up device memory.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Configure IPv6 fast forwarding.
   - Enable IPv6 fast forwarding.

     ```
     ipv6 fast-forwarding enable
     ```

   - Disable IPv6 fast forwarding.

     ```
     undo ipv6 fast-forwarding enable
     ```

   By default, IPv6 fast forwarding is enabled.

Configuring the aging time for IPv6 fast forwarding entries

About this task

The IPv6 fast forwarding table uses an aging timer for each forwarding entry. If an entry is not updated before the timer expires, the device deletes the entry. If an entry has a hit within the aging time, the aging timer restarts.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Set the aging time for IPv6 fast forwarding entries.

   ```
   ipv6 fast-forwarding aging-time aging-time
   ```

   By default, the aging time is 30 seconds.

Configuring IPv6 fast forwarding load sharing

About this task

IPv6 fast forwarding load sharing enables the device to identify a data flow by using the packet information.

If IPv6 fast forwarding load sharing is disabled, the device identifies a data flow by the packet information and the input interface.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Configure IPv6 fast forwarding load sharing. Choose one option as needed:
   - Enable IPv6 fast forwarding load sharing.

     ```
     Ipv6 fast-forwarding load-sharing
     ```

   - Disable IPv6 fast forwarding load sharing.

     ```
     undo ipv6 fast-forwarding load-sharing
     ```

   By default, IPv6 fast forwarding load sharing is enabled.

Display and maintenance commands for IPv6 fast forwarding

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the aging time of the IPv6 fast forwarding entries.	**display ipv6 fast-forwarding aging-time**
Display IPv6 fast forwarding entries.	**display ipv6 fast-forwarding cache** [*ipv6-address*] [**slot** *slot-number*]
Display IPv6 fast forwarding entries for fragmented datagrams.	**display ipv6 fast-forwarding fragcache** [*ipv6-address*] [**slot** *slot-number*]
Clear the IPv6 fast forwarding table.	**reset ipv6 fast-forwarding cache** [**slot** *slot-number*]

Contents

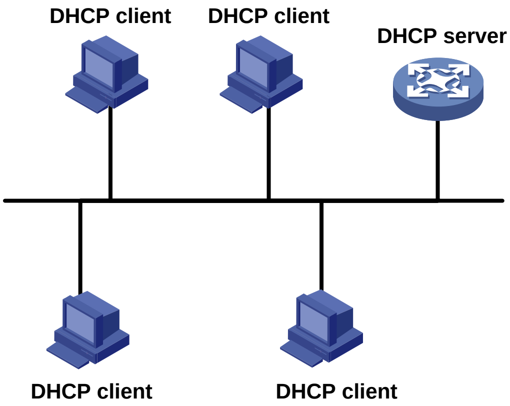
DHCP overview

DHCP network model

The Dynamic Host Configuration Protocol (DHCP) provides a framework to assign configuration information to network devices.

Figure 1 shows a typical DHCP application scenario where the DHCP clients and the DHCP server reside on the same subnet. The DHCP clients can also obtain configuration parameters from a DHCP server on another subnet through a DHCP relay agent. For more information about the DHCP relay agent, see "Configuring the DHCP relay agent."

Figure 1 A typical DHCP application



DHCP address allocation

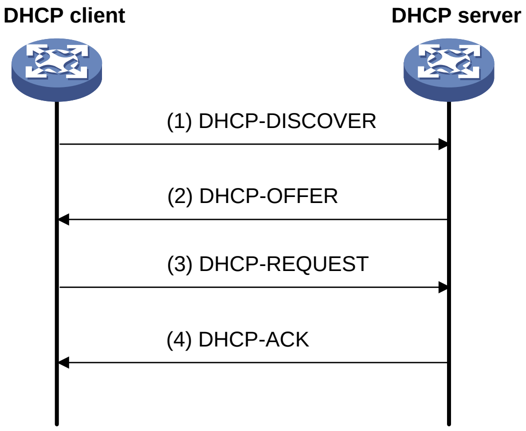
Allocation mechanisms

DHCP supports the following allocation mechanisms:

- **Static allocation**—The network administrator assigns an IP address to a client, such as a WWW server, and DHCP conveys the assigned address to the client.
- **Automatic allocation**—DHCP assigns a permanent IP address to a client.
- **Dynamic allocation**—DHCP assigns an IP address to a client for a limited period of time, which is called a lease. Most DHCP clients obtain their addresses in this way.

IP address allocation process

Figure 2 IP address allocation process



As shown in Figure 2, a DHCP server assigns an IP address to a DHCP client in the following process:

1. The client broadcasts a DHCP-DISCOVER message to locate a DHCP server.
2. Each DHCP server offers configuration parameters such as an IP address to the client in a DHCP-OFFER message. The sending mode of the DHCP-OFFER is determined by the flag field in the DHCP-DISCOVER message. For more information, see "DHCP message format."
3. If the client receives multiple offers, it accepts the first received offer, and broadcasts it in a DHCP-REQUEST message to formally request the IP address. (IP addresses offered by other DHCP servers can be assigned to other clients.)
4. All DHCP servers receive the DHCP-REQUEST message. However, only the server selected by the client does one of the following operations:
    - Returns a DHCP-ACK message to confirm that the IP address has been allocated to the client.
    - Returns a DHCP-NAK message to deny the IP address allocation.

After receiving the DHCP-ACK message, the client verifies the following details before using the assigned IP address:

- The assigned IP address is not in use. To verify this, the client broadcasts a gratuitous ARP packet. The assigned IP address is not in use if no response is received within the specified time.
- The assigned IP address is not on the same subnet as any IP address in use on the client.

Otherwise, the client sends a DHCP-DECLINE message to the server to request an IP address again.

IP address lease extension

A dynamically assigned IP address has a lease. When the lease expires, the IP address is reclaimed by the DHCP server. To continue using the IP address, the client must extend the lease duration.

When about half of the lease duration elapses, the DHCP client unicasts a DHCP-REQUEST to the DHCP server to extend the lease. Depending on the availability of the IP address, the DHCP server returns one of the following messages:

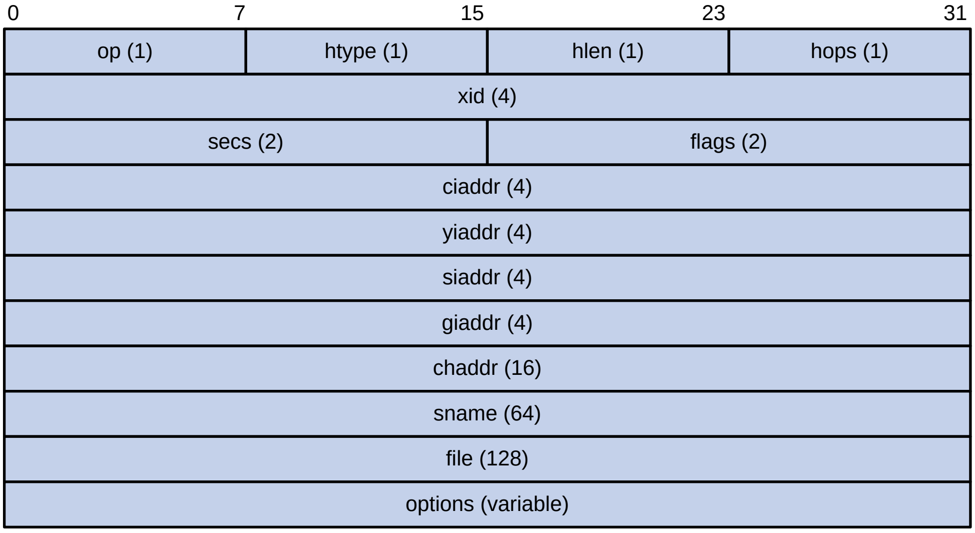
- A DHCP-ACK unicast confirming that the client's lease duration has been extended.
- A DHCP-NAK unicast denying the request.

If the client receives no reply, it broadcasts another DHCP-REQUEST message for lease extension when about seven-eighths of the lease duration elapses. Again, depending on the availability of the IP address, the DHCP server returns either a DHCP-ACK unicast or a DHCP-NAK unicast.

DHCP message format

Figure 3 shows the DHCP message format. DHCP uses some of the fields in significantly different ways. The numbers in parentheses indicate the size of each field in bytes.

Figure 3 DHCP message format

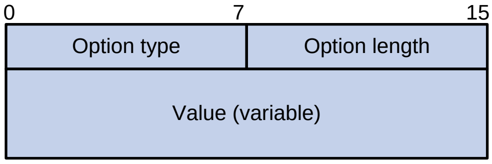


- **op**—Message type defined in options field. 1 = REQUEST, 2 = REPLY
- **htype**, **hlen**—Hardware address type and length of the DHCP client.
- **hops**—Number of relay agents a request message traveled.
- **xid**—Transaction ID, a random number chosen by the client to identify an IP address allocation.
- **secs**—Filled in by the client, the number of seconds elapsed since the client began address acquisition or renewal process. This field is reserved and set to 0.
- **flags**—The leftmost bit is defined as the BROADCAST (B) flag. If this flag is set to 0, the DHCP server sent a reply back by unicast. If this flag is set to 1, the DHCP server sent a reply back by broadcast. The remaining bits of the flags field are reserved for future use.
- **ciaddr**—Client IP address if the client has an IP address that is valid and usable. Otherwise, set to zero. (The client does not use this field to request an IP address to lease.)
- **yiaddr**—Your IP address. It is an IP address assigned by the DHCP server to the DHCP client.
- **siaddr**—Server IP address, from which the client obtained configuration parameters.
- **giaddr**—Gateway IP address. It is the IP address of the first relay agent to which a request message travels.
- **chaddr**—Client hardware address.
- **sname**—Server host name, from which the client obtained configuration parameters.
- **file**—Boot file (also called system software image) name and path information, defined by the server to the client.
- **options**—Optional parameters field that is variable in length. Optional parameters include the message type, lease duration, subnet mask, domain name server IP address, and WINS IP address.

DHCP options

DHCP extends the message format as an extension to BOOTP for compatibility. DHCP uses the options field to carry information for dynamic address allocation and provide additional configuration information for clients.

Figure 4 DHCP option format



Common DHCP options

The following are common DHCP options:

- **Option 3**—Router option. It specifies the gateway address to be assigned to the clients.
- **Option 6**—DNS server option. It specifies the DNS server IP address to be assigned to the clients.
- **Option 33**—Static route option. It specifies a list of classful static routes (the destination addresses in these static routes are classful) that a client should add into its routing table. If both Option 33 and Option 121 exist, Option 33 is ignored.
- **Option 51**—IP address lease option.
- **Option 53**—DHCP message type option. It identifies the type of the DHCP message.
- **Option 55**—Parameter request list option. It is used by a DHCP client to request specified configuration parameters. The option includes values that correspond to the parameters requested by the client.
- **Option 60**—Vendor class identifier option. A DHCP client uses this option to identify its vendor. A DHCP server uses this option to distinguish DHCP clients, and assigns IP addresses to them.
- **Option 66**—TFTP server name option. It specifies the TFTP server domain name to be assigned to the clients.
- **Option 67**—Boot file name option. It specifies the boot file name to be assigned to the client.
- **Option 121**—Classless route option. It specifies a list of classless static routes (the destination addresses in these static routes are classless) that a client should add into its routing table. If both Option 33 and Option 121 exist, Option 33 is ignored.
- **Option 150**—TFTP server IP address option. It specifies the TFTP server IP address to be assigned to the clients.

For more information about DHCP options, see RFC 2132 and RFC 3442.

Custom DHCP options

Some options, such as Option 43, Option 82, and Option 184, have no standard definitions in RFC 2132.

Vendor-specific option (Option 43)

Option 43 function

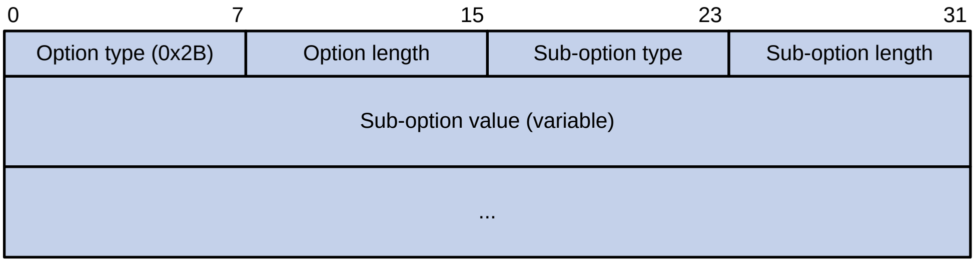
DHCP servers and clients use Option 43 to exchange vendor-specific configuration information.

The DHCP client can obtain the following information through Option 43:

- ACS parameters, including the ACS URL, username, and password.
- PXE server address, which is used to obtain the boot file or other control information from the PXE server.

Option 43 format

Figure 5 Option 43 format



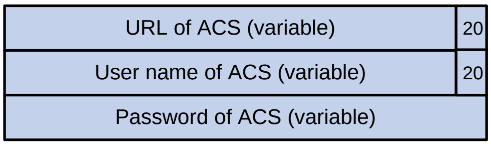
Network configuration parameters are carried in different sub-options of Option 43 as shown in Figure 5.

- **Sub-option type**—The field value can be 0x01 (ACS parameter sub-option), 0x02 (service provider identifier sub-option), or 0x80 (PXE server address sub-option).
- **Sub-option length**—Excludes the sub-option type and sub-option length fields.
- **Sub-option value**—The value format varies by sub-option.

Sub-option value field format

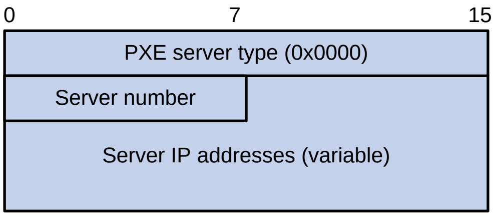
- **ACS parameter sub-option value field**—Includes the ACS URL, username, and password separated by spaces (hexadecimal number 20) as shown in Figure 6.

  Figure 6 ACS parameter sub-option value field



- **Service provider identifier sub-option value field**—Includes the service provider identifier.
- **PXE server address sub-option value field**—Includes the PXE server type that can only be 0, the server number that indicates the number of PXE servers contained in the sub-option, and server IP addresses, as shown in Figure 7.

  Figure 7 PXE server address sub-option value field



Relay agent option (Option 82)

Option 82 is the relay agent option. It records the location information about the DHCP client. When a DHCP relay agent or DHCP snooping device receives a client's request, it adds Option 82 to the request and sends it to the server.

The administrator can use Option 82 to locate the DHCP client and further implement security control and accounting. The DHCP server can use Option 82 to provide individual configuration policies for the clients.

Option 82 can include a maximum of 255 sub-options and must include a minimum of one sub-option. Option 82 supports the following sub-options: sub-option 1 (Circuit ID), and sub-option 2 (Remote ID). Option 82 has no standard definition. Its padding formats vary by vendor.

- Circuit ID has the following padding modes:
    - **String padding mode**—Includes a character string specified by the user.
    - **Normal padding mode**—Includes the VLAN ID and interface number of the interface that receives the client's request.
    - **Verbose padding mode**—Includes the access node identifier specified by the user, and the VLAN ID, interface number and interface type of the interface that receives the client's request.
- Remote ID has the following padding modes:
    - **String padding mode**—Includes a character string specified by the user.
    - **Normal padding mode**—Includes the MAC address of the DHCP relay agent interface or the MAC address of the DHCP snooping device that receives the client's request.
    - **Sysname padding mode**—Includes the name of the device. To set the device name, use the **`sysname`** command in system view.

Option 184

Option 184 is a reserved option. You can define the parameters in the option as needed. The device supports Option 184 carrying voice related parameters, so a DHCP client with voice functions can get voice parameters from the DHCP server.

Option 184 has the following sub-options:

- **Sub-option 1**—Specifies the IP address of the primary network calling processor. The primary processor acts as the network calling control source and provides program download services. For Option 184, you must define sub-option 1 to make other sub-options take effect.
- **Sub-option 2**—Specifies the IP address of the backup network calling processor. DHCP clients contact the backup processor when the primary one is unreachable.
- **Sub-option 3**—Specifies the voice VLAN ID and the result whether the DHCP client takes this VLAN as the voice VLAN.
- **Sub-option 4**—Specifies the failover route that includes the IP address and the number of the target user. A SIP VoIP user uses this IP address and number to directly establish a connection to the target SIP user when both the primary and backup calling processors are unreachable.

Protocols and standards

- RFC 2131, *Dynamic Host Configuration Protocol*

Configuring the DHCP server

About DHCP server

A DHCP server manages a pool of IP addresses and client configuration parameters. It selects an IP address and configuration parameters from the address pool and allocates them to a requesting DHCP client.

DHCP address assignment mechanisms

Configure the following address assignment mechanisms as needed:

- **Static address allocation**—Manually bind the MAC address or ID of a client to an IP address in a DHCP address pool. When the client requests an IP address, the DHCP server assigns the IP address in the static binding to the client.
- **Dynamic address allocation**—Specify IP address ranges in a DHCP address pool. Upon receiving a DHCP request, the DHCP server dynamically selects an IP address from the matching IP address range in the address pool.

You can specify IP address ranges in an address pool by using either of the following methods:

- **Method 1**—A primary subnet being divided into multiple address ranges in an address pool
- **Method 2**—A primary subnet and multiple secondary subnets in an address pool

A primary subnet being divided into multiple address ranges in an address pool

An address range includes a common IP address range and IP address ranges for DHCP user classes.

Upon receiving a DHCP request, the DHCP server finds a user class matching the client and selects an IP address in the address range of the user class for the client. A user class can include multiple matching rules, and a client matches the user class as long as it matches any of the rules. In address pool view, you can specify different address ranges for different user classes.

The DHCP server selects an IP address for a client by performing the following steps:

1. DHCP server compares the client against DHCP user classes in the order they are configured.
2. If the client matches a user class, the DHCP server selects an IP address from the address range of the user class.
3. If the matching user class has no assignable addresses, the DHCP server compares the client against the next user class. If all the matching user classes have no assignable addresses, the DHCP server selects an IP address from the common address range.
4. If the DHCP client does not match any DHCP user class, the DHCP server selects an address in the IP address range specified by the **`address range`** command. If the address range has no assignable IP addresses or it is not configured, the address allocation fails.

NOTE:

All address ranges must belong to the primary subnet. If an address range does not reside on the primary subnet, DHCP cannot assign the addresses in the address range.

A primary subnet and multiple secondary subnets in an address pool

The DHCP server selects an IP address from the primary subnet first. If there is no assignable IP address on the primary subnet, the DHCP server selects an IP address from secondary subnets in the order they are configured.

Principles for selecting an address pool

The DHCP server observes the following principles to select an address pool for a client:

1. If there is an address pool where an IP address is statically bound to the MAC address or ID of the client, the DHCP server selects this address pool and assigns the statically bound IP address and other configuration parameters to the client.
2. If the receiving interface has a DHCP policy and the DHCP client matches a user class, the DHCP server selects the address pool that is bound to the matching user class. If no matching user class is found, the server assigns an IP address and other parameters from the default DHCP address pool. If no default address pool is specified or the default address pool does not have assignable IP addresses, the address assignment fails.
3. If the receiving interface has an address pool applied, the DHCP server selects an IP address and other configuration parameters from this address pool.
4. If the above conditions are not met, the DHCP server selects an address pool depending on the client location.
   - **Client on the same subnet as the server**—The DHCP server compares the IP address of the receiving interface with the primary subnets of all address pools.
     - If a match is found, the server selects the address pool with the longest-matching primary subnet.
     - If no match is found, the DHCP server compares the IP address with the secondary subnets of all address pools. The server selects the address pool with the longest-matching secondary subnet.
   - **Client on a different subnet than the server**—The DHCP server compares the IP address in the **giaddr** field of the DHCP request with the primary subnets of all address pools.
     - If a match is found, the server selects the address pool with the longest-matching primary subnet.
     - If no match is found, the DHCP server compares the IP address with the secondary subnets of all address pools. The server selects the address pool with the longest-matching secondary subnet.

For example, two address pools 1.1.1.0/24 and 1.1.1.0/25 are configured but not applied to any DHCP server's interfaces.

- If the IP address of the receiving interface is 1.1.1.1/25, the DHCP server selects the address pool 1.1.1.0/25. If the address pool has no available IP addresses, the DHCP server will not select the other pool and the address allocation will fail.
- If the IP address of the receiving interface is 1.1.1.130/25, the DHCP server selects the address pool 1.1.1.0/24.

To ensure correct address allocation, keep the IP addresses used for dynamic allocation on one of the subnets:

- **Clients on the same subnet as the server**—Subnet where the DHCP server receiving interface resides.
- **Clients on a different subnet than the server**—Subnet where the first DHCP relay interface that faces the clients resides.

NOTE:

As a best practice, configure a minimum of one matching primary subnet in your network. Otherwise, the DHCP server selects only the first matching secondary subnet for address allocation. If the network has more DHCP clients than the assignable IP addresses in the secondary subnet, not all DHCP clients can obtain IP addresses.

IP address allocation sequence

The DHCP server selects an IP address for a client in the following sequence:

1. IP address statically bound to the client's MAC address or ID.
2. IP address that was ever assigned to the client.
3. IP address designated by the Option 50 field in the DHCP-DISCOVER message sent by the client.

   Option 50 is the Requested IP Address option. The client uses this option to specify the wanted IP address in a DHCP-DISCOVER message. The content of Option 50 is user defined.
4. First assignable IP address found in the way discussed in "DHCP address assignment mechanisms" and "Principles for selecting an address pool."
5. IP address that was a conflict or passed its lease duration. If no IP address is assignable, the server does not respond.

NOTE:

- If a client moves to another subnet, the DHCP server selects an IP address in the address pool matching the new subnet. It does not assign the IP address that was once assigned to the client.
- Conflicted IP addresses can be assigned to other DHCP clients only after the addresses are in conflict for an hour.

DHCP server tasks at a glance

To configure the DHCP server, perform the following tasks:

1. (Optional.) Creating a DHCP user class
2. Configuring an address pool on the DHCP server
3. (Optional.) Modifying the address pool selection method on the DHCP server
   - Applying an address pool to an interface
   - Configuring a DHCP policy for dynamic assignment
4. Enabling DHCP
5. Enabling the DHCP server on an interface
6. (Optional.) Configuring advanced DHCP features
   - Configuring IP address conflict detection
   - Enabling handling of Option 82
   - Configuring DHCP server compatibility
   - Setting the DSCP value for DHCP packets sent by the DHCP server
   - Configuring DHCP binding auto backup
   - Enabling client offline detection on the DHCP server
7. (Optional.) Configuring SNMP notification and logging
   - Configuring address pool usage alarming
   - Enabling DHCP logging on the DHCP server

Creating a DHCP user class

About this task

The DHCP server classifies DHCP users into different user classes according to the hardware address, option information, or the **giaddr** field in the received DHCP requests. The server allocates IP addresses and configuration parameters to DHCP clients in different user classes.

Procedure

1. Enter system view.

   `system-view`

2. Create a DHCP user class and enter DHCP user class view.

   `dhcp class` *`class-name`*

3. Configure a match rule for the DHCP user class.

   `if-match rule` *`rule-number`* { **`hardware-address`** *`hardware-address`* **`mask`** *`hardware-address-mask`* | **`option`** *`option-code`* [**`ascii`** *`ascii-string`* [**`offset`** *`offset`* | **`partial`**] | **`hex`** *`hex-string`* [**`mask`** *`mask`* | **`offset`** *`offset`* **`length`** *`length`* | **`partial`**]] | **`relay-agent`** *`gateway-address`* }

   By default, no match rule is configured for a DHCP user class.

Configuring an address pool on the DHCP server

DHCP address pool tasks at a glance

To configure a DHCP address pool, perform the following tasks:

1. Creating a DHCP address pool
2. Specifying IP address ranges in a DHCP address pool

   In one DHCP address pool, the two dynamic allocation methods cannot be both configured, but static and dynamic address allocations can be both implemented.

   - Specifying a primary subnet and multiple address ranges in a DHCP address pool
   - Specifying a primary subnet and multiple secondary subnets in a DHCP address pool
   - Configuring a static binding in a DHCP address pool
3. Specifying other configuration parameters to be assigned to DHCP clients
   - Specifying gateways for DHCP clients
   - Specifying a domain name suffix for DHCP clients
   - Specifying DNS servers for DHCP clients
   - Specifying WINS servers and NetBIOS node type for DHCP clients
   - Specifying BIMS server for DHCP clients
   - Specifying the configuration file for DHCP client automatic configuration
   - Specifying a server for DHCP clients
   - Configuring Option 184 parameters for DHCP clients
   - Customizing DHCP options
4. (Optional.) Applying a DHCP address pool to a VPN instance
5. (Optional.) Configuring the DHCP user class whitelist
6. (Optional.) Binding gateways to DHCP server's MAC address
7. (Optional.) Advertising subnets that are assigned to clients

Creating a DHCP address pool

1. Enter system view.

   system-view

2. Create a DHCP address pool and enter its view.

   dhcp server ip-pool *pool-name*

Specifying a primary subnet and multiple address ranges in a DHCP address pool

About this task

Some scenarios need to classify DHCP clients on the same subnet into different address groups. To meet this need, you can configure DHCP user classes and specify different address ranges for the classes. The clients matching a user class can then get the IP addresses of an address range. In addition, you can specify a common address range for the clients that do not match any user class. If no common address range is specified, such clients fail to obtain IP addresses.

If there is no need to classify clients, you do not need to configure DHCP user classes or their address ranges.

Restrictions and guidelines

- If you execute the **network** or **address range** command multiple times for the same address pool, the most recent configuration takes effect.
- If you execute the **forbidden-ip** or **forbidden-ip-range** command multiple times, you exclude multiple addresses from dynamic allocation.
- IP addresses specified by the **forbidden-ip** or **forbidden-ip-range** command are not assignable in the current address pool, but are assignable in other address pools. IP addresses specified by the **dhcp server forbidden-ip** command are not assignable in any address pool.
- You can use **class range** to modify an existing address range, and the new address range can include IP addresses that are being used by clients. Upon receiving a lease extension request for such an IP address, the DHCP server allocates a new IP address to the requesting client. But the original lease continues aging in the address pool, and will be released when the lease duration is reached. To release such lease without waiting for its timeout, execute the **reset dhcp server ip-in-use** command.

Procedure

1. Enter system view.

   system-view

2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*

3. Specify the primary subnet in the address pool.

   network *network-address* [*mask-length* | **mask** *mask*]

   By default, no primary subnet is specified.

4. (Optional.) Specify the common address range.

   address range *start-ip-address end-ip-address*

   By default, no IP address range is specified.

5. (Optional.) Specify an IP address range for a DHCP user class.

   class *class-name* **range** *start-ip-address end-ip-address*

By default, no IP address range is specified for a user class.

The DHCP user class must already be created by using the **dhcp class** command.

6. (Optional.) Set the address lease duration.

   expired { **day** *day* [**hour** *hour* [**minute** *minute* [**second** *second*]]] | **unlimited** }

   The default setting is 1 day.

7. (Optional.) Exclude the specified IP addresses in the address pool from dynamic allocation.

   forbidden-ip *ip-address*&<1-8>

   By default, no IP addresses in the DHCP address pool are excluded from dynamic allocation.

8. (Optional.) Exclude the specified IP address range in the address pool from dynamic allocation.

   forbidden-ip-range *start-ip-address* [*end-ip-address*]

   By default, no IP address ranges in the DHCP address pool are excluded from dynamic allocation.

9. (Optional.) Exclude the specified IP addresses from automatic allocation in system view.

   a. Return to system view.

      quit

   b. Exclude the specified IP addresses from automatic allocation globally.

      dhcp server forbidden-ip *start-ip-address* [*end-ip-address*] [**vpn-instance** *vpn-instance-name*]

      By default, except for the IP address of the DHCP server interface, IP addresses in all address pools are assignable.

Specifying a primary subnet and multiple secondary subnets in a DHCP address pool

About this task

If an address pool has a primary subnet and multiple secondary subnets, the server assigns IP addresses on a secondary subnet when the primary subnet has no assignable IP addresses.

Restrictions and guidelines

IP addresses specified by the **forbidden-ip** or **forbidden-ip-range** command are not assignable in the current address pool, but are assignable in other address pools. IP addresses specified by the **dhcp server forbidden-ip** command are not assignable in any address pool.

Specifying a primary subnet and multiple secondary subnets

1. Enter system view.

   system-view

2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*

3. Specify the primary subnet.

   network *network-address* [*mask-length* | **mask** *mask*]

   By default, no primary subnet is specified.

   You can specify only one primary subnet in each address pool. If you execute the **network** command multiple times, the most recent configuration takes effect.

4. (Optional.) Specify a secondary subnet.

   network *network-address* [*mask-length* | **mask** *mask*] **secondary**

   By default, no secondary subnet is specified.

You can specify a maximum of 32 secondary subnets in one address pool.

5. (Optional.) Return to address pool view.

   quit

Setting the lease duration for dynamically allocation IP addresses

1. Enter system view.

   system-view

2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*

3. Set the address lease duration.

   expired { **day** *day* [**hour** *hour* [**minute** *minute* [**second** *second*]]] | **unlimited** }

   The default setting is 1 day.

Excluding IP addresses from dynamic allocation

1. Enter system view.

   system-view

2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*

3. Exclude the specified IP addresses from dynamic allocation.

   forbidden-ip *ip-address*&<1-8>

   By default, no IP addresses in the DHCP address pool are excluded from dynamic allocation.

   To exclude multiple addresses from the address pool, repeat this step.

4. (Optional.) Exclude the specified IP address range in the address pool from dynamic allocation.

   forbidden-ip-range *start-ip-address* [*end-ip-address*]

   By default, no IP address ranges in the DHCP address pool are excluded from dynamic allocation.

   To exclude multiple address ranges from the address pool, repeat this step.

5. (Optional.) Exclude the specified IP addresses from dynamic allocation in system view.

   a. Return to system view.

      quit

   b. Exclude the specified IP addresses from dynamic allocation globally.

      dhcp server forbidden-ip *start-ip-address* [*end-ip-address*] [**vpn-instance** *vpn-instance-name*]

      By default, except for the IP address of the DHCP server interface, IP addresses in all address pools are assignable.

      To exclude multiple address ranges globally, repeat this step.

Configuring a static binding in a DHCP address pool

About this task

Some DHCP clients, such as a WWW server, need fixed IP addresses. To provide a fixed IP address for a client, you can statically bind the MAC address or ID of the client to an IP address in a DHCP address pool. When the client requests an IP address, the DHCP server assigns the IP address in the static binding to the client.

Restrictions and guidelines

- The IP address of a static binding cannot be the address of the DHCP server interface. Otherwise, an IP address conflict occurs and the bound client cannot obtain an IP address correctly.
- Multiple interfaces on the same device might all use DHCP to request a static IP address. In this case, use client IDs rather than the device's MAC address to identify the interfaces. Otherwise, IP address allocation will fail.

Procedure

1. Enter system view.

   `system-view`

2. Enter DHCP address pool view.

   `dhcp server ip-pool` *`pool-name`*

3. Configure a static binding.

   `static-bind ip-address` *`ip-address`* [*`mask-length`* | **`mask`** *`mask`*] { **`client-identifier`** *`client-identifier`* | **`hardware-address`** *`hardware-address`* [**`ethernet`** | **`token-ring`**] } [**`description`** *`description-text`*]

   By default, no static binding is configured.

   One IP address can be bound to only one client MAC or client ID. You cannot modify bindings that have been created. To change the binding for a DHCP client, you must delete the existing binding first.

4. (Optional.) Set the lease duration for the IP address.

   `expired` { **`day`** *`day`* [**`hour`** *`hour`* [**`minute`** *`minute`* [**`second`** *`second`*]]] | **`unlimited`** }

   By default, the lease duration is 1 day.

Specifying gateways for DHCP clients

About this task

DHCP clients send packets destined for other networks to a gateway. The DHCP server can assign the gateway address to the DHCP clients.

Restrictions and guidelines

You can specify gateway addresses in each address pool on the DHCP server. A maximum of 64 gateways can be specified in DHCP address pool view or secondary subnet view.

The DHCP server assigns gateway addresses to clients on a secondary subnet in the following ways:

- If gateways are specified in both address pool view and secondary subnet view, DHCP assigns those specified in the secondary subnet view.
- If gateways are specified in address pool view but not in secondary subnet view, DHCP assigns those specified in address pool view.

Procedure

1. Enter system view.

   `system-view`

2. Enter DHCP address pool view.

   `dhcp server ip-pool` *`pool-name`*

3. Specify gateways.

gateway-list *ip-address*&<1-64>

By default, no gateway is specified.

4. (Optional.) Specify gateways in secondary subnet view.
   a. Enter secondary subnet view.
      network *network-address* [*mask-length* | **mask** *mask*] **secondary**
   b. Specify gateways.
      gateway-list *ip-address*&<1-64>
      By default, no gateway is specified.

Specifying a domain name suffix for DHCP clients

About this task

You can specify a domain name suffix in a DHCP address pool on the DHCP server. With this suffix assigned, the client only needs to input part of a domain name, and the system adds the domain name suffix for name resolution. For more information about DNS, see "Configuring DNS."

Procedure

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
3. Specify a domain name suffix.
   domain-name *domain-name*
   By default, no domain name is specified.

Specifying DNS servers for DHCP clients

About this task

To access hosts on the Internet through domain names, a DHCP client must contact a DNS server to resolve names. You can specify up to eight DNS servers in a DHCP address pool.

Procedure

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
3. Specify DNS servers.
   dns-list *ip-address*&<1-8>
   By default, no DNS server is specified.

Specifying WINS servers and NetBIOS node type for DHCP clients

About this task

A Microsoft DHCP client using NetBIOS protocol must contact a WINS server for name resolution.

In addition, you must specify one of the following NetBIOS node types to approach name resolution:

- **b (broadcast)-node**—A b-node client sends the destination name in a broadcast message. The destination returns its IP address to the client after receiving the message.
- **p (peer-to-peer)-node**—A p-node client sends the destination name in a unicast message to the WINS server. The WINS server returns the destination IP address.
- **m (mixed)-node**—An m-node client broadcasts the destination name. If it receives no response, it unicasts the destination name to the WINS server to get the destination IP address.
- **h (hybrid)-node**—An h-node client unicasts the destination name to the WINS server. If it receives no response, it broadcasts the destination name to get the destination IP address.

Procedure

1. Enter system view.

   system-view

2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*

   By default, no DHCP address pool exists.

3. Specify WINS servers.

   nbns-list *ip-address*&<1-8>

   By default, no WINS server is specified.

   This step is optional for b-node. You can specify a maximum of eight WINS servers for such clients in one DHCP address pool.

4. Specify the NetBIOS node type.

   netbios-type { **b-node** | **h-node** | **m-node** | **p-node** }

   By default, no NetBIOS node type is specified.

Specifying BIMS server for DHCP clients

About this task

Perform this task to provide the BIMS server IP address, port number, and shared key for the clients. The DHCP clients contact the BIMS server to get configuration files and perform software upgrade and backup.

Procedure

1. Enter system view.

   system-view

2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*

3. Specify the BIMS server IP address, port number, and shared key.

   bims-server ip *ip-address* [**port** *port-number*] **sharekey** { **cipher** | **simple** } *string*

   By default, no BIMS server information is specified.

Specifying the configuration file for DHCP client automatic configuration

About this task

Automatic configuration enables a device to automatically obtain a set of configuration settings at startup. The server-based automatic configuration requires the cooperation of the DHCP server and file server (TFTP or HTTP server). The device uses the obtained parameters to contact the file server to get the configuration file. For more information about automatic configuration, see *Fundamentals Configuration Guide*.

Specifying the configuration file on a TFTP file server

1. Enter system view.

   `system-view`

2. Enter DHCP address pool view.

   `dhcp server ip-pool` *`pool-name`*

   By default, no DHCP address pool exists.

3. Specify the IP address or the name of a TFTP server.
   - Specify the IP address of the TFTP server.

     `tftp-server ip-address` *`ip-address`*

     By default, no TFTP server IP address is specified.
   - Specify the name of the TFTP server.

     `tftp-server domain-name` *`domain-name`*

     By default, no TFTP server name is specified.

4. Specify the configuration file name.

   `bootfile-name` *`bootfile-name`*

   By default, no configuration file name is specified.

Specifying the URL of the configuration file on an HTTP file server

1. Enter system view.

   `system-view`

2. Enter DHCP address pool view.

   `dhcp server ip-pool` *`pool-name`*

3. Specify the URL of the configuration file.

   `bootfile-name` *`url`*

   By default, no configuration file URL is specified.

Specifying a server for DHCP clients

About this task

Some DHCP clients need to obtain configuration information from a server, such as a TFTP server. You can specify the IP address of that server. The DHCP server sends the server's IP address to DHCP clients along with other configuration information.

Procedure

1. Enter system view.

   `system-view`

2. Enter DHCP address pool view.

   `dhcp server ip-pool` *`pool-name`*

3. Specify the IP address of a server.

   `next-server` *`ip-address`*

   By default, no server is specified.

Configuring Option 184 parameters for DHCP clients

About this task

To assign calling parameters to DHCP clients with voice service, you must configure Option 184 on the DHCP server. For more information about Option 184, see "Option 184."

Procedure

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
3. Specify the IP address of the primary network calling processor.
   voice-config ncp-ip *ip-address*
   By default, no primary network calling processor is specified.
   After you configure this command, the other Option 184 parameters take effect.
4. (Optional.) Specify the IP address of the backup server.
   voice-config as-ip *ip-address*
   By default, no backup network calling processor is specified.
5. (Optional.) Configure the voice VLAN.
   voice-config voice-vlan *vlan-id* { **disable** | **enable** }
   By default, no voice VLAN is configured.
6. (Optional.) Specify the failover IP address and dialer string.
   voice-config fail-over *ip-address dialer-string*
   By default, no failover IP address or dialer string is specified.

Customizing DHCP options

DHCP option customization applications

You can customize DHCP options for the following purposes:

- Add newly released options.
- Add options for which the vendor defines the contents, for example, Option 43.
- Add options for which the CLI does not provide a dedicated configuration command. For example, you can use the **option 4 ip-address 1.1.1.1** command to define the time server address 1.1.1.1 for DHCP clients.
- Add all option values if the actual requirement exceeds the limit for a dedicated option configuration command. For example, the **dns-list** command can specify up to eight DNS servers. To specify more than eight DNS servers, you must use the **option 6** command to define all DNS servers.

Common DHCP options

Table 1 lists common DHCP options and their parameters.

Table 1 Common DHCP options

Option	Option name	Corresponding command	Recommended parameter in the option command
3	Router Option	**gateway-list**	**ip-address**

Option	Option name	Corresponding command	Recommended parameter in the option command
6	Domain Name Server Option	**dns-list**	**ip-address**
15	Domain Name	**domain-name**	**ascii**
44	NetBIOS over TCP/IP Name Server Option	**nbns-list**	**ip-address**
46	NetBIOS over TCP/IP Node Type Option	**netbios-type**	**hex**
66	TFTP server name	**tftp-server**	**ascii**
67	Boot file name	**bootfile-name**	**ascii**
43	Vendor Specific Information	N/A	**hex**

Restrictions and guidelines

Use caution when customizing DHCP options because the configuration might affect DHCP operation.

You can customize a DHCP option in a DHCP address pool

You can customize a DHCP option in a DHCP option group, and specify the option group for a user class in an address pool. A DHCP client in the user class will obtain the option configuration.

Customizing a DHCP option in a DHCP address pool

1. Enter system view.

   system-view

2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*

3. Customize a DHCP option.

   option *code* { **ascii** *ascii-string* | **hex** *hex-string* | **ip-address** *ip-address*&<1-8> }

   By default, no DHCP option is customized in a DHCP address pool.

   DHCP options specified in DHCP option groups take precedence over those specified in DHCP address pools.

Customizing a DHCP option in a DHCP option group

1. Enter system view.

   system-view

2. Create a DHCP option group and enter DHCP option group view.

   dhcp option-group *option-group-number*

3. Customize a DHCP option.

   option *code* { **ascii** *ascii-string* | **hex** *hex-string* | **ip-address** *ip-address*&<1-8> }

   By default, no DHCP option is customized in a DHCP option group.

   If multiple DHCP option groups have the same option, the server selects the option in the DHCP option group first matching the user class.

4. Return to system view.

   quit

5. Enter DHCP address pool view.

```
dhcp server ip-pool pool-name
```

6. Specify the DHCP option group for the DHCP user class.

   ```
   class class-name option-group option-group-number
   ```

   By default, no DHCP option group is specified for a DHCP user class.

Applying a DHCP address pool to a VPN instance

About this task

If a DHCP address pool is applied to a VPN instance, the DHCP server assigns IP addresses in this address pool to clients in the VPN instance. Addresses in this address pool will not be assigned to clients on the public network.

The DHCP server can obtain the VPN instance to which a DHCP client belongs from the following information:

- The client's VPN information stored in authentication modules, such as IPoE.
- The VPN information of the DHCP server's interface that receives DHCP packets from the client.

If both VPN instances can be obtained, the VPN information from authentication modules takes priority over the VPN information of the receiving interface.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter DHCP address pool view.

   ```
   dhcp server ip-pool pool-name
   ```

3. Apply the address pool to a VPN instance.

   ```
   vpn-instance vpn-instance-name
   ```

   By default, the address pool is not applied to any VPN instance.

Configuring the DHCP user class whitelist

About this task

The DHCP user class whitelist allows the DHCP server to process requests only from clients on the DHCP user class whitelist.

Restrictions and guidelines

The whitelist does not take effect on clients who request static IP addresses, and the server always processes their requests.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter DHCP address pool view.

   ```
   dhcp server ip-pool pool-name
   ```

3. Enable the DHCP user class whitelist.

   ```
   verify class
   ```

   By default, the DHCP user class whitelist is disabled.

4. Add DHCP user classes to the DHCP user class whitelist.

```
valid class class-name&<1-8>
```

By default, no DHCP user class is on the DHCP user class whitelist.

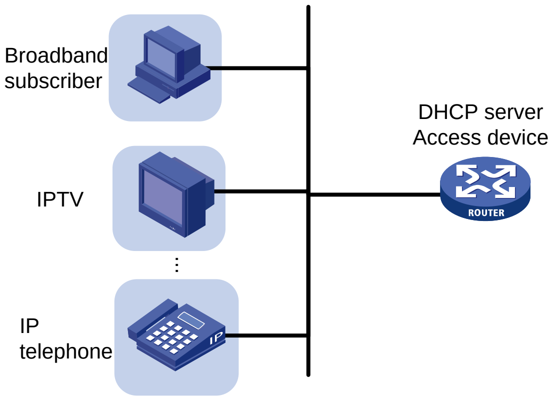
Binding gateways to DHCP server's MAC address

About this task

This feature enables the DHCP server to assign different gateway IP addresses to DHCP clients. In addition, the DHCP server uses the gateway IP addresses and the server's MAC address to reply to ARP requests from the clients.

As shown in Figure 8, the DHCP server is configured on the access device that provides access for clients of different service types, such as broadband, IPTV, and IP telephone. The clients of different types obtain IP addresses on different subnets. For the clients to access the network, the access interface typically has no IP address configured. You must bind the gateways to the DHCP server's MAC address when specifying gateways for the DHCP clients.

Figure 8 Network diagram



Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter DHCP address pool view.

   ```
   dhcp server ip-pool pool-name
   ```

3. Bind the gateways to the device's MAC address.

   ```
   gateway-list ip-address&<1-64> export-route
   ```

   By default, gateways are not bound to any MAC address.

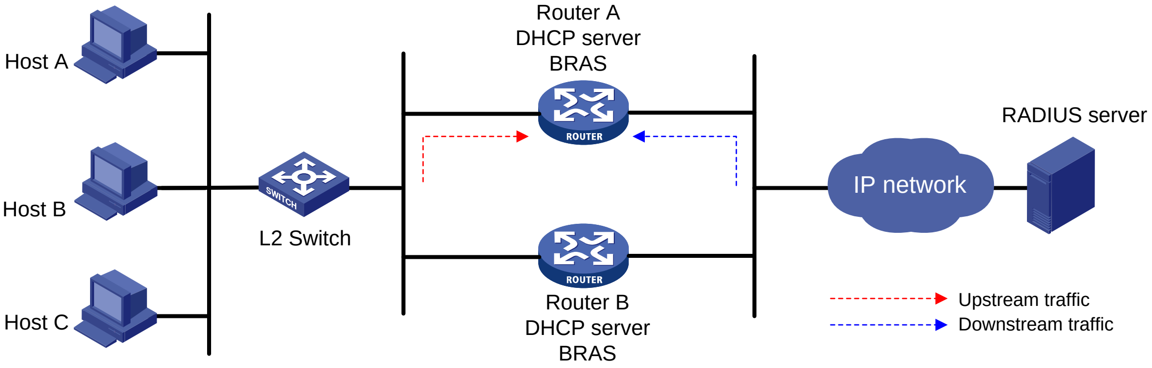
Advertising subnets that are assigned to clients

About this task

This feature enables the route management module to advertise subnets assigned to DHCP clients. This feature achieves symmetric routing for traffic of the same host.

As shown in Figure 9, Router A and Router B act as both the DHCP server and the BRAS device. The BRAS devices send accounting packets to the RADIUS server. To enable the BRAS devices to collect correct accounting information for each RADIUS user, configure the DHCP server to advertise subnets assigned to clients. The upstream and downstream traffic of a RADIUS user will pass through the same BRAS device.

Figure 9 Network diagram



Procedure

1. Enter system view.

   `system-view`

2. Create a DHCP address pool and enter its view.

   `dhcp server ip-pool` *`pool-name`*

3. Advertise subnets assigned to DHCP clients.

   `network` *`network-address`* [*`mask-length`* | **`mask`** *`mask`*] [**`secondary`**] **`export-route`**

   By default, the subnets assigned to DHCP clients are not advertised.

Applying an address pool to an interface

About this task

Perform this task to apply a DHCP address pool to an interface.

Upon receiving a DHCP request from the interface, the DHCP server performs address allocation in the following ways:

- If a static binding is found for the client, the server assigns the static IP address and configuration parameters from the address pool that contains the static binding.
- If no static binding is found for the client, the server uses the address pool applied to the interface for address and configuration parameter allocation.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Apply an address pool to the interface.

   `dhcp server apply ip-pool` *`pool-name`*

   By default, no address pool is applied to an interface.

   If the applied address pool does not exist, the DHCP server fails to perform dynamic address allocation.

Configuring a DHCP policy for dynamic assignment

About this task

In a DHCP policy, each DHCP user class has a bound DHCP address pool. Clients matching different user classes obtain IP addresses and other parameters from different address pools. The DHCP policy must be applied to the interface that acts as the DHCP server. When receiving a DHCP request, the DHCP server compares the packet against the user classes in the order that they are configured.

- If a matching user class is found and the bound address pool has assignable IP addresses, the server assigns an IP address and other parameters from the address pool. If the address pool does not have assignable IP addresses, the address assignment fails.
- If no match is found, the server assigns an IP address and other parameters from the default DHCP address pool. If no default address pool is specified or the default address pool does not have assignable IP addresses, the address assignment fails.

For successful address assignment, make sure the applied DHCP policy and the bound address pools exist.

Restrictions and guidelines

A DHCP policy take effect only after it is applied to an interface.

Procedure

1. Enter system view.

   `system-view`

2. Create a DHCP policy and enter DHCP policy view.

   `dhcp policy` *`policy-name`*

3. Specify a DHCP address pool for a DHCP user class.

   `class` *`class-name`* **`ip-pool`** *`pool-name`*

   By default, no address pool is specified for a user class.

4. Specify the default DHCP address pool.

   `default ip-pool` *`pool-name`*

   By default, no default address pool is specified.

5. Return to system view.

   `quit`

6. Enter interface view.

   `interface` *`interface-type interface-number`*

7. Apply the DHCP policy to the interface.

   `dhcp apply-policy` *`policy-name`*

   By default, no DHCP policy is applied to an interface.

Enabling DHCP

Restrictions and guideline

You must enable DHCP to make other DHCP configurations take effect.

Procedure

1. Enter system view.

   system-view

2. Enable DHCP.

   dhcp enable

   By default, DHCP is disabled.

Enabling the DHCP server on an interface

About this task

Perform this task to enable the DHCP server on an interface. Upon receiving a DHCP request on the interface, the DHCP server assigns the client an IP address and other configuration parameters from a DHCP address pool.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the DHCP server on the interface.

   dhcp select server

   By default, the DHCP server is enabled on the interface.

Configuring IP address conflict detection

About this task

Before assigning an IP address, the DHCP server pings that IP address.

- If the server receives a response within the specified period, it selects and pings another IP address.
- If it receives no response, the server continues to ping the IP address until the maximum number of ping packets are sent. If still no response is received, the server assigns the IP address to the requesting client. The DHCP client uses gratuitous ARP to perform IP address conflict detection.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Set the maximum number of ping packets to be sent for conflict detection.

   dhcp server ping packets *number*

   The default setting is one.

   To disable IP address conflict detection, set the value to **0**.

3. (Optional.) Set the ping timeout time.

   dhcp server ping timeout *milliseconds*

   The default setting is 500 ms.

   To disable IP address conflict detection, set the value to **0**.

Enabling handling of Option 82

About this task

Perform this task to enable the DHCP server to handle Option 82. Upon receiving a DHCP request that contains Option 82, the DHCP server adds Option 82 into the DHCP response.

If you disable the DHCP to handle Option 82, it does not add Option 82 into the response message.

You must enable handling of Option 82 on both the DHCP server and the DHCP relay agent to ensure correct processing for Option 82. For information about enabling handling of Option 82 on the DHCP relay agent, see "Configuring DHCP relay agent support for Option 82."

Procedure

1. Enter system view.

   `system-view`

2. Enable the server to handle Option 82.

   `dhcp server relay information enable`

   By default, handling of Option 82 is enabled.

Configuring DHCP server compatibility

Perform this task to enable the DHCP server to support DHCP clients that are incompliant with RFC.

Configuring the DHCP server to always broadcast responses

About this task

By default, the DHCP server broadcasts a response only when the broadcast flag in the DHCP request is set to 1. You can configure the DHCP server to ignore the broadcast flag and always broadcast a response. This feature is useful when some clients set the broadcast flag to 0 but do not accept unicast responses.

The DHCP server always unicasts a response in the following situations, regardless of whether this feature is configured or not:

- The DHCP request is from a DHCP client that has an IP address (the **ciaddr** field is not 0).
- The DHCP request is forwarded by a DHCP relay agent from a DHCP client (the **giaddr** field is not 0).

Procedure

1. Enter system view.

   `system-view`

2. Enable the DHCP server to always broadcast all responses.

   `dhcp server always-broadcast`

   By default, the DHCP server reads the broadcast flag to decide whether to broadcast or unicast a response.

Configuring the DHCP server to ignore BOOTP requests

About this task

The lease duration of the IP addresses obtained by the BOOTP clients is unlimited. For some scenarios that do not allow unlimited leases, you can configure the DHCP server to ignore BOOTP requests.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Configure the DHCP server to ignore BOOTP requests.

   ```
   dhcp server bootp ignore
   ```

   By default, the DHCP server processes BOOTP requests.

Configuring the DHCP server to send BOOTP responses in RFC 1048 format

About this task

Not all BOOTP clients can send requests that are compatible with RFC 1048. By default, the DHCP server does not process the Vend field of RFC 1048-incompliant requests but copies the Vend field into responses.

This feature enables the DHCP server to fill the Vend field in RFC 1048-compliant format in DHCP responses to RFC 1048-incompliant requests sent by BOOTP clients.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable the DHCP server to send BOOTP responses in RFC 1048 format to the RFC 1048-incompliant BOOTP requests.

   ```
   dhcp server bootp reply-rfc-1048
   ```

   By default, the DHCP server directly copies the Vend field of such requests into the responses.

Disabling Option 60 encapsulation in DHCP replies

About this task

If one or more DHCP clients cannot resolve Option 60, disable the DHCP server from encapsulating Option 60 in DHCP replies. If you do not disable the capability, the DHCP server encapsulates Option 60 in a DHCP reply in the following situations:

- The received DHCP packet contains Option 60.
- Option 60 is configured for the address pool.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Disable the DHCP server from encapsulating Option 60 in DHCP replies.

   ```
   dhcp server reply-exclude-option60
   ```

   By default, the DHCP server can encapsulate Option 60 in DHCP replies.

Setting the DSCP value for DHCP packets sent by the DHCP server

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet.

Procedure

1. Enter system view.

   system-view

2. Set the DSCP value for DHCP packets sent by the DHCP server.

   dhcp dscp *dscp-value*

   By default, the DSCP value in DHCP packets sent by the DHCP server is 56.

Configuring DHCP binding auto backup

About this task

The auto backup feature saves bindings to a backup file and allows the DHCP server to download the bindings from the backup file at the server reboot. The bindings include the lease bindings and conflicted IP addresses. They cannot survive a reboot on the DHCP server.

The DHCP server does not provide services during the download process. If a connection error occurs during the process and cannot be repaired in a short amount of time, you can terminate the download operation. Manual interruption allows the DHCP server to provide services without waiting for the connection to be repaired.

Procedure

1. Enter system view.

   system-view

2. Configure the DHCP server to back up the bindings to a file.

   dhcp server database filename { *filename* | **url** *url* [**username** *username* [**password** { **cipher** | **simple** } *string*]] }

   By default, the DHCP server does not back up the DHCP bindings.

   With this command executed, the DHCP server backs up its bindings immediately and runs auto backup.

3. (Optional.) Manually save the DHCP bindings to the backup file.

   dhcp server database update now

4. (Optional.) Set the waiting time after a DHCP binding change for the DHCP server to update the backup file.

   dhcp server database update interval *interval*

   By default, the DHCP server waits 300 seconds to update the backup file after a DHCP binding change. If no DHCP binding changes, the backup file is not updated.

5. (Optional.) Terminate the download of DHCP bindings from the backup file.

   dhcp server database update stop

   This command only triggers one termination.

Enabling client offline detection on the DHCP server

About this task

The client offline detection feature reclaims an assigned IP address and deletes the binding entry when the ARP entry for the IP address ages out.

Restrictions and guidelines

The feature does not function if an ARP entry is manually deleted.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Enable client offline detection.

   `dhcp client-detect`

   By default, client offline detection is disabled on the DHCP server.

Configuring address pool usage alarming

About this task

Perform this task to set the threshold for address pool usage alarming. When the threshold is exceeded, the system sends notifications to the SNMP module. For DHCP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter DHCP address pool view.

   `dhcp server ip-pool` *`pool-name`*

3. (Optional.) Set the threshold for address pool usage alarming.

   `ip-in-use threshold` *`threshold-value`*

   The default threshold is 100%.

Enabling DHCP logging on the DHCP server

About this task

The DHCP logging feature enables the DHCP server to generate DHCP logs and send them to the information center. The information helps administrators locate and solve problems. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

As a best practice, disable this feature if the log generation affects the device performance or reduces the address allocation efficiency. For example, this situation might occur when a large number of clients frequently come online or go offline.

Procedure

1. Enter system view.
   system-view
2. Enable DHCP logging.
   dhcp log enable
   By default, DHCP logging is disabled.

Display and maintenance commands for DHCP server

IMPORTANT:

A restart of the DHCP server or execution of the **reset dhcp server ip-in-use** command deletes all lease information. The DHCP server denies any DHCP request for lease extension, and the client must request an IP address again.

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about IP address conflicts.	**display dhcp server conflict** [**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*]
Display information about DHCP binding auto backup.	**display dhcp server database**
Display information about lease-expired IP addresses.	**display dhcp server expired** [[**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]
Display information about assignable IP addresses.	**display dhcp server free-ip** [**pool** *pool-name* | **vpn-instance** *vpn-instance-name*]

Troubleshooting DHCP server configuration

Failure to obtain a non-conflicting IP address

Symptom

A client's IP address obtained from the DHCP server conflicts with an IP address of another host.

Solution

Another host on the subnet might have the same IP address.

To resolve the problem:

1. Disable the client's network adapter or disconnect the client's network cable. Ping the IP address of the client from another host to check whether there is a host using the same IP address.
2. If a ping response is received, the IP address has been manually configured on a host. Execute the **dhcp server forbidden-ip** command on the DHCP server to exclude the IP address from dynamic allocation.
3. Enable the network adapter or connect the network cable, release the IP address, and obtain another one on the client. For example, to release the IP address and obtain another one on a Windows XP DHCP client:
   a. In Windows environment, execute the **cmd** command to enter the DOS environment.
   b. Enter **ipconfig /release** to relinquish the IP address.
   c. Enter **ipconfig /renew** to obtain another IP address.

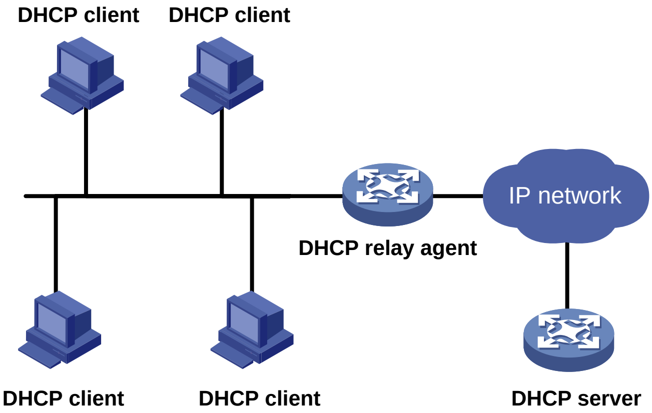
Configuring the DHCP relay agent

About DHCP relay agent

The DHCP relay agent enables clients to get IP addresses and configuration parameters from a DHCP server on another subnet.

Figure 10 shows a typical application of the DHCP relay agent.

Figure 10 DHCP relay agent application

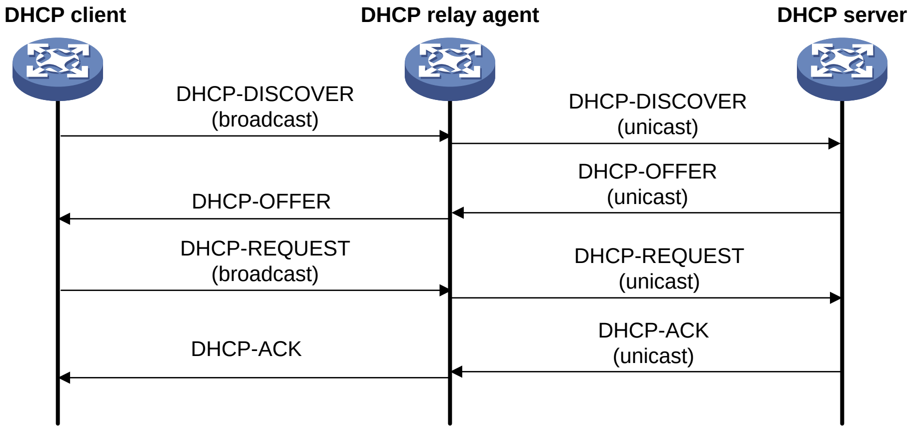


DHCP relay agent operation

The DHCP server and client interact with each other in the same way regardless of whether the relay agent exists. For the interaction details, see "IP address allocation process." The following only describes steps related to the DHCP relay agent:

1. After receiving a DHCP-DISCOVER or DHCP-REQUEST broadcast message from a DHCP client, the DHCP relay agent processes the message as follows:
   a. Fills the **giaddr** field of the message with its IP address.
   b. Unicasts the message to the designated DHCP server.
2. Based on the **giaddr** field, the DHCP server returns an IP address and other configuration parameters in a response.
3. The relay agent conveys the response to the client.

Figure 11 DHCP relay agent operation



DHCP relay agent support for Option 82

Option 82 records the location information about the DHCP client. It enables the administrator to perform the following tasks:

- Locate the DHCP client for security and accounting purposes.
- Assign IP addresses in a specific range to clients.

For more information about Option 82, see "Relay agent option (Option 82)."

If the DHCP relay agent supports Option 82, it handles DHCP requests by following the strategies described in Table 2.

If a response returned by the DHCP server contains Option 82, the DHCP relay agent removes the Option 82 before forwarding the response to the client.

Table 2 Handling strategies of the DHCP relay agent

If a DHCP request has…	Handling strategy	The DHCP relay agent…
Option 82	Drop	Drops the message.
	Keep	Forwards the message without changing Option 82.
	Replace	Forwards the message after replacing the original Option 82 with the Option 82 padded according to the configured padding format, padding content, and code type.
No Option 82	N/A	Forwards the message after adding Option 82 padded according to the configured padding format, padding content, and code type.

DHCP relay agent tasks at a glance

To configure a DHCP relay agent, perform the following tasks:

1. Enabling DHCP
2. Enabling the DHCP relay agent on an interface
3. Specifying DHCP servers
4. (Optional.) Specifying a DHCP relay address pool for DHCP clients
5. (Optional.) Configuring the DHCP relay agent security features

6. (Optional.) Configuring the DHCP relay agent to release an IP address
7. (Optional.) Configuring DHCP relay agent support for Option 82
8. (Optional.) Setting the DSCP value for DHCP packets sent by the DHCP relay agent
9. (Optional.) Specifying the DHCP relay agent address for the giaddr field
10. (Optional.) Specifying the source IP address for relayed DHCP requests
11. (Optional.) Configuring forwarding DHCP replies based on Option 82

Enabling DHCP

Restrictions and guidelines

You must enable DHCP to make other DHCP relay agent settings take effect.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable DHCP.
   ```
   dhcp enable
   ```
   By default, DHCP is disabled.

Enabling the DHCP relay agent on an interface

About this task

With the DHCP relay agent enabled, an interface forwards incoming DHCP requests to a DHCP server.

An IP address pool that contains the IP address of the DHCP relay interface must be configured on the DHCP server. Otherwise, the DHCP clients connected to the relay agent cannot obtain correct IP addresses.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enter interface view.
   ```
   interface interface-type interface-number
   ```
3. Enable the DHCP relay agent.
   ```
   dhcp select relay
   ```
   By default, when DHCP is enabled, an interface operates in the DHCP server mode.

Specifying DHCP servers

Specifying DHCP servers on a relay agent

About this task

To improve availability, you can specify several DHCP servers on the DHCP relay agent. When the interface receives request messages from clients, the relay agent forwards them to all DHCP servers.

Restrictions and guidelines

The IP address of any specified DHCP server must not reside on the same subnet as the IP address of the relay interface. Otherwise, the clients might fail to obtain IP addresses.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Specify a DHCP server address on the relay agent.

   `dhcp relay server-address` *`ip-address`*

   By default, no DHCP server address is specified on the relay agent.

   To specify multiple DHCP server addresses, repeat this step. You can specify a maximum of eight DHCP servers.

Specifying DHCP servers in a DHCP relay address pool

About this task

DHCP address pools created on a DHCP relay agent are called DHCP relay address pools. You can create a relay address pool and specify DHCP servers in this address pool. This feature allows DHCP clients of the same type to obtain IP addresses and other configuration parameters from the DHCP servers specified in the matching DHCP relay address pool.

It applies to scenarios where the DHCP relay agent connects to clients of the same access type but classified into different types by their locations. In this case, the relay interface typically has no IP address configured. You can use the **`gateway-list`** command to specify gateway addresses for clients matching the same DHCP relay address pool and bind the gateway addresses to the device's MAC address. Example network is the IPoE network.

Upon receiving a DHCP DISCOVER or REQUEST from a client that matches a DHCP relay address pool, the relay agent processes the packet as follows:

- Fills the **giaddr** field of the packet with a specified gateway address.
- Forwards the packet to all DHCP servers in the matching DHCP relay address pool.

The DHCP servers select a DHCP address pool according to the gateway address.

Restrictions and guidelines

If PPPoE users are in the network, follow these restrictions and guidelines when you configure the DHCP relay address pool:

- Enable the DHCP relay agent to record DHCP relay entries by using the **`dhcp relay client-information record`** command. When a PPPoE user goes offline, the DHCP relay agent can find a matching relay entry and send a DHCP-RELEASE message to the DHCP server. This mechanism ensures the DHCP server is aware of the releasing of the IP address in a timely manner.
- The **`remote-server`** command also configures the device as a DHCP relay agent. You do not need to enable the DHCP relay agent by using the **`dhcp select relay`** command.

Procedure

1. Enter system view.

   `system-view`

2. Create a DHCP relay address pool and enter its view.

   `dhcp server ip-pool` *`pool-name`*

3. Specify gateways in the DHCP relay address pool.

   `gateway-list` *`ip-address`*`&<1-64>` [**`export-route`**]

   By default, no gateway address is specified.

4. Specify DHCP servers in the DHCP relay address pool.

   `remote-server` *`ip-address`*`&<1-8>`

   By default, no DHCP server is specified in the DHCP relay address pool.

   You can specify a maximum of eight DHCP servers in one DHCP relay address pool for high availability.

Specifying a DHCP relay address pool for DHCP clients

About this task

After you configure multiple DHCP relay address pools on a DHCP relay agent, you can specify these pools on an interface. To match DHCP clients based on options, you can define option settings when you specify the relay address pools.

Procedure

1. Enter system view.

   `system-view`

2. Create a DHCP relay address pool and enter its view.

   `dhcp server ip-pool` *`pool-name`*

   By default, no DHCP relay address pools exist.

3. Specify DHCP servers in the DHCP relay address pool.

   `remote-server` *`ip-address`*&<1-8>

   By default, no DHCP server is specified in the DHCP relay address pool.

4. Specify gateway addresses for the clients matching the DHCP relay address pool.

   `gateway-list` *`ip-address`*&<1-64>

   By default, no gateway address is specified.

Configuring the DHCP relay agent security features

Enabling the DHCP relay agent to record relay entries

About this task

Perform this task to enable the DHCP relay agent to automatically record clients' IP-to-MAC bindings (relay entries) after they obtain IP addresses through DHCP.

Some security features use the relay entries to check incoming packets and block packets that do not match any entry. In this way, illegal hosts are not able to access external networks through the relay agent. Examples of the security features are ARP address check and authorized ARP.

Rustications and guidelines

The DHCP relay agent does not record IP-to-MAC bindings for DHCP clients running on synchronous/asynchronous serial interfaces.

Procedure

1. Enter system view.

   `system-view`

2. Enable the relay agent to record relay entries.

   `dhcp relay client-information record`

   By default, the relay agent does not record relay entries.

Enabling periodic refresh of dynamic relay entries

About this task

A DHCP client unicasts a DHCP-RELEASE message to the DHCP server to release its IP address. The DHCP relay agent conveys the message to the DHCP server and does not remove the IP-to-MAC entry of the client.

With this feature, the DHCP relay agent uses the IP address of a relay entry to periodically send a DHCP-REQUEST message to the DHCP server.

The relay agent maintains the relay entries depending on what it receives from the DHCP server:

- If the server returns a DHCP-ACK message or does not return any message within an interval, the DHCP relay agent removes the relay entry. In addition, upon receiving the DHCP-ACK message, the relay agent sends a DHCP-RELEASE message to release the IP address.
- If the server returns a DHCP-NAK message, the relay agent keeps the relay entry.

Procedure

1. Enter system view.

   `system-view`

2. Enable periodic refresh of dynamic relay entries.

   `dhcp relay client-information refresh enable`

   By default, periodic refresh of dynamic relay entries is enabled.

3. (Optional.) Set the refresh interval.

   `dhcp relay client-information refresh` `[` **`auto`** `|` **`interval`** *`interval`* `]`

   By default, the refresh interval is **`auto`**, which is calculated based on the number of total relay entries.

Enabling DHCP starvation attack protection

About this task

A DHCP starvation attack occurs when an attacker constantly sends forged DHCP requests using different MAC addresses in the **chaddr** field to a DHCP server. This exhausts the IP address resources of the DHCP server so legitimate DHCP clients cannot obtain IP addresses. The DHCP server might also fail to work because of exhaustion of system resources. The following methods are available to relieve or prevent such attacks.

- To relieve a DHCP starvation attack that uses DHCP packets encapsulated with different source MAC addresses, you can use one of the following methods:
  - Limit the number of ARP entries that a Layer 3 interface can learn.
  - Set the MAC learning limit for a Layer 2 port, and disable unknown frame forwarding when the MAC learning limit is reached.
- To prevent a DHCP starvation attack that uses DHCP requests encapsulated with the same source MAC address, you can enable MAC address check on the DHCP relay agent. The DHCP relay agent compares the **chaddr** field of a received DHCP request with the source MAC

address in the frame header. If they are the same, the DHCP relay agent forwards the request to the DHCP server. If not, the relay agent discards the request.

Enable MAC address check only on the DHCP relay agent directly connected to the DHCP clients. A DHCP relay agent changes the source MAC address of DHCP packets before sending them.

A MAC address check entry has an aging time. When the aging time expires, both of the following occur:

- The entry ages out.
- The DHCP relay agent rechecks the validity of DHCP requests sent from the MAC address in the entry.

Procedure

1. Enter system view.

   system-view

2. Set the aging time for MAC address check entries.

   dhcp relay check mac-address aging-time *time*

   The default aging time is 30 seconds.

   This command takes effect only after you execute the **dhcp relay check mac-address** command.

3. Enter the interface view.

   interface *interface-type interface-number*

4. Enable MAC address check.

   dhcp relay check mac-address

   By default, MAC address check is disabled.

Enabling DHCP server proxy on the DHCP relay agent

About this task

The DHCP server proxy feature isolates DHCP servers from DHCP clients and protects DHCP servers against attacks.

Upon receiving a response from the server, the DHCP server proxy modifies the server's IP address as the relay interface's IP address before sending out the response. The DHCP client takes the DHCP relay agent as the DHCP server.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable DHCP relay agent and DHCP server proxy on the interface.

   dhcp select relay proxy

   By default, the interface operates in DHCP server mode after DHCP is enabled.

Enabling client offline detection on the DHCP relay agent

About this task

The client offline detection on the DHCP relay agent detects the user online status based on the ARP entry aging. When an ARP entry ages out, the DHCP client offline detection feature deletes the relay entry for the IP address and sends a RELEASE message to the DHCP server.

Restrictions and guidelines

The feature does not function if an ARP entry is manually deleted.

Procedure

1. Enter system view.

   `system-view`

2. Enable the relay agent to record relay entries.

   `dhcp relay client-information record`

   By default, the relay agent does not record relay entries.

   Without relay entries, client offline detection cannot function correctly.

3. Enter interface view.

   `interface` *`interface-type interface-number`*

4. Enable the DHCP relay agent.

   `dhcp select relay`

   By default, when DHCP is enabled, an interface operates in the DHCP server mode.

5. Enable client offline detection.

   `dhcp client-detect`

   By default, client offline detection is disabled on the DHCP relay agent.

Configuring the DHCP relay agent to release an IP address

About this task

Configure the relay agent to release the IP address for a relay entry. The relay agent sends a DHCP-RELEASE message to the server and meanwhile deletes the relay entry. Upon receiving the DHCP-RELEASE message, the DHCP server releases the IP address.

This command can release only the IP addresses in the recorded relay entries.

Procedure

1. Enter system view.

   `system-view`

2. Configure the DHCP relay agent to release an IP address.

   `dhcp relay release ip` *`ip-address`* `[` **`vpn-instance`** *`vpn-instance-name`* `]`

Configuring DHCP relay agent support for Option 82

To support Option 82, you must perform related configuration on both the DHCP server and relay agent. For DHCP server Option 82 configuration, see "Enabling handling of Option 82."

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the relay agent to handle Option 82.

   dhcp relay information enable

   By default, handling of Option 82 is disabled.

4. (Optional.) Configure the strategy for handling DHCP requests that contain Option 82.

   dhcp relay information strategy { **drop** | **keep** | **replace** }

   By default, the handling strategy is **replace**.

   If the handling strategy is **replace**, configure a padding mode and a padding format for Option 82. If the handling strategy is **keep** or **drop**, you do not need to configure a padding mode or padding format for Option 82.

5. (Optional.) Configure the padding mode and padding format for the Circuit ID sub-option.

   dhcp relay information circuit-id { **bas** [**sub-interface-vlan**] | **string** *circuit-id* | { **normal** | **verbose** [**node-identifier** { **mac** | **sysname** | **user-defined** *node-identifier* }] [**interface**] [**sub-interface-vlan**] } [**format** { **ascii** | **hex** }] }

   By default, the padding mode for Circuit ID sub-option is **normal**, and the padding format is **hex**.

   The device name (**sysname**) must not include spaces if it is configured as the padding content for sub-option 1. Otherwise, the DHCP relay agent will fail to add or replace Option 82.

6. (Optional.) Configure the padding mode and padding format for the Remote ID sub-option.

   dhcp relay information remote-id {**normal** [**format** { **ascii** | **hex** }] | **string** *remote-id* | **sysname** }

   By default, the padding mode for the Remote ID sub-option is **normal**, and the padding format is **hex**.

Setting the DSCP value for DHCP packets sent by the DHCP relay agent

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet.

Procedure

1. Enter system view.

   system-view

2. Set the DSCP value for DHCP packets sent by the DHCP relay agent.

   dhcp dscp *dscp-value*

   By default, the DSCP value in DHCP packets sent by the DHCP relay agent is 56.

Specifying the DHCP relay agent address for the **giaddr** field

Manually specifying the DHCP relay agent address for the **giaddr** field

About this task

This task allows you to specify the IP addresses to be encapsulated to the **giaddr** field of the DHCP requests. If you do not specify any DHCP relay agent address, the primary IP address of the DHCP relay interface is encapsulated to the **giaddr** field of DHCP requests.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify the DHCP relay agent address to be encapsulated in relayed DHCP requests.

   dhcp relay gateway *ip-address*

   By default, the primary IP address of the DHCP relay interface is encapsulated in the relayed DHCP requests.

Configuring smart relay to specify the DHCP relay agent address for the **giaddr** field

About this task

By default, the relay agent only encapsulates the primary IP address to the **giaddr** field of all requests before relaying them to the DHCP server. The DHCP server then selects an IP address on the same subnet as the address in the **giaddr** filed. If no assignable addresses on the subnet are available, the DHCP server does not assign any IP address. The DHCP smart relay feature is introduced to allow the DHCP relay agent to encapsulate secondary IP addresses when the DHCP server does not send back a DHCP-OFFER message.

The relay agent initially encapsulates its primary IP address to the **giaddr** field before forwarding a request to the DHCP server. If no DHCP-OFFER is received, the relay agent allows the client to send a maximum of two requests to the DHCP server by using the primary IP address. If no DHCP-OFFER is returned after two retries, the relay agent switches to a secondary IP address. If the DHCP server still does not respond, the next secondary IP address is used. After the secondary IP addresses are all tried and the DHCP server does not respond, the relay agent repeats the process by starting from the primary IP address.

Procedure

1. Enter system view.

   system-view

2. Enable the DHCP smart relay feature.

```
dhcp smart-relay enable
```

By default, the DHCP smart relay feature is disabled.

Specifying the source IP address for relayed DHCP requests

About this task

This task is required if multiple relay interfaces share the same IP address or if a relay interface does not have routes to DHCP servers. You can specify an IP address or the IP address of another interface, typically the loopback interface, on the DHCP relay agent as the source IP address for DHCP requests. The relay interface inserts the source IP address in the source IP address field as well as the **giaddr** field in DHCP requests.

If multiple relay interfaces share the same IP address, you must also configure the relay interface to support Option 82. Upon receiving a DHCP request, the relay interface inserts the subnet information in sub-option 5 in Option 82. The DHCP server assigns an IP address according to sub-option 5. The DHCP relay agent looks up the output interface in the MAC address table to forward the DHCP reply.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Specify the source IP address for DHCP requests.

   ```
   dhcp relay source-address { ip-address | gateway | relay-interface }
   ```

   The relay agent chooses the default source IP address for relayed requests depending on whether its server-side interface and the DHCP server belong to the same VPN instance:

   - If they belong to the same VPN instance, the relay agent uses the IP address of the output interface for relayed requests as the default source IP address.
   - If they belong to different VPN instances, the relay agent uses the lowest IP address that is in the same VPN instance as the DHCP server as the default source address.

Configuring forwarding DHCP replies based on Option 82

About this task

Configure this feature if the DHCP relay agent is required to forward DHCP replies to DHCP clients based on Option 82.

For example, an IPRAN network has a primary gateway and a secondary gateway. An L3VE interface is configured as the relay interface on each gateway. Multiple L2VE subinterfaces are configured to receive packets. One L2VE subinterface corresponds to one PW. Only the primary gateway receives DHCP requests, but both the primary and secondary gateways might receive DHCP replies. The primary gateway can forward DHCP replies based on locally recorded user information, but the secondary gateway cannot. The secondary gateway can only forward DHCP replies to all PWs.

To enable the secondary gateway to forward a DHCP reply only to the intended PW, perform the following tasks:

- Configure the **dhcp relay information enable** and **dhcp relay information circuit-id** (with **sub-interface-vlan** specified) commands on the primary gateway. Then, when the primary gateway receives a DHCP request, it adds Option 82 to the reply and records the VLAN ID of the L2VE subinterface.
- Configure the **dhcp relay information enable**, **dhcp relay information circuit-id** (with **sub-interface-vlan** specified), and **dhcp relay forward reply by-option82** commands on the secondary gateway. Then, when the secondary gateway receives a DHCP reply, it resolves Option 82, records the VLAN ID of the L2VE subinterface, and forwards the reply to the PW.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the relay agent to handle Option 82.

   dhcp relay information enable

   By default, handling of Option 82 is disabled.

4. Configure the padding mode and padding format for the Circuit ID sub-option.

   dhcp relay information circuit-id { **bas** [**sub-interface-vlan**] | **string** *circuit-id* | { **normal** | **verbose** [**node-identifier** { **mac** | **sysname** | **user-defined** *node-identifier* }] [**interface**] } [**sub-interface-vlan**] [**format** { **ascii** | **hex** }] }

   By default, the padding mode for Circuit ID sub-option is **normal**, and the padding format is **hex**.

   The device name (**sysname**) must not include spaces if it is configured as the padding content for sub-option 1. Otherwise, the DHCP relay agent will fail to add or replace Option 82.

5. Configure the DHCP relay agent to forward DHCP replies based on Option 82.

   dhcp relay forward reply by-option82

   By default, the DHCP relay agent does not forward DHCP replies based on Option 82.

Display and maintenance commands for DHCP relay agent

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display MAC address check entries on the DHCP relay agent.	**display dhcp relay check mac-address**
Display relay entries on the DHCP relay agent.	**display dhcp relay client-information** [**interface** *interface-type interface-number* | **ip** *ip-address* [**vpn-instance** *vpn-instance-name*]]
Display Option 82 configuration information on the DHCP relay agent.	**display dhcp relay information** [**interface** *interface-type interface-number*]
Display information about DHCP servers	**display dhcp relay server-address**

Task	Command
on an interface.	[**interface** *interface-type* *interface-number*]
Display packet statistics on the DHCP relay agent.	**display dhcp relay statistics** [**interface** *interface-type interface-number*]
Clear relay entries on the DHCP relay agent.	**reset dhcp relay client-information** [**interface** *interface-type* *interface-number* | **ip** *ip-address* [**vpn-instance** *vpn-instance-name*]]
Clear packet statistics on the DHCP relay agent.	**reset dhcp relay statistics** [**interface** *interface-type interface-number*]

Troubleshooting DHCP relay agent configuration

Failure of DHCP clients to obtain configuration parameters through the DHCP relay agent

Symptom

DHCP clients cannot obtain configuration parameters through the DHCP relay agent.

Solution

Some problems might occur with the DHCP relay agent or server configuration.

To locate the problem, enable debugging and execute the **display** command on the DHCP relay agent to view the debugging information and interface state information.

Check that:

- DHCP is enabled on the DHCP server and relay agent.
- The DHCP server has an address pool on the same subnet as the DHCP clients.
- The DHCP server and DHCP relay agent can reach each other.
- The DHCP server address specified on the DHCP relay interface connected to the DHCP clients is correct.

Configuring the DHCP client

About DHCP client

With DHCP client enabled, an interface uses DHCP to obtain configuration parameters from the DHCP server, for example, an IP address.

Restrictions and guidelines: DHCP client configuration

The DHCP client configuration is supported only on Layer 3 Ethernet interfaces (or subinterfaces), VLAN interfaces, and Layer 3 aggregate interfaces.

DHCP client tasks at a glance

To configure a DHCP client, perform the following tasks:

1. Enabling the DHCP client on an interface
2. Configuring a DHCP client ID for an interface

   Perform this task if the DHCP client uses the client ID to obtain IP addresses.
3. (Optional.) Enabling duplicated address detection
4. (Optional.) Setting the DSCP value for DHCP packets sent by the DHCP client

Enabling the DHCP client on an interface

Restrictions and guidelines

- If the number of IP address request failures reaches the system-defined amount, the DHCP client-enabled interface uses a default IP address.
- An interface can be configured to acquire an IP address in multiple ways. The new configuration overwrites the old.
- Secondary IP addresses cannot be configured on an interface that is enabled with the DHCP client.
- If the interface obtains an IP address on the same segment as another interface on the device, the interface does not use the assigned address. Instead, it requests a new IP address from the DHCP server.

Procedure

1. Enter system view.

   `system-view`
2. Enter interface view.

   `interface` *`interface-type interface-number`*
3. Configure an interface to use DHCP for IP address acquisition.

   `ip address dhcp-alloc`

   By default, an interface does not use DHCP for IP address acquisition.

Configuring a DHCP client ID for an interface

About this task

A DHCP client ID is added to the DHCP option 61 to uniquely identify a DHCP client. A DHCP server can assign IP addresses to clients based on their DHCP client IDs.

DHCP client ID includes an ID type and a type value. Each ID type has a fixed type value. You can specify a DHCP client ID by using one of the following methods:

- Use an ASCII string as the client ID. If an ASCII string is used, the type value is 00.
- Use a hexadecimal number as the client ID. If a hexadecimal number is used, the type value is the first two characters in the number.
- Use the MAC address of an interface to generate a client ID. If this method is used, the type value is 01.

The type value of a DHCP client ID can be displayed by the **`display dhcp server ip-in-use`** or **`display dhcp client`** command.

Restrictions and guidelines

Make sure the ID for each DHCP client is unique.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure a DHCP client ID for the interface.

   `dhcp client identifier` { **`ascii`** *`ascii-string`* | **`hex`** *`hex-string`* | **`mac`** *`interface-type interface-number`* }

   By default, an interface generates the DHCP client ID based on its MAC address. If the interface has no MAC address, it uses the MAC address of the first Ethernet interface to generate its client ID.

Enabling duplicated address detection

About this task

DHCP client detects IP address conflict through ARP packets. An attacker can act as the IP address owner to send an ARP reply. The spoofing attack makes the client unable to use the IP address assigned by the server. As a best practice, disable duplicate address detection when ARP attacks exist on the network.

Procedure

1. Enter system view.

   `system-view`

2. Enable duplicate address detection.

   `dhcp client dad enable`

   By default, the duplicate address detection feature is enabled on an interface.

Setting the DSCP value for DHCP packets sent by the DHCP client

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet.

Procedure

1. Enter system view.

   `system-view`

2. Set the DSCP value for DHCP packets sent by the DHCP client.

   `dhcp client dscp` *`dscp-value`*

   By default, the DSCP value in DHCP packets sent by the DHCP client is 56.

Display and maintenance commands for DHCP client

Execute **`display`** command in any view.

Task	Command
Display DHCP client information.	**`display dhcp client`** [**`verbose`**] [**`interface`** *`interface-type interface-number`*]

Configuring the BOOTP client

About BOOTP client

BOOTP client application

An interface that acts as a BOOTP client can use BOOTP to obtain information (such as IP address) from the BOOTP server.

To use BOOTP, an administrator must configure a BOOTP parameter file for each BOOTP client on the BOOTP server. The parameter file contains information such as MAC address and IP address of a BOOTP client. When a BOOTP client sends a request to the BOOTP server, the BOOTP server searches for the BOOTP parameter file and returns the corresponding configuration information.

BOOTP is usually used in relatively stable environments. In network environments that change frequently, DHCP is more suitable.

Because a DHCP server can interact with a BOOTP client, you can use the DHCP server to assign an IP address to the BOOTP client. You do not need to configure a BOOTP server. The DHCP server will assign an IP address to the BOOTP client based on the IP address allocation sequence.

Obtaining an IP address dynamically

A BOOTP client dynamically obtains an IP address from a BOOTP server as follows:

1. The BOOTP client broadcasts a BOOTP request, which contains its own MAC address.
2. Upon receiving the request, the BOOTP server searches the configuration file for the IP address and other information according to the BOOTP client's MAC address.
3. The BOOTP server returns a BOOTP response to the BOOTP client.
4. The BOOTP client obtains the IP address from the received response.

A DHCP server can take the place of the BOOTP server in the following dynamic IP address acquisition.

Protocols and standards

- RFC 951, *Bootstrap Protocol (BOOTP)*
- RFC 2132, *DHCP Options and BOOTP Vendor Extensions*
- RFC 1542, *Clarifications and Extensions for the Bootstrap Protocol*

Configuring an interface to use BOOTP for IP address acquisition

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

   BOOTP client configuration applies only to Layer 3 Ethernet interfaces (including subinterfaces), Layer 3 aggregate interfaces, and VLAN interfaces.

3. Configure an interface to use BOOTP for IP address acquisition.

   ip address bootp-alloc

   By default, an interface does not use BOOTP for IP address acquisition.

Display and maintenance commands for BOOTP client

Execute **display** command in any view.

Task	Command
Display BOOTP client information.	**display bootp client** [**interface** *interface-type interface-number*]

Contents

DHCPv6 overview

DHCPv6 provides a framework to assign IPv6 prefixes, IPv6 addresses, and other configuration parameters to hosts.

DHCPv6 address/prefix assignment

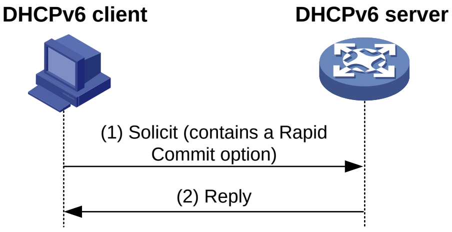
An address/prefix assignment process involves two or four messages.

Rapid assignment involving two messages

As shown in Figure 1, rapid assignment operates in the following steps:

1. The DHCPv6 client sends to the DHCPv6 server a Solicit message that contains a Rapid Commit option to prefer rapid assignment.
2. If the DHCPv6 server supports rapid assignment, it responds with a Reply message containing the assigned IPv6 address/prefix and other configuration parameters. If the DHCPv6 server does not support rapid assignment, Assignment involving four messages is performed.

Figure 1 Rapid assignment involving two messages

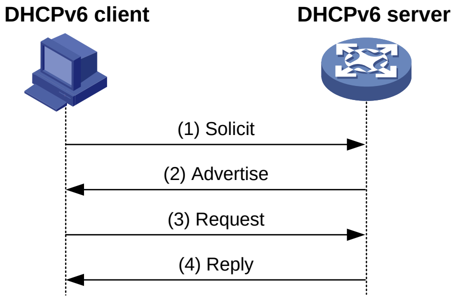


Assignment involving four messages

As shown in Figure 2, four-message assignment operates using the following steps:

1. The DHCPv6 client sends a Solicit message to request an IPv6 address/prefix and other configuration parameters.
2. The DHCPv6 server responds with an Advertise message that contains the assignable address/prefix and other configuration parameters if either of the following conditions exists:
    - The Solicit message does not contain a Rapid Commit option.
    - The DHCPv6 server does not support rapid assignment even though the Solicit message contains a Rapid Commit option.
3. The DHCPv6 client might receive multiple Advertise messages offered by different DHCPv6 servers. It selects an offer according to the receiving sequence and server priority, and sends a Request message to the selected server for confirmation.
4. The DHCPv6 server sends a Reply message to the client, confirming that the address/prefix and other configuration parameters are assigned to the client.

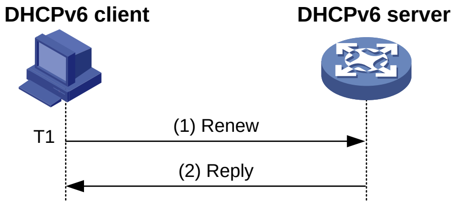
Figure 2 Assignment involving four messages



Address/prefix lease renewal

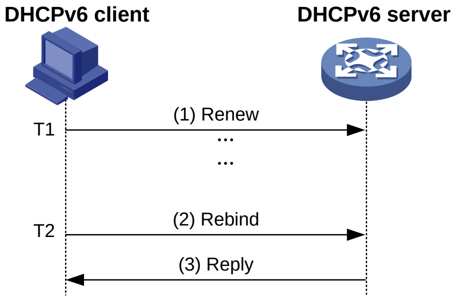
An IPv6 address/prefix assigned by a DHCPv6 server has a valid lifetime. After the valid lifetime expires, the DHCPv6 client cannot use the IPv6 address/prefix. To use the IPv6 address/prefix, the DHCPv6 client must renew the lease time.

Figure 3 Using the Renew message for address/prefix lease renewal



As shown in Figure 3, at T1, the DHCPv6 client sends a Renew message to the DHCPv6 server. The recommended value of T1 is half the preferred lifetime. The DHCPv6 server responds with a Reply message, informing the client whether the lease is renewed.

Figure 4 Using the Rebind message for address/prefix lease renewal



As shown in Figure 4:

- If the DHCPv6 client does not receive a response from the DHCPv6 server after sending a Renew message at T1, it multicasts a Rebind message to all DHCPv6 servers at T2. Typically, the value of T2 is 0.8 times the preferred lifetime.
- The DHCPv6 server responds with a Reply message, informing the client whether the lease is renewed.
- If the DHCPv6 client does not receive a response from any DHCPv6 server before the valid lifetime expires, the client stops using the address/prefix.

For more information about the valid lifetime and the preferred lifetime, see "Configuring basic IPv6 settings."

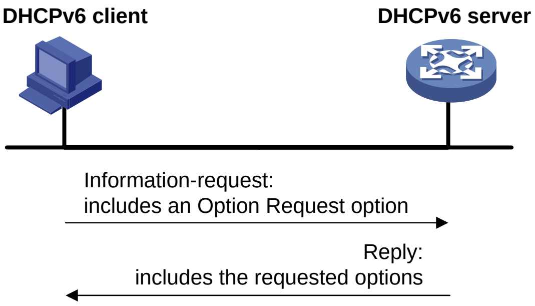
Stateless DHCPv6

Stateless DHCPv6 enables a device that has obtained an IPv6 address/prefix to get other configuration parameters from a DHCPv6 server.

The device performs stateless DHCPv6 if an RA message with the following flags is received from the router during stateless address autoconfiguration:

- The managed address configuration flag (M flag) is set to 0.
- The other stateful configuration flag (O flag) is set to 1.

Figure 5 Stateless DHCPv6 operation



DHCPv6 client
DHCPv6 server
Information-request:
includes an Option Request option
Reply:
includes the requested options

As shown in Figure 5, stateless DHCPv6 operates in the following steps:

1. The DHCPv6 client sends an Information-request message to the multicast address of all DHCPv6 servers and DHCPv6 relay agents. The Information-request message contains an Option Request option that specifies the requested configuration parameters.
2. The DHCPv6 server returns to the client a Reply message containing the requested configuration parameters.
3. The client checks the Reply message. If the obtained configuration parameters match those requested in the Information-request message, the client uses these parameters to complete configuration. If not, the client ignores the configuration parameters. If the client receives multiple replies with configuration parameters matching those requested in the Information-request message, it uses the first received reply.

DHCPv6 options

Option 18

Option 18, also called the interface-ID option, is used by the DHCPv6 relay agent to determine the interface to use to forward RELAY-REPLY message.

The DHCPv6 snooping device adds Option 18 to the received DHCPv6 request message before forwarding it to the DHCPv6 server. The server then assigns IP address to the client based on the client information in Option 18.

Figure 6 Option 18 format

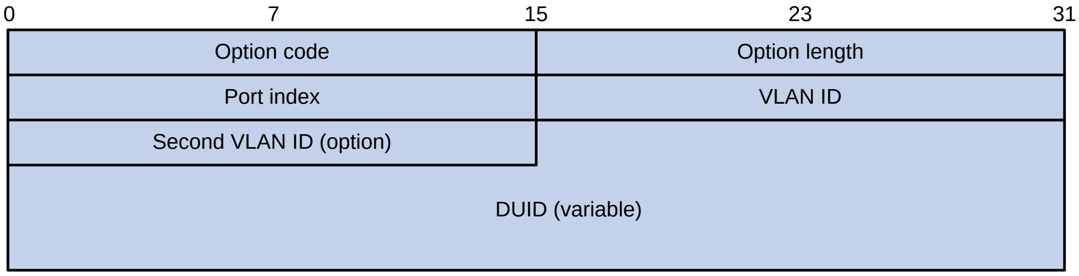


Figure 6 shows the Option 18 format, which includes the following fields:

- **Option code**—Option code. The value is 18.
- **Option length**—Size of the option data.
- **Port index**—Port that receives the DHCPv6 request from the client.
- **VLAN ID**—ID of the outer VLAN.
- **Second VLAN ID**—ID of the inner VLAN. This field is optional. If the received DHCPv6 request does not contain a second VLAN, Option 18 also does not contain it.
- **DUID**—DUID of the DHCPv6 client.

Option 37

Option 37, also called the remote-ID option, is used to identify the client.

The DHCPv6 snooping device adds Option 37 to the received DHCPv6 request message before forwarding it to the DHCPv6 server. This option provides client information about address allocation.

Figure 7 Option 37 format

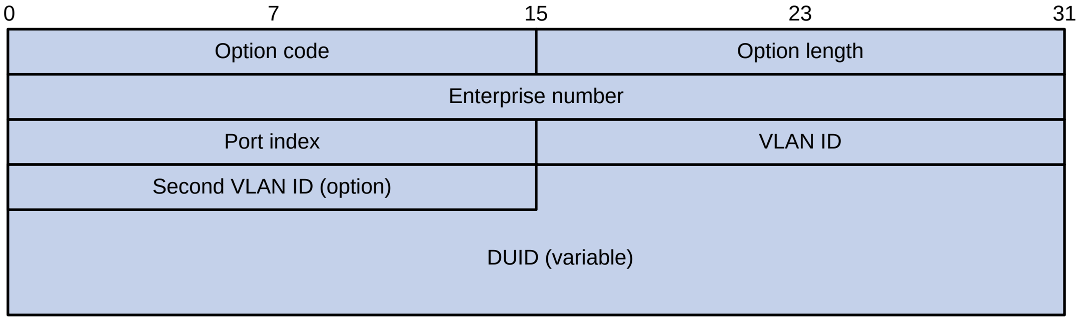

Figure 7 shows the Option 37 format, which includes the following fields:

- **Option code**—Option code. The value is 37.
- **Option length**—Size of the option data.
- **Enterprise number**—Enterprise number.
- **Port index**—Port that receives the DHCPv6 request from the client.
- **VLAN ID**—ID of the outer VLAN.
- **Second VLAN ID**—ID of the inner VLAN. This field is optional. If the received DHCPv6 request does not contain a second VLAN, Option 37 also does not contain it.
- **DUID**—DUID of the DHCPv6 client.

Protocols and standards

- RFC 3736, *Stateless Dynamic Host Configuration Protocol (DHCP) Service for IPv6*
- RFC 3315, *Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*
- RFC 2462, *IPv6 Stateless Address Autoconfiguration*
- RFC 3633, *IPv6 Prefix Options for Dynamic Host Configuration Protocol (DHCP) version 6*

Configuring the DHCPv6 server

About DHCPv6 server

A DHCPv6 server can assign IPv6 addresses, IPv6 prefixes, and other configuration parameters to DHCPv6 clients.

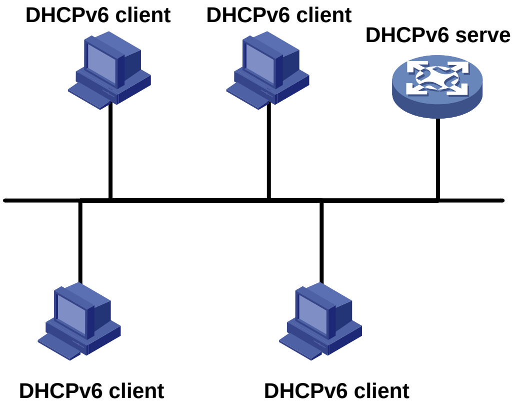
IPv6 address assignment

As shown in Figure 8, the DHCPv6 server assigns IPv6 addresses, domain name suffixes, DNS server addresses, and other configuration parameters to DHCPv6 clients.

The IPv6 addresses assigned to the clients include the following types:

- **Temporary IPv6 addresses**—Frequently changed without lease renewal.
- **Non-temporary IPv6 addresses**—Correctly used by DHCPv6 clients, with lease renewal.

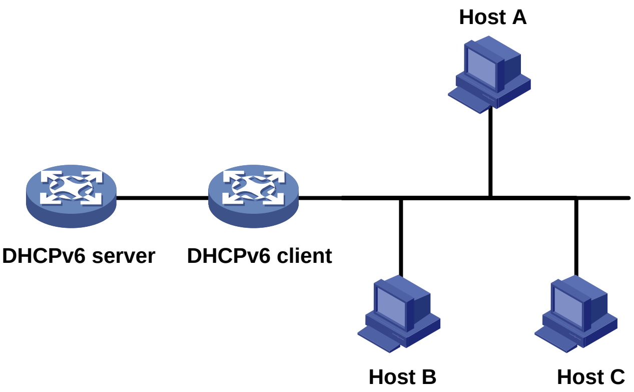
Figure 8 IPv6 address assignment



IPv6 prefix assignment

As shown in Figure 9, the DHCPv6 server assigns an IPv6 prefix to the DHCPv6 client. The client advertises the prefix information in a multicast RA message so that hosts on the subnet can automatically configure their IPv6 addresses by using the prefix.

Figure 9 IPv6 prefix assignment



Concepts

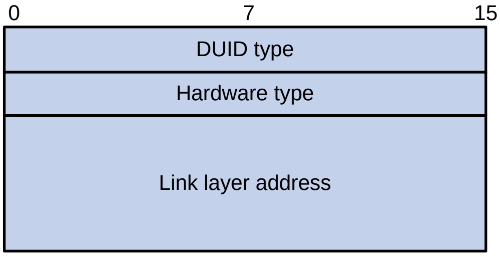
Multicast addresses used by DHCPv6

DHCPv6 uses the multicast address FF05::1:3 to identify all site-local DHCPv6 servers. It uses the multicast address FF02::1:2 to identify all link-local DHCPv6 servers and relay agents.

DUID

A DHCP unique identifier (DUID) uniquely identifies a DHCPv6 device (DHCPv6 client, server, or relay agent). A DHCPv6 device adds its DUID in a sent packet.

Figure 10 DUID-LL format



The device supports the DUID format based on link-layer address (DUID-LL) defined in RFC 3315. Figure 10 shows the DUID-LL format, which includes the following fields:

- **DUID type**—The device supports the DUID type of DUID-LL with the value of 0x0003.
- **Hardware type**—The device supports the hardware type of Ethernet with the value of 0x0001.
- **Link layer address**—Takes the value of the bridge MAC address of the device.

IA

Identified by an IAID, an identity association (IA) provides a construct through which a client manages the obtained addresses, prefixes, and other configuration parameters. A client can have multiple IAs, for example, one for each of its interfaces.

IAID

An IAID uniquely identifies an IA. It is chosen by the client and must be unique on the client.

PD

The DHCPv6 server creates a prefix delegation (PD) for each assigned prefix to record the following details:

- IPv6 prefix.
- Client DUID.
- IAID.
- Valid lifetime.
- Preferred lifetime.
- Lease expiration time.
- IPv6 address of the requesting client.

DHCPv6 address pool

The DHCP server selects IPv6 addresses, IPv6 prefixes, and other parameters from an address pool, and assigns them to the DHCP clients.

Address allocation mechanisms

DHCPv6 supports the following address allocation mechanisms:

- **Static address allocation**—To implement static address allocation for a client, create a DHCPv6 address pool, and manually bind the DUID and IAID of the client to an IPv6 address in the DHCPv6 address pool. When the client requests an IPv6 address, the DHCPv6 server assigns the IPv6 address in the static binding to the client.
- **Dynamic address allocation**—To implement dynamic address allocation for clients, create a DHCPv6 address pool, specify a subnet for the pool, and divide the subnet into temporary and non-temporary IPv6 address ranges. Upon receiving a DHCP request, the DHCPv6 server selects an IPv6 address from the temporary or non-temporary IPv6 address range based on the address type in the client request.

Prefix allocation mechanisms

DHCPv6 supports the following prefix allocation mechanisms:

- **Static prefix allocation**—To implement static prefix allocation for a client, create a DHCPv6 address pool, and manually bind the DUID and IAID of the client to an IPv6 prefix in the DHCPv6 address pool. When the client requests an IPv6 prefix, the DHCPv6 server assigns the IPv6 prefix in the static binding to the client.
- **Dynamic prefix allocation**—To implement dynamic prefix allocation for clients, create a DHCPv6 address pool and a prefix pool, specify a subnet for the address pool, and apply the prefix pool to the address pool. Upon receiving a DHCP request, the DHCPv6 server dynamically selects an IPv6 prefix from the prefix pool in the address pool.

Address pool selection

The DHCPv6 server observes the following principles when selecting an IPv6 address or prefix for a client:

1. If there is an address pool where an IPv6 address is statically bound to the DUID or IAID of the client, the DHCPv6 server selects this address pool. It assigns the statically bound IPv6 address or prefix and other configuration parameters to the client.
2. If the receiving interface has a DHCP policy and the DHCP client matches a user class, the DHCP server selects the address pool that is bound to the matching user class. If no matching user class is found, the server assigns an IP address and other parameters from the default DHCP address pool. If no default address pool is specified or the default address pool does not have assignable IP addresses, the address assignment fails.
3. If the receiving interface has an address pool applied, the DHCP server selects an IPv6 address or prefix and other configuration parameters from this address pool.
4. If the above conditions are not met, the DHCPv6 server selects an address pool depending on the client location.
   - **Client on the same subnet as the server**—The DHCPv6 server compares the IPv6 address of the receiving interface with the subnets of all address pools. It selects the address pool with the longest-matching subnet.
   - **Client on a different subnet than the server**—The DHCPv6 server compares the IPv6 address of the DHCPv6 relay agent interface closest to the client with the subnets of all address pools. It also selects the address pool with the longest-matching subnet.

   To make sure IPv6 address allocation functions correctly, keep the subnet used for dynamic assignment consistent with the subnet where the interface of the DHCPv6 server or DHCPv6 relay agent resides.

IPv6 address/prefix allocation sequence

The DHCPv6 server selects an IPv6 address/prefix for a client in the following sequence:

1. IPv6 address/prefix statically bound to the client's DUID and IAID and expected by the client.

2. IPv6 address/prefix statically bound to the client's DUID and IAID.
3. IPv6 address/prefix statically bound to the client's DUID and expected by the client.
4. IPv6 address/prefix statically bound to the client's DUID.
5. Assignable IPv6 address/prefix in the address pool/prefix pool expected by the client.
6. IPv6 address/prefix that was ever assigned to the client.
7. Assignable IPv6 address/prefix in the address pool/prefix pool.
8. IPv6 address/prefix that was a conflict or passed its lease duration. If no IPv6 address/prefix is assignable, the server does not respond.

If a client moves to another subnet, the DHCPv6 server selects an IPv6 address/prefix from the address pool that matches the new subnet.

Conflicted IPv6 addresses can be assigned to other DHCPv6 clients only after the addresses are in conflict for one hour.

DHCPv6 server tasks at a glance

To configure the DHCPv6 server, perform the following tasks:

1. Configuring the DHCPv6 server to assign IPv6 prefixes, IPv6 addresses, and other network parameters

   Choose the following tasks as needed:
   - Configuring IPv6 prefix assignment
   - Configuring IPv6 address assignment
   - Configuring network parameters assignment
2. Modifying the address pool selection method on the DHCPv6 server

   Choose the following tasks as needed:
   - Configuring the DHCPv6 server on an interface
   - Configuring a DHCPv6 policy for IPv6 address and prefix assignment
3. (Optional.) Setting the DSCP value for DHCPv6 packets sent by the DHCPv6 server
4. (Optional.) Configuring DHCPv6 binding auto backup
5. (Optional.) Advertising subnets assigned to clients
6. (Optional.) Applying a DHCPv6 address pool to a VPN instance
7. (Optional.) Enabling DHCPv6 logging on the DHCPv6 server

Configuring IPv6 prefix assignment

About this task

Use the following methods to configure IPv6 prefix assignment:

- **Configure a static IPv6 prefix binding in an address pool**—If you bind a DUID and an IAID to an IPv6 prefix, the DUID and IAID in a request must match those in the binding before the DHCPv6 server can assign the IPv6 prefix to the DHCPv6 client. If you only bind a DUID to an IPv6 prefix, the DUID in the request must match the DUID in the binding before the DHCPv6 server can assign the IPv6 prefix to the DHCPv6 client.
- **Apply a prefix pool to an address pool**—The DHCPv6 server dynamically assigns an IPv6 prefix from the prefix pool in the address pool to a DHCPv6 client.

Restrictions and guidelines

When you configure IPv6 prefix assignment, follow these restrictions and guidelines:

- An IPv6 prefix can be bound to only one DHCPv6 client. You cannot modify bindings that have been created. To change the binding for a DHCPv6 client, you must delete the existing binding first.
- One address pool can have only one prefix pool applied. You cannot modify prefix pools that have been applied. To change the prefix pool for an address pool, you must remove the prefix pool application first.
- You can apply a prefix pool that has not been created to an address pool. The setting takes effect after the prefix pool is created.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Specify the IPv6 prefixes excluded from dynamic assignment.

   ipv6 dhcp server forbidden-prefix *start-prefix*/*prefix-len* [*end-prefix*/*prefix-len*] [**vpn-instance** *vpn-instance-name*]

   By default, no IPv6 prefixes in the prefix pool are excluded from dynamic assignment.

   If the excluded IPv6 prefix is in a static binding, the prefix still can be assigned to the client.

3. Create a prefix pool.

   ipv6 dhcp prefix-pool *prefix-pool-number* **prefix** { *prefix-number* | *prefix*/*prefix-len* } **assign-len** *assign-len* [**vpn-instance** *vpn-instance-name*]

   This step is required for dynamic prefix assignment.

   If you specify an IPv6 prefix by its ID, make sure the IPv6 prefix is in effect. Otherwise, the configuration does not take effect.

4. Enter DHCP address pool view.

   ipv6 dhcp pool *pool-name*

5. Specify an IPv6 subnet for dynamic assignment.

   network { *prefix/prefix-length* | **prefix** *prefix-number* [*sub-prefix/sub-prefix-length*] } [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

   By default, no IPv6 subnet is specified for dynamic assignment.

   The IPv6 subnets cannot be the same in different address pools.

   If you specify an IPv6 prefix by its ID, make sure the IPv6 prefix is in effect. Otherwise, the configuration does not take effect.

6. Configure the prefix assignment. Choose the options to configure as needed:
   - Configure a static prefix binding:

     static-bind prefix *prefix*/*prefix-len* **duid** *duid* [**iaid** *iaid*] [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*] [**description** *description-text*]

     By default, no static prefix binding is configured.

     To add multiple static IPv6 prefix bindings, repeat this step.
   - Apply the prefix pool to the address pool:

     prefix-pool *prefix-pool-number* [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

     By default, static or dynamic prefix assignment is not configured for an address pool.

Configuring IPv6 address assignment

About this task

Use one of the following methods to configure IPv6 address assignment:

- Configure a static IPv6 address binding in an address pool.

  If you bind a DUID and an IAID to an IPv6 address, the DUID and IAID in a request must match those in the binding before the DHCPv6 server can assign the IPv6 address to the requesting client. If you only bind a DUID to an IPv6 address, the DUID in a request must match the DUID in the binding before the DHCPv6 server can assign the IPv6 address to the requesting client.
- Specify a subnet and address ranges in an address pool.
  - **Non-temporary address assignment**—The server selects addresses from the non-temporary address range specified by the **`address range`** command. If no non-temporary address range is specified, the server selects addresses on the subnet specified by the **`network`** command.
  - **Temporary address assignment**—The server selects addresses from the temporary address range specified by the **`temporary address range`** command. If no temporary address range is specified in the address pool, the DHCPv6 server cannot assign temporary addresses to clients.

Restrictions and guidelines

- You can specify only one non-temporary address range and one temporary address range in an address pool.
- The address ranges specified by the **`address range`** and **`temporary address range`** commands must be on the subnet specified by the **`network`** command. Otherwise, the addresses are unassignable.
- An IPv6 address can be bound to only one DHCPv6 client. You cannot modify bindings that have been created. To change the binding for a DHCPv6 client, you must delete the existing binding first.
- Only one subnet can be specified in an address pool. If you use the **`network`** command multiple times in a DHCPv6 address pool, the most recent configuration takes effect. If you use this command to specify only new lifetimes, the settings do not affect existing leases. The IPv6 addresses assigned after the modification will use the new lifetimes.

Procedure

1. Enter system view.

   ```
   system-view
   ```
2. (Optional.) Specify the IPv6 addresses excluded from dynamic assignment.

   ```
   ipv6 dhcp server forbidden-address start-ipv6-address
   [ end-ipv6-address ] [ vpn-instance vpn-instance-name ]
   ```

   By default, all IPv6 addresses except for the DHCPv6 server's IP address in a DHCPv6 address pool are assignable.

   If the excluded IPv6 address is in a static binding, the address still can be assigned to the client.
3. Enter DHCPv6 address pool view.

   ```
   ipv6 dhcp pool pool-name
   ```
4. Specify an IPv6 subnet for dynamic assignment.

   ```
   network { prefix/prefix-length | prefix prefix-number
   [ sub-prefix/sub-prefix-length ] } [ preferred-lifetime
   preferred-lifetime valid-lifetime valid-lifetime ]
   ```

   By default, no IPv6 address subnet is specified.

The IPv6 subnets cannot be the same in different address pools.

If you specify an IPv6 prefix by its ID, make sure the IPv6 prefix is in effect. Otherwise, the configuration does not take effect.

5. (Optional.) Specify a non-temporary IPv6 address range.

   address range *start-ipv6-address end-ipv6-address* [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

   By default, no non-temporary IPv6 address range is specified, and all unicast addresses on the subnet are assignable.

6. (Optional.) Specify a temporary IPv6 address range.

   temporary address range *start-ipv6-address end-ipv6-address* [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

   By default, no temporary IPv6 address range is specified, and the DHCPv6 server cannot assign temporary IPv6 addresses.

7. (Optional.) Create a static binding.

   static-bind address *ipv6-address/addr-prefix-length* **duid** *duid* [**iaid** *iaid*] [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*] [**description** *description-text*]

   By default, no static binding is configured.

   To add more static bindings, repeat this step.

Configuring network parameters assignment

About network parameters assignment

In addition to IPv6 prefixes and IPv6 addresses, you can configure the following network parameters in an address pool:

- A maximum of eight DNS server addresses.
- One domain name.
- A maximum of eight SIP server addresses.
- A maximum of eight SIP server domain names.

You can configure network parameters on a DHCPv6 server by using one of the following methods:

- Configure network parameters in a DHCPv6 address pool.
- Configure network parameters in a DHCPv6 option group, and specify the option group for a DHCPv6 address pool.

Network parameters configured in a DHCPv6 address pool take precedence over those configured in a DHCPv6 option group.

Configuring network parameters in a DHCPv6 address pool

1. Enter system view.

   system-view

2. Enter DHCPv6 address pool view.

   ipv6 dhcp pool *pool-name*

3. Specify an IPv6 subnet for dynamic assignment.

network { *prefix/prefix-length* | **prefix** *prefix-number* [*sub-prefix/sub-prefix-length*] } [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

By default, no IPv6 subnet is specified.

The IPv6 subnets cannot be the same in different address pools.

If you specify an IPv6 prefix by its ID, make sure the IPv6 prefix is in effect. Otherwise, the configuration does not take effect.

4. Specify a DNS server address.

   dns-server *ipv6-address*

   By default, no DNS server address is specified.

5. Specify a domain name.

   domain-name *domain-name*

   By default, no domain name is specified.

6. Specify a SIP server address or domain name.

   sip-server { **address** *ipv6-address* | **domain-name** *domain-name* }

   By default, no SIP server address or domain name is specified.

7. Configure a self-defined DHCPv6 option.

   option *code* **hex** *hex-string*

   By default, no self-defined DHCPv6 option is configured.

Configuring network parameters in a DHCPv6 option group

About this task

A DHCPv6 option group can be created by using the following methods:

- Create a static DHCPv6 option group by using the **ipv6 dhcp option-group** command. The static DHCPv6 option group takes precedence over the dynamic DHCPv6 option group.
- When the device acts as a DHCPv6 client, it automatically creates a dynamic DHCPv6 option group for saving the obtained parameters. For more information about creating a dynamic DHCPv6 option group, see "Configuring the DHCPv6 client."

Procedure

1. Enter system view.

   system-view

2. Create a static DHCPv6 option group and enter its view.

   ipv6 dhcp option-group *option-group-number*

3. Specify a DNS server address.

   dns-server *ipv6-address*

   By default, no DNS server address is specified.

4. Specify a domain name suffix.

   domain-name *domain-name*

   By default, no domain name suffix is specified.

5. Specify a SIP server address or domain name.

   sip-server { **address** *ipv6-address* | **domain-name** *domain-name* }

   By default, no SIP server address or domain name is specified.

6. Configure a self-defined DHCPv6 option.

   option *code* **hex** *hex-string*

By default, no self-defined DHCPv6 option is configured.

7. Return to system view.

   quit

8. Enter DHCPv6 address pool view.

   ipv6 dhcp pool *pool-name*

9. Specify a DHCPv6 option group.

   option-group *option-group-number*

   By default, no DHCPv6 option group is specified.

Configuring the DHCPv6 server on an interface

About this task

Enable the DHCP server and configure one of the following address/prefix assignment methods on an interface:

- **Apply an address pool on the interface**—The DHCPv6 server selects an IPv6 address/prefix from the applied address pool for a requesting client. If there is no assignable IPv6 address/prefix in the address pool, the DHCPv6 server cannot to assign an IPv6 address/prefix to a client.
- **Configure global address assignment on the interface**—The DHCPv6 server selects an IPv6 address/prefix in the global DHCPv6 address pool that matches the server interface address or the DHCPv6 relay agent address for a requesting client.

If you configure both methods on an interface, the DHCPv6 server uses the specified address pool for address assignment without performing global address assignment.

Restrictions and guidelines

- An interface cannot act as a DHCPv6 server and DHCPv6 relay agent at the same time.
- Do not enable DHCPv6 server and DHCPv6 client on the same interface.
- You can apply an address pool that has not been created to an interface. The setting takes effect after the address pool is created.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the DHCPv6 server on the interface.

   ipv6 dhcp select server

   By default, the interface does not act as a DHCP server or a DHCP relay agent, and discards DHCPv6 packets from DHCPv6 clients.

4. Configure an assignment method.
   - Configure global address assignment.

     ipv6 dhcp server { **allow-hint** | **preference** *preference-value* | **rapid-commit** } *

     By default, the server supports global address assignment, but does not support desired address/prefix assignment or rapid assignment. The server preference is not set.
   - Apply a DHCPv6 address pool to the interface.

     ipv6 dhcp server apply pool *pool-name* [**allow-hint** | **preference** *preference-value* | **rapid-commit**] *

By default, no DHCPv6 address pool is applied to the interface.

Configuring a DHCPv6 policy for IPv6 address and prefix assignment

About this task

In a DHCPv6 policy, each DHCPv6 user class has a bound DHCPv6 address pool. Clients matching different user classes obtain IPv6 addresses, IPv6 prefixes, and other parameters from different address pools. When receiving a DHCPv6 request, the DHCPv6 server compares the packet against the user classes in the order that they are configured.

If a match is found and the bound address pool has assignable IPv6 addresses or prefixes, the server uses the address pool for assignment. If the bound address pool does not have assignable IPv6 addresses or prefixes, the assignment fails.

If no match is found, the server uses the default DHCPv6 address pool for assignment. If no default address pool is specified or the default address pool does not have assignable IPv6 addresses or prefixes, the assignment fails.

For successful assignment, make sure the applied DHCPv6 policy and the bound address pools exist.

A match rule cannot match an option added by the DHCPv6 device, for example, Option 18 or Option 37.

Procedure

1. Enter system view.

   system-view

2. Create a DHCPv6 user class and enter DHCPv6 user class view.

   ipv6 dhcp class *class-name*

3. Configure a match rule for the DHCPv6 user class.

   if-match rule *rule-number* { **option** *option-code* [**ascii** *ascii-string* [**offset** *offset* | **partial**] | **hex** *hex-string* [**mask** *mask* | **offset** *offset* **length** *length* | **partial**]] | **relay-agent** *gateway-ipv6-address* }

   By default, no match rule is configured for a DHCPv6 user class.

4. Return to system view.

   quit

5. Create a DHCPv6 policy and enter DHCPv6 policy view.

   ipv6 dhcp policy *policy-name*

   The DHCPv6 policy takes effect only after it is applied to the interface that acts as the DHCPv6 server.

6. Specify a DHCPv6 address pool for a DHCPv6 user class.

   class *class-name* **pool** *pool-name*

   By default, no address pool is specified for a user class.

7. (Optional.) Specify the default DHCPv6 address pool.

   default pool *pool-name*

   By default, the default address pool is not specified.

8. Return to system view.

   quit

9. Enter interface view.

```
interface interface-type interface-number
```

10. Apply the DHCPv6 policy to the interface.

```
ipv6 dhcp apply-policy policy-name
```

By default, no DHCPv6 policy is applied to an interface.

Setting the DSCP value for DHCPv6 packets sent by the DHCPv6 server

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet.

Procedure

1. Enter system view.

```
system-view
```

2. Set the DSCP value for DHCPv6 packets sent by the DHCPv6 server.

```
ipv6 dhcp dscp dscp-value
```

By default, the DSCP value in DHCPv6 packets sent by the DHCPv6 server is 56.

Configuring DHCPv6 binding auto backup

About this task

The auto backup feature saves DHCPv6 bindings to a backup file, and allows the DHCPv6 server to download the bindings from the backup file at the server reboot. The bindings include the lease bindings and conflicted IPv6 addresses. They cannot survive a reboot on the DHCPv6 server.

The DHCPv6 server does not provide services during the download process. If a connection error occurs during the process and cannot be repaired in a short amount of time, you can terminate the download operation. Manual interruption allows the DHCPv6 server to provide services without waiting for the connection to be repaired.

Procedure

1. Enter system view.

```
system-view
```

2. Configure the DHCPv6 server to back up the bindings to a file.

```
ipv6 dhcp server database filename { filename | url url [ username
username [ password { cipher | simple } string ] ] }
```

By default, the DHCPv6 server does not back up the DHCPv6 bindings.

With this command executed, the DHCPv6 server backs up its bindings immediately and runs auto backup.

3. (Optional.) Manually save the DHCPv6 bindings to the backup file.

```
ipv6 dhcp server database update now
```

4. (Optional.) Set the waiting time after a DHCPv6 binding change for the DHCPv6 server to update the backup file.

```
ipv6 dhcp server database update interval interval
```

By default, the DHCP server waits 300 seconds to update the backup file after a DHCP binding change. If no DHCP binding changes, the backup file is not updated.

5. (Optional.) Terminate the download of DHCPv6 bindings from the backup file.

ipv6 dhcp server database update stop

This command only triggers one termination.

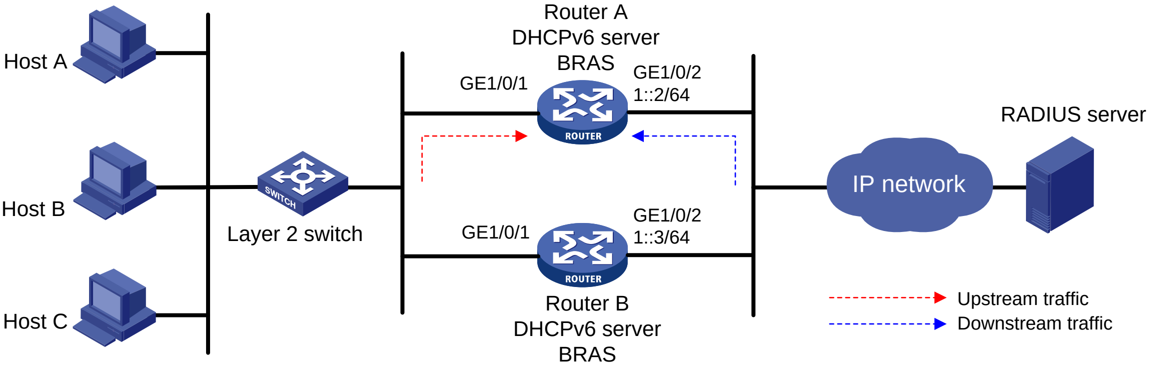
Advertising subnets assigned to clients

About this task

This feature enables the route management module to advertise subnets assigned to DHCPv6 clients. This feature achieves symmetric routing for traffic of the same host.

As shown in Figure 11, Router A and Router B act as both the DHCPv6 server and the BRAS device. The BRAS devices send accounting packets to the RADIUS server. To enable the BRAS devices to collect correct accounting information for each RADIUS user, configure the DHCPv6 server to advertise subnets assigned to clients. The upstream and downstream traffic of a RADIUS user will pass through the same BRAS device.

Figure 11 Network diagram



Procedure

1. Enter system view.

   system-view

2. Enter DHCP address pool view.

   ipv6 dhcp pool *pool-name*

3. Advertise the subnet that is assigned to DHCPv6 clients.

   network { *prefix/prefix-length* | **prefix** *prefix-number* [*sub-prefix/sub-prefix-length*] } [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*] **export-route**

   By default, the subnet assigned to DHCPv6 clients is not advertised.

Applying a DHCPv6 address pool to a VPN instance

About this task

If a DHCPv6 address pool is applied to a VPN instance, the DHCPv6 server assigns IPv6 addresses in this address pool to clients in the VPN instance. Addresses in this address pool will not be assigned to clients on the public network.

The DHCPv6 server can obtain the VPN instance to which a DHCPv6 client belongs from the following information:

- The client's VPN information stored in authentication modules.
- The VPN information of the DHCPv6 server's interface that receives DHCPv6 packets from the client.

The VPN information from authentication modules takes priority over the VPN information of the receiving interface.

Procedure

1. Enter system view.
   `system-view`
2. Enter DHCP address pool view.
   `ipv6 dhcp pool` *`pool-name`*
3. Apply the address pool to a VPN instance.
   `vpn-instance` *`vpn-instance-name`*
   By default, the address pool is not applied to any VPN instance.

Enabling DHCPv6 logging on the DHCPv6 server

About this task

The DHCPv6 logging feature enables the DHCPv6 server to generate DHCPv6 logs and send them to the information center. The information helps administrators locate and solve problems. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

As a best practice, disable this feature if the log generation affects the device performance or reduces the address and prefix allocation efficiency. For example, this situation might occur when a large number of clients frequently come online or go offline.

Procedure

1. Enter system view.
   `system-view`
2. Enable DHCPv6 logging.
   `ipv6 dhcp log enable`
   By default, DHCPv6 logging is disabled.

Display and maintenance commands for DHCPv6 server

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display the DUID of the local device.	**`display ipv6 dhcp duid`**
Display information about a DHCPv6 option group.	**`display ipv6 dhcp option-group`** [*`option-group-number`*]
Display DHCPv6 address pool information.	**`display ipv6 dhcp pool`** [*`pool-name`* | **`vpn-instance`** *`vpn-instance-name`*]

Task	Command
Display prefix pool information.	**display ipv6 dhcp prefix-pool** [*prefix-pool-number*] [**vpn-instance** *vpn-instance-name*]
Display DHCPv6 server information on an interface.	**display ipv6 dhcp server** [**interface** *interface-type interface-number*]
Display information about IPv6 address conflicts.	**display ipv6 dhcp server conflict** [**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*]
Display information about DHCPv6 binding auto backup	**display ipv6 dhcp server database**
Display information about expired IPv6 addresses.	**display ipv6 dhcp server expired** [[**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]
Display information about IPv6 address bindings.	**display ipv6 dhcp server ip-in-use** [[**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]
Display information about IPv6 prefix bindings.	**display ipv6 dhcp server pd-in-use** [**pool** *pool-name* | [**prefix** *prefix/prefix-len*] [**vpn-instance** *vpn-instance-name*]]
Display packet statistics on the DHCPv6 server.	**display ipv6 dhcp server statistics** [**pool** *pool-name* | **vpn-instance** *vpn-instance-name*]
Clear information about IPv6 address conflicts.	**reset ipv6 dhcp server conflict** [**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*]
Clear information about expired IPv6 address bindings.	**reset ipv6 dhcp server expired** [[**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]
Clear information about IPv6 address bindings.	**reset ipv6 dhcp server ip-in-use** [[**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]
Clear information about IPv6 prefix bindings.	**reset ipv6 dhcp server pd-in-use** [**pool** *pool-name* | [**prefix** *prefix/prefix-len*] [**vpn-instance** *vpn-instance-name*]]
Clear packets statistics on the DHCPv6 server.	**reset ipv6 dhcp server statistics** [**vpn-instance** *vpn-instance-name*]

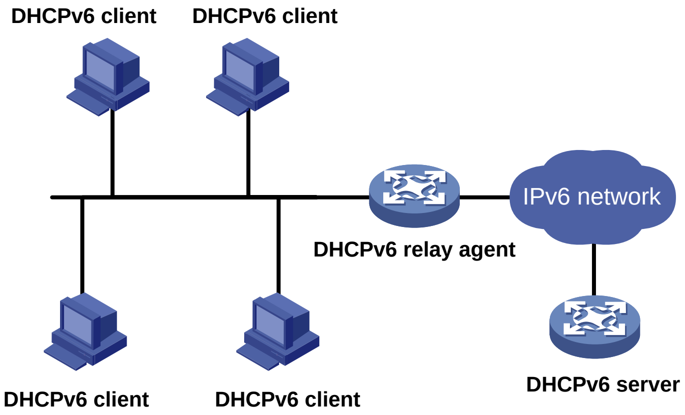
Configuring the DHCPv6 relay agent

About DHCPv6 relay agent

Typical application

A DHCPv6 client usually uses a multicast address to contact the DHCPv6 server on the local link to obtain an IPv6 address and other configuration parameters. As shown in Figure 12, if the DHCPv6 server resides on another subnet, the DHCPv6 clients need a DHCPv6 relay agent to contact the server. The relay agent feature avoids deploying a DHCPv6 server on each subnet.

Figure 12 Typical DHCPv6 relay agent application

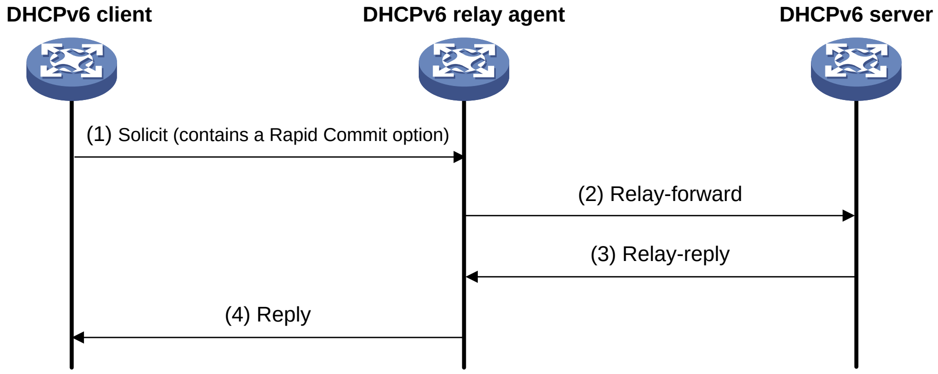


DHCPv6 relay agent operating process

As shown in Figure 13, a DHCPv6 client obtains an IPv6 address and other network configuration parameters from a DHCPv6 server through a DHCPv6 relay agent. The following example uses rapid assignment to describe the process:

- The DHCPv6 client sends a Solicit message containing the Rapid Commit option to the multicast address FF02::1:2 of all the DHCPv6 servers and relay agents.
- After receiving the Solicit message, the DHCPv6 relay agent encapsulates the message into the Relay Message option of a Relay-forward message, and sends the message to the DHCPv6 server.
- After obtaining the Solicit message from the Relay-forward message, the DHCPv6 server performs the following tasks:
  - Selects an IPv6 address and other required parameters.
  - Adds them to a reply that is encapsulated within the Relay Message option of a Relay-reply message.
  - Sends the Relay-reply message to the DHCPv6 relay agent.
- The DHCPv6 relay agent obtains the reply from the Relay-reply message and sends the reply to the DHCPv6 client.
- The DHCPv6 client uses the IPv6 address and other network parameters assigned by the DHCPv6 server to complete network configuration.

Figure 13 Operating process of a DHCPv6 relay agent



DHCPv6 relay agent tasks at a glance

To configure a DHCPv6 relay agent, perform the following tasks:

1. Enabling the DHCPv6 relay agent on an interface
2. Specifying DHCPv6 servers on the relay agent
3. (Optional.) Specifying a gateway address for DHCPv6 clients
4. (Optional.) Setting the DSCP value for DHCPv6 packets sent by the DHCPv6 relay agent
5. (Optional.) Specifying a padding mode for the Interface-ID option

Enabling the DHCPv6 relay agent on an interface

Restrictions and guidelines

As a best practice, do not enable DHCPv6 relay agent and DHCPv6 client on the same interface.

Procedure

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Enable DHCPv6 relay agent on the interface.
   `ipv6 dhcp select relay`
   By default, the DHCPv6 relay agent is disabled on the interface.

Specifying DHCPv6 servers on the relay agent

Specifying DHCPv6 server IP addresses

Restrictions and guidelines

- You can use the **`ipv6 dhcp relay server-address`** command to specify a maximum of eight DHCPv6 servers on the DHCPv6 relay agent interface. The DHCPv6 relay agent forwards DHCP requests to all the specified DHCPv6 servers.

- If a DHCPv6 server address is a link-local address or multicast address, you must specify an outgoing interface by using the **`interface`** keyword in this command. Otherwise, DHCPv6 packets might fail to reach the DHCPv6 server.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Specify a DHCPv6 server.

   `ipv6 dhcp relay server-address` *`ipv6-address`* [**`interface`** *`interface-type interface-number`*]

   By default, no DHCPv6 server is specified.

Specifying DHCPv6 servers for a DHCPv6 address pool on the DHCPv6 relay agent

About this task

This feature allows DHCPv6 clients of the same type to obtain IPv6 addresses, IPv6 prefixes, and other configuration parameters from the DHCPv6 servers in the matching DHCPv6 address pool.

It applies to scenarios where the DHCPv6 relay agent connects to clients of the same access type but classified into different types by their locations. In this case, the relay interface typically has no IPv6 address configured. You can use the **`gateway-list`** command to specify the gateway addresses for clients matching the same DHCPv6 address pool.

Upon receiving a DHCPv6 Solicit or Request from a client that matches a DHCPv6 address pool, the relay agent processes the packet as follows:

- Fills the **link-address** field of the packet with a specified gateway address.
- Forwards the packet to all DHCPv6 servers in the matching DHCPv6 address pool.

The DHCPv6 servers select a DHCPv6 address pool according to the gateway address.

Restrictions and guidelines

- You can specify a maximum of eight DHCPv6 servers for one DHCPv6 address pool for high availability. The relay agent forwards DHCPv6 Solicit and Request packets to all DHCPv6 servers in the DHCPv6 address pool.
- If this feature is used in the PPPoE scenario, execute the **`ipv6 dhcp relay client-information record`** command to enable the DHCPv6 relay agent to record relay entries. When a PPPoE user gets offline, the DHCPv6 relay agent locates the matching relay entry and sends a Release message to the DHCPv6 server.
- If this feature is used in the PPPoE scenario, you do not need to execute the **`ipv6 dhcp select relay`** command. This is because the **`remote-server`** command is a must in this configuration task and it implies that this device is a relay device.

Procedure

1. Enter system view.

   `system-view`

2. Create a DHCPv6 address pool and enter its view.

   `ipv6 dhcp pool` *`pool-name`*

3. Specify gateway addresses for the clients matching the DHCPv6 address pool.

```
gateway-list ipv6-address&<1-8>
```

By default, no gateway address is specified.

4. Specify DHCPv6 servers for the DHCPv6 address pool.

   ```
   remote-server ipv6-address [ interface interface-type
   interface-number ]
   ```

   By default, no DHCPv6 server is specified for the DHCPv6 address pool.

Specifying a gateway address for DHCPv6 clients

About this task

By default, the DHCPv6 relay agent fills the **link-address** field of DHCPv6 Solicit and Request packets with the first IPv6 address of the relay interface. You can specify a gateway address on the relay agent for DHCPv6 clients. The DHCPv6 relay agent uses the specified gateway address to fill the **link-address** field of DHCPv6 Solicit and Request packets.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Specify a gateway address for DHCPv6 clients.

   ```
   ipv6 dhcp relay gateway ipv6-address
   ```

   By default, the DHCPv6 relay agent uses the first IPv6 address of the relay interface as the clients' gateway address.

Setting the DSCP value for DHCPv6 packets sent by the DHCPv6 relay agent

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Set the DSCP value for DHCPv6 packets sent by the DHCPv6 relay agent.

   ```
   ipv6 dhcp dscp dscp-value
   ```

   The default DSCP value is 56.

Specifying a padding mode for the Interface-ID option

About this task

This feature enables the relay agent to fill the Interface-ID option in the specified mode. When receiving a DHCPv6 packet from a client, the relay agent fills the Interface-ID option in the mode and then forwards the packet to the DHCPv6 server.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Specify a padding mode for the Interface-ID option.

   `ipv6 dhcp relay interface-id` { **`bas`** | **`interface`** }

   By default, the relay agent fills the Interface-ID option with the interface index of the interface.

Display and maintenance commands for DHCPv6 relay agent

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display the DUID of the local device.	**`display ipv6 dhcp duid`**
Display DHCPv6 server addresses specified on the DHCPv6 relay agent.	**`display ipv6 dhcp relay server-address`** [**`interface`** *`interface-type interface-number`*]
Display packet statistics on the DHCPv6 relay agent.	**`display ipv6 dhcp relay statistics`** [**`interface`** *`interface-type interface-number`*]
Clear packets statistics on the DHCPv6 relay agent.	**`reset ipv6 dhcp relay statistics`** [**`interface`** *`interface-type interface-number`*]

Configuring the DHCPv6 client

About the DHCPv6 client

With DHCPv6 client configured, an interface can obtain configuration parameters from the DHCPv6 server.

A DHCPv6 client can use DHCPv6 to complete the following functions:

- Obtain an IPv6 address, an IPv6 prefix, or both, and obtain other configuration parameters. If DHCPv6 server is enabled on the device, the client can automatically save the obtained parameters to a DHCPv6 option group. With the obtained IPv6 prefix, the client can generate its global unicast address.
- Support stateless DHCPv6 to obtain configuration parameters except IPv6 address and IPv6 prefix. The client obtains an IPv6 address through stateless IPv6 address autoconfiguration. If the client receives an RA message with the M flag set to 0 and the O flag set to 1 during address acquisition, stateless DHCPv6 starts.

Restrictions and guidelines: DHCPv6 client configuration

Do not configure the DHCPv6 client on the same interface as the DHCPv6 server or the DHCPv6 relay agent.

DHCPv6 client tasks at a glance

To configure a DHCPv6 client, perform the following tasks:

1. (Optional.) Configuring the DHCPv6 client DUID
2. Configuring the DHCPv6 client to obtain IPv6 addresses, IPv6 prefixes and other network parameters

   Choose the following tasks as needed:

   - Configuring IPv6 address acquisition
   - Configuring IPv6 prefix acquisition
   - Configuring IPv6 address and prefix acquisition
   - Configuring acquisition of configuration parameters except IP addresses and prefixes
3. (Optional.) Setting the DSCP value for DHCPv6 packets sent by the DHCPv6 client

Configuring the DHCPv6 client DUID

About this task

The DUID of a DHCPv6 client is the globally unique identifier of the client. The client pads its DUID into Option 1 of the DHCPv6 packet that it sends to the DHCPv6 server. The DHCPv6 server can assign specific IPv6 addresses or prefixes to DHCPv6 clients with specific DUIDs.

Restrictions and guidelines

Make sure the DUID that you configure is unique.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the DHCPv6 client DUID.

   ipv6 dhcp client duid { **ascii** *ascii-string* | **hex** *hex-string* | **mac** *interface-type interface-number* }

   By default, the interface uses the device bridge MAC address to generate its DHCPv6 client DUID.

Configuring IPv6 address acquisition

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the interface to use DHCPv6 to obtain an IPv6 address and other configuration parameters.

   ipv6 address dhcp-alloc [**option-group** *group-number* | **rapid-commit**] *****

   By default, the interface does not use DHCPv6 for IPv6 address acquisition.

Configuring IPv6 prefix acquisition

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the interface to use DHCPv6 to obtain an IPv6 prefix and other configuration parameters.

   ipv6 dhcp client pd *prefix-number* [**option-group** *group-number* | **rapid-commit**] *

   By default, the interface does not use DHCPv6 for IPv6 prefix acquisition.

Configuring IPv6 address and prefix acquisition

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the interface to use DHCPv6 to obtain an IPv6 address, an IPv6 prefix, and other configuration parameters.

   ipv6 dhcp client stateful prefix *prefix-number* [**option-group** *option-group-number* | **rapid-commit**] *

   By default, the interface does not use DHCPv6 for IPv6 address and prefix acquisition.

Configuring acquisition of configuration parameters except IP addresses and prefixes

About this task

When a DHCPv6 client has obtained an IPv6 address and prefix, you can configure the following methods for the client to obtain other network configuration parameters:

- Execute the **`ipv6 address auto`** command to enable an interface to automatically generate an IPv6 global unicast address and a link-local address. Then stateless DHCPv6 will be triggered when the M flag is set to 0 and the O flag is set to 1 in a received RA message. For more information about the commands, see *Layer 3—IP services Command Reference*.
- Executing the **`ipv6 dhcp client stateless enable`** command on an interface to enable the interface to act as a DHCPv6 client to obtain configuration parameters from a DHCPv6 server.

If you execute both the **`ip address auto`** and **`ipv6 dhcp client stateless enable`** commands, the interface acts as follows:

- Generate a global unicast address and a link-local address.
- Obtain other configuration parameters from a DHCPv6 server.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enter interface view.
   ```
   interface interface-type interface-number
   ```
3. Configure the interface to support stateless DHCPv6. Choose the options to configure as needed:
   - Enable stateless IPv6 address autoconfiguration:
     ```
     ipv6 address auto
     ```
   - Configure the client to obtain network parameters from DHCPv6 servers:
     ```
     ipv6 dhcp client stateless enable
     ```

   By default, the interface does not support stateless DHCPv6.

Setting the DSCP value for DHCPv6 packets sent by the DHCPv6 client

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Set the DSCP value for DHCPv6 packets sent by the DHCPv6 client.
   ```
   ipv6 dhcp client dscp dscp-value
   ```
   By default, the DSCP value in DHCPv6 packets sent by the DHCPv6 client is 56.

Display and maintenance commands for DHCPv6 client

Execute the **display** commands in any view, and execute the **reset** command in user view.

Task	Command
Display the DHCPv6 client information.	**display ipv6 dhcp client** [**interface** *interface-type interface-number*]
Display the DHCPv6 client statistics.	**display ipv6 dhcp client statistics** [**interface** *interface-type interface-number*]
Clear the DHCPv6 client statistics.	**reset ipv6 dhcp client statistics** [**interface** *interface-type interface-number*]

Contents

Configuring DNS

About DNS

Domain Name System (DNS) is a distributed database used by TCP/IP applications to translate domain names into IP addresses. The domain name-to-IP address mapping is called a DNS entry.

Types of DNS services

DNS services can be static or dynamic. After a user specifies a name, the device checks the static name resolution table for an IP address. If no IP address is available, it uses a DNS server group or a DNS server for dynamic name resolution, which takes more time than static name resolution. To improve efficiency, you can put frequently queried name-to-IP address mappings in the local static name resolution table.

Static domain name resolution

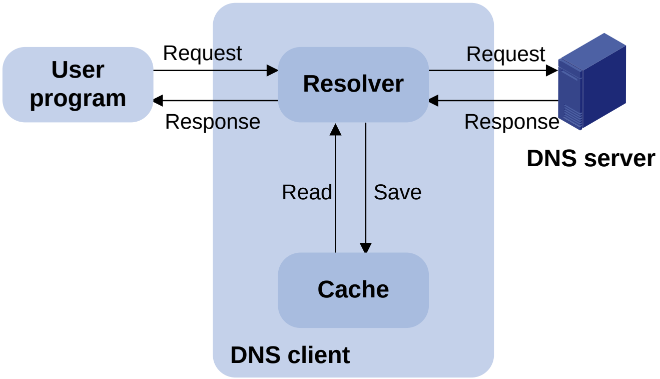
Static domain name resolution means manually creating mappings between domain names and IP addresses. For example, you can create a static DNS mapping for a device so that you can Telnet to the device by using the domain name.

DNS server-based domain name resolution

Architecture

Figure 1 shows the relationship between the user program, DNS client, and DNS server. The DNS client includes the resolver and cache. The user program and DNS client can run on the same device or different devices. The DNS server and the DNS client usually run on different devices.

Figure 1 DNS server-based dynamic domain name resolution



The device can function as a DNS client, but not a DNS server.

If an alias is configured for a domain name on the DNS server, the device can resolve the alias into the IP address of the host.

Resolution process

The DNS server-based dynamic domain name resolution process is as follows:

1. A user program sends a name query to the resolver of the DNS client.

2. The DNS resolver looks up the local domain name cache for a match. If the resolver finds a match, it sends the corresponding IP address back. If not, it sends a query to the DNS server.
3. The DNS server looks up the corresponding IP address of the domain name in its DNS database. If no match is found, the server sends a query to other DNS servers. This process continues until a result, whether successful or not, is returned.
4. After receiving a response from the DNS server, the DNS client returns the resolution result to the user program.

Caching

DNS server-based dynamic domain name resolution allows the DNS client to store latest DNS entries in the DNS cache. The DNS client does not need to send a request to the DNS server for a repeated query within the aging time. To make sure the entries from the DNS server are up to date, a DNS entry is removed when its aging timer expires. The DNS server determines how long a mapping is valid, and the DNS client obtains the aging information from DNS responses.

DNS suffixes

You can configure a domain name suffix list so that the resolver can use the list to supply the missing part of an incomplete name.

For example, you can configure **com** as the suffix for aabbcc.com. The user only needs to enter **aabbcc** to obtain the IP address of aabbcc.com. The resolver adds the suffix and delimiter before passing the name to the DNS server.

The name resolver handles the queries based on the domain names that the user enters:

- If the user enters a domain name without a dot (.) (for example, aabbcc), the resolver considers the domain name to be a host name. It adds a DNS suffix to the host name before performing the query operation. If no match is found for any host name and suffix combination, the resolver uses the user-entered domain name (for example, aabbcc) for the IP address query.
- If the user enters a domain name with a dot (.) among the letters (for example, www.aabbcc), the resolver directly uses this domain name for the query operation. If the query fails, the resolver adds a DNS suffix for another query operation.
- If the user enters a domain name with a dot (.) at the end (for example, aabbcc.com.), the resolver considers the domain name an FQDN and returns the successful or failed query result. The dot at the end of the domain name is considered a terminating symbol.

DNS proxy

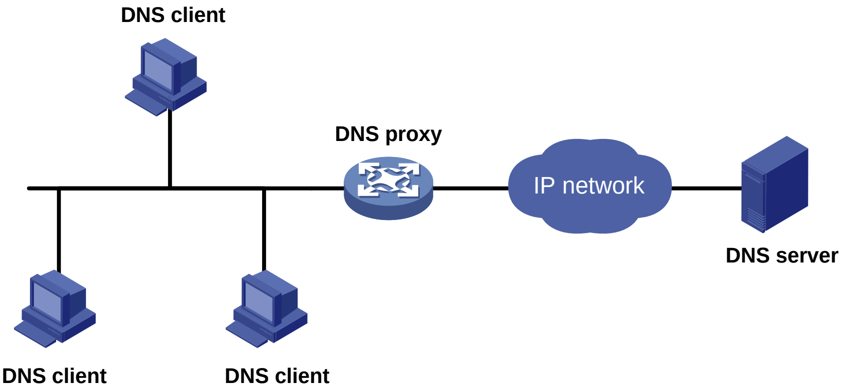
The DNS proxy performs the following functions:

- Forwards the request from the DNS client to the designated DNS server.
- Conveys the reply from the DNS server to the client.

The DNS proxy simplifies network management. When the DNS server address is changed, you can change the configuration only on the DNS proxy instead of on each DNS client.

Figure 2 shows the typical DNS proxy application.

Figure 2 DNS proxy application



A DNS proxy operates as follows:

1. A DNS client considers the DNS proxy as the DNS server, and sends a DNS request to the DNS proxy. The destination address of the request is the IP address of the DNS proxy.
2. The DNS proxy searches the local static domain name resolution table and dynamic domain name resolution cache after receiving the request. If the requested information is found, the DNS proxy returns a DNS reply to the client.
3. If the requested information is not found, the DNS proxy forwards the request as follows:
    a. If a matching domain name rule exists, the proxy forwards the request to DNS servers in the DNS server group bound to the rule.
    b. If no matching DNS server group exists but a DNS server is specified, the DNS proxy sends the request to the DNS server for domain name resolution.
4. After receiving a reply from the DNS server, the DNS proxy records the DNS mapping and forwards the reply to the DNS client.

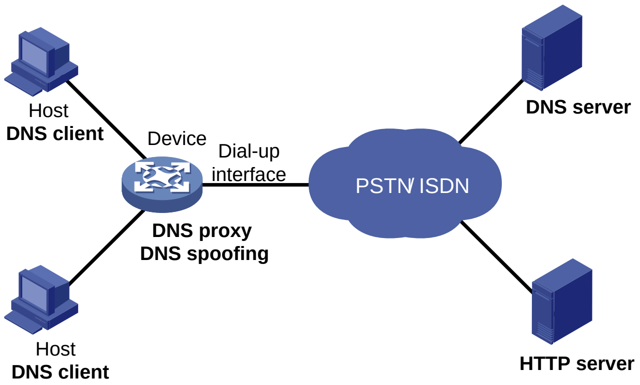
If no DNS server is designated or no route is available to the designated DNS server, the DNS proxy does not forward DNS requests.

DNS spoofing

As shown in Figure 3, DNS spoofing is applied to the dial-up network.

- The device connects to a PSTN network through a dial-up interface. The device triggers the establishment of a dial-up connection only when packets are to be forwarded through the dial-up interface.
- The device acts as a DNS proxy and is specified as a DNS server on the hosts. After the dial-up connection is established, the device dynamically obtains the DNS server address through DHCP or another autoconfiguration mechanism.

Figure 3 DNS spoofing application



The DNS proxy does not have the DNS server address or cannot reach the DNS server after startup. A host accesses the HTTP server in the following steps:

1. The host sends a DNS request to the device to resolve the domain name of the HTTP server into an IP address.
2. Upon receiving the request, the device searches the local static and dynamic DNS entries for a match. Because no match is found, the device spoofs the host by replying a configured IP address. The device must have a route to the IP address with the dial-up interface as the output interface.

   The IP address configured for DNS spoofing is not the actual IP address of the requested domain name. Therefore, the TTL field is set to 0 in the DNS reply. When the DNS client receives the reply, it creates a DNS entry and ages it out immediately.
3. Upon receiving the reply, the host sends an HTTP request to the replied IP address.
4. When forwarding the HTTP request through the dial-up interface, the device performs the following operations:
   - Establishes a dial-up connection with the network.
   - Dynamically obtains the DNS server address through DHCP or another autoconfiguration mechanism.
5. Because the DNS entry ages out immediately upon creation, the host sends another DNS request to the device to resolve the HTTP server domain name.
6. The device operates the same as a DNS proxy. For more information, see "DNS proxy."
7. After obtaining the IP address of the HTTP server, the host can access the HTTP server.

Without DNS spoofing, the device forwards the DNS requests from the host to the DNS server if it cannot find a matching local DNS entry. However, the device cannot obtain the DNS server address, because no dial-up connection is established. Therefore, the device cannot forward or answer the requests from the client. DNS resolution fails, and the client cannot access the HTTP server.

DNS tasks at a glance

To configure DNS, perform the following tasks:

1. Configuring the DNS client

   Choose the following tasks as needed:
   - Configuring static domain name resolution
   - Configuring DNS server-based domain name resolution
2. (Optional.) Configuring the DNS proxy
   - Configuring the DNS proxy

   - Configuring the DNS transparent proxy
3. (Optional.) Configuring DNS spoofing

   This feature is applied to the dial-up network.
4. (Optional.) Configuring DNS security features
   - Configuring DNS snooping
   - Enabling DNS snooping logging
   - Configuring a DNS packet rate limit
   - Configuring the DNS trusted interface
5. (Optional.) Configuring DNS packet parameters
   - Specifying the source interface for DNS packets
   - Setting the DSCP value for outgoing DNS packets
6. (Optional.) Configuring DNS filtering

Configuring the DNS client

About domain name resolution on the DNS client

A DNS client resolves a domain name in the following order:

1. Locally saved DNS mappings that have been resolved.
2. DNS server group-based domain name resolution.
3. Static domain name resolution.
4. DNS server-based domain name resolution.

The resolution fails if domain name cannot be resolved after all these methods are used.

Configuring static domain name resolution

Restrictions and guidelines

For the public network or a VPN instance, each host name maps to only one IPv4 address and one IPv6 address.

A maximum of 2048 DNS entries can be configured for the public network or each VPN instance. You can configure DNS entries for both public network and VPN instances.

Procedure

1. Enter system view.

   `system-view`
2. Configure a host name-to-address mapping.

   IPv4:

   `ip host` *`host-name ip-address`* [**`vpn-instance`** *`vpn-instance-name`*]

   IPv6:

   `ipv6 host` *`host-name ipv6-address`* [**`vpn-instance`** *`vpn-instance-name`*]

Configuring DNS server-based domain name resolution

Restrictions and guidelines

- The limit on the number of DNS servers on the device is as follows:

    - In system view, you can specify a maximum of six DNS server IPv4 addresses for the public network or each VPN instance. You can specify DNS server IPv4 addresses for both public network and VPN instances.
    - In system view, you can specify a maximum of six DNS server IPv6 addresses for the public network or each VPN instance. You can specify DNS server IPv6 addresses for both public network and VPN instances.
    - In interface view, you can specify a maximum of six DNS server IPv4 addresses for the public network or each VPN instance. You can specify DNS server IPv4 addresses for both public network and VPN instances.
- A DNS server address is required so that DNS queries can be sent to a correct server for resolution. If you specify both an IPv4 address and an IPv6 address, the device performs the following operations:
    - Sends an IPv4 DNS query first to the DNS server IPv4 addresses. If the query fails, the device turns to the DNS server IPv6 addresses.
    - Sends an IPv6 DNS query first to the DNS server IPv6 addresses. If the query fails, the device turns to the DNS server IPv4 addresses.
- A DNS server address specified in system view takes priority over a DNS server address specified in interface view. A DNS server address specified earlier has a higher priority. A DNS server address manually specified takes priority over a DNS server address dynamically obtained, for example, through DHCP. The device first sends a DNS query to the DNS server address of the highest priority. If the first query fails, it sends the DNS query to the DNS server address of the second highest priority, and so on.
- You can configure a DNS suffix that the system automatically adds to the incomplete domain name that a user enters.
    - You can configure a maximum of 16 DNS suffixes for the public network or each VPN instance. You can configure DNS suffixes for both public network and VPN instances.
    - A DNS suffix manually configured takes priority over a DNS suffix dynamically obtained, for example, through DHCP. A DNS suffix configured earlier has a higher priority. The device first uses the suffix that has the highest priority. If the query fails, the device uses the suffix that has the second highest priority, and so on.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Set the TTL value for DNS entries.

   dns cache ttl { **maximum** *max-value* | **minimum** *min-value* } *

   By default, the TTL value for DNS entries is the TTL value in the DNS reply.

3. (Optional.) Configure a DNS suffix.

   dns domain *domain-name* [**vpn-instance** *vpn-instance-name*]

   By default, no DNS suffix is configured and only the domain name that a user enters is resolved.

4. Specify a DNS server address.
    - Specify a DNS server address in system view.

      IPv4:

      dns server *ip-address* [**vpn-instance** *vpn-instance-name*]

      IPv6:

      ipv6 dns server *ipv6-address* [*interface-type interface-number*] [**vpn-instance** *vpn-instance-name*]
    - Execute the following commands in sequence to specify a DNS server IPv4 address in interface view.

      interface *interface-type interface-number*

dns server ip-address [**vpn-instance** *vpn-instance-name*]

By default, no DNS server address is specified.

Configuring the DNS proxy

Enabling DNS proxy

1. Enter system view.

   system-view

2. Enable DNS proxy.

   dns proxy enable

   By default, DNS proxy is disabled.

Specifying DNS server addresses

Restrictions and guidelines

You can specify multiple DNS servers. The DNS proxy forwards a request to the DNS server that has the highest priority. If it does not receive a reply, the proxy forwards the request to a DNS server that has the second highest priority, and so on.

You can specify both an IPv4 address and an IPv6 address.

- A DNS proxy forwards an IPv4 name query first to IPv4 DNS servers. If no reply is received, it forwards the request to IPv6 DNS servers.
- A DNS proxy forwards an IPv6 name query first to IPv6 DNS servers. If no reply is received, it forwards the request to IPv4 DNS servers.

Procedure

1. Enter system view.

   system-view

2. Specify a DNS server address.

   - Specify a DNS server address in system view.

     IPv4:

     dns server *ip-address* [**vpn-instance** *vpn-instance-name*]

     IPv6:

     ipv6 dns server *ipv6-address* [*interface-type interface-number*] [**vpn-instance** *vpn-instance-name*]

   - Execute the following commands in sequence to specify a DNS server IPv4 address in interface view.

     interface *interface-type interface-number*

     dns server ip-address [**vpn-instance** *vpn-instance-name*]

   By default, no DNS server address is specified.

Configuring the DNS transparent proxy

About this task

DNS transparent proxy modifies the source address in the DNS request so that the DNS client seems to receive a DNS reply directly from the DNS server. This feature is applicable to domain name-based policies, such as security policies and bandwidth policies.

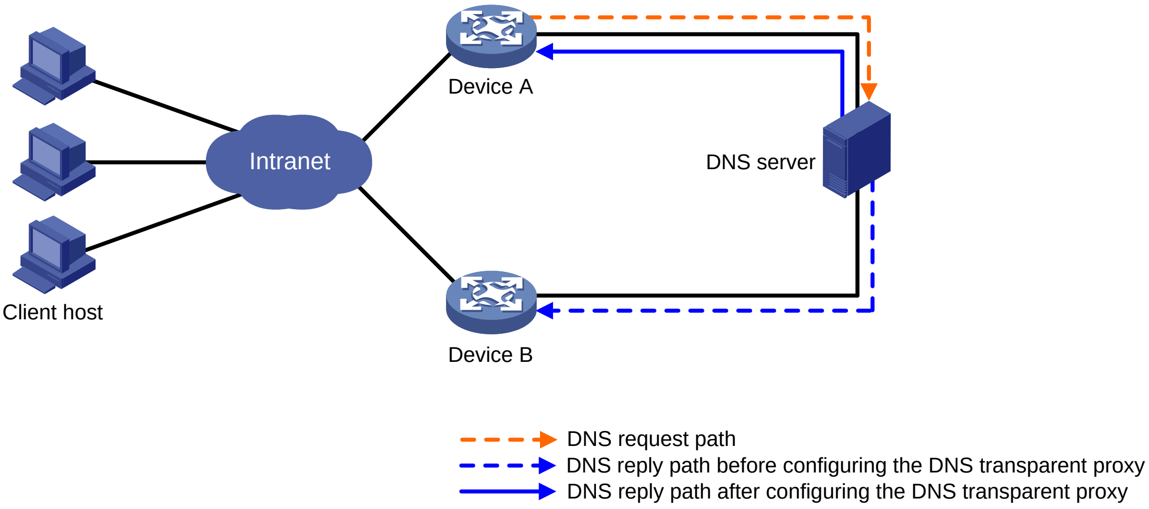
The DNS client does not configure the DNS server address as the DNS transparent proxy address, which simplifies DNS client configurations. As a best practice, enable DNS transparent proxy in some load balancing scenarios.

The device enabled with DNS transparent proxy monitors received DNS requests and replies and records the DNS mapping as follows:

1. The DNS transparent proxy monitors all received DNS packets. After receiving a DNS request, the DNS transparent proxy specifies a local IP address that can reach the DNS server as the source IP address in the request.
2. After receiving the DNS reply, the DNS transparent proxy records the DNS mapping and forwards the reply to the DNS client.
3. The DNS transparent proxy searches the local entries after receiving another request. If the requested information is found, the DNS transparent proxy returns a DNS reply to the client. If the requested information is not found, the DNS proxy forwards the query to the DNS server for domain name resolution.

Figure 4 shows the DNS transparent proxy conceptual diagram.

Figure 4 DNS transparent proxy conceptual diagram



Device A
DNS server
Intranet
Client host
Device B
DNS request path
DNS reply path before configuring the DNS transparent proxy
DNS reply path after configuring the DNS transparent proxy

A DNS transparency proxy operates as follows:

1. Device A is enabled with DNS transparency proxy. After receiving a DNS request, Device A changes the source address in the request to its own address and forwards the query to the DNS server.
2. After receiving the DNS reply, Device A records the DNS mapping and forwards the reply to the DNS client.

Restrictions and guidelines

The DNS transparent proxy and DNS snooping features cannot be both configured.

The DNS transparent proxy is not VPN-aware. The input interface and output interface of DNS packets must belong to the same VPN.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Set the TTL value for DNS entries.

   dns cache ttl { **maximum** *max-value* | **minimum** *min-value* } *

   By default, the TTL value for DNS entries is the TTL value in the DNS reply.

3. Enable DNS transparent proxy.

   dns transparent-proxy enable

   By default, DNS transparent proxy is disabled.

Configuring DNS spoofing

Restrictions and guidelines

- You can configure only one replied IPv4 address and one replied IPv6 address for the public network or a VPN instance. If you execute the command multiple times, the most recent configuration takes effect.
- You can configure DNS spoofing for both public network and VPN instances.
- After DNS spoofing takes effect, the device spoofs a DNS request even though a matching static DNS entry exists.

Prerequisites

The DNS proxy is enabled on the device.

No DNS server or route to any DNS server is specified on the device.

Procedure

1. Enter system view.

   system-view

2. Enable DNS proxy.

   dns proxy enable

   By default, DNS proxy is disabled.

3. Enable DNS spoofing and specify the IP address used to spoof DNS requests. Choose one option as needed:

   IPv4:

   dns spoofing *ip-address* [**vpn-instance** *vpn-instance-name*]

   IPv6:

   ipv6 dns spoofing *ipv6-address* [**vpn-instance** *vpn-instance-name*]

   By default, DNS spoofing is disabled.

Configuring DNS snooping

About this task

DNS snooping is applicable to domain name-based policies, such as security policies and bandwidth policies. To filter traffic based on domain names, the DNS mapping is required. The device enabled with DNS snooping monitors received DNS requests and replies. If the domain name in a DNS request matches a policy, the device records the DNS mapping after receiving a DNS reply and reports the mapping to the policy for traffic filtering. If the domain name does not match a policy, the device does not record the DNS mapping.

Restrictions and guidelines

DNS snooping only works between the DNS client and DNS server, or the DNS client and DNS proxy.

The DNS snooping and DNS transparent proxy features cannot be both configured.

The DNS snooping feature is not VPN-aware. The input interface and output interface of DNS packets must belong to the same VPN.

Procedure

1. Enter system view.

   `system-view`

2. (Optional.) Set the TTL value for DNS entries.

   dns cache ttl { **maximum** *max-value* | **minimum** *min-value* } *

   By default, the TTL value for DNS entries is the TTL value in the DNS reply.

3. Enable DNS snooping.

   `dns snooping enable`

   By default, DNS snooping is disabled.

Enabling DNS snooping logging

About this task

The DNS proxy searches the static domain name resolution table and dynamic domain name resolution cache after receiving a request.

- If the requested information is found, the DNS proxy returns a DNS reply to the client.
- If the requested information is not found, the DNS proxy sends the request to the designated DNS server.

Too many requests received at the same time will increase network load and affect the performance of the DNS proxy and DNS server. To avoid this issue, you can configure DNS snooping logging on the device between the DNS client and DNS proxy, or the DNS client and DNS server.

The device configured with DNS snooping monitors and records for received DNS queries and responses. Also, you can configure the device to generate and send DNS snooping logs to the fast log module. The administrator can locate and troubleshoot issues based on the logs. For information about the fast log output configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enable DNS snooping logging.

   `dns snooping log enable`

   By default, DNS snooping logging is enabled.

Configuring a DNS packet rate limit

About this task

Perform this task to limit the rate of incoming DNS packets on interfaces. An interface will discard DNS packets exceeding the specified rate limit.

Restrictions and guidelines

This feature takes effect only when the DNS transparent proxy or DNS snooping logging feature is enabled.

Procedure

1. Enter system view.

   system-view

2. Set the DNS packet rate limit.

   dns snooping rate-limit *rate*

   By default, the rate of incoming DNS packets is not limited.

Configuring the DNS trusted interface

About this task

This task enables the device to use only the DNS suffix and domain name server information obtained through the trusted interface. The device can then obtain the correct resolved IP address. This feature protects the device against attackers that act as the DHCP server to assign incorrect DNS suffix and domain name server address.

Restrictions and guidelines

You can configure a maximum of 128 DNS trusted interfaces.

Procedure

1. Enter system view.

   system-view

2. Specify the DNS trusted interface.

   dns trust-interface *interface-type interface-number*

   By default, no DNS trusted interface is specified.

Specifying the source interface for DNS packets

About this task

This task enables the device to always use the primary IP address of the specified source interface as the source IP address of outgoing DNS packets. This feature applies to scenarios in which the DNS server responds only to DNS requests sourced from a specific IP address. If no IP address is configured on the source interface, no DNS packets can be sent out.

Restrictions and guidelines

When sending an IPv6 DNS request, the device follows the method defined in RFC 3484 to select an IPv6 address of the source interface.

You can configure only one source interface on the public network or a VPN instance. You can configure source interfaces for both public network and VPN instances.

Make sure the source interface belongs to the specified VPN instance if you specify the **vpn-instance** *vpn-instance-name* option.

Procedure

1. Enter system view.

   system-view

2. Specify the source interface for DNS packets.

dns source-interface *interface-type interface-number* [**vpn-instance** *vpn-instance-name*]

By default, no source interface for DNS packets is specified.

Setting the DSCP value for outgoing DNS packets

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Procedure

1. Enter system view.

   system-view

2. Set the DSCP value for DNS packets sent by a DNS client or a DNS proxy.

   IPv4:

   dns dscp *dscp-value*

   By default, the DSCP value is 0 in IPv4 DNS packets sent by a DNS client or a DNS proxy.

   IPv6:

   ipv6 dns dscp *dscp-value*

   By default, the DSCP value is 0 in IPv6 DNS packets sent by a DNS client or a DNS proxy.

Configuring DNS filtering

About this task

Enabled with DNS filtering, the DNS proxy matches the domain names in DNS requests with the host names on the allowlist or denylist to filter in or discard DNS requests.

The DNS proxy uses DNS filtering to filter DNS requests as follows:

- If the allowlist has a matching host name or the denylist has no matching host name with the domain name in the received DNS request, the DNS proxy filters in the request. After receiving a DNS reply, the DNS proxy records the DNS mapping and forwards the reply to the DNS client.
- If the denylist has a matching host name or the allowlist has no matching host name with the domain name in the received DNS request, the DNS proxy discards the DNS request.

To implement a strict access control, use an allowlist to filter DNS requests. To implement a loose access control, use a denylist to filter DNS requests.

Restrictions and guidelines

To add multiple host names to the allowlist or denylist, repeat this command. However, a host name cannot be added to both the denylist and allowlist.

Procedure

1. Enter system view.

   system-view

2. Enable DNS filtering and add a host name to the allowlist or denylist.

   dns filter { **allowlist** | **denylist** } *hostname*

   By default, DNS filtering is disabled.

Display and maintenance commands for DNS

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display DNS suffixes.	**display dns domain** [**dynamic**] [**vpn-instance** *vpn-instance-name*]
Display the domain name resolution table.	**display dns host** [**ip** | **ipv6**] [**vpn-instance** *vpn-instance-name*]
Display IPv4 DNS server information.	**display dns server** [**dynamic**] [**vpn-instance** *vpn-instance-name*]
Display IPv6 DNS server information.	**display ipv6 dns server** [**dynamic**] [**vpn-instance** *vpn-instance-name*]
Clear dynamic DNS entries.	**reset dns host** [**ip** | **ipv6**] [**vpn-instance** *vpn-instance-name*]
Clear log statistics for incoming DNS packets.	**reset dns snooping log statistics**

Troubleshooting DNS configuration

Failure to resolve IPv4 addresses

Symptom

After enabling dynamic domain name resolution, the user cannot get the correct IP address.

Solution

To resolve the problem:

1. Use the **display dns host ip** command to verify that the specified domain name is in the cache.
2. If the specified domain name does not exist, check that the DNS client can communicate with the DNS server.
3. If the specified domain name is in the cache, but the IP address is incorrect, check that the DNS client has the correct IP address of the DNS server.
4. Verify that the mapping between the domain name and IP address is correct on the DNS server.

Failure to resolve IPv6 addresses

Symptom

After enabling dynamic domain name resolution, the user cannot get the correct IPv6 address.

Solution

To resolve the problem:

1. Use the **display dns host ipv6** command to verify that the specified domain name is in the cache.

2. If the specified domain name does not exist, check that dynamic domain name resolution is enabled, and that the DNS client can communicate with the DNS server.
3. If the specified domain name is in the cache, but the IPv6 address is incorrect, check that the DNS client has the correct IPv6 address of the DNS server.
4. Verify that the mapping between the domain name and IPv6 address is correct on the DNS server.

Contents

Optimizing IP performance

IP performance optimization tasks at a glance

All IP performance optimization tasks are optional.

1. Configuring features for IP packets
   - Enabling an interface to receive and forward directed broadcasts destined for the directly connected network
   - Setting the interface MTU for IPv4 packets
   - Enabling IPv4 local fragment reassembly

     This feature is applicable in IRF networks.
   - Enabling IPv4 virtual fragment reassembly
   - Enabling fragment centralization for IPv4 VFR
   - Forcibly disabling IPv4 VFR
   - Enabling fragment centralization for IPv6 VFR
   - Forcibly disabling IPv6 VFR
   - Configuring the DF bit for IP packets
2. Configuring features for ICMP messages
   - Enabling sending ICMP error messages
   - Configuring rate limit for ICMP error messages
   - Specifying the source address for ICMP packets
3. Configuring features for TCP packets
   - Setting TCP MSS for an interface
   - Configuring TCP path MTU discovery
   - Enabling SYN Cookie
   - Setting the TCP buffer size
   - Setting TCP timers
   - Enabling carrying the TCP timestamp option in outgoing TCP packets

Enabling an interface to receive and forward directed broadcasts destined for the directly connected network

About forwarding broadcasts destined for the directly connected network

A directed broadcast packet is destined for all hosts on a specific network. In the destination IP address of the directed broadcast, the network ID identifies the target network, and the host ID is made up of all ones.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the interface to receive and forward directed broadcasts destined for the directly connected network.

   ip forward-broadcast

   By default, an interface can receive directed broadcasts destined for the directly connected network, but it cannot forward these broadcasts.

Setting the interface MTU for IPv4 packets

About this task

The interface MTU for IPv4 packets defines the largest size of an IPv4 packet that an interface can transmit without fragmentation. When a packet exceeds the MTU of the sending interface, the device processes the packet in one of the following ways:

- If the packet disallows fragmentation, the device discards it.
- If the packet allows fragmentation, the device fragments it and forwards the fragments.

Fragmentation and reassembling consume system resources, so set the MTU based on the network environment to avoid fragmentation.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the interface MTU for IPv4 packets.

   ip mtu *mtu-size*

   By default, the interface MTU is not set.

Enabling IPv4 local fragment reassembly

About this task

Use this feature on a device to improve fragment reassembly efficiency. This feature enables the LPU to reassemble the IPv4 fragments of a packet if all the fragments arrive at it. If this feature is disabled, all IPv4 fragments are delivered to the active MPU for reassembly. The feature applies only to fragments destined for the same LPU.

Use this feature on a multichassis IRF fabric to improve fragment reassembly efficiency. This feature enables a subordinate to reassemble the IPv4 fragments of a packet if all the fragments arrive at it. If this feature is disabled, all IPv4 fragments are delivered to the master device for reassembly. The feature applies only to fragments destined for the same subordinate.

Procedure

1. Enter system view.

   system-view

2. Enable IPv4 local fragment reassembly.

   ```
   ip reassemble local enable
   ```

   By default, IPv4 local fragment reassembly is disabled.

Enabling IPv4 virtual fragment reassembly

About this task

To prevent each service module from processing packet fragments that do not arrive in order, you can enable the virtual fragment reassembly (VFR) feature. This feature virtually reassembles the fragments of a datagram through fragment check, sequencing, and caching, ensuring fragments arrive at each service module in order.

VFR can detect and prevent the following types of attacks:

- **Tiny fragment attack**—The first fragment size is too small to hold the Layer 4 (such as TCP and UDP) header field, which is forced into the second fragment. VFR discards all tiny fragments.
- **Overlapping fragment attack**—Two consecutive incoming fragments are identical or overlap with each other. If an overlapping fragment is detected, VFR discards all fragments within a fragment chain.
- **Fragment flooding attack**—The maximum number of concurrent preassemblies or the number of fragments per datagram exceeds the upper limits. VFR discards subsequent fragments if the upper limit is reached.

Restrictions and guidelines

The enabling status of VFR can be managed at CLI or the enabling status of a service module that can call VFR. VRF is enabled in either of the following conditions:

- A service module that can call it is enabled.
- The **ip virtual-reassembly enable** command is executed.

If fragment reassembly is required, but a service module cannot call it, execute this command at CLI.

The **ip virtual-reassembly suppress** command can forcibly disable the VFR feature enabled through CLI or service calling.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable IPv4 virtual fragment reassembly.

   ```
   ip virtual-reassembly enable
   ```

   By default, IPv4 virtual fragment reassembly is disabled.

Enabling fragment centralization for IPv4 VFR

About this task

On an HA network, if an HA device enabled with IPv4 VFR does not receive all fragments of a datagram, it cannot reassemble the datagram and will discard the received fragments. To resolve this issue, you can enable this feature. Devices that do not receive the first fragment of a datagram forward the received fragments of this datagram to the device that receives the first fragment for VFR.

Restrictions and guidelines

This feature is applicable to devices enabled with IPv4 VFR on a HA network.

For more information about HA network, see high availability group configuration in *High Availability Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Enable fragment centralization for IPv4 VFR.
   `ip virtual-reassembly centralize`
   By default, fragment centralization is disabled for IPv4 VFR.

Forcibly disabling IPv4 VFR

About this task

IPv4 VFR checks, sequences, and caches fragments upon fragment receiving to ensure that fragments to assemble are in the correct order. By default, IPv4 VFR is enabled.

On an HA network, if an HA device does not receive all fragments of a datagram, it cannot reassemble the datagram and will discard the received fragments. For the devices to permit the received fragments to pass, you can forcibly disable IPv4 VFR. The **`ip virtual-reassembly suppress`** command can forcibly disable the VFR feature enabled through CLI or service calling.

With IPv4 VFR disabled forcibly, ASPF and connection limit do not take effect on the received IPv4 fragments and the fragments will be forwarded directly.

Restrictions and guidelines

Use this feature according to the demands of VFR.

For more information about HA network, see high availability group configuration in *High Availability Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Forcibly disable IPv4 VFR.
   `ip virtual-reassembly suppress`
   By default, forcibly disabling IPv4 VFR is enabled.

Enabling fragment centralization for IPv6 VFR

About this task

On an HA network, if an HA device enabled with IPv6 VFR does not receive all fragments of a datagram, it cannot reassemble the datagram and will discard all the received fragments. To resolve this issue, you can enable this feature. Devices that do not receive the first fragment of a datagram forward the received fragments of this datagram to the device that receives the first fragment for VFR.

Restrictions and guidelines

This feature is applicable to devices enabled with IPv6 VFR on a HA network.

For more information about HA network, see high availability group configuration in *High Availability Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enable fragment centralization for IPv6 VFR.

   `ipv6 virtual-reassembly centralize`

   By default, fragment centralization is disabled for IPv6 VFR.

Forcibly disabling IPv6 VFR

About this task

IPv6 VFR checks, sequences, and caches fragments upon fragment receiving to ensure that fragments to assemble are in the correct order. By default, IPv6 VFR is enabled.

On an HA network, if an HA device does not receive all fragments of a datagram, it cannot reassemble the datagram and will discard the received fragments. For the devices to permit the received fragments to pass, you can forcibly disable IPv6 VFR.

With IPv6 VFR disabled forcibly, ASPF and connection limit do not take effect on the received IPv6 fragments and the fragments will be forwarded directly.

Restrictions and guidelines

Use this feature according to the demands of VFR.

For more information about HA network, see high availability group configuration in *High Availability Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Forcibly disable IPv6 VFR.

   `ipv6 virtual-reassembly suppress`

   By default, forcibly disabling IPv6 VFR is enabled.

Configuring the DF bit for IP packets

About this task

This task configures the Don't Fragment (DF) bit for the IP packets to be forwarded:

- **set**—Sets the DF bit in the IP packets to 1 to prevent the devices on the path from fragmenting the IP packets. If the path MTU is less than the size of the IP packets and DF bit is set, communication interruption occurs. The devices on the path will drop the IP packets and reply ICMP error messages to the IP packet sender.
- **clear**—Sets the DF bit in the IP packets to 0. The devices can fragment the IP packets before forwarding them.

This feature does not apply to IP packets generated by the local device.

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080,	Yes

NFNX3-HDB680, NFNX3-HDB1080	
NFNX3-HDB1180, NFNX3-HDB1480	No

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Configure the DF bit for IP packets.

   ```
   ip df-bit { clear | set }
   ```

   By default, the DF bit value of IP packets is retained as it is.

Enabling sending ICMP error messages

About sending ICMP error messages

ICMP messages are used by network layer and transport layer protocols to communicate updates and errors with other devices, facilitating network management.

Sending excessive ICMP messages increases network traffic. The device performance degrades if it receives a lot of malicious ICMP messages that cause it to respond with ICMP error messages. To prevent such problems, the sending of ICMP error messages is disabled by default. You can enable sending ICMP error messages of different types as needed.

ICMP error messages include redirect messages, time exceeded messages, and destination unreachable messages.

Enabling sending ICMP redirect messages

About this task

A host that has only one default route sends all packets to the default gateway. The default gateway sends an ICMP redirect message to inform the host of a correct next hop when the following conditions are met:

- The receiving and sending interfaces are the same.
- The packet source IP address and the IP address of the packet receiving interface are on the same segment.
- There is no source route option in the received packet.

ICMP redirect messages simplify host management and enable hosts to gradually optimize their routing table.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable sending ICMP redirect messages.

   ```
   ip redirects enable
   ```

   By default, the sending of ICMP redirect messages is disabled.

Enabling sending ICMP time exceeded messages

About this task

A device sends ICMP time exceeded messages by following these rules:

- The device sends the source an ICMP TTL exceeded in transit message when the following conditions are met:
    - The received packet is not destined for the device.
    - The TTL field of the packet is 1.
- When the device receives the first fragment of an IP datagram destined for it, it starts a timer. If the timer expires before all the fragments of the datagram are received, the device sends an ICMP fragment reassembly time exceeded message to the source.

Restrictions and guidelines

If the ICMP time exceeded message sending is disabled, the device does not send ICMP TTL exceeded in transit messages. However, it can still send ICMP fragment reassembly time exceeded messages.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable sending ICMP time exceeded messages.

   ```
   ip ttl-expires enable
   ```

   By default, the sending of ICMP time exceeded messages is disabled.

Enable sending ICMP destination unreachable messages

About this task

A device sends ICMP destination unreachable messages by following these rules:

- The device sends the source an ICMP network unreachable message when the following conditions are met:
    - The packet does not match any route.
    - No default route exists in the routing table.
- The device sends the source an ICMP protocol unreachable message when the following conditions are met:
    - The packet is destined for the device.
    - The transport layer protocol of the packet is not supported by the device.
- The device sends the source an ICMP port unreachable message when the following conditions are met:
    - The UDP packet is destined for the device.
    - The packet's port number does not match the corresponding process.
- The device sends the source an ICMP source route failed message when the following conditions are met:
    - The source uses Strict Source Routing to send packets.
    - The intermediate device finds that the next hop specified by the source is not directly connected.
- The device sends the source an ICMP fragmentation needed and DF set message when the following conditions are met:
    - The MTU of the sending interface is smaller than the packet.

- The packet has DF set.

Restrictions and guidelines

If a DHCP-enabled device receives an ICMP echo reply without sending any ICMP echo requests, the device does not send any ICMP protocol unreachable messages to the source. To enable DHCP, use the **`dhcp enable`** command. For more information about this command, see *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable sending ICMP destination unreachable messages.

   ```
   ip unreachables enable
   ```

   By default, the sending of ICMP destination unreachable messages is disabled.

Configuring rate limit for ICMP error messages

About this task

To avoid sending excessive ICMP error messages within a short period that might cause network congestion, you can limit the rate at which ICMP error messages are sent. A token bucket algorithm is used with one token representing one ICMP error message.

A token is placed in the bucket at intervals until the maximum number of tokens that the bucket can hold is reached.

A token is removed from the bucket when an ICMP error message is sent. When the bucket is empty, ICMP error messages are not sent until a new token is placed in the bucket.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Set the interval for tokens to arrive in the bucket and the bucket size for ICMP error messages.

   ```
   ip icmp error-interval interval [ bucketsize ]
   ```

   By default, a token is placed in the bucket at intervals of 100 milliseconds and the bucket allows a maximum of 10 tokens.

   To disable the ICMP rate limit, set the interval to 0 milliseconds.

Specifying the source address for ICMP packets

About this task

Specifying the source IP address for outgoing ping echo requests and ICMP error messages helps users to locate the sending device easily. As a best practice, specify the IP address of the loopback interface as the source IP address.

Restrictions and guidelines

If you specify an IP address in the **`ping`** command, ping echo requests use the specified address as the source IP address rather than the IP address specified by the **`ip icmp source`** command.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Specify the source address for outgoing ICMP packets.

   ```
   ip icmp source [ vpn-instance vpn-instance-name ] ip-address
   ```

   By default, no source address is specified for outgoing ICMP packets. The default source IP addresses for different types of ICMP packets vary as follows:

   - For an ICMP error message, the source IP address is the IP address of the receiving interface of the packet that triggers the ICMP error message. ICMP error messages include Time Exceeded, Port Unreachable, and Parameter Problem messages.
   - For an ICMP echo request, the source IP address is the IP address of the sending interface.
   - For an ICMP echo reply, the source IP address is the destination IP address of the ICMP echo request specific to this reply.

Setting TCP MSS for an interface

About this task

The maximum segment size (MSS) option informs the receiver of the largest segment that the sender can accept. Each end announces its MSS during TCP connection establishment. If the size of a TCP segment is smaller than the MSS of the receiver, TCP sends the TCP segment without fragmentation. If not, it fragments the segment according to the receiver's MSS.

Restrictions and guidelines

- If you set the TCP MSS on an interface, the size of each TCP segment received or sent on the interface cannot exceed the MSS value.
- This configuration takes effect only for TCP connections established after the configuration rather than the TCP connections that already exist.
- This configuration is effective only for IP packets.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Set the TCP MSS for the interface.

   ```
   tcp mss value
   ```

   By default, the TCP MSS is not set.

Configuring TCP path MTU discovery

About this task

TCP path MTU discovery (in RFC 1191) discovers the path MTU between the source and destination ends of a TCP connection. The device uses the path MTU to calculate the MSS to avoid IP fragmentation. The path MTU uses an aging mechanism to ensure that the source device can increase the path MTU when the minimum link MTU on the path increases.

TCP path MTU discovery works as follows:

1. A TCP source device sends a packet with the Don't Fragment (DF) bit set.
2. A router discards the packet that exceeds the MTU of the outgoing interface and returns an ICMP error message. The error message contains the MTU of the outgoing interface.
3. Upon receiving the ICMP message, the TCP source device calculates the current path MTU of the TCP connection.

4. The TCP source device sends subsequent TCP segments that are smaller than the MSS (MSS = path MTU – IP header length – TCP header length).

If the TCP source device still receives ICMP error messages when the MSS is smaller than 32 bytes, the TCP source device will fragment packets.

An ICMP error message received from a router that does not support RFC 1191 has the MTU of the outgoing interface set to 0. Upon receiving the ICMP message, the TCP source device selects the path MTU smaller than the current path MTU from the MTU table as described in RFC 1191. Based on the selected path MTU, the TCP source device calculates the TCP MSS. The MTU table contains MTUs of 68, 296, 508, 1006, 1280, 1492, 2002, 4352, 8166, 17914, 32000, and 65535 bytes. Because the minimum TCP MSS specified by the system is 32 bytes, the actual minimum MTU is 72 bytes.

The aging mechanism of the path MTU is as follows:

- When the TCP source device receives an ICMP error message, it reduces the path MTU and starts an aging timer for the path MTU.
- After the aging timer expires, the source device uses a larger MSS in the MTU table, as described in RFC 1191.
- If no ICMP error message is received within two minutes, the source device increases the MSS again until the MSS negotiated during TCP three-way handshake is reached.

Prerequisites

Make sure all devices on a TCP connection are enabled to send ICMP error messages by using the **`ip unreachables enable`** command.

Procedure

1. Enter system view.

   `system-view`

2. Enable TCP path MTU discovery.

   `tcp path-mtu-discovery` [**`aging`** *`age-time`* | **`no-aging`**]

   By default, TCP path MTU discovery is disabled.

Enabling SYN Cookie

About this task

A TCP connection is established through a three-way handshake. An attacker can exploit this mechanism to mount SYN Flood attacks. The attacker sends a large number of SYN packets, but does not respond to the SYN ACK packets from the server. As a result, the server establishes a large number of TCP semi-connections and can no longer handle normal services.

SYN Cookie can protect the server from SYN Flood attacks. When the server receives a SYN packet, it responds with a SYN ACK packet without establishing a TCP semi-connection. The server establishes a TCP connection and enters ESTABLISHED state only when it receives an ACK packet from the client.

Procedure

1. Enter system view.

   `system-view`

2. Enable SYN Cookie.

   `tcp syn-cookie enable`

   By default, SYN Cookie is disabled.

Setting the TCP buffer size

1. Enter system view.

   ```
   system-view
   ```

2. Set the size of TCP receive/send buffer.

   ```
   tcp window window-size
   ```

   The default buffer size is 63 KB.

Setting TCP timers

About this task

You can set the following TCP timers:

- **SYN wait timer**—TCP starts the SYN wait timer after sending a SYN packet. Within the SYN wait timer if no response is received or the upper limit on TCP connection tries is reached, TCP fails to establish the connection.
- **FIN wait timer**—TCP starts the FIN wait timer when TCP changes the connection state to FIN_WAIT_2. If no FIN packet is received within the timer interval, TCP terminates the connection. If a FIN packet is received, TCP changes the connection state to TIME_WAIT. If a non-FIN packet is received, TCP restarts the timer, and tears down the connection when the timer expires.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Set the TCP SYN wait timer.

   ```
   tcp timer syn-timeout time-value
   ```

   By default, the TCP SYN wait timer is 75 seconds.

3. Set the TCP FIN wait timer.

   ```
   tcp timer fin-timeout time-value
   ```

   By default, the TCP FIN wait timer is 675 seconds.

Enabling carrying the TCP timestamp option in outgoing TCP packets

About this task

The TCP timestamp option in TCP packets is used to calculate the RTT between two communicating devices. In some networks, it is required to prevent the intermediate devices from obtaining the TCP timestamps in packets passing through. Then you can disable carrying the TCP timestamp option in outgoing packets on a device at either end.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable carrying the TCP timestamp option in outgoing TCP packets.

   ```
   tcp timestamps enable
   ```

   By default, the device adds the TCP timestamp option in outgoing TCP packets.

Display and maintenance commands for IP performance optimization

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display ICMP statistics.	**display icmp statistics** [**slot** *slot-number*]
Display IP packet statistics.	**display ip statistics** [**slot** *slot-number*]
Display brief information about RawIP connections.	**display rawip** [**slot** *slot-number*]
Display detailed information about RawIP connections.	**display rawip verbose** [**slot** *slot-number* [**pcb** *pcb-index*]]
Display brief information about TCP connections.	**display tcp** [**slot** *slot-number*]
Display TCP traffic statistics.	**display tcp statistics** [**slot** *slot-number*]
Display detailed information about TCP connections.	**display tcp verbose** [**slot** *slot-number* [**pcb** *pcb-index*]]
Display brief information about TCP proxy.	**display tcp-proxy slot** *slot-number*
Display the usage of non-well known ports for TCP proxy.	**display tcp-proxy port-info slot** *slot-number*
Display brief information about UDP connections.	**display udp** [**slot** *slot-number*]
Display UDP traffic statistics.	**display udp statistics** [**slot** *slot-number*]
Display detailed information about UDP connections.	**display udp verbose** [**slot** *slot-number* [**pcb** *pcb-index*]]
Clear IP packet statistics.	**reset ip statistics** [**slot** *slot-number*]
Clear TCP traffic statistics.	**reset tcp statistics**
Clear UDP traffic statistics.	**reset udp statistics**

Contents

Configuring multi-CPU packet distribution

About multi-CPU packet distribution

On a multi-CPU device, packets can be distributed among CPUs based on one of the following policies:

- **Flow-based policy**—Forwards packets of a flow to one CPU or multiple CPUs. The CPU processes flow packets by following the first-in first-out rule. The device supports using the source IP address, destination IP address, source port number, destination port number, and protocol number to identify a flow.
- **Packet-based policy**—Forwards packets in sequence to different CPUs, even though they are the same flow. This policy does not ensure packet order.

Restrictions and guidelines: Multi-CPU packet distribution configuration

If a service requires packets of a flow to be received by the same CPU, you must use the flow-based policy.

Specifying a packet distribution policy

1. Enter system view.

   `system-view`

2. Specify a packet distribution policy.

   `forwarding policy` { **`per-flow`** [**`three-tuple`** | **`mode`** { **`source-ip`** | **`destination-ip`** | **`source-port`** | **`destination-port`** }] | **`per-packet`** }

   By default, the device uses the flow-based policy that identifies a flow by source IP address, destination IP address, source port number, destination port number, and protocol number.

   Support for the **`three-tuple`** and **`mode`** keywords depends on the device model. For more information, see the command reference.

Displaying the adjacency table

About the adjacency table

The adjacency table stores information about directly connected neighbors for IP forwarding. The neighbor information in this chapter refers to non-Ethernet neighbor information.

This table is not user configurable. The neighbor information is generated, updated, and deleted by link layer protocols through negotiation (such as PPP dynamic negotiation) or through manual configuration. An adjacency entry includes the following information:

- Neighbor network layer address (next hop).
- Output interface.
- Link layer protocol type.
- Link layer address. This field is not available for PPP.

When forwarding an IP packet, the device performs the following tasks:

- Searches the FIB to find the output interface and next hop.
- Uses the output interface and next hop address to search the adjacency table for link layer forwarding information.

NOTE:

Ethernet and non-Ethernet neighbor information is stored and managed together.

Display and maintenance commands for adjacency table

Execute **display** commands in any view.

Task	Command
Display IPv4 adjacency table information.	**display adjacent-table** { **all** | **physical-interface** *interface-type interface-number* | **routing-interface** *interface-type interface-number* | **slot** *slot-number* } [**count** | **verbose**]
Display IPv6 adjacency table information.	**display ipv6 adjacent-table** { **all** | **physical-interface** *interface-type interface-number* | **routing-interface** *interface-type interface-number* | **slot** *slot-number* } [**count** | **verbose**]

Configuring Web caching

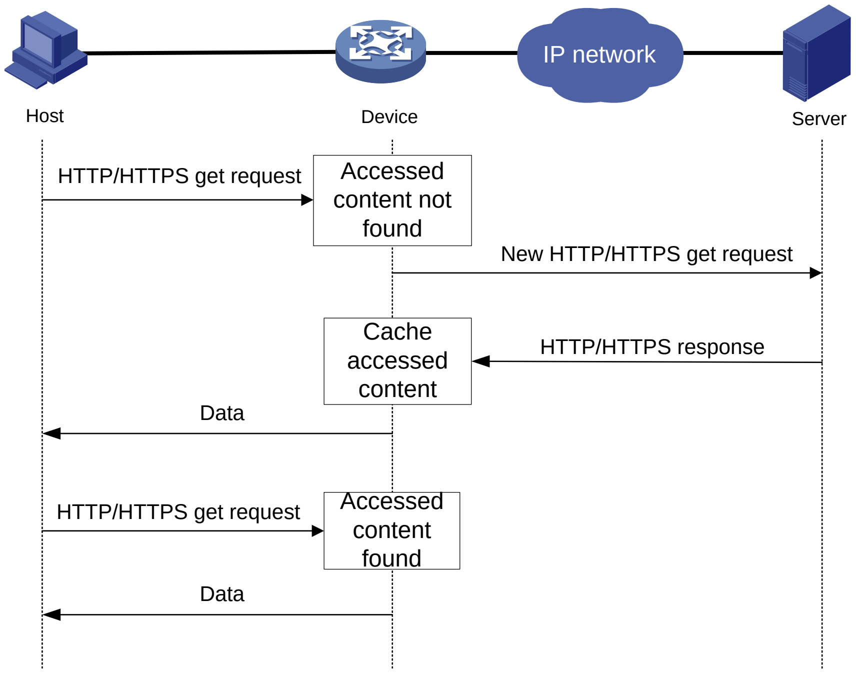
About Web caching

The Web caching feature saves specific webpage content requested by HTTP or HTTPS users from specific Web servers to files in the Web cache directory. If users access the same content before the content is aged out, the device retrieves the content from the files and sends the content to the users. Web caching can reduce the traffic between the device and the Web servers, lower Web content transmission costs, relieve pressure on Web servers, and improve user Web access speed.

Web caching mechanism

Figure 1 shows the Web caching mechanism.

Figure 1 Web caching mechanism



1. The host sends an HTTP or HTTPS GET request to the device.
2. The device identifies whether the Web caching feature is configured to cache Web content from the Web server.
   - If not, the device forwards the request directly to the Web server. The Web caching feature does not take part in the communication between the host and the Web server.
   - If yes, the device forwards the request to the Web caching process.
3. The Web caching process obtains the URL of the request and looks up its cache for the requested content.
   - If the requested content is found in the cache, the device retrieves the content and sends the content to the host. The HTTP or HTTPS GET operation is completed.
   - If the requested content is not found, the device re-constructs the request and sends the request to the Web server.
4. The Web server sends the requested content to the device.

5. The device identifies whether the Web caching feature is configured to cache the content.
    - If yes, the device uses the Web caching feature to cache the content, re-constructs a response, and sends the response to the host.
    - If not, the device re-constructs a response and sends the response to the host.

Web caching backup

The Web cache backup feature enhances the high availability of the Web caching service. You can specify a primary slot and a backup slot for Web caching. When the primary slot fails, the backup slot will take over to provide the Web caching service to ensure service continuity. When the primary slot recovers, the Web caching service switches back to the primary slot.

Basic concepts

- **Web cache files and Web cache directory**—The Web caching feature saves its operation data and the Web content to be cached to files in the Web cache directory. After the effective maximum total size for Web cache files is reached, the device deletes the oldest Web cache file to save the new Web cache file.
- **Web cache file aging time**—The Web cache file aging time is fixed at 30 days. When the device reboots or receives a request for the cached content in a file, it restarts the aging timer. If no users request the cached content before the aging timer expires, the device deletes the file.

Restrictions: Software version compatibility with Web caching

Web caching is supported only in RXX60P20 and later.

License requirement for Web caching

The Web caching feature requires a license. If you configure the feature without a license, the settings will be lost after a device reboot. For information about feature licensing, see *Fundamentals Configuration Guide*.

Restrictions and guidelines: Web caching configuration

Before configuring or modifying Web caching parameters, you must disable Web caching. After configuring or modifying Web caching parameters, enable Web caching again.

Web caching tasks at a glance

To configure Web caching, perform the following tasks:

1. Configuring Web caching parameters
2. Enabling Web caching

Configuring Web caching parameters

Restrictions and guidelines

Before configuring or modifying Web caching parameters, you must disable Web caching. After configuring or modifying Web caching parameters, enable Web caching again.

The Web cache directory for a Web cache view must reside on the same slot as the Web view.

Before specifying a Web cache directory, make sure all files in the upper-level directory are using a different name than the Web cache directory or have a file extension.

Make sure the storage medium where the Web cache directory resides has sufficient storage space. The directory typically needs a storage space of over 1 GB.

Prerequisites

To cache only Web content from certain Web servers, configure an IPv4 object group to identify the Web servers. For more information about the IPv4 object group feature, see object group configuration in *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create and enter Web cache view.

   web-cache slot *slot-number*

3. Specify the types of the webpage files to be cached.

   cached-data { **apk** | **bmp** | **doc** | **docx** | **gif** | **gzip** | **ipa** | **jar** | **jpg** | **jpeg** | **mp4** | **pdf** | **png** | **ppt** | **pptx** | **rar** | **swf** | **tar** | **txt** | **xls** | **xlsx** | **zip** } *

   By default, no webpage file types are specified. The Web caching feature does not cache any types of files on webpages.

4. (Optional.) Specify webpage files to be cached.

   cached-file *file-name*

   By default, no webpage files to be cached are specified.

   If you specify both webpage files and types of the webpage files to be cached, the device caches matching webpage files of the specified types.

5. Set the Web caching listening port number.

   - Set the port number for Web caching to listen for HTTP packets.

     listen-port *port-number*

   - Set the port number for Web caching to listen for HTTPS packets.

     https listen-port *port-number*

   By default, Web caching uses port 80 to listen for HTTP packets and port 443 to listen for HTTPS packets.

   Make sure the specified TCP port number is not being used by any other services on the device. To display TCP port numbers in use, execute the **display tcp verbose** command.

6. (Optional.) Specify an IPv4 object group used to filter Web content to be cached.

   object-group [**source**] **ip** *object-group-name*

   By default, no IPv4 object group is specified for the Web caching feature to filter Web content. The Web caching feature caches Web content from all Web servers.

   To cache Web content requested by specific Web clients, specify the **source** keyword. To cache Web content sent from specific Web servers, do not specify the **source** keyword.

7. Set the primary Web cache directory.

   file-directory *directory*

   By default, the primary Web cache directory is not set.

8. (Optional.) Set the maximum total size of Web cache files.

   cache-limit *size*

   By default, the maximum total size of Web cache files is 4 GB.

   The maximum total size for Web cache files must be smaller than the maximum storage space size in the working directory.

9. (Optional.) Configure the Web caching backup feature.

   a. Specify the backup Web caching slot.

      backup slot *slot-number*

      By default, no backup Web caching slot is specified.

   b. Set the backup Web cache directory.

      file-directory backup *directory*

      By default, no backup Web cache directory is set.

Enabling Web caching

Restrictions and guidelines

Before enabling Web caching, you must configure the types of the webpage files to be cached and the Web cache directory.

Web caching will restart in one of the following situations:

- When HTTP-based Web caching is configured, enable HTTPS-based Web caching.
- When HTTPS-based Web caching is configured, enable HTTP-based Web caching.
- When both HTTP-based and HTTPS-based Web caching are configured, disable HTTP-based or HTTPS-based Web caching.

Procedure

1. Enter system view.

   system-view

2. Create and enter Web cache view.

   web-cache slot *slot-number*

3. Enable Web caching. Choose the options to configure as needed:

   - Enable HTTP-based Web caching.

     http enable

     By default, HTTP-based Web caching is disabled.

   - Enable HTTPS-based Web caching.

     https enable

     By default, HTTPS-based Web caching is disabled.

Display and maintenance commands for Web caching

Execute the **display** command in any view.

Task	Command
Display Web caching information.	**display web-cache** [**history** [**last** { **day** | **30-days** | **365-days** | **hour** | **minute** | **week** } | **verbose**]]

Troubleshooting Web caching

Web caching enabling failure

Symptom

Web caching failed to be enabled.

Analysis

The TCP port number specified for Web caching must belong to Web caching exclusively. If any other services on the device are using the same TCP port number, Web caching cannot be enabled.

Solution

To resolve the problem:

1. Execute the **display tcp verbose** command to display TCP port numbers being used.
2. Specify an unused TCP port number as the Web caching listening port number.

Web caching backup failure

Symptom

The device does not use the backup Web caching slot for Web caching after the primary Web caching slot reboots.

Analysis

If the storage medium of the backup Web caching slot is inaccessible or is not correctly configured, the Web caching service cannot be enabled on the backup Web caching slot.

Solution

To resolve the problem:

1. Execute the **dir** command to display information about the backup Web caching slot and then make sure the storage medium of the directory is accessible.

   For more information about the **dir** command, see file system management commands in *Fundamentals Command Reference.*
2. If the issue persists, contact NSFOCUS Support.

NSFOCUS Firewall Series

NF Layer 3—IP Routing

Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for routing protocols, including basic IP routing, static routing, RIP, OSPF, IS-IS, BGP, policy-based routing, IPv6 static routing, IPv6 policy-based routing, RIPng, OSPFv3, Guard route, RIR and routing policies.
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
ⓘ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Configuring basic IP routing

This chapter focuses on unicast routing protocols. For more information about multicast routing protocols, see *IP Multicast Configuration Guide*.

About IP routing

IP routing directs IP packet forwarding on routers. Based on the destination IP address in the packet, a router looks up a route for the packet in a routing table and forwards the packet to the next hop. Routes are path information used to direct IP packets.

Routing table

A RIB contains the global routing information and related information, including route recursion, route redistribution, and route extension information. The router selects optimal routes from the routing table and puts them into the FIB table. It uses the FIB table to forward packets. For more information about the FIB table, see *Layer 3—IP Services Configuration Guide*.

Route categories

Table 1 categorizes routes by different criteria.

Table 1 Route categories

Criterion	Categories
Origin	• **Direct route**—A direct route is discovered by the data link protocol on an interface, and is also called an interface route. • **Static route**—A static route is manually configured by an administrator. • **Dynamic route**—A dynamic route is dynamically discovered by a routing protocol.
Destination	• **Network route**—The destination is a network. The subnet mask is less than 32 bits. • **Host route**—The destination is a host. The subnet mask is 32 bits.
Whether the destination is directly connected	• **Direct route**—The destination is directly connected. • **Indirect route**—The destination is indirectly connected.

Dynamic routing protocols

Static routes work well in small, stable networks. They are easy to configure and require fewer system resources. However, in networks where topology changes occur frequently, a typical practice is to configure a dynamic routing protocol. Compared with static routing, a dynamic routing protocol is complicated to configure, requires more router resources, and consumes more network resources.

Dynamic routing protocols dynamically collect and report reachability information to adapt to topology changes. They are suitable for large networks.

Dynamic routing protocols can be classified by different criteria, as shown in Table 2.

Table 2 Categories of dynamic routing protocols

Criterion	Categories
Operation scope	• **IGPs**—Work within an AS. Examples include RIP, OSPF, and IS-IS. • **EGPs**—Work between ASs. The most popular EGP is BGP.
Routing algorithm	• **Distance-vector protocols**—Examples include RIP and BGP. BGP is also considered a path-vector protocol. • **Link-state protocols**—Examples include OSPF and IS-IS.
Destination address type	• **Unicast routing protocols**—Examples include RIP, OSPF, BGP, and IS-IS. • **Multicast routing protocols**—Examples include PIM-SM and PIM-DM.
IP version	• **IPv4 routing protocols**—Examples include RIP, OSPF, BGP, and IS-IS. • **IPv6 routing protocols**—Examples include RIPng, OSPFv3, IPv6 BGP, and IPv6 IS-IS.

An AS refers to a group of routers that use the same routing policy and work under the same administration.

Route preference

Routing protocols, including static and direct routing, each by default have a preference. If they find multiple routes to the same destination, the router selects the route with the highest preference as the optimal route.

The preference of a direct route is always 0 and cannot be changed. You can configure a preference for each static route and each dynamic routing protocol. The following table lists the route types and default preferences. The smaller the value, the higher the preference.

Table 3 Route types and default route preferences

Route type	Preference
Direct route	0
Multicast static route	1
OSPF	10
IS-IS	15
Unicast static route	60
RIP	100
OSPF ASE	150
OSPF NSSA	150
Guard	254
IBGP	255
EBGP	255
Unknown (route from an untrusted source)	256

Load sharing

A routing protocol might find multiple optimal equal-cost routes to the same destination. You can use these routes to implement equal-cost multi-path (ECMP) load sharing.

Static routing, IPv6 static routing, RIP, RIPng, OSPF, OSPFv3, BGP, IPv6 BGP, IS-IS, and IPv6 IS-IS support ECMP load sharing.

Route backup

Route backup can improve network availability. Among multiple routes to the same destination, the route with the highest priority is the primary route and others are secondary routes.

The router forwards matching packets through the primary route. When the primary route fails, the route with the highest preference among the secondary routes is selected to forward packets. When the primary route recovers, the router uses it to forward packets.

Route recursion

To use a BGP, static, or RIP route that has an indirectly connected next hop, a router must perform route recursion to find the output interface to reach the next hop.

Link-state routing protocols, such as OSPF and IS-IS, do not need route recursion, because they obtain directly connected next hops through route calculation.

The RIB records and saves route recursion information, including brief information about related routes, recursive paths, and recursion depth.

Route redistribution

Route redistribution enables routing protocols to learn routing information from each other. A dynamic routing protocol can redistribute routes from other routing protocols, including direct and static routing. For more information, see the respective chapters on those routing protocols in this configuration guide.

The RIB records redistribution relationships of routing protocols.

Extension attribute redistribution

Extension attribute redistribution enables routing protocols to learn route extension attributes from each other, including BGP extended community attributes, OSPF area IDs, route types, and router IDs.

The RIB records extended attributes of each routing protocol and redistribution relationships of different routing protocol extended attributes.

Setting the maximum lifetime for routes in the RIB

About this task

Perform this task to prevent routes of a certain protocol from being aged out due to slow protocol convergence resulting from a large number of route entries or long GR period.

Restrictions and guidelines

The configuration takes effect at the next protocol or RIB process switchover.

Procedure (IPv4)

1. Enter system view.
   system-view
2. Enter RIB view.
   rib
3. Create the RIB IPv4 address family and enter its view.
   address-family ipv4
4. Set the maximum lifetime for IPv4 routes in the RIB.
   protocol *protocol* **lifetime** *seconds*

   By default, the maximum lifetime for routes in the RIB is 480 seconds.

Procedure (IPv6)

1. Enter system view.
   system-view
2. Enter RIB view.
   rib
3. Create the RIB IPv6 address family and enter its view.
   address-family ipv6
4. Set the maximum lifetime for IPv6 routes in the RIB.
   protocol *protocol* **lifetime** *seconds*

   By default, the maximum lifetime for routes in the RIB is 480 seconds.

Setting the maximum lifetime for routes in the FIB

About this task

When GR or NSR is disabled, FIB entries must be retained for some time after a protocol process switchover or RIB process switchover. When GR or NSR is enabled, FIB entries must be removed immediately after a protocol or RIB process switchover to avoid routing issues. Perform this task to meet such requirements.

Procedure (IPv4)

1. Enter system view.
   system-view
2. Enter RIB view.
   rib
3. Create the RIB IPv4 address family and enter its view.
   address-family ipv4
4. Set the maximum lifetime for IPv4 routes in the FIB.
   fib lifetime *seconds*

   By default, the maximum lifetime for routes in the FIB is 600 seconds.

Procedure (IPv6)

1. Enter system view.
   system-view
2. Enter RIB view.
   rib

3. Create the RIB IPv6 address family and enter its view.

   ```
   address-family ipv6
   ```

4. Set the maximum lifetime for IPv6 routes in the FIB.

   ```
   fib lifetime seconds
   ```

   By default, the maximum lifetime for routes in the FIB is 600 seconds.

Setting the maximum number of ECMP routes

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB680, NFNX3-HDB1080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB1780, NFNX3-HDB3080	No

Restrictions and guidelines

This configuration takes effect at reboot. Make sure the reboot does not impact your network.

Procedure (IPv4)

1. Enter system view.

   ```
   system-view
   ```

2. Set the maximum number of ECMP routes.

   ```
   max-ecmp-num number
   ```

   The default maximum number of ECMP routes varies by device model. For more information, see the command reference.

Procedure (IPv6)

1. Enter system view.

   ```
   system-view
   ```

2. Set the maximum number of ECMP routes.

   ```
   ipv6 max-ecmp-num number
   ```

   The default maximum number of ECMP routes varies by device model. For more information, see the command reference.

Configuring RIB NSR

About this task

When an active/standby switchover occurs, nonstop routing (NSR) backs up routing information from the active process to the standby process to avoid routing flapping and ensure forwarding continuity.

RIB NSR provides faster route convergence than protocol NSR during an active/standby switchover.

Restrictions and guidelines

Use this feature with protocol GR or NSR to avoid route timeouts and traffic interruption.

Procedure (IPv4)

1. Enter system view.

   system-view

2. Enter RIB view.

   rib

3. Create the RIB IPv4 address family and enter its view.

   address-family ipv4

4. Enable IPv4 RIB NSR.

   non-stop-routing

   By default, RIB NSR is disabled.

Procedure (IPv6)

1. Enter system view.

   system-view

2. Enter RIB view.

   rib

3. Create the RIB IPv6 address family and enter its view.

   address-family ipv6

4. Enable IPv6 RIB NSR.

   non-stop-routing

   By default, RIB NSR is disabled.

Configuring inter-protocol FRR

About this task

Inter-protocol fast reroute (FRR) enables fast rerouting between routes of different protocols. A backup next hop is automatically selected to reduce the service interruption time caused by unreachable next hops. When the next hop of the primary link fails, the traffic is redirected to the backup next hop.

Among the routes to the same destination in the RIB, a router adds the route with the highest preference to the FIB table. For example, if a static route and an OSPF route in the RIB have the same destination, the router adds the OSPF route to the FIB table by default. The next hop of the static route is selected as the backup next hop for the OSPF route. When the next hop of the OSPF route is unreachable, the backup next hop is used.

Restrictions and guidelines

This feature uses the next hop of a route from a different protocol as the backup next hop, which might cause loops.

Procedure (IPv4)

1. Enter system view.

   system-view

2. Enter RIB view.

   rib

3. Create the RIB IPv4 address family and enter its view.

   address-family ipv4

4. Enable IPv4 RIB inter-protocol FRR.

inter-protocol fast-reroute [**vpn-instance** *vpn-instance-name*]

By default, inter-protocol FRR is disabled.

If you do not specify a VPN instance, inter-protocol FRR is enabled for the public network.

Procedure (IPv6)

1. Enter system view.
   system-view
2. Enter RIB view.
   rib
3. Create the RIB IPv6 address family and enter its view.
   address-family ipv6
4. Enable IPv6 RIB inter-protocol FRR.
   inter-protocol fast-reroute [**vpn-instance** *vpn-instance-name*]
   By default, inter-protocol FRR is disabled.
   If you do not specify a VPN instance, inter-protocol FRR is enabled for the public network.

Display and maintenance commands for basic IP routing

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display routing table information.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] [**verbose**]
Display information about routes permitted by an IPv4 basic ACL.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] **acl** *ipv4-acl-number* [**verbose**]
Display information about routes to a specific destination address.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] *ip-address* [*mask-length* | *mask*] [**longer-match**] [**verbose**]
Display information about routes to a range of destination addresses.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] *ip-address1* **to** *ip-address2* [**verbose**]
Display information about routes permitted by an IP prefix list.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] **prefix-list** *prefix-list-name* [**verbose**]
Display information about routes installed by a protocol.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] **protocol** *protocol* [**inactive** | **verbose**]
Display IPv4 route statistics.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] **statistics**
Display brief IPv4 routing table information.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] **summary**
Display route attribute information in the IPv6 RIB.	**display ipv6 rib attribute** [*attribute-id*]

Task	Command
Display IPv6 RIB GR state information.	**display ipv6 rib graceful-restart**
Display next hop information in the IPv6 RIB.	**display ipv6 rib nib** [**self-originated**] [*nib-id*] [**verbose**] **display ipv6 rib nib protocol** *protocol* [**verbose**]
Display next hop information for IPv6 direct routes.	**display ipv6 route-direct nib** [*nib-id*] [**verbose**]
Display IPv6 routing table information.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] [**verbose**]
Display information about routes permitted by an IPv6 basic ACL.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] **acl** *ipv6-acl-number* [**verbose**]
Display information about routes to an IPv6 destination address.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] *ipv6-address* [*prefix-length*] [**longer-match**] [**verbose**]
Display information about routes to a range of IPv6 destination addresses.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] *ipv6-address1* **to** *ipv6-address2* [**verbose**]
Display information about routes permitted by an IPv6 prefix list.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] **prefix-list** *prefix-list-name* [**verbose**]
Display information about routes installed by an IPv6 protocol.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] **protocol** *protocol* [**inactive** | **verbose**]
Display IPv6 route statistics.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] **statistics**
Display brief IPv6 routing table information.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] **summary**
Display route attribute information in the RIB.	**display rib attribute** [*attribute-id*]
Display RIB GR state information.	**display rib graceful-restart**
Display next hop information in the RIB.	**display rib nib** [**self-originated**] [*nib-id*] [**verbose**] **display rib nib protocol** *protocol* [**verbose**]
Display next hop information for direct routes.	**display route-direct nib** [*nib-id*] [**verbose**]
Clear IPv4 route statistics.	**reset ip routing-table statistics protocol** [**vpn-instance** *vpn-instance-name*] { *protocol* | **all** }
Clear IPv6 route statistics.	**reset ipv6 routing-table statistics protocol** [**vpn-instance** *vpn-instance-name*] { *protocol* | **all** }

Contents

Configuring static routing

About static routes

Static routes are manually configured. If a network's topology is simple, you only need to configure static routes for the network to work correctly.

Static routes cannot adapt to network topology changes. If a fault or a topological change occurs in the network, the network administrator must modify the static routes manually.

Configuring a static route

1. Enter system view.

   ```
   system-view
   ```

2. Configure a static route.

   Public network:

   ```
   ip route-static dest-address { mask-length | mask } { interface-type
   interface-number [ next-hop-address ] | next-hop-address |
   vpn-instance d-vpn-instance-name next-hop-address } [ permanent |
   track track-entry-number ] [ preference preference ] [ tag tag-value ]
   [ description text ]
   ```

   By default, no static route is configured.

   You can associate Track with a static route to monitor the reachability of the next hops. For more information about Track, see *Network Management and Monitoring Configuration Guide*.

   VPN:

   ```
   ip route-static vpn-instance s-vpn-instance-name dest-address
   { mask-length | mask } { interface-type interface-number
   [ next-hop-address ] | next-hop-address [ public ] | vpn-instance
   d-vpn-instance-name next-hop-address } [ permanent | track
   track-entry-number ] [ preference preference ] [ tag tag-value ]
   [ description text ]
   ```

   By default, no static route is configured.

   You can associate Track with a static route to monitor the reachability of the next hops. For more information about Track, see *Network Management and Monitoring Configuration Guide*.

3. (Optional.) Configure the default preference for static routes.

   ```
   ip route-static default-preference default-preference
   ```

   The default setting is 60.

Configuring a static route group

About this task

This task allows you to batch create static routes with different prefixes but the same output interface and next hop.

You can create a static route group, and specify the static group in the **ip route-static** command. All prefixes in the static route group will be assigned the next hop and output interface specified in the **ip route-static** command.

Procedure

1. Enter system view.

   system-view

2. Create a static route group and enter its view.

   ip route-static-group *group-name*

   By default, no static route group is configured.

3. Add a static route prefix to the static route group.

   prefix *dest-address* { *mask-length* | *mask* }

   By default, no static route prefix is added to the static route group.

4. Return to system view.

   quit

5. Configure a static route.

   Public network:

   ip route-static group *group-name* { *interface-type interface-number* [*next-hop-address*] | *next-hop-address* | **vpn-instance** *d-vpn-instance-name next-hop-address* } [**permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   VPN:

   ip route-static vpn-instance *s-vpn-instance-name* **group** *group-name* { *interface-type interface-number* [*next-hop-address*] | *next-hop-address* [**public**] | **vpn-instance** *d-vpn-instance-name next-hop-address* } [**permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, no static route is configured.

Configuring the DHCP-designated default router as the next hop of a static route

About this task

After an interface obtains an IP address and gateway address through DHCP, the device automatically generates a static route with the interface as the output interface. The destination address of the static route is 0.0.0.0/0 and the next hop of the static route is the default router (the gateway address designated by the DHCP server). This static route cannot form ECMP routes with manually configured static routes. The device uses this static route to guide traffic forwarding only after the manually configured static routes become invalid.

Perform this task to use both the automatically generated static route and the manually configured static routes to guide traffic forwarding. The task is applicable when the device has dual egress WAN links.

This task enables the device to automatically generate a static route destined for the specified network with the DHCP-designated default router of the output interface as the next hop. This static route takes effect only after the output interface obtains an IP address and gateway address through DHCP, and becomes invalid upon the DHCP lease expiration. The next hop of this static route changes as the gateway address of the output interface changes. In addition, this static route can form ECMP routes with manually configured static routes.

Restrictions and guidelines

When you configure the next hop of a static route as the DHCP-designated default router, make sure the output interface of the static route is a broadcast interface.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Configure a static route and specify the default router designated by the DHCP server for the output interface as the next hop of the static route.

   Public network:

   ```
   ip route-static { dest-address { mask-length | mask } | group group-name }
   interface-type interface-number dhcp [ backup-interface
   interface-type interface-number [ backup-nexthop
   backup-nexthop-address ] [ permanent ] | permanent | track
   track-entry-number ] [ preference preference ] [ tag tag-value ]
   [ description text ]
   ```

   VPN:

   ```
   ip route-static vpn-instance s-vpn-instance-name dest-address
   { mask-length | mask } interface-type interface-number dhcp
   [ backup-interface interface-type interface-number [ backup-nexthop
   backup-nexthop-address ] [ permanent ] | permanent | track
   track-entry-number ] [ preference preference ] [ tag tag-value ]
   [ description text ]
   ```

   ```
   ip route-static vpn-instance s-vpn-instance-name group group-name
   interface-type interface-number dhcp [ backup-interface
   interface-type interface-number [ backup-nexthop
   backup-nexthop-address ] [ permanent ] ] [ preference preference ] [ tag
   tag-value ] [ description text ]
   ```

   By default, no static route is configured with the DHCP-designated default router as the next hop.

Deleting static routes

About this task

To delete a static route, use the **undo ip route-static** command. To delete all static routes including the default route, use the **delete static-routes all** command.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Delete all static routes.

   Public network:

   ```
   delete static-routes all
   ```

   VPN:

   ```
   delete vpn-instance vpn-instance-name static-routes all
   ```

CAUTION:

This command might interrupt network communication and cause packet forwarding failure. Before executing the command, make sure you fully understand the potential impact on the network.

Configuring BFD for static routes

IMPORTANT:

Enabling BFD for a flapping route could worsen the situation.

About BFD

BFD provides a general-purpose, standard, medium-, and protocol-independent fast failure detection mechanism. It can uniformly and quickly detect the failures of the bidirectional forwarding paths between two routers for protocols, such as routing protocols.

For more information about BFD, see *Network Management and Monitoring Configuration Guide*.

Configuring BFD control packet mode

About this task

This mode uses BFD control packets to detect the status of a link bidirectionally at a millisecond level.

BFD control packet mode can be applied to static routes with a direct next hop or with an indirect next hop.

Restrictions and guidelines for BFD control packet mode

If you use BFD control packet mode at the local end, you must use this mode also at the peer end.

Configuring BFD control packet mode for a static route (direct next hop)

1. Enter system view.

   `system-view`

2. Configure BFD control packet mode for a static route.

   Public network:

   ip route-static *dest-address* { *mask-length* | *mask* } *interface-type interface-number* { **dhcp** | *next-hop-address* } **bfd** { **control-packet** | **static** *session-name* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   VPN:

   ip route-static vpn-instance *s-vpn-instance-name dest-address* { *mask-length* | *mask* } *interface-type interface-number* { **dhcp** | *next-hop-address* } **bfd** { **control-packet** | **static** *session-name* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, BFD control packet mode for a static route is not configured.

Configuring BFD control packet mode for a static route (indirect next hop)

1. Enter system view.

   `system-view`

2. Configure BFD control packet mode for a static route.

   Public network:

   ip route-static *dest-address* { *mask-length* | *mask* } { *next-hop-address* **bfd control-packet bfd-source** *ip-address* | **vpn-instance**

```
d-vpn-instance-name next-hop-address bfd { control-packet bfd-source
ip-address | static session-name } } [ preference preference ] [ tag
tag-value ] [ description text ]
```

VPN:

```
ip route-static vpn-instance s-vpn-instance-name dest-address
{ mask-length | mask } { next-hop-address bfd { control-packet
bfd-source ip-address | static session-name } | vpn-instance
d-vpn-instance-name next-hop-address bfd { control-packet bfd-source
ip-address | static session-name } } [ preference preference ] [ tag
tag-value ] [ description text ]
```

By default, BFD control packet mode for a static route is not configured.

Configuring BFD echo packet mode

About this task

With BFD echo packet mode enabled for a static route, the output interface sends BFD echo packets to the destination device, which loops the packets back to test the link reachability.

Restrictions and guidelines

You do not need to configure BFD echo packet mode at the peer end.

Do not use BFD for a static route with the output interface in spoofing state.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Configure the source address of echo packets.

   ```
   bfd echo-source-ip ip-address
   ```

   By default, the source address of echo packets is not configured.

   For more information about this command, see *Network Management and Monitoring Command Reference*.

3. Configure BFD echo packet mode for a static route.

   Public network:

   ```
   ip route-static dest-address { mask-length | mask } interface-type
   interface-number { dhcp | next-hop-address } bfd { echo-packet | static
   session-name } [ preference preference ] [ tag tag-value ] [ description
   text ]
   ```

   VPN:

   ```
   ip route-static vpn-instance s-vpn-instance-name dest-address
   { mask-length | mask } interface-type interface-number { dhcp |
   next-hop-address } bfd { echo-packet | static session-name }
   [ preference preference ] [ tag tag-value ] [ description text ]
   ```

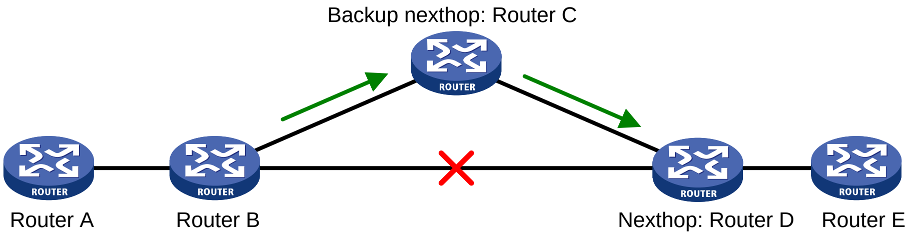
   By default, BFD echo packet mode for a static route is not configured.

Configuring static route FRR

About static route FRR

A link or router failure on a path can cause packet loss. Static route fast reroute (FRR) enables fast rerouting to minimize the impact of link or node failures.

Figure 1 Network diagram



As shown in Figure 1, upon a link failure, packets are directed to the backup next hop to avoid traffic interruption. You can either specify a backup next hop for FRR or enable FRR to automatically select a backup next hop (which must be configured in advance).

Restrictions and guidelines for static route FRR

Do not use static route FRR and BFD (for a static route) at the same time.

Equal-cost routes do not support static route FRR.

Besides the configured static route for FRR, the device must have another route to reach the destination. When the state of the primary link (with Layer 3 interfaces staying up) changes from bidirectional to unidirectional or down, static route FRR quickly redirects traffic to the backup next hop. When the Layer 3 interfaces of the primary link are down, static route FRR temporarily redirects traffic to the backup next hop. In addition, the device searches for another route to reach the destination and redirects traffic to the new path if a route is found. If no route is found, traffic interruption occurs.

Configuring static route FRR by specifying a backup next hop

Restrictions and guidelines

A static route does not take effect when the backup output interface is unavailable.

To change the backup output interface or next hop, you must first remove the current setting. The backup output interface and next hop must be different from the primary output interface and next hop.

Procedure

1. Enter system view.

   system-view

2. Configure static route FRR.

   Public network:

   ip route-static *dest-address* { *mask-length* | *mask* } *interface-type interface-number* [{ **dhcp** | *next-hop-address* } [**backup-interface** *interface-type interface-number* [**backup-nexthop** *backup-nexthop-address*]]] [**permanent**] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   VPN:

   ip route-static vpn-instance *s-vpn-instance-name dest-address* { *mask-length* | *mask* } *interface-type interface-number* [{ **dhcp** | *next-hop-address* } [**backup-interface** *interface-type interface-number* [**backup-nexthop** *backup-nexthop-address*]]] [**permanent**] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, static route FRR is disabled.

Configuring static route FRR to automatically select a backup next hop

1. Enter system view.

   system-view

2. Configure static route FRR to automatically select a backup next hop.

   ip route-static fast-reroute auto

   By default, static route FRR is disabled from automatically selecting a backup next hop.

Enabling BFD echo packet mode for static route FRR

About this task

By default, static route FRR uses ARP to detect primary link failures. Perform this task to enable static route FRR to use BFD echo packet mode for fast failure detection on the primary link.

Procedure

1. Enter system view.

   system-view

2. Configure the source IP address of BFD echo packets.

   bfd echo-source-ip *ip-address*

   By default, the source IP address of BFD echo packets is not configured.

   The source IP address cannot be on the same network segment as any local interface's IP address.

   For more information about this command, see *Network Management and Monitoring Command Reference*.

3. Enable BFD echo packet mode for static route FRR.

   ip route-static primary-path-detect bfd echo

   By default, BFD echo packet mode for static route FRR is disabled.

Display and maintenance commands for static routing

Execute **display** commands in any view.

Task	Command
Display static route information.	**display ip routing-table protocol static** [**inactive** | **verbose**]
Display static route next hop information.	**display route-static nib** [*nib-id*] [**verbose**]
Display static routing table information.	**display route-static routing-table** [**vpn-instance** *vpn-instance-name*] [*ip-address* { *mask-length* | *mask* }]

For more information about the **display ip routing-table protocol static** [**inactive** | **verbose**] command, see basic IP routing in *Layer 3—IP Routing Command Reference*.

Configuring a default route

A default route is used to forward packets that do not match any specific routing entry in the routing table. Without a default route, packets that do not match any routing entries are discarded and an ICMP destination-unreachable packet is sent to the source.

A default route can be configured in either of the following ways:

- The network administrator can configure a default route with both destination and mask being 0.0.0.0. For more information, see "Configuring static routing."
- Some dynamic routing protocols (such as OSPF and RIP) can generate a default route. For example, an upstream router running OSPF can generate a default route and advertise it to other routers. These routers install the default route with the next hop being the upstream router. For more information, see the respective chapters on these routing protocols in this configuration guide.

Contents

Configuring IPv6 static routing

About IPv6 static routing

Static routes are manually configured and cannot adapt to network topology changes. If a fault or a topological change occurs in the network, the network administrator must modify the static routes manually. IPv6 static routing works well in a simple IPv6 network.

Configuring an IPv6 static route

1. Enter system view.

   ```
   system-view
   ```

2. Configure an IPv6 static route.

   Public network:

   ```
   ipv6 route-static ipv6-address prefix-length { interface-type
   interface-number [ next-hop-address ] | next-hop-address |
   vpn-instance d-vpn-instance-name next-hop-address } [ permanent |
   track track-entry-number ] [ preference preference ] [ tag tag-value ]
   [ description text ]
   ```

   By default, no IPv6 static route is configured.

   VPN:

   ```
   ipv6 route-static vpn-instance s-vpn-instance-name ipv6-address
   prefix-length { interface-type interface-number [ next-hop-address ] |
   next-hop-address [ public ] | vpn-instance d-vpn-instance-name
   next-hop-address } [ permanent | track track-entry-number ]
   [ preference preference ] [ tag tag-value ] [ description text ]
   ```

   ```
   ipv6 route-static vpn-instance s-vpn-instance-name ipv6-address
   prefix-length nexthop-address [ public ] [ permanent ] [ preference
   preference ] [ tag tag-value ] [ description text ]
   ```

   By default, no IPv6 static route is configured.

3. (Optional.) Set the default preference for IPv6 static routes.

   ```
   ipv6 route-static default-preference default-preference
   ```

   The default setting is 60.

Deleting IPv6 static routes

About this task

To delete an IPv6 static route, use the **undo ipv6 route-static** command. To delete all IPv6 static routes including the default route, use the **delete ipv6 static-routes all** command.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Delete all IPv6 static routes, including the default route.

   ```
   delete ipv6 [ vpn-instance vpn-instance-name ] static-routes all
   ```

△ **CAUTION:**

This command might interrupt network communication and cause packet forwarding failure. Before executing the command, make sure you fully understand the potential impact on the network.

Configuring BFD for IPv6 static routes

About BFD for IPv6 static routes

BFD provides a general purpose, standard, and medium- and protocol-independent fast failure detection mechanism. It can uniformly and quickly detect the failures of the bidirectional forwarding paths between two routers for protocols, such as routing protocols. BFD for IPv6 static routes tests the reachability of the next hop for each IPv6 static route. If a next hop is unreachable, BFD deletes the associated IPv6 static route.

For more information about BFD, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines for BFD

When you configure BFD for IPv6 static routes, follow these restrictions and guidelines:

- If you specify a source IPv6 address for BFD packets on the local device, you must specify that IPv6 address as the next hop IPv6 address on the peer device.
- If you specify a non-P2P output interface and a direct next hop, specify the **bfd-source** *ipv6-address* option as a best practice. Make sure the source IPv6 address of BFD packets meets the following requirements:
    - The address is the same as the IPv6 address of the output interface.
    - The address is on the same network segment as the next hop IPv6 address of the same type.

      For example, if the next hop IPv6 address is a link-local address, the source IPv6 address of BFD packets must also be a link-local address.
- Enabling BFD for a flapping route could worsen the situation.

Configuring BFD control packet mode

About this task

This mode uses BFD control packets to detect the status of a link bidirectionally at a millisecond level.

BFD control packet mode can be applied to IPv6 static routes with a direct next hop or with an indirect next hop.

Restrictions and guidelines for BFD control packet mode

If you configure BFD control packet mode at the local end, you must also configure this mode at the peer end.

Configuring BFD control packet mode for an IPv6 static route (direct next hop)

1. Enter system view.

   system-view
2. Configure BFD control packet mode for an IPv6 static route.

ipv6 route-static [**vpn-instance** *s-vpn-instance-name*] *ipv6-address prefix-length interface-type interface-number next-hop-address* **bfd control-packet** [**bfd-source** *ipv6-address*] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

By default, BFD control packet mode for an IPv6 static route is not configured.

Configuring BFD control packet mode for an IPv6 static route (indirect next hop)

1. Enter system view.

   system-view
2. Configure BFD control packet mode for an IPv6 static route.

   ipv6 route-static [**vpn-instance** *s-vpn-instance-name*] *ipv6-address prefix-length* [**vpn-instance** *d-vpn-instance-name*] { *next-hop-address* **bfd control-packet bfd-source** *ipv6-address* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, BFD control packet mode for an IPv6 static route is not configured.

Configuring BFD echo packet mode

About this task

With BFD echo packet mode enabled for a static route, the output interface sends BFD echo packets to the destination device, which loops the packets back to test the link reachability.

Restrictions and guidelines

You do not need to configure BFD echo packet mode at the peer end.

Do not use BFD for a static route with the output interface in spoofing state.

Procedure

1. Enter system view.

   system-view
2. Configure the source address of echo packets.

   bfd echo-source-ipv6 *ipv6-address*

   By default, the source address of echo packets is not configured.

   The source address of echo packets must be a global unicast address.

   For more information about this command, see *Network Management and Monitoring Command Reference*.
3. Configure BFD echo packet mode for an IPv6 static route.

   ipv6 route-static [**vpn-instance** *s-vpn-instance-name*] *ipv6-address prefix-length interface-type interface-number next-hop-address* **bfd echo-packet** [**bfd-source** *ipv6-address*] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, BFD echo packet mode for an IPv6 static route is not configured.

   The next hop IPv6 address must be a global unicast address.

Display and maintenance commands for IPv6 static routing

Execute **display** commands in any view.

Task	Command
Display IPv6 static route next hop information.	**display ipv6 route-static nib** [*nib-id*] [**verbose**]
Display IPv6 static routing table information.	**display ipv6 route-static routing-table** [**vpn-instance** *vpn-instance-name*] [*ipv6-address prefix-length*]
Display IPv6 static route information.	**display ipv6 routing-table protocol static** [**inactive** | **verbose**]

For more information about the **display ipv6 routing-table protocol static** [**inactive** | **verbose**] command, see basic IP routing in *Layer 3—IP Routing Command Reference*.

Configuring an IPv6 default route

A default IPv6 route is used to forward packets that match no entry in the routing table.

A default IPv6 route can be configured in either of the following ways:

- The network administrator can configure a default route with a destination prefix of **::/0**. For more information, see "Configuring IPv6 static routing."
- Some dynamic routing protocols (such as OSPFv3, IPv6 IS-IS, and RIPng) can generate a default IPv6 route. For example, an upstream router running OSPFv3 can generate a default IPv6 route and advertise it to other routers. These routers install the default IPv6 route with the next hop being the upstream router. For more information, see the respective chapters on those routing protocols in this configuration guide.

Contents

Configuring RIP

About RIP

Routing Information Protocol (RIP) is a distance-vector IGP suited to small-sized networks. It employs UDP to exchange route information through port 520.

RIP routing metrics

RIP uses a hop count to measure the distance to a destination. The hop count from a router to a directly connected network is 0. The hop count from a router to a directly connected router is 1. To limit convergence time, RIP restricts the value range of the metric from 0 to 15. A destination with a metric value of 16 (or greater) is considered unreachable. For this reason, RIP is not suitable for large-sized networks.

RIP route entries

RIP stores routing entries in a database. Each routing entry contains the following elements:

- **Destination address**—IP address of a destination host or a network.
- **Next hop**—IP address of the next hop.
- **Egress interface**—Egress interface of the route.
- **Metric**—Cost from the local router to the destination.
- **Route time**—Time elapsed since the last update. The time is reset to 0 when the routing entry is updated.
- **Route tag**—Used for route control. For more information, see "Configuring routing policies."

RIP operation

RIP works as follows:

1. RIP sends request messages to neighboring routers. Neighboring routers return response messages that contain their routing tables.
2. RIP uses the received responses to update the local routing table and sends triggered update messages to its neighbors. All RIP routers on the network do this to learn latest routing information.
3. RIP periodically sends the local routing table to its neighbors. After a RIP neighbor receives the message, it updates its routing table, selects optimal routes, and sends an update to other neighbors. RIP ages routes to keep only valid routes.

Routing loop prevention

RIP uses the following mechanisms to prevent routing loops:

- **Counting to infinity**—A destination with a metric value of 16 is considered unreachable. When a routing loop occurs, the metric value of a route will increment to 16 to avoid endless looping.
- **Triggered updates**—RIP immediately advertises triggered updates for topology changes to reduce the possibility of routing loops and to speed up convergence.
- **Split horizon**—Disables RIP from sending routes through the interface where the routes were learned to prevent routing loops and save bandwidth.

- **Poison reverse**—Enables RIP to set the metric of routes received from a neighbor to 16 and sends these routes back to the neighbor. The neighbor can delete such information from its routing table to prevent routing loops.

RIP versions

There are two RIP versions, RIPv1 and RIPv2.

RIPv1 is a classful routing protocol. It advertises messages only through broadcast. RIPv1 messages do not carry mask information, so RIPv1 can only recognize natural networks such as Class A, B, and C. For this reason, RIPv1 does not support discontiguous subnets.

RIPv2 is a classless routing protocol. It has the following advantages over RIPv1:

- Supports route tags to implement flexible route control through routing policies.
- Supports masks, route summarization, and CIDR.
- Supports designated next hops to select the best ones on broadcast networks.
- Supports multicasting route updates so only RIPv2 routers can receive these updates to reduce resource consumption.
- Supports plain text authentication and MD5 authentication to enhance security.

RIPv2 supports two transmission modes: broadcast and multicast. Multicast is the default mode using 224.0.0.9 as the multicast address. An interface operating in RIPv2 broadcast mode can also receive RIPv1 messages.

Protocols and standards

- RFC 1058, *Routing Information Protocol*
- RFC 1723, *RIP Version 2 - Carrying Additional Information*
- RFC 1721, *RIP Version 2 Protocol Analysis*
- RFC 1722, *RIP Version 2 Protocol Applicability Statement*
- RFC 1724, *RIP Version 2 MIB Extension*
- RFC 2082, *RIPv2 MD5 Authentication*
- RFC 2091, *Triggered Extensions to RIP to Support Demand Circuits*
- RFC 2453, *RIP Version 2*

RIP tasks at a glance

To configure RIP, perform the following tasks:

1. Configuring basic RIP
   a. Enabling RIP
   b. (Optional.) Controlling RIP reception and advertisement on interfaces
   c. (Optional.) Configuring a RIP version
   d. Specifying a RIP neighbor

      To enable RIP on a link that does not support broadcast or multicast, you must manually specify a RIP neighbor.
2. (Optional.) Configuring RIP route control
   - Configuring an additional routing metric
   - Configuring RIPv2 route summarization
   - Disabling host route reception

   - Advertising a default route
   - Configuring received/redistributed route filtering
   - Setting a preference for RIP
   - Configuring RIP route redistribution
3. (Optional.) Tuning and optimizing RIP networks
   - Setting RIP timers
   - Enabling split horizon and poison reverse
   - Setting the maximum number of RIP ECMP routes
   - Setting the RIP triggered update interval
   - Configuring the RIP packet sending rate
   - Setting the maximum length of RIP packets
4. (Optional.) Configuring RIP network management
5. Enhancing RIP availability
   - Configuring RIP GR
   - Enabling RIP NSR
   - Configuring BFD for RIP
   - Configuring RIP FRR
6. (Optional.) Enhancing RIP security
   - Enabling zero field check for incoming RIPv1 messages
   - Enabling source IP address check for incoming RIP updates
   - Configuring RIPv2 message authentication

Configuring basic RIP

Restrictions and guidelines for configuring basic RIP

To enable multiple RIP processes on a router, you must specify an ID for each process. A RIP process ID has only local significance. Two RIP routers having different process IDs can also exchange RIP packets.

Enabling RIP

About this task

You can enable RIP on a network and specify a wildcard mask for the network. After that, only the interface attached to the network runs RIP.

Restrictions and guidelines

If you configure RIP settings in interface view before enabling RIP, the settings do not take effect until RIP is enabled.

If a physical interface is attached to multiple networks, you cannot advertise these networks in different RIP processes.

You cannot enable multiple RIP processes on a physical interface.

The **rip enable** command takes precedence over the **network** command.

Enabling RIP on a network

1. Enter system view.

system-view

2. Enable RIP and enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

   By default, RIP is disabled.

3. Enable RIP on a network.

   network *network-address* [*wildcard-mask*]

   By default, RIP is disabled on a network.

   The **network** 0.0.0.0 command can enable RIP on all interfaces in a single process, but does not apply to multiple RIP processes.

Enabling RIP on an interface

1. Enter system view.

   system-view

2. Enable RIP and enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

   By default, RIP is disabled.

3. Return to system view.

   quit

4. Enter interface view.

   interface *interface-type interface-number*

5. Enable RIP on the interface.

   rip *process-id* **enable** [**exclude-subip**]

   By default, RIP is disabled on an interface.

Controlling RIP reception and advertisement on interfaces

About this task

You can perform this task to configure the following features:

- Suppressing an interface. The suppressed interface can receive RIP messages but cannot send RIP messages.
- Disabling an interface from sending RIP messages.
- Disabling an interface from receiving RIP messages.

Restrictions and guidelines for RIP reception and advertisement control on interfaces

An interface suppressed by using the **silent-interface** command can only receive RIP messages. It cannot send RIP messages. You can use the **silent-interface all** command to suppress all interfaces. The **silent-interface** command takes precedence over the **rip input** and **rip output** commands.

Suppressing an interface

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Suppress an interface.

   silent-interface { *interface-type interface-number* | **all** }

   By default, all RIP-enabled interfaces can send RIP messages.

The suppressed interface can still receive RIP messages and respond to unicast requests containing unknown ports.

Disabling an interface from receiving RIP messages

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Disable an interface from receiving RIP messages.

   `undo rip input`

   By default, a RIP-enabled interface can receive RIP messages.

Disabling an interface from sending RIP messages

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Disable an interface from sending RIP messages.

   `undo rip output`

   By default, a RIP-enabled interface can send RIP messages.

Configuring a RIP version

About this task

You can configure a global RIP version in RIP view or an interface-specific RIP version in interface view.

An interface preferentially uses the interface-specific RIP version. If no interface-specific version is specified, the interface uses the global RIP version. If neither a global nor interface-specific RIP version is configured, the interface sends RIPv1 broadcasts and can receive the following:

- RIPv1 broadcasts and unicasts.
- RIPv2 broadcasts, multicasts, and unicasts.

Procedure

1. Enter system view.

   `system-view`

2. Specify a RIP version.
   - Execute the following commands in sequence to specify a global RIP version:

     `rip` [*`process-id`*] [**`vpn-instance`** *`vpn-instance-name`*]

     `version` { **`1`** | **`2`** }

     By default, no global version is specified. An interface sends RIPv1 broadcasts, and can receive RIPv1 broadcasts and unicasts, and RIPv2 broadcasts, multicasts, and unicasts.
   - Execute the following commands in sequence to specify a RIP version on an interface:

     `interface` *`interface-type interface-number`*

     `rip version` { **`1`** | **`2`** [**`broadcast`** | **`multicast`**] }

     By default, no interface-specific RIP version is specified. The interface sends RIPv1 broadcasts, and can receive RIPv1 broadcasts and unicasts, and RIPv2 broadcasts, multicasts, and unicasts.

Specifying a RIP neighbor

About this task

Typically RIP messages are sent in broadcast or multicast. To enable RIP on a link that does not support broadcast or multicast, you must manually specify a RIP neighbor.

Restrictions and guidelines

As a best practice, do not use the **peer** *ip-address* command to specify a directly connected neighbor. The neighbor might receive a route update in both unicast and multicast (or broadcast) messages from the device.

Procedure

1. Enter system view.

   `system-view`

2. Enter RIP view.

   `rip` [*`process-id`*] [**`vpn-instance`** *`vpn-instance-name`*]

3. Specify a RIP neighbor.

   `peer` *`ip-address`*

   By default, RIP does not unicast updates to any peer.

4. Disable source IP address check on inbound RIP updates.

   `undo validate-source-address`

   By default, source IP address check is enabled on inbound RIP updates.

   If the specified neighbor is not directly connected, disable source address check on incoming updates.

Configuring RIP route control

Configuring an additional routing metric

About this task

An additional routing metric (hop count) can be added to the metric of an inbound or outbound RIP route.

- An outbound additional metric is added to the metric of a sent route, and it does not change the route's metric in the routing table.
- An inbound additional metric is added to the metric of a received route before the route is added into the routing table, and the route's metric is changed. If the sum of the additional metric and the original metric is greater than 16, the metric of the route is 16.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Specify an inbound additional routing metric.

   `rip metricin` [**`route-policy`** *`route-policy-name`*] *`value`*

   By default, the additional metric of an inbound route is 0.

4. Specify an outbound additional routing metric.

rip metricout [**route-policy** *route-policy-name*] *value*

By default, the additional metric of an outbound route is 1.

Configuring RIPv2 route summarization

About this task

Perform this task to summarize contiguous subnets into a summary network and sends the network to neighbors. The smallest metric among all summarized routes is used as the metric of the summary route.

You can use the following methods to summarize routes in RIPv2:

- **Automatic summarization**—Configure RIPv2 to generate a natural network for contiguous subnets. For example, suppose there are three subnet routes 10.1.1.0/24, 10.1.2.0/24, and 10.1.3.0/24. Automatic summarization automatically creates and advertises a summary route 10.0.0.0/8 instead of the more specific routes.
- **Manual summarization**—Manually configure a summary route. RIPv2 advertises the summary route rather than more specific routes. For example, suppose contiguous subnets routes 10.1.1.0/24, 10.1.2.0/24, and 10.1.3.0/24 exist in the routing table. You can create a summary route 10.1.0.0/16 on GigabitEthernet 1/0/1 to advertise the summary route instead of the more specific routes. By default, natural masks are used to advertise summary routes. To manually configure a summary route on an interface, you must first disable RIPv2 automatic route summarization.

Restrictions and guidelines

To prevent loops caused by route summarization, create a black hole route by specifying interface NULL 0 as the output interface of the summary route. Packets that match the black hole route are dropped.

Enabling RIPv2 automatic route summarization

1. Enter system view.

   system-view
2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enable RIPv2 automatic route summarization.

   summary

   By default, RIPv2 automatic route summarization is enabled.

   If subnets in the routing table are not contiguous, disable automatic route summarization to advertise more specific routes.

Advertising a summary route

1. Enter system view.

   system-view
2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Disable RIPv2 automatic route summarization.

   undo summary

   By default, RIPv2 automatic route summarization is enabled.
4. Return to system view.

   quit
5. Enter interface view.

interface *interface-type interface-number*

6. Configure a summary route.

   rip summary-address *ip-address* { *mask-length* | *mask* }

   By default, no summary route is configured.

Disabling host route reception

About this task

This task disables RIPv2 from receiving host routes from the same network to save network resources. This feature does not apply to RIPv1.

Procedure

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Disable RIP from receiving host routes.

   undo host-route

   By default, RIP receives host routes.

Advertising a default route

About this task

You can advertise a default route on all RIP interfaces in RIP view or on a specific RIP interface in interface view. The interface view setting takes precedence over the RIP view settings.

To disable an interface from advertising a default route, use the **rip default-route no-originate** command on the interface.

The router enabled to advertise a default route does not accept default routes from RIP neighbors.

Procedure

1. Enter system view.

   system-view

2. Advertise a default route.

   - Execute the following commands in sequence to configure RIP to advertise a default route:

     rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

     default-route { **only** | **originate** } [**cost** *cost-value* | **route-policy** *route-policy-name*] *

     By default, RIP does not advertise a default route.

   - Execute the following commands in sequence to configure a RIP interface to advertise a default route:

     interface *interface-type interface-number*

     rip default-route { { **only** | **originate** } [**cost** *cost-value* | **route-policy** *route-policy-name*] * | **no-originate** }

     By default, a RIP interface can advertise a default route if the RIP process is enabled to advertise a default route.

Configuring received/redistributed route filtering

About this task

This task allows you to create a policy to filter received or redistributed routes that match specific criteria such as an ACL or IP prefix list.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter RIP view.

   ```
   rip [ process-id ] [ vpn-instance vpn-instance-name ]
   ```

3. Configure the filtering of received routes.

   ```
   filter-policy { ipv4-acl-number | gateway prefix-list-name |
   prefix-list prefix-list-name [ gateway prefix-list-name ] } import
   [ interface-type interface-number ]
   ```

   By default, the filtering of received routes is not configured.

   This command filters received routes. Filtered routes are not installed into the routing table or advertised to neighbors.

4. Configure the filtering of redistributed routes.

   ```
   filter-policy { ipv4-acl-number | prefix-list prefix-list-name }
   export [ interface-type interface-number | bgp | direct | [ isis | ospf |
   rip ] [ process-id ] | static ]
   ```

   By default, the filtering of redistributed routes is not configured.

   This command filters redistributed routes, including routes redistributed with the **import-route** command.

Setting a preference for RIP

About this task

If multiple IGPs find routes to the same destination, the route found by the IGP that has the highest priority is selected as the optimal route. Perform this task to assign a preference to RIP. The smaller the preference value, the higher the priority.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter RIP view.

   ```
   rip [ process-id ] [ vpn-instance vpn-instance-name ]
   ```

3. Set a preference for RIP.

   ```
   preference { preference | route-policy route-policy-name } *
   ```

   The default preference for RIP is 100.

Configuring RIP route redistribution

About this task

Perform this task to configure RIP to redistribute routes from other routing protocols, including OSPF, IS-IS, BGP, static, and direct.

Procedure

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Configure route redistribution.

   ○ Redistribute routes from BGP.

   import-route bgp [*as-number*] [**allow-ibgp**] [**cost** *cost-value* | **route-policy** *route-policy-name* | **tag** *tag*] *

   ○ Redistribute direct or static routes.

   import-route { **direct** | **static** } [**cost** *cost-value* | **route-policy** *route-policy-name* | **tag** *tag*] *

   ○ Redistribute routes from IS-IS, OSPF, or other RIP processes.

   import-route { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] [**allow-direct** | **cost** *cost-value* | **route-policy** *route-policy-name* | **tag** *tag*] *

   By default, RIP does not redistribute routes.

   This command can redistribute only active routes. To view active routes, use the **display ip routing-table protocol** command.

4. (Optional.) Set a default cost for redistributed routes.

   default cost *cost-value*

   The default cost for redistributed routes is 0.

Tuning and optimizing RIP networks

Setting RIP timers

About this task

You can change the RIP network convergence speed by adjusting the following RIP timers:

- **Update timer**—Specifies the interval between route updates.
- **Timeout timer**—Specifies the route aging time. If no update for a route is received within the aging time, the metric of the route is set to 16.
- **Suppress timer**—Specifies how long a RIP route stays in suppressed state. When the metric of a route is 16, the route enters the suppressed state. A suppressed route can be replaced by an updated route that is received from the same neighbor before the suppress timer expires and has a metric less than 16.
- **Garbage-collect timer**—Specifies the interval from when the metric of a route becomes 16 to when it is deleted from the routing table. RIP advertises the route with a metric of 16. If no update is announced for that route before the garbage-collect timer expires, the route is deleted from the routing table.

Restrictions and guidelines

To avoid unnecessary traffic or route flapping, configure identical RIP timer settings on RIP routers.

Procedure

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set RIP timers.

   timers { **garbage-collect** *garbage-collect-value* | **suppress** *suppress-value* | **timeout** *timeout-value* | **update** *update-value* } *

   The default settings are as follows:

   - The garbage-collect timer is 120 seconds.
   - The suppress timer is 120 seconds.
   - The timeout timer is 180 seconds.
   - The update timer is 30 seconds.

Enabling split horizon and poison reverse

About this task

The split horizon and poison reverse features can prevent routing loops.

- Split horizon disables RIP from sending routes through the interface where the routes were learned to prevent routing loops between adjacent routers.
- Poison reverse allows RIP to send routes through the interface where the routes were learned. The metric of these routes is always set to 16 (unreachable) to avoid routing loops between neighbors.

Restrictions and guidelines

If both split horizon and poison reverse are configured, only the poison reverse feature takes effect.

Enabling split horizon

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable split horizon.

   rip split-horizon

   By default, split horizon is enabled.

Enabling poison reverse

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable poison reverse.

   rip poison-reverse

   By default, poison reverse is disabled.

Setting the maximum number of RIP ECMP routes

About this task

Perform this task to use ECMP routes to share the load of the RIP network.

Procedure

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set the maximum number of RIP ECMP routes.

   maximum load-balancing *number*

   By default, the maximum number of RIP ECMP routes equals the maximum number of ECMP routes supported by the system.

Setting the RIP triggered update interval

About this task

Perform this task to avoid network overhead and reduce system resource consumption caused by frequent RIP triggered updates.

You can use the **timer triggered** command to set the maximum interval, minimum interval, and incremental interval for sending RIP triggered updates.

- For a stable network, the *minimum-interval* is used.
- If network changes become frequent, the incremental interval *incremental-interval* is used to extend the triggered update sending interval until the *maximum-interval* is reached.

Procedure

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set the RIP triggered update interval.

   timer triggered *maximum-interval* [*minimum-interval* [*incremental-interval*]]

   The default settings are as follows:

   - The maximum interval is 5 seconds.
   - The minimum interval is 50 milliseconds.
   - The incremental interval is 200 milliseconds.

Configuring the RIP packet sending rate

About this task

Perform this task to set the interval for sending RIP packets and the maximum number of RIP packets that can be sent at each interval. This feature can avoid excessive RIP packets from affecting system performance and consuming too much bandwidth.

Procedure

1. Enter system view.

   system-view

2. Configure the RIP packet sending rate.

   - Execute the following commands in sequence to configure the RIP packet sending rate for all interfaces:

```
rip [ process-id ] [ vpn-instance vpn-instance-name ]
output-delay time count count
```

By default, an interface sends up to three RIP packets every 20 milliseconds.

- Execute the following commands in sequence to configure the RIP packet sending rate for an interface:

```
interface interface-type interface-number
rip output-delay time count count
```

By default, the interface uses the RIP packet sending rate configured for the RIP process that the interface runs.

Setting the maximum length of RIP packets

About this task

The packet length of RIP packets determines how many routes can be carried in a RIP packet. Set the maximum length of RIP packets to make good use of link bandwidth.

When authentication is enabled, follow these guidelines to ensure packet forwarding:

- For simple authentication, the maximum length of RIP packets must be no less than 52 bytes.
- For MD5 authentication (with packet format defined in RFC 2453), the maximum length of RIP packets must be no less than 56 bytes.
- For MD5 authentication (with packet format defined in RFC 2082), the maximum length of RIP packets must be no less than 72 bytes.

Procedure

1. Enter system view.

```
system-view
```

2. Enter interface view.

```
interface interface-type interface-number
```

3. Set the maximum length of RIP packets.

```
rip max-packet-length value
```

By default, the maximum length of RIP packets is 512 bytes.

Configuring RIP network management

About this task

You can use network management software to manage the RIP process to which MIB is bound.

Procedure

1. Enter system view.

```
system-view
```

2. Bind MIB to a RIP process.

```
rip mib-binding process-id
```

By default, MIB is bound to the RIP process with the smallest process ID.

Configuring RIP GR

About this task

GR ensures forwarding continuity when a routing protocol restarts or an active/standby switchover occurs.

Two routers are required to complete a GR process. The following are router roles in a GR process:

- **GR restarter**—Graceful restarting router. It must have GR capability.
- **GR helper**—A neighbor of the GR restarter. It helps the GR restarter to complete the GR process.

After RIP restarts on a router, the router must learn RIP routes again and update its FIB table, which causes network disconnections and route reconvergence.

With the GR feature, the restarting router (known as the GR restarter) can notify the event to its GR capable neighbors. GR capable neighbors (known as GR helpers) maintain their adjacencies with the router within a GR interval. During this process, the FIB table of the router does not change. After the restart, the router contacts its neighbors to retrieve its FIB.

By default, a RIP-enabled device acts as the GR helper. Perform this task on the GR restarter.

Restrictions and guidelines

You cannot enable RIP NSR on a device that acts as GR restarter.

Procedure

1. Enter system view.
   `system-view`
2. Enter RIP view.
   `rip` [*`process-id`*] [**`vpn-instance`** *`vpn-instance-name`*]
3. Enable GR for RIP.
   `graceful-restart`
   By default, RIP GR is disabled.
4. (Optional.) Set the GR interval.
   `graceful-restart interval` *`interval`*
   By default, the GR interval is 60 seconds.

Enabling RIP NSR

About this task

Nonstop Routing (NSR) allows the device to back up the routing information from the active RIP process to the standby RIP process. After an active/standby switchover, NSR can complete route regeneration without tearing down adjacencies or impacting forwarding services.

NSR does not require the cooperation of neighboring devices to recover routing information, and it is typically used more often than GR.

Restrictions and guidelines

A device that has RIP NSR enabled cannot act as GR restarter.

Procedure

1. Enter system view.
   `system-view`

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable RIP NSR.

   non-stop-routing

   By default, RIP NSR is disabled.

   RIP NSR enabled for a RIP process takes effect only on that process. As a best practice, enable RIP NSR for each process if multiple RIP processes exist.

Configuring BFD for RIP

About BFD for RIP

RIP detects route failures by periodically sending requests. If it receives no response for a route within a certain time, RIP considers the route unreachable. To speed up convergence, perform this task to enable BFD for RIP. For more information about BFD, see *Network Management and Monitoring Configuration Guide*.

RIP supports the following BFD detection modes:

- **Single-hop echo detection**—Detection mode for a directly connected neighbor. In this mode, a BFD session is established only when the directly connected neighbor has route information to send.
- **Single-hop echo detection for a specific destination**—Detection mode for a directly connected neighbor. In this mode, a BFD session is established to the specified RIP neighbor when RIP is enabled on the local interface. When BFD detects a unidirectional link, the local device will not receive or send any RIP packets through the interface to improve convergence speed. When the link recovers, the interface can send RIP packets again.
- **Bidirectional control detection**—Detection mode for both directly and indirectly connected neighbors. In this mode, a BFD session is established only when both ends have routes to send and BFD is enabled on the receiving interface.

Restrictions and guidelines

The **rip bfd enable** and **rip bfd enable destination** commands are mutually exclusive.

The **bfd all-interfaces enable** command in RIP view enables BFD for RIP on all interfaces of the RIP process. When link flapping occurs on one of the interfaces, you can disable BFD for RIP on that interface to avoid network instability. For this purpose, you must use the **rip bfd disable** command instead of the **undo rip bfd enable** command in interface view.

Configuring single-hop echo detection (for a directly connected RIP neighbor)

1. Enter system view.

   system-view

2. Configure the source IP address of BFD echo packets.

   bfd echo-source-ip *ip-address*

   By default, the source IP address of BFD echo packets is not configured.

3. Enable BFD for RIP.

   - Execute the following commands in sequence to enable BFD on all interfaces of a RIP process:

rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

bfd all-interfaces enable

- Execute the following commands in sequence to enable BFD on an interface:

  interface *interface-type interface-number*

  rip bfd enable

By default, BFD for RIP is disabled.

Configuring single-hop echo detection (for a specific destination)

Restrictions and guidelines

This feature applies only to RIP neighbors that are directly connected.

Procedure

1. Enter system view.

   system-view

2. Configure the source IP address of BFD echo packets.

   bfd echo-source-ip *ip-address*

   By default, no source IP address is configured for BFD echo packets.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable BFD for RIP.

   rip bfd enable destination *ip-address*

   By default, BFD for RIP is disabled.

Configuring bidirectional control detection for an indirectly connected neighbor

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Specify a RIP neighbor.

   peer *ip-address*

   By default, RIP does not unicast updates to any peer.

   Because the **undo peer** command does not remove the neighbor relationship immediately, executing the command cannot bring down the BFD session immediately.

4. Enable BFD for RIP.

   - Execute the following commands in sequence to enable BFD on all interfaces of a RIP process:

     bfd all-interfaces enable

   - Execute the following commands in sequence to enable BFD on an interface:

     interface *interface-type interface-number*

     rip bfd enable

By default, BFD for RIP is disabled.

Configuring bidirectional control detection for a directly connected neighbor

1. Enter system view.

   system-view

2. Enable BFD for RIP.
   - Execute the following commands in sequence to enable BFD on all interfaces of a RIP process:

     rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

     bfd all-interfaces enable ctrl

   - Execute the following commands in sequence to enable BFD on an interface:

     interface *interface-type interface-number*

     rip bfd enable ctrl

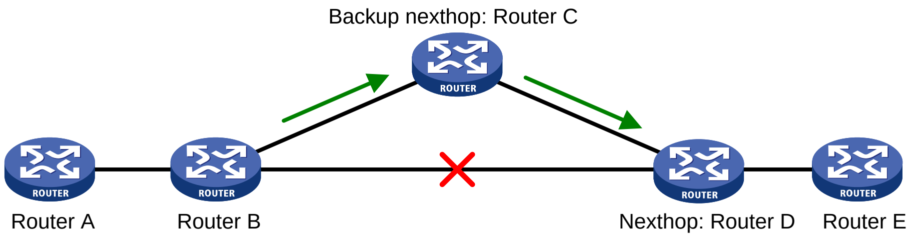
   By default, BFD for RIP is disabled.

Configuring RIP FRR

About RIP FRR

A link or router failure on a path can cause packet loss and even routing loop until RIP completes routing convergence based on the new network topology. FRR enables fast rerouting to minimize the impact of link or node failures.

Figure 1 Network diagram for RIP FRR



As shown in Figure 1, configure FRR on Router B by using a routing policy to specify a backup next hop. When the primary link fails, RIP directs packets to the backup next hop. At the same time, RIP calculates the shortest path based on the new network topology, and forwards packets over that path after network convergence.

Restrictions and guidelines for RIP FRR

RIP FRR takes effect only for RIP routes learned from directly connected neighbors.

RIP FRR is available only when the state of primary link (with Layer 3 interfaces staying up) changes from bidirectional to unidirectional or down.

Equal-cost routes do not support RIP FRR.

Enabling RIP FRR

1. Enter system view.

   system-view

2. Configure a routing policy for FRR.

   You must specify a next hop by using the **apply fast-reroute backup-interface** command in the routing policy.

   For more information about routing policy configuration, see "Configuring routing policies."

3. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

4. Enable RIP FRR.

   fast-reroute route-policy *route-policy-name*

   By default, RIP FRR is disabled.

Enabling BFD bidirectional control detection for RIP FRR

About this task

By default, RIP FRR does not use BFD to detect primary link failures. For quicker RIP FRR, use BFD on the primary link of redundant links to detect link failure.

Restrictions and guidelines

You must configure bidirectional control detection on both ends of a link for it to take effect.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable BFD bidirectional control detection for RIP FRR.

   rip primary-path-detect bfd ctrl

   By default, BFD bidirectional control detection for RIP FRR is disabled.

Enabling BFD single-hop echo detection for RIP FRR

About this task

By default, RIP FRR does not use BFD to detect primary link failures. For quicker RIP FRR, use BFD single-hop echo detection on the primary link of redundant links to detect link failure.

Procedure

1. Enter system view.

   system-view

2. Configure the source IP address of BFD echo packets.

   bfd echo-source-ip *ip-address*

   By default, the source IP address of BFD echo packets is not configured.

   The source IP address cannot be on the same network segment as any local interfaces.

   For more information about this command, see BFD commands in *Network Management and Monitoring Command Reference*.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable BFD single-hop echo detection for RIP FRR.

   rip primary-path-detect bfd echo

   By default, BFD single-hop echo detection for RIP FRR is disabled.

Enhancing RIP security

Enabling zero field check for incoming RIPv1 messages

About this task

Some fields in the RIPv1 message must be set to zero. These fields are called "zero fields." You can enable zero field check for incoming RIPv1 messages. If a zero field of a message contains a non-zero value, RIP does not process the message. If you are certain that all messages are trustworthy, disable zero field check to save CPU resources.

This feature does not apply to RIPv2 packets, because they have no zero fields.

Procedure

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable zero field check for incoming RIPv1 messages.

   checkzero

   By default, zero field check is disabled for incoming RIPv1 messages.

Enabling source IP address check for incoming RIP updates

About this task

Perform this task to enable source IP address check for incoming RIP updates.

- Upon receiving a message on an Ethernet interface, RIP compares the source IP address of the message with the IP address of the interface. If they are not in the same network segment, RIP discards the message.
- Upon receiving a message on a PPP interface, RIP checks whether the source address of the message is the IP address of the peer interface. If not, RIP discards the message.

Procedure

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable source IP address check for incoming RIP messages.

   validate-source-address

   By default, source IP address check is disabled for incoming RIP updates.

Configuring RIPv2 message authentication

About this task

Perform this task to enable authentication on RIPv2 messages.

RIPv2 supports simple authentication, MD5 authentication, and keychain authentication. For more information about keychains, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure RIPv2 authentication.

   `rip authentication-mode` { **`keychain`** *`keychain-name`* { **`rfc2453`** | **`rfc4822`** } | **`md5`** { **`rfc2082`** { **`cipher`** | **`plain`** } *`string key-id`* | **`rfc2453`** { **`cipher`** | **`plain`** } *`string`* } | **`simple`** { **`cipher`** | **`plain`** } *`string`* }

   By default, RIPv2 authentication is not configured.

   RIPv1 does not support authentication. Although you can specify an authentication mode for RIPv1 in interface view, the configuration does not take effect.

Display and maintenance commands for RIP

Execute **`display`** commands in any view and execute **`reset`** commands in user view.

Task	Command
Display RIP current status and configuration information.	**`display rip`** [*`process-id`*]
Display RIP GR information.	**`display rip`** [*`process-id`*] **`graceful-restart`**
Display RIP NSR information.	**`display rip`** [*`process-id`*] **`non-stop-routing`**
Display active routes in the RIP database.	**`display rip`** *`process-id`* **`database`** [*`ip-address`* { *`mask-length`* | *`mask`* }]
Display RIP interface information.	**`display rip`** *`process-id`* **`interface`** [*`interface-type interface-number`*]
Display neighbor information for a RIP process.	**`display rip`** *`process-id`* **`neighbor`** [*`interface-type interface-number`*]
Display routing information for a RIP process.	**`display rip`** *`process-id`* **`route`** [*`ip-address`* { *`mask-length`* | *`mask`* } [**`verbose`**] | **`peer`** *`ip-address`* | **`statistics`**]
Reset a RIP process.	**`reset rip`** *`process-id`* **`process`**
Clear the statistics for a RIP process.	**`reset rip`** *`process-id`* **`statistics`**

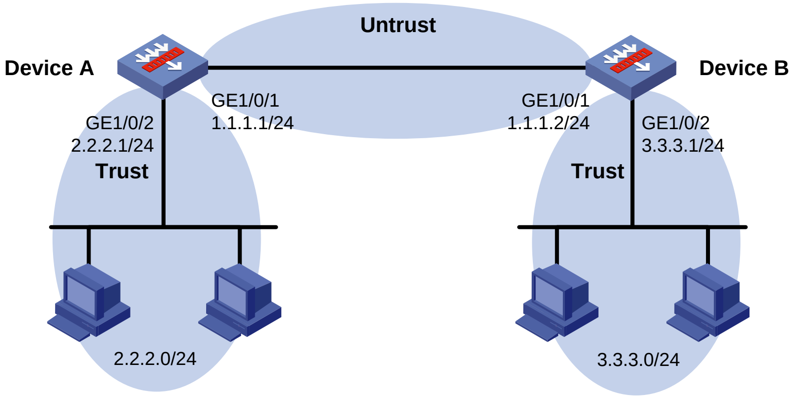
RIP configuration examples

Example: Configuring basic RIP

Network configuration

As shown in Figure 2, Device A and Device B are attached to networks 2.2.2.0/24 and 3.3.3.0/24, respectively. Configure RIPv2 on Device A and Device B to enable communication between the two networks.

Figure 2 Network diagram



Configuring Device A

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 1.1.1.1 255.255.255.0
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [DeviceA] security-zone name untrust
   [DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
   [DeviceA-security-zone-Untrust] quit
   [DeviceA] security-zone name trust
   [DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
   [DeviceA-security-zone-Trust] quit
   ```

3. Configure security policies:

   a. Configure a security policy to permit traffic between the **Untrust** and **Local** security zones, and enable the devices to establish RIP neighbor relationship with each other.

      # Configure a rule named **riplocalin** to allow Device A to receive RIP packets from Device B.

      ```
      [DeviceA] security-policy ip
      [DeviceA-security-policy-ip] rule name riplocalin
      [DeviceA-security-policy-ip-0-riplocalin] source-zone untrust
      [DeviceA-security-policy-ip-0-riplocalin] destination-zone local
      [DeviceA-security-policy-ip-0-riplocalin] service rip
      ```

```
[DeviceA-security-policy-ip-0-riplocalin] action pass
[DeviceA-security-policy-ip-0-riplocalin] quit
```

# Configure a rule named **riplocalout** to allow Device A to send RIP packets to Device B.

```
[DeviceA-security-policy-ip] rule name riplocalout
[DeviceA-security-policy-ip-1-riplocalout] source-zone local
[DeviceA-security-policy-ip-1-riplocalout] destination-zone untrust
[DeviceA-security-policy-ip-1-riplocalout] service rip
[DeviceA-security-policy-ip-1-riplocalout] action pass
[DeviceA-security-policy-ip-1-riplocalout] quit
```

b. Configure a security policy to permit traffic between the **Trust** and **Untrust** security zones, and enable communication between network 2.2.2.0/24 and network 3.3.3.0/24.

# Configure a rule named **trust-untrust** to permit packets from network 2.2.2.0/24 to network 3.3.3.0/24.

```
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-2-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-2-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-2-trust-untrust] source-ip-subnet 2.2.2.0 24
[DeviceA-security-policy-ip-2-trust-untrust] destination-ip-subnet 3.3.3.0 24
[DeviceA-security-policy-ip-2-trust-untrust] action pass
[DeviceA-security-policy-ip-2-trust-untrust] quit
```

# Configure a rule named **untrust-trust** to permit packets from network 3.3.3.0/24 to network 2.2.2.0/24.

```
[DeviceA-security-policy-ip] rule name untrust-trust
[DeviceA-security-policy-ip-3-untrust-trust] source-zone untrust
[DeviceA-security-policy-ip-3-untrust-trust] destination-zone trust
[DeviceA-security-policy-ip-3-untrust-trust] source-ip-subnet 3.3.3.0 24
[DeviceA-security-policy-ip-3-trust-untrust] destination-ip-subnet 2.2.2.0 24
[DeviceA-security-policy-ip-3-untrust-trust] action pass
[DeviceA-security-policy-ip-3-untrust-trust] quit
[DeviceA-security-policy-ip-3] quit
```

4. Configure basic RIP functions.

```
[DeviceA] rip
[DeviceA-rip-1] network 1.1.1.0
[DeviceA-rip-1] network 2.2.2.0
[DeviceA-rip-1] version 2
[DeviceA-rip-1] undo summary
[DeviceA-rip-1] quit
```

Configuring Device B

1. Assign IP addresses to interfaces:

# Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 1.1.1.2 255.255.255.0
[DeviceB-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
```

```
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

3. Configure security policies:
   a. Configure a security policy to permit traffic between the **Untrust** and **Local** security zones, and enable the devices to establish RIP neighbor relationship with each other.

      # Configure a rule named **riplocalin** to allow Device B to receive RIP packets from Device A.

      ```
      [DeviceB] security-policy ip
      [DeviceB-security-policy-ip] rule name riplocalin
      [DeviceB-security-policy-ip-0-riplocalin] source-zone untrust
      [DeviceB-security-policy-ip-0-riplocalin] destination-zone local
      [DeviceB-security-policy-ip-0-riplocalin] service rip
      [DeviceB-security-policy-ip-0-riplocalin] action pass
      [DeviceB-security-policy-ip-0-riplocalin] quit
      ```

      # Configure a rule named **riplocalout** to allow Device B to send RIP packets to Device A.

      ```
      [DeviceB-security-policy-ip] rule name riplocalout
      [DeviceB-security-policy-ip-1-riplocalout] source-zone local
      [DeviceB-security-policy-ip-1-riplocalout] destination-zone untrust
      [DeviceB-security-policy-ip-1-riplocalout] service rip
      [DeviceB-security-policy-ip-1-riplocalout] action pass
      [DeviceB-security-policy-ip-1-riplocalout] quit
      ```

   b. Configure a security policy to permit traffic between the **Trust** and **Untrust** security zones, and enable communication between network 3.3.3.0/24 and network 2.2.2.0/24.

      # Configure a rule named **trust-untrust** to permit packets from network 3.3.3.0/24 to network 2.2.2.0/24.

      ```
      [DeviceB-security-policy-ip] rule name trust-untrust
      [DeviceB-security-policy-ip-2-trust-untrust] source-zone trust
      [DeviceB-security-policy-ip-2-trust-untrust] destination-zone untrust
      [DeviceB-security-policy-ip-2-trust-untrust] source-ip-subnet 3.3.3.0 24
      [DeviceB-security-policy-ip-2-trust-untrust] destination-ip-subnet 2.2.2.0 24
      [DeviceB-security-policy-ip-2-trust-untrust] quit
      ```

      # Configure a rule named **untrust-trust** to permit packets from network 2.2.2.0/24 to network 3.3.3.0/24.

      ```
      [DeviceB-security-policy-ip] rule name untrust-trust
      [DeviceB-security-policy-ip-3-untrust-trust] source-zone untrust
      [DeviceB-security-policy-ip-3-untrust-trust] destination-zone trust
      [DeviceB-security-policy-ip-3-untrust-trust] source-ip-subnet 2.2.2.0 24
      [DeviceB-security-policy-ip-3-untrust-trust] destination-ip-subnet 3.3.3.0 24
      [DeviceB-security-policy-ip-3-untrust-trust] action pass
      [DeviceB-security-policy-ip-3-untrust-trust] quit
      [DeviceB-security-policy-ip-3] quit
      ```

4. Configure basic RIP functions.

   ```
   [DeviceB] rip
   [DeviceB-rip-1] version 2
   [DeviceB-rip-1] undo summary
   [DeviceB-rip-1] quit
   ```

```
    [DeviceB] interface gigabitethernet 1/0/1
    [DeviceB-GigabitEthernet1/0/1] rip 1 enable
    [DeviceB-GigabitEthernet1/0/1] quit
    [DeviceB] interface gigabitethernet 1/0/2
    [DeviceB-GigabitEthernet1/0/2] rip 1 enable
    [DeviceB-GigabitEthernet1/0/2] quit
```

Verifying the configuration

# Display the RIP routing table of Device A.

```
[Device A] display rip 1 route
 Route Flags: R - RIP
              P - Permanent, A - Aging, S - Suppressed, G - Garbage-collect
              D - Direct, O - Optimal, F - Flush to RIB
----------------------------------------------------------------------------
 Peer 1.1.1.2 on GigabitEthernet1/0/1
      Destination/Mask        Nexthop           Cost    Tag     Flags   Sec
      3.3.3.0/24              1.1.1.1           1       0       RAOF    10
 Local route
      Destination/Mask        Nexthop           Cost    Tag     Flags   Sec
      2.2.2.0/24              0.0.0.0           0       0       RDOF    -
      1.1.1.0/24              0.0.0.0           0       0       RDOF    -
```

The output shows that the hosts in network 2.2.2.0/24 can communicate with the hosts in network 3.3.3.0/24.

Contents

Configuring RIPng

About RIPng

RIP next generation (RIPng), as an extension of RIP-2 for support of IPv6, is a distance vector routing protocol. It employs UDP to exchange route information through port 521. Most RIP concepts are applicable to RIPng.

RIPng routing metrics

RIPng uses a hop count to measure the distance to a destination. The hop count is the metric or cost. The hop count from a router to a directly connected network is 0. The hop count between two directly connected routers is 1. When the hop count is greater than or equal to 16, the destination network or host is unreachable.

RIPng route entries

RIPng stores route entries in a database. Each route entry contains the following elements:

- **Destination address**—IPv6 address of a destination host or a network.
- **Next hop address**—IPv6 address of the next hop.
- **Egress interface**—Egress interface of the route.
- **Metric**—Cost from the local router to the destination.
- **Route time**—Time elapsed since the most recent update. The time is reset to 0 every time the route entry is updated.
- **Route tag**—Used for route control. For more information, see "Configuring routing policies."

RIPng packets and advertisement

RIPng multicasts request and response packets to exchange routing information. It uses FF02::9 as the destination address and link-local address FE80::/10 as the source address. RIPng exchanges routing information as follows:

1. When RIPng starts or needs to update some route entries, it sends a multicast request packet to neighbors.
2. When a RIPng neighbor receives the request packet, it sends back a response packet that contains the local routing table. RIPng can also advertise route updates in response packets periodically or advertise a triggered update caused by a route change.
3. After RIPng receives the response, it checks the validity of the response before adding routes to its routing table, including the following details:
    - Whether the source IPv6 address is the link-local address.
    - Whether the port number is correct.
4. A response packet that fails the check is discarded.

Protocols and standards

- RFC 2080, *RIPng for IPv6*
- RFC 2081, *RIPng Protocol Applicability Statement*

RIPng tasks at a glance

To configure RIPng, perform the following tasks:

1. Configuring basic RIPng
2. (Optional.) Configuring RIPng route control
   - Configuring an additional routing metric
   - Configuring RIPng route summarization
   - Advertising a default route
   - Configuring received/redistributed route filtering
   - Setting a preference for RIPng
   - Configuring RIPng route redistribution
3. (Optional.) Tuning and optimizing the RIPng network
   - Setting RIPng timers
   - Configuring split horizon and poison reverse
   - Setting the maximum number of ECMP routes
   - Configuring the RIPng packet sending rate
   - Setting the interval for sending triggered updates
4. (Optional.) Enhancing RIPng availability
   - Configuring RIPng GR
   - Configuring RIPng NSR
   - Configuring RIPng FRR
5. (Optional.) Enhancing RIPng security
   - Configuring zero field check for RIPng packets
   - Applying an IPsec profile

Configuring basic RIPng

1. Enter system view.

   ```
   system-view
   ```

2. Enable RIPng and enter its view.

   ```
   ripng [ process-id ] [ vpn-instance vpn-instance-name ]
   ```

   By default, RIPng is disabled.

3. Return to system view.

   ```
   quit
   ```

4. Enter interface view.

   ```
   interface interface-type interface-number
   ```

5. Enable RIPng on the interface.

   ```
   ripng process-id enable
   ```

   By default, RIPng is disabled on the interface.

   If RIPng is not enabled on an interface, the interface does not send or receive any RIPng route.

Configuring RIPng route control

Configuring an additional routing metric

About this task

An additional routing metric (hop count) can be added to the metric of an inbound or outbound RIPng route.

- An outbound additional metric is added to the metric of a sent route, and it does not change the route's metric in the routing table.
- An inbound additional metric is added to the metric of a received route before the route is added into the routing table, and the route's metric is changed.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify an inbound additional routing metric.

   ripng metricin *value*

   The default additional metric of an inbound route is 0.

4. Specify an outbound additional routing metric.

   ripng metricout *value*

   The default additional metric of an outbound route is 1.

Configuring RIPng route summarization

About this task

RIPng route summarization is interface-based. RIPng advertises a summary route based on the longest match.

RIPng route summarization improves network scalability, reduces routing table size, and increases routing table lookup efficiency.

RIPng advertises a summary route with the smallest metric of all the specific routes.

For example, RIPng has two specific routes to be advertised through an interface: 1:11:11::24 with a metric of a 2 and 1:11:12::34 with a metric of 3. Configure route summarization on the interface, so RIPng advertises a single route 11::0/16 with a metric of 2.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Advertise a summary IPv6 prefix.

   ripng summary-address *ipv6-address prefix-length*

   By default, no summary IPv6 prefix is configured on the interface.

Advertising a default route

About this task

You can configure RIPng to advertise a default route with the specified cost to its neighbors.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure RIPng to advertise a default route.

   ripng default-route { **only** | **originate** } [**cost** *cost-value* | **route-policy** *route-policy-name*] *

   By default, RIPng does not advertise a default route.

   This command advertises a default route on the current interface regardless of whether the default route exists in the local IPv6 routing table.

Configuring received/redistributed route filtering

About this task

Perform this task to filter received or redistributed routes by using an IPv6 ACL or IPv6 prefix list. You can also configure RIPng to filter routes redistributed from other routing protocols and routes from a specified neighbor.

Procedure

1. Enter system view.

   system-view

2. Enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Configure a filter policy to filter received routes.

   filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* } **import**

   By default, RIPng does not filter received routes.

4. Configure a filter policy to filter redistributed routes.

   filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* } **export** [*protocol* [*process-id*]]

   By default, RIPng does not filter redistributed routes.

Setting a preference for RIPng

About this task

Routing protocols each have a preference. When they find routes to the same destination, the route found by the routing protocol with the highest preference is selected as the optimal route. You can manually set a preference for RIPng. The smaller the value, the higher the preference.

Procedure

1. Enter system view.

   system-view

2. Enter RIPng view.

   ```
   ripng [ process-id ] [ vpn-instance vpn-instance-name ]
   ```

3. Set a preference for RIPng.

   ```
   preference { preference | route-policy route-policy-name } *
   ```

   By default, the preference of RIPng is 100.

Configuring RIPng route redistribution

1. Enter system view.

   ```
   system-view
   ```

2. Enter RIPng view.

   ```
   ripng [ process-id ] [ vpn-instance vpn-instance-name ]
   ```

3. Configure route redistribution.
   - Redistribute routes from BGP4+.

     ```
     import-route bgp4+ [ as-number ] [ allow-ibgp ] [ cost cost-value |
     route-policy route-policy-name ] *
     ```

   - Redistribute direct or static routes.

     ```
     import-route { direct | static } [ cost cost-value | route-policy
     route-policy-name ] *
     ```

   - Redistribute routes from IPv6 IS-IS, OSPFv3, or other RIPng processes.

     ```
     import-route { isisv6 | ospfv3 | ripng } [ process-id ] [ allow-direct
     | cost cost-value | route-policy route-policy-name ] *
     ```

   By default, RIPng does not redistribute routes.

4. (Optional.) Set a default routing metric for redistributed routes.

   ```
   default cost cost-value
   ```

   The default metric of redistributed routes is 0.

Tuning and optimizing the RIPng network

Setting RIPng timers

About this task

You can adjust RIPng timers to optimize the performance of the RIPng network.

Restrictions and guidelines

When you adjust RIPng timers, consider the network performance, and perform unified configurations on routers running RIPng to avoid unnecessary network traffic or route oscillation.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter RIPng view.

   ```
   ripng [ process-id ] [ vpn-instance vpn-instance-name ]
   ```

3. Set RIPng timers.

   ```
   timers { garbage-collect garbage-collect-value | suppress
   suppress-value | timeout timeout-value | update update-value } *
   ```

The default settings are as follows:

- The update timer is 30 seconds.
- The timeout timer is 180 seconds.
- The suppress timer is 120 seconds.
- The garbage-collect timer is 120 seconds.

Configuring split horizon and poison reverse

Restrictions and guidelines for split horizon and poison reverse

When you configure split horizon and poison reverse, following these restrictions and guidelines:

- If both split horizon and poison reverse are configured, only the poison reverse feature takes effect.
- Split horizon disables RIPng from sending routes through the interface where the routes were learned to prevent routing loops between neighbors. As a best practice, enable split horizon to prevent routing loops in normal cases.
- Poison reverse enables a route learned from an interface to be advertised through the interface. However, the metric of the route is set to 16, which means the route is unreachable.

Configuring split horizon

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Enable split horizon.

   `ripng split-horizon`

   By default, split horizon is enabled.

Configuring poison reverse

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Enable poison reverse.

   `ripng poison-reverse`

   By default, poison reverse is disabled.

Setting the maximum number of ECMP routes

1. Enter system view.

   `system-view`

2. Enter RIPng view.

   `ripng` `[` *`process-id`* `] [` **`vpn-instance`** *`vpn-instance-name`* `]`

3. Set the maximum number of ECMP routes.

   `maximum load-balancing` *`number`*

Configuring the RIPng packet sending rate

About this task

Perform this task to specify the interval for sending RIPng packets and the maximum number of RIPng packets that can be sent at each interval. This feature can avoid excessive RIPng packets from affecting system performance and consuming too much bandwidth.

Procedure

1. Enter system view.

   `system-view`

2. Enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Configuring the RIPng packet sending rate.

   - Execute the following commands in sequence to configure the RIPng packet sending rate in RIPng view:

     ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

     output-delay *time* **count** *count*

     By default, an interface that runs the RIPng process sends a maximum of three RIPng packets every 20 milliseconds.

   - Execute the following commands in sequence to configure the RIPng packet sending rate in interface view:

     interface *interface-type interface-number*

     ripng output-delay *time* **count** *count*

     By default, an interface uses the RIPng packet sending rate of the RIPng process that it runs.

Setting the interval for sending triggered updates

About this task

Perform this task to avoid network overhead and reduce system resource consumption caused by frequent RIPng triggered updates.

You can use the **timer triggered** command to set the maximum interval, minimum interval, and incremental interval for sending RIPng triggered updates.

For a stable network, the minimum interval is used. If network changes become frequent, the triggered update sending interval is incremented by the incremental interval × 2^{n-2} for each triggered update until the maximum interval is reached. The value *n* is the number of triggered update times.

Procedure

1. Enter system view.

   `system-view`

2. Enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set the interval for sending triggered updates.

   timer triggered *maximum-interval* [*minimum-interval* [*incremental-interval*]]

   The default maximum interval is 5 seconds, the default minimum interval is 50 milliseconds, and the default incremental interval is 200 milliseconds.

Configuring RIPng GR

About this task

GR ensures forwarding continuity when a routing protocol restarts or an active/standby switchover occurs.

Two routers are required to complete a GR process. The following are router roles in a GR process:

- **GR restarter**—Graceful restarting router. It must have GR capability.
- **GR helper**—A neighbor of the GR restarter. It helps the GR restarter to complete the GR process.

After RIPng restarts on a router, the router must learn RIPng routes again and updates its FIB table, which causes network disconnections and route reconvergence.

With the GR feature, the restarting router (known as the GR restarter) can notify the event to its GR capable neighbors. GR capable neighbors (known as GR helpers) maintain their adjacencies with the router within a configurable GR interval. During this process, the FIB table of the router does not change. After the restart, the router contacts its neighbors to retrieve its FIB.

By default, a RIPng-enabled device acts as the GR helper. Perform this task on the GR restarter.

Restrictions and guidelines

You cannot enable RIPng NSR on a device that acts as GR restarter.

Procedure

1. Enter system view.

   `system-view`

2. Enable RIPng and enter RIPng view.

   `ripng` [*`process-id`*] [**`vpn-instance`** *`vpn-instance-name`*]

3. Enable the GR capability for RIPng.

   `graceful-restart`

   By default, RIPng GR is disabled.

4. (Optional.) Set the GR interval.

   `graceful-restart interval` *`interval`*

   The default GR interval is 60 seconds.

Configuring RIPng NSR

About this task

Nonstop routing (NSR) backs up RIPng routing information from the active process to the standby process. After an active/standby switchover, NSR can complete route regeneration without tearing down adjacencies or impacting forwarding services.

NSR does not require the cooperation of neighboring devices to recover routing information, and it is typically used more often than GR.

Restrictions and guidelines

RIPng NSR enabled for a RIPng process takes effect only on that process. If multiple RIPng processes exist, enable RIPng NSR for each process as a best practice.

A device that has RIPng NSR enabled cannot act as GR restarter.

Procedure

1. Enter system view.

   `system-view`

2. Enter RIPng view.

   `ripng` [*`process-id`*] [**`vpn-instance`** *`vpn-instance-name`*]

3. Enable RIPng NSR.

   `non-stop-routing`

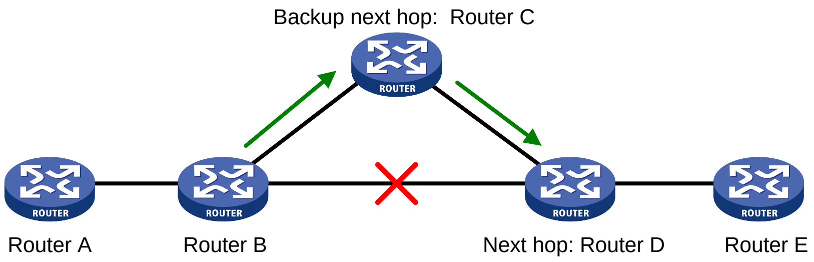
   By default, RIPng NSR is disabled.

Configuring RIPng FRR

About RIPng FRR

A link or router failure on a path can cause packet loss and even routing loop until RIPng completes routing convergence based on the new network topology. FRR enables fast rerouting to minimize the impact of link or node failures.

Figure 1 Network diagram for RIPng FRR



As shown in Figure 1, configure FRR on Router B by using a routing policy to specify a backup next hop. When the primary link fails, RIPng directs packets to the backup next hop. At the same time, RIPng calculates the shortest path based on the new network topology. Then, the device forwards packets over that path after network convergence.

Restrictions and guidelines for RIPng FRR

RIPng FRR is available only when the state of the primary link (with Layer 3 interfaces staying up) changes from bidirectional to unidirectional or down.

RIPng FRR is only effective for RIPng routes that are learned from directly connected neighbors.

Equal-cost routes do not support RIPng FRR.

Enabling RIPng FRR

1. Enter system view.

   `system-view`

2. Configure a routing policy.

   You must specify a next hop by using the **`apply ipv6 fast-reroute backup-interface`** command in a routing policy and specify the routing policy for FRR.

   For more information about routing policy configuration, see "Configuring routing policies."

3. Enter RIPng view.

ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

4. Enable RIPng FRR.

   fast-reroute route-policy *route-policy-name*

   By default, RIPng FRR is disabled.

Enabling BFD for RIPng FRR

About this task

By default, RIPng FRR does not use BFD to detect primary link failures. For quicker RIPng FRR, use BFD single-hop echo detection on the primary link of redundant links to detect link failure.

Procedure

1. Enter system view.

   system-view

2. Configure the source IP address of BFD echo packets.

   bfd echo-source-ipv6 *ipv6-address*

   By default, the source IP address of BFD echo packets is not configured.

   As a best practice, do not configure the source IP address on the same network segment as any local interfaces.

   For more information about this command, see *Network Management and Monitoring Command Reference*.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable BFD single-hop echo detection for RIPng FRR.

   ripng primary-path-detect bfd echo

   By default, BFD single-hop echo detection is disabled for RIPng FRR.

Enhancing RIPng security

Configuring zero field check for RIPng packets

About this task

Some fields in the RIPng packet header must be zero. These fields are called zero fields. You can enable zero field check for incoming RIPng packets. If a zero field of a packet contains a non-zero value, RIPng does not process the packets. If you are certain that all packets are trustworthy, disable the zero field check to save CPU resources.

Procedure

1. Enter system view.

   system-view

2. Enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable the zero field check for incoming RIPng packets.

   checkzero

   By default, zero field check for incoming RIPng packets is enabled.

Applying an IPsec profile

About this task

To protect routing information and prevent attacks, you can configure RIPng to authenticate protocol packets by using an IPsec profile.

An IPsec profile contains inbound and outbound security parameter indexes (SPIs). RIPng compares the inbound SPI defined in the IPsec profile with the outbound SPI in the received packets. Two RIPng devices accept the packets from each other and establish a neighbor relationship only if the SPIs are the same and the relevant IPsec profiles match.

For more information about IPsec profiles, see *Security Configuration Guide*.

Restrictions and guidelines

You can apply an IPsec profile to a RIPng process or to an interface. If an interface and its process each have an IPsec profile, the IPsec profile applied to the interface takes effect.

Applying an IPsec profile to a process

1. Enter system view.
   system-view
2. Enter RIPng view.
   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Apply an IPsec profile to the process.
   enable ipsec-profile *profile-name*
   By default, no IPsec profile is applied.

Applying an IPsec profile to an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Apply an IPsec profile to the interface.
   ripng ipsec-profile *profile-name*
   By default, no IPsec profile is applied.

Display and maintenance commands for RIPng

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display configuration information for a RIPng process.	**display ripng** [*process-id*]
Display RIPng GR information.	**display ripng** [*process-id*] **graceful-restart**
Display RIPng NSR information.	**display ripng** [*process-id*] **non-stop-routing**
Display routes in the RIPng database.	**display ripng** *process-id* **database** [*ipv6-address prefix-length*]
Display interface information for a RIPng	**display ripng** *process-id* **interface**

Task	Command
process.	[*interface-type interface-number*]
Display neighbor information for a RIPng process.	**display ripng** *process-id* **neighbor** [*interface-type interface-number*]
Display the routing information for a RIPng process.	**display ripng** *process-id* **route** [*ipv6-address prefix-length* [**verbose**] | **peer** *ipv6-address* | **statistics**]
Restart a RIPng process.	**reset ripng** *process-id* **process**
Clear statistics for a RIPng process.	**reset ripng** *process-id* **statistics**

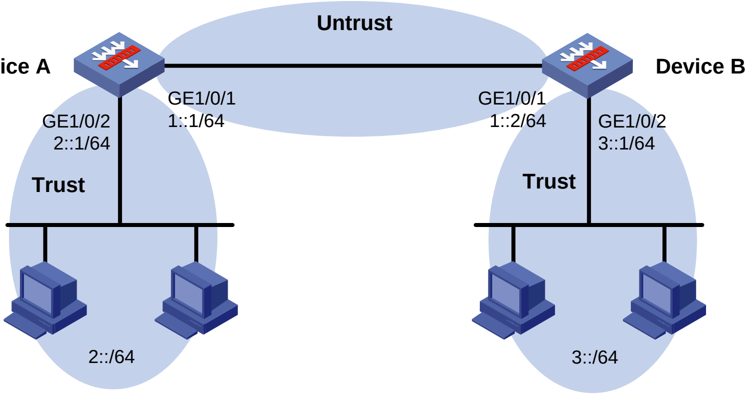
RIPng configuration examples

Example: Configuring basic RIPng

Network configuration

As shown in Figure 2, Device A and Device B are attached to networks 2::/64 and 3::/64, respectively. Configure RIPng on Device A and Device B to enable communication between the two networks.

Figure 2 Network diagram



Configuring Device A

1. Assign IPv6 addresses to interfaces:

   # Assign an IPv6 address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ipv6 address 1::1 64
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Assign IPv6 addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [DeviceA] security-zone name untrust
   [DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
   [DeviceA-security-zone-Untrust] quit
   [DeviceA] security-zone name trust
   [DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
   ```

```
[DeviceA-security-zone-Trust] quit
```

3. Configure security policies:
   a. Configure a security policy to permit traffic between the **Untrust** and **Local** security zones, and enable the devices to establish RIPng neighbor relationship with each other.

      # Configure a rule named **ripnglocalin** to allow Device A to receive RIPng packets from Device B.

      ```
      [DeviceA] security-policy ipv6
      [DeviceA-security-policy-ipv6] rule name ripnglocalin
      [DeviceA-security-policy-ipv6-0-ripnglocalin] source-zone untrust
      [DeviceA-security-policy-ipv6-0-ripnglocalin] destination-zone local
      [DeviceA-security-policy-ipv6-0-ripnglocalin] service rip
      [DeviceA-security-policy-ipv6-0-ripnglocalin] action pass
      [DeviceA-security-policy-ipv6-0-ripnglocalin] quit
      ```

      # Configure a rule named **ripnglocalout** to allow Device A to send RIPng packets to Device B.

      ```
      [DeviceA-security-policy-ipv6] rule name ripnglocalout
      [DeviceA-security-policy-ipv6-1-ripnglocalout] source-zone local
      [DeviceA-security-policy-ipv6-1-ripnglocalout] destination-zone untrust
      [DeviceA-security-policy-ipv6-1-ripnglocalout] service rip
      [DeviceA-security-policy-ipv6-1-ripnglocalout] action pass
      [DeviceA-security-policy-ipv6-1-ripnglocalout] quit
      ```

   b. Configure a security policy to permit traffic between the **Trust** and **Untrust** security zones, and enable communication between network 2::/64 and network 3::/64.

      # Configure a rule named **trust-untrust** to permit packets from network 2::/64 to network 3::/64.

      ```
      [DeviceA-security-policy-ipv6] rule name trust-untrust
      [DeviceA-security-policy-ipv6-2-trust-untrust] source-zone trust
      [DeviceA-security-policy-ipv6-2-trust-untrust] destination-zone untrust
      [DeviceA-security-policy-ipv6-2-trust-untrust] source-ip-subnet 2:: 64
      [DeviceA-security-policy-ipv6-2-trust-untrust] destination-ip-subnet 3:: 64
      [DeviceA-security-policy-ipv6-2-trust-untrust] action pass
      [DeviceA-security-policy-ipv6-2-trust-untrust] quit
      ```

      # Configure a rule named **untrust-trust** to permit packets from network 3::/64 to network 2::/64.

      ```
      [DeviceA-security-policy-ipv6] rule name untrust-trust
      [DeviceA-security-policy-ipv6-3-untrust-trust] source-zone untrust
      [DeviceA-security-policy-ipv6-3-untrust-trust] destination-zone trust
      [DeviceA-security-policy-ipv6-3-untrust-trust] source-ip-subnet 3:: 64
      [DeviceA-security-policy-ipv6-3-trust-untrust] destination-ip-subnet 2:: 64
      [DeviceA-security-policy-ipv6-3-untrust-trust] action pass
      [DeviceA-security-policy-ipv6-3-untrust-trust] quit
      [DeviceA-security-policy-ipv6] quit
      ```

4. Configure basic RIPng functions.

   ```
   [DeviceA] ripng 1
   [DeviceA-ripng-1] quit
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ripng 1 enable
   [DeviceA-GigabitEthernet1/0/1] quit
   [DeviceA] interface gigabitethernet 1/0/2
   ```

```
[DeviceA-GigabitEthernet1/0/2] ripng 1 enable
[DeviceA-GigabitEthernet1/0/2] quit
```

Configuring Device B

1. Assign IPv6 addresses to interfaces:

   # Assign an IPv6 address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceB> system-view
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] ipv6 address 1::2 64
   [DeviceB-GigabitEthernet1/0/1] quit
   ```

   # Assign IPv6 addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [DeviceB] security-zone name untrust
   [DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
   [DeviceB-security-zone-Untrust] quit
   [DeviceB] security-zone name trust
   [DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
   [DeviceB-security-zone-Trust] quit
   ```

3. Configure security policies:

   a. Configure a security policy to permit traffic between the **Untrust** and **Local** security zones, and enable the devices to establish RIPng neighbor relationship with each other.

      # Configure a rule named **ripnglocalin** to allow Device B to receive RIPng packets from Device A.

      ```
      [DeviceB] security-policy ipv6
      [DeviceB-security-policy-ipv6] rule name ripnglocalin
      [DeviceB-security-policy-ipv6-0-ripnglocalin] source-zone untrust
      [DeviceB-security-policy-ipv6-0-ripnglocalin] destination-zone local
      [DeviceB-security-policy-ipv6-0-ripnglocalin] service rip
      [DeviceB-security-policy-ipv6-0-ripnglocalin] action pass
      [DeviceB-security-policy-ipv6-0-ripnglocalin] quit
      ```

      # Configure a rule named **ripnglocalout** to allow Device B to send RIPng packets to Device A.

      ```
      [DeviceB-security-policy-ipv6] rule name ripnglocalout
      [DeviceB-security-policy-ipv6-1-ripnglocalout] source-zone local
      [DeviceB-security-policy-ipv6-1-ripnglocalout] destination-zone untrust
      [DeviceB-security-policy-ipv6-1-ripnglocalout] service rip
      [DeviceB-security-policy-ipv6-1-ripnglocalout] action pass
      [DeviceB-security-policy-ipv6-1-ripnglocalout] quit
      ```

   b. Configure a security policy to permit traffic between the **Trust** and **Untrust** security zones, and enable communication between network 2::/64 and network 3::/64.

      # Configure a rule named **trust-untrust** to permit packets from network 3::/64 to network 2::/64.

      ```
      [DeviceB-security-policy-ipv6] rule name trust-untrust
      [DeviceB-security-policy-ipv6-2-trust-untrust] source-zone trust
      [DeviceB-security-policy-ipv6-2-trust-untrust] destination-zone untrust
      [DeviceB-security-policy-ipv6-2-trust-untrust] source-ip-subnet 3:: 64
      [DeviceB-security-policy-ipv6-2-trust-untrust] destination-ip-subnet 2:: 64
      [DeviceB-security-policy-ipv6-2-trust-untrust] action pass
      [DeviceB-security-policy-ipv6-2-trust-untrust] quit
      ```

# Configure a rule named **untrust-trust** to permit packets from network 2::/64 to network 3::/64.

```
[DeviceB-security-policy-ipv6] rule name untrust-trust
[DeviceB-security-policy-ipv6-3-untrust-trust] source-zone untrust
[DeviceB-security-policy-ipv6-3-untrust-trust] destination-zone trust
[DeviceB-security-policy-ipv6-3-untrust-trust] source-ip-subnet 2:: 64
[DeviceB-security-policy-ipv6-3-trust-untrust] destination-ip-subnet 3:: 64
[DeviceB-security-policy-ipv6-3-untrust-trust] action pass
[DeviceB-security-policy-ipv6-3-untrust-trust] quit
[DeviceB-security-policy-ipv6] quit
```

4. Configure basic RIPng functions.

```
[DeviceB] ripng 1
[DeviceB-ripng-1] quit
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ripng 1 enable
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] ripng 1 enable
[DeviceB-GigabitEthernet1/0/2] quit
```

Verifying the configuration

# Display the RIPng routing table of Device A.

```
[Device A] display ripng 1 route
 Route Flags: A - Aging, S - Suppressed, G - Garbage-collect, D - Direct
               O - Optimal, F - Flush to RIB
----------------------------------------------------------------------------
 Peer FE80::76A5::A3FF:FE7B:205 on GigabitEthernet1/0/1
 Destination 3::/64,
     via FE80::76A5:A3FF:FE7B:205, cost 1, tag 0, AOF, 17 secs
 Local route
 Destination 2::/64,
     via ::, cost 0, tag 0, DOF
 Destination 1::/64,
     via ::, cost 0, tag 0, DOF
```

The output shows that the hosts in network 2::/64 can communicate with the hosts in network 3::/64.

Configuring OSPF

About OSPF

Open Shortest Path First (OSPF) is a link-state IGP developed by the OSPF working group of the IETF. OSPF version 2 is used for IPv4. OSPF refers to OSPFv2 throughout this chapter.

OSPF features

OSPF has the following features:

- **Wide scope**—Supports multiple network sizes and several hundred routers in an OSPF routing domain.
- **Fast convergence**—Advertises routing updates instantly upon network topology changes.
- **Loop free**—Computes routes with the SPF algorithm to avoid routing loops.
- **Area-based network partition**—Splits an AS into multiple areas to facilitate management. This feature reduces the LSDB size on routers to save memory and CPU resources, and reduces route updates transmitted between areas to save bandwidth.
- **ECMP routing**—Supports multiple equal-cost routes to a destination.
- **Routing hierarchy**—Supports a 4-level routing hierarchy that prioritizes routes into intra-area, inter-area, external Type-1, and external Type-2 routes.
- **Authentication**—Supports area- and interface-based packet authentication to ensure secure packet exchange.
- **Support for multicasting**—Multicasts protocol packets on some types of links to avoid impacting other devices.

OSPF packets

OSPF messages are carried directly over IP. The protocol number is 89.

OSPF uses the following packet types:

- **Hello**—Periodically sent to find and maintain neighbors, containing timer values, information about the DR, BDR, and known neighbors.
- **Database description (DD)**—Describes the digest of each LSA in the LSDB, exchanged between two routers for data synchronization.
- **Link state request (LSR)**—Requests needed LSAs from a neighbor. After exchanging the DD packets, the two routers know which LSAs of the neighbor are missing from their LSDBs. They then exchange LSR packets requesting the missing LSAs. LSR packets contain the digest of the missing LSAs.
- **Link state update (LSU)**—Transmits the requested LSAs to the neighbor.
- **Link state acknowledgment (LSAck)**—Acknowledges received LSU packets. It contains the headers of received LSAs (an LSAck packet can acknowledge multiple LSAs).

LSA types

OSPF advertises routing information in Link State Advertisements (LSAs). The following LSAs are commonly used:

- **Router LSA**—Type-1 LSA, originated by all routers and flooded throughout a single area only. This LSA describes the collected states of the router's interfaces to an area.
- **Network LSA**—Type-2 LSA, originated for broadcast and NBMA networks by the designated router, and flooded throughout a single area only. This LSA contains the list of routers connected to the network.
- **Network Summary LSA**—Type-3 LSA, originated by Area Border Routers (ABRs), and flooded throughout the LSA's associated area. Each summary-LSA describes a route to a destination outside the area, yet still inside the AS (an inter-area route).
- **ASBR Summary LSA**—Type-4 LSA, originated by ABRs and flooded throughout the LSA's associated area. Type 4 summary-LSAs describe routes to Autonomous System Boundary Router (ASBR).
- **AS External LSA**—Type-5 LSA, originated by ASBRs, and flooded throughout the AS (except stub and NSSA areas). Each AS-external-LSA describes a route to another AS.
- **NSSA LSA**—Type-7 LSA, as defined in RFC 1587, originated by ASBRs in NSSAs and flooded throughout a single NSSA. NSSA LSAs describe routes to other ASs.
- **Opaque LSA**—LSA for OSPF extensions. Its format consists of a standard LSA header and application specific information. The opaque LSA includes Type 9, Type 10, and Type 11. The Type 9 opaque LSA is flooded into the local subnet. Grace LSA, used by graceful restart, is Type 9 LSA. The Type 11 is flooded throughout the AS.

OSPF areas

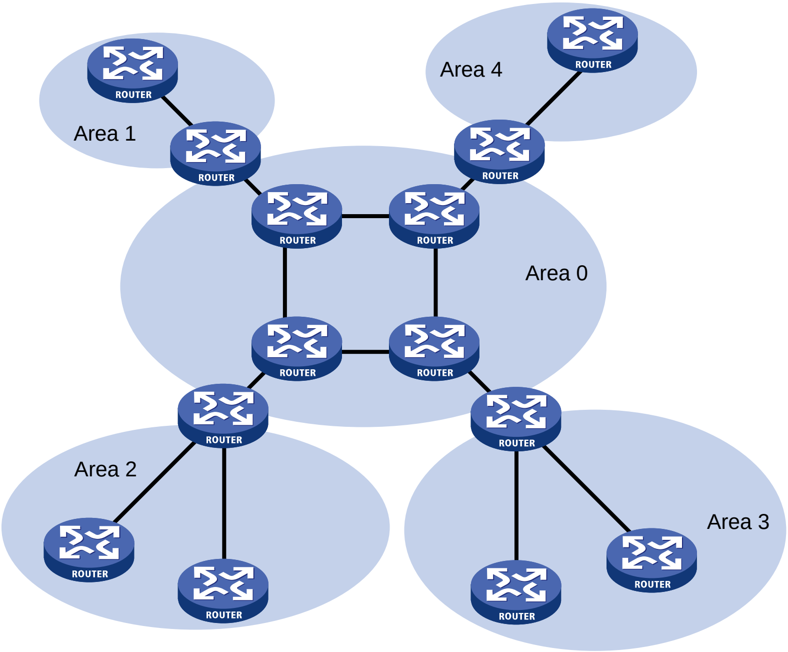
Area-based OSPF network partition

In large OSPF routing domains, SPF route computations consume too many storage and CPU resources, and enormous OSPF packets generated for route synchronization occupy excessive bandwidth.

To resolve these issues, OSPF splits an AS into multiple areas. Each area is identified by an area ID. The boundaries between areas are routers rather than links. A network segment (or a link) can only reside in one area as shown in Figure 1.

You can configure route summarization on ABRs to reduce the number of LSAs advertised to other areas and minimize the effect of topology changes.

Figure 1 Area-based OSPF network partition



Backbone area

Each AS has a backbone area that distributes routing information between non-backbone areas. Routing information between non-backbone areas must be forwarded by the backbone area. OSPF has the following requirements:

- All non-backbone areas must maintain connectivity to the backbone area.
- The backbone area must maintain connectivity within itself.

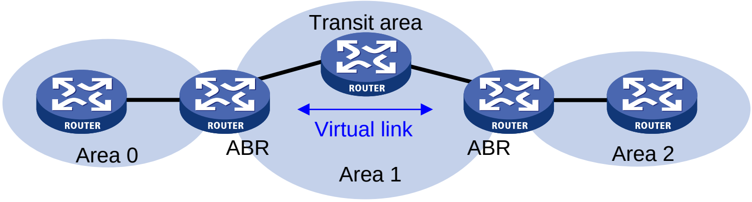
In practice, these requirements might not be met due to lack of physical links. OSPF virtual links can solve this issue.

Virtual links

A virtual link is established between two ABRs through a non-backbone area. It must be configured on both ABRs to take effect. The non-backbone area is called a transit area.

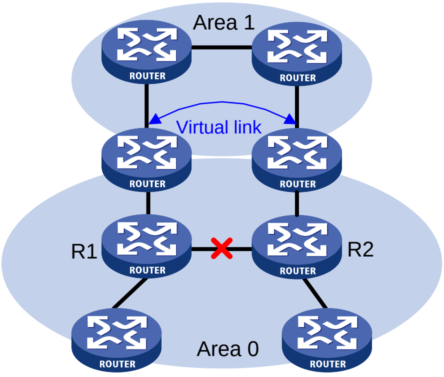
As shown in Figure 2, Area 2 has no direct physical link to the backbone Area 0. You can configure a virtual link between the two ABRs to connect Area 2 to the backbone area.

Figure 2 Virtual link application 1



Virtual links can also be used as redundant links. If a physical link failure breaks the internal connectivity of the backbone area, you can configure a virtual link to replace the failed physical link, as shown in Figure 3.

Figure 3 Virtual link application 2



The virtual link between the two ABRs acts as a point-to-point connection. You can configure interface parameters, such as hello interval, on the virtual link as they are configured on a physical interface.

The two ABRs on the virtual link unicast OSPF packets to each other, and the OSPF routers in between convey these OSPF packets as normal IP packets.

Stub area and totally stub area

A stub area does not distribute Type-5 LSAs to reduce the routing table size and LSAs advertised within the area. The ABR of the stub area advertises a default route in a Type-3 LSA so that the routers in the area can reach external networks through the default route.

To further reduce the routing table size and advertised LSAs, you can configure the stub area as a totally stub area. The ABR of a totally stub area does not advertise inter-area routes or external routes. It advertises a default route in a Type-3 LSA so that the routers in the area can reach external networks through the default route.

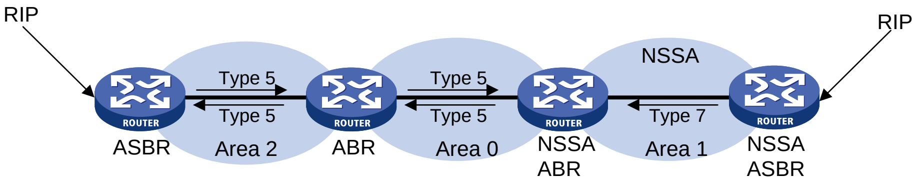
NSSA area and totally NSSA area

An NSSA area does not import AS external LSAs (Type-5 LSAs) but can import Type-7 LSAs generated by the NSSA ASBR. The NSSA ABR translates Type-7 LSAs into Type-5 LSAs and advertises the Type-5 LSAs to other areas.

As shown in Figure 4, the OSPF AS contains Area 1, Area 2, and Area 0. The other two ASs run RIP. Area 1 is an NSSA area where the ASBR redistributes RIP routes in Type-7 LSAs into Area 1. Upon receiving the Type-7 LSAs, the NSSA ABR translates them to Type-5 LSAs, and advertises the Type-5 LSAs to Area 0.

The ASBR of Area 2 redistributes RIP routes in Type-5 LSAs into the OSPF routing domain. However, Area 1 does not receive Type-5 LSAs because it is an NSSA area.

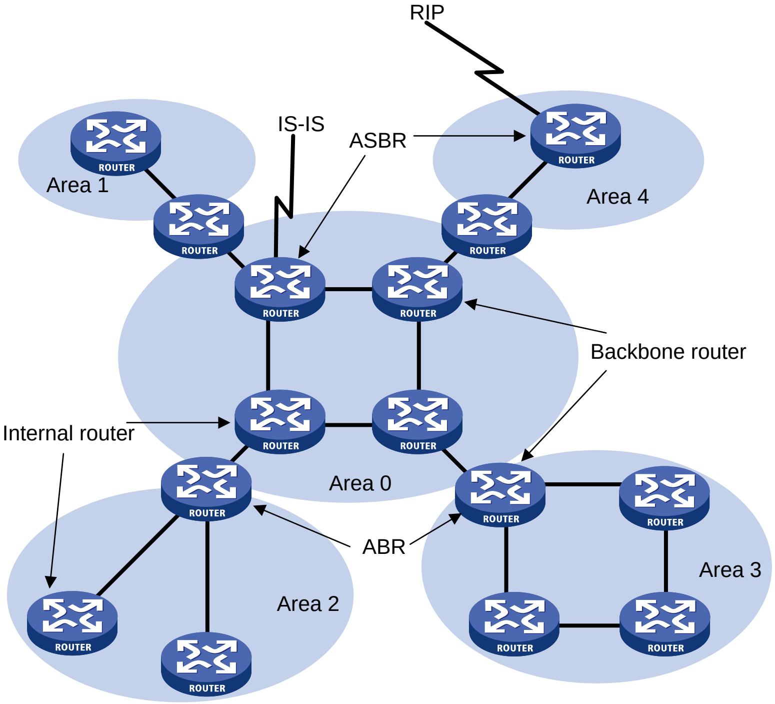
Figure 4 NSSA area



Router types

As shown in Figure 5, OSPF routers are classified into different types, including internal routers, ABRs, backbone routers, and ASBRs.

Figure 5 OSPF router types



Internal router

All interfaces on an internal router belong to one OSPF area.

ABR

An ABR belongs to more than two areas, one of which must be the backbone area. ABR connects the backbone area to a non-backbone area. An ABR and the backbone area can be connected through a physical or logical link.

Backbone router

No less than one interface of a backbone router must reside in the backbone area. All ABRs and internal routers in Area 0 are backbone routers.

ASBR

An ASBR exchanges routing information with another AS. An ASBR might not reside on the border of the AS. It can be an internal router or an ABR.

Route types

OSPF prioritizes routes into the following route levels:

- Intra-area route.
- Inter-area route.
- Type-1 external route.
- Type-2 external route.

The intra-area and inter-area routes describe the network topology of the AS. The external routes describe routes to external ASs.

A Type-1 external route has high credibility. The cost of a Type-1 external route = the cost from the router to the corresponding ASBR + the cost from the ASBR to the destination of the external route.

A Type-2 external route has low credibility. OSPF considers that the cost from the ASBR to the destination of a Type-2 external route is much greater than the cost from the ASBR to an OSPF internal router. The cost of a Type-2 external route = the cost from the ASBR to the destination of the Type-2 external route. If two Type-2 routes to the same destination have the same cost, OSPF takes the cost from the router to the ASBR into consideration to determine the best route.

Router ID

A router ID uniquely identifies a router in an AS. For a router to run OSPF, it must have a router ID. You can choose to manually specify a router ID or use the global router ID for an OSPF process.

Manual configuration

When you create an OSPF process, you can manually specify a router ID. To make sure the router ID is unique in the AS, you can specify the IP address of an interface on the router as the router ID.

Autoconfiguration

When you create an OSPF process, you can enable the OSPF process to automatically obtain a router ID. The OSPF process obtains a router ID in the following ways:

- During the startup of the OSPF process, the primary IPv4 address of the first interface that runs the process is specified as the router ID.
- During the reboot of the router, the primary IPv4 address of the first interface that runs the process is specified as the router ID.
- During the restart of the OSPF process, the highest primary IPv4 address of the loopback interface that runs the process is specified as the router ID. If no loopback address is available, the highest primary IPv4 address of the interface that runs the process is used, regardless of the interface state (up or down).

Using the global router ID

If you do not specify a router ID when creating an OSPF process, the global router ID is used. As a best practice, manually specify a router ID or enable the OSPF process to automatically obtain a router ID when you create the OSPF process.

Route calculation

OSPF computes routes in an area as follows:

- Each router generates LSAs based on the network topology around itself, and sends them to other routers in update packets.
- Each OSPF router collects LSAs from other routers to compose an LSDB. An LSA describes the network topology around a router, and the LSDB describes the entire network topology of the area.
- Each router transforms the LSDB to a weighted directed graph that shows the topology of the area. All the routers within the area have the same graph.
- Each router uses the SPF algorithm to compute a shortest path tree that shows the routes to the nodes in the area. The router itself is the root of the tree.

OSPF network types

OSPF classifies networks into the following types, depending on different link layer protocols:

- **Broadcast**—If the link layer protocol is Ethernet or FDDI, OSPF considers the network type as broadcast by default. On a broadcast network, hello, LSU, and LSAck packets are multicast to 224.0.0.5 that identifies all OSPF routers or to 224.0.0.6 that identifies the DR and BDR. DD packets and LSR packets are unicast.

- **NBMA**—If the link layer protocol is Frame Relay, ATM, or X.25, OSPF considers the network type as NBMA by default. OSPF packets are unicast on an NBMA network.
- **P2MP**—No link is P2MP type by default. P2MP must be a conversion from other network types such as NBMA. On a P2MP network, OSPF packets are multicast to 224.0.0.5.
- **P2P**—If the link layer protocol is PPP or HDLC, OSPF considers the network type as P2P. On a P2P network, OSPF packets are multicast to 224.0.0.5.

The following are the differences between NBMA and P2MP networks:

- NBMA networks are fully meshed. P2MP networks are not required to be fully meshed.
- NBMA networks require DR and BDR election. P2MP networks do not have DR or BDR.
- On an NBMA network, OSPF packets are unicast, and neighbors are manually configured. On a P2MP network, OSPF packets are multicast by default, and you can configure OSPF to unicast protocol packets.

DR and BDR

DR and BDR mechanism

On a broadcast or NBMA network, any two routers must establish an adjacency to exchange routing information with each other. If n routers are present on the network, n(n-1)/2 adjacencies are established. Any topology change on the network results in an increase in traffic for route synchronization, which consumes a large amount of system and bandwidth resources.

Using the DR and BDR mechanisms can solve this problem.

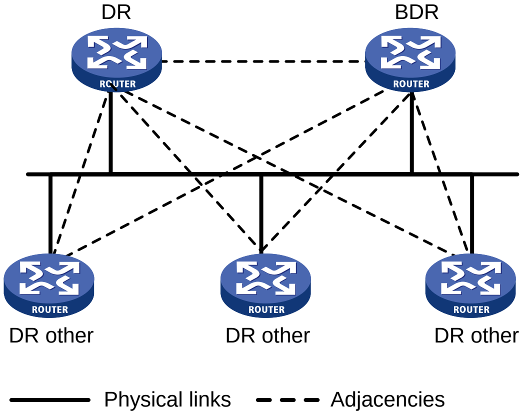
- **DR**—Elected to advertise routing information among other routers. If the DR fails, routers on the network must elect another DR and synchronize information with the new DR. Using this mechanism without BDR is time-consuming and is prone to route calculation errors.
- **BDR**—Elected along with the DR to establish adjacencies with all other routers. If the DR fails, the BDR immediately becomes the new DR, and other routers elect a new BDR.

Routers other than the DR and BDR are called DR Others. They do not establish adjacencies with one another, so the number of adjacencies is reduced.

The role of a router is subnet (or interface) specific. It might be a DR on one interface and a BDR or DR Other on another interface.

As shown in Figure 6, solid lines are Ethernet physical links, and dashed lines represent OSPF adjacencies. With the DR and BDR, only seven adjacencies are established.

Figure 6 DR and BDR in a network



NOTE:

In OSPF, neighbor and adjacency are different concepts. After startup, OSPF sends a hello packet on each OSPF interface. A receiving router checks parameters in the packet. If the parameters match its own, the receiving router considers the sending router an OSPF neighbor. Two OSPF neighbors establish an adjacency relationship after they synchronize their LSDBs through exchange of DD packets and LSAs.

DR and BDR election

DR election is performed on broadcast or NBMA networks but not on P2P and P2MP networks.

Routers in a broadcast or NBMA network elect the DR and BDR by router priority and ID. Routers with a router priority value higher than 0 are candidates for DR and BDR election.

The election votes are hello packets. Each router sends the DR elected by itself in a hello packet to all the other routers. If two routers on the network declare themselves as the DR, the router with the higher router priority wins. If router priorities are the same, the router with the higher router ID wins.

If a router with a higher router priority becomes active after DR and BDR election, the router cannot replace the DR or BDR until a new election is performed. Therefore, the DR of a network might not be the router with the highest priority, and the BDR might not be the router with the second highest priority.

OSPF state machines

Interface state machine

On receipt of link state information, OSPF establishes adjacency relationships with neighboring devices, and then exchanges LSAs with them. The state of an OSPF interface indicates the role of the device in an OSPF link. Two neighboring devices can correctly form an adjacency relationship by checking the other's interface state.

The interface state machine involves the following interface states:

- **Down**—Initial interface state.

  An OSPF interface in this state cannot be used for traffic sending or receiving.

- **Loopback**—The network-facing interface is looped back on the device.

  A loopback interface is not available for regular data transmission. However, to obtain link quality information on the interface, you might either send ICMP ping packets to the loopback interface or have a bit error test. To meet this potential requirement, each OSPF device advertises loopback interface information in Router LSAs.

- **Waiting**—The device is determining the DR and BDR for the network.

  When the device does not run for the DR or BDR, the interface starts a wait timer. The hello packets sent by the device does not contain any DR or BDR information unless the wait timer expires. The device cannot be elected as the DR or BDR on the network until it exits from **Waiting** state. The wait timer mechanism prevents unnecessary DR and BDR changes.

  This interface state is supported only on NBMA networks and broadcast networks.

- **Point-to-point**—The interface is connected to a physical P2P network or to a virtual link.

  If an interface enters this state, it attempts to establish an adjacency relationship with the neighboring device.

- **DR Other**—The interface is connected to a broadcast or NBMA network on which another device has been elected as the DR.

  A device in **DR Other** state is neither elected as the DR nor the BDR. When DR and BDR election is complete on the network, each DR Other device establishes adjacencies with both the DR and the BDR.

- **BDR**—The device is the BDR on the attached network.

As the BDR, the device establishes adjacencies with all other devices on the attached network. It will immediately become the new DR if the existing DR fails.

- **DR**—The device is the DR on the attached network.

  As the DR, the device establishes adjacencies with all other devices on the attached network.

A number of input events (IE) can cause OSPF interface state changes. As shown in Figure 7, the relationships between IEs and state changes form the OSPF interface state machine.

Figure 7 OSPF interface state machine

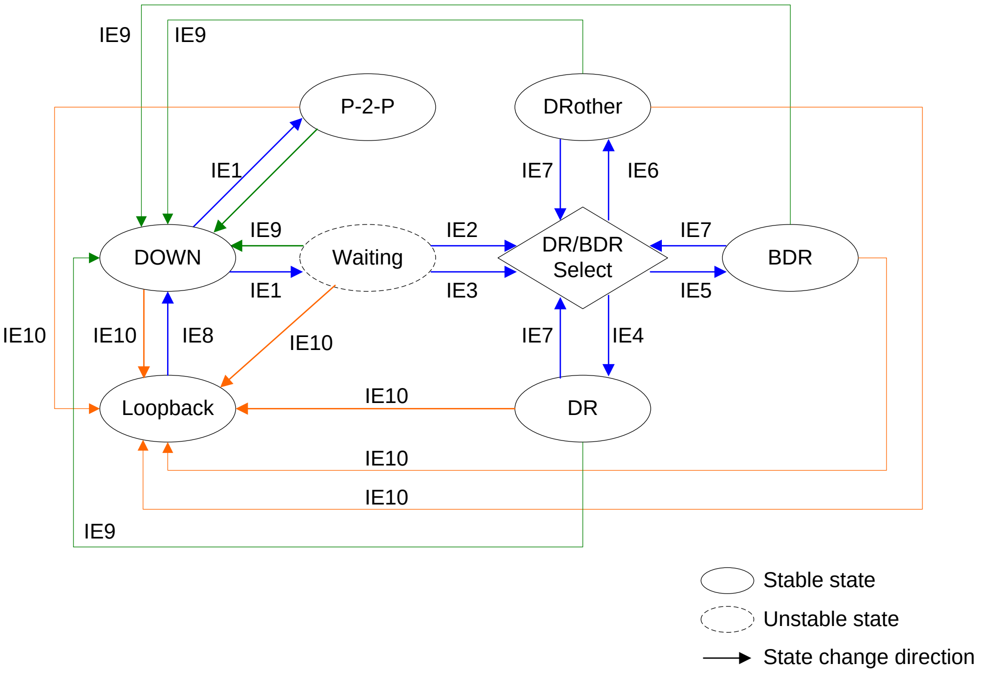


Table 1 shows the IEs that can cause interface state changes.

Table 1 Input events

Input event	Description
IE1	InterfaceUp event: Lower-level protocols have indicated that the interface is operational.
IE2	WaitTimer event: The wait timer has expired and the device can run for the DR or the BDR.
IE3	BackupSeen event: The device has detected the existence or non-existence of a BDR on the attached network through one of the following methods: • The interface receives a hello packet from a neighbor that claims itself to be the BDR. • The interface receives a hello packet from a neighbor that claims itself to be the DR. The hello packet also indicates that there is no BDR. This event marks an end to **Waiting** state and indicates that the device and the neighbor can have bidirectional communication.
IE4	The interface is elected as the DR.
IE5	The interface is elected as the BDR.
IE6	The interface is neither elected as the DR nor the BDR.
IE7	NeighborChange event: A neighbor associated with the interface has a change. The DR and BDR need to be re-elected. The following neighbor changes might lead to the re-election of DR and BDR:

	• The device can have bidirectional communication with a neighbor. • The device no longer has bidirectional communication with a neighbor. • A neighbor claims itself as DR or BDR. The device detects this event again by examining the hello packets from the neighbor. • A neighbor no longer claims itself as DR or BDR. The device detects this event again by examining the hello packets from the neighbor. • The DR priority for a neighbor has changed. The device detects this event again by examining the hello packets from the neighbor.
IE8	UnloopInd event: Network management or lower-level protocols has indicated that the interface is no longer looped back.
IE9	InterfaceDown event: Lower-level protocols has indicated that the interface is not operational. If this event occurs, the interface state might change to Down.
IE10	LoopInd event: Network management or lower-level protocols has indicated that the interface is looped back. If this event occurs, the interface state might change to Loopback.

Neighbor state machine

The process of OSPF adjacency establishment involves a series of neighbor state changes that transition from **Down** state to **Full** state.

The neighbor state machine involves the following neighbor states:

- **Down**—Intial state of a neighbor conversation.

  This state indicates that the device does not received any hello packets from the neighbor within the neighbor dead interval. An OSPF device sends hello packets at intervals of PollInterval.

  Whether an OSPF device sends hello packets to neighbors in **Down** state depends on its network type. The device sends hello packets to neighbors in **Down** state only when its network type is NBMA.
- **Attempt**—In this state, the device attempts to establish neighbor relationships with the maually specified neighbors by sending hello packets at intervals of HelloInterval.

  This state is valid only for the neighbors on NBMA networks.
- **Init**—This state indicates that the OSPF device has received a hello packet from a neighbor before the neighbor dead interval elapses. However, the OSPF device has not established bidirectional communication with the neighbor, because the received hello packet does not contain the OSPF device's router ID.
- **2-Way**—This state indicates that the OSPF device has established a neighbor relationship with a neighboring device. Each of the two devices has received a hello packet from another and has seen its own router ID in the received hello packet.

  If the neighbor relationship between two devices does not prompt to an adjacency, the neighbot state will remain 2-Way.

  DR and BDR election starts only when the neighbor state is 2-Way or greater.
- **ExStart**—This state indicates that the OSPF device and the neighbor is deciding which is the master. This step is to determine the sequence number for initial DD packets. The devices can then exchange DD packets in order.
- **Exhange**—This state indicates that the OSPF device is exchanging DD packets with the neighbor. The device describes its LSDB information in DD packets and sends them to the neighbor.
- **Loading**—This state indicates that the OSPF device and the neighbor are having bidirectional LSDB synchronization. They send LSRs to each other to request the most recent LSAs, and then synchronize their LSDBs through exchanges of LSUs and LSAcks.
- **Full**—This state indicates that the OSPF device and the neighbor has completed bidirectional LSDB synchronization and they are fully adjacent.

As shown in Figure 8, the relationships between IEs and state changes form the OSPF neighbor state machine.

Figure 8 OSPF neighbor state machine

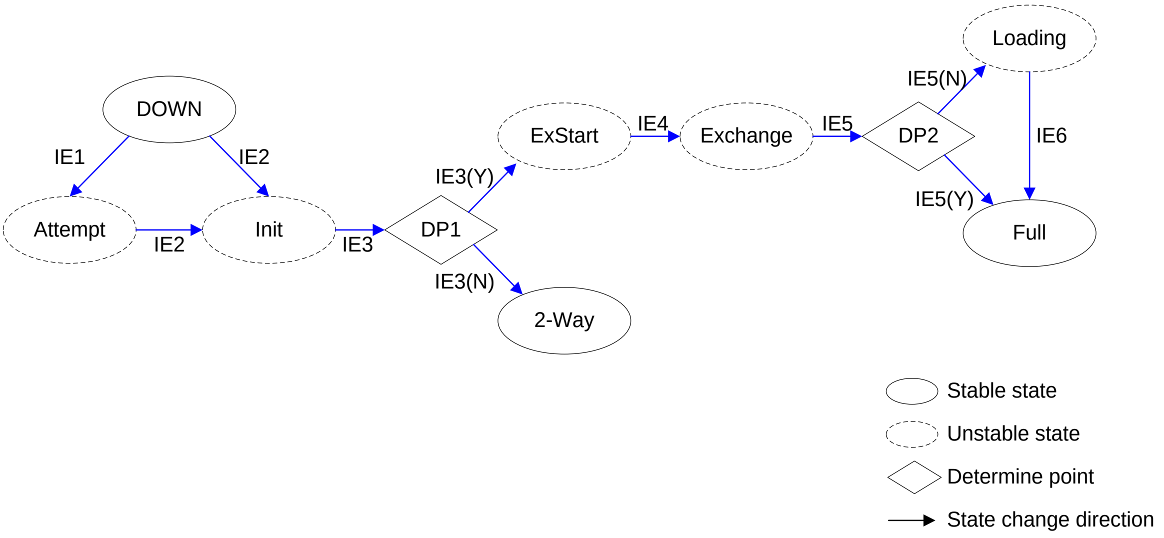

Table 2 shows the IEs that can cause neighbor state changes.

Table 2 Input events

Input event	Description
IE1	Start event: The OSPF device attempts to establish a neighbor relationship with the neighbor by sending hello packets at intervals of HelloInterval. This event is supported only on NBMA networks.
IE2	HelloReceived event: The OSPF device has received a hello packet from the neighbor.
IE3	2-WayReceived event: The OSPF device has received a hello packet from the neighbor and has seen its router ID in the received hello packet. The two neighboring devices have established bidirectional communication. The OSPF device then performs the following task: • If the OSPF device needs to form an adjacency with the neighbor, it changes the neighbor state to ExStart. • If the OSPF device should not form an adjacency with the neighbor, it changes the neighbor state to 2-Way.
IE4	NegotiationDone event: The OSPF device and the neighbor have completed master/secondary relationship negotiation and have determined the sequence number for initial DD packets.
IE5	ExchangeDone event: The OSPF device have exchangd DD packets with the neighbor. The OSPF device then performs the following task: • If the LSR list is empty, the device changes the neighbor state to Full. This neighbor state indicates that bidirectional LSDB sychronization is complete and the device has established an adjacency with the neighbor. • If the LSR list is not empty, the device changes the neighbor state to Loading, and then sends LSRs to the neighbor to request missing link state information. If the OSPF device should not form an adjacency with the neighbor, it changes the neighbor state to 2-Way.
IE6	LoadingDone event: The LSR list is already empty.

Restrictions and guidelines: OSPF configuration

To run OSPF, you must first enable OSPF on the router. Make a proper configuration plan to avoid incorrect settings that can result in route blocking and routing loops.

OSPF tasks at a glance

To configure OSPF, perform the following tasks:

1. Configuring basic OSPF functions
   - Enabling an OSPF process
   - Creating an OSPF area
   - Enabling OSPF
   - Configuring OSPF dynamic host name mappings
2. (Optional.) Configuring OSPF stub and NSSA areas

- Configuring a stub area
- Configuring an NSSA area
- Configuring a virtual link

3. (Optional.) Configuring OSPF network types
    - Configuring the broadcast network type for an interface
    - Configuring the NBMA network type for an interface
    - Configuring the P2MP network type for an interface
    - Configuring the P2P network type for an interface
4. (Optional.) Configuring OSPF route control
    - Configuring OSPF inter-area route summarization
    - Configuring redistributed route summarization
    - Configuring received OSPF route filtering
    - Configuring Type-3 LSA filtering
    - Setting an OSPF cost for an interface
    - Setting the maximum number of ECMP routes
    - Setting OSPF preference
    - Configuring discard routes for summary networks
    - Redistributing routes from another routing protocol
    - Redistributing a default route
    - Advertising a host route
    - Advertising OSPF link state information to BGP
5. (Optional.) Setting OSPF timers
    - Configuring OSPF packet timers
    - Setting LSA transmission delay
    - Setting SPF calculation interval
    - Setting the minimum LSA arrival interval
    - Setting the LSA generation interval
    - Setting OSPF exit overflow interval
6. (Optional.) Configuring OSPF packet parameters
    - Disabling interfaces from receiving and sending OSPF packets
    - Adding the interface MTU into DD packets
    - Setting the DSCP value for outgoing OSPF packets
    - Setting the LSU transmit rate
7. (Optional.) Controlling LSA generation, advertisement, and reception
    - Setting the maximum number of external LSAs in LSDB
    - Filtering outbound LSAs on an interface
    - Filtering LSAs for the specified neighbor
8. (Optional.) Accelerating OSPF convergence speed
    - Enabling OSPF ISPF
    - Configuring prefix suppression
    - Configuring prefix prioritization
    - Configuring OSPF PIC
9. (Optional.) Configuring advanced OSPF features
    - Configuring stub routers

- Enabling compatibility with RFC 1583
- Enabling OSPF to group ECMP routes

10. (Optional.) Enhancing OSPF availability
    - Configuring OSPF GR
    - Configuring OSPF NSR
    - Configuring BFD for OSPF
    - Configuring OSPF FRR
11. (Optional.) Configuring OSPF security features
    - Configuring OSPF authentication
    - Configuring GTSM for OSPF
12. (Optional.) Configuring OSPF logging and SNMP notifications
    - Logging neighbor state changes
    - Configuring the OSPF logging feature
    - Configuring OSPF network management

Configuring basic OSPF functions

Enabling an OSPF process

1. Enter system view.

   system-view

2. (Optional.) Configure a global router ID.

   router id *router-id*

   By default, no global router ID is configured.

   If no global router ID is configured, the highest loopback interface IP address, if any, is used as the router ID. If no loopback interface IP address is available, the highest physical interface IP address is used, regardless of the interface status (up or down).

3. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

   By default, OSPF is disabled.

4. (Optional.) Configure a description for the OSPF process.

   description *text*

   By default, no description is configured for the OSPF process.

   As a best practice, configure a description for each OSPF process.

Creating an OSPF area

1. Enter system view.

   system-view

2. (Optional.) Configure a global router ID.

   router id *router-id*

   By default, no global router ID is configured.

3. Enter OSPF view.

ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

By default, OSPF is disabled.

4. (Optional.) Configure a description for the OSPF process.

   description *text*

   By default, no description is configured for the OSPF process.

   As a best practice, configure a description for each OSPF process.

5. Create an OSPF area and enter OSPF area view.

   area *area-id*

6. (Optional.) Configure a description for the area.

   description *text*

   By default, no description is configured for the area.

   As a best practice, configure a description for each OSPF area.

Enabling OSPF

About this task

To enable OSPF on a router, you must perform the following tasks:

1. Create an OSPF process.
2. Create an OSPF area for the process.
3. Specify a network in the area.

The interface attached to the network will run the OSPF process in the area. OSPF advertises direct routes of the interface.

OSPF supports multiple processes. To run multiple OSPF processes, you must specify an ID for each process. The process IDs take effect locally and has no influence on packet exchange between routers. Two routers with different process IDs can exchange packets.

Restrictions and guidelines for enabling OSPF

When you configure OSPF on an interface, follow these restrictions and guidelines:

- You can enable OSPF on the network where the interface resides or directly enable OSPF on that interface. If you configure both, the latter takes precedence.
- If the specified OSPF process and area do not exist, the operation creates an OSPF process and area for the interface. Disabling an OSPF process on an interface does not delete the OSPF process or the area.

Enabling OSPF on a network

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Create an OSPF area and enter OSPF area view.

   area *area-id*

4. Specify a network to enable the interface attached to the network to run the OSPF process in the area.

   network *ip-address wildcard-mask*

   By default, no network is specified to enable OSPF on the interface attached to the network.

A network can be added to only one area.

Enabling OSPF on an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable an OSPF process on the interface.

   ospf *process-id* **area** *area-id* [**exclude-subip**]

   By default, OSPF is disabled on an interface.

Configuring OSPF dynamic host name mappings

About this task

OSPF uses a router ID to uniquely identify a router in an AS. The length of router IDs is fixed at 4 bytes. It is inconvenient for the network administrator to memorize the router IDs in dotted decimal notation when verifying the OSPF neighbor relationships, routing tables, and LSDBs.

This task allows you to map a router ID to a host name. The mapping table is maintained by OSPF routers. Host names are more straightforward than router IDs in network maintenance, management, and failure diagnosis.

Restrictions and guidelines

OSPF uses Type-11 LSAs to carry information about the dynamic host name attribute. Therefore, make sure the opaque LSA reception and advertisement capability is enabled.

Procedure

1. Enter system view.

   system-view

2. Enable OSPF, and enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enable the opaque LSA reception and advertisement capability.

   opaque-capability enable

   By default, the opaque LSA reception and advertisement capability is enabled.

4. Enable the OSPF dynamic host name mapping feature.

   hostname [*host-name*]

   By default, the OSPF dynamic host name mapping feature is disabled.

Configuring OSPF stub and NSSA areas

About OSPF stub and NSSA area configuration

This task allows you to configure an OSPF area as a stub area or NSSA area. It also allows you to create a virtual link if no connectivity can be achieved between a non-backbone area and backbone area, or in the backbone area.

Configuring a stub area

About this task

You can configure a non-backbone area at an AS edge as a stub area. To do so, execute the **stub** command on all routers attached to the area. The routing table size is reduced because Type-5 LSAs will not be flooded within the stub area. The ABR generates a default route into the stub area so all packets destined outside of the AS are sent through the default route.

To further reduce the routing table size and routing information exchanged in the stub area, configure a totally stub area by using the **stub no-summary** command on the ABR. AS external routes and inter-area routes will not be distributed into the area. All the packets destined for outside of the AS or area will be sent to the ABR for forwarding.

A stub or totally stub area cannot have an ASBR because external routes cannot be distributed into the area.

Restrictions and guidelines

Do not configure the backbone area as a stub area or totally stub area.

To configure an area as a stub area, execute the **stub** command on all routers attached to the area.

To configure an area as a totally stub area, execute the **stub** command on all routers attached to the area, and execute the **stub no-summary** command on the ABR.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enter area view.

   area *area-id*

4. Configure the area as a stub area.

   stub [**default-route-advertise-always** | **no-summary**] *

   By default, no stub area is configured.

5. (Optional.) Set a cost for the default route advertised to the stub area.

   default-cost *cost-value*

   By default, the cost for the default route advertised to the stub area is 1.

   This command takes effect only on the ABR of a stub area or totally stub area.

Configuring an NSSA area

About this task

A stub area cannot import external routes, but an NSSA area can import external routes into the OSPF routing domain while retaining other stub area characteristics.

To configure an area as a totally NSSA area, use the **nssa no-summary** command. The ABR of the area does not advertise inter-area routes into the area.

Restrictions and guidelines

Do not configure the backbone area as an NSSA area or totally NSSA area.

To configure an NSSA area, configure the **nssa** command on all the routers attached to the area.

To configure a totally NSSA area, configure the **nssa** command on all the routers attached to the area and configure the **nssa no-summary** command on the ABR.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enter area view.

   area *area-id*

4. Configure the area as an NSSA area.

   nssa [**default-route-advertise** [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **type** *type*] * | **no-import-route** | **no-summary** | **suppress-fa** | [[[**translate-always**] [**translate-ignore-checking-backbone**]] | **translate-never**] | **translator-stability-interval** *value*] *

   By default, no area is configured as an NSSA area.

5. (Optional.) Set a cost for the default route advertised to the NSSA area.

   default-cost *cost-value*

   By default, the cost for the default route advertised to the NSSA area is 1.

   This command takes effect only on the ABR/ASBR on an NSSA area or totally NSSA area.

Configuring a virtual link

About this task

You can configure a virtual link to maintain connectivity between a non-backbone area and the backbone, or in the backbone itself.

Restrictions and guidelines

A virtual link cannot traverse a stub area, totally stub area, NSSA area, or totally NSSA area.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Create an OSPF area and enter OSPF area view.

   area *area-id*

4. Configure a virtual link.

   vlink-peer *router-id* [**dead** *seconds* | **hello** *seconds* | { { **hmac-md5** | **hmac-sha-256** | **md5** } *key-id* { **cipher** | **plain** } *string* | **keychain** *keychain-name* | **simple** { **cipher** | **plain** } *string* } | **retransmit** *seconds* | **trans-delay** *seconds*] *

   Configure this command on both ends of a virtual link. The **hello** and **dead** intervals must be identical on both ends of the virtual link.

Configuring OSPF network types

Based on the link layer protocol, OSPF classifies networks into different types, including broadcast, NBMA, P2MP, and P2P.

Restrictions and guidelines for configuring OSPF network types

When an NBMA network becomes fully meshed, change the network type to broadcast to avoid manual configuration of neighbors.

If any routers in a broadcast network do not support multicasting, change the network type to NBMA.

An NBMA network must be fully meshed. OSPF requires that an NBMA network be fully meshed. If a network is partially meshed, change the network type to P2MP.

If only two routers running OSPF exist on a network segment, you can change the network type to P2P to save costs.

Two broadcast-, NBMA-, and P2MP-interfaces can establish a neighbor relationship only when they are on the same network segment.

Configuring the broadcast network type for an interface

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure the OSPF network type for the interface as broadcast.

   `ospf network-type broadcast`

   By default, the network type of an interface depends on the link layer protocol.

   When the link layer protocol is Ethernet or FDDI, OSPF classifies the network type as broadcast by default.

4. (Optional.) Set a router priority for the interface.

   `ospf dr-priority` *`priority`*

   The default router priority is 1.

Configuring the NBMA network type for an interface

Restrictions and guidelines

After you configure the network type as NBMA, you must specify neighbors and their router priorities because NBMA interfaces cannot find neighbors by broadcasting hello packets.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure the OSPF network type for the interface as NBMA.

   `ospf network-type nbma`

By default, the network type of an interface varies by physical media.

4. (Optional.) Set a router priority for the interface.

   ospf dr-priority *priority*

   The default router priority for an interface is 1.

   The router priority configured with this command is for DR election.

5. Return to system view.

   quit

6. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

7. Specify an NBMA neighbor.

   peer *ip-address* [**dr-priority** *priority*]

   By default, no neighbor is specified.

   The priority configured with this command indicates whether a neighbor has the election right or not. If you configure the router priority for a neighbor as 0, the local router determines the neighbor has no election right. It does not send hello packets to this neighbor. However, if the local router is the DR or BDR, it still sends hello packets to the neighbor for neighbor relationship establishment.

Configuring the P2MP network type for an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the OSPF network type for the interface as P2MP.

   ospf network-type p2mp [**unicast**]

   By default, the network type of an interface depends on the link layer protocol.

   After you configure the OSPF network type for an interface as P2MP unicast, all packets are unicast over the interface. The interface cannot broadcast hello packets to discover neighbors, so you must manually specify the neighbors.

4. Return to system view.

   quit

5. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

6. Specify a P2MP neighbor.

   peer *ip-address* [**cost** *cost-value*]

   By default, no neighbor is specified

   This step is required if the interface network type is P2MP unicast.

Configuring the P2P network type for an interface

1. Enter system view.

   system-view

2. Enter interface view.

interface *interface-type interface-number*

3. Configure the OSPF network type for the interface as P2P.

   ospf network-type p2p [**peer-address-check**]

   By default, the network type of an interface depends on the link layer protocol.

   When the link layer protocol is PPP, the interface network type is P2P by default.

Configuring OSPF route control

This section describes how to control the advertisement and reception of OSPF routing information, as well as route redistribution from other protocols.

Configuring OSPF inter-area route summarization

About this task

OSPF inter-area route summarization reduces the routing information exchanged between areas and the size of routing tables, and improves routing performance.

OSPF inter-area route summarization enables an ABR to summarize contiguous networks into a single network and advertise the network to other areas. For example, three internal networks 19.1.1.0/24, 19.1.2.0/24, and 19.1.3.0/24 are available within an area. You can configure the ABR to summarize the three networks into network 19.1.0.0/16, and advertise the summary network to other areas in a Type-3 LSA. This configuration reduces the scale of LSDBs on routers in other areas and the influence of topology changes.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Create an OSPF area and enter OSPF area view.

   area *area-id*

4. Configure ABR route summarization.

   abr-summary *ip-address* { *mask-length* | *mask* } [**advertise** | **not-advertise**] [**cost** *cost-value*]

   By default, route summarization is not configured on an ABR.

Configuring redistributed route summarization

About this task

Perform this task to enable an ASBR to summarize external routes within the specified address range into a single route. The ASBR advertises only Type-5 LSAs to reduce the number of LSAs in the LSDB.

An ASBR can summarize routes in the following LSAs:

- Type-5 LSAs.
- Type-7 LSAs in an NSSA area.

Restrictions and guidelines

If an ASBR (also an ABR) is a translator in an NSSA area, it summarizes routes in Type-5 LSAs translated from Type-7 LSAs. If it is not a translator, it does not summarize routes in in Type-5 LSAs translated from Type-7 LSAs.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Configure ASBR route summarization.

   asbr-summary *ip-address* { *mask-length* | *mask* } [**cost** *cost-value* | **not-advertise** | **nssa-only** | **tag** *tag*] *

   By default, route summarization is not configured on an ASBR.

Configuring received OSPF route filtering

About this task

Perform this task to filter routes calculated using received LSAs.

The following filtering methods are available:

- Use an ACL or IP prefix list to filter routing information by destination address.
- Use the **gateway** *prefix-list-name* option to filter routing information by next hop.
- Use an ACL or IP prefix list to filter routing information by destination address. At the same time use the **gateway** *prefix-list-name* option to filter routing information by next hop.
- Use the **route-policy** *route-policy-name* option to filter routing information.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Configure OSPF to filter routes calculated using received LSAs.

   filter-policy { *ipv4-acl-number* [**gateway** *prefix-list-name*] | **gateway** *prefix-list-name* | **prefix-list** *prefix-list-name* [**gateway** *prefix-list-name*] | **route-policy** *route-policy-name* } **import**

   By default, OSPF accepts all routes calculated by using received LSAs.

Configuring Type-3 LSA filtering

About this task

Perform this task to filter Type-3 LSAs advertised into the local area or other areas on an ABR.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Create an OSPF area and enter OSPF area view.

   area *area-id*

4. Configure Type-3 LSA filtering.

   filter { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } { **export** | **import** }

   By default, the ABR does not filter Type-3 LSAs.

Setting an OSPF cost for an interface

About this task

Set an OSPF cost for an interface by using either of the following methods:

- Set the cost value in interface view.
- Set a bandwidth reference value for the interface. OSPF computes the cost with this formula: Interface OSPF cost = Bandwidth reference value (100 Mbps) / Expected interface bandwidth (Mbps). The expected bandwidth of an interface is configured with the **bandwidth** command (see *Interface Command Reference*).
  - If the calculated cost is greater than 65535, the value of 65535 is used. If the calculated cost is less than 1, the value of 1 is used.
  - If no cost or bandwidth reference value is configured for an interface, OSPF computes the interface cost based on the interface bandwidth and default bandwidth reference value.

Setting an OSPF cost for an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set an OSPF cost for the interface.

   ospf cost *cost-value*

   By default, the OSPF cost is calculated according to the interface bandwidth. For a loopback interface, the OSPF cost is 0 by default.

Setting a bandwidth reference value

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Set a bandwidth reference value.

   bandwidth-reference *value*

   The default setting is 100 Mbps.

Setting the maximum number of ECMP routes

About this task

OSPF might find multiple optimal equal-cost routes to the same destination, which can be used to share the traffic load. This task allows you to set the maximum number of ECMP routes for OSPF.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Set the maximum number of ECMP routes.

   maximum load-balancing *number*

   By default, the maximum number of ECMP routes equals the maximum number of ECMP routes supported by the system.

Setting OSPF preference

About this task

A router can run multiple routing protocols, and each protocol is assigned a preference. If multiple routes are available to the same destination, the one with the highest protocol preference is selected as the best route.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Set a preference for OSPF.

   preference [**ase**] { *preference* | **route-policy** *route-policy-name* } *

   By default, the preference of OSPF internal routes is 10 and the preference of OSPF external routes is 150.

Configuring discard routes for summary networks

About this task

Perform this task on an ABR or ASBR to specify whether to generate discard routes for summary networks. You can also specify a preference for the discard routes.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Configure discard routes for summary networks.

discard-route { **external** { *preference* | **suppression** } | **internal** { *preference* | **suppression** } } *

By default, the ABR or ASBR generates discard routes for summary networks and the default preference of discard routes is 255.

Redistributing routes from another routing protocol

About this task

On a router running OSPF and other routing protocols, you can configure OSPF to redistribute routes from other protocols. OSPF advertises the routes in Type-5 LSAs or Type-7 LSAs. In addition, you can configure OSPF to filter redistributed routes so that OSPF advertises only permitted routes.

Restrictions and guidelines

OSPF redistributes only active routes. To view route status information, use the **display ip routing-table protocol** command.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Configure route redistribution.

   import-route bgp [*as-number*] [**allow-ibgp**] [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

   import-route { **direct** | **guard** | **static** } [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

   import-route { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] [**allow-direct** | **cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

   By default, OSPF does not redistribute routes.

   The **import-route bgp** command redistributes only EBGP routes. The **import-route bgp allow-ibgp** command redistributes both EBGP and IBGP routes, which might cause routing loops. Therefore, use it with caution. Support for the **allow-ibgp** keyword depends on the device model.

4. (Optional.) Configure OSPF to filter redistributed routes.

   filter-policy { *ipv4-acl-number* | **prefix-list** *prefix-list-name* } **export** [[**bgp** | **direct** | { **isis** | **ospf** | **rip** } [*process-id*] | **static**]

   By default, OSPF accepts all redistributed routes.

5. Configure the default parameters for redistributed routes (cost, tag, and type).

   default { **cost** *cost-value* | **tag** *tag* | **type** *type* } *

   By default, the cost is 1, the tag is 1, and the route type is 2

Redistributing a default route

About this task

The **import-route** command cannot redistribute a default external route. Perform this task to redistribute a default route.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Redistribute a default route.

   default-route-advertise [[**always** | **permit-calculate-other**] | **cost** *cost-value* | **route-policy** *route-policy-name* | **type** *type*] *

   default-route-advertise [**summary cost** *cost-value*]

   By default, no default route is redistributed.

   This command is applicable only to VPNs. The PE router advertises a default route in a Type-3 LSA to a CE router.

4. Configure the default parameters for redistributed routes (cost, tag, and type).

   default { **cost** *cost-value* | **tag** *tag* | **type** *type* } *

   By default, the cost is 1, the tag is 1, and the route type is 2

Advertising a host route

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enter area view.

   area *area-id*

4. Advertise a host route.

   host-advertise *ip-address cost-value*

   By default, OSPF does not advertise host routes that are not in the area.

Advertising OSPF link state information to BGP

About this task

After the device advertises OSPF link state information to BGP, BGP can advertise the information for intended applications. For more information about BGP LS, see "Configuring BGP."

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Advertise OSPF link state information to BGP.

   distribute bgp-ls [**instance-id** *id*] [**strict-link-checking**]

   By default, the device does not advertise OSPF link state information to BGP.

Setting OSPF timers

About setting OSPF timers

This task allows you to change OSPF packet timers to adjust the convergence speed and network load and tune the delay time for sending LSAs on low-speed links.

Configuring OSPF packet timers

About this task

An OSPF interface includes the following timers:

- **Hello timer**—Interval for sending hello packets. It must be identical on OSPF neighbors.
- **Poll timer**—Interval for sending hello packets to a neighbor that is down on the NBMA network.
- **Dead timer**—Interval within which if the interface does not receive any hello packet from the neighbor, it declares the neighbor is down.
- **LSA retransmission timer**—Interval within which if the interface does not receive any acknowledgment packets after sending an LSA to the neighbor, it retransmits the LSA.

Restrictions and guidelines

The default value for the hello interval and neighbor dead interval depends on the network type. When the network type for an interface is changed, the default hello interval and neighbor dead interval are restored. Make sure two neighboring interfaces are configured with the same hello interval and neighbor dead interval. Inconsistent settings will affect the OSPF neighbor relationship establishment.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the hello interval.

   ospf timer hello *seconds*

   The default hello interval on P2P and broadcast interfaces is 10 seconds. The default hello interval on P2MP and NBMA interfaces is 30 seconds.

4. Set the poll interval.

   ospf timer poll *seconds*

   The default setting is 120 seconds.

   The poll interval is a minimum of four times the hello interval.

5. Set the dead interval.

   ospf timer dead *seconds*

   The default dead interval on P2P and broadcast interfaces is 40 seconds. The default dead interval on P2MP and NBMA interfaces is 120 seconds.

   The dead interval must be a minimum of four times the hello interval on an interface.

6. Set the retransmission interval.

   ospf timer retransmit *interval*

   The default retransmission interval is 5 seconds.

A retransmission interval setting that is too small can cause unnecessary LSA retransmissions. Typically set a bigger interval than the round-trip time of a packet between two neighbors.

Setting LSA transmission delay

About this task

To avoid LSAs from aging out during transmission, set an LSA retransmission delay especially for low speed links.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Set the LSA transmission delay.

   `ospf trans-delay` *`seconds`*

   The default LSA transmission delay is 1 second.

Setting SPF calculation interval

About this task

LSDB changes result in SPF calculations. When the topology changes frequently, a large amount of network and router resources are occupied by SPF calculation. You can adjust the SPF calculation interval to reduce the impact.

For a stable network, the minimum interval is used. If network changes become frequent, the SPF calculation interval increases by the incremental interval × 2^{n-2} for each calculation until the maximum interval is reached. The value *n* is the number of calculation times.

Procedure

1. Enter system view.

   `system-view`

2. Enter OSPF view.

   `ospf` [*`process-id`* | **`router-id`** { **`auto-select`** | *`router-id`* } | **`vpn-instance`** *`vpn-instance-name`*] *

3. Set the SPF calculation interval.

   `spf-schedule-interval` { *`maximum-interval`* [*`minimum-interval`* [*`incremental-interval`*]] | **`millisecond`** *`interval`* }

   By default, the maximum interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Setting the minimum LSA arrival interval

About this task

OSPF drops any duplicate LSAs (with the same LSA type, LS ID, and router ID) within the minimum LSA arrival interval. This helps avoid overuse of bandwidth and router resources due to frequent network changes.

Procedure

1. Enter system view.

system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Set the minimum LSA arrival interval.

   lsa-arrival-interval *interval*

   By default, the minimum LSA arrival interval is 1000 milliseconds.

Setting the LSA generation interval

About this task

Adjust the LSA generation interval to protect network resources and routers from being overwhelmed by LSAs at the time of frequent network changes.

For a stable network, the minimum interval is used. If network changes become frequent, the LSA generation interval increases by the incremental interval × 2^{n-2} for each generation until the maximum interval is reached. The value *n* is the number of generation times.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Set the LSA generation interval.

   lsa-generation-interval *maximum-interval* [*minimum-interval* [*incremental-interval*]]

   By default, the maximum interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Setting OSPF exit overflow interval

About this task

When the number of LSAs in the LSDB exceeds the upper limit, the LSDB is in an overflow state. In this state, OSPF does not receive any external LSAs and deletes the external LSAs generated by itself to save system resources.

This task allows you to configure the interval that OSPF exits overflow state.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Set the interval that OSPF exits overflow state.

   lsdb-overflow-interval *interval*

   By default, the OSPF exit overflow interval is 300 seconds. An interval of 0 means that OSPF does not exit overflow state.

Configuring OSPF packet parameters

Disabling interfaces from receiving and sending OSPF packets

About this task

To enhance OSPF adaptability and reduce resource consumption, you can set an OSPF interface to "silent." A silent OSPF interface blocks OSPF packets and cannot establish any OSPF neighbor relationship. However, other interfaces on the router can still advertise direct routes of the interface in Router LSAs.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Disable interfaces from receiving and sending OSPF packets.

   silent-interface { *interface-type interface-number* | **all** }

   By default, an OSPF interface can receive and send OSPF packets.

   This command disables only the interfaces associated with the current process rather than other processes. Multiple OSPF processes can disable the same interface from receiving and sending OSPF packets.

Adding the interface MTU into DD packets

About this task

By default, an OSPF interface adds a value of 0 into the interface MTU field of a DD packet rather than the actual interface MTU. You can enable an interface to add its MTU into DD packets.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the interface to add its MTU into DD packets.

   ospf mtu-enable

   By default, the interface adds an MTU value of 0 into DD packets.

Setting the DSCP value for outgoing OSPF packets

About this task

The DSCP value specifies the precedence of outgoing packets.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Set the DSCP value for outgoing OSPF packets.

   dscp *dscp-value*

   By default, the DSCP value for outgoing OSPF packets is 48.

Setting the LSU transmit rate

About this task

During LSDB synchronization, if the local router has multiple neighbors, it must send many LSUs to each neighbor. When a neighbor receives excessive LSUs within a short time period, the following events might occur:

- The neighbor experiences degraded performance because it uses too many system resources to process the received LSU packets.
- The neighbor drops hello packets used for maintaining the neighbor relationship because it is busy dealing with the LSUs. As a result, the neighbor relationship is torn down. To reestablish a relationship to the neighbor, the local router must send more LSUs to the neighbor. This exacerbates the performance degradation.

This task allows you to limit the LSU transmit rate by setting the LSU transmit interval and the maximum number of LSUs that can be sent at each interval.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. (Optional.) Set the LSU transmit interval and the maximum number of LSUs that can be sent at each interval.

   transmit-pacing interval *interval* **count** *count*

   By default, an OSPF interface sends a maximum of three LSU packets every 20 milliseconds.

Controlling LSA generation, advertisement, and reception

Setting the maximum number of external LSAs in LSDB

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Set the maximum number of external LSAs in the LSDB.

   lsdb-overflow-limit *number*

   By default, the maximum number of external LSAs in the LSDB is not limited.

Filtering outbound LSAs on an interface

About this task

To reduce the LSDB size for the neighbor and save bandwidth, you can perform this task on an interface to filter LSAs to be sent to the neighbor.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Filter outbound LSAs on the interface.

   ospf database-filter { **all** | { **ase** [**acl** *ipv4-acl-number*] | **nssa** [**acl** *ipv4-acl-number*] | **summary** [**acl** *ipv4-acl-number*] } * }

   By default, the outbound LSAs are not filtered on the interface.

Filtering LSAs for the specified neighbor

About this task

On a P2MP network, a router might have multiple P2MP type OSPF neighbors. Perform this task to prevent the router from sending LSAs to the specified P2MP neighbor.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Filter LSAs for the specified P2MP neighbor.

   database-filter peer *ip-address* { **all** | { **ase** [**acl** *ipv4-acl-number*] | **nssa** [**acl** *ipv4-acl-number*] | **summary** [**acl** *ipv4-acl-number*] } * }

   By default, the LSAs for the specified P2MP neighbor are not filtered.

Accelerating OSPF convergence speed

Enabling OSPF ISPF

About this task

When the topology changes, Incremental Shortest Path First (ISPF) computes only the affected part of the SPT, instead of the entire SPT.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enable OSPF ISPF.

   ispf enable

   By default, OSPF ISPF is enabled.

Configuring prefix suppression

About this task

By default, an OSPF interface advertises all of its prefixes in LSAs. To speed up OSPF convergence, you can suppress interfaces from advertising all of their prefixes. This feature helps improve network security by preventing IP routing to the suppressed networks.

When prefix suppression is enabled:

- On P2P and P2MP networks, OSPF does not advertise Type-3 links in Type-1 LSAs. Other routing information can still be advertised to ensure traffic forwarding.
- On broadcast and NBMA networks, the DR generates Type-2 LSAs with a mask length of 32 to suppress network routes. Other routing information can still be advertised to ensure traffic forwarding. If no neighbors exist, the DR does not advertise Type-3 links in Type-1 LSAs.

Restrictions and guidelines for prefix suppression

As a best practice, configure prefix suppression on all OSPF routers if you want to use prefix suppression.

Configuring prefix suppression for an OSPF process

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enable prefix suppression for the OSPF process.

   prefix-suppression

   By default, prefix suppression is disabled for an OSPF process.

   This feature does not suppress the prefixes of secondary IP addresses, loopback interfaces, and passive interfaces.

Configuring prefix suppression for an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable prefix suppression for the interface.

   ospf prefix-suppression [**disable**]

   By default, prefix suppression is disabled on an interface.

   This feature does not suppress prefixes of secondary IP addresses.

Configuring prefix prioritization

About this task

This feature enables the device to install prefixes in descending priority order: critical, high, medium, and low. The prefix priorities are assigned through routing policies. When a route is assigned multiple prefix priorities, the route uses the highest priority.

By default, the 32-bit OSPF host routes have a medium priority and other routes have a low priority.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enable prefix prioritization.

   prefix-priority route-policy *route-policy-name*

   By default, prefix prioritization is disabled.

Configuring OSPF PIC

About this task

Prefix Independent Convergence (PIC) enables the device to speed up network convergence by ignoring the number of prefixes.

Restrictions and guidelines for OSPF PIC

When both OSPF PIC and OSPF FRR are configured, OSPF FRR takes effect.

OSPF PIC applies only to inter-area routes and external routes.

Enabling OSPF PIC

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enable PIC for OSPF.

   pic [**additional-path-always**]

   By default, OSPF PIC is enabled.

Configuring BFD control packet mode for OSPF PIC

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable BFD control packet mode for OSPF PIC.

   ospf primary-path-detect bfd ctrl

   By default, BFD control packet mode is disabled for OSPF PIC.

   This mode requires BFD configuration on both OSPF routers on the link.

Configuring BFD echo packet mode for OSPF PIC

1. Enter system view.

   system-view

2. Configure the source IP address of BFD echo packets.

   bfd echo-source-ip *ip-address*

   By default, the source IP address of BFD echo packets is not configured.

   The source IP address cannot be on the same network segment as any local interfaces.

   For more information about this command, see BFD commands in *Network Management and Monitoring Command Reference*.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable BFD echo packet mode for OSPF PIC.

   ospf primary-path-detect bfd echo

   By default, BFD echo packet mode is disabled for OSPF PIC.

   This mode requires BFD configuration on one OSPF router on the link.

Configuring advanced OSPF features

Configuring stub routers

About this task

A stub router is used for traffic control. It reports its status as a stub router to neighboring OSPF routers. The neighboring routers can have a route to the stub router, but they do not use the stub router to forward data.

Router LSAs from the stub router might contain different link type values. A value of 3 means a link to a stub network, and the cost of the link will not be changed by default. To set the cost of the link to 65535, specify the **include-stub** keyword in the **stub-router** command. A value of 1, 2 or 4 means a point-to-point link, a link to a transit network, or a virtual link. On such links, a maximum cost value of 65535 is used. Neighbors do not send packets to the stub router as long as they have a route with a smaller cost.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Configure the router as a stub router.

   stub-router [**external-lsa** [*max-metric-value*] | **include-stub** | **on-startup** { *seconds* | **wait-for-bgp** [*seconds*] } | **summary-lsa** [*max-metric-value*]] *

   By default, the router is not configured as a stub router.

   A stub router is not related to a stub area.

Enabling compatibility with RFC 1583

About this task

RFC 1583 specifies a different method than RFC 2328 for selecting the optimal route to a destination in another AS. When multiple routes are available to the ASBR, OSPF selects the optimal route by using the following procedure:

1. Selects the route with the highest preference.
   - If RFC 2328 is compatible with RFC 1583, all these routes have equal preference.
   - If RFC 2328 is not compatible with RFC 1583, the intra-area route in a non-backbone area is preferred to reduce the burden of the backbone area. The inter-area route and intra-area route in the backbone area have equal preference.
2. Selects the route with the lower cost if two routes have equal preference.
3. Selects the route with the larger originating area ID if two routes have equal cost.

Restrictions and guidelines

To avoid routing loops, set identical RFC 1583-compatibility on all routers in a routing domain.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enable compatibility with RFC 1583.

   rfc1583 compatible

   By default, compatibility with RFC 1583 is enabled.

Enabling OSPF to group ECMP routes

About this task

Perform this task to enable OSPF to group ECMP routes by prefix to speed up route convergence.

This feature is applicable to a network when the network has a large number of ECMP routes and different route prefixes in the network have the same next hops. For example, OSPF learns 10000 route prefixes and all route prefixes have the same 16 next hops (1.1.1.1 to 1.1.1.16). Without this feature, OSPF has to send all ECMP routes of every route prefix (10000 × 16 routes) to the route management module. After you enable this feature, OSPF groups the ECMP routes by prefix and sends the route groups (10000 route groups) to the route management module.

Restrictions and guidelines

If the output interfaces to the next hops of ECMP routes are TE tunnel interfaces, OSPF groups the ECMP routes regardless of whether you enable this feature or not.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enable OSPF to group ECMP routes.

ecmp-group enable

By default, OSPF does not group ECMP routes.

Configuring OSPF GR

About OSPF GR

GR ensures forwarding continuity when a routing protocol restarts or an active/standby switchover occurs.

Two routers are required to complete a GR process. The following are router roles in a GR process:

- **GR restarter**—Graceful restarting router. It must have GR capability.
- **GR helper**—A neighbor of the GR restarter. It helps the GR restarter to complete the GR process.

OSPF GR has the following types:

- **IETF GR**—Uses Opaque LSAs to implement GR.
- **Non-IETF GR**—Uses link local signaling (LLS) to advertise GR capability and uses out of band synchronization to synchronize the LSDB.

A device can act as a GR restarter and GR helper at the same time.

Restrictions and guidelines for OSPF GR

You cannot enable OSPF NSR on a device that acts as GR restarter.

Configuring OSPF GR restarter

Configuring the IETF OSPF GR restarter

1. Enter system view.

   system-view

2. Enable OSPF and enter its view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enable opaque LSA reception and advertisement capability.

   opaque-capability enable

   By default, opaque LSA reception and advertisement capability is enabled.

4. Enable the IETF GR.

   graceful-restart ietf [**global** | **planned-only**] *

   By default, the IETF GR capability is disabled.

5. (Optional.) Set the GR interval.

   graceful-restart interval *interval*

   By default, the GR interval is 120 seconds.

Configuring the non-IETF OSPF GR restarter

1. Enter system view.

   system-view

2. Enable OSPF and enter its view.

```
ospf [ process-id | router-id { auto-select | router-id } |
vpn-instance vpn-instance-name ] *
```

3. Enable the link-local signaling capability.

   ```
   enable link-local-signaling
   ```

   By default, the link-local signaling capability is disabled.

4. Enable the out-of-band re-synchronization capability.

   ```
   enable out-of-band-resynchronization
   ```

   By default, the out-of-band re-synchronization capability is disabled.

5. Enable non-IETF GR.

   ```
   graceful-restart [ nonstandard ] [ global | planned-only ] *
   ```

   By default, non-IETF GR capability is disabled.

6. (Optional.) Set the GR interval.

   ```
   graceful-restart interval interval
   ```

   By default, the GR interval is 120 seconds.

Configuring OSPF GR helper

Configuring the IETF OSPF GR helper

1. Enter system view.

   ```
   system-view
   ```

2. Enable OSPF and enter its view.

   ```
   ospf [ process-id | router-id { auto-select | router-id } |
   vpn-instance vpn-instance-name ] *
   ```

3. Enable opaque LSA reception and advertisement capability.

   ```
   opaque-capability enable
   ```

   By default, opaque LSA reception and advertisement capability is enabled.

4. Enable GR helper capability.

   ```
   graceful-restart helper enable [ planned-only ]
   ```

   By default, GR helper capability is enabled.

5. (Optional.) Enable strict LSA checking for the GR helper.

   ```
   graceful-restart helper strict-lsa-checking
   ```

   By default, strict LSA checking for the GR helper is disabled.

   When an LSA change on the GR helper is detected, the GR helper device exits the GR helper mode.

Configuring the non-IETF OSPF GR helper

1. Enter system view.

   ```
   system-view
   ```

2. Enable OSPF and enter its view.

   ```
   ospf [ process-id | router-id { auto-select | router-id } |
   vpn-instance vpn-instance-name ] *
   ```

3. Enable the link-local signaling capability.

   ```
   enable link-local-signaling
   ```

   By default, the link-local signaling capability is disabled.

4. Enable the out-of-band re-synchronization capability.

enable out-of-band-resynchronization

By default, the out-of-band re-synchronization capability is disabled.

5. Enable GR helper.

   graceful-restart helper enable

   By default, GR helper is enabled.

6. (Optional.) Enable strict LSA checking for the GR helper.

   graceful-restart helper strict-lsa-checking

   By default, strict LSA checking for the GR helper is disabled.

   When an LSA change on the GR helper is detected, the GR helper device exits the GR helper mode.

Triggering OSPF GR

About this task

You can trigger OSPF GR by performing an active/standby switchover or using the **reset ospf process** command.

Procedure

To trigger OSPF GR, execute the **reset ospf** [*process-id*] **process graceful-restart** command in user view.

Configuring OSPF NSR

About this task

Nonstop routing (NSR) backs up OSPF link state information from the active process to the standby process. After an active/standby switchover, NSR can complete link state recovery and route regeneration without tearing down adjacencies or impacting forwarding services.

NSR does not require the cooperation of neighboring devices to recover routing information, and it is typically used more often than GR.

Restrictions and guidelines

A device that has OSPF NSR enabled cannot act as GR restarter.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enable OSPF NSR.

   non-stop-routing

   By default, OSPF NSR is disabled.

   This command takes effect only for the current process. As a best practice, enable OSPF NSR for each process if multiple OSPF processes exist.

Configuring BFD for OSPF

About BFD for OSPF

BFD provides a single mechanism to quickly detect and monitor the connectivity of links between OSPF neighbors, which improves the network convergence speed.For more information about BFD, see *Network Management and Monitoring Configuration Guide*.

OSPF supports the following BFD detection modes:

- **Bidirectional control detection**—Requires BFD configuration to be made on both OSPF routers on the link.
- **Single-hop echo detection**—Requires BFD configuration to be made on one OSPF router on the link.

Configuring bidirectional control detection

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable BFD bidirectional control detection.
   ospf bfd enable

   By default, BFD bidirectional control detection is disabled.

   Both ends of a BFD session must be on the same network segment and in the same area.

Configuring single-hop echo detection

1. Enter system view.
   system-view
2. Configure the source address of echo packets.
   bfd echo-source-ip *ip-address*

   By default, the source address of echo packets is not configured.

   The source IP address cannot be on the same network segment as any local interfaces.

   For more information about this command, see BFD commands in *Network Management and Monitoring Command Reference*.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable BFD single-hop echo detection.
   ospf bfd enable echo

   By default, BFD single-hop echo detection is disabled.

Configuring OSPF FRR

About OSPF FRR

OSPF Fast Reroute (FRR) calculates a backup path based on the LSDB or specifies a backup path by using a routing policy. Then, it saves the backup path information to the FIB. When the primary path fails, the system immediately switches traffic to the backup path to prevent traffic loss and reduce the route convergence time.

OSPF supports only Loop Free Alternate (LFA) FRR.

The following OSPF FRR traffic protection types are available:

- **Link protection**—Protects traffic that traverses a specific link.
- **Node protection**—Protects traffic that traverses a specific node.

Node protection takes precedence over link protection.

Restrictions and guidelines for OSPF FRR

If both OSPF FRR and PIC are configured, OSPF FRR takes effect.

OSPF FRR tasks at a glance

To configure OSPF FRR, perform the following tasks:

1. Configuring an OSPF backup path

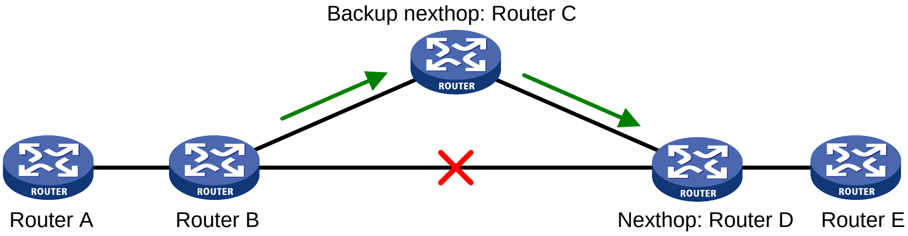
   Perform a minimum of one task.
   - Configuring OSPF LFA FRR
   - Configuring OSPF FRR to use a backup next hop specified in a routing policy
2. (Optional.) Setting the priority for FRR backup path selection policies
3. (Optional.) Configuring BFD for OSPF FRR
   - Configuring BFD control packet mode for OSPF FRR
   - Configuring BFD echo packet mode for OSPF FRR

Configuring OSPF LFA FRR

About this task

A link or router failure on a path can cause packet loss until OSPF completes routing convergence based on the new network topology. FRR enables fast rerouting to minimize the impact of link or node failures.

Figure 9 Network diagram for OSPF FRR



As shown in Figure 9, configure FRR on Router B by using a routing policy to specify a backup next hop. When the primary link fails, OSPF directs packets to the backup next hop. At the same time, OSPF calculates the shortest path based on the new network topology. It forwards packets over the path after network convergence.

You can configure OSPF FRR to calculate a backup next hop by using the loop free alternate (LFA) algorithm, or specify a backup next hop by using a routing policy.

Restrictions and guidelines for OSPF FRR

Do not use the **fast-reroute lfa** command together with the **vlink-peer** command.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. (Optional.) Enable LFA on an interface.

   ospf fast-reroute lfa-backup

   By default, the interface is enabled with LFA and it can be selected as a backup interface.
4. Return to system view.

   quit
5. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *
6. Enable OSPF FRR to use the LFA algorithm to calculate a backup next hop.

   fast-reroute lfa [**abr-only**]

   By default, OSPF FRR is disabled.

   If **abr-only** is specified, only the route to the ABR is selected as the backup path.

Configuring OSPF FRR to use a backup next hop specified in a routing policy

About this task

Before you perform this task, use the **apply fast-reroute backup-interface** command to specify a backup next hop in a routing policy for OSPF FRR. For more information about the **apply fast-reroute backup-interface** command and routing policy configuration, see "Configuring routing policies."

Procedure

1. Enter system view.

   system-view
2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *
3. Enable OSPF FRR to use a backup next hop specified in a routing policy.

   fast-reroute route-policy *route-policy-name*

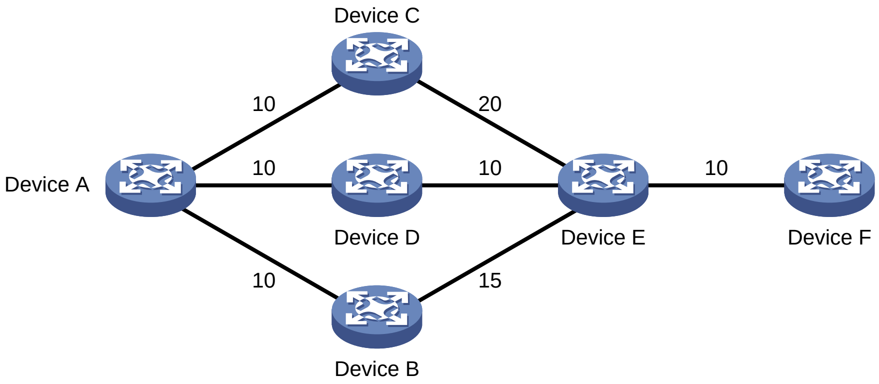
   By default, OSPF FRR is disabled.

Setting the priority for FRR backup path selection policies

About this task

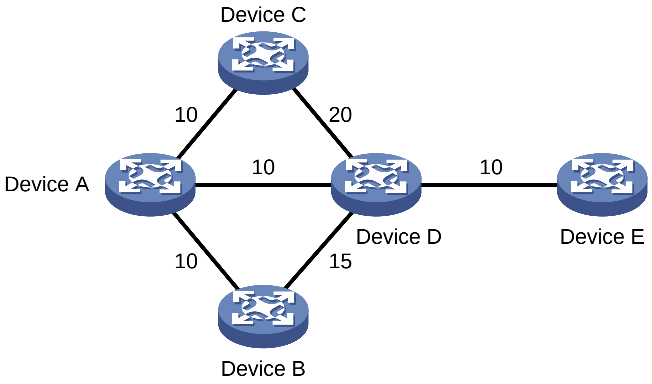
By default, OSPF uses the node-protection policy to select the backup path. As shown in Figure 10, traffic forwarding path **Device A->Device D->Device E->Device F** has two backup paths: **Device A->Device C->Device E->Device F** and **Device A->Device B->Device E->Device F**. Because Device C has higher forwarding capability than Device B, OSPF prefers backup path **Device A->Device C->Device E->Device F**.

Figure 10 Node-protection backup path selection



To apply the lowest-cost policy that is more applicable in certain networks, perform this task to set a higher priority for it than the node-protection policy. As shown in Figure 11, traffic forwarding path **Device A->Device D->Device E** has two backup paths: **Device A->Device C->Device D->Device E** and **Device A->Device B->Device D->Device E**. By default, OSPF selects backup path **Device A->Device C->Device D->Device E** according to the node-protection policy. For OSPF to select backup path **Device A->Device B->Device D->Device E**, set a higher priority for the lowest-cost policy than the node-protection policy.

Figure 11 Lowest-cost backup path selection



Restrictions and guidelines

If the node-protection policy has the higher priority but the backup path calculation still fails, OSPF uses the lowest-cost policy for further calculation.

If the lowest-cost policy has the higher priority but the backup path calculation still fails, OSPF does not perform further backup path calculation.

Procedure

1. Enter system view.

system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Set the priority for the node-protection or lowest-cost backup path selection policy.

   fast-reroute tiebreaker { **lowest-cost** | **node-protecting** } **preference** *preference*

   By default, the priority values of the node-protection and lowest-cost backup path selection policies are 40 and 20, respectively.

Configuring BFD control packet mode for OSPF FRR

About this task

By default, OSPF FRR does not use BFD to detect primary link failures. To speed up OSPF convergence, enable BFD control packet mode for OSPF FRR to detect primary link failures. This mode requires BFD configuration on both OSPF routers on the link.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable BFD control packet mode for OSPF FRR.

   ospf primary-path-detect bfd ctrl

   By default, BFD control packet mode is disabled for OSPF FRR.

Configuring BFD echo packet mode for OSPF FRR

About this task

By default, OSPF FRR does not use BFD to detect primary link failures. To speed up OSPF convergence, enable BFD echo packet mode for OSPF FRR to detect primary link failures. This mode requires BFD configuration on one OSPF router on the link.

Procedure

1. Enter system view.

   system-view

2. Configure the source IP address of BFD echo packets.

   bfd echo-source-ip *ip-address*

   By default, the source IP address of BFD echo packets is not configured.

   The source IP address cannot be on the same network segment as any local interfaces.

   For more information about this command, see BFD commands in *Network Management and Monitoring Command Reference*.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable BFD echo packet mode for OSPF FRR.

   ospf primary-path-detect bfd echo

   By default, BFD echo packet mode is disabled for OSPF FRR.

Configuring OSPF authentication

About OSPF area and interface authentication

Perform this task to configure OSPF area and interface authentication.

OSPF adds the configured key into sent packets, and uses the key to authenticate received packets. Only packets that pass the authentication can be received. If a packet fails the authentication, the OSPF neighbor relationship cannot be established.

If you configure OSPF authentication for both an area and an interface in that area, the interface uses the OSPF authentication configured on it.

Configuring OSPF area authentication

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enter area view.

   area *area-id*

4. Configure area authentication mode.
   - Configure HMAC-MD5/MD5 authentication.

     authentication-mode { **hmac-md5** | **hmac-sha-256** | **md5** } *key-id* { **cipher** | **plain** } *string*
   - Configure simple authentication.

     authentication-mode simple { **cipher** | **plain** } *string*
   - Configure keychain authentication.

     authentication-mode keychain *keychain-name*

     For more information about keychains, see keychain configuration in *Security Configuration Guide*.

   By default, no authentication is configured.

   You must configure the same authentication mode and key on all the routers in an area.

Configuring OSPF interface authentication

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure interface authentication mode.
   - Configure simple authentication.

     ospf authentication-mode simple { **cipher** | **plain** } *string*
   - Configure HMAC-MD5/MD5 authentication.

     ospf authentication-mode { **hmac-md5** | **hmac-sha-256** | **md5** } *key-id* { **cipher** | **plain** } *string*

- Configure keychain authentication.

  ospf authentication-mode keychain *keychain-name*

  For information about keychains, see *Security Configuration Guide*.

By default, no authentication is configured.

You must configure the same authentication mode and key on both the local interface and its peer interface.

Configuring GTSM for OSPF

About GTSM

The Generalized TTL Security Mechanism (GTSM) protects the device by comparing the TTL value in the IP header of incoming OSPF packets against a valid TTL range. If the TTL value is within the valid TTL range, the packet is accepted. If not, the packet is discarded.

The valid TTL range is from 255 – the configured hop count + 1 to 255.

When GTSM is configured, the OSPF packets sent by the device have a TTL of 255.

Restrictions and guidelines for GTSM

To use GTSM, you must configure GTSM on both the local and peer devices. You can specify different *hop-count* values for them.

The configuration in OSPF area view applies to all OSPF interfaces in the area. The configuration in interface view takes precedence over the configuration in OSPF area view.

Configuring GTSM in OSPF area view

1. Enter system view.

   system-view
2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *
3. Enter OSPF area view.

   area *area-id*
4. Enable GTSM for the OSPF area.

   ttl-security [**hops** *hop-count*]

   By default, GTSM is disabled for the OSPF area.

Configuring GTSM in interface view

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure GTSM for the interface.
   - Enable GTSM for the interface.

     ospf ttl-security [**hops** *hop-count*]

- Disable GTSM for the interface.

  ospf ttl-security disable

  Disable GTSM for an interface when the following conditions exist:

  - The area to which the interface belongs is enabled with GTSM.
  - The neighbor of the interface does not support GTSM.

By default, an interface uses the GTSM configuration of the area to which the interface belongs.

Configuring OSPF logging and SNMP notifications

Logging neighbor state changes

About this task

Perform this task to enable output of neighbor state change logs to the information center. The information center processes the logs according to user-defined output rules (whether and where to output logs). For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Enable the logging of neighbor state changes.

   log-peer-change

   By default, this feature of logging neighbor state changes is enabled.

Configuring the OSPF logging feature

About this task

OSPF logs include LSA aging logs, route calculation logs, neighbor logs, OSPF route logs, and self-originated and received LSA logs.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

3. Set the number of OSPF logs.

   event-log { **hello** { **received** [**abnormal** | **dropped**] | **sent** [**abnormal** | **failed**] } | **lsa-flush** | **peer** | **spf** } **size** *count*

   By default, the device can generate a maximum of 100 OSPF logs for each type.

Configuring OSPF network management

About this task

This task involves the following configurations:

- Bind an OSPF process to MIB so that you can use network management software to manage the specified OSPF process.
- Enable SNMP notifications for OSPF to report important events.
- Configure the SNMP notification output interval and the maximum number of SNMP notifications that can be output at each interval.

To report critical OSPF events to an NMS, enable SNMP notifications for OSPF. For SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.

   system-view

2. Bind MIB to an OSPF process.

   ospf mib-binding *process-id*

   By default, MIB is bound to the process with the smallest process ID.

3. Enable SNMP notifications for OSPF.

   snmp-agent trap enable ospf [**authentication-failure** | **bad-packet** | **config-error** | **grhelper-status-change** | **grrestarter-status-change** | **if-state-change** | **lsa-maxage** | **lsa-originate** | **lsdb-approaching-overflow** | **lsdb-overflow** | **neighbor-state-change** | **nssatranslator-status-change** | **retransmit** | **virt-authentication-failure** | **virt-bad-packet** | **virt-config-error** | **virt-retransmit** | **virtgrhelper-status-change** | **virtif-state-change** | **virtneighbor-state-change**] *

   By default, SNMP notifications for OSPF are enabled.

4. Enter OSPF view.

   ospf [*process-id* | **router-id** { **auto-select** | *router-id* } | **vpn-instance** *vpn-instance-name*] *

5. Configure the SNMP notification output interval and the maximum number of SNMP notifications that can be output at each interval.

   snmp trap rate-limit interval *trap-interval* **count** *trap-number*

   By default, OSPF outputs a maximum of seven SNMP notifications within 10 seconds.

Display and maintenance commands for OSPF

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display summary route information on the OSPF ABR.	**display ospf** [*process-id*] [**area** *area-id*] **abr-summary** [*ip-address* { *mask-length* | *mask* }] [**verbose**]
Display OSPF FRR backup next hop information.	**display ospf** [*process-id*] [**area** *area-id*] **fast-reroute lfa-candidate**

Task	Command
Display OSPF SPF information.	**display ospf** [*process-id*] [**area** *area-id*] **spf-tree** [**verbose**]
Display OSPF process information.	**display ospf** [*process-id*] [**verbose**]
Display OSPF ABR and ASBR information.	**display ospf** [*process-id*] **abr-asbr** [**verbose**]
Display OSPF ASBR route summarization information.	**display ospf** [*process-id*] **asbr-summary** [*ip-address* { *mask-length* | *mask* }]
Display OSPF log information.	**display ospf** [*process-id*] **event-log** { **lsa-flush** | **peer** [*neighbor-id*] [**slot** *slot-number*] | **spf** }
Display OSPF log information about received or sent hello packets.	display ospf [process-id] event-log **hello** { **received** [**abnormal** | **dropped**] | **sent** } [*neighbor-id*] [**slot** *slot-number*] **display ospf** [*process-id*] **event-log hello sent** { **abnormal** | **failed** } [*neighbor-address*] [**slot** *slot-number*]
Display OSPF GR information.	**display ospf** [*process-id*] **graceful-restart** [**verbose**]
Display the router ID-to-host name mapping table.	**display ospf** [*process-id*] **hostname-table**
Display OSPF interface information.	**display ospf** [*process-id*] **interface** [*interface-type interface-number* | **verbose**]
Display information about hello packets sent by OSPF interfaces.	**display ospf** [*process-id*] **interface** [*interface-type interface-number*] **hello**
Display OSPF LSDB information.	**display ospf** [*process-id*] [**area** *area-id*] **lsdb** { **asbr** | **network** | **nssa** | **opaque-link** | **router** | **summary** } [*link-state-id*] [**originate-router** *advertising-router-id* | **self-originate**] [**age** { **max-value** *max-age-value* | **min-value** *min-age-value* } *] [**resolve-hostname**] **display ospf** [*process-id*] [**area** *area-id*] **lsdb** { **asbr** | **network** | **nssa** | **opaque-link** | **router** | **summary** } [*link-state-id*] **hostname** *host-name* [**age** { **max-value** *max-age-value* | **min-value** *min-age-value* } *] **display ospf** [*process-id*] **lsdb** [**brief** | **originate-router** *advertising-router-id* | **self-originate**] [**age** { **max-value** *max-age-value* | **min-value** *min-age-value* } *] [**resolve-hostname**] **display ospf** [*process-id*] **lsdb hostname** *host-name* [**age** { **max-value** *max-age-value* | **min-value** *min-age-value* } *] **display ospf** [*process-id*] **lsdb** { **ase** | **opaque-as** } [*link-state-id*] [**originate-router** *advertising-router-id* |

Task	Command
	self-originate] [**age** { **max-value** *max-age-value* | **min-value** *min-age-value* } *] [**resolve-hostname**] **display ospf** [*process-id*] **lsdb** { **ase** | **opaque-as** } [*link-state-id*] **hostname** *host-name* [**age** { **max-value** *max-age-value* | **min-value** *min-age-value* } *]
Display OSPF next hop information.	**display ospf** [*process-id*] **nexthop**
Display OSPF NSR information.	**display ospf** [*process-id*] **non-stop-routing status**
Display OSPF neighbor information.	**display ospf** [*process-id*] **peer** [**hello** | **verbose**] [*interface-type interface-number*] [[*neighbor-id*] [**resolve-hostname**] | **hostname** *host-name*]
Display neighbor statistics for OSPF areas.	**display ospf** [*process-id*] **peer statistics**
Display OSPF request queue information.	**display ospf** [*process-id*] **request-queue** [*interface-type interface-number*] [*neighbor-id*]
Display OSPF retransmission queue information.	**display ospf** [*process-id*] **retrans-queue** [*interface-type interface-number*] [*neighbor-id*]
Display OSPF routing table information.	**display ospf** [*process-id*] **routing** [*ip-address* { *mask-length* | *mask* }] [**interface** *interface-type interface-number*] [**nexthop** *nexthop-address*] [**verbose**]
Display OSPF statistics.	**display ospf** [*process-id*] **statistics** [**error** | **packet** [**hello** | *interface-type interface-number*]]
Display OSPF virtual link information.	**display ospf** [*process-id*] **vlink**
Display the global route ID.	**display router id**
Clear OSPF log information.	**reset ospf** [*process-id*] **event-log** [**lsa-flush** | **peer** [**slot** slot-number] | **spf**]
Clear OSPF log information about received or sent hello packets.	**reset ospf** [*process-id*] **event-log hello** { **received** [**abnormal** | **dropped**] | **sent** [**abnormal** | **failed**] } [**slot** *slot-number*]
Restart an OSPF process.	**reset ospf** [*process-id*] **process** [**graceful-restart**]
Re-enable OSPF route redistribution.	**reset ospf** [*process-id*] **redistribution**
Clear OSPF statistics.	**reset ospf** [*process-id*] **statistics**

OSPF configuration examples

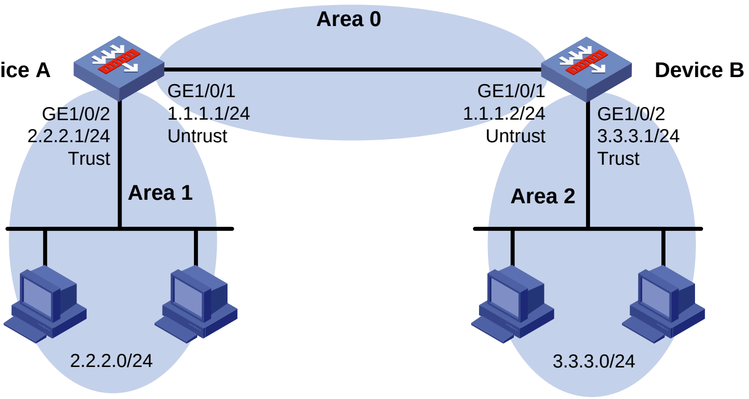
Example: Configuring basic OSPF

Network configuration

As shown in Figure 12:

- Enable OSPF on all devices, and split the AS into three areas.
- Configure Device A and Device B as ABRs.

Figure 12 Network diagram



Procedure

# Configure Device A.

1. Configure IP addresses for interfaces correctly according to Figure 12.
   a. Configure an IP address for GigabitEthernet 1/0/1.
```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 1.1.1.1 255.255.255.0
[DeviceA-GigabitEthernet1/0/1] quit
```
   b. Configure IP addresses for other interfaces in the same way GigabitEthernet 1/0/1 is configured. (Details not shown.)
2. Add each interface on Device A to a security zone.
```
[DeviceA] security-zone name untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] quit
[DeviceA] security-zone name trust
[DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceA-security-zone-Trust] quit
```
3. Configure security policies.
   a. Configure a security policy to allow OSPF neighbor relationship establishment by permitting traffic between security zone **untrust** and security zone **local**.

   # Create security policy rule **ospflocalin** and permit Device A to receive OSPF packets from Device B.
```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name ospflocalin
[DeviceA-security-policy-ip-0-ospflocalin] source-zone untrust
```

```
[DeviceA-security-policy-ip-0-ospflocalin] destination-zone local
[DeviceA-security-policy-ip-0-ospflocalin] service ospf
[DeviceA-security-policy-ip-0-ospflocalin] action pass
[DeviceA-security-policy-ip-0-ospflocalin] quit
```

# Create security policy rule **ospflocalout** and permit Device A to send OSPF packets to Device B.

```
[DeviceA-security-policy-ip] rule name ospflocalout
[DeviceA-security-policy-ip-1-ospflocalout] source-zone local
[DeviceA-security-policy-ip-1-ospflocalout] destination-zone untrust
[DeviceA-security-policy-ip-1-ospflocalout] service ospf
[DeviceA-security-policy-ip-1-ospflocalout] action pass
[DeviceA-security-policy-ip-1-ospflocalout] quit
```

b. Configure a security policy to permit traffic between security zone **untrust** and security zone **trust**.

# Create security policy rule **trust-untrust** and permit packets from security zone **trust** to security zone **untrust** to pass.

```
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-2-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-2-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-2-trust-untrust] source-ip-subnet 2.2.2.0 24
[DeviceA-security-policy-ip-2-trust-untrust] destination-ip-subnet 3.3.3.0 24
[DeviceA-security-policy-ip-2-trust-untrust] action pass
[DeviceA-security-policy-ip-2-trust-untrust] quit
```

# Create security policy rule **untrust-trust** and permit packets from security zone **untrust** to security zone **trust** to pass.

```
[DeviceA-security-policy-ip] rule name untrust-trust
[DeviceA-security-policy-ip-3-untrust-trust] source-zone untrust
[DeviceA-security-policy-ip-3-untrust-trust] destination-zone trust
[DeviceA-security-policy-ip-3-untrust-trust] source-ip-subnet 3.3.3.0 24
[DeviceA-security-policy-ip-3-untrust-trust] destination-ip-subnet 2.2.2.0 24
[DeviceA-security-policy-ip-3-untrust-trust] action pass
[DeviceA-security-policy-ip-3-untrust-trust] quit
[DeviceA-security-policy-ip] quit
```

4. Enable basic OSPF functions.

```
[DeviceA] router id 2.2.2.1
[DeviceA] ospf
[DeviceA-ospf-1] area 0
[DeviceA-ospf-1-area-0.0.0.0] network 1.1.1.0 0.0.0.255
[DeviceA-ospf-1-area-0.0.0.0] quit
[DeviceA-ospf-1] area 1
[DeviceA-ospf-1-area-0.0.0.1] network 2.2.2.0 0.0.0.255
[DeviceA-ospf-1-area-0.0.0.1] quit
[DeviceA-ospf-1] quit
```

# Configure Device B.

1. Configure IP addresses for interfaces correctly according to Figure 12.

a. Configure an IP address for GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
```

```
[DeviceB-GigabitEthernet1/0/1] ip address 1.1.1.2 255.255.255.0
[DeviceB-GigabitEthernet1/0/1] quit
```

   b. Configure IP addresses for other interfaces in the same way GigabitEthernet 1/0/1 is configured. (Details not shown.)

2. Add each interface on Device B to a security zone.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

3. Configure security policies.

   a. Configure a security policy to allow OSPF neighbor relationship establishment by permitting traffic between security zone **untrust** and security zone **local**.

   # Create security policy rule **ospflocalin** and permit Device B to receive OSPF packets from Device A.

```
[DeviceB] security-policy ip
[DeviceB-security-policy-ip] rule name ospflocalin
[DeviceB-security-policy-ip-0-ospflocalin] source-zone untrust
[DeviceB-security-policy-ip-0-ospflocalin] destination-zone local
[DeviceB-security-policy-ip-0-ospflocalin] service ospf
[DeviceB-security-policy-ip-0-ospflocalin] action pass
[DeviceB-security-policy-ip-0-ospflocalin] quit
```

   # Create security policy rule **ospflocalout** and permit Device B to send OSPF packets to Device A.

```
[DeviceB-security-policy-ip] rule name ospflocalout
[DeviceB-security-policy-ip-1-ospflocalout] source-zone local
[DeviceB-security-policy-ip-1-ospflocalout] destination-zone untrust
[DeviceB-security-policy-ip-1-ospflocalout] service ospf
[DeviceB-security-policy-ip-1-ospflocalout] action pass
[DeviceB-security-policy-ip-1-ospflocalout] quit
```

   b. Configure a security policy to permit traffic between security zone **untrust** and security zone **trust**.

   # Create security policy rule **trust-untrust** and permit packets from security zone **trust** to security zone **untrust** to pass.

```
[DeviceB-security-policy-ip] rule name trust-untrust
[DeviceB-security-policy-ip-2-trust-untrust] source-zone trust
[DeviceB-security-policy-ip-2-trust-untrust] destination-zone untrust
[DeviceB-security-policy-ip-2-trust-untrust] source-ip-subnet 3.3.3.0 24
[DeviceB-security-policy-ip-2-trust-untrust] destination-ip-subnet 2.2.2.0 24
[DeviceB-security-policy-ip-2-trust-untrust] action pass
[DeviceB-security-policy-ip-2-trust-untrust] quit
```

   # Create security policy rule **untrust-trust** and permit packets from security zone **untrust** to security zone **trust** to pass.

```
[DeviceB-security-policy-ip] rule name untrust-trust
[DeviceB-security-policy-ip-3-untrust-trust] source-zone untrust
[DeviceB-security-policy-ip-3-untrust-trust] destination-zone trust
[DeviceB-security-policy-ip-3-untrust-trust] source-ip-subnet 2.2.2.0 24
[DeviceB-security-policy-ip-3-untrust-trust] destination-ip-subnet 3.3.3.0 24
```

```
   [DeviceB-security-policy-ip-3-untrust-trust] action pass
   [DeviceB-security-policy-ip-3-untrust-trust] quit
   [DeviceB-security-policy-ip] quit
```

4. Enable basic OSPF functions.

```
[DeviceB] router id 3.3.3.1
[DeviceB] ospf
[DeviceB-ospf-1] area 0
[DeviceB-ospf-1-area-0.0.0.0] network 1.1.1.0 0.0.0.255
[DeviceB-ospf-1-area-0.0.0.0] quit
[DeviceB-ospf-1] area 2
[DeviceB-ospf-1-area-0.0.0.2] network 3.3.3.0 0.0.0.255
[DeviceB-ospf-1-area-0.0.0.2] quit
[DeviceB-ospf-1] quit
```

Verifying the configuration

# View detailed information about OSPF neighbors on Device A.

```
[DeviceA] display ospf peer verbose

         OSPF Process 1 with Router ID 2.2.2.1
                 Neighbors

 Area 0.0.0.0 interface 1.1.1.1(GigabitEthernet1/0/1)'s neighbors

Configuring OSPFv3

About OSPFv3

This chapter describes how to configure RFC 2740-compliant Open Shortest Path First version 3 (OSPFv3) for an IPv6 network.

Comparison of OSPFv3 with OSPFv2

OSPFv3 and OSPFv2 have the following in common:

- 32-bit router ID and area ID.
- Hello, Database Description (DD), Link State Request (LSR), Link State Update (LSU), Link State Acknowledgment (LSAck).
- Mechanisms for finding neighbors and establishing adjacencies.
- Mechanisms for advertising and aging LSAs.

OSPFv3 and OSPFv2 have the following differences:

- OSPFv3 runs on a per-link basis. OSPFv2 runs on a per-IP-subnet basis.
- OSPFv3 supports running multiple processes on an interface, but OSPFv2 does not support.
- OSPFv3 identifies neighbors by router ID. OSPFv2 identifies neighbors by IP address.

For more information about OSPFv2, see "Configuring OSPF."

OSPFv3 packets

OSPFv3 uses the following packet types:

- **Hello**—Periodically sent to find and maintain neighbors, containing timer values, information about the DR, BDR, and known neighbors.
- **DD**—Describes the digest of each LSA in the LSDB, exchanged between two routers for data synchronization.
- **LSR**—Requests needed LSAs from the neighbor. After exchanging the DD packets, the two routers know which LSAs of the neighbor are missing from their LSDBs. They then send an LSR packet to each other, requesting the missing LSAs. The LSA packet contains the digest of the missing LSAs.
- **LSU**—Transmits the requested LSAs to the neighbor.
- **LSAck**—Acknowledges received LSU packets.

OSPFv3 LSA types

OSPFv3 sends routing information in LSAs. The following LSAs are commonly used:

- **Router LSA**—Type-1 LSA, originated by all routers. This LSA describes the collected states of the router's interfaces to an area, and is flooded throughout a single area only.
- **Network LSA**—Type-2 LSA, originated for broadcast and NBMA networks by the DR. This LSA contains the list of routers connected to the network, and is flooded throughout a single area only.
- **Inter-Area-Prefix LSA**—Type-3 LSA, originated by ABRs and flooded throughout the LSA's associated area. Each Inter-Area-Prefix LSA describes a route with IPv6 address prefix to a destination outside the area, yet still inside the AS.

- **Inter-Area-Router LSA**—Type-4 LSA, originated by ABRs and flooded throughout the LSA's associated area. Each Inter-Area-Router LSA describes a route to ASBR.
- **AS External LSA**—Type-5 LSA, originated by ASBRs, and flooded throughout the AS, except stub areas and Not-So-Stubby Areas (NSSAs). Each AS External LSA describes a route to another AS. A default route can be described by an AS External LSA.
- **NSSA LSA**—Type-7 LSA, originated by ASBRs in NSSAs and flooded throughout a single NSSA. NSSA LSAs describe routes to other ASs.
- **Link LSA**—Type-8 LSA. A router originates a separate Link LSA for each attached link. Link LSAs have link-local flooding scope. Each Link LSA describes the IPv6 address prefix of the link and Link-local address of the router.
- **Intra-Area-Prefix LSA**—Type-9 LSA. Each Intra-Area-Prefix LSA contains IPv6 prefix information on a router, stub area, or transit area information, and has area flooding scope. It was introduced because Router LSAs and Network LSAs contain no address information.
- **Grace LSA**—Type-11 LSA, generated by a GR restarter at reboot and transmitted on the local link. The GR restarter describes the cause and interval of the reboot in the Grace LSA to notify its neighbors that it performs a GR operation.

OSPFv3 tasks at a glance

To configure OSPFv3, perform the following tasks:

1. Enabling OSPFv3
2. (Optional.) Configuring OSPFv3 area parameters
   - Configuring a stub area
   - Configuring an NSSA area
   - Configuring an OSPFv3 virtual link

     Perform this task on an ABR to create a virtual link when connectivity cannot be maintained between a non-backbone area and the backbone, or within the backbone.
3. (Optional.) Configuring OSPFv3 network types
   - Setting the broadcast network type for an OSPFv3 interface
   - Setting the NBMA network type for an OSPFv3 interface

   - Setting the P2MP network type for an OSPFv3 interface
   - Setting the P2P network type for an OSPFv3 interface
4. (Optional.) Configuring OSPFv3 route control
   - Configuring OSPFv3 inter-area route summarization
   - Configuring OSPFv3 received route filtering
   - Configuring Inter-Area-Prefix LSA filtering
   - Setting an OSPFv3 cost for an interface
   - Setting the maximum number of OSPFv3 ECMP routes
   - Setting a preference for OSPFv3
   - Configuring OSPFv3 route redistribution
5. (Optional.) Setting OSPFv3 timers
   - Setting OSPFv3 packet timers
   - Setting LSA transmission delay
   - Setting SPF calculation interval
   - Setting the LSA generation interval
   - Setting the LSU transmit rate
6. (Optional.) Setting a DR priority for an interface
7. (Optional.) Configuring OSPFv3 packet parameters
   - Ignoring MTU check for DD packets
   - Disabling interfaces from receiving and sending OSPFv3 packets
8. (Optional.) Configuring prefix suppression
9. (Optional.) Configuring a stub router
10. (Optional.) Enhancing OSPFv3 availability
    - Configuring OSPFv3 GR
    - Configuring OSPFv3 NSR
    - Configuring BFD for OSPFv3
    - Configuring OSPFv3 FRR
11. (Optional.) Configuring OSPFv3 logging and SNMP notifications
    - Enabling logging for neighbor state changes
    - Setting the maximum number of OSPFv3 logs
    - Configuring OSPFv3 network management

Enabling OSPFv3

About this task

To enable an OSPFv3 process on a router:

1. Enable the OSPFv3 process globally.
2. Assign the OSPFv3 process a router ID.
3. Enable the OSPFv3 process on related interfaces.

An OSPFv3 process ID has only local significance. Process 1 on a router can exchange packets with process 2 on another router.

OSPFv3 requires you to manually specify a router ID for each router in an AS. Make sure all assigned router IDs in the AS are unique.

Restrictions and guideline

If a router runs multiple OSPFv3 processes, specify a unique router ID for each process as a best practice.

Procedure

1. Enter system view.
   system-view
2. Enable an OSPFv3 process and enter its view.
   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *
   By default, no OSPFv3 processes are enabled.
3. Specify a router ID.
   router-id *router-id*
   By default, no router ID is configured.
4. Enter interface view.
   interface *interface-type interface-number*
5. Enable an OSPFv3 process on the interface.
   ospfv3 *process-id* **area** *area-id* [**instance** *instance-id*]
   By default, no OSPFv3 processes are enabled on an interface.

Configuring OSPFv3 area parameters

About OSPFv3 areas

OSPFv3 has the same stub area, NSSA area, and virtual link features as OSPFv2.

After you split an OSPFv3 AS into multiple areas, the LSA number is reduced and OSPFv3 applications are extended. To further reduce the size of routing tables and the number of LSAs, configure the non-backbone areas at an AS edge as stub areas.

A stub area cannot import external routes, but an NSSA area can import external routes into the OSPFv3 routing domain while retaining other stub area characteristics.

Non-backbone areas exchange routing information through the backbone area, so the backbone and non-backbone areas (including the backbone itself) must be fully meshed. If no connectivity can be achieved, configure virtual links.

Configuring a stub area

Restrictions and guidelines

To configure a stub area, you must perform this task on all routers attached to the area.

Procedure

1. Enter system view.
   system-view
2. Enter OSPFv3 view.
   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *
3. Enter OSPFv3 area view.
   area *area-id*
4. Configure the area as a stub area.

stub [**default-route-advertise-always** | **no-summary**] *

By default, no area is configured as a stub area.

The **no-summary** keyword is only available on the ABR of a stub area. If you specify the **no-summary** keyword, the ABR only advertises a default route in an Inter-Area-Prefix LSA into the stub area.

5. (Optional.) Set a cost for the default route advertised to the stub area.

   default-cost *cost-value*

   By default, the cost for the default route advertised to the stub area is 1.

Configuring an NSSA area

Restrictions and guidelines

To configure an NSSA area, you must perform this task on all routers attached to the area.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enter OSPFv3 area view.

   area *area-id*

4. Configure the area as an NSSA area.

   nssa [**default-route-advertise** [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] * | **no-import-route** | **no-summary** | [**translate-always** | **translate-never**] | **suppress-fa** | **translator-stability-interval** *value*] *

   By default, no area is configured as an NSSA area.

   To configure a totally NSSA area, execute the **nssa no-summary** command on the ABR. The ABR of a totally NSSA area does not advertise inter-area routes into the area.

5. (Optional.) Set a cost for the default route advertised to the NSSA area.

   default-cost *cost-value*

   By default, the cost for the default route advertised to the NSSA area is 1.

   This command takes effect only on the ABR/ASBR of an NSSA or totally NSSA area.

Configuring an OSPFv3 virtual link

About this task

You can configure a virtual link to maintain connectivity between a non-backbone area and the backbone, or in the backbone itself.

Restrictions and guidelines

Both ends of a virtual link are ABRs that must be configured with the **vlink-peer** command.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enter OSPFv3 area view.

   area *area-id*

4. Configure a virtual link.

   vlink-peer *router-id* [**dead** *seconds* | **hello** *seconds* | **instance** *instance-id* | **ipsec-profile** *profile-name* | **keychain** *keychain-name* | **retransmit** *seconds* | **trans-delay** *seconds*] *

Configuring OSPFv3 network types

Restrictions and guidelines for OSPFv3 network type configuration

Based on the link layer protocol, OSPFv3 classifies networks into different types, including broadcast, NBMA, P2MP, and P2P.

- If any routers in a broadcast network do not support multicasting, you can change the network type to NBMA.
- An NBMA network must be fully connected. Any two routers in the network must be directly reachable to each other through a virtual circuit. If no such direct link is available, you must change the network type through a command.
- If direct connections are not available between some routers on an NBMA network, the type of interfaces associated must be configured as P2MP.
- If only two routers running OSPFv3 exist on a network segment, you can change the network type to P2P to save costs.

Setting the broadcast network type for an OSPFv3 interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the network type to broadcast for the OSPFv3 interface.

   ospfv3 network-type broadcast [**instance** *instance-id*]

   By default, the network type of an interface depends on the media type of the interface.

   When the link layer protocol is Ethernet or FDDI, the network type is broadcast by default.

Setting the NBMA network type for an OSPFv3 interface

Restrictions and guidelines

For NBMA interfaces, you must specify the link-local IP addresses and DR priorities for their neighbors because these interfaces cannot find neighbors by broadcasting hello packets.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the network type to NBMA for the OSPFv3 interface.

   ospfv3 network-type nbma [**instance** *instance-id*]

4. (Optional.) Set the router priority for the interface

   ospfv3 dr-priority *priority*

   By default, an interface has a router priority of 1.

   An interface's router priority determines its privilege in DR/BDR selection.

5. Specify an NBMA neighbor.

   ospfv3 peer *ipv6-address* [**cost** *cost-value* | **dr-priority** *priority*] [**instance** *instance-id*]

   By default, no link-local address is specified for the neighbor interface.

Setting the P2MP network type for an OSPFv3 interface

Restrictions and guidelines

For P2MP interfaces (only when in unicast mode), you must specify the link-local IP addresses of their neighbors because these interfaces cannot find neighbors by broadcasting hello packets.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the network type to P2MP for the OSPFv3 interface.

   ospfv3 network-type p2mp [**unicast**] [**instance** *instance-id*]

   By default, the network type of an interface depends on the media type of the interface.

4. Specify a P2MP unicast neighbor.

   ospfv3 peer *ipv6-address* [**cost** *cost-value* | **dr-priority** *priority*] [**instance** *instance-id*]

   By default, no link-local address is specified for the neighbor interface.

Setting the P2P network type for an OSPFv3 interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the network type to P2P for the OSPFv3 interface.

   ospfv3 network-type p2p [**instance** *instance-id*]

   When the link layer protocol is PPP, the network type is P2P by default.

Configuring OSPFv3 route control

Configuring OSPFv3 inter-area route summarization

About this task

If contiguous network segments exist in an area, you can summarize them into one network segment on the ABR. The ABR will advertise only the summary route. Any LSA on the specified network segment will not be advertised, reducing the LSDB size in other areas.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enter OSPFv3 area view.

   area *area-id*

4. Configure route summarization on the ABR.

   abr-summary *ipv6-address prefix-length* [**not-advertise**] [**cost** *cost-value*]

   By default, route summarization is not configured on an ABR.

Configuring redistributed route summarization

About this task

Perform this task to enable an ASBR to summarize external routes within the specified address range into a single route.

An ASBR can summarize routes in the following LSAs:

- Type-5 LSAs.
- Type-7 LSAs in an NSSA area.
- Type-5 LSAs translated from Type-7 LSAs in an NSSA area if the ASBR (also an ABR) is a translator. If the ASBR is not a translator, it cannot summarize routes in Type-5 LSAs translated from Type-7 LSAs.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Configure route summarization on an ASBR.

   asbr-summary *ipv6-address prefix-length* [**cost** *cost-value* | **not-advertise** | **nssa-only** | **tag** *tag*] *

   By default, route summarization is not configured on an ASBR.

Configuring OSPFv3 received route filtering

About this task

This task allows you to filter routes calculated by using received LSAs.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Configure OSPFv3 to filter routes calculated by using received LSAs.

   filter-policy { *ipv6-acl-number* [**gateway** *prefix-list-name*] | **prefix-list** *prefix-list-name* [**gateway** *prefix-list-name*] | **gateway** *prefix-list-name* | **route-policy** *route-policy-name* } **import**

   By default, OSPFv3 accepts all routes calculated by using received LSAs.

   This command can only filter routes computed by OSPFv3. Only routes not filtered out can be added into the local routing table.

Configuring Inter-Area-Prefix LSA filtering

Restrictions and guidelines

The **filter** command takes effect only on ABRs.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enter OSPFv3 area view.

   area *area-id*

4. Configure OSPFv3 to filter Inter-Area-Prefix LSAs.

   filter { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } { **export** | **import** }

   By default, OSPFv3 accepts all Inter-Area-Prefix LSAs.

Setting an OSPFv3 cost for an interface

About this task

You can set an OSPFv3 cost for an interface with one of the following methods:

- Set the cost value in interface view.
- Set a bandwidth reference value for the interface, and OSPFv3 computes the cost automatically based on the bandwidth reference value by using the following formula:

  Interface OSPFv3 cost = Bandwidth reference value (100 Mbps) / Interface bandwidth (Mbps)

  - If the calculated cost is greater than 65535, the value of 65535 is used.
  - If the calculated cost is smaller than 1, the value of 1 is used.
- If no cost is set for an interface, OSPFv3 automatically computes the cost for the interface.

Setting a cost in interface view

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set an OSPFv3 cost for the interface.

   ospfv3 cost *cost-value* [**instance** *instance-id*]

   By default, the OSPFv3 cost is 1 for a VLAN interface and 0 for a loopback interface. The OSPFv3 cost is automatically computed according to the interface bandwidth for other interfaces.

Setting a bandwidth reference value

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Set a bandwidth reference value.

   bandwidth-reference *value*

   The default bandwidth reference value is 100 Mbps.

Setting the maximum number of OSPFv3 ECMP routes

About this task

OSPFv3 might find multiple equal-cost routes to the same destination, which can be used to share the traffic load. This task allows you to set the maximum number of ECMP routes.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Set the maximum number of ECMP routes.

   maximum load-balancing *number*

   The maximum number of OSPFv3 ECMP routes equals the maximum number of ECMP routes supported by the system.

Setting a preference for OSPFv3

About this task

A router can run multiple routing protocols. The system assigns a priority for each protocol. When these routing protocols find the same route, the route found by the protocol with the highest priority is selected.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

```
ospfv3 [ process-id | vpn-instance vpn-instance-name ] *
```

3. Set a preference for OSPFv3.

```
preference [ ase ] { preference | route-policy route-policy-name } *
```

By default, the preference of OSPFv3 internal routes is 10, and the preference of OSPFv3 external routes is 150.

Configuring OSPFv3 route redistribution

Restrictions and guidelines

Because OSPFv3 is a link state routing protocol, it cannot directly filter LSAs to be advertised. OSPFv3 filters only redistributed routes. Only routes that are not filtered out can be advertised in LSAs.

Procedure

1. Enter system view.

```
system-view
```

2. Enter OSPFv3 view.

```
ospfv3 [ process-id | vpn-instance vpn-instance-name ] *
```

3. Configure route redistribution.

```
import-route { direct | guard | static } [ cost cost-value | nssa-only |
route-policy route-policy-name | tag tag | type type ] *
```

```
import-route { isisv6 | ospfv3 | ripng } [ process-id | all-processes ]
[ allow-direct | cost cost-value | nssa-only | route-policy
route-policy-name | tag tag | type type ] *
```

By default, OSPFv3 does not redistribute routes.

The **import-route bgp4+** command redistributes only EBGP routes. The **import-route bgp4+ allow-ibgp** command redistributes both EBGP and IBGP routes, which might cause routing loops. There, use the **import-route bgp4+ allow-ibgp** command with caution.

4. (Optional.) Configure OSPFv3 to filter redistributed routes.

```
filter-policy { ipv6-acl-number | prefix-list prefix-list-name }
export [ bgp4+ | direct | { isisv6 | ospfv3 | ripng } [ process-id ] |
static ]
```

By default, OSPFv3 accepts all redistributed routes.

This command filters only routes redistributed by the **import-route** command. If no routes are redistributed by the **import-route** command, this command does not take effect.

5. Set a tag for redistributed routes.

```
default tag tag
```

By default, the tag of redistributed routes is 1.

Configuring default route redistribution

About this task

The **import-route** command cannot redistribute a default external route. To redistribute a default route, perform this task.

Procedure

1. Enter system view.

```
system-view
```

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Redistribute a default route.

   default-route-advertise [[**always** | **permit-calculate-other**] | **cost** *cost-value* | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

   By default, no default route is redistributed.

4. Set a tag for redistributed routes.

   default tag *tag*

   By default, the tag of redistributed routes is 1.

Setting OSPFv3 timers

Setting OSPFv3 packet timers

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the hello interval.

   ospfv3 timer hello *seconds* [**instance** *instance-id*]

   The default hello interval on P2P and broadcast interfaces is 10 seconds. The default hello interval on P2MP and NBMA interfaces is 30 seconds.

4. Set the dead interval.

   ospfv3 timer dead *seconds* [**instance** *instance-id*]

   The default dead interval on P2P and broadcast interfaces is 40 seconds. The default dead interval on P2MP and NBMA interfaces is 120 seconds.

   The dead interval set on neighboring interfaces cannot be too short. If the interval is too short, a neighbor is easily down.

5. Set the poll interval.

   ospfv3 timer poll *seconds* [**instance** *instance-id*]

   By default, the poll interval is 120 seconds.

6. Set the LSA retransmission interval.

   ospfv3 timer retransmit *interval* [**instance** *instance-id*]

   The default LSA retransmission interval is 5 seconds.

   The LSA retransmission interval cannot be too short. If the interval is too short, unnecessary retransmissions will occur.

Setting LSA transmission delay

About this task

Each LSA in the LSDB has an age that increases by 1 every second, but the age does not change during transmission. Therefore, it is necessary to add a transmission delay into the age time, especially for low-speed links.

Procedure

1. Enter system view.

system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the LSA transmission delay.

   ospfv3 trans-delay *seconds* [**instance** *instance-id*]

   By default, the LSA transmission delay is 1 second.

Setting SPF calculation interval

About this task

LSDB changes result in SPF calculations. When the topology changes frequently, a large amount of network and router resources are occupied by SPF calculation. You can adjust the SPF calculation interval to reduce the impact.

For a stable network, the minimum interval is used. If network changes become frequent, the SPF calculation interval increases by the incremental interval × 2^{n-2} for each calculation until the maximum interval is reached. The value *n* is the number of calculation times.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Set the SPF calculation interval.

   spf-schedule-interval *maximum-interval* [*minimum-interval* [*incremental-interval*]]

   By default, the maximum interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Setting the LSA generation interval

About this task

You can adjust the LSA generation interval to protect network resources and routers from being over consumed by frequent network changes.

For a stable network, the minimum interval is used. If network changes become frequent, the LSA generation interval increases by the incremental interval × 2^{n-2} for each generation until the maximum interval is reached. The value *n* is the number of generation times.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Set the LSA generation interval.

   lsa-generation-interval *maximum-interval* [*minimum-interval* [*incremental-interval*]]

   By default, the maximum interval is 5 seconds, the minimum interval is 0 milliseconds, and the incremental interval is 0 milliseconds.

Setting the LSU transmit rate

About this task

Sending large numbers of LSU packets affects router performance and consumes a large amount of network bandwidth. You can configure the router to send LSU packets at an interval and to limit the maximum number of LSU packets sent out of an OSPFv3 interface at each interval.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Set the LSU transmit rate.

   transmit-pacing interval *interval* **count** *count*

   By default, an OSPFv3 interface sends a maximum of three LSU packets every 20 milliseconds.

Setting a DR priority for an interface

About this task

The router priority is used for DR election. Interfaces having the priority 0 cannot become a DR or BDR.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set a router priority.

   ospfv3 dr-priority *priority* [**instance** *instance-id*]

   The default router priority is 1.

Configuring OSPFv3 packet parameters

Ignoring MTU check for DD packets

About this task

When LSAs are few in DD packets, it is unnecessary to check the MTU in DD packets to improve efficiency.

Restrictions and guidelines

A neighbor relationship can be established only if the interface's MTU is the same as that of the peer.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

interface *interface-type interface-number*

3. Ignore MTU check for DD packets.

   ospfv3 mtu-ignore [**instance** *instance-id*]

   By default, OSPFv3 does not ignore MTU check for DD packets.

Disabling interfaces from receiving and sending OSPFv3 packets

About this task

After an OSPFv3 interface is set to **silent**, direct routes of the interface can still be advertised in Intra-Area-Prefix LSAs through other interfaces, but other OSPFv3 packets cannot be advertised. No neighboring relationship can be established on the interface. This feature can enhance the adaptability of OSPFv3 networking.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Disable interfaces from receiving and sending OSPFv3 packets.

   silent-interface { *interface-type interface-number* | **all** }

   By default, the interfaces can receive and send OSPFv3 packets.

   This command disables only the interfaces that run the current process. However, multiple OSPFv3 processes can disable the same interface from receiving and sending OSPFv3 packets.

Configuring prefix suppression

About prefix suppression

By default, an OSPFv3 interface advertises all of its prefixes in LSAs. To speed up OSPFv3 convergence, you can suppress interfaces from advertising all of their prefixes. This feature helps improve network security by preventing IP routing to the suppressed networks.

When prefix suppression is enabled:

- OSPFv3 does not advertise the prefixes of suppressed interfaces in Type-8 LSAs.
- On broadcast and NBMA networks, the DR does not advertise the prefixes of suppressed interfaces in Type-9 LSAs that reference Type-2 LSAs.
- On P2P and P2MP networks, OSPFv3 does not advertise the prefixes of suppressed interfaces in Type-9 LSAs that reference Type-1 LSAs.

Restrictions and guidelines for prefix suppression

As a best practice, configure prefix suppression on all OSPFv3 routers if you want to use prefix suppression.

Configuring prefix suppression for an OSPFv3 process

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enable prefix suppression for the OSPFv3 process.

   prefix-suppression

   By default, prefix suppression is disabled for an OSPFv3 process.

   Enabling prefix suppression for an OSPFv3 process does not suppress the prefixes of loopback interfaces and passive interfaces.

Configuring prefix suppression for an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable prefix suppression for the interface.

   ospfv3 prefix-suppression [**disable**] [**instance** *instance-id*]

   By default, prefix suppression is disabled for an interface.

Configuring a stub router

About this task

A stub router is used for traffic control. It reports its status as a stub router to neighboring OSPFv3 routers. The neighboring routers can have a route to the stub router, but they do not use the stub router to forward data.

Use either of the following methods to configure a router as a stub router:

- Clear the R-bit of the Option field in Type-1 LSAs. When the R-bit is clear, the OSPFv3 router can participate in OSPFv3 topology distribution without forwarding traffic.
- Use the OSPFv3 max-metric router LSA feature. This feature enables OSPFv3 to advertise its locally generated Type-1 LSAs with a maximum cost of 65535. Neighbors do not send packets to the stub router as long as they have a route with a smaller cost.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Configure the router as a stub router.

   - Configure the router as a stub router and clear the R-bit of the Option field in Type-1 LSAs.

     stub-router r-bit [**include-stub** | **on-startup** { *seconds* | **wait-for-bgp** [*seconds*] }] *

   - Configure the router as a stub router and advertise the locally generated Type-1 LSAs with the maximum cost of 65535.

stub-router max-metric [**external-lsa** [*max-metric-value*] | **summary-lsa** [*max-metric-value*] | **include-stub** | **on-startup** { *seconds* | **wait-for-bgp** [*seconds*] }] *

By default, the router is not configured as a stub router.

A stub router is not related to a stub area.

Configuring OSPFv3 GR

About OSPFv3 GR

GR ensures forwarding continuity when a routing protocol restarts or an active/standby switchover occurs.

Two routers are required to complete a GR process. The following are router roles in a GR process:

- **GR restarter**—Graceful restarting router. It must be Graceful Restart capable.
- **GR helper**—The neighbor of the GR restarter. It helps the GR restarter to complete the GR process.

To prevent service interruption after a master/backup switchover, a GR restarter running OSPFv3 must perform the following tasks:

- Keep the GR restarter forwarding entries stable during reboot.
- Establish all adjacencies and obtain complete topology information after reboot.

After the active/standby switchover, the GR restarter sends a Grace LSA to tell its neighbors that it performs a GR. Upon receiving the Grace LSA, the neighbors with the GR helper capability enter the helper mode (and are called GR helpers). Then, the GR restarter retrieves its adjacencies and LSDB with the help of the GR helpers.

Restrictions and guidelines for OSPFv3 GR

You cannot enable OSPFv3 NSR on a device that acts as GR restarter.

Configuring GR restarter

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enable the GR capability.

   graceful-restart enable [**global** | **planned-only**] *

   By default, OSPFv3 GR restarter capability is disabled.

4. (Optional.) Set the GR interval.

   graceful-restart interval *interval*

   By default, the GR interval is 120 seconds.

Configuring GR helper

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enable the GR helper capability.

   graceful-restart helper enable [**planned-only**]

   By default, the GR helper capability is enabled.

4. Enable strict LSA checking.

   graceful-restart helper strict-lsa-checking

   By default, strict LSA checking is disabled.

Triggering OSPFv3 GR

About this task

OSPFv3 GR is triggered by an active/standby switchover or when this task is performed.

Procedure

To trigger OSPFv3 GR, execute the **reset ospfv3** [*process-id*] **process graceful-restart** command in user view.

Configuring OSPFv3 NSR

About this task

Nonstop routing (NSR) backs up OSPFv3 link state information from the active process to the standby process. After an active/standby switchover, NSR can complete link state recovery and route regeneration without tearing down adjacencies or impacting forwarding services.

NSR does not require the cooperation of neighboring devices to recover routing information, and it is typically used more often than GR.

Restrictions and guidelines

A device that has OSPFv3 NSR enabled cannot act as GR restarter.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enable OSPFv3 NSR.

   non-stop-routing

   By default, OSPFv3 NSR is disabled.

   This command takes effect only for the current process. As a best practice, enable OSPFv3 NSR for each process if multiple OSPFv3 processes exist.

Configuring BFD for OSPFv3

About this task

Bidirectional forwarding detection (BFD) provides a mechanism to quickly detect the connectivity of links between OSPFv3 neighbors, improving the convergence speed of OSPFv3.For more information about BFD, see BFD configuration in *Network Management and Monitoring Configuration Guide*.

After discovering neighbors by sending hello packets, OSPFv3 notifies BFD of the neighbor addresses, and BFD uses these addresses to establish sessions. Before a BFD session is established, it is in the down state. In this state, BFD control packets are sent at an interval of no less than 1 second to reduce BFD control packet traffic. After the BFD session is established, BFD control packets are sent at the negotiated interval, thereby implementing fast fault detection.

To configure BFD for OSPFv3, you need to configure OSPFv3 first.

Procedure

1. Enter system view.

system-view

2. Enter OSPFv3 view.

ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Specify a router ID.

router-id *router-id*

4. Quit the OSPFv3 view.

quit

5. Enter interface view.

interface *interface-type interface-number*

6. Enable an OSPFv3 process on the interface.

ospfv3 *process-id* **area** *area-id* [**instance** *instance-id*]

7. Enable BFD on the interface.

ospfv3 bfd enable [**instance** *instance-id*]

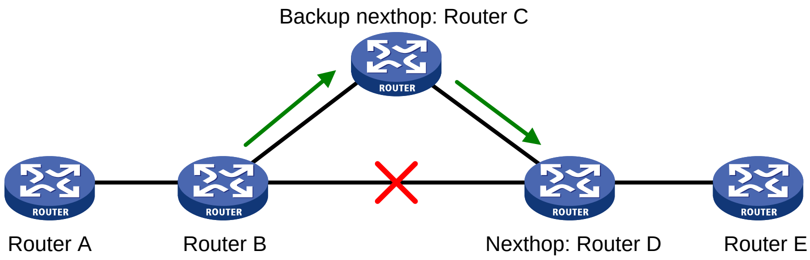
By default, BFD is disabled on the OSPFv3 interface.

Configuring OSPFv3 FRR

About OSPFv3 FRR

A primary link failure can cause packet loss and even a routing loop until OSPFv3 completes routing convergence based on the new network topology. OSPFv3 FRR enables fast rerouting to minimize the failover time.

Figure 1 Network diagram for OSPFv3 FRR



As shown in Figure 1, configure FRR on Router B. OSPFv3 FRR automatically calculates a backup next hop or specifies a backup next hop by using a routing policy. When the primary link fails, OSPFv3 directs packets to the backup next hop. At the same time, OSPFv3 calculates the shortest path based on the new network topology. It forwards packets over the path after network convergence.

You can configure OSPFv3 FRR to calculate a backup next hop by using the loop free alternate (LFA) algorithm, or specify a backup next hop by using a routing policy.

Configuring OSPFv3 FRR to use the LFA algorithm to calculate a backup next hop

Restrictions and guidelines

Do not use the **fast-reroute lfa** command together with the **vlink-peer** command.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. (Optional.) Disable LFA on an interface.

   ospfv3 fast-reroute lfa-backup exclude

   By default, the interface on which LFA is enabled can be selected as a backup interface.

4. Return to system view.

   quit

5. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

6. Enable OSPFv3 FRR to use the LFA algorithm to calculate a backup next hop.

   fast-reroute lfa [**abr-only**]

   By default, OSPFv3 FRR is disabled.

   If **abr-only** is specified, the route to the ABR is selected as the backup path.

Configuring OSPFv3 FRR to use a backup next hop in a routing policy

About this task

Before you perform this task, use the **apply ipv6 fast-reroute backup-interface** command to specify a backup next hop in the routing policy to be used. For more information about the **apply ipv6 fast-reroute backup-interface** command and routing policy configuration, see "Configuring routing policies."

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. (Optional.) Disable LFA on an interface.

   ospfv3 fast-reroute lfa-backup exclude

   By default, the interface is enabled with LFA and it can be selected as a backup interface.

4. Return to system view.

   quit

5. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

6. Configure OSPFv3 FRR to use a backup next hop in a routing policy.

   fast-reroute route-policy *route-policy-name*

   By default, OSPFv3 FRR is disabled.

Configuring BFD control packet mode for OSPFv3 FRR

About this task

By default, OSPFv3 FRR does not use BFD to detect primary link failures. To speed up OSPFv3 convergence, enable BFD control packet mode for OSPFv3 FRR to detect primary link failures. This mode requires BFD configuration on both OSPFv3 routers on the link.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable BFD control packet mode for OSPFv3 FRR.

   ospfv3 primary-path-detect bfd ctrl [**instance** *instance-id*]

   By default, BFD control packet mode is disabled for OSPFv3 FRR.

Configuring BFD echo packet mode for OSPFv3 FRR

About this task

By default, OSPFv3 FRR does not use BFD to detect primary link failures. To speed up OSPFv3 convergence, enable BFD echo packet mode for OSPFv3 FRR to detect primary link failures. This mode requires BFD configuration on one OSPFv3 router on the link.

Procedure

1. Enter system view.

   system-view

2. Configure the source IPv6 address of BFD echo packets.

   bfd echo-source-ipv6 *ipv6-address*

   By default, the source IPv6 address of BFD echo packets is not configured.

   The source IPv6 address cannot be on the same network segment as any local interface's IP address.

   For more information about this command, see BFD commands in *Network Management and Monitoring Command Reference*.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable BFD echo packet mode for OSPFv3 FRR.

   ospfv3 primary-path-detect bfd echo [**instance** *instance-id*]

   By default, BFD echo packet mode is disabled for OSPFv3 FRR.

Configuring OSPFv3 security features

Configuring OSPFv3 authentication

About this task

Perform this task to configure OSPFv3 area and interface authentication by using a keychain.

OSPFv3 adds the configured key into outgoing packets, and uses the key to authenticate incoming packets. Only the packets that pass the authentication can be received. If a packet fails the authentication, the OSPFv3 neighbor relationship cannot be established.

Restrictions and guidelines for OSPFv3 authentication

If you configure OSPFv3 authentication for both an area and an interface in that area, the interface uses the OSPFv3 authentication configured on it.

Configuring OSPFv3 area authentication

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enter OSPFv3 area view.

   area *area-id*

4. Configure area authentication.

   authentication-mode keychain *keychain-name*

   By default, no authentication is configured.

   For more information about keychains, see keychain configuration in *Security Configuration Guide*.

Configuring OSPF interface authentication

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure interface authentication.

   ospfv3 authentication-mode keychain *keychain-name* [**instance** *instance-id*]

   By default, no authentication is configured.

   For more information about keychains, see keychain configuration in *Security Configuration Guide*.

Applying an IPsec profile for authenticating OSPFv3 packets

About this task

To protect routing information and prevent attacks, you can configure OSPFv3 to authenticate protocol packets by using an IPsec profile.

An IPsec profile contains inbound and outbound security parameter indexes (SPIs). OSPFv3 compares the inbound SPI defined in the IPsec profile with the outbound SPI in the received packets.

Two OSPFv3 devices accept the packets from each other and establish a neighbor relationship only if the SPIs are the same and the relevant IPsec profiles match.

For more information about IPsec profiles, see *Security Configuration Guide*.

Restrictions and guidelines for applying an IPsec profile

You can configure an IPsec profile for an area, an interface, or a virtual link.

- To implement area-based IPsec protection, configure the same IPsec profile on the routers in the target area.
- To implement interface-based IPsec protection, configure the same IPsec profile on the interfaces between two neighboring routers.
- To implement virtual link-based IPsec protection, configure the same IPsec profile on the two routers connected over the virtual link.
- If an interface and its area each have an IPsec profile configured, the interface uses its own IPsec profile.
- If a virtual link and area 0 each have an IPsec profile configured, the virtual link uses its own IPsec profile.

Applying an IPsec profile to an area

1. Enter system view.
   ```
   system-view
   ```
2. Enter OSPFv3 view.
   ```
   ospfv3 [ process-id | vpn-instance vpn-instance-name ] *
   ```
3. Enter OSPFv3 area view.
   ```
   area area-id
   ```
4. Apply an IPsec profile to the area.
   ```
   enable ipsec-profile profile-name
   ```
   By default, no IPsec profile is applied.

Applying an IPsec profile to an interface

1. Enter system view.
   ```
   system-view
   ```
2. Enter interface view.
   ```
   interface interface-type interface-number
   ```
3. Apply an IPsec profile to the interface.
   ```
   ospfv3 ipsec-profile profile-name [ instance instance-id ]
   ```
   By default, no IPsec profile is applied.

Applying an IPsec profile to a virtual link

1. Enter system view.
   ```
   system-view
   ```
2. Enter OSPFv3 view.
   ```
   ospfv3 [ process-id | vpn-instance vpn-instance-name ] *
   ```
3. Enter OSPFv3 area view.
   ```
   area area-id
   ```
4. Apply an IPsec profile to a virtual link.
   ```
   vlink-peer router-id [ dead seconds | hello seconds | instance
   instance-id | ipsec-profile profile-name | retransmit seconds |
   trans-delay seconds ] *
   ```

By default, no IPsec profile is applied.

Configuring OSPFv3 logging and SNMP notifications

Enabling logging for neighbor state changes

About this task

With this feature enabled, the router delivers logs about neighbor state changes to its information center. The information center processes logs according to user-defined output rules (whether to output logs and where to output). For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enable logging for neighbor state changes.

   log-peer-change

   By default, this feature is enabled.

Setting the maximum number of OSPFv3 logs

About this task

OSPFv3 logs include route calculation logs, neighbor logs, and LSA aging logs.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Set the maximum number of OSPFv3 logs.

   event-log { **lsa-flush** | **peer** | **spf** } **size** *count*

   By default, the maximum number of LSA aging logs, neighbor logs, or route calculation logs is 10.

Configuring OSPFv3 network management

About this task

This task involves the following configurations:

- Bind an OSPFv3 process to MIB so that you can use network management software to manage the specified OSPFv3 process.
- Enable SNMP notifications for OSPFv3 to report important events.
- Set the SNMP notification output interval and the maximum number of SNMP notifications that can be output at each interval.

To report critical OSPFv3 events to an NMS, enable SNMP notifications for OSPFv3. For SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

The standard OSPFv3 MIB provides only single-instance MIB objects. To identify multiple OSPFv3 processes in the standard OSPFv3 MIB, you must assign a unique context name to each OSPFv3 process.

Context is a method introduced to SNMPv3 for multiple-instance management. For SNMPv1/v2c, you must specify a community name as a context name for protocol identification.

Procedure

1. Enter system view.

   system-view

2. Bind MIB to an OSPFv3 process.

   ospfv3 mib-binding *process-id*

   By default, MIB is bound to the process with the smallest process ID.

3. Enable SNMP notifications for OSPFv3.

   snmp-agent trap enable ospfv3 [**grrestarter-status-change** | **grhelper-status-change** | **if-state-change** | **if-cfg-error** | **if-bad-pkt** | **neighbor-state-change** | **nssatranslator-status-change** | **virtif-bad-pkt** | **virtif-cfg-error** | **virtif-state-change** | **virtgrhelper-status-change** | **virtneighbor-state-change**]*

   By default, SNMP notifications for OSPFv3 are enabled.

4. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

5. Configure an SNMP context for the OSPFv3 process.

   snmp context-name *context-name*

   By default, no SNMP context is configured for the OSPFv3 process.

6. (Optional.) Set the SNMP notification output interval and the maximum number of SNMP notifications that can be output at each interval.

   snmp trap rate-limit interval *trap-interval* **count** *trap-number*

   By default, OSPFv3 outputs a maximum of seven SNMP notifications within 10 seconds.

Display and maintenance commands for OSPFv3

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display summary route information on the OSPFv3 ABR.	**display ospfv3** [*process-id*] [**area** *area-id*] **abr-summary** [*ipv6-address prefix-length*] [**verbose**]
Display OSPFv3 neighbor information.	**display ospfv3** [*process-id*] [**area** *area-id*] **peer** [[*interface-type interface-number*] [**verbose**] | *peer-router-id* | **statistics**]
Display OSPFv3 request list information.	**display ospfv3** [*process-id*] [**area** *area-id*] **request-queue** [*interface-type interface-number*] [*neighbor-id*]
Display OSPFv3 retransmission list	**display ospfv3** [*process-id*] [**area** *area-id*]

Task	Command
information.	**retrans-queue** [*interface-type interface-number*] [*neighbor-id*]
Display OSPFv3 topology information.	**display ospfv3** [*process-id*] [**area** *area-id*] **spf-tree** [**verbose**]
Display OSPFv3 process information.	**display ospfv3** [*process-id*] [**verbose**]
Display information about the routes to OSPFv3 ABR and ASBR.	**display ospfv3** [*process-id*] **abr-asbr**
Display summary route information on the OSPFv3 ASBR.	**display ospfv3** [*process-id*] **asbr-summary** [*ipv6-address prefix-length*] [**verbose**]
Display OSPFv3 log information.	**display ospfv3** [*process-id*] **event-log** { **lsa-flush** | **peer** | **spf** }
Display OSPFv3 GR information.	**display ospfv3** [*process-id*] **graceful-restart** [**verbose**]
Display OSPFv3 interface information.	**display ospfv3** [*process-id*] **interface** [*interface-type interface-number* | **verbose**]
Display OSPFv3 LSDB information.	**display ospfv3** [*process-id*] **lsdb** [{ **external** | **grace** | **inter-prefix** | **inter-router** | **intra-prefix** | **link** | **network** | **nssa** | **router** | **unknown** [*type*] } [*link-state-id*] [**originate-router** *router-id* | **self-originate**] | **statistics** | **total** | **verbose**]
Display OSPFv3 next hop information.	**display ospfv3** [*process-id*] **nexthop**
Display OSPFv3 NSR information.	**display ospfv3** [*process-id*] **non-stop-routing**
Display OSPFv3 routing information.	**display ospfv3** [*process-id*] **routing** [*ipv6-address prefix-length*]
Display OSPFv3 statistics.	**display ospfv3** [*process-id*] **statistics** [**error**]
Display OSPFv3 virtual link information.	**display ospfv3** [*process-id*] **vlink**
Clear OSPFv3 log information.	**reset ospfv3** [*process-id*] **event-log** [**lsa-flush** | **peer** | **spf**]
Restart an OSPFv3 process.	**reset ospfv3** [*process-id*] **process** [**graceful-restart**]
Restart OSPFv3 route redistribution.	**reset ospfv3** [*process-id*] **redistribution**
Clear OSPFv3 statistics.	**reset ospfv3** [*process-id*] **statistics**

OSPFv3 configuration examples

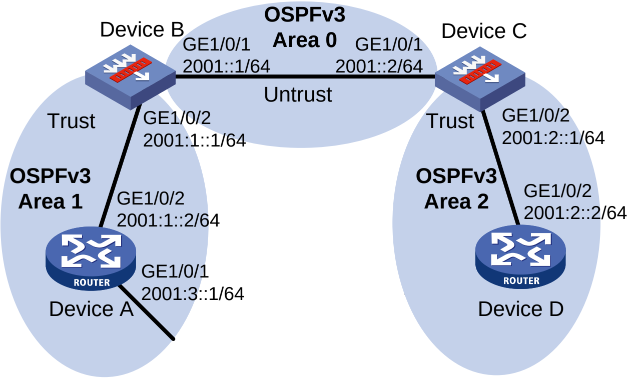
Example: Configuring OSPFv3 stub area

Network configuration

As shown in Figure 2:

- Enable OSPFv3 on all devices.
- Split the AS into three areas.
- Configure Device B and Device C as ABRs to forward routing information between areas.
- Configure Area 2 as a stub area to reduce LSAs in the area without affecting route reachability.

Figure 2 Network diagram



Procedure

# Configure Device B.

1. Configure IPv6 addresses for interfaces correctly according to Figure 2.
   a. Configure an IP address for GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ipv6 address 2001::1 64
[DeviceB-GigabitEthernet1/0/1] quit
```

   b. Configure IP addresses for other interfaces in the same way GigabitEthernet 1/0/1 is configured. (Details not shown.)

2. Add each interface on Device B to a security zone.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

3. Configure security policies.
   a. Configure a security policy to allow OSPFv3 neighbor relationship establishment by permitting traffic between security zone **untrust** and security zone **local**.

   # Create security policy rule **ospflocalin** and permit Device B to receive OSPFv3 packets from Device C.

```
[DeviceB] security-policy ipv6
```

```
[DeviceB-security-policy-ipv6] rule name ospflocalin
[DeviceB-security-policy-ipv6-0-ospflocalin] source-zone untrust
[DeviceB-security-policy-ipv6-0-ospflocalin] destination-zone local
[DeviceB-security-policy-ipv6-0-ospflocalin] service ospf
[DeviceB-security-policy-ipv6-0-ospflocalin] action pass
[DeviceB-security-policy-ipv6-0-ospflocalin] quit
```

# Create security policy rule **ospflocalout** and permit Device B to send OSPFv3 packets to Device C.

```
[DeviceB-security-policy-ipv6] rule name ospflocalout
[DeviceB-security-policy-ipv6-1-ospflocalout] source-zone local
[DeviceB-security-policy-ipv6-1-ospflocalout] destination-zone untrust
[DeviceB-security-policy-ipv6-1-ospflocalout] service ospf
[DeviceB-security-policy-ipv6-1-ospflocalout] action pass
[DeviceB-security-policy-ipv6-1-ospflocalout] quit
```

b. Configure a security policy to allow OSPFv3 neighbor relationship establishment by permitting traffic between security zone **trust** and security zone **local**.

# Create security policy rule **trust-local** and permit Device A to send OSPFv3 packets to Device B.

```
[DeviceB-security-policy-ipv6] rule name trust-local
[DeviceB-security-policy-ipv6-2-trust-local] source-zone trust
[DeviceB-security-policy-ipv6-2-trust-local] destination-zone local
[DeviceB-security-policy-ipv6-2-trust-local] service ospf
[DeviceB-security-policy-ipv6-2-trust-local] action pass
[DeviceB-security-policy-ipv6-2-trust-local] quit
```

# Create security policy rule **local-trust** and permit Device B to send OSPFv3 packets to Device A.

```
[DeviceB-security-policy-ip] rule name local-trust
[DeviceB-security-policy-ipv6-3-local-trust] source-zone local
[DeviceB-security-policy-ipv6-3-local-trust] destination-zone trust
[DeviceB-security-policy-ipv6-3-local-trust] service ospf
[DeviceB-security-policy-ipv6-3-local-trust] action pass
[DeviceB-security-policy-ipv6-3-local-trust] quit
```

c. Configure a security policy to permit traffic between security zone **untrust** and security zone **trust**.

# Create security policy rule **trust-untrust** and permit packets from security zone **trust** to security zone **untrust** to pass.

```
[DeviceB-security-policy-ipv6] rule name trust-untrust
[DeviceB-security-policy-ipv6-4-trust-untrust] source-zone trust
[DeviceB-security-policy-ipv6-4-trust-untrust] destination-zone untrust
[DeviceB-security-policy-ipv6-4-trust-untrust] source-ip-subnet 2001:1:: 64
[DeviceB-security-policy-ipv6-4-trust-untrust] destination-ip-subnet 2001:2::
64
[DeviceB-security-policy-ipv6-4-trust-untrust] action pass
[DeviceB-security-policy-ipv6-4-trust-untrust] quit
```

# Create security policy rule **untrust-trust** and permit packets from security zone **untrust** to security zone **trust** to pass.

```
[DeviceB-security-policy-ipv6] rule name untrust-trust
[DeviceB-security-policy-ipv6-5-untrust-trust] source-zone untrust
[DeviceB-security-policy-ipv6-5-untrust-trust] destination-zone trust
```

```
[DeviceB-security-policy-ipv6-5-untrust-trust] source-ip-subnet 2001:2:: 64
[DeviceB-security-policy-ipv6-5-untrust-trust] destination-ip-subnet 2001:1::
64
[DeviceB-security-policy-ipv6-5-untrust-trust] service ospf
[DeviceB-security-policy-ipv6-5-untrust-trust] quit
[DeviceB-security-policy-ipv6] quit
```

# Configure Device C.

1. Configure IPv6 addresses for interfaces correctly according to Figure 2.
   a. Configure an IP address for GigabitEthernet 1/0/1.

```
<DeviceC> system-view
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] ipv6 address 2001::2 64
[DeviceC-GigabitEthernet1/0/1] quit
```

   b. Configure IP addresses for other interfaces in the same way GigabitEthernet 1/0/1 is configured. (Details not shown.)

2. Add each interface on Device C to a security zone.

```
[DeviceC] security-zone name untrust
[DeviceC-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceC-security-zone-Untrust] quit
[DeviceC] security-zone name trust
[DeviceC-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceC-security-zone-Trust] quit
```

3. Configure security policies.
   a. Configure a security policy to allow OSPFv3 neighbor relationship establishment by permitting traffic between security zone **untrust** and security zone **local**.

   # Create security policy rule **ospflocalin** and permit Device C to receive OSPFv3 packets from Device B.

```
[DeviceC] security-policy ipv6
[DeviceC-security-policy-ipv6] rule name ospflocalin
[DeviceC-security-policy-ipv6-0-ospflocalin] source-zone untrust
[DeviceC-security-policy-ipv6-0-ospflocalin] destination-zone local
[DeviceC-security-policy-ipv6-0-ospflocalin] service ospf
[DeviceC-security-policy-ipv6-0-ospflocalin] action pass
[DeviceC-security-policy-ipv6-0-ospflocalin] quit
```

   # Create security policy rule **ospflocalout** and permit Device C to send OSPFv3 packets to Device B.

```
[DeviceC-security-policy-ipv6] rule name ospflocalout
[DeviceC-security-policy-ipv6-1-ospflocalout] source-zone local
[DeviceC-security-policy-ipv6-1-ospflocalout] destination-zone untrust
[DeviceC-security-policy-ipv6-1-ospflocalout] service ospf
[DeviceC-security-policy-ipv6-1-ospflocalout] action pass
[DeviceC-security-policy-ipv6-1-ospflocalout] quit
```

   b. Configure a security policy to allow OSPFv3 neighbor relationship establishment by permitting traffic between security zone **trust** and security zone **local**.

   # Create security policy rule **trust-local** and permit Device D to send OSPFv3 packets to Device C.

```
[DeviceC-security-policy-ipv6] rule name trust-local
[DeviceC-security-policy-ipv6-2-trust-local] source-zone trust
```

```
[DeviceC-security-policy-ipv6-2-trust-local] destination-zone local
[DeviceC-security-policy-ipv6-2-trust-local] service ospf
[DeviceC-security-policy-ipv6-2-trust-local] action pass
[DeviceC-security-policy-ipv6-2-trust-local] quit
```

# Create security policy rule **local-trust** and permit Device C to send OSPFv3 packets to Device D.

```
[DeviceC-security-policy-ipv6] rule name local-trust
[DeviceC-security-policy-ipv6-3-local-trust] source-zone local
[DeviceC-security-policy-ipv6-3-local-trust] destination-zone trust
[DeviceC-security-policy-ipv6-3-local-trust] service ospf
[DeviceC-security-policy-ipv6-3-local-trust] action pass
[DeviceC-security-policy-ipv6-3-local-trust] quit
```

c. Configure a security policy to permit traffic between security zone **untrust** and security zone **trust**.

# Create security policy rule **trust-untrust** and permit packets from security zone **trust** to security zone **untrust** to pass.

```
[DeviceC-security-policy-ipv6] rule name trust-untrust
[DeviceC-security-policy-ipv6-4-trust-untrust] source-zone trust
[DeviceC-security-policy-ipv6-4-trust-untrust] destination-zone untrust
[DeviceC-security-policy-ipv6-4-trust-untrust] source-ip-subnet 2001:2:: 64
[DeviceC-security-policy-ipv6-4-trust-untrust] destination-ip-subnet 2001:1::
64
[DeviceC-security-policy-ipv6-4-trust-untrust] action pass
[DeviceC-security-policy-ipv6-4-trust-untrust] quit
```

# Create security policy rule **untrust-trust** and permit packets from security zone **untrust** to security zone **trust** to pass.

```
[DeviceC-security-policy-ipv6] rule name untrust-trust
[DeviceC-security-policy-ipv6-5-untrust-trust] source-zone untrust
[DeviceC-security-policy-ipv6-5-untrust-trust] destination-zone trust
[DeviceC-security-policy-ipv6-5-untrust-trust] source-ip-subnet 2001:1:: 64
[DeviceC-security-policy-ipv6-5-untrust-trust] destination-ip-subnet 2001:2::
64
[DeviceC-security-policy-ipv6-5-trust-untrust] action pass
[DeviceC-security-policy-ipv6-5-trust-untrust] quit
[DeviceC-security-policy-ipv6] quit
```

4. Configure basic OSPFv3 functions:

# On Device A, enable OSPFv3 and specify the device ID as 1.1.1.1.

```
<DeviceA> system-view
[DeviceA] ospfv3 1
[DeviceA-ospfv3-1] router-id 1.1.1.1
[DeviceA-ospfv3-1] quit
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ospfv3 1 area 1
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] ospfv3 1 area 1
[DeviceA-GigabitEthernet1/0/2] quit
```

# On Device B, enable OSPFv3 and specify the device ID as 2.2.2.2.

```
[DeviceB] ospfv3 1
```

```
[DeviceB-ospfv3-1] router-id 2.2.2.2
[DeviceB-ospfv3-1] quit
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ospfv3 1 area 0
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] ospfv3 1 area 1
[DeviceB-GigabitEthernet1/0/2] quit
```

# On Device C, enable OSPFv3 and specify the device ID as 3.3.3.3.

```
[DeviceC] ospfv3 1
[DeviceC-ospfv3-1] router-id 3.3.3.3
[DeviceC-ospfv3-1] quit
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] ospfv3 1 area 0
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] ospfv3 1 area 2
[DeviceC-GigabitEthernet1/0/2] quit
```

# On Device D, enable OSPFv3 and specify the device ID as 4.4.4.4.

```
<DeviceD> system-view
[DeviceD] ospfv3 1
[DeviceD-ospfv3-1] router-id 4.4.4.4
[DeviceD-ospfv3-1] quit
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] ospfv3 1 area 2
[DeviceD-GigabitEthernet1/0/2] quit
```

5. Configure Area 2 as a stub area:

   # Configure Device D.

```
[DeviceD] ospfv3
[DeviceD-ospfv3-1] area 2
[DeviceD-ospfv3-1-area-0.0.0.2] stub
[DeviceD-ospfv3-1-area-0.0.0.2] quit
[DeviceD-ospfv3-1] quit
```

   # Configure Device C, and specify the cost of the default route sent to the stub area as 10.

```
[DeviceC] ospfv3
[DeviceC-ospfv3-1] area 2
[DeviceC-ospfv3-1-area-0.0.0.2] stub
[DeviceC-ospfv3-1-area-0.0.0.2] default-cost 10
```

Verifying the configuration

# Display OSPFv3 routing table on Device D.

```
[DeviceD] display ospfv3 routing

               OSPFv3 Process 1 with Router ID 4.4.4.4
-------------------------------------------------------------------------
 I  - Intra area route,  E1 - Type 1 external route,  N1 - Type 1 NSSA route
 IA - Inter area route,  E2 - Type 2 external route,  N2 - Type 2 NSSA route
 *  - Selected route
```

Configuring IS-IS

About IS-IS

IS-IS is an IGP used within an AS. It uses the SPF algorithm for route calculation.

Terminology

- **Intermediate system**—Similar to a router in TCP/IP, IS is the basic unit used in an IS-IS routing domain to generate and propagate routing information. Throughout this chapter, an IS refers to a router.
- **End system**—Similar to a host in TCP/IP, an ES does not run IS-IS. ISO defines the ES-IS protocol for communication between an ES and an IS.
- **Routing domain**—An RD comprises a group of ISs that exchange routing information with each other by using the same routing protocol.
- **Area**—An IS-IS routing domain can be split into multiple areas.
- **Link State Database**—All link states in the network form the LSDB. Each IS has a minimum of one LSDB. An IS uses the SPF algorithm and LSDB to generate IS-IS routes.
- **Link State Protocol Data Unit or Link State Packet**—An IS advertises link state information in an LSP.
- **Network Protocol Data Unit**—An NPDU is a network layer protocol packet in OSI, similar to an IP packet in TCP/IP.
- **Designated IS**—A DIS is elected on a broadcast network.
- **Network service access point**—An NSAP is an OSI network layer address. The NSAP identifies an abstract network service access point and describes the network address format in the OSI reference model.

IS-IS address

As shown in Figure 1, an NSAP address comprises the Initial Domain Part (IDP) and the Domain Specific Part (DSP). The IDP is analogous to the network ID of an IP address, and the DSP is analogous to the subnet and host ID.

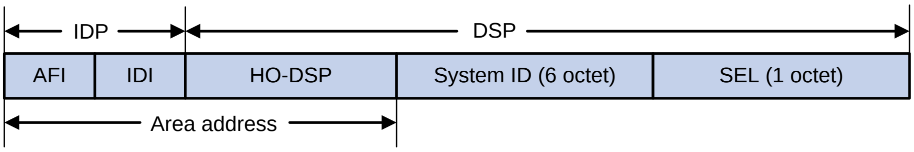
The IDP includes the Authority and Format Identifier (AFI) and the Initial Domain Identifier (IDI).

The DSP includes:

- **High Order Part of DSP (HO-DSP)**—Identifies the area.
- **System ID**—Identifies the host.
- **SEL**—Also known as the N-SEL or the NSAP selector (SEL). It is similar to the protocol identifier in IP and is used to identify the type of service. Different transport layer protocols correspond to different SELs.

The IDP and DSP are variable in length. The length of an NSAP address is in the range of 8 to 20 bytes.

Figure 1 NSAP address format



An IS-IS address contains the following components:

- Area address

  The area address comprises the IDP and the HO-DSP of the DSP, which identify the area and the routing domain. Different routing domains cannot have the same area address.

  Typically, a router only needs one area address, and all nodes in the same area must have the same area address. To support smooth area merging, partitioning, and switching, a router can have a maximum of three area addresses.

- System ID

  A system ID uniquely identifies a host or router. It has a fixed length of 48 bits (6 bytes).

  The system ID of a device can be generated from the router ID. For example, suppose a router uses the IP address 168.10.1.1 of Loopback 0 as the router ID. The system ID can be obtained in the following steps:

  a. Extend each decimal number of the IP address to three digits by adding 0s from the left, such as 168.010.001.001.

  b. Divide the extended IP address into three sections that each has four digits to get the system ID 1680.1000.1001.

  If you use other methods to define a system ID, make sure that it can uniquely identify the host or router.

- SEL

  An SEL is used to identify the type of service. Different transport layer protocols correspond to different SELs. It has a fixed length of 8 bits. All SELs in IP are 00.

NET

A network entity title (NET) identifies the network layer information of an IS. It does not include transport layer information. A NET is a special NSAP address with the SEL being 0. The length of a NET is in the range of 8 to 20 bytes, same as a NSAP address.

A NET includes the following parts:

- **Area ID**—Has a length of 1 to 13 bytes.
- **System ID**—A system ID uniquely identifies a host or router in the area and has a fixed length of 6 bytes.
- **SEL**—Has a value of 0 and a fixed length of 1 byte.

For example, for a NET ab.cdef.1234.5678.9abc.00, the area ID is ab.cdef, the system ID is 1234.5678.9abc, and the SEL is 00.

Typically, a router only needs one NET, but it can have a maximum of three NETs for smooth area merging and partitioning. When you configure multiple NETs, make sure the system IDs are the same.

IS-IS area

IS-IS has a 2-level hierarchy to support large-scale networks. A large-scale routing domain is divided into multiple areas. Typically, a Level-1 router is deployed within an area. A Level-2 router is deployed between areas. A Level-1-2 router is deployed between Level-1 and Level-2 routers.

Level-1 router

A Level-1 router establishes neighbor relationships with Level-1 and Level-1-2 routers in the same area. It maintains an LSDB comprising intra-area routing information. A Level-1 router forwards packets destined for external areas to the nearest Level-1-2 router. Level-1 routers in different areas cannot establish neighbor relationships.

Level-2 router

A Level-2 router establishes neighbor relationships with Level-2 and Level-1-2 routers in the same area or in different areas. It maintains a Level-2 LSDB containing inter-area routing information. All the Level-2 and Level-1-2 routers must be contiguous to form the backbone of the IS-IS routing domain. Level-2 routers can establish neighbor relationships even if they are in different areas.

Level-1-2 router

A router with both Level-1 and Level-2 router functions is a Level-1-2 router. It can establish Level-1 neighbor relationships with Level-1 and Level-1-2 routers in the same area. It can establish Level-2 neighbor relationships with Level-2 and Level-1-2 routers in different areas. A Level-1 router can reach other areas only through a Level-1-2 router. The Level-1-2 router maintains two LSDBs, a Level-1 LSDB for intra-area routing and a Level-2 LSDB for inter-area routing.

IS-IS topology

Figure 2 shows one IS-IS network topology. Area 1 is the backbone that comprises a set of Level-2 routers. The other four areas are non-backbone areas connected to the backbone through Level-1-2 routers.

Figure 2 IS-IS topology 1

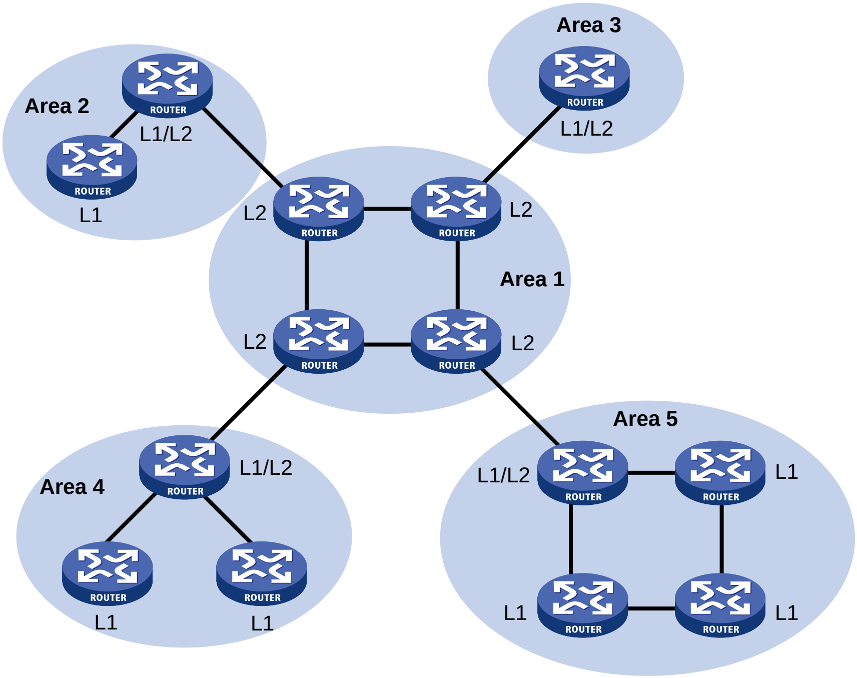


Figure 3 shows another IS-IS topology. No area is defined as the backbone in this topology. The backbone comprises all contiguous Level-2 and Level-1-2 routers in different areas. The IS-IS backbone does not need to be a specific area.

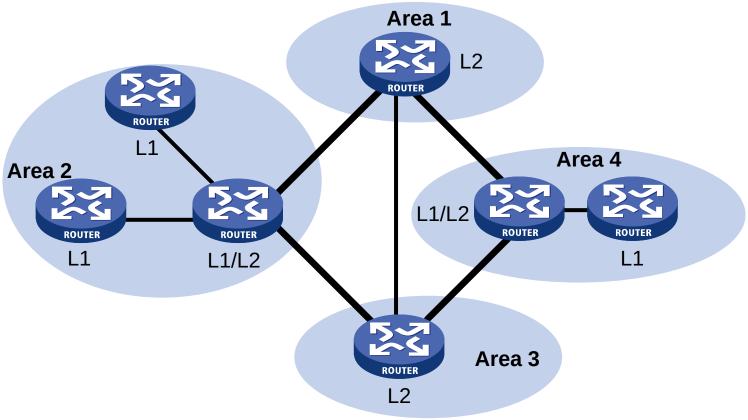
Figure 3 IS-IS topology 2



Both the Level-1 and Level-2 routers use the SPF algorithm to generate the shortest path tree.

Route leaking

Level-2 and Level-1-2 routers form a Level-2 area. An IS-IS routing domain comprises only one Level-2 area and multiple Level-1 areas. A Level-1 area must connect to the Level-1-2 area rather than another Level-1 area.

Level-1-2 routers send the routing information of Level-1 areas to the Level-2 area. Level-2 routers know the routing information of the entire IS-IS routing domain. By default, a Level-2 router does not advertise the routing information of other areas to a Level-1 area. A Level-1 router simply sends packets destined for other areas to the nearest Level-1-2 router. The path passing through the Level-1-2 router might not be the best. To solve this problem, IS-IS provides the route leaking feature.

Route leaking enables a Level-1-2 router to advertise the routes of other areas to the connected Level-1 area so that the Level-1 routers can select the optimal routes.

IS-IS network types

IS-IS supports broadcast networks (for example, Ethernet and Token Ring) and point-to-point networks (for example, PPP).

IS-IS cannot run on P2MP links.

DIS and pseudonodes

IS-IS routers on a broadcast network must elect a DIS.

The Level-1 and Level-2 DISs are elected separately. You can assign different priorities to a router for different level DIS elections. The higher the router priority, the more likely the router becomes the DIS. If multiple routers with the same highest DIS priority exist, the one with the highest Subnetwork Point of Attachment (SNPA) address will be elected. On a broadcast network, the SNPA address is the MAC address. A router can be the DIS for different levels.

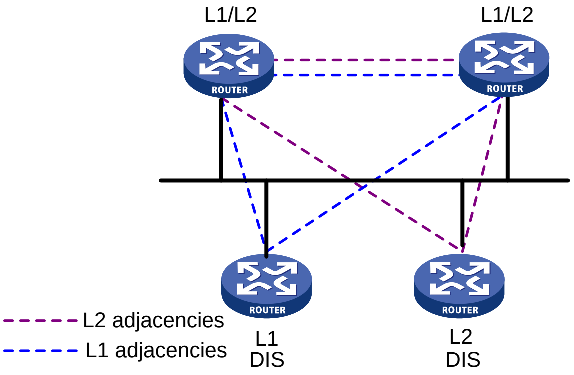
IS-IS DIS election differs from OSPF DIS election in the following ways:

- A router with priority 0 can also participate in the DIS election.

- When a router with a higher priority is added to the network, an LSP flooding process is performed to elect the router as the new DIS.

As shown in Figure 4, the same level routers on a network, including non-DIS routers, establish adjacency with each other.

Figure 4 DIS in the IS-IS broadcast network



The DIS creates and updates pseudonodes, and generates LSPs for the pseudonodes, to describe all routers on the network.

A pseudonode represents a virtual node on the broadcast network. It is not a real router. In IS-IS, it is identified by the system ID of the DIS and a 1-byte Circuit ID (a non-zero value).

Using pseudonodes simplifies network topology and can reduce the amount of resources consumed by SPF.

NOTE:

On an IS-IS broadcast network, all routers establish adjacency relationships, but they synchronize their LSDBs through the DIS.

IS-IS PDUs

PDU

IS-IS PDUs are encapsulated into link layer frames. An IS-IS PDU has two parts, the headers and the variable length fields. The headers comprise the PDU common header and the PDU specific header. All PDUs have the same PDU common header. The specific headers vary by PDU type.

Figure 5 PDU format

PDU common header	PDU specific header	Variable length fields (CLV)

Table 1 PDU types

Type	PDU Type	Acronym
15	Level-1 LAN IS-IS hello PDU	L1 LAN IIH
16	Level-2 LAN IS-IS hello PDU	L2 LAN IIH
17	Point-to-Point IS-IS hello PDU	P2P IIH
18	Level-1 Link State PDU	L1 LSP
20	Level-2 Link State PDU	L2 LSP
24	Level-1 Complete Sequence Numbers PDU	L1 CSNP

Type	PDU Type	Acronym
25	Level-2 Complete Sequence Numbers PDU	L2 CSNP
26	Level-1 Partial Sequence Numbers PDU	L1 PSNP
27	Level-2 Partial Sequence Numbers PDU	L2 PSNP

Hello PDU

IS-to-IS hello (IIH) PDUs are used by routers to establish and maintain neighbor relationships. On broadcast networks, Level-1 routers use Level-1 LAN IIHs, and Level-2 routers use Level-2 LAN IIHs. The P2P IIHs are used on point-to-point networks.

LSP

The LSPs carry link state information. LSPs include Level-1 LSPs and Level-2 LSPs. The Level-2 LSPs are sent by the Level-2 routers, and the Level-1 LSPs are sent by the Level-1 routers. The Level-1-2 router can send both types of LSPs.

SNP

A sequence number PDU (SNP) describes the complete or partial LSPs for LSDB synchronization.

SNPs include CSNP and PSNP, which are further divided into Level-1 CSNP, Level-2 CSNP, Level-1 PSNP, and Level-2 PSNP.

A CSNP describes the summary of all LSPs for LSDB synchronization between neighboring routers. On broadcast networks, CSNPs are sent by the DIS periodically (every 10 seconds by default). On point-to-point networks, CSNPs are sent only during the first adjacency establishment.

A PSNP only contains the sequence numbers of one or multiple latest received LSPs. It can acknowledge multiple LSPs at one time. When LSDBs are not synchronized, a PSNP is used to request missing LSPs from a neighbor.

CLV

The variable fields of PDU comprise multiple Code-Length-Value (CLV) triplets.

Figure 6 CLV format

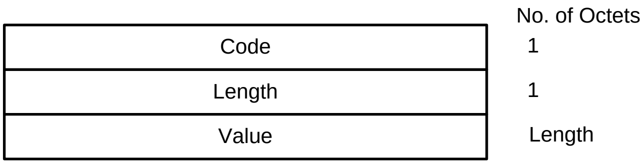


Table 2 shows that different PDUs contain different CLVs. Codes 1 through 10 are defined in ISO 10589 (code 3 and 5 are not shown in the table). Codes 128 through 132 are defined in RFC 1195. Codes 222 through 237 are defined in RFC 5120.

Table 2 CLV codes and PDU types

CLV Code	Name	PDU Type
1	Area Addresses	IIH, LSP
2	IS Neighbors (LSP)	LSP
4	Partition Designated Level 2 IS	L2 LSP
6	IS Neighbors (MAC Address)	LAN IIH
7	IS Neighbors (SNPA Address)	LAN IIH
8	Padding	IIH

CLV Code	Name	PDU Type
9	LSP Entries	SNP
10	Authentication Information	IIH, LSP, SNP
128	IP Internal Reachability Information	LSP
129	Protocols Supported	IIH, LSP
130	IP External Reachability Information	L2 LSP
131	Inter-Domain Routing Protocol Information	L2 LSP
132	IP Interface Address	IIH, LSP
222	MT-ISN	LSP
229	M-Topologies	IIH, LSP
235	MT IP. Reach	LSP
237	MT IPv6 IP. Reach	LSP

IPv6 IS-IS

IS-IS supports multiple network protocols, including IPv6. To support IPv6, the IETF added two type-length-values (TLVs) and a new network layer protocol identifier (NLPID).

The TLVs are as follows:

- **IPv6 Reachability**—Contains routing prefix and metric information to describe network reachability and has a type value of 236 (0xEC).
- **IPv6 Interface Address**—Same as the "IP Interface Address" TLV in IPv4 ISIS, except that the 32-bit IPv4 address is translated to the 128-bit IPv6 address.

The new NLPID is an 8-bit field that identifies which network layer protocol is supported. For IPv6, the NLPID is 142 (0x8E).

IPv4 IS-IS tasks at a glance

To configure IPv4 IS-IS, perform the following tasks:

1. Configuring basic IS-IS
   a. Enabling IPv4 IS-IS
   b. (Optional.) Setting the IS level and circuit level
   c. (Optional.) Configuring P2P network type for an interface

2. (Optional.) Configuring IS-IS route control
    - Configuring IS-IS link cost
    - Specifying a preference for IS-IS
    - Configuring the maximum number of ECMP routes
    - Configuring IS-IS route summarization
    - Advertising a default route
    - Configuring IS-IS route redistribution
    - Filtering routes calculated from received LSPs
    - Filtering redistributed routes
    - Configuring IS-IS route leaking
    - Advertising IS-IS link state information to BGP
3. (Optional.) Configuring IS-IS timers
    - Specifying the interval for sending IS-IS hello packets
    - Specifying the interval for sending IS-IS CSNP packets
    - Setting the maximum age of LSPs
    - Setting the LSP refresh interval and generation interval
    - Setting LSP sending intervals
    - Setting the SPF calculation interval
4. (Optional.) Configuring IS-IS packet-related features
    - Configuring a DIS priority for an interface
    - Configuring the tag value for an interface
    - Specifying the IS-IS hello multiplier
    - Disabling an interface from sending/receiving IS-IS packets
    - Enabling an interface to send small hello packets
    - Setting LSP lengths
    - Enabling LSP flash flooding
    - Enabling LSP fragment extension
5. (Optional.) Configuring advanced IS-IS features
    - Enabling source address check for hello packets on a P2P interface
    - Configuring convergence priorities for specific routes
    - Setting the LSDB overload bit
    - Configuring the ATT bit
    - Configuring system ID to host name mappings
    - Enabling IS-IS to group ECMP routes
6. (Optional.) Configuring IS-IS logging and SNMP notifications
    - Enabling the logging of neighbor state changes
    - Configuring IS-IS network management
7. (Optional.) Configuring IS-IS fast convergence
    - Enabling ISPF
    - Enabling prefix suppression
    - Configuring IS-IS PIC
8. (Optional.) Enhancing IS-IS network security
    - Configuring neighbor relationship authentication
    - Configuring area authentication

- Configuring routing domain authentication

9. (Optional.) Enhancing IS-IS network reliability
   - Configuring IS-IS GR
   - Configuring IS-IS NSR
   - Configuring BFD for IS-IS
   - Controlling adjacency establishment and maintenance based on BFD session state
   - Configuring IS-IS FRR

IPv6 IS-IS tasks at a glance

To configure IPv6 IS-IS, perform the following tasks:

1. Configuring basic IS-IS
   a. Enabling IPv6 IS-IS
   b. (Optional.) Setting the IS level and circuit level
   c. (Optional.) Configuring P2P network type for an interface
2. (Optional.) Configuring IPv6 IS-IS MTR
3. (Optional.) Configuring IS-IS route control
   - Configuring IS-IS link cost
   - Specifying a preference for IS-IS
   - Configuring the maximum number of ECMP routes
   - Configuring IS-IS route summarization
   - Advertising a default route
   - Configuring IS-IS route redistribution
   - Filtering routes calculated from received LSPs
   - Filtering redistributed routes
   - Configuring IS-IS route leaking
   - Advertising IS-IS link state information to BGP
4. (Optional.) Configuring IS-IS timers
   - Specifying the interval for sending IS-IS hello packets
   - Specifying the interval for sending IS-IS CSNP packets
   - Setting the maximum age of LSPs
   - Setting the LSP refresh interval and generation interval
   - Setting LSP sending intervals
   - Setting the SPF calculation interval
5. (Optional.) Configuring IS-IS packet-related features
   - Configuring a DIS priority for an interface
   - Configuring the tag value for an interface
   - Specifying the IS-IS hello multiplier
   - Disabling an interface from sending/receiving IS-IS packets
   - Enabling an interface to send small hello packets
   - Setting LSP lengths
   - Enabling LSP flash flooding
   - Enabling LSP fragment extension
6. (Optional.) Configuring advanced IS-IS features

- Enabling source address check for hello packets on a P2P interface
- Configuring convergence priorities for specific routes
- Setting the LSDB overload bit
- Configuring the ATT bit
- Enabling IS-IS to group ECMP routes

7. (Optional.) Configuring IS-IS logging and SNMP notifications
   - Enabling the logging of neighbor state changes
   - Configuring IS-IS network management
8. (Optional.) Configuring IS-IS fast convergence
   - Enabling ISPF
   - Enabling prefix suppression
   - Configuring IS-IS PIC
9. (Optional.) Enhancing IS-IS network security
   - Configuring neighbor relationship authentication
   - Configuring area authentication
   - Configuring routing domain authentication
10. (Optional.) Enhancing IS-IS network reliability
    - Configuring IS-IS GR
    - Configuring IS-IS NSR
    - Configuring BFD for IS-IS
    - Controlling adjacency establishment and maintenance based on BFD session state
    - Configuring IS-IS FRR

Configuring basic IS-IS

Enabling IPv4 IS-IS

1. Enter system view.

   system-view
2. Enable IS-IS and enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   By default, IS-IS is disabled.
3. Assign a NET.

   network-entity *net*

   By default, NET is not assigned.

CAUTION:

When you execute the **network-entity** command together with the **cost-style** and **is-level** commands for the same IS-IS process, execute the **network-entity** command at last. Incorrect configuration order might cause data loss because the IS-IS process will restart.

4. Return to system view.

   quit
5. Enter interface view.

interface *interface-type interface-number*

6. Enable IS-IS on the interface.

   isis enable [*process-id*]

   By default, IS-IS is disabled.

Enabling IPv6 IS-IS

1. Enter system view.

   system-view

2. Enable an IS-IS process and enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   By default, no IS-IS process is enabled.

3. Configure the NET for the IS-IS process.

   network-entity *net*

   By default, the NET is not configured.

△ **CAUTION:**

When you execute the **network-entity** command together with the **cost-style** and **is-level** commands for the same IS-IS process, execute the **network-entity** command at last. Incorrect configuration order might cause data loss because the IS-IS process will restart.

4. Create the IPv6 address family and enter its view.

   address-family ipv6 [**unicast**]

5. Return to IS-IS view.

   quit

6. Return to system view.

   quit

7. Enter interface view.

   interface *interface-type interface-number*

8. Enable IPv6 for IS-IS on the interface.

   isis ipv6 enable [*process-id*]

   By default, IPv6 is disabled for IS-IS on an interface.

Setting the IS level and circuit level

About this task

Follow these guidelines when you configure the IS level for routers in only one area:

- Set the IS level of all routers to Level-1 or Level-2 rather than different levels because the routers do not need to maintain two identical LSDBs.
- Set the IS level to Level-2 on all routers in an IP network for good scalability.

For an interface of a Level-1 or Level-2 router, the circuit level can only be Level-1 or Level-2. For an interface of a Level-1-2 router, the default circuit level is Level-1-2. If the router only needs to form Level-1 or Level-2 neighbor relationships, set the circuit level for its interfaces to Level-1 or Level-2. This will limit neighbor relationship establishment.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Specify the IS level.

   is-level { **level-1** | **level-1-2** | **level-2** }

   By default, the IS level is Level-1-2.

4. Return to system view.

   quit

5. Enter interface view.

   interface *interface-type interface-number*

6. Specify the circuit level.

   isis circuit-level [**level-1** | **level-1-2** | **level-2**]

   By default, an interface can establish either the Level-1 or Level-2 adjacency.

Configuring P2P network type for an interface

About this task

Interfaces with different network types operate differently. For example, broadcast interfaces on a network must elect the DIS and flood CSNP packets to synchronize the LSDBs. However, P2P interfaces on a network do not need to elect the DIS, and have a different LSDB synchronization mechanism.

If only two routers exist on a broadcast network, set the network type of attached interfaces to P2P. This avoids DIS election and CSNP flooding, saving network bandwidth and speeding up network convergence.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure P2P network type for an interface.

   isis circuit-type p2p

   By default, the network type of an interface is broadcast.

   Perform this task only for a broadcast network that has up to two attached routers.

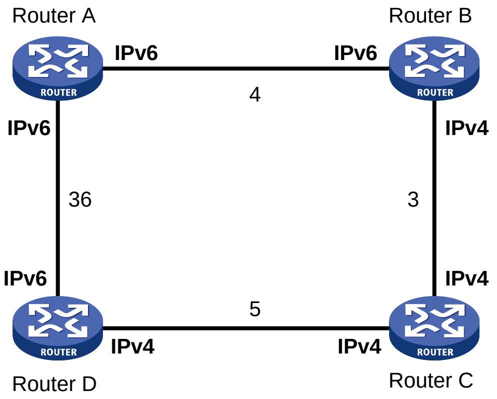
Configuring IPv6 IS-IS MTR

About this task

On a network, IPv4 and IPv6 topologies must be consistent so that both IPv6 IS-IS and IPv4 IS-IS can use the SPF algorithm to perform route calculation. If they are different, routers supporting both IPv4 and IPv6 might send IPv6 packets to routers that do not support IPv6, resulting in packet loss.

To resolve this issue, configure IPv6 IS-IS MTR to perform route calculation separately in IPv4 and IPv6 topologies.

Figure 7 Network diagram



As shown in Figure 7, the numbers refer to the link costs. Router A, Router B, and Router D support both IPv4 and IPv6. Router C supports only IPv4 and cannot forward IPv6 packets.

Enable IPv6 IS-IS MTR on Router A, Router B, Router C, and Router D to make them perform route calculation separately in IPv4 and IPv6 topologies. With this configuration, Router A does not forward IPv6 packets destined to Router D through Router B, avoiding packet loss.

Restrictions and guidelines

As a best practice to avoid route calculation failures, configure this feature when both IPv4 and IPv6 topologies exist in the network.

Procedure

1. Enter system view.

`system-view`

2. Enter IS-IS view.

`isis` [*`process-id`*] [**`vpn-instance`** *`vpn-instance-name`*]

3. Specify an IS-IS cost style.

`cost-style` { **`compatible`** | **`wide`** | **`wide-compatible`** }

By default, IS-IS only transmits and receives packets using the **`narrow`** cost style.

4. Enter IPv6 address family view.

`address-family ipv6` [**`unicast`**]

5. Enable IPv6 IS-IS MTR.

`multi-topology` [**`compatible`**]

By default, IPv6 IS-IS MTR is disabled.

Configuring IS-IS route control

Configuring IS-IS link cost

About this task

The IS-IS cost of an interface is determined in the following order:

1. IS-IS cost specified in interface view.

2. IS-IS cost specified in system view.

The cost is applied to the interfaces associated with the IS-IS process.

3. Automatically calculated cost.

If the cost style is **wide** or **wide-compatible**, IS-IS automatically calculates the cost using the formula: Interface cost = (Bandwidth reference value / Expected interface bandwidth) × 10, in the range of 1 to 16777214. For other cost styles, Table 3 applies.

Configure the expected bandwidth of an interface with the **bandwidth** command.

Table 3 Automatic cost calculation scheme for cost styles other than wide and wide-compatible

Interface bandwidth	Interface cost
≤ 10 Mbps	60
≤ 100 Mbps	50
≤ 155 Mbps	40
≤ 622 Mbps	30
≤ 2500 Mbps	20
> 2500 Mbps	10

4. If none of the above costs is used, a default cost of 10 applies.

Configuring an IPv4 IS-IS cost for an interface

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. (Optional.) Specify an IS-IS cost style.

   cost-style { **narrow** | **wide** | **wide-compatible** | { **compatible** | **narrow-compatible** } [**relax-spf-limit**] }

   By default, the IS-IS cost type is **narrow**.

4. Return to system view.

   quit

5. Enter interface view.

   interface *interface-type interface-number*

6. Specify a cost for the IS-IS interface.

   isis cost *cost-value* [**level-1** | **level-2**]

   By default, no cost for the interface is specified.

Configuring a global IPv4 IS-IS cost

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Specify a global IS-IS cost.

   circuit-cost *cost-value* [**level-1** | **level-2**]

   By default, no global cost is specified.

Enabling automatic IPv4 IS-IS cost calculation

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable automatic IS-IS cost calculation.

   auto-cost enable

   By default, automatic IS-IS cost calculation is disabled.

4. (Optional.) Configure a bandwidth reference value for automatic IS-IS cost calculation.

   bandwidth-reference *value*

   The default setting is 100 Mbps.

Configuring an IPv6 IS-IS cost for an interface

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. (Optional.) Specify an IS-IS cost style.

   cost-style { **narrow** | **wide** | **wide-compatible** | { **compatible** | **narrow-compatible** } [**relax-spf-limit**] }

   By default, the IS-IS cost type is **narrow**.

4. Enter IPv6 address family view.

   address-family ipv6 [**unicast**]

5. Return to IS-IS view.

   quit

6. Return to system view.

   quit

7. Enter interface view.

   interface *interface-type interface-number*

8. Enable IPv6 for IS-IS on the interface.

   isis ipv6 enable [*process-id*]

   By default, IPv6 is disabled for IS-IS on an interface.

9. Specify an IPv6 cost for the IS-IS interface.

   isis ipv6 cost *cost-value* [**level-1** | **level-2**]

   By default, no IPv6 cost is specified for the interface.

Configuring a global IPv6 IS-IS cost

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Specify a global IPv6 IS-IS cost.

   circuit-cost *cost-value* [**level-1** | **level-2**]

   By default, no global IPv6 cost is specified.

Enabling automatic IPv6 IS-IS cost calculation

1. Enter system view.

system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Specify an IS-IS cost style.

   cost-style { **wide** | **wide-compatible** }

   By default, the IS-IS cost style is **narrow**.

4. Enter IPv6 address family view.

   address-family ipv6 [**unicast**]

5. Enable automatic IPv6 IS-IS cost calculation.

   auto-cost enable

   By default, automatic IPv6 IS-IS cost calculation is disabled.

6. (Optional.) Configure a bandwidth reference value for automatic IPv6 IS-IS cost calculation.

   bandwidth-reference *value*

   By default, the bandwidth reference value is 100 Mbps.

Specifying a preference for IS-IS

About this task

If multiple routing protocols find routes to the same destination, the route found by the routing protocol that has the highest preference is selected as the optimal route.

Perform this task to assign a preference to IS-IS directly or by using a routing policy. For more information about the routing policy, see "Configuring routing policies."

Configuring a preference for IPv4 IS-IS

1. Enter system view.

   system-view

2. Enter IS-IS IPv4 unicast address family view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   address-family ipv4 [**unicast**]

3. Configure a preference for IPv4 IS-IS.

   preference { *preference* | **route-policy** *route-policy-name* } *

   The default setting is 15.

Configuring a preference for IPv6 IS-IS

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Configure a preference for IPv6 IS-IS.

   preference { **route-policy** *route-policy-name* | *preference* } *

   The default setting is 15.

Configuring the maximum number of ECMP routes

About this task

Perform this task to implement load sharing over ECMP routes.

Configuring the maximum number of ECMP routes for IPv4 IS-IS

1. Enter system view.

   system-view

2. Enter IS-IS IPv4 unicast address family view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   address-family ipv4 [**unicast**]

3. Specify the maximum number of ECMP routes.

   maximum load-balancing *number*

   By default, the maximum number of ECMP routes supported by IPv4 IS-IS equals the maximum number of ECMP routes supported by the system.

Configuring the maximum number of ECMP routes for IPv6 IS-IS

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Specify the maximum number of ECMP routes.

   maximum load-balancing *number*

   By default, the maximum number of ECMP routes supported by IPv6 IS-IS equals the maximum number of ECMP routes supported by the system.

Configuring IS-IS route summarization

About this task

Perform this task to summarize specific routes, including IS-IS routes and redistributed routes, into a single route. Route summarization can reduce the routing table size and the LSDB scale.

Route summarization applies only to locally generated LSPs.

Configuring IPv4 IS-IS route summarization

1. Enter system view.

   system-view

2. Enter IS-IS IPv4 unicast address family view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   address-family ipv4 [**unicast**]

3. Configure IPv4 IS-IS route summarization.

   summary *ip-address* { *mask-length* | *mask* } [**avoid-feedback** | **generate_null0_route** | [**level-1** | **level-1-2** | **level-2**] | **tag** *tag*] *

   By default, IPv4 IS-IS route summarization is not configured.

   The cost of the summary route is the lowest one among the costs of the more-specific routes.

Configuring IPv6 IS-IS route summarization

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Configure IPv6 IS-IS route summarization.

   summary *ipv6-prefix prefix-length* [**avoid-feedback** | **generate_null0_route** | [**level-1** | **level-1-2** | **level-2**] | **tag** *tag*] *

   By default, IPv6 IS-IS route summarization is not configured.

Advertising a default route

About this task

IS-IS cannot redistribute a default route to its neighbors. This task enables IS-IS to advertise a default route of 0.0.0.0/0 in an LSP to the same-level neighbors. Upon receiving the default route, the neighbors add it into their routing table.

Advertising an IPv4 IS-IS default route

1. Enter system view.

   system-view

2. Enter IS-IS IPv4 unicast address family view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   address-family ipv4 [**unicast**]

3. Advertise a Level-1 or Level-2 default route.

   default-route-advertise [[**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name*] *

   By default, IPv4 IS-IS does not advertise a Level-1 or Level-2 default route.

Advertising an IPv6 IS-IS default route

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Advertise a Level-1 or Level-2 default route.

   default-route-advertise [**avoid-learning** | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

   By default, IPv6 IS-IS does not advertise a Level-1 or Level-2 default route.

Configuring IS-IS route redistribution

About this task

Perform this task to redistribute routes from other routing protocols into IS-IS. You can specify a cost for redistributed routes and specify the maximum number of redistributed routes.

Restrictions and guidelines

This command redistributes only active routes. To display active routes, use the **`display ip routing-table protocol`** command.

Configuring IPv4 IS-IS route redistribution

1. Enter system view.

   ```
   system-view
   ```

2. Enter IS-IS IPv4 unicast address family view.

   ```
   isis [ process-id ] [ vpn-instance vpn-instance-name ]
   address-family ipv4 [ unicast ]
   ```

3. Redistribute routes from other routing protocols or other IS-IS processes.

   ```
   import-route bgp [ as-number ] [ allow-ibgp ] [ cost cost-value |
   cost-type { external | internal } | [ level-1 | level-1-2 | level-2 ] |
   route-policy route-policy-name | tag tag ] *
   ```

   ```
   import-route { direct | static } [ cost cost-value | cost-type { external
   | internal } | [ level-1 | level-1-2 | level-2 ] | route-policy
   route-policy-name | tag tag ] *
   ```

   ```
   import-route [ allow-direct | cost cost-value | cost-type { external |
   internal } | [ level-1 | level-1-2 | level-2 ] | route-policy
   route-policy-name | tag tag ] *
   ```

   ```
   import-route { isis | ospf | rip } [ process-id | all-processes ]
   [ allow-direct | cost cost-value | cost-type { external | internal } |
   [ level-1 | level-1-2 | level-2 ] | route-policy route-policy-name | tag
   tag ] *
   ```

   By default, IS-IS does not redistribute routes.

4. (Optional.) Configure the maximum number of redistributed Level 1/Level 2 IPv4 routes.

   ```
   import-route limit number
   ```

   By default, IS-IS does not redistribute Level 1/Level 2 IPv4 routes.

Configuring IPv6 IS-IS route redistribution

1. Enter system view.

   ```
   system-view
   ```

2. Enter IS-IS view.

   ```
   isis [ process-id ] [ vpn-instance vpn-instance-name ]
   ```

3. Enter IS-IS IPv6 address family view.

   ```
   address-family ipv6 [ unicast ]
   ```

4. Redistribute routes from other routing protocols or other IS-IS processes.

   ```
   import-route protocol [ as-number | process-id ] [ allow-ibgp ]
   [ allow-direct | cost cost-value | [ level-1 | level-1-2 | level-2 ] |
   route-policy route-policy-name | tag tag ] *
   ```

   By default, IPv6 IS-IS does not redistribute routes.

5. (Optional.) Configure the maximum number of redistributed Level 1/Level 2 IPv6 routes.

import-route limit *number*

By default, IS-IS does not redistribute Level 1/Level 2 IPv6 routes.

Filtering routes calculated from received LSPs

About this task

IS-IS saves LSPs received from neighbors in the LSDB, and uses the SPF algorithm to calculate the shortest path tree with itself as the root. IS-IS installs the calculated routes to the IS-IS routing table and the optimal routes to the IP routing table.

Perform this task to filter calculated routes. Only routes that are not filtered can be added to the IP routing table. The filtered routes retain in the IS-IS routing table and can be advertised to neighbors.

Filtering IPv4 IS-IS routes calculated from received LSPs

1. Enter system view.

   system-view
2. Enter IS-IS IPv4 unicast address family view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   address-family ipv4 [**unicast**]
3. Filter routes calculated using received LSPs.

   filter-policy { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **import**

   By default, IPv4 IS-IS route filtering is not configured.

Filtering IPv6 IS-IS routes calculated from received LSPs

1. Enter system view.

   system-view
2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]
4. Filter routes calculated using received LSPs.

   filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **import**

   By default, IPv6 IS-IS route filtering is not configured.

Filtering redistributed routes

About this task

IS-IS can redistribute routes from other routing protocols or other IS-IS processes, add them to the IS-IS routing table, and advertise them in LSPs.

Perform this task to filter redistributed routes. Only routes that are not filtered can be added to the IS-IS routing table and advertised to neighbors.

Restrictions and guidelines

Use this command together with the **import-route** command.

Filtering redistributed IPv4 IS-IS routes

1. Enter system view.

```
system-view
```

2. Enter IS-IS IPv4 unicast address family view.

   ```
   isis [ process-id ] [ vpn-instance vpn-instance-name ]
   address-family ipv4 [ unicast ]
   ```

3. Filter routes redistributed from other routing protocols or IS-IS processes.

   ```
   filter-policy { ipv4-acl-number | prefix-list prefix-list-name |
   route-policy route-policy-name } export [ bgp | direct | { isis | ospf |
   rip } process-id | static ]
   ```

   By default, IPv4 IS-IS route filtering is not configured.

Filtering redistributed IPv6 IS-IS routes

1. Enter system view.

   ```
   system-view
   ```

2. Enter IS-IS view.

   ```
   isis [ process-id ] [ vpn-instance vpn-instance-name ]
   ```

3. Enter IS-IS IPv6 address family view.

   ```
   address-family ipv6 [ unicast ]
   ```

4. Filter routes redistributed from other routing protocols or IS-IS processes.

   ```
   filter-policy { ipv6-acl-number | prefix-list prefix-list-name |
   route-policy route-policy-name } export [ bgp4+ | direct | { isisv6 |
   ospfv3 | ripng } process-id | static ]
   ```

   By default, IPv6 IS-IS route filtering is not configured.

Configuring IS-IS route leaking

About this task

Perform this task to control route advertisement (route leaking) between Level-1 and Level-2.

You can configure IS-IS to advertise routes from Level-2 to Level-1, and to not advertise routes from Level-1 to Level-2.

Configuring IPv4 IS-IS route leaking

1. Enter system view.

   ```
   system-view
   ```

2. Enter IS-IS IPv4 unicast address family view.

   ```
   isis [ process-id ] [ vpn-instance vpn-instance-name ]
   address-family ipv4 [ unicast ]
   ```

3. Configure route leaking from Level-1 to Level-2.

   ```
   import-route isis level-1 into level-2 [ filter-policy
   { ipv4-acl-number | prefix-list prefix-list-name | route-policy
   route-policy-name } | tag tag ] *
   ```

   By default, IS-IS advertises routes from Level-1 to Level-2.

4. Configure route leaking from Level-2 to Level-1.

   ```
   import-route isis level-2 into level-1 [ filter-policy
   { ipv4-acl-number | prefix-list prefix-list-name | route-policy
   route-policy-name } | tag tag ] *
   ```

   By default, IS-IS does not advertise routes from Level-2 to Level-1.

Configuring IPv6 IS-IS route leaking

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Configure route leaking from Level-2 to Level-1.

   import-route isisv6 level-2 into level-1 [**filter-policy** { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } | **tag** *tag*] *

   By default, IS-IS does not advertise routes from Level-2 to Level-1.

5. Configure route leaking from Level-1 to Level-2.

   import-route isisv6 level-1 into level-2 [**filter-policy** { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } | **tag** *tag*] *

   By default, IS-IS advertises routes from Level-1 to Level-2.

Advertising IS-IS link state information to BGP

About this task

After the device advertises IS-IS link state information to BGP, BGP can advertise the information for intended applications. For more information about BGP LS, see "Configuring BGP."

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Advertise IS-IS link state information to BGP.

   distribute bgp-ls [**instance-id** *id*] [**level-1** | **level-2**]

   By default, the device does not advertise IS-IS link state information to BGP.

Configuring IS-IS timers

Specifying the interval for sending IS-IS hello packets

About this task

If a neighbor does not receive any hello packets from the router within the advertised hold time, it considers the router down and recalculates the routes. The hold time is the hello multiplier multiplied by the hello interval.

Restrictions and guidelines

The interval between hello packets sent by the DIS is 1/3 the hello interval set with the **isis timer hello** command.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify the interval for sending hello packets.

   isis timer hello *seconds* [**level-1** | **level-2**]

   The default setting is 10 seconds.

Specifying the interval for sending IS-IS CSNP packets

About this task

On a broadcast network, perform this task on the DIS that uses CSNP packets to synchronize LSDBs.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify the interval for sending CSNP packets on the DIS of a broadcast network.

   isis timer csnp *seconds* [**level-1** | **level-2**]

   The default setting is 10 seconds.

Setting the maximum age of LSPs

About this task

Each LSP has an age that decreases in the LSDB. Any LSP with an age of 0 is deleted from the LSDB. You can adjust the age value based on the scale of a network.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set the maximum LSP age.

   timer lsp-max-age *seconds*

   The default setting is 1200 seconds.

Setting the LSP refresh interval and generation interval

About this task

Each router needs to refresh its LSPs at a configurable interval and send them to other routers to prevent valid routes from aging out. A smaller refresh interval speeds up network convergence but consumes more bandwidth.

When network topology changes such as neighbor state, interface metric, system ID, or area ID changes occur, the router generates an LSP after a configurable interval. If such a change occurs frequently, excessive LSPs are generated, consuming a large amount of router resources and bandwidth. To solve the problem, you can adjust the LSP generation interval.

Restrictions and guidelines

Follow these restrictions and guidelines when you configure the **timer lsp-generation** command:

- If you specify only the *maximum-interval* argument, the LSP generation interval is *maximum-interval*.
- If you do not specify the *incremental-interval* argument, the LSP generation interval is in the range of *minimum-interval* to *maximum-interval*.
- If you specify the *incremental-interval* argument, the LSP generation interval is as follows:
    - When network changes are not frequent, the *minimum-interval* is adopted.
    - If network changes are frequent, the LSP generation interval increases by *incremental-interval* × 2^{n-2} (n is the number of calculation times) each time a generation occurs until the *maximum-interval* is reached.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set the LSP refresh interval.

   timer lsp-refresh *seconds*

   By default, the LSP refresh interval is 900 seconds.

4. Set the LSP generation interval.

   timer lsp-generation *maximum-interval* [*minimum-interval* [*incremental-interval*]] [**level-1** | **level-2**]

   By default:

    - The maximum interval is 5 seconds.
    - The minimum interval is 50 milliseconds.
    - The incremental interval is 200 milliseconds.

Setting LSP sending intervals

About this task

If a change occurs in the LSDB, IS-IS advertises the changed LSP to neighbors. You can specify the minimum interval for sending these LSPs to control the amount of LSPs on the network.

On a P2P link, IS-IS requires an advertised LSP be acknowledged. If no acknowledgment is received within a configurable interval, IS-IS will retransmit the LSP.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify the minimum interval for sending LSPs and the maximum LSP number that can be sent at a time.

   isis timer lsp *time* [**count** *count*]

   By default, the minimum interval is 33 milliseconds, and the maximum LSP number that can be sent at a time is 5.

4. Specify the LSP retransmission interval on a P2P link.

   isis timer retransmit *seconds*

   By default, the LSP retransmission interval on a P2P link is 5 seconds.

Setting the SPF calculation interval

About this task

Based on the LSDB, an IS-IS router uses the SPF algorithm to calculate the shortest path tree with itself being the root, and uses the shortest path tree to determine the next hop to a destination network. By adjusting the SPF calculation interval, you can prevent bandwidth and router resources from being over consumed due to frequent topology changes.

When network changes are not frequent, the *minimum-interval* is adopted. If network changes become frequent, the SPF calculation interval increases by *incremental-interval* × 2^{n-2} (n is the number of calculation times) each time a calculation occurs until the *maximum-interval* is reached.

Setting the IPv4 SPF calculation interval

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set the SPF calculation interval.

   timer spf *maximum-interval* [*minimum-interval* [*incremental-interval*]]

   By default:

   - The maximum interval is 5 seconds.
   - The minimum interval is 50 milliseconds.
   - The incremental interval is 200 milliseconds.

Setting the IPv6 SPF calculation interval

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Set the SPF calculation interval.

   timer spf *maximum-interval* [*minimum-interval* [*incremental-interval*]]

   By default:

   - The maximum interval is 5 seconds.
   - The minimum interval is 50 milliseconds.

- The incremental interval is 200 milliseconds.

Configuring IS-IS packet-related features

Configuring a DIS priority for an interface

About this task

On a broadcast network, IS-IS must elect a router as the DIS at a routing level. You can specify a DIS priority at a level for an interface. The greater the interface's priority, the more likely it becomes the DIS. If multiple routers in the broadcast network have the same highest DIS priority, the router with the highest MAC address becomes the DIS.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure a DIS priority for the interface.

   `isis dis-priority` *`priority`* [**`level-1`** | **`level-2`**]

   The default setting is 64.

Configuring the tag value for an interface

About this task

Perform this task when the link cost style is **wide**, **wide-compatible**, or **compatible**.

When IS-IS advertises a prefix with a tag value, IS-IS adds the tag to the IP reachability information TLV of the prefix.

Configuring the IPv4 IS-IS tag value for an interface

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure the IPv4 IS-IS tag value for the interface.

   `isis tag` *`tag`*

   By default, the IPv4 IS-IS tag value of the interface is not configured.

Configuring the IPv6 IS-IS tag value for an interface

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure the IPv6 IS-IS tag value for the interface.

   `isis ipv6 tag` *`tag`*

   By default, the IPv6 IS-IS tag value of the interface is not configured.

   When IS-IS advertises an IPv6 prefix with a tag value, it adds the tag to the IPv6 reachability information TLV, regardless of the link cost style.

Specifying the IS-IS hello multiplier

About this task

The hello multiplier is the number of hello packets a neighbor must miss before it declares that the router is down.

If a neighbor receives no hello packets from the router within the advertised hold time, it considers the router down and recalculates the routes. The hold time is the hello multiplier multiplied by the hello interval.

On a broadcast link, Level-1 and Level-2 hello packets are advertised separately. You must set a hello multiplier for each level.

On a P2P link, Level-1 and Level-2 hello packets are advertised in P2P hello packets. You do not need to specify Level-1 or Level-2.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Specify the hello multiplier.

   `isis timer holding-multiplier` *`value`* [**`level-1`** | **`level-2`**]

   The default setting is 3.

Disabling an interface from sending/receiving IS-IS packets

About this task

After being disabled from sending and receiving hello packets, an interface cannot form any neighbor relationship, but can advertise directly connected networks in LSPs through other interfaces. This can save bandwidth and CPU resources, and ensures that other routers know networks directly connected to the interface.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Disable the interface from sending and receiving IS-IS packets.

   `isis silent`

   By default, the interface can send and receive IS-IS packets.

Enabling an interface to send small hello packets

About this task

IS-IS messages cannot be fragmented at the IP layer because they are directly encapsulated in frames. Any two IS-IS neighboring routers must negotiate a common MTU. To avoid sending big hellos to save bandwidth, enable the interface to send small hello packets without CLVs.

Procedure

1. Enter system view.

system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the interface to send small hello packets without CLVs.

   isis small-hello

   By default, the interface sends standard hello packets.

Setting LSP lengths

About this task

IS-IS messages cannot be fragmented at the IP layer because they are directly encapsulated in frames. IS-IS routers in an area must send LSPs smaller than the smallest interface MTU in the area.

If the IS-IS routers have different interface MTUs, configure the maximum size of generated LSP packets to be smaller than the smallest interface MTU in the area. Without the configuration, the routers must dynamically adjust the LSP packet size to fit the smallest interface MTU, which takes time and affects other services.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Specify the maximum length of generated Level-1 LSPs or Level-2 LSPs.

   lsp-length originate *size* [**level-1** | **level-2**]

   By default, the maximum length of generated Level-1 LSPs or Level-2 LSPs is 1497 bytes.

4. Specify the maximum length of received LSPs.

   lsp-length receive *size*

   By default, the maximum length of received LSPs is 1497 bytes.

Enabling LSP flash flooding

About this task

Changed LSPs can trigger SPF recalculation. To advertise the changed LSPs before the router recalculates routes for faster network convergence, enable LSP flash flooding.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable LSP flash flooding.

   flash-flood [**flood-count** *flooding-count* | **max-timer-interval** *flooding-interval* | [**level-1** | **level-2**]] *

   By default, LSP flash flooding is disabled.

Enabling LSP fragment extension

1. Enter system view.

   `system-view`

2. Enter IS-IS view.

   `isis` [*`process-id`*] [**`vpn-instance`** *`vpn-instance-name`*]

3. Enable LSP fragment extension.

   `lsp-fragments-extend` [**`level-1`** | **`level-1-2`** | **`level-2`**]

   By default, LSP fragment extension is disabled.

   The MTUs of all interfaces running the IS-IS process must not be less than 512. Otherwise, LSP fragment extension does not take effect.

4. Configure a virtual system ID.

   `virtual-system` *`virtual-system-id`*

   By default, no virtual system ID is configured.

   Configure a minimum of one virtual system to generate extended LSP fragments.

Configuring advanced IS-IS features

Enabling source address check for hello packets on a P2P interface

About this task

An IS-IS P2P interface can have a peer on a different network. Perform this task to configure an IS-IS P2P interface to establish neighbor relationship only with a peer on the same network.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Enable source address check for hello packets on a P2P interface.

   `isis peer-ip-check`

   By default, an IS-IS P2P interface can have a peer on a different network.

Configuring convergence priorities for specific routes

About this task

A topology change causes IS-IS routing convergence. To improve convergence speed, you can assign convergence priorities to IS-IS routes. Convergence priority levels are critical, high, medium, and low. The higher the convergence priority, the faster the convergence speed.

By default, IS-IS host routes have medium convergence priority, and other IS-IS routes have low convergence priority.

Configuring convergence priorities for specific IPv4 IS-IS routes

1. Enter system view.

   `system-view`

2. Enter IS-IS IPv4 unicast address family view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   address-family ipv4 [**unicast**]

3. Assign convergence priorities to specific IPv4 IS-IS routes.
   - Assign a convergence priority to IPv4 IS-IS routes matching the specified prefix list.

     prefix-priority { **critical** | **high** | **medium** } { **prefix-list** *prefix-list-name* | **tag** *tag-value* }
   - Assign a convergence priority to IPv4 IS-IS routes by using a route policy.

     prefix-priority route-policy *route-policy-name*

   By default, IPv4 IS-IS routes, except IS-IS host routes, have the low convergence priority.

Configuring convergence priorities for specific IPv6 IS-IS routes

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Assign convergence priorities to specific IPv6 IS-IS routes.

   prefix-priority { **critical** | **high** | **medium** } { **prefix-list** *prefix-list-name* | **tag** *tag-value* }

   prefix-priority route-policy *route-policy-name*

   By default, IPv6 IS-IS routes, except IS-IS host routes, have the low convergence priority.

Setting the LSDB overload bit

About this task

By setting the overload bit in sent LSPs, a router informs other routers of failures that make it unable to select routes and forward packets.

When an IS-IS router cannot record the complete LSDB, for example, because of memory insufficiency, it will calculate wrong routes. To make troubleshooting easier, temporarily isolate the router from the IS-IS network by setting the overload bit.

Setting the LSDB overload bit for IPv4 IS-IS

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set the overload bit.

   set-overload [**on-startup** [[**start-from-nbr** *system-id* [*timeout1* [*nbr-timeout*]]] | *timeout2* | **wait-for-bgp** [*timeout3*]]] [**allow** { **external** | **interlevel** } *]

   By default, the overload bit is not set.

Setting the LSDB overload bit for IPv6 IS-IS

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Set the overload bit.

   set-overload [**on-startup** [[**start-from-nbr** *system-id* [*timeout1* [*nbr-timeout*]]] | *timeout2* | **wait-for-bgp4+** [*timeout3*]]] [**allow** { **external** | **interlevel** } *]

   By default, the overload bit is not set.

Configuring the ATT bit

About this task

The ATT bit is used to identify the connection status between a Level-1 area and other areas. By default, a Level-1-2 router sets the ATT bit for Level-1 LSPs as follows:

- The Level-1-2 router sets the ATT bit in Level-1 LSPs to inform the Level-1 routers that it can reach other areas. After a Level-1 router receives a Level-1 LSP with the ATT bit set, it generates a default route destined for the Level-1-2 router.
- The Level-1-2 router does not set the ATT bit in Level-1 LSPs if it can reach only one area.

To edit the default ATT bit setting rule for a Level-1-2 router, perform the following tasks as needed:

- To enable ATT bit setting for all Level-1 LSPs, execute the **set-att always** command on the Level-1-2 router.
- To disable a Level-1 router from generating a default route upon receiving an ATT-bit-set Level-1 LSP from the Level-1-2 router, you can perform one of the following tasks:
  - Execute the **ignore-att** command on the Level-1 router.
  - Execute the **set-att never** command on the Level-1-2 router.

Configuring IS-IS not to calculate the default route through the ATT bit

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Configure IS-IS not to calculate the default route through the ATT bit.

   ignore-att

   By default, IS-IS uses the ATT bit to calculate the default route.

Setting the ATT bit of IPv4 Level-1 LSPs

1. Enter system view.

   system-view

2. Enter IS-IS view

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set the ATT bit of IPv4 Level-1 LSPs.

   set-att { **always** | **never** }

   By default, the Level-1-2 router sets the ATT bit for IPv4 Level-1 LSPs in accordance with the default ATT bit setting rule.

Setting the ATT bit of IPv6 Level-1 LSPs

1. Enter system view.

   system-view

2. Enter IS-IS view

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Set the ATT bit of IPv6 Level-1 LSPs.

   set-att { **always** | **never** }

   By default, the Level-1-2 router sets the ATT bit for IPv6 Level-1 LSPs in accordance with the default ATT bit setting rule.

Configuring system ID to host name mappings

About this task

A 6-byte system ID in hexadecimal notation uniquely identifies a router or host in an IS-IS network. To make a system ID easy to read, the system allows you to use host names to identify devices. It also provides mappings between system IDs and host names.

The mappings can be configured manually or dynamically.

- **Static system ID to host name mapping**—You must manually configure a mapping for each router in the network. When a new router is added to the network or a mapping must be modified, you must configure all routers manually.
- **Dynamic system ID to host name mapping**—You only need to configure a host name for each router in the network. Each router advertises the host name in a dynamic host name CLV to other routers so all routers in the network can have all mappings. To help check the origin of LSPs in the LSDB, you can configure a name for the DIS in a broadcast network.

Restrictions and guidelines

Follow these guidelines when you configure the mappings:

- To view host names rather than system IDs by using the **display isis lsdb** command, you must enable dynamic system ID to host name mapping.
- If you configure both dynamic mapping and static mapping on a router, the host name specified for dynamic mapping applies.

Configuring a static system ID to host name mapping

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Configure a system ID to host name mapping for a remote IS.

   is-name map *sys-id map-sys-name*

   By default, no system ID to host name mapping is configured for a remote IS.

   A system ID can correspond to only one host name.

Configuring dynamic system ID to host name mapping

1. Enter system view.

   system-view

2. Enter IS-IS view.

isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Specify a host name for the IS and enable dynamic system ID to host name mapping.

   is-name *sys-name*

   By default, dynamic system ID to host name mapping is disabled and no host name is specified for the router.

4. Return to system view.

   quit

5. Enter interface view.

   interface *interface-type interface-number*

6. Configure a DIS name.

   isis dis-name *symbolic-name*

   By default, no DIS name is configured.

   This command takes effect only on a router enabled with dynamic system ID to host name mapping.

   This command is not available on P2P interfaces.

Enabling IS-IS to group ECMP routes

About this task

Perform this task to enable IS-IS to group ECMP routes by prefix to speed up route convergence.

This feature is applicable to a network when the network has a large number of ECMP routes and different route prefixes in the network have the same next hops. For example, IS-IS learns 10000 route prefixes and all route prefixes have the same 16 next hops (1.1.1.1 to 1.1.1.16). Without this feature, IS-IS has to send all ECMP routes of every route prefix (10000 × 16 routes) to the route management module. After you enable this feature, IS-IS groups the ECMP routes by prefix and sends the route groups (10000 route groups) to the route management module.

Restrictions and guidelines

If the output interfaces to the next hops of ECMP routes are TE tunnel interfaces, IS-IS groups the ECMP routes regardless of whether you enable this feature or not.

Enabling IPv4 IS-IS to group ECMP routes

1. Enter system view.

   system-view

2. Execute the following commands in sequence to enter IS-IS IPv4 unicast address family view:

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   address-family ipv4 [**unicast**]

3. Enable IPv4 IS-IS to group ECMP routes.

   ecmp-group enable

   By default, IPv4 IS-IS does not group ECMP routes.

Enabling IPv6 IS-IS to group ECMP routes

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Enable IPv6 IS-IS to group ECMP routes.

   ecmp-group enable

   By default, IPv6 IS-IS does not group ECMP routes.

Configuring IS-IS logging and SNMP notifications

Enabling the logging of neighbor state changes

About this task

With this feature enabled, the router delivers logs about neighbor state changes to its information center. The information center processes the logs according to user-defined output rules (whether to output logs and where to output). For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable the logging of neighbor state changes.

   log-peer-change

   By default, the logging of neighbor state changes is enabled.

Configuring IS-IS network management

About this task

This task includes the following configurations:

- Bind an IS-IS process to MIB so that you can use network management software to manage the specified IS-IS process.
- Enable IS-IS notifications to report important events.

To report critical IS-IS events to an NMS, enable SNMP notifications for IS-IS. For SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.

   system-view

2. Bind MIB to an IS-IS process.

   isis mib-binding *process-id*

   By default, MIB is bound to the IS-IS process with the smallest process ID.

3. Enable IS-IS notification sending.

   snmp-agent trap enable isis [**adjacency-state-change** | **area-mismatch** | **authentication** | **authentication-type** | **buffsize-mismatch** | **id-length-mismatch** | **lsdboverload-state-change** | **lsp-corrupt** | **lsp-parse-error** | **lsp-size-exceeded** | **manual-address-drop** | **max-seq-exceeded** | **maxarea-mismatch** | **own-lsp-purge** |

protocol-support | **rejected-adjacency** | **skip-sequence-number** | **version-skew**] *

By default, IS-IS notification sending is enabled.

4. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

5. Configure the context name for the SNMP object for managing IS-IS.

   snmp context-name *context-name*

   By default, no context name is set for the SNMP object for managing IS-IS.

Configuring IS-IS fast convergence

Enabling ISPF

About this task

When the network topology changes, Incremental Shortest Path First (ISPF) computes only the affected part of the SPT, instead of the entire SPT.

Enabling IPv4 IS-IS ISPF

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable IPv4 IS-IS ISPF.

   ispf enable

   By default, IPv4 IS-IS ISPF is enabled.

Enabling IPv6 IS-IS ISPF

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Enable IPv6 IS-IS ISPF.

   ispf enable

   By default, IPv6 IS-IS ISPF is enabled.

Enabling prefix suppression

About this task

Perform this task to disable an interface from advertising its prefix in LSPs. This enhances network security by preventing IP routing to the interval nodes and speeds up network convergence.

Enabling IPv4 IS-IS prefix suppression

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable IPv4 IS-IS prefix suppression on the interface.

   isis prefix-suppression

   By default, IPv4 IS-IS prefix suppression is disabled on the interface.

   This command is also applicable to the secondary IP address of the interface.

Enabling IPv6 IS-IS prefix suppression

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable IPv6 IS-IS prefix suppression on the interface.

   isis ipv6 prefix-suppression

   By default, IPv6 IS-IS prefix suppression is disabled on the interface.

Configuring IS-IS PIC

About this task

Prefix Independent Convergence (PIC) enables the device to speed up network convergence by ignoring the number of prefixes.

Restrictions and guidelines for IS-IS PIC

Follow these restrictions and guidelines when you configure IS-IS PIC:

- When both IS-IS PIC and IS-IS FRR are configured, IS-IS FRR takes effect.
- IS-IS PIC applies only to LSPs sent by neighbors.

Enabling IS-IS PIC

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable PIC for IS-IS.

   pic [**additional-path-always**]

   By default, IS-IS PIC is disabled.

Enabling BFD control packet mode for IS-IS PIC

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable BFD control packet mode for IS-IS PIC.

   isis primary-path-detect bfd ctrl

   By default, BFD control packet mode is disabled for IS-IS PIC.

   To use BFD (control packet mode) to detect primary link failures, you must enable BFD control packet mode on both ends of the link.

Enabling BFD echo packet mode for IS-IS PIC

1. Enter system view.

   system-view

2. Configure the source IP address of BFD echo packets.

   bfd echo-source-ip *ip-address*

   By default, the source IP address of BFD echo packets is not configured.

   The source IP address cannot be on the same network segment as any local interface's IP address.

   For more information about this command, see *Network Management and Monitoring Command Reference*.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable BFD echo packet mode for IS-IS PIC.

   isis primary-path-detect bfd echo

   By default, BFD echo packet mode is disabled for IS-IS PIC.

   To use BFD (echo packet mode) to detect primary link failures, you only need to enable BFD echo packet mode on one end of the link.

Enhancing IS-IS network security

To enhance the security of an IS-IS network, you can configure IS-IS authentication. IS-IS authentication involves neighbor relationship authentication, area authentication, and routing domain authentication.

Configuring neighbor relationship authentication

About this task

With neighbor relationship authentication configured, an interface adds the key in the specified mode into hello packets to the peer and checks the key in the received hello packets. If the authentication succeeds, it forms the neighbor relationship with the peer.

The authentication mode and key at both ends must be identical.

To prevent packet exchange failure in case of an authentication key change, configure the interface not to check the authentication information in the received packets.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify the authentication mode and key.

   isis authentication-mode { { **gca** *key-id* { **hmac-sha-1** | **hmac-sha-224** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** } [**nonstandard**] | **md5** | **simple** } { **cipher** | **plain** } *string* | **keychain** *keychain-name* } [**level-1** | **level-2**] [**ip** | **osi**]

   By default, the authentication mode and key are not configured.

4. (Optional.) Configure the interface not to check the authentication information in the received hello packets.

isis authentication send-only [**level-1** | **level-2**]

When the authentication mode and key are configured, the interface checks the authentication information in the received packets by default.

Configuring area authentication

About this task

Area authentication prevents the router from installing routing information from untrusted routers into the Level-1 LSDB. The router encapsulates the authentication key in the specified mode in Level-1 packets (LSP, CSNP, and PSNP). It also checks the key in received Level-1 packets.

Routers in a common area must have the same authentication mode and key.

To prevent packet exchange failure in case of an authentication key change, configure IS-IS not to check the authentication information in the received packets.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Specify the area authentication mode and key.

   area-authentication-mode { { **gca** *key-id* { **hmac-sha-1** | **hmac-sha-224** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** } [**nonstandard**] | **md5** | **simple** } { **cipher** | **plain** } *string* | **keychain** *keychain-name* } [**ip** | **osi**]

   By default, the area authentication mode and key are not configured.

4. (Optional.) Configure the interface not to check the authentication information in the received Level-1 packets, including LSPs, CSNPs, and PSNPs.

   area-authentication send-only

   When the authentication mode and key are configured, the interface checks the authentication information in the received packets by default.

Configuring routing domain authentication

About this task

Routing domain authentication prevents untrusted routing information from entering into a routing domain. A router with the authentication configured encapsulates the key in the specified mode into Level-2 packets (LSP, CSNP, and PSNP) and check the key in received Level-2 packets.

All the routers in the backbone must have the same authentication mode and key.

To prevent packet exchange failure in case of an authentication key change, configure IS-IS not to check the authentication information in the received packets.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Specify the routing domain authentication mode and key.

domain-authentication-mode { { **gca** *key-id* { **hmac-sha-1** | **hmac-sha-224** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** } [**nonstandard**] | **md5** | **simple** } { **cipher** | **plain** } *string* | **keychain** *keychain-name* } [**ip** | **osi**]

By default, the routing domain authentication mode and key are not configured.

4. (Optional.) Configure the interface not to check the authentication information in the received Level-2 packets, including LSPs, CSNPs, and PSNPs.

domain-authentication send-only

When the authentication mode and key are configured, the interface checks the authentication information in the received packets by default.

Configuring IS-IS GR

About this task

GR ensures forwarding continuity when a routing protocol restarts or an active/standby switchover occurs.

Two routers are required to complete a GR process. The following are router roles in a GR process.

- **GR restarter**—Graceful restarting router. It must have GR capability.
- **GR helper**—A neighbor of the GR restarter. It assists the GR restarter to complete the GR process. By default, the device acts as the GR helper.

Configure IS-IS GR on the GR restarter.

GR restarter uses the following timers:

- **T1 timer**—Specifies the times that GR restarter can send a Restart TLV with the RR bit set. When rebooted, the GR restarter sends a Restart TLV with the RR bit set to its neighbor. If the GR restarter receives a Restart TLV with the RA set from its neighbor before the T1 timer expires, the GR process starts. Otherwise, the GR process fails.
- **T2 timer**—Specifies the LSDB synchronization interval. Each LSDB has a T2 timer. The Level-1-2 router has a Level-1 timer and a Level-2 timer. If the LSDBs have not synchronized before the two timers expire, the GR process fails.
- **T3 timer**—Specifies the GR interval. The GR interval is set as the holdtime in hello PDUs. Within the interval, the neighbors maintain their adjacency with the GR restarter. If the GR process has not completed within the holdtime, the neighbors tear down the neighbor relationship and the GR process fails.

Restrictions and guidelines

IS-IS GR and IS-IS NSR are mutually exclusive. Do not configure them at the same time.

The product of the T1 timer and the number of times that the T1 timer can expire must be smaller than the T2 timer.

The T2 timer must be smaller than the T3 timer.

Procedure

1. Enter system view.

system-view

2. Enable IS-IS and enter IS-IS view.

isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable IS-IS GR.

graceful-restart

By default, the GR capability for IS-IS is disabled.

4. (Optional.) Suppress the SA bit during restart.

graceful-restart suppress-sa

By default, the SA bit is not suppressed.

By enabling the GR restarter to suppress the Suppress-Advertisement (SA) bit in the hello PDUs, the neighbors will still advertise their adjacency with the GR restarter.

5. (Optional.) Configure the T1 timer.

   graceful-restart t1 *seconds* **count** *count*

   By default, the T1 timer is 3 seconds and can expire 10 times.

6. (Optional.) Configure the T2 timer.

   graceful-restart t2 *seconds*

   By default, the T2 timer is 60 seconds.

7. (Optional.) Configure the T3 timer.

   graceful-restart t3 *seconds*

   By default, the T2 timer is 300 seconds.

Configuring IS-IS NSR

About this task

After an active/standby switchover, the GR restarter obtains routing information from its neighbors, and the IS-IS process must learn all the routes. If the network topology changes during the switchover, removed routes cannot be updated to the device, which can result in blackhole routes.

NSR solves the problem by backing up IS-IS link state information from the active process to the standby process. After an active/standby switchover, NSR can complete link state recovery and route regeneration without requiring the cooperation of other devices.

Restrictions and guidelines

IS-IS NSR and IS-IS GR are mutually exclusive. Do not configure them at the same time.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable IS-IS NSR.

   non-stop-routing

   By default, IS-IS NSR is disabled.

   IS-IS NSR takes effect on a per-process basis. As a best practice, enable NSR for each IS-IS process.

Configuring BFD for IS-IS

About this task

BFD provides a single mechanism to quickly detect and monitor the connectivity of links between IS-IS neighbors, reducing network convergence time.For more information about BFD, see BFD configuration in *Network Management and Monitoring Configuration Guide*.

Configuring BFD for IPv4 IS-IS

1. Enter system view.

```
system-view
```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Enable BFD on an IPv4 IS-IS interface.

   ```
   isis bfd enable
   ```

   By default, an IPv4 IS-IS interface is not enabled with BFD.

Configuring BFD for IPv6 IS-IS

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Enable BFD on an IPv6 IS-IS interface.

   ```
   isis ipv6 bfd enable
   ```

   By default, an IPv6 IS-IS interface is not enabled with BFD.

Controlling adjacency establishment and maintenance based on BFD session state

About this task

When BFD detects a Layer 3 forwarding failure between two routers, the BFD session goes down, which causes the IS-IS adjacency to go down. If Layer 2 forwarding is still available, the routers can exchange IS-IS packets and re-establish the adjacency, which might cause traffic loss.

To avoid the issue, enable this feature on the BFD-enabled interfaces of the local and remote routers, enabling the interfaces to carry BFD-enabled TLVs in hello packets. After the BFD session goes down, the routers do not establish an adjacency if the exchanged BFD-enabled TLVs are identical.

If two IS-IS routers establish both IPv4 and IPv6 adjacency relationships, the following rules apply:

- If route calculation is not performed separately for the IPv4 and IPv6 topologies, the IPv4 or IPv6 adjacency relationship is up only when both the IPv4 and IPv6 BFD sessions are up.
- If route calculation is performed separately for the IPv4 and IPv6 topologies, the IPv4 or IPv6 adjacency relationship is up when the corresponding IPv4 or IPv6 BFD session is up.

If two IS-IS routers establish only an IPv4 or IPv6 adjacency relationship, the adjacency relationship is up when the corresponding IPv4 or IPv6 BFD session is up.

For more information about BFD, see BFD configuration in *Network Management and Monitoring Configuration Guide*.

Enabling IPv4 IS-IS adjacency establishment and maintenance control based on BFD session state

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Enable IPv4 IS-IS BFD on the interface.

   ```
   isis bfd enable
   ```

   By default, IPv4 IS-IS BFD is disabled on an interface.

4. Enable adjacency establishment and maintenance control based on BFD session state.

```
isis bfd session-restrict-adj
```

By default, adjacency establishment and maintenance control based on BFD session state is disabled.

Enabling IPv6 IS-IS adjacency establishment and maintenance control based on BFD session state

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Enable IPv6 IS-IS BFD on the interface.

   ```
   isis ipv6 bfd enable
   ```

   By default, IPv6 IS-IS BFD is disabled on an interface.

4. Enable adjacency establishment and maintenance control based on BFD session state.

   ```
   isis ipv6 bfd session-restrict-adj
   ```

   By default, adjacency establishment and maintenance control based on BFD session state is disabled.

Configuring IS-IS FRR

About IS-IS FRR

IS-IS Fast Reroute (FRR) calculates a backup path based on the LSDB and saves the backup path information to the FIB. When the primary path fails, the system immdiately switches traffic to the backup path to prevent traffic loss and reduce the route convergence time.

IS-IS supports Loop Free Alternate (LFA) FRR and remote LFA FRR.

The following IS-IS FRR traffic protection types are available:

- **Link protection**—Protects traffic that traverses a specific link.
- **Node protection**—Protects traffic that traverses a specific node.

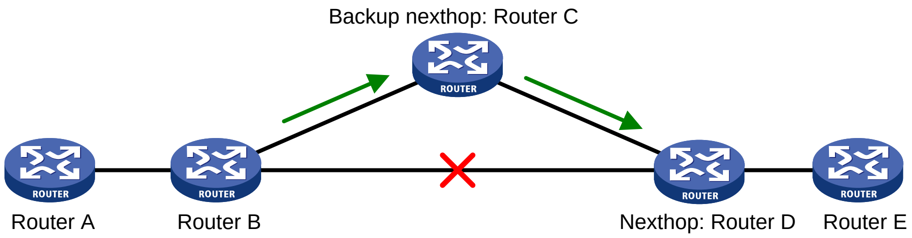
Node protection takes precedence over link protection.

Configuring IS-IS LFA FRR

About this task

A link or router failure on a path can cause packet loss. IS-IS FRR enables fast rerouting to minimize the failover time.

Figure 8 Network diagram for IS-IS FRR



In Figure 8, after you enable FRR on Router B, IS-IS automatically calculates or designates a backup next hop when a link failure is detected. In this way, packets are directed to the backup next hop to reduce traffic recovery time. Meanwhile, IS-IS calculates the shortest path based on the new network topology, and forwards packets over the path after network convergence.

You can assign a backup next hop for IS-IS FRR through the following ways:

- Enable IS-IS FRR to calculate a backup next hop through Loop Free Alternate (LFA) calculation.
- Designate a backup next hop with a routing policy for routes matching specific criteria.

Restrictions and guidelines

The LFA calculation of FRR and that of TE are mutually exclusive.

Configuring IPv4 IS-IS FRR to calculate a backup next hop through LFA calculation

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. (Optional.) Disable LFA calculation on the interface.
   isis fast-reroute lfa-backup exclude [**level-1** | **level-2**]
   By default, the interface participates in LFA calculation, and can be elected as a backup interface.
4. Return to system view.
   quit
5. Enter IS-IS IPv4 unicast address family view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
   address-family ipv4 [**unicast**]
6. Enable IS-IS FRR to calculate a backup next hop through LFA calculation.
   fast-reroute lfa [**level-1** | **level-2**]
   By default, IS-IS FRR is disabled.

Configuring IPv4 IS-IS FRR using a routing policy

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. (Optional.) Disable LFA calculation on the interface.
   isis fast-reroute lfa-backup exclude [**level-1** | **level-2**]
   By default, the interface participates in LFA calculation, and can be elected as a backup interface.
4. Return to system view.
   quit
5. Enter IS-IS IPv4 unicast address family view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
   address-family ipv4 [**unicast**]
6. Enable IPv4 IS-IS FRR using a routing policy.
   - Create a routing policy and specify a backup next hop.
     apply fast-reroute backup-interface

For more information about the **apply fast-reroute backup-interface** command and routing policy, see *Layer 3—IP Routing Configuration Guide*.

- Configure IPv4 IS-IS FRR.

  fast-reroute route-policy *route-policy-name*

By default, IPv4 IS-IS FRR is disabled.

Enabling BFD control packet mode for IPv4 IS-IS FRR

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable BFD control packet mode for IPv4 IS-IS FRR.

   isis primary-path-detect bfd ctrl

   By default, BFD control packet mode is disabled for IPv4 IS-IS FRR.

   To use BFD (control packet mode) to detect primary link failures, you must enable BFD control packet mode on both ends of the link.

Enabling BFD echo packet mode for IPv4 IS-IS FRR

1. Enter system view.

   system-view

2. Configure the source IP address of BFD echo packets.

   bfd echo-source-ip *ip-address*

   By default, the source IP address of BFD echo packets is not configured.

   The source IP address cannot be on the same network segment as any local interface's IP address.

   For more information about this command, see *Network Management and Monitoring Command Reference*.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable BFD echo packet mode for IPv4 IS-IS FRR.

   isis primary-path-detect bfd echo

   By default, BFD echo packet mode is disabled for IPv4 IS-IS FRR.

   To use BFD (echo packet mode) to detect primary link failures, you only need to enable BFD echo packet mode on one end of the link.

Configuring IPv6 IS-IS FRR to calculate a backup next hop through LFA calculation

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. (Optional.) Disable LFA calculation on the interface.

   isis ipv6 fast-reroute lfa-backup exclude [**level-1** | **level-2**]

   By default, the interface participates in LFA calculation, and can be elected as a backup interface.

4. Return to system view.

   quit

5. Enter IS-IS view.

isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

6. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

7. Enable IPv6 IS-IS FRR to calculate a backup next hop through LFA calculation.

   fast-reroute lfa [**level-1** | **level-2**]

   By default, IPv6 IS-IS FRR is disabled.

Configuring IPv6 IS-IS FRR using a routing policy

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. (Optional.) Disable LFA calculation on the interface.

   isis ipv6 fast-reroute lfa-backup exclude [**level-1** | **level-2**]

   By default, the interface participates in LFA calculation, and can be elected as a backup interface.

4. Return to system view.

   quit

5. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

6. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

7. Enable IPv6 IS-IS FRR using a routing policy.

   - Create a routing policy and specify a backup next hop.

     apply ipv6 fast-reroute backup-interface

     For more information about the **apply ipv6 fast-reroute backup-interface** command and routing policy, see *Layer 3—IP Routing Configuration Guide*.

   - Configure IPv6 IS-IS FRR.

     fast-reroute route-policy *route-policy-name*

   By default, IPv6 IS-IS FRR is disabled.

Enabling BFD control packet mode for IPv6 IS-IS FRR

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable BFD control packet mode for IPv6 IS-IS FRR.

   isis ipv6 primary-path-detect bfd ctrl

   By default, BFD control packet mode is disabled for IPv6 IS-IS FRR.

   To use BFD (control packet mode) to detect primary link failures, you must enable BFD control packet mode on both ends of the link.

Enabling BFD echo packet mode for IPv6 IS-IS FRR

1. Enter system view.

   system-view

2. Configure the source IPv6 address of BFD echo packets.

```
bfd echo-source-ipv6 ip-address
```

By default, the source IPv6 address of BFD echo packets is not configured.

The source IPv6 address cannot be on the same network segment as any local interface's IPv6 address.

For more information about this command, see *Network Management and Monitoring Command Reference*.

3. Enter interface view.

```
interface interface-type interface-number
```

4. Enable BFD echo packet mode for IPv6 IS-IS FRR.

```
isis ipv6 primary-path-detect bfd echo
```

By default, BFD echo packet mode is disabled for IPv6 IS-IS FRR.

To use BFD (echo packet mode) to detect primary link failures, you only need to enable BFD echo packet mode on one end of the link.

Setting the priority for FRR backup path selection policies

About this task

IS-IS FRR uses specific policies for backup path calculation. This command defines the priority for the backup path selection policy. The higher the value, the higher the priority of the associated backup path selection policy. Changing the backup path selection policy priority can affect the backup path calculation result for IS-IS FRR. The backup paths can provide node protection or link protection for traffic, or provide both node protection and link protection.

IS-IS FRR supports the following backup path selection policies that are used to generate different topologies for backup path calculation:

- **Node protection**—IS-IS FRR performs backup path calculation after excluding the primary next hop node.
- **Lowest cost**—IS-IS FRR performs backup path calculation after excluding the direct primary link.
- **SRLG disjoint**—When one link in the SRLG fails, the other links in the SRLG might also fail. If you use a link in this SRLG as the backup link for the failed link, protection does not take effect. To avoid this issue, IS-IS FRR excludes the local links in the same SRLG as the direct primary link and then performs backup path calculation.

For IS-IS FRR, the SRLG disjoint policy depends on the node protection and lowest cost policies.

If multiple backup path selection policies exist in an IS-IS process, the policy with the highest priority is used to calculate the backup path. If the policy fails to calculate the backup path, another policy with higher priority is used. IS-IS performs backup path calculation by using the node protection and lowest cost policies as follows:

- If the node protection policy has higher priority and fails to calculate the backup path, IS-IS uses the lowest cost policy to calculate the backup path. If the lowest cost policy still fails to calculate the backup path, reliability cannot be ensured upon primary link failure.
- If the lowest cost policy has higher priority and fails to calculate the backup path, IS-IS does not perform further backup path calculation with the node protection policy. Reliability cannot be ensured upon primary link failure.

Table 4 shows the backup path selection mechanism for IS-IS FRR based on priorities of backup path selection policies.

Table 4 Backup path selection mechanism for IS-IS FRR based on priorities of link selection policies

Priorities of link selection policies	Backup path selection mechanism for IS-IS FRR
Node protection > lowest cost > SRLG-disjoint	IS-IS FRR performs calculations based on the node protection and lowest cost policies in descending of priority. IS-IS FRR performs a maximum of two calculations. If IS-IS FRR calculates a backup path with a link selection policy, it does not perform further calculations.
Node protection > SRLG-disjoint > lowest cost	IS-IS FRR performs calculations based on the node protection, node protection + SRLG-disjoint, lowest cost + SRLG-disjoint, and lowest cost policies in descending of priority. IS-IS FRR performs a maximum of four calculations. If IS-IS FRR calculates a backup path with a link selection policy, it does not perform further calculations.
SRLG-disjoint > node protection > lowest cost	IS-IS FRR performs calculations based on the node protection + SRLG-disjoint, lowest cost + SRLG-disjoint, node protection, and lowest cost policies in descending of priority. IS-IS FRR performs a maximum of four calculations. If IS-IS FRR calculates a backup path with a link selection policy, it does not perform further calculations.
Lowest cost > node protection > SRLG-disjoint	IS-IS FRR performs calculations based on the lowest cost policy. IS-IS FRR performs only one calculation.
Lowest cost > SRLG-disjoint > node protection	IS-IS FRR performs calculations based on the lowest cost policy. IS-IS FRR performs only one calculation.
SRLG-disjoint > lowest cost > node protection	IS-IS FRR performs calculations based on the node protection + SRLG-disjoint, lowest cost + SRLG-disjoint, and lowest cost policies in descending of priority. IS-IS FRR performs a maximum of three calculations. If IS-IS FRR calculates a backup path with a link selection policy, it does not perform further calculations.

Setting the priority for IPv4 IS-IS FRR backup path selection policies

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv4 address family view.

   address-family ipv4 [**unicast**]

4. Set the priority for the node-protection or lowest-cost backup path selection policy.

   fast-reroute tiebreaker { **lowest-cost** | **node-protecting** | **srlg-disjoint** } **preference** *preference* [**level-1** | **level-2**]

   By default, the priority values of the node-protection, lowest-cost, and shared risk link group (SRLG)-disjoint backup path selection policies are 40, 20, and 10, respectively.

Setting the priority for IPv6 IS-IS FRR backup path selection policies

1. Enter system view.

   system-view

2. Enter IS-IS view.

isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Set the priority for the node-protection or lowest-cost backup path selection policy.

   fast-reroute tiebreaker { **lowest-cost** | **node-protecting** } **preference** *preference* [**level-1** | **level-2**]

   By default, the priority values of the node-protection and lowest-cost backup path selection policies are 40 and 20, respectively.

Display and maintenance commands for IS-IS

Execute **display** commands in any view and the **reset** command in user view.

Displaying and maintaining IPv4 IS-IS

Task	Command

IS-IS configuration examples

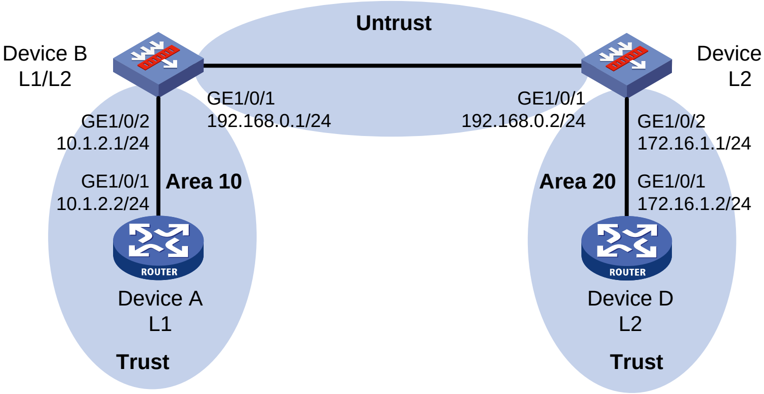
Example: Configuring basic IS-IS

Network configuration

As shown in Figure 9, Device A, Device B, Device C, and Device D reside in an AS.

Device A is a Level-1 device, Device C and Device D are Level-2 devices, and Device B is a Level-1-2 device connecting two areas. Device A and Device B are in area 10. Device C and Device D are in area 20.

Figure 9 Network diagram



Procedure

# Configure Device B.

1. Configure IP addresses for interfaces correctly according to the network diagram above.
   a. Configure an IP address for GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
```

```
[DeviceB-GigabitEthernet1/0/1] ip address 192.168.0.1 24
[DeviceB-GigabitEthernet1/0/1] quit
```

b. Configure IP addresses for other interfaces in the same way GigabitEthernet 1/0/1 is configured. (Details not shown.)

2. Add each interface on Device B to a security zone.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

3. Configure security policies.

a. Configure a security policy to allow IS-IS neighbor relationship establishment by permitting traffic between security zone **untrust** and security zone **local**.

# Create security policy rule **is-islocalin** and permit Device B to receive IS-IS packets from Device C.

```
[DeviceB] security-policy ip
[DeviceB-security-policy-ip] rule name is-islocalin
[DeviceB-security-policy-ip-0-is-islocalin] source-zone untrust
[DeviceB-security-policy-ip-0-is-islocalin] destination-zone local
[DeviceB-security-policy-ip-0-is-islocalin] action pass
[DeviceB-security-policy-ip-0-is-islocalin] quit
```

# Create security policy rule **is-islocalout** and permit Device B to send IS-IS packets to Device C.

```
[DeviceB-security-policy-ip] rule name is-islocalout
[DeviceB-security-policy-ip-1-is-islocalout] source-zone local
[DeviceB-security-policy-ip-1-is-islocalout] destination-zone untrust
[DeviceB-security-policy-ip-1-is-islocalout] action pass
[DeviceB-security-policy-ip-1-is-islocalout] quit
```

b. Configure a security policy to permit traffic between security zone **trust** and security zone **local**.

# Create security policy rule **trust-local** and permit Device A to send IS-IS packets to Device B.

```
[DeviceB-security-policy-ip] rule name trust-local
[DeviceB-security-policy-ip-2-trust-local] source-zone trust
[DeviceB-security-policy-ip-2-trust-local] destination-zone local
[DeviceB-security-policy-ip-2-trust-local] action pass
[DeviceB-security-policy-ip-2-trust-local] quit
```

# Create security policy rule **local-trust** and permit Device B to send IS-IS packets to Device A.

```
[DeviceB-security-policy-ip] rule name local-trust
[DeviceB-security-policy-ip-3-local-trust] source-zone local
[DeviceB-security-policy-ip-3-local-trust] destination-zone trust
[DeviceB-security-policy-ip-3-local-trust] action pass
[DeviceB-security-policy-ip-3-local-trust] quit
```

c. Configure a security policy that permits traffic between security zone **untrust** and security zone **trust** to permit traffic between area 10 and area 20.

# Create security policy rule **trust-untrust** and permit packets from security zone **trust** to security zone **untrust** to pass.

```
[DeviceB-security-policy-ip] rule name trust-untrust
[DeviceB-security-policy-ip-4-trust-untrust] source-zone trust
[DeviceB-security-policy-ip-4-trust-untrust] destination-zone untrust
[DeviceB-security-policy-ip-4-trust-untrust] source-ip-subnet 10.1.2.0 24
[DeviceB-security-policy-ip-4-trust-untrust] destination-ip-subnet 172.16.1.0 24
[DeviceB-security-policy-ip-4-trust-untrust] action pass
[DeviceB-security-policy-ip-4-trust-untrust] quit
```

# Create security policy rule **untrust-trust** and permit packets from security zone **untrust** to security zone **trust** to pass.

```
[DeviceB-security-policy-ip] rule name untrust-trust
[DeviceB-security-policy-ip-5-untrust-trust] source-zone untrust
[DeviceB-security-policy-ip-5-untrust-trust] destination-zone trust
[DeviceB-security-policy-ip-5-untrust-trust] source-ip-subnet 172.16.1.0 24
[DeviceB-security-policy-ip-5-untrust-trust] destination-ip-subnet 10.1.2.0 24
[DeviceB-security-policy-ip-5-untrust-trust] action pass
[DeviceB-security-policy-ip-5-untrust-trust] quit
[DeviceB-security-policy-ip] quit
```

4. Enable IS-IS.

```
[DeviceB] isis 1
[DeviceB-isis-1] network-entity 10.0000.0000.0001.00
[DeviceB-isis-1] quit
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] isis enable 1
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] isis enable 1
[DeviceB-GigabitEthernet1/0/2] quit
```

# Configure Device C.

1. Configure IP addresses for interfaces correctly according to the network diagram above.
   a. Configure an IP address for GigabitEthernet 1/0/1.

```
<DeviceC> system-view
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] ip address 192.168.0.2 24
[DeviceC-GigabitEthernet1/0/1] quit
```

   b. Configure IP addresses for other interfaces in the same way GigabitEthernet 1/0/1 is configured. (Details not shown.)

2. Add each interface on Device C to a security zone.

```
[DeviceC] security-zone name untrust
[DeviceC-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceC-security-zone-Untrust] quit
[DeviceC] security-zone name trust
[DeviceC-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceC-security-zone-Trust] quit
```

3. Configure security policies.
   a. Configure a security policy to allow IS-IS neighbor relationship establishment by permitting traffic between security zone **untrust** and security zone **local**.

# Create security policy rule **is-islocalin** and permit Device C to receive IS-IS packets from Device B.

```
[DeviceC] security-policy ip
[DeviceC-security-policy-ip] rule name is-islocalin
[DeviceC-security-policy-ip-0-is-islocalin] source-zone untrust
[DeviceC-security-policy-ip-0-is-islocalin] destination-zone local
[DeviceC-security-policy-ip-0-is-islocalin] action pass
[DeviceC-security-policy-ip-0-is-islocalin] quit
```

# Create security policy rule **is-islocalout** and permit Device C to send IS-IS packets to Device B.

```
[DeviceC-security-policy-ip] rule name is-islocalout
[DeviceC-security-policy-ip-1-is-islocalout] source-zone local
[DeviceC-security-policy-ip-1-is-islocalout] destination-zone untrust
[DeviceC-security-policy-ip-1-is-islocalout] action pass
[DeviceC-security-policy-ip-1-is-islocalout] quit
```

b. Configure a security policy to permit traffic between security zone **trust** and security zone **local**.

# Create security policy rule **trust-local** and permit Device D to send IS-IS packets to Device C.

```
[DeviceC-security-policy-ip] rule name trust-local
[DeviceC-security-policy-ip-2-trust-local] source-zone trust
[DeviceC-security-policy-ip-2-trust-local] destination-zone local
[DeviceC-security-policy-ip-2-trust-local] action pass
[DeviceC-security-policy-ip-2-trust-local] quit
```

# Create security policy rule **local-trust** and permit Device C to send IS-IS packets to Device D.

```
[DeviceC-security-policy-ip] rule name local-trust
[DeviceC-security-policy-ip-3-local-trust] source-zone local
[DeviceC-security-policy-ip-3-local-trust] destination-zone trust
[DeviceC-security-policy-ip-3-local-trust] action pass
[DeviceC-security-policy-ip-3-local-trust] quit
```

c. Configure a security policy that permits traffic between security zone **untrust** and security zone **trust** to permit traffic between area 10 and area 20.

# Create security policy rule **trust-untrust** and permit packets from security zone **trust** to security zone **untrust** to pass.

```
[DeviceC-security-policy-ip] rule name trust-untrust
[DeviceC-security-policy-ip-4-trust-untrust] source-zone trust
[DeviceC-security-policy-ip-4-trust-untrust] destination-zone untrust
[DeviceC-security-policy-ip-4-trust-untrust] source-ip-subnet 172.16.1.0 24
[DeviceC-security-policy-ip-4-trust-untrust] destination-ip-subnet 10.1.2.0 24
[DeviceC-security-policy-ip-4-trust-untrust] action pass
[DeviceC-security-policy-ip-4-trust-untrust] quit
```

# Create security policy rule **untrust-trust** and permit packets from security zone **untrust** to security zone **trust** to pass.

```
[DeviceC-security-policy-ip] rule name untrust-trust
[DeviceC-security-policy-ip-5-untrust-trust] source-zone untrust
[DeviceC-security-policy-ip-5-untrust-trust] destination-zone trust
[DeviceC-security-policy-ip-5-untrust-trust] source-ip-subnet 10.1.2.0 24
```

```
[DeviceC-security-policy-ip-5-untrust-trust] destination-ip-subnet 172.16.1.0
24
[DeviceC-security-policy-ip-5-untrust-trust] action pass
[DeviceC-security-policy-ip-5-untrust-trust] quit
[DeviceC-security-policy-ip] quit
```

4. Enable IS-IS.

```
[DeviceC] isis 1
[DeviceC-isis-1] is-level level-2
[DeviceC-isis-1] network-entity 20.0000.0000.0001.00
[DeviceC-isis-1] quit
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] isis enable 1
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] isis enable 1
[DeviceC-GigabitEthernet1/0/2] quit
```

# Configure Device A.

1. Configure an IP address for GigabitEthernet 1/0/1 correctly according to the network diagram above.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 10.1.1.2 24
[DeviceA-GigabitEthernet1/0/1] quit
```

2. Enable IS-IS.

```
[DeviceA] isis 1
[DeviceA-isis-1] is-level level-1
[DeviceA-isis-1] network-entity 10.0000.0000.0002.00
[DeviceA-isis-1] quit
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] isis enable 1
[DeviceA-GigabitEthernet1/0/1] quit
```

# Configure Device D.

1. Configure an IP address for GigabitEthernet 1/0/1 correctly according to the network diagram above.

```
<DeviceD> system-view
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] ip address 172.16.1.2 24
[DeviceD-GigabitEthernet1/0/1] quit
```

2. Enable IS-IS.

```
[DeviceD] isis 1
[DeviceD-isis-1] is-level level-2
[DeviceD-isis-1] network-entity 20.0000.0000.0002.00
[DeviceD-isis-1] quit
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] isis enable 1
[DeviceD-GigabitEthernet1/0/1] quit
```

Verifying the configuration

# View IS-IS routing information on Device B.

```
[Device B] display isis route

                         Route information for IS-IS(1)

# Verify that devices in area 10 can ping the devices in area 20, and vice versa.

IPv6 IS-IS configuration examples

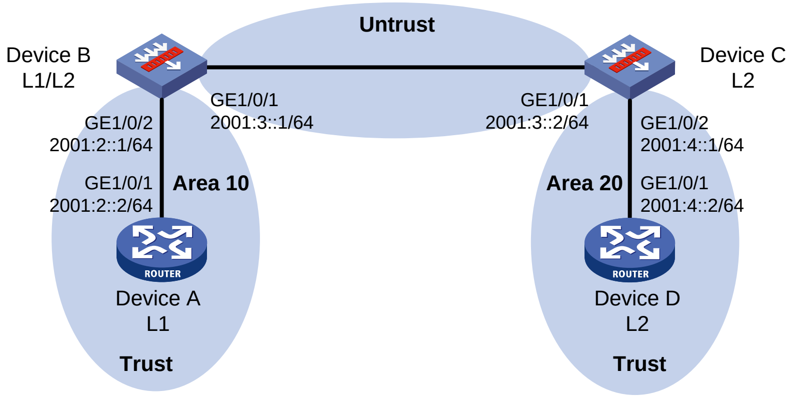
Example: Configuring IPv6 IS-IS basics

Network configuration

As shown in Figure 10, Device A, Device B, Device C, and Device D reside in an AS.

Device A is a Level-1 device, Device C and Device D are Level-2 devices, and Device B is a Level-1-2 device connecting two areas. Device A and Device B are in area 10. Device C and Device D are in area 20.

Figure 10 Network diagram



Procedure

# Configure Device B.

1. Configure IPv6 addresses for interfaces correctly according to the network diagram above.
   a. Configure an IPv6 address for GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ipv6 address 2001:3::1 64
[DeviceB-GigabitEthernet1/0/1] quit
```

   b. Configure IPv6 addresses for other interfaces in the same way GigabitEthernet 1/0/1 is configured. (Details not shown.)

2. Add each interface on Device B to a security zone.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

3. Configure security policies.
   a. Configure a security policy to allow IPv6 IS-IS neighbor relationship establishment by permitting traffic between security zone **untrust** and security zone **local**.

   # Create security policy rule **is-islocalin** and permit Device B to receive IPv6 IS-IS packets from Device C.

```
[DeviceB] security-policy ipv6
[DeviceB-security-policy-ipv6] rule name is-islocalin
[DeviceB-security-policy-ipv6-0-is-islocalin] source-zone untrust
[DeviceB-security-policy-ipv6-0-is-islocalin] destination-zone local
[DeviceB-security-policy-ipv6-0-is-islocalin] action pass
[DeviceB-security-policy-ipv6-0-is-islocalin] quit
```

   # Create security policy rule **is-islocalout** and permit Device B to send IPv6 IS-IS packets to Device C.

```
[DeviceB-security-policy-ipv6] rule name is-islocalout
[DeviceB-security-policy-ipv6-1-is-islocalout] source-zone local
[DeviceB-security-policy-ipv6-1-is-islocalout] destination-zone untrust
[DeviceB-security-policy-ipv6-1-is-islocalout] action pass
[DeviceB-security-policy-ipv6-1-is-islocalout] quit
```

b. Configure a security policy to permit traffic between security zone **trust** and security zone **local**.

   # Create security policy rule **trust-local** and permit Device A to send IPv6 IS-IS packets to Device B.

   ```
   [DeviceB-security-policy-ipv6] rule name trust-local
   [DeviceB-security-policy-ipv6-2-trust-local] source-zone trust
   [DeviceB-security-policy-ipv6-2-trust-local] destination-zone local
   [DeviceB-security-policy-ipv6-2-trust-local] action pass
   [DeviceB-security-policy-ipv6-2-trust-local] quit
   ```

   # Create security policy rule **local-trust** and permit Device B to send IPv6 IS-IS packets to Device A.

   ```
   [DeviceB-security-policy-ipv6] rule name local-trust
   [DeviceB-security-policy-ipv6-3-local-trust] source-zone local
   [DeviceB-security-policy-ipv6-3-local-trust] destination-zone trust
   [DeviceB-security-policy-ipv6-3-local-trust] action pass
   [DeviceB-security-policy-ipv6-3-local-trust] quit
   [DeviceB-security-policy-ipv6] quit
   ```

c. Configure a security policy that permits traffic between security zone **untrust** and security zone **trust** to permit traffic between area 10 and area 20.

   # Create security policy rule **trust-untrust** and permit packets from security zone **trust** to security zone **untrust** to pass.

   ```
   [DeviceB-security-policy-ipv6] rule name trust-untrust
   [DeviceB-security-policy-ipv6-4-trust-untrust] source-zone trust
   [DeviceB-security-policy-ipv6-4-trust-untrust] destination-zone untrust
   [DeviceB-security-policy-ipv6-4-trust-untrust] source-ip-subnet 2001:2:: 64
   [DeviceB-security-policy-ipv6-4-trust-untrust] destination-ip-subnet 2001:4::
   64
   [DeviceB-security-policy-ipv6-4-trust-untrust] action pass
   [DeviceB-security-policy-ipv6-4-trust-untrust] quit
   ```

   # Create security policy rule **untrust-trust** and permit packets from security zone **untrust** to security zone **trust** to pass.

   ```
   [DeviceB-security-policy-ipv6] rule name untrust-trust
   [DeviceB-security-policy-ipv6-5-untrust-trust] source-zone untrust
   [DeviceB-security-policy-ipv6-5-untrust-trust] destination-zone trust
   [DeviceB-security-policy-ipv6-5-untrust-trust] source-ip-subnet 2001:4:: 64
   [DeviceB-security-policy-ipv6-5-untrust-trust] destination-ip-subnet 2001:2::
   64
   [DeviceB-security-policy-ipv6-5-untrust-trust] action pass
   [DeviceB-security-policy-ipv6-5-untrust-trust] quit
   [DeviceB-security-policy-ipv6] quit
   ```

4. Enable IS-IS.

```
[DeviceB] isis 1
[DeviceB-isis-1] network-entity 10.0000.0000.0001.00
[DeviceB-isis-1] address-family ipv6
[DeviceB-isis-1-ipv6] quit
[DeviceB-isis-1] quit
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] isis ipv6 enable 1
[DeviceB-GigabitEthernet1/0/1] quit
```

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] isis ipv6 enable 1
[DeviceB-GigabitEthernet1/0/2] quit
```

# Configure Device C.

1. Configure IPv6 addresses for interfaces correctly according to the network diagram above.
   a. Configure an IPv6 address for GigabitEthernet 1/0/1.
   ```
   <DeviceC> system-view
   [DeviceC] interface gigabitethernet 1/0/1
   [DeviceC-GigabitEthernet1/0/1] ipv6 address 2001:3::2 64
   [DeviceC-GigabitEthernet1/0/1] quit
   ```
   b. Configure IPv6 addresses for other interfaces in the same way GigabitEthernet 1/0/1 is configured. (Details not shown.)
2. Add each interface on Device C to a security zone.
   ```
   [DeviceC] security-zone name untrust
   [DeviceC-security-zone-Untrust] import interface gigabitethernet 1/0/1
   [DeviceC-security-zone-Untrust] quit
   [DeviceC] security-zone name trust
   [DeviceC-security-zone-Trust] import interface gigabitethernet 1/0/2
   [DeviceC-security-zone-Trust] quit
   ```
3. Configure security policies.
   a. Configure a security policy to allow IS-IS neighbor relationship establishment by permitting traffic between security zone **untrust** and security zone **local**.

   # Create security policy rule **is-islocalin** and permit Device C to receive IPv6 IS-IS packets from Device B.
   ```
   [DeviceC] security-policy ipv6
   [DeviceC-security-policy-ipv6] rule name is-islocalin
   [DeviceC-security-policy-ipv6-0-is-islocalin] source-zone untrust
   [DeviceC-security-policy-ipv6-0-is-islocalin] destination-zone local
   [DeviceC-security-policy-ipv6-0-is-islocalin] action pass
   [DeviceC-security-policy-ipv6-0-is-islocalin] quit
   ```
   # Create security policy rule **is-islocalout** and permit Device C to send IPv6 IS-IS packets to Device B.
   ```
   [DeviceC-security-policy-ipv6] rule name is-islocalout
   [DeviceC-security-policy-ipv6-1-is-islocalout] source-zone local
   [DeviceC-security-policy-ipv6-1-is-islocalout] destination-zone untrust
   [DeviceC-security-policy-ipv6-1-is-islocalout] action pass
   [DeviceC-security-policy-ipv6-1-is-islocalout] quit
   ```
   b. Configure a security policy to permit traffic between security zone **trust** and security zone **local**.

   # Create security policy rule **trust-local** and permit Device D to send IPv6 IS-IS packets to Device C.
   ```
   [DeviceC-security-policy-ipv6] rule name trust-local
   [DeviceC-security-policy-ipv6-2-trust-local] source-zone trust
   [DeviceC-security-policy-ipv6-2-trust-local] destination-zone local
   [DeviceC-security-policy-ipv6-2-trust-local] action pass
   [DeviceC-security-policy-ipv6-2-trust-local] quit
   ```
   # Create security policy rule **local-trust** and permit Device C to send IPv6 IS-IS packets to Device D.

```
[DeviceC-security-policy-ipv6] rule name local-trust
[DeviceC-security-policy-ipv6-3-local-trust] source-zone local
[DeviceC-security-policy-ipv6-3-local-trust] destination-zone trust
[DeviceC-security-policy-ipv6-3-local-trust] action pass
[DeviceC-security-policy-ipv6-3-local-trust] quit
```

c. Configure a security policy that permits traffic between security zone **untrust** and security zone **trust** to permit traffic between area 10 and area 20.

   # Create security policy rule **trust-untrust** and permit packets from security zone **trust** to security zone **untrust** to pass.

```
[DeviceC-security-policy-ipv6] rule name trust-untrust
[DeviceC-security-policy-ipv6-4-trust-untrust] source-zone trust
[DeviceC-security-policy-ipv6-4-trust-untrust] destination-zone untrust
[DeviceC-security-policy-ipv6-4-trust-untrust] source-ip-subnet 2001:4:: 64
[DeviceC-security-policy-ipv6-4-trust-untrust] destination-ip-subnet 2001:2::
64
[DeviceC-security-policy-ipv6-4-trust-untrust] action pass
[DeviceC-security-policy-ipv6-4-trust-untrust] quit
```

   # Create security policy rule **untrust-trust** and permit packets from security zone **untrust** to security zone **trust** to pass.

```
[DeviceC-security-policy-ipv6] rule name untrust-trust
[DeviceC-security-policy-ipv6-5-untrust-trust] source-zone untrust
[DeviceC-security-policy-ipv6-5-untrust-trust] destination-zone trust
[DeviceC-security-policy-ipv6-5-untrust-trust] source-ip-subnet 2001:2:: 64
[DeviceC-security-policy-ipv6-5-untrust-trust] destination-ip-subnet 2001:4::
64
[DeviceC-security-policy-ipv6-5-untrust-trust] action pass
[DeviceC-security-policy-ipv6-5-untrust-trust] quit
[DeviceC-security-policy-ipv6] quit
```

4. Enable IPv6 IS-IS.

```
[DeviceC] isis 1
[DeviceC-isis-1] is-level level-2
[DeviceC-isis-1] network-entity 20.0000.0000.0001.00
[DeviceC-isis-1] address-family ipv6
[DeviceC-isis-1-ipv6] quit
[DeviceC-isis-1] quit
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] isis ipv6 enable 1
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] isis ipv6 enable 1
[DeviceC-GigabitEthernet1/0/2] quit
```

# Configure Device A.

1. Configure an IPv6 address for GigabitEthernet 1/0/1 correctly according to the network diagram above.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ipv6 address 2001:2::2 64
[DeviceA-GigabitEthernet1/0/1] quit
```

2. Enable IPv6 IS-IS.

```
[DeviceA] isis 1
[DeviceA-isis-1] is-level level-1
[DeviceA-isis-1] network-entity 10.0000.0000.0002.00
[DeviceA-isis-1] address-family ipv6
[DeviceA-isis-1-ipv6] quit
[DeviceA-isis-1] quit
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] isis ipv6 enable 1
[DeviceA-GigabitEthernet1/0/1] quit
```

# Configure Device D.

1. Configure an IPv6 address for GigabitEthernet 1/0/1 correctly according to the network diagram above.

```
<DeviceD> system-view
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] ipv6 address 2001:4::2 64
[DeviceD-GigabitEthernet1/0/1] quit
```

2. Enable IPv6 IS-IS.

```
[DeviceD] isis 1
[DeviceD-isis-1] is-level level-2
[DeviceD-isis-1] network-entity 20.0000.0000.0002.00
[DeviceD-isis-1] address-family ipv6
[DeviceD-isis-1-ipv6] quit
[DeviceD-isis-1] quit
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] isis ipv6 enable 1
[DeviceD-GigabitEthernet1/0/1] quit
```

Verifying the configuration

# View IPv6 IS-IS routing information on Device B.

```
[DeviceB] display isis route ipv6

                         Route information for IS-IS(1)
                         ------------------------------

# Verify that devices in area 10 can ping the devices in area 20, and vice versa.

Contents

BGP overview

Border Gateway Protocol (BGP) is an exterior gateway protocol (EGP). It is called internal BGP (IBGP) when it runs within an AS and called external BGP (EBGP) when it runs between ASs. The current version in use is BGP-4 (RFC 4271).

BGP characteristics

BGP has the following characteristics:

- Focuses on route control and selection rather than route discovery and calculation.
- Uses TCP to enhance reliability.
- Measures the distance of a route by using a list of ASs that the route must travel through to reach the destination. BGP is also called a path-vector protocol.
- Supports CIDR.
- Reduces bandwidth consumption by advertising only incremental updates. BGP is very suitable to advertise large numbers of routes on the Internet.
- Eliminates routing loops by adding AS path information to BGP route updates.
- Uses policies to implement flexible route filtering and selection.
- Has good scalability.

BGP speaker and BGP peer

A router running BGP is a BGP speaker. A BGP speaker establishes peer relationships with other BGP speakers to exchange routing information over TCP connections.

BGP peers include the following types:

- **IBGP peers**—Reside in the same AS as the local router.
- **EBGP peers**—Reside in different ASs from the local router.

BGP message types

BGP uses the following message types:

- **Open**—After establishing a TCP connection, BGP sends an OPEN message to establish a session to the peer.
- **Update**—BGP sends UPDATE messages to exchange routing information between peers. Each UPDATE message can advertise a group of feasible routes with identical attributes and multiple withdrawn routes.
- **Keepalive**—BGP sends KEEPALIVE messages between peers to maintain connectivity.
- **Route-refresh**—BGP sends a ROUTE-REFRESH message to request the routing information for a specific address family from a peer.
- **Notification**—BGP sends a NOTIFICATION message upon detecting an error and immediately closes the connection.

BGP path attributes

BGP uses the following path attributes in UPDATE messages for route filtering and selection:

ORIGIN

The ORIGIN attribute specifies the origin of BGP routes. This attribute has the following types:

- **IGP**—Has the highest priority. Routes generated in the local AS have the IGP attribute.
- **EGP**—Has the second highest priority. Routes obtained through EGP have the EGP attribute.
- **INCOMPLETE**—Has the lowest priority. The source of routes with this attribute is unknown. Routes redistributed from other routing protocols have the INCOMPLETE attribute.

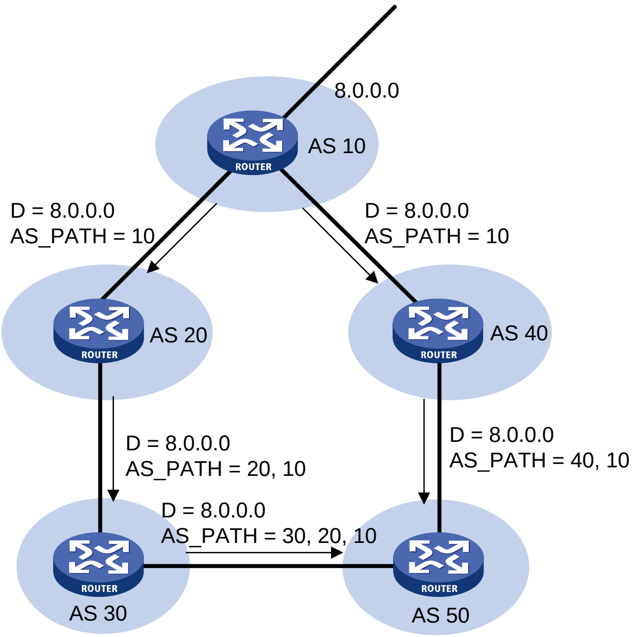
AS_PATH

The AS_PATH attribute identifies the ASs through which a route has passed. Before advertising a route to another AS, BGP adds the local AS number into the AS_PATH attribute, so the receiver can determine ASs to route the message back.

The AS_PATH attribute has the following types:

- **AS_SEQUENCE**—Arranges AS numbers in sequence. As shown in Figure 1, the number of the AS closest to the receiver's AS is leftmost.
- **AS_SET**—Arranges AS numbers randomly.

Figure 1 AS_PATH attribute



BGP uses the AS_PATH attribute to implement the following functions:

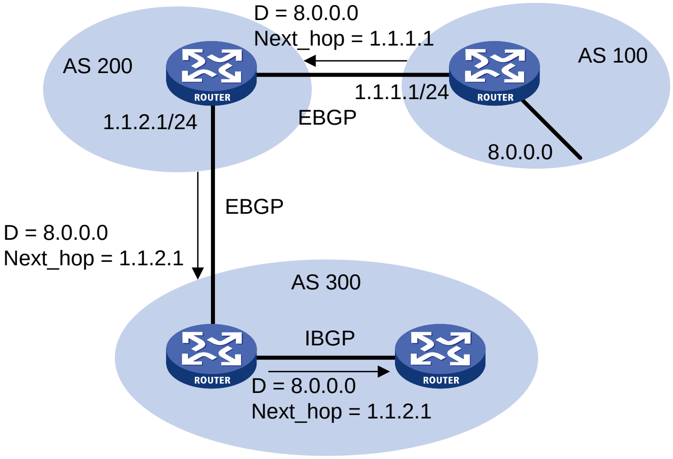
- **Avoid routing loops**—A BGP router does not receive routes containing the local AS number to avoid routing loops.
- **Affect route selection**—BGP gives priority to the route with the shortest AS_PATH length if other factors are the same. As shown in Figure 1, the BGP router in AS 50 gives priority to the route passing AS 40 for sending data to the destination 8.0.0.0. In some applications, you can apply a routing policy to control BGP route selection by modifying the AS_PATH length. For more information about routing policy, see "Configuring routing policies."
- **Filter routes**—By using an AS path list, you can filter routes based on AS numbers contained in the AS_PATH attribute. For more information about AS path list, see "Configuring routing policies."

NEXT_HOP

The NEXT_HOP attribute may not be the IP address of a directly connected router. Its value is determined as follows:

- When a BGP speaker advertises a self-originated route to a BGP peer, it sets the address of the sending interface as the NEXT_HOP.
- When a BGP speaker sends a received route to an EBGP peer, it sets the address of the sending interface as the NEXT_HOP.
- When a BGP speaker sends a route received from an EBGP peer to an IBGP peer, it does not modify the NEXT_HOP attribute. If load balancing is configured, BGP modifies the NEXT_HOP attribute for the equal-cost routes. For load balancing information, see "BGP load balancing."

Figure 2 NEXT_HOP attribute

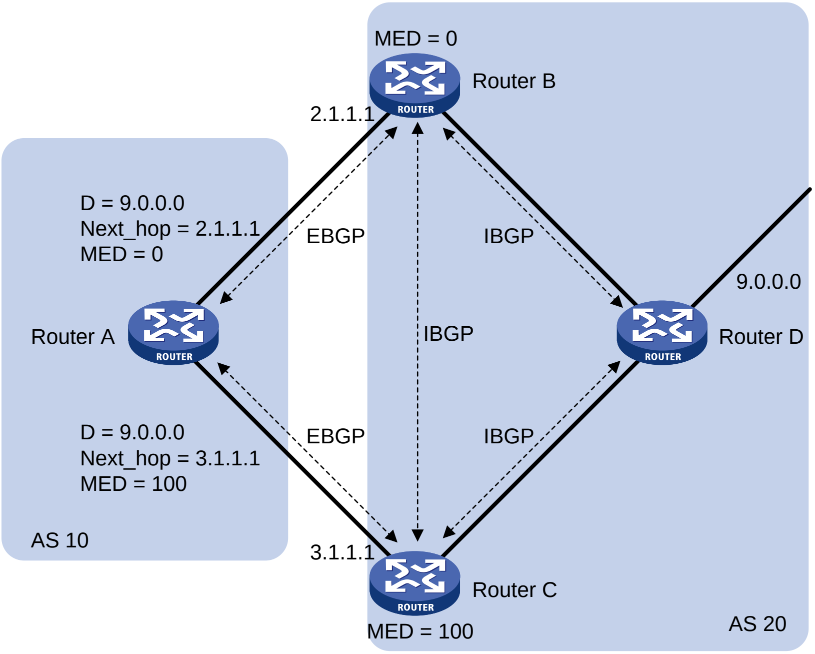


MED (MULTI_EXIT_DISC)

BGP advertises the MED attribute between two neighboring ASs, each of which does not advertise the attribute to any other AS.

Similar to metrics used by IGPs, MED is used to determine the optimal route for traffic going into an AS. When a BGP router obtains multiple routes to the same destination but with different next hops, it selects the route with the smallest MED value as the optimal route. As shown in Figure 3, traffic from AS 10 to AS 20 travels through Router B that is selected according to MED.

Figure 3 MED attribute



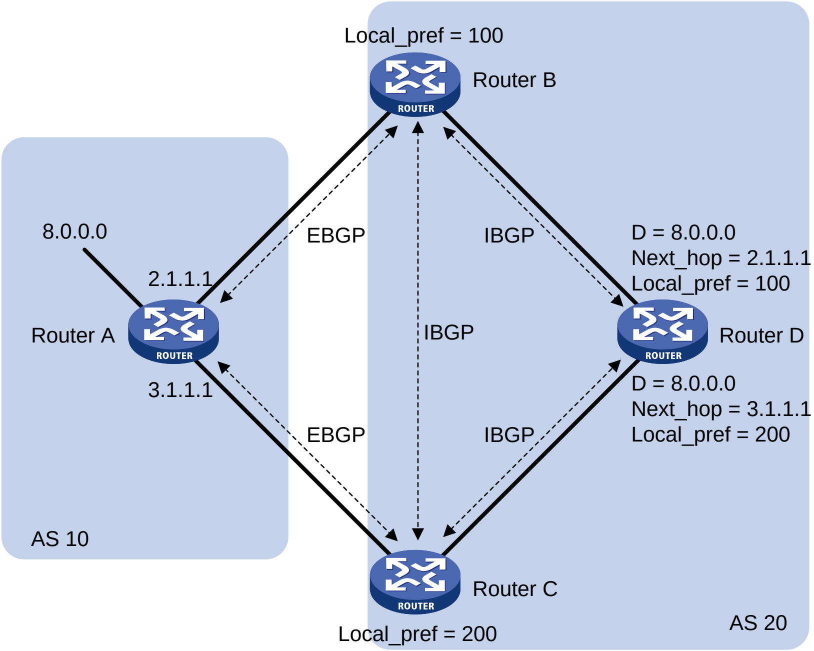
Generally BGP only compares MEDs of routes received from the same AS. You can also use the **compare-different-as-med** command to force BGP to compare MED values of routes received from different ASs.

LOCAL_PREF

The LOCAL_PREF attribute is exchanged between IBGP peers only, and is not advertised to any other AS. It indicates the priority of a BGP router.

BGP uses LOCAL_PREF to determine the optimal route for traffic leaving the local AS. When a BGP router obtains multiple routes to the same destination but with different next hops, it selects the route with the highest LOCAL_PREF value as the optimal route. As shown in Figure 4, traffic from AS 20 to AS 10 travels through Router C that is selected according to LOCAL_PREF.

Figure 4 LOCAL_PREF attribute



COMMUNITY

The COMMUNITY attribute identifies the community of BGP routes. A BGP community is a group of routes with the same characteristics. It has no geographical boundaries. Routes of different ASs can belong to the same community.

A route can carry one or more COMMUNITY attribute values (each of which is represented by a 4-byte integer). A router uses the COMMUNITY attribute to determine whether to advertise the route and the advertising scope without using complex filters such as ACLs. This mechanism simplifies routing policy configuration, management, and maintenance.

Well-known COMMUNITY attributes involve the following:

- **INTERNET**—By default, all routes belong to the Internet community. Routes with this attribute can be advertised to all BGP peers.
- **NO_EXPORT**—Routes with this attribute cannot be advertised out of the local AS or out of the local confederation, but can be advertised to other sub-ASs in the confederation. For confederation information, see "Settlements for problems in large-scale BGP networks."
- **No_ADVERTISE**—Routes with this attribute cannot be advertised to other BGP peers.
- **No_EXPORT_SUBCONFED**—Routes with this attribute cannot be advertised out of the local AS or other sub-ASs in the local confederation.

You can configure BGP community lists to filter BGP routes based on the BGP COMMUNITY attribute.

Extended community attribute

To meet new demands, BGP defines the extended community attribute. The extended community attribute has the following advantages over the COMMUNITY attribute:

- Provides more attribute values by extending the attribute length to eight bytes.
- Allows for using different types of extended community attributes in different scenarios to enhance route filtering and control and simplify configuration and management.

The device supports the route target attribute and Site of Origin (SoO) extended community attribute.

The SoO attribute specifies the site where the route originated. It prevents advertising a route back to the originating site. If the AS-path attribute is lost, the router can use the SoO attribute to avoid routing loops.

The SoO attribute has the following formats:

- *16-bit AS number:32-bit user-defined number*. For example, 100:3.
- *32-bit IP address:16-bit user-defined number*. For example, 192.168.122.15:1.
- *32-bit AS number:16-bit user-defined number*, where the minimum value of the AS number is 65536. For example, 65536:1.

BGP route selection

BGP discards routes with unreachable NEXT_HOPs. If multiple routes to the same destination are available, BGP selects the optimal route in the following sequence:

1. The route with the highest Preferred_value.
2. The route with the highest LOCAL_PREF.
3. The route generated by the **network** command, the route redistributed by the **import-route** command, or the summary route in turn.
4. The route with the shortest AS_PATH.
5. The IGP, EGP, or INCOMPLETE route in turn.
6. The route with the lowest MED value.
7. The route learned from EBGP, confederation EBGP, confederation IBGP, or IBGP in turn.
8. The route with the smallest IGP metric.
9. The route with the smallest recursion depth.
10. If a route received from an EBGP peer is the current optimal route, BGP does not change the optimal route when it receives routes from other EBGP peers.
11. The route advertised by the router with the smallest router ID.

    If one of the routes is advertised by a route reflector, BGP compares the ORIGINATOR_ID of the route with the router IDs of other routers. Then, BGP selects the route with the smallest ID as the optimal route.
12. The route with the shortest CLUSTER_LIST.
13. The route advertised by the peer with the lowest IP address.

The CLUSTER_IDs of route reflectors form a CLUSTER_LIST. If a route reflector receives a route that contains its own CLUSTER ID in the CLUSTER_LIST, the router discards the route to avoid routing loops.

If load balancing is configured, the system selects available routes to implement load balancing.

BGP route advertisement rules

BGP follows these rules for route advertisement:

- When multiple feasible routes to a destination exist, BGP advertises only the optimal route to its peers. If the **`advertise-rib-active`** command is configured, BGP advertises the optimal route in the IP routing table. If not, BGP advertises the optimal route in the BGP routing table.
- BGP advertises only routes that it uses.
- BGP advertises routes learned from an EBGP peer to all BGP peers, including both EBGP and IBGP peers.
- BGP advertises routes learned from an IBGP peer to EBGP peers, rather than other IBGP peers.
- After establishing a session to a new BGP peer, BGP advertises all the routes matching the above rules to the peer. After that, BGP advertises only incremental updates to the peer.

BGP load balancing

BGP load balancing is applicable between EBGP peers, between IBGP peers, and between confederations.

BGP implements load balancing through route recursion and route selection.

BGP load balancing through route recursion

The next hop of a BGP route might not be directly connected. One of the reasons is that the next hop information exchanged between IBGP peers is not modified. The BGP router must find the directly connected next hop through IGP. The matching route with the direct next hop is called the recursive route. The process of finding a recursive route is route recursion.

If multiple recursive routes to the same destination are load balanced, BGP generates the same number of next hops to forward packets.

BGP load balancing based on route recursion is always enabled in the system.

BGP load balancing through route selection

IGP routing protocols, such as RIP and OSPF, can use route metrics as criteria to load balance between routes that have the same metric. BGP cannot load balance between routes by route metrics as an IGP protocol does, because BGP does not have a route computation algorithm.

BGP uses the following load balancing criteria to determine load balanced routes:

- The routes have the same ORIGIN, LOCAL_PREF, and MED attributes.
- The routes meet the following requirements on the AS_PATH attribute:
    - If the **`balance as-path-neglect`** command is configured, the routes can have different AS_PATH attributes.
    - If only the **`balance as-path-relax`** command is configured, the routes can have different AS_PATH attributes, but the length of the AS_PATH attributes must be the same.
    - If neither the **`balance as-path-neglect`** nor the **`balance as-path-relax`** command is configured, the routes must have the same AS_PATH attribute.
- The next hops of the routes meet the following requirements on IGP metrics:
    - If the **`bestroute igp-metric-ignore`** command is not configured, the next hops of the routes must have the same IGP metric value.
    - If the **`bestroute igp-metric-ignore`** command is configured, the next hops of the routes can have different IGP metric values.

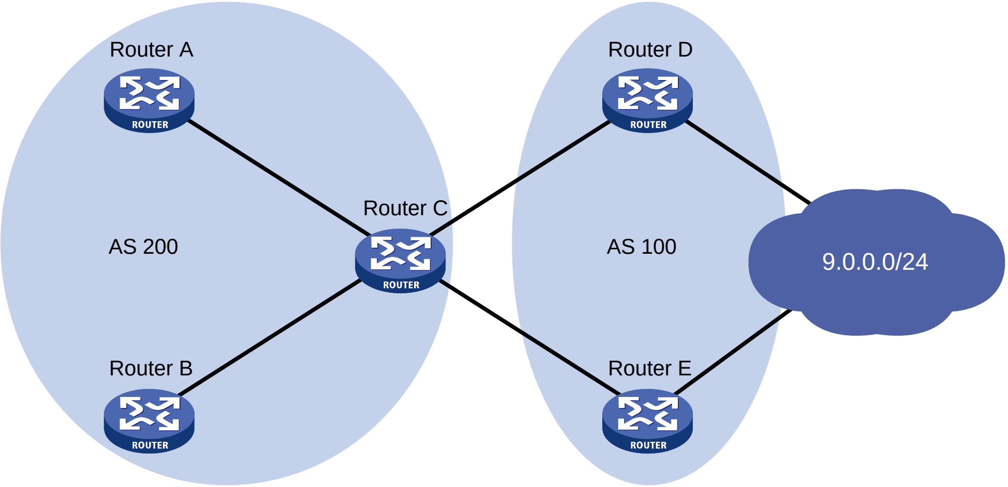
BGP does not use the route selection rules described in "BGP route selection" for load balancing.

As shown in Figure 5, Router A and Router B are IBGP peers of Router C. Router C allows a maximum number of two ECMP routes for load balancing.

Router D and Router E both advertise a route 9.0.0.0 to Router C. Router C installs the two routes to its routing table for load balancing if the routes meet the BGP load balancing criteria. After that, Router C forwards to Router A and Router B a single route whose attributes are changed as follows:

- AS_PATH attribute:
  - If the **`balance as-path-neglect`** and **`balance as-path-relax`** commands are not configured, the AS_PATH attribute does not change.
  - If the **`balance as-path-neglect`** or **`balance as-path-relax`** command is configured, the AS_PATH attribute is changed to the attribute of the optimal route.
- The NEXT_HOP attribute is changed to the IP address of Router C.
- Other attributes are changed to be the same as the optimal route.

Figure 5 Network diagram



Settlements for problems in large-scale BGP networks

You can use the following methods to facilitate management and improve route distribution efficiency on a large-scale BGP network.

Route summarization

Route summarization can reduce the BGP routing table size by advertising summary routes rather than more specific routes.

The system supports both manual and automatic route summarization. Manual route summarization allows you to determine the attribute of a summary route and whether to advertise more specific routes.

Route dampening

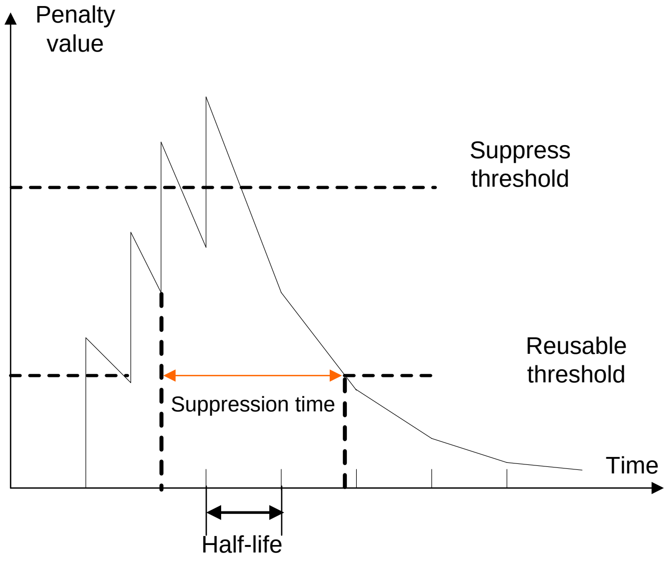
Route flapping (a route comes up and disappears in the routing table frequently) causes BGP to send many routing updates. It can consume too many resources and affect other operations.

In most cases, BGP runs in complex networks where route changes are more frequent. To solve the problem caused by route flapping, you can use BGP route dampening to suppress unstable routes.

BGP route dampening uses a penalty value to judge the stability of a route. The bigger the value, the less stable the route. Each time a route state changes from reachable to unreachable, or a reachable route's attribute changes, BGP adds a penalty value of 1000 to the route. When the penalty value of the route exceeds the suppress value, the route is suppressed and cannot become the optimal route. When the penalty value reaches the upper limit, no penalty value is added.

If the suppressed route does not flap, its penalty value gradually decreases to half of the suppress value after a period of time. This period is called "Half-life." When the value decreases to the reusable threshold value, the route is usable again.

Figure 6 BGP route dampening



Peer group

You can organize BGP peers with the same attributes into a group to simplify their configurations.

When a peer joins the peer group, the peer obtains the same configuration as the peer group. If the configuration of the peer group is changed, the configuration of group members is changed.

Community

You can apply a community list or an extended community list to a routing policy for route control. For more information, see "BGP path attributes."

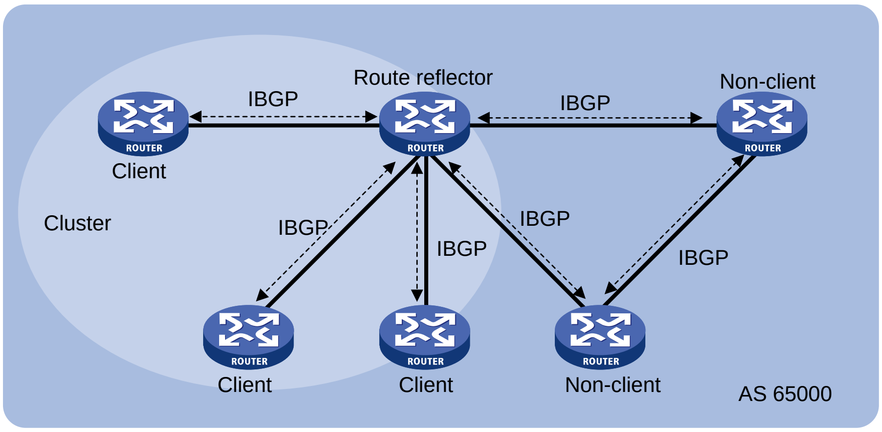
Route reflector

IBGP peers must be fully meshed to maintain connectivity. If n routers exist in an AS, the number of IBGP connections is n(n-1)/2. If a large number of IBGP peers exist, large amounts of network and CPU resources are consumed to maintain sessions.

Using route reflectors can solve this issue. In an AS, a router acts as a route reflector, and other routers act as clients connecting to the route reflector. The route reflector forwards routing information received from a client to other clients. In this way, all clients can receive routing information from one another without establishing BGP sessions.

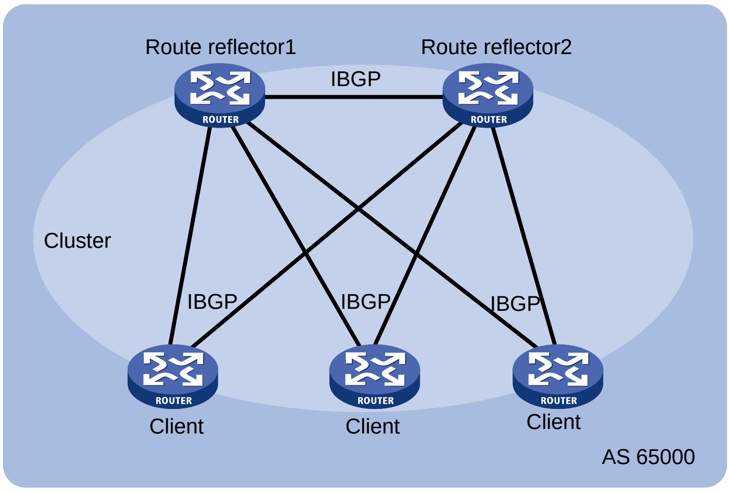
A router that is neither a route reflector nor a client is a non-client, which, as shown in Figure 7, must establish BGP sessions to the route reflector and other non-clients.

Figure 7 Network diagram for a route reflector



The route reflector and clients form a cluster. Typically a cluster has one route reflector. The ID of the route reflector is the Cluster_ID. You can configure more than one route reflector in a cluster to improve availability, as shown in Figure 8. The configured route reflectors must have the same Cluster_ID to avoid routing loops.

Figure 8 Network diagram for route reflectors



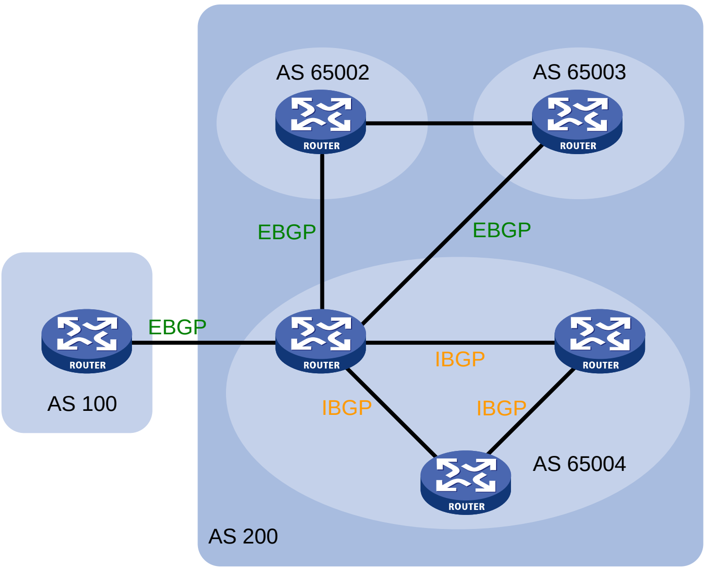
When the BGP routers in an AS are fully meshed, route reflection is unnecessary because it consumes more bandwidth resources. You can use commands to disable route reflection instead of modifying network configuration or changing network topology.

After route reflection is disabled between clients, routes can still be reflected between a client and a non-client.

Confederation

Confederation is another method to manage growing IBGP connections in an AS. It splits an AS into multiple sub-ASs. In each sub-AS, IBGP peers are fully meshed. As shown in Figure 9, intra-confederation EBGP connections are established between sub-ASs in AS 200.

Figure 9 Confederation network diagram



A non-confederation BGP speaker does not need to know sub-ASs in the confederation. To the BGP speaker, the confederation is one AS and the confederation ID is the AS number. In the above figure, AS 200 is the confederation ID.

Confederation has a deficiency. When you change an AS into a confederation, you must reconfigure the routers, and the topology will be changed.

In large-scale BGP networks, you can use both route reflector and confederation.

MP-BGP

Supported address families

BGP-4 can only advertise IPv4 unicast routing information. Multiprotocol Extensions for BGP-4 (MP-BGP) can advertise routing information for the following address families:

- IPv6 unicast address family.
- IPv4 multicast address family and IPv6 multicast address family.

  PIM uses static and dynamic unicast routes (including RIP, OSPF, IS-IS, BGP) to perform RPF check before creating multicast routing entries. When the multicast and unicast topologies are different, you can use MP-BGP to advertise the routes for RPF check. MP-BGP stores the routes in the BGP multicast routing table. For more information about PIM and RPF check, see *IP Multicast Configuration Guide*.
- VPNv4 address family and VPNv6 address family.

MP-BGP extended attributes

Prefixes and next hops are key routing information. BGP-4 uses UPDATE messages to carry the following information:

- Feasible route prefixes in the Network Layer Reachability Information (NLRI) field.
- Unfeasible route prefixes in the withdrawn routes field.
- Next hops in the NEXT_HOP attribute.

BGP-4 cannot carry routing information for multiple network layer protocols.

To support multiple network layer protocols, MP-BGP defines the following path attributes:

- **MP_REACH_NLRI**—Carries feasible route prefixes and next hops for multiple network layer protocols.
- **MP_UNREACH_NLRI**—Carries unfeasible route prefixes for multiple network layer protocols.

MP-BGP uses these two attributes to advertise feasible and unfeasible routes for different network layer protocols. BGP speakers not supporting MP-BGP ignore updates containing these attributes and do not forward them to its peers.

Address family

MP-BGP uses address families and subsequent address families to identify different network layer protocols for routes contained in the MP_REACH_NLRI and MP_UNREACH_NLRI attributes. For example, an Address Family Identifier (AFI) of 2 and a Subsequent Address Family Identifier (SAFI) of 1 identify IPv6 unicast routing information carried in the MP_REACH_NLRI attribute. For address family values, see RFC 1700.

BGP multi-instance

A BGP router can run multiple BGP processes. Each BGP process corresponds to a BGP instance. BGP maintains an independent routing table for each BGP instance.

BGP configuration views

BGP uses different views to manage routing information for different BGP instances, VPN instances, and address families. Most BGP commands are available in all BGP views. BGP supports multiple VPN instances by establishing a separate routing table for each VPN instance.

Table 1 describes different BGP configuration views.

Table 1 BGP configuration views

View names	Ways to enter the views	Remarks

BGP instance view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc]`
		You can create a BGP instance and enter its view by specifying the **`instance`** keyword in the **`bgp`** command.
		Configurations in this view apply to all public address families for the specified BGP instance. Some configurations (such as confederation, GR, and logging configurations) also apply to the address families of VPN instances.

BGP IPv4 unicast address family view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc] address-family ipv4 unicast`
	`[Sysname-bgp-abc-ipv4]`
		Configurations in this view apply to public IPv4 unicast routes and peers of the specified BGP instance.

BGP IPv6 unicast address family view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc] address-family ipv6 unicast`
	`[Sysname-bgp-abc-ipv6]`
		Configurations in this view apply to public IPv6 unicast routes and peers of the specified BGP instance.

BGP IPv4 multicast address family view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
		Configurations in this view apply to IPv4 multicast routes and peers of

View names	Ways to enter the views	Remarks

	`[Sysname-bgp-abc] address-family ipv4 multicast`
	`[Sysname-bgp-abc-mul-ipv4]`
		the specified BGP instance.

BGP IPv6 multicast address family view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc] address-family ipv6 multicast`
	`[Sysname-bgp-abc-mul-ipv6]`
		Configurations in this view apply to IPv6 multicast routes and peers of the specified BGP instance.

BGP VPNv4 address family view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc] address-family vpnv4`
	`[Sysname-bgp-abc-vpnv4]`
		Configurations in this view apply to VPNv4 routes and peers of the specified BGP instance.

BGP VPNv6 address family view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc] address-family vpnv6`
	`[Sysname-bgp-abc-vpnv6]`
		Configurations in this view apply to VPNv6 routes and peers of the specified BGP instance.

BGP-VPN instance view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc] ip vpn-instance vpn1`
	`[Sysname-bgp-abc-vpn1]`
		Configurations in this view apply to all address families in the specified VPN instance of the specified BGP instance.

BGP-VPN IPv4 unicast address family view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc] ip vpn-instance vpn1`
	`[Sysname-bgp-abc-vpn1] address-family ipv4 unicast`
	`[Sysname-bgp-abc-ipv4-vpn1]`
		Configurations in this view apply to IPv4 unicast routes and peers in the specified VPN instance of the specified BGP instance.

BGP-VPN IPv6 unicast address family view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc] ip vpn-instance vpn1`
	`[Sysname-bgp-abc-vpn1] address-family ipv6 unicast`
	`[Sysname-bgp-abc-ipv6-vpn1]`
		Configurations in this view apply to IPv6 unicast routes and peers in the specified VPN instance of the specified BGP instance.

BGP IPv4 MVPN address family view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc] address-family ipv4 mvpn`
	`[Sysname-bgp-abc-mvpn]`
		Configurations in this view apply to MVPN routes and peers of the specified BGP instance.

BGP LS address family view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc] address-family link-state`
	`[Sysname-bgp-abc-ls]`
		Configurations in this view apply to LS messages and peers of the specified BGP instance.

View names	Ways to enter the views	Remarks

BGP IPv4 RT filter address family view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc] address-family ipv4 rtfilter`
	`[Sysname-bgp-abc-rtf-ipv4]`
		Configurations in this view apply to IPv4 RT filter routes and peers of the specified BGP instance.

Building basic BGP networks

Restrictions and guidelines: BGP configuration

You can create multiple public address families for a BGP instance. However, each public address family (except for public VPNv4 and VPNv6 address families) can belong to only one BGP instance.

You can create multiple VPN instances for a BGP instance, and each VPN instance can have multiple address families. A VPN instance can belong to only one BGP instance.

You cannot specify the same peer for the same address family of different BGP instances.

Different BGP instances can have the same AS number but cannot have the same name.

Basic BGP network configuration tasks at a glance (IPv4 unicast/IPv4 multicast)

To build basic BGP networks for the IPv4 unicast or IPv4 multicast address family, perform the following tasks:

1. Configuring basic BGP
   a. Enabling BGP
   b. Configuring a BGP peer
   c. Configuring dynamic BGP peers
   d. Configuring an IBGP peer group

      Configure BGP peer groups on large-scale BGP networks for easy configuration and maintenance.
   e. Configuring an EBGP peer group

      Configure BGP peer groups on large-scale BGP networks for easy configuration and maintenance.
   f. (Optional.) Specifying the source address of TCP connections
2. Controlling BGP route generation

   Choose the following tasks as needed:
   - Injecting a local network
   - Redistributing IGP routes
   - (Optional.) Configuring BGP route summarization
   - (Optional.) Advertising a default route to a peer or peer group
3. (Optional.) Controlling BGP route advertisement
   - Advertising optimal routes in the IP routing table

     BGP cannot advertise optimal routes in the IP routing table for IPv4 multicast address family.
   - Configuring BGP route distribution filtering policies
   - Configuring BGP to delay sending route updates on reboot
4. (Optional.) Controlling BGP route reception
   - Limiting routes received from a peer or peer group
   - Configuring BGP route reception filtering policies
   - Configuring the SoO attribute

5. (Optional.) Configuring BGP timers
    - Configuring the keepalive interval and hold time
    - Setting the session retry timer
    - Configuring the interval for sending updates for the same route
6. (Optional.) Configuring BGP logging and notifications
    - Enabling logging for session state changes
    - Configuring BGP network management

Basic BGP network configuration tasks at a glance (IPv6 unicast/IPv6 multicast)

To build basic BGP networks for the IPv6 unicast or IPv6 multicast address family, perform the following tasks:

1. Configuring basic BGP
    a. Enabling BGP
    b. Configuring a BGP peer
    c. Configuring dynamic BGP peers
    d. Configuring an IBGP peer group

       Configure BGP peer groups on large-scale BGP networks for easy configuration and maintenance.
    e. Configuring an EBGP peer group

       Configure BGP peer groups on large-scale BGP networks for easy configuration and maintenance.
    f. (Optional.) Specifying the source address of TCP connections
2. Controlling BGP route generation

   Choose the following tasks as needed:
    - Injecting a local network
    - Redistributing IGP routes
    - (Optional.) Configuring BGP route summarization
    - (Optional.) Advertising a default route to a peer or peer group
3. (Optional.) Controlling BGP route advertisement
    - Advertising optimal routes in the IP routing table

      BGP cannot advertise optimal routes in the IP routing table for IPv6 multicast address family.
    - Configuring BGP route distribution filtering policies
    - Configuring BGP to delay sending route updates on reboot
4. (Optional.) Controlling BGP route reception
    - Limiting routes received from a peer or peer group
    - Configuring BGP route reception filtering policies
    - Configuring the SoO attribute
5. (Optional.) Configuring BGP timers
    - Configuring the keepalive interval and hold time
    - Setting the session retry timer
    - Configuring the interval for sending updates for the same route

6. (Optional.) Configuring BGP logging and notifications
   - Enabling logging for session state changes
   - Configuring BGP network management

Configuring basic BGP

Enabling BGP

Restrictions and guidelines

A router ID is the unique identifier of a BGP router in an AS.

- To ensure the uniqueness of a router ID and enhance availability, specify in BGP instance view the IP address of a local loopback interface as the router ID. Different BGP instances can have the same router ID.
- If no router ID is specified in BGP instance view, the global router ID is used.
- To modify a non-zero router ID of a BGP instance , use the **router-id** command in BGP instance view, rather than the **router id** command in system view.
- If you specify a router ID in BGP instance view and then remove the interface that owns the router ID, the router does not select a new router ID. To select a new router ID, use the **undo router-id** command in BGP instance view.

Procedure

1. Enter system view.

   system-view

2. Configure a global router ID.

   router id *router-id*

   By default, no global router ID is configured.

   If no global router ID is configured, the following rules apply:

   - If loopback interfaces configured with an IP address exist, BGP uses the highest loopback interface IP address as the router ID.
   - If no loopback interface IP address is available, BGP uses the highest physical interface IP address as the route ID regardless of the interface status.

3. Enable BGP and enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

   By default, BGP is disabled and no BGP instances exist.

4. (Optional.) Configure a router ID for the BGP instance.

   router-id *router-id*

   By default, no router ID is configured for a BGP instance, and the BGP instance uses the global router ID configured by the **router-id** command in system view.

5. (Optional.) Enter BGP-VPN instance view.

   ip vpn-instance *vpn-instance-name*

   The specified VPN instance must have been created and have an RD.

6. (Optional.) Configure a router ID for the BGP VPN instance.

   router-id { *router-id* | **auto-select** }

   By default, no router ID is configured for a BGP VPN instance.

The BGP VPN instance uses the router ID configured in BGP instance view. If no router ID is configured in BGP instance view, the BGP VPN instance uses the global router ID configured in system view.

Configuring a BGP peer

Restrictions and guidelines

A BGP peer at an IPv6 link-local address must be directly connected to the local router. On the local router, you must use the **peer connect-interface** command to specify the interface directly connected to the BGP peer as the source interface of TCP connections.

Procedure (IPv4 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an IPv4 BGP peer and specify its AS number.

   peer *ipv4-address* **as-number** *as-number*

4. (Optional.) Configure a description for a peer.

   peer *ipv4-address* **description** *text*

   By default, no description is configured for a peer.

5. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

6. Enable the router to exchange IPv4 unicast routing information with the specified peer.

   peer *ipv4-address* **enable**

   By default, the router cannot exchange IPv4 unicast routing information with the peer.

Procedure (IPv6 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an IPv6 BGP peer and specify its AS number.

   peer *ipv6-address* **as-number** *as-number*

4. (Optional.) Configure a description for a peer.

   peer *ipv6-address* **description** *text*

   By default, no description is configured for a peer.

5. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

6. Enable the router to exchange IPv6 unicast routing information with the specified peer.

   peer *ipv6-address* **enable**

   By default, the router cannot exchange IPv6 unicast routing information with the peer.

Procedure (IPv4 multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an IPv4 BGP peer and specify its AS number.

   peer *ipv4-address* **as-number** *as-number*

4. (Optional.) Configure a description for the peer.

   peer *ipv4-address* **description** *text*

   By default, no description is configured for a peer.

5. Create the BGP IPv4 multicast address family and enter its view.

   address-family ipv4 multicast

6. Enable the router to exchange IPv4 unicast routing information used for RPF check with the specified peer.

   peer *ipv4-address* **enable**

   By default, the router cannot exchange IPv4 unicast routing information used for RPF check with the peer.

Procedure (IPv6 multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an IPv6 BGP peer and specify its AS number.

   peer *ipv6-address* **as-number** *as-number*

4. (Optional.) Configure a description for the peer.

   peer *ipv6-address* **description** *text*

   By default, no description is configured for a peer.

5. Create the BGP IPv6 multicast address family and enter its view.

   address-family ipv6 multicast

6. Enable the router to exchange IPv6 unicast routing information used for RPF check with the specified peer.

   peer *ipv6-address* **enable**

   By default, the router cannot exchange IPv6 unicast routing information used for RPF check with the peer.

Configuring dynamic BGP peers

About this task

This feature enables BGP to establish dynamic BGP peer relationships with devices in a network. BGP accepts connection requests from the network but it does not initiate connection requests to the network.

After a device in the network initiates a connection request, BGP establishes a dynamic peer relationship with the device.

If multiple BGP peers reside in the same network, you can use this feature to simplify BGP peer configuration.

Restrictions and guidelines

For a remote device to establish a peer relationship with the local device, you must specify the IP address of the local device on the remote device.

A BGP peer at an IPv6 link-local address must be directly connected to the local router. On the local router, you must use the **peer connect-interface** command to specify the interface directly connected to the BGP peer as the source interface of TCP connections.

Procedure (IPv4 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Specify devices in a network as dynamic BGP peers and specify an AS number for the peers.

   peer *ipv4-address mask-length* **as-number** *as-number*

4. (Optional.) Configure a description for dynamic BGP peers.

   peer *ipv4-address mask-length* **description** *text*

   By default, no description is configured for dynamic BGP peers.

5. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

6. Enable BGP to exchange IPv4 unicast routing information with dynamic BGP peers in the specified network.

   peer *ipv4-address mask-length* **enable**

   By default, BGP cannot exchange IPv4 unicast routing information with dynamic BGP peers.

Procedure (IPv6 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

3. Specify devices in a network as dynamic BGP peers and specify an AS number for the peers.

   peer *ipv6-address prefix-length* **as-number** *as-number*

4. (Optional.) Configure a description for dynamic BGP peers.

   peer *ipv6-address prefix-length* **description** *text*

   By default, no description is configured for dynamic BGP peers.

5. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

6. Enable BGP to exchange IPv6 unicast routing information with dynamic BGP peers in the specified network.

   peer *ipv6-address prefix-length* **enable**

   By default, BGP cannot exchange IPv6 unicast routing information with dynamic BGP peers.

Procedure (IPv4 multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Specify devices in a network as dynamic BGP peers and specify an AS number for the peers.

   peer *ipv4-address mask-length* **as-number** *as-number*

4. (Optional.) Configure a description for dynamic BGP peers.

   peer *ipv4-address mask-length* **description** *text*

   By default, no description is configured for dynamic BGP peers.

5. Create the BGP IPv4 multicast address family and enter its view.

   address-family ipv4 multicast

6. Enable BGP to exchange IPv4 unicast routing information used for RPF check with dynamic BGP peers in the specified network.

   peer *ipv4-address mask-length* **enable**

   By default, BGP cannot exchange IPv4 unicast routing information used for RPF check with dynamic BGP peers.

Procedure (IPv6 multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Specify devices in a network as dynamic BGP peers and specify an AS number for the peers.

   peer *ipv6-address prefix-length* **as-number** *as-number*

4. (Optional.) Configure a description for dynamic BGP peers.

   peer *ipv6-address prefix-length* **description** *text*

   By default, no description is configured for dynamic BGP peers.

5. Create the BGP IPv6 multicast address family and enter its view.

   address-family ipv6 multicast

6. Enable BGP to exchange IPv6 unicast routing information used for RPF check with dynamic BGP peers in the specified network.

   peer *ipv6-address prefix-length* **enable**

   By default, BGP cannot exchange IPv6 unicast routing information used for RPF check with dynamic BGP peers.

Configuring an IBGP peer group

About this task

A peer group is an IBGP peer group if peers in it belong to the same AS as the local router.

After you create an IBGP peer group and then add a peer into it, the system creates the peer in BGP instance view and specifies the local AS number for the peer.

Restrictions and guidelines

A BGP peer at an IPv6 link-local address must be directly connected to the local router. On the local router, you must use the **peer connect-interface** command to specify the interface directly connected to the BGP peer as the source interface of TCP connections.

If you configure a BGP setting at both the peer group and the peer level, the most recent configuration takes effect on the peer.

Procedure (IPv4 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an IBGP peer group.

   group *group-name* [**internal**]

4. Add a peer into the IBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the local AS number.

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

6. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

7. Enable the router to exchange IPv4 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information with the peers.

Procedure (IPv4 multicast address family)

1. Enter system view.

system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an IBGP peer group.

   group *group-name* [**internal**]

4. Add an IPv4 peer into the IBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the local AS number.

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

6. Create the BGP IPv4 multicast address family and enter its view.

   address-family ipv4 multicast

7. Enable the router to exchange IPv4 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information used for RPF check with the peers in the peer group.

Procedure (IPv6 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.

   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an IBGP peer group.

   group *group-name* [**internal**]

4. Add a peer into the IBGP peer group.

   peer *ipv6-address* [*prefix-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the local AS number.

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

6. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

7. Enable the router to exchange IPv6 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information with the peers.

Procedure (IPv6 multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an IBGP peer group.

   group *group-name* [**internal**]

4. Add a peer into the IBGP peer group.

   peer *ipv6-address* [*prefix-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the local AS number.

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

6. Create the BGP IPv6 multicast address family and enter its view.

   address-family ipv6 multicast

7. Enable the router to exchange IPv6 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information used for RPF check with the peers in the peer group.

Configuring an EBGP peer group

About this task

A peer group is an EBGP peer group if peers in it belong to different ASs.

If peers in an EBGP group belong to the same external AS, the EBGP peer group is a pure EBGP peer group. If not, it is a mixed EBGP peer group.

Restrictions and guidelines

Use one of the following methods to configure an EBGP peer group:

- **Method 1**—Create an EBGP peer group, specify its AS number, and add peers into it. All the added peers have the same AS number. All peers in the peer group have the same AS number as the peer group. You can specify an AS number for a peer before adding it into the peer group. The AS number must be the same as that of the peer group.
- **Method 2**—Create an EBGP peer group, specify an AS number for a peer, and add the peer into the peer group. Peers added in the group can have different AS numbers.
- **Method 3**—Create an EBGP peer group and add a peer with an AS number into it. Peers added in the group can have different AS numbers.

If you configure a BGP setting at both the peer group and the peer level, the most recent configuration takes effect on the peer.

Configuring an EBGP peer group by using Method 1 (IPv4 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.

   - Enter BGP instance view.

bgp *as-number* [**instance** *instance-name*]

- Execute the following commands in sequence to enter BGP-VPN instance view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

3. Create an EBGP peer group.

   group *group-name* **external**

4. Specify the AS number of the group.

   peer *group-name* **as-number** *as-number*

   By default, no AS number is specified.

   If a peer group contains peers, you cannot remove or change its AS number.

5. Add a peer into the EBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *group-name* **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

7. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

8. Enable the router to exchange IPv4 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information with the peers.

Configuring an EBGP peer group by using Method 2 (IPv4 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.

   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an EBGP peer group.

   group *group-name* **external**

4. Create an IPv4 BGP peer and specify its AS number.

   peer *ipv4-address* [*mask-length*] **as-number** *as-number*

5. Add the peer into the EBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *ipv4-address* [*mask-length*] **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

peer *group-name* **description** *text*

By default, no description is configured for the peer group.

7. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

8. Enable the router to exchange IPv4 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information with the peers.

Configuring an EBGP peer group by using Method 3 (IPv4 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an EBGP peer group.

   group *group-name* **external**

4. Add a peer into the EBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* **as-number** *as-number*

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

6. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

7. Enable the router to exchange IPv4 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information with the peers.

Configuring an EBGP peer group by using Method 1 (IPv4 multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an EBGP peer group.

   group *group-name* **external**

4. Specify the AS number of the group.

   peer *group-name* **as-number** *as-number*

   By default, no AS number is specified.

   If a peer group contains peers, you cannot remove or change its AS number.

5. Add an IPv4 BGP peer into the EBGP peer group.

peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

The **as-number** *as-number* option must specify the same AS number as the **peer** *group-name* **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

7. Create the BGP IPv4 multicast address family and enter its view.

   address-family ipv4 multicast

8. Enable the router to exchange IPv4 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information used for RPF check with the peers in the group.

Configuring an EBGP peer group by using Method 2 (IPv4 multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an EBGP peer group.

   group *group-name* **external**

4. Create an IPv4 BGP peer and specify its AS number.

   peer *ipv4-address* [*mask-length*] **as-number** *as-number*

5. Add the peer into the EBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *ipv4-address* [*mask-length*] **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

7. Create the BGP IPv4 multicast address family and enter its view.

   address-family ipv4 multicast

8. Enable the router to exchange IPv4 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information used for RPF check with the peers in the group.

Configuring an EBGP peer group by using Method 3 (IPv4 multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an EBGP peer group.

   group *group-name* **external**

4. Add an IPv4 BGP peer into the EBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* **as-number** *as-number*

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

6. Create the BGP IPv4 multicast address family and enter its view.

   address-family ipv4 multicast

7. Enable the router to exchange IPv4 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information used for RPF check with the peers.

Configuring an EBGP peer group by using Method 1 (IPv6 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an EBGP peer group.

   group *group-name* **external**

4. Specify the AS number of the group.

   peer *group-name* **as-number** *as-number*

   By default, no AS number is specified.

   If a peer group contains peers, you cannot remove or change its AS number.

5. Add a peer into the EBGP peer group.

   peer *ipv6-address* [*prefix-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *group-name* **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

7. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

8. Enable the router to exchange IPv6 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information with the peers.

Configuring an EBGP peer group by using Method 2 (IPv6 unicast address family)

1. Enter system view.

system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Create an EBGP peer group.

   group *group-name* **external**
4. Create an IPv6 BGP peer and specify its AS number.

   peer *ipv6-address* [*prefix-length*] **as-number** *as-number*
5. Add the peer into the EBGP peer group.

   peer *ipv6-address* [*prefix-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *ipv6-address* [*prefix-length*] **as-number** *as-number* command.
6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.
7. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]
8. Enable the router to exchange IPv6 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information with the peers.

Configuring an EBGP peer group by using Method 3 (IPv6 unicast address family)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Create an EBGP peer group.

   group *group-name* **external**
4. Add a peer into the EBGP peer group.

   peer *ipv6-address* [*prefix-length*] **group** *group-name* **as-number** *as-number*
5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

6. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

7. Enable the router to exchange IPv6 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information with the peers.

Configuring an EBGP peer group by using Method 1 (IPv6 multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an EBGP peer group.

   group *group-name* **external**

4. Specify the AS number of the group.

   peer *group-name* **as-number** *as-number*

   By default, no AS number is specified.

   If a peer group contains peers, you cannot remove or change its AS number.

5. Add an IPv6 BGP peer into the EBGP peer group.

   peer *ipv6-address* [*prefix-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *group-name* **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

7. Create the BGP IPv6 multicast address family and enter its view.

   address-family ipv6 multicast

8. Enable the router to exchange IPv6 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information used for RPF check with the peers in the group.

Configuring an EBGP peer group by using Method 2 (IPv6 multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an EBGP peer group.

   group *group-name* **external**

4. Create an IPv6 BGP peer and specify its AS number.

   peer *ipv6-address* [*prefix-length*] **as-number** *as-number*

5. Add the peer into the EBGP peer group.

```
peer ipv6-address [ prefix-length ] group group-name [ as-number
as-number ]
```

The **as-number** *as-number* option must specify the same AS number as the **peer** *ipv6-address* [*prefix-length*] **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   ```
   peer group-name description text
   ```

   By default, no description is configured for the peer group.

7. Create the BGP IPv6 multicast address family and enter its view.

   ```
   address-family ipv6 multicast
   ```

8. Enable the router to exchange IPv6 unicast routing information used for RPF check with peers in the specified peer group.

   ```
   peer group-name enable
   ```

   By default, the router cannot exchange IPv6 unicast routing information used for RPF check with the peers in the group.

Configuring an EBGP peer group by using Method 3 (IPv6 multicast address family)

1. Enter system view.

   ```
   system-view
   ```

2. Enter BGP instance view.

   ```
   bgp as-number [ instance instance-name ]
   ```

3. Create an EBGP peer group.

   ```
   group group-name external
   ```

4. Add an IPv6 BGP peer into the EBGP peer group.

   ```
   peer ipv6-address [ prefix-length ] group group-name as-number
   as-number
   ```

5. (Optional.) Configure a description for the peer group.

   ```
   peer group-name description text
   ```

   By default, no description is configured for the peer group.

6. Create the BGP IPv6 multicast address family and enter its view.

   ```
   address-family ipv6 multicast
   ```

7. Enable the router to exchange IPv6 unicast routing information used for RPF check with peers in the specified peer group.

   ```
   peer group-name enable
   ```

   By default, the router cannot exchange IPv6 unicast routing information used for RPF check with the peers in the group.

Specifying the source address of TCP connections

About this task

BGP uses TCP as the transport layer protocol. Perform this task in the following scenarios to specify the source address or source interface of TCP connections to a peer or peer group:

- The peer's IPv4/IPv6 address does not belong to the interface directly connected to the local router. To ensure successful TCP connection establishment, use one of the following methods:
  - Specify the interface to which the IPv4/IPv6 address belongs as the source interface on the peer.
  - Specify the IPv4/IPv6 address of the interface directly connected to the local router as the source address on the peer.

- A BGP peer at an IPv6 link-local address must be directly connected to the local router. On the local router, you must use the **peer connect-interface** command to specify the interface directly connected to the BGP peer as the source interface of TCP connections.
- On a BGP router that has multiple links to a peer, the source interface for TCP connection changes because the primary source interface fails. To avoid this problem, specify a loopback interface as the source interface or specify the IP address of a loopback interface as the source address.
- You want to establish multiple BGP sessions to a router. In this case, BGP might fail to determine the source address for each TCP connection based on the optimal route to the peer. To prevent this problem, use one of the following methods:
    - If the BGP sessions use IP addresses of different interfaces, specify a source interface or source address for each session.
    - If the BGP sessions use different IP addresses of the same interface, specify a source address for each session.

Restrictions and guidelines

BGP immediately tears down the session to an IBGP peer or peer group when the following conditions exist:

- The source interface of TCP connections to the IBGP peer or peer group is a physical interface.
- The source interface fails and the link to the IBGP peer or peer group goes down.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
    - Enter BGP instance view.

      bgp *as-number* [**instance** *instance-name*]

    - Execute the following commands in sequence to enter BGP-VPN instance view:

      bgp *as-number* [**instance** *instance-name*]

      ip vpn-instance *vpn-instance-name*

3. Specify the source address or source interface of TCP connections to a peer or peer group.
    - Specify the source address of TCP connections to a peer or peer group.

      peer { *group-name* | *ipv4-address* [*mask-length*] } **source-address** *source-ipv4-address*

    - Specify the source interface of TCP connections to a peer or peer group.

      peer { *group-name* | *ipv4-address* [*mask-length*] } **connect-interface** *interface-type interface-number*

   By default, BGP uses the primary IPv4 address of the output interface in the optimal route to a peer or peer group as the source address of TCP connections to the peer or peer group.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
    - Enter BGP instance view.

      bgp *as-number* [**instance** *instance-name*]

    - Execute the following commands in sequence to enter BGP-VPN instance view:

      bgp *as-number* [**instance** *instance-name*]

      ip vpn-instance *vpn-instance-name*

3. Specify the source IPv6 address or source interface of TCP connections to a peer or peer group.
   - Specify the source IPv6 address of TCP connections to a peer or peer group.

     peer { *group-name* | *ipv6-address* [*prefix-length*] } **source-address** *source-ipv6-address*
   - Specify the source interface of TCP connections to a peer or peer group.

     peer { *group-name* | *ipv6-address* [*prefix-length*] } **connect-interface** *interface-type interface-number*

   By default, BGP uses the IPv6 address of the output interface in the optimal route to the BGP peer or peer group as the source address of TCP connections to the peer or peer group.

Controlling BGP route generation

Injecting a local network

About this task

Perform this task to inject a network in the local routing table to the BGP routing table, so BGP can advertise the network to BGP peers. The ORIGIN attribute of BGP routes advertised in this way is IGP. You can also use a routing policy to control route advertisement.

The specified network must be available and active in the local IP routing table.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast
3. Configure BGP to advertise a local network.

   network *ipv4-address* [*mask-length* | *mask*] [**route-policy** *route-policy-name*]

   By default, BGP does not advertise local networks.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Configure BGP to advertise a local network.

   network *ipv6-address prefix-length* [**route-policy** *route-policy-name*]

   By default, BGP does not advertise local networks.

Redistributing IGP routes

About this task

Perform this task to configure route redistribution from an IGP to BGP.

By default, BGP does not redistribute default IGP routes. You can use the **default-route imported** command to redistribute default IGP routes into the BGP routing table.

The ORIGIN attribute of BGP routes redistributed from IGPs is INCOMPLETE.

Only active routes can be redistributed. To view route state information, use the **display ip routing-table protocol** or **display ipv6 routing-table protocol** command. For more information about the commands, see *Layer 3—IP Routing Command Reference*.

If you execute the **import-route** command multiple times for an IGP process, the most recent configuration takes effect. To redistribute more routes from an IGP process without overwriting the routes redistributed before, use the **import-route-append** command.

When you execute both the **import-route** and **import-route-append** commands for an IGP process, the commands take effect as follows:

- A route is redistributed as long as it matches the criteria of either command.
- If a route matches the criteria of both commands, the route is redistributed, and the apply clauses in the routing policies specified in the two commands take effect as follows:
  - If the apply clauses do not conflict, all apply clauses take effect.
  - If conflicts occur between the apply clauses, only the apply clauses in the **import-route-append** command take effect.
- The MED value specified by the **import-route-append** command takes precedence over that specified by the **import-route** command.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast
3. Enable route redistribution from the specified IGP into BGP.
   - Redistribute **IS-IS, OSPF, or RIP routes.**

     import-route { **isis** | **ospf** | **rip** } [{ *process-id* | **all-processes** } [**allow-direct** | **med** *med-value* | **route-policy** *route-policy-name*] *]
   - Redistribute direct or static routes.

     import-route { **direct** | **static** } [**med** *med-value* | **route-policy** *route-policy-name*] *

   By default, BGP does not redistribute IGP routes.
4. (Optional.) Redistribute routes from an IGP without overwriting the routes redistributed by the **import-route** command.
   - Redistribute IS-IS, OSPF, or RIP routes.

     import-route-append { **isis** | **ospf** | **rip** } [{ *process-id* | **all-processes** } [**allow-direct** | **med** *med-value* | **route-policy** *route-policy-name*] *]
   - Redistribute direct or static routes.

     import-route-append { **direct** | **static** } [**med** *med-value* | **route-policy** *route-policy-name*] *

   By default, BGP does not redistribute IGP routes.
5. (Optional.) Enable default route redistribution into BGP.

   default-route imported

   By default, BGP does not redistribute default routes.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv6 multicast

3. Enable route redistribution from the specified IGP into BGP.

   - Redistribute IPv6 **IS-IS, OSPFv3, or RIPng routes.**

     import-route { **isisv6** | **ospfv3** | **ripng** } [{ *process-id* | **all-processes** } [**allow-direct** | **med** *med-value* | **route-policy** *route-policy-name*] *]

   - Redistribute direct or static routes.

     import-route { **direct** | **static** } [**med** *med-value* | **route-policy** *route-policy-name*] *

   By default, BGP does not redistribute IGP routes.

4. (Optional.) Redistribute routes from an IGP without overwriting the routes redistributed by the **import-route** command.

   - Redistribute IPv6 IS-IS, OSPFv3, or RIPng routes.

     import-route-append { **isisv6** | **ospfv3** | **ripng** } [{ *process-id* | **all-processes** } [**allow-direct** | **med** *med-value* | **route-policy** *route-policy-name*] *]

   - Redistribute direct or static routes.

     import-route-append { **direct** | **static** } [**med** *med-value* | **route-policy** *route-policy-name*] *

   By default, BGP does not redistribute IGP routes.

5. (Optional.) Enable default route redistribution into BGP.

   default-route imported

   By default, BGP does not redistribute default routes.

Configuring BGP route summarization

About this task

Route summarization can reduce the number of redistributed routes and the routing table size. IPv4 BGP supports automatic route summarization and manual route summarization. Manual summarization takes precedence over automatic summarization. IPv6 BGP supports only manual route summarization.

Automatic route summarization enables BGP to summarize IGP subnet routes redistributed by the **import-route** command, so BGP advertises only natural network routes.

By configuring manual route summarization, you can do the following:

- Summarize both redistributed routes and routes injected using the **network** command.
- Determine the mask length for a summary route.

Restrictions and guidelines for configuring BGP route summarization

The output interface of a BGP summary route is Null 0 on the originating router. Therefore, a summary route must not be an optimal route on the originating router. Otherwise, BGP will fail to forward packets matching the route. If a summarized specific route has the same mask as the summary route, but has a lower priority, the summary route becomes the optimal route. To ensure correct packet forwarding, change the priority of the summary or specific route to make the specific route the optimal route.

Configuring automatic route summarization (IPv4 unicast/multicast address family)

1. Enter system view.

   `system-view`

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Configure automatic route summarization.

   `summary automatic`

   By default, automatic route summarization is not configured.

Configuring manual route summarization (IPv4 unicast/multicast address family)

1. Enter system view.

   `system-view`

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Create a summary route in the BGP routing table.

   aggregate *ipv4-address* { *mask-length* | *mask* } [**as-set** | **attribute-policy** *route-policy-name* | **detail-suppressed** | **origin-policy** *route-policy-name* | **suppress-policy** *route-policy-name*] *

   By default, no summary routes are configured.

Configuring BGP manual route summarization (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Create a summary route in the IPv6 BGP routing table.

   aggregate *ipv6-address prefix-length* [**as-set** | **attribute-policy** *route-policy-name* | **detail-suppressed** | **origin-policy** *route-policy-name* | **suppress-policy** *route-policy-name*] *

   By default, no summary routes are configured.

Advertising a default route to a peer or peer group

About this task

Perform this task to advertise a default BGP route with the next hop being the advertising router to a peer or peer group.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv4 multicast

3. Advertise a default route to a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **default-route-advertise** [**route-policy** *route-policy-name*]

   By default, no default route is advertised.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Advertise a default route to a peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **default-route-advertise** [**route-policy** *route-policy-name*]

   By default, no default route is advertised.

Controlling BGP route advertisement

Advertising optimal routes in the IP routing table

About this task

By default, BGP advertises optimal routes in the BGP routing table, which may not be optimal in the IP routing table. This task allows you to advertise BGP routes that are optimal in the IP routing table.

Procedure (IPv4 unicast)

1. Enter system view.

   system-view

2. Enter BGP instance view.

bgp *as-number* [**instance** *instance-name*]

3. Enable BGP to advertise optimal routes in the IP routing table.

   advertise-rib-active

   By default, BGP advertises optimal routes in the BGP routing table.

4. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Enter BGP IPv4 unicast address family view.

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

5. Enable BGP to advertise optimal routes in the IP routing table of the address family in the VPN instance.

   advertise-rib-active

   By default, the setting is the same as that in BGP instance view.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enable BGP to advertise optimal routes in the IPv6 routing table.

   advertise-rib-active

   By default, BGP advertises optimal routes in the BGP routing table.

4. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.
   - Enter BGP IPv6 unicast address family view.

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast]**

5. Enable BGP to advertise optimal routes in the IPv6 routing table of the address family in the VPN instance.

   advertise-rib-active

   By default, the setting is the same as that in BGP instance view.

Configuring BGP route distribution filtering policies

About this task

To configure BGP route distribution filtering policies, use the following methods:

- Use an ACL or prefix list to filter routing information advertised to all peers.
- Use a routing policy, ACL, conditional advertisement policy (existent policy or nonexistent policy), AS path list, or prefix list to filter routing information advertised to a peer or peer group.

If you configure multiple filtering policies, apply them in the following sequence:

1. **peer prefix-list export**

2. **`peer filter-policy export`**
3. **`peer as-path-acl export`**
4. **`filter-policy export`**
5. **`peer advertise-policy exist-policy`**
6. **`peer advertise-policy non-exist-policy`**
7. **`peer route-policy export`**

Only routes passing all the configured policies can be advertised.

Prerequisites

Before you configure BGP routing filtering policies, configure the following filters used for route filtering as needed:

- ACL (see *ACL and QoS Configuration Guide*).
- Prefix list (see "Configuring routing policies").
- Routing policy (see "Configuring routing policies").
- AS path list (see "Configuring routing policies").

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Configure BGP route distribution filtering policies. Choose the options to configure as needed:
   - Reference an ACL or IP prefix list to filter advertised BGP routes.

     filter-policy { *ipv4-acl-number* | **prefix-list** *ipv4-prefix-list-name* } **export** [**direct** | { **isis** | **ospf** | **rip** } *process-id* | **static**]
   - Specify a routing policy as the existent policy to control route advertisement.

     peer { *group-name* | *ipv4-address* [*mask-length*] } **advertise-policy** *advertise-policy-name* **exist-policy** *exist-policy-name*

     This command is supported only in BGP IPv4 unicast address family view.
   - Specify a routing policy as the nonexistent policy to control route advertisement.

     peer { *group-name* | *ipv4-address* [*mask-length*] } **advertise-policy** *advertise-policy-name* **non-exist-policy** *non-exist-policy-name*

  This command is supported only in BGP IPv4 unicast address family view.

- Reference a routing policy to filter BGP routes advertised to a peer or peer group.

  peer { *group-name* | *ipv4-address* [*mask-length*] } **route-policy** *route-policy-name* **export**

- Reference an ACL to filter BGP routes advertised to a peer or peer group.

  peer { *group-name* | *ipv4-address* [*mask-length*] } **filter-policy** { *ipv4-acl-number* } **export**

- Reference an AS path list to filter BGP routes advertised to a peer or peer group.

  peer { *group-name* | *ipv4-address* [*mask-length*] } **as-path-acl** *as-path-acl-number* **export**

- Reference an IPv4 prefix list to filter BGP routes advertised to a peer or peer group.

  peer { *group-name* | *ipv4-address* [*mask-length*] } **prefix-list** *ipv4-prefix-list-name* **export**

By default, no BGP distribution filtering policy is configured.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Configure BGP route distribution filtering policies. Choose the options to configure as needed:

   - Reference an ACL or IPv6 prefix list to filter advertised BGP routes.

     filter-policy { *ipv6-acl-number* | **prefix-list** *ipv6-prefix-list-name* } **export** [**direct** | { **isisv6** | **ospfv3** | **ripng** } *process-id* | **static**]

   - Specify a routing policy as the existent policy to control route advertisement.

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise-policy** *advertise-policy-name* **exist-policy** *exist-policy-name*

     This command is supported only in BGP IPv6 unicast address family view.

   - Specify a routing policy as the nonexistent policy to control route advertisement.

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise-policy** *advertise-policy-name* **non-exist-policy** *non-exist-policy-name*

This command is supported only in BGP IPv6 unicast address family view.

- Reference a routing policy to filter BGP routes advertised to a peer or peer group.

  peer { *group-name* | *ipv6-address* [*prefix-length*] } **route-policy** *route-policy-name* **export**

- Reference an ACL to filter BGP routes advertised to a peer or peer group.

  peer { *group-name* | *ipv6-address* [*prefix-length*] } **filter-policy** { *ipv6-acl-number* } **export**

- Reference an AS path list to filter BGP routes advertised to a peer or peer group.

  peer { *group-name* | *ipv6-address* [*prefix-length*] } **as-path-acl** *as-path-acl-number* **export**

- Reference an IPv6 prefix list to filter BGP routes advertised to a peer or peer group.

  peer { *group-name* | *ipv6-address* [*prefix-length*] } **prefix-list** *ipv6-prefix-list-name* **export**

By default, no BGP distribution filtering policy is configured.

Configuring BGP to delay sending route updates on reboot

About this task

This task reduces traffic loss. With this task performed, BGP delays sending route updates when it restores after a device reboot. During the delay time, BGP learns all routes from other neighbors, and then selects the optimal route. After the delay time elapses, BGP will advertise the optimal route.

You can specify a prefix list and configure BGP to immediately send route updates for routes that match the prefix list.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Configure BGP to delay sending route updates when it restores after a device reboot.

   bgp update-delay on-startup *seconds*

   By default, BGP immediately sends route updates to BGP peers in established state when it restores after a device reboot.

4. (Optional.) Configure BGP to immediately send route updates for routes that match a prefix list.

   bgp update-delay on-startup prefix-list *ipv4-prefix-list-name*

   By default, no prefix list is specified to filter routes.

Controlling BGP route reception

Limiting routes received from a peer or peer group

About this task

This feature can prevent attacks that send a large number of BGP routes to the router.

If the number of routes received from a peer or peer group exceeds the upper limit, the router takes one of the following actions based on your configuration:

- Tears down the BGP session to the peer or peer group and does not attempt to re-establish the session.
- Continues to receive routes from the peer or peer group and generates a log message.
- Retains the session to the peer or peer group, but it discards excess routes and generates a log message.
- Tears down the BGP session to the peer or peer group and, after a specific period of time, re-establishes a BGP session to the peer or peer group.

You can specify a percentage threshold for the router to generate a log message. When the ratio of the number of received routes to the maximum number reaches the percentage value, the router generates a log message.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   ```
   system-view
   ```

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     ```
     bgp as-number [ instance instance-name ]
     address-family ipv4 [ unicast ]
     ```

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     ```
     bgp as-number [ instance instance-name ]
     ip vpn-instance vpn-instance-name
     address-family ipv4 [ unicast ]
     ```

   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     ```
     bgp as-number [ instance instance-name ]
     address-family ipv4 multicast
     ```

3. Specify the maximum number of routes that a router can receive from a peer or peer group.

   ```
   peer { group-name | ipv4-address [ mask-length ] } route-limit
   prefix-number [ { alert-only | discard | reconnect reconnect-time } |
   percentage-value ] *
   ```

   By default, the number of routes that a router can receive from a peer or peer group is not limited.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   ```
   system-view
   ```

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     ```
     bgp as-number [ instance instance-name ]
     address-family ipv6 [ unicast ]
     ```

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     ```
     bgp as-number [ instance instance-name ]
     ```

ip vpn-instance *vpn-instance-name*

address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv6 multicast

3. Specify the maximum number of routes that a router can receive from a peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **route-limit** *prefix-number* [{ **alert-only** | **discard** | **reconnect** *reconnect-time* } | *percentage-value*] *

   By default, the number of routes that a router can receive from a peer or peer group is not limited.

Configuring BGP route reception filtering policies

About this task

You can use the following methods to configure BGP route reception filtering policies:

- Use an ACL or prefix list to filter routing information received from all peers.
- Use a routing policy, ACL, AS path list, or prefix list to filter routing information received from a peer or peer group.

If you configure multiple filtering policies, apply them in the following sequence:

1. **peer filter-policy import**
2. **peer prefix-list import**
3. **peer as-path-acl import**
4. **filter-policy import**
5. **peer route-policy import**

Only routes passing all the configured policies can be received.

Prerequisites

Before you configure BGP route reception filtering policies, configure the following filters used for route filtering as needed:

- ACL (see *ACL and QoS Configuration Guide*).
- Prefix list (see "Configuring routing policies").
- Routing policy (see "Configuring routing policies").
- AS path list (see "Configuring routing policies").

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

```
bgp as-number [ instance instance-name ]
ip vpn-instance vpn-instance-name
address-family ipv4 [ unicast ]
```

- Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

  ```
  bgp as-number [ instance instance-name ]
  address-family ipv4 multicast
  ```

3. Configure BGP route reception filtering policies. Choose the options to configure as needed:
   - Reference an ACL or IP prefix list to filter BGP routes received from all peers.

     ```
     filter-policy { ipv4-acl-number | prefix-list
     ipv4-prefix-list-name } import
     ```
   - Reference a routing policy to filter BGP routes received from a peer or peer group.

     ```
     peer { group-name | ipv4-address [ mask-length ] } route-policy
     route-policy-name import
     ```
   - Reference an ACL to filter BGP routes received from a peer or peer group.

     ```
     peer { group-name | ipv4-address [ mask-length ] } filter-policy
     { ipv4-acl-number } import
     ```
   - Reference an AS path list to filter BGP routes received from a peer or peer group.

     ```
     peer { group-name | ipv4-address [ mask-length ] } as-path-acl
     as-path-acl-number import
     ```
   - Reference an IPv4 prefix list to filter BGP routes received from a peer or peer group.

     ```
     peer { group-name | ipv4-address [ mask-length ] } prefix-list
     ipv4-prefix-list-name import
     ```

   By default, no route reception filtering is configured.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   ```
   system-view
   ```
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     ```
     bgp as-number [ instance instance-name ]
     address-family ipv6 [ unicast ]
     ```
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     ```
     bgp as-number [ instance instance-name ]
     ip vpn-instance vpn-instance-name
     address-family ipv6 [ unicast ]
     ```
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     ```
     bgp as-number [ instance instance-name ]
     address-family ipv6 multicast
     ```
3. Configure BGP route reception filtering policies. Choose the options to configure as needed:
   - Reference ACL or IPv6 prefix list to filter BGP routes received from all peers.

     ```
     filter-policy { ipv6-acl-number | prefix-list
     ipv6-prefix-list-name } import
     ```

- Reference a routing policy to filter BGP routes received from a peer or peer group.

  peer { *group-name* | *ipv6-address* [*prefix-length*] } **route-policy** *route-policy-name* **import**

- Reference an ACL to filter BGP routes received from a peer or peer group.

  peer { *group-name* | *ipv6-address* [*prefix-length*] } **filter-policy** { *ipv6-acl-number* } **import**

- Reference an AS path list to filter BGP routes received from a peer or peer group.

  peer { *group-name* | *ipv6-address* [*prefix-length*] } **as-path-acl** *as-path-acl-number* **import**

- Reference an IPv6 prefix list to filter BGP routes received from a peer or peer group.

  peer { *group-name* | *ipv6-address* [*prefix-length*] } **prefix-list** *ipv6-prefix-list-name* **import**

By default, no route reception filtering is configured.

Configuring the SoO attribute

About this task

After you configure the SoO attribute for a BGP peer or peer group, BGP adds the SoO attribute into the route updates received from the BGP peer or peer group. In addition, before advertising route updates to the peer or peer group, BGP checks the SoO attribute of the route update against the configured SoO attribute. If they are the same, BGP does not advertise the route updates to the BGP peer or peer group.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Configure the SoO attribute for a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **soo** *site-of-origin*

   By default, no SoO attribute is configured for a peer or peer group.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Configure the SoO attribute for a peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **soo** *site-of-origin*

   By default, no SoO attribute is configured for a peer or peer group.

Configuring BGP timers

Configuring the keepalive interval and hold time

About this task

BGP sends KEEPALIVE messages regularly to keep the BGP session between two routers.

If a router receives no KEEPALIVE or UPDATE message from a peer within the hold time, it tears down the session.

You can configure the keepalive interval and hold time globally or for a peer or peer group. The individual settings take precedence over the global settings.

The actual keepalive interval and hold time are determined as follows:

- If the hold time settings on the local and peer routers are different, the smaller setting is used. If the hold time is 0, BGP does not send KEEPALIVE messages to its peers and never tears down the session.
- If the keepalive interval is not 0, the actual keepalive interval is the smaller one between 1/3 of the hold time and the keepalive interval.

Restrictions and guidelines

The hold time must be a minimum of three times the keepalive interval.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

3. Configure the keepalive interval and hold time.
   - Configure the global keepalive interval and hold time.

     timer keepalive *keepalive* **hold** *holdtime*

     This command takes effect for new BGP sessions and does not affect existing sessions.
   - Configure the keepalive interval and hold time for a peer or peer group.

     peer { *group-name* | *ipv4-address* [*mask-length*] } **timer keepalive** *keepalive* **hold** *holdtime*

   By default, the keepalive interval is 60 seconds, and hold time is 180 seconds.

   The timers configured with the **timer** and **peer timer** commands do not take effect until a session is re-established (for example, a session is reset).

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Configure the keepalive interval and hold time.
   - Configure the global keepalive interval and hold time.

     timer keepalive *keepalive* **hold** *holdtime*

     This command takes effect for new BGP sessions and does not affect existing sessions.
   - Configure the keepalive interval and hold time for a peer or peer group.

     peer { *group-name* | *ipv6-address* [*prefix-length*] } **timer keepalive** *keepalive* **hold** *holdtime*

   By default, the keepalive interval is 60 seconds, and hold time is 180 seconds.

   The timers configured with the **timer** and **peer timer** commands do not take effect until a session is re-established (for example, a session is reset).

Setting the session retry timer

About this task

To speed up session establishment to a peer or peer group and route convergence, set a small session retry timer. If the BGP session flaps, you can set a large session retry timer to reduce the impact.

Restrictions and guidelines

The timer set by the **peer timer connect-retry** command takes precedence over the timer set by the **timer connect-retry** command.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.

- Enter BGP instance view.

  bgp *as-number* [**instance** *instance-name*]
- Execute the following commands in sequence to enter BGP-VPN instance view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

3. Set the session retry timer.
   - Set the session retry timer for all peers or peer groups.

     timer connect-retry *retry-time*
   - Set the session retry timer for a peer or peer group.

     peer { *group-name* | *ipv4-address* [*mask-length*] } **timer connect-retry** *retry-time*

   By default, the session retry timer is 32 seconds for a peer or peer group.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Set the session retry timer.
   - Set the session retry timer for all peers or peer groups.

     timer connect-retry *retry-time*
   - Set the session retry timer for a peer or peer group.

     peer { *group-name* | *ipv6-address* [*prefix-length*] } **timer connect-retry** *retry-time*

   By default, the session retry timer is 32 seconds for a peer or peer group.

Configuring the interval for sending updates for the same route

About this task

A BGP router sends an UPDATE message to its peers when a route is changed. If the route changes frequently, the BGP router keeps sending updates for the same route, resulting route flapping. To prevent this situation, perform this task to configure the interval for sending updates for the same route to a peer or peer group.

This feature does not take effect on withdrawn routes. For withdrawn routes, BGP sends the withdrawal messages immediately.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

bgp *as-number* [**instance** *instance-name*]

- Execute the following commands in sequence to enter BGP-VPN instance view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

3. Configure the interval for sending updates for the same route to a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **route-update-interval** *interval*

   By default, the interval is 15 seconds for an IBGP peer and 30 seconds for an EBGP peer.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.

   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure the interval for sending updates for the same route to a peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **route-update-interval** *interval*

   By default, the interval is 15 seconds for an IBGP peer and 30 seconds for an EBGP peer.

Configuring BGP logging and notifications

Enabling logging for session state changes

About this task

Perform this task to enable BGP to log BGP session establishment and disconnection events. To display the log information, use the **display bgp peer ipv4 unicast log-info** command or the **display bgp peer ipv6 unicast log-info** command. The logs are sent to the information center. The output rules of the logs (whether to output the logs and where to output) are determined by the information center configuration.

For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure (IPv4 unicast/IPv4 multicast)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enable logging for session state changes globally.

   log-peer-change

   By default, logging for session state changes is enabled globally.

4. (Optional.) Enter BGP-VPN instance view.

   ip vpn-instance *vpn-instance-name*

5. Enable logging for session state changes for a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **log-change**

   By default, logging for session state changes is enabled for all peers and peer groups.

Procedure (IPv6 unicast/IPv6 multicast)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enable logging for session state changes globally.

   log-peer-change

   By default, logging for session state changes is enabled globally.

4. (Optional.) Enter BGP-VPN instance view.

   ip vpn-instance *vpn-instance-name*

5. Enable logging for session state changes for a peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **log-change**

   By default, logging for session state changes is enabled for all peers and peer groups.

Configuring BGP network management

About this task

After you enable SNMP notifications for BGP, the device generates a notification when a BGP neighbor state change occurs. The notification includes the neighbor address, the error code and subcode of the most recent error, and the current neighbor state. For BGP notifications to be sent correctly, you must also configure SNMP on the device.

BGP does not know the BGP instance to which a managed MIB node belongs. To resolve this issue, configure different SNMP contexts for different BGP instances.

The device selects a MIB for an SNMP packet according to the context (for SNMPv3) or community name (for SNMPv1/v2c) in the following ways:

- For an SNMPv3 packet:
  - The device selects the MIB of the default BGP instance if the packet does not carry a context and no SNMP context is configured for the default BGP instance.
  - The device selects the MIB of a BGP instance if the packet meets the following conditions:
    - Carries a context that is configured with the **snmp-agent context** command in system view.
    - Matches the context of the BGP instance.
  - The device does not process any MIBs in other situations.
- For an SNMPv1/v2c packet:
  - The device selects the MIB of the default BGP instance if the following conditions are met:
    - No community name-to-SNMP context mapping is configured with the **snmp-agent community-map** command in system view.
    - No SNMP context is configured for the default BGP instance.
  - The device selects the MIB of a BGP instance if the community name is mapped to an SNMP context and the context matches the context of the BGP instance.
  - The device does not process any MIBs in other situations.

For more information about SNMP contexts and community names, see SNMP configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for BGP.
   snmp-agent trap enable bgp [**instance** *instance-name*]
   By default, SNMP notifications for BGP are enabled.
3. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
4. Configure an SNMP context for the BGP instance.
   snmp context-name *context-name*
   By default, no SNMP context is configured for the BGP instance.

Display and maintenance commands for basic BGP network building

Displaying BGP

Execute **display** commands in any view.

Displaying BGP (IPv4 unicast address family)

Task	Command
Display BGP IPv4 unicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**group-name** *group-name*]
Display information about routes advertised by the **network** command and shortcut routes configured by the **network short-cut** command.	**display bgp** [**instance** *instance-name*] **network ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Display BGP IPv4 unicast peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address* *mask-length* | { *ipv4-address* | **group-name** *group-name* } **log-info** | [*ipv4-address*] **verbose**]
Display BGP IPv4 unicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | **as-path-acl** *as-path-acl-number*]
Display BGP IPv4 unicast routing information.	**display bgp** [**instance** *instance-name*] **routing-table ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address* [{ *mask-length* | *mask* }

Task	Command
	[**longest-match**]] | *ipv4-address* [*mask-length* | *mask*] **advertise-info** | **as-path-acl** *as-path-acl-number* | **community-list** { { *basic-community-list-number* | *comm-list-name* } [**whole-match**] | *adv-community-list-number* } | **peer** *ipv4-address* { **advertised-routes** | **received-routes** } [*ipv4-address* [*mask-length* | *mask*] | **statistics**] | **statistics**]
Display BGP IPv4 unicast address family update group information.	**display bgp** [**instance** *instance-name*] **update-group ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address*]
Display information about all BGP instances.	**display bgp instance-info**

Displaying BGP (IPv6 unicast address family)

Task	Command
Display BGP IPv6 unicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**group-name** *group-name*]
Display information about routes advertised by the **network** command and shortcut routes configured by the **network short-cut** command.	**display bgp** [**instance** *instance-name*] **network ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Display BGP IPv6 unicast peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv6-address* *prefix-length* | { *ipv6-address* | **group-name** *group-name* } **log-info** | [*ipv6-address*] **verbose**] **display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] [*ipv4-address* *mask-length* | *ipv4-address* **log-info** | [*ipv4-address*] **verbose**]
Display BGP IPv6 unicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv6-address* *prefix-length* | **as-path-acl** *as-path-acl-number*]
Display BGP IPv6 unicast routing information.	**display bgp** [**instance** *instance-name*] **routing-table ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv6-address* *prefix-length* [**advertise-info**] | **as-path-acl**

Task	Command
	as-path-acl-number | **community-list** { { *basic-community-list-number* | *comm-list-name* } [**whole-match**] | *adv-community-list-number* } | **peer** *ipv6-address* { **advertised-routes** | **received-routes** } [*ipv6-address prefix-length* | **statistics**] | **statistics**] **display bgp** [**instance** *instance-name*] **routing-table ipv6** [**unicast**] **peer** *ipv4-address* { **advertised-routes** | **received-routes** } [*ipv6-address prefix-length* | **statistics**]
Display BGP IPv6 unicast address family update group information.	**display bgp** [**instance** *instance-name*] **update-group ipv6** [**unicast**] [*ipv4-address* | *ipv6-address*] **display bgp** [**instance** *instance-name*] **update-group ipv6** [**unicast**] **vpn-instance** *vpn-instance-name* [*ipv6-address*]
Display information about all BGP instances.	**display bgp instance-info**

Displaying BGP (IPv4 multicast address family)

Task	Command
Display BGP IPv4 multicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv4 multicast** [**group-name** *group-name*]
Display information about routes advertised by the **network** command and shortcut routes configured by the **network short-cut** command.	**display bgp** [**instance** *instance-name*] **network ipv4 multicast**
Display BGP path attribute information.	**display bgp** [**instance** *instance-name*] **paths** [*as-regular-expression*]
Display BGP IPv4 multicast peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer ipv4 multicast** [*ipv4-address mask-length* | { *ipv4-address* | **group-name** *group-name* } **log-info** | [*ipv4-address*] **verbose**]
Display BGP IPv4 multicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv4 multicast** [*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | **as-path-acl** *as-path-acl-number*]
Display BGP IPv4 multicast routing information.	**display bgp** [**instance** *instance-name*] **routing-table ipv4 multicast** [*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | *ipv4-address* [*mask-length* | *mask*] **advertise-info** |

Task	Command
	as-path-acl *as-path-acl-number* | **community-list** { { *basic-community-list-number* | *comm-list-name* } [**whole-match**] | *adv-community-list-number* } | **peer** *ipv4-address* { **advertised-routes** | **received-routes** } [*ipv4-address* [*mask-length* | *mask*] | **statistics**] | **statistics**]
Display BGP IPv4 multicast address family update group information.	**display bgp** [**instance** *instance-name*] **update-group ipv4 multicast** [*ipv4-address*]
Display information about all BGP instances.	**display bgp instance-info**

Displaying BGP (IPv6 multicast address family)

Task	Command
Display BGP IPv6 multicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv6 multicast** [**group-name** *group-name*]
Display information about routes advertised by the **network** command and shortcut routes configured by the **network short-cut** command.	**display bgp** [**instance** *instance-name*] **network ipv6 multicast**
Display BGP path attribute information.	**display bgp** [**instance** *instance-name*] **paths** [*as-regular-expression*]
Display BGP IPv6 multicast peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer ipv6 multicast** [*ipv6-address prefix-length* | { *ipv6-address* | **group-name** *group-name* } **log-info** | [*ipv6-address*] **verbose**]
Display BGP IPv6 multicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv6 multicast** [*ipv6-address prefix-length* | **as-path-acl** *as-path-acl-number*]
Display BGP IPv6 multicast routing information.	**display bgp** [**instance** *instance-name*] **routing-table ipv6 multicast** [*ipv6-address prefix-length* [**advertise-info**] | **as-path-acl** *as-path-acl-number* | **community-list** { { *basic-community-list-number* | *comm-list-name* } [**whole-match**] | *adv-community-list-number* } | **peer** *ipv6-address* { **advertised-routes** | **received-routes** } [*ipv6-address prefix-length* | **statistics**] | **statistics**]
Display BGP IPv6 multicast address family update group information.	**display bgp** [**instance** *instance-name*] **update-group ipv6 multicast**

Task	Command
	[*ipv6-address*]
Display information about all BGP instances.	**display bgp instance-info**

Resetting BGP sessions

CAUTION:

A reset operation tears down BGP sessions for a short period of time.

Execute **reset** commands in user view.

Task	Command
Reset BGP sessions for IPv4 unicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv4-address* [*mask-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Reset BGP sessions for IPv4 multicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv4-address* [*mask-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv4 multicast**
Reset BGP sessions for IPv6 unicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] **reset bgp** *ipv4-address* [*mask-length*] **ipv6** [**unicast**]
Reset BGP sessions for IPv6 multicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv6 multicast**
Reset all BGP sessions.	**reset bgp** [**instance** *instance-name*] **all**

Clearing BGP information

Execute **reset** commands in user view.

Task	Command
Clear flap information for BGP IPv4 unicast routes.	**reset bgp** [**instance** *instance-name*] **flap-info ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address* [*mask-length* | *mask*] | **as-path-acl** *as-path-acl-number* | **peer** *ipv4-address* [*mask-length*]]
Clear flap information for BGP IPv4	**reset bgp** [**instance** *instance-name*]

Task	Command
multicast routes.	**flap-info ipv4 multicast** [*ipv4-address* [*mask-length* | *mask*] | **as-path-acl** *as-path-acl-number* | **peer** *ipv4-address* [*mask-length*]]
Clear flap information for BGP IPv6 unicast routes.	**reset bgp** [**instance** *instance-name*] **flap-info ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv6-address* *prefix-length* | **as-path-acl** *as-path-acl-number* | **peer** *ipv6-address* [*prefix-length*]]
Clear flap information for BGP IPv6 multicast routes.	**reset bgp** [**instance** *instance-name*] **flap-info ipv6 multicast** [*ipv6-address* *prefix-length* | **as-path-acl** *as-path-acl-number* | **peer** *ipv6-address* [*prefix-length*]]

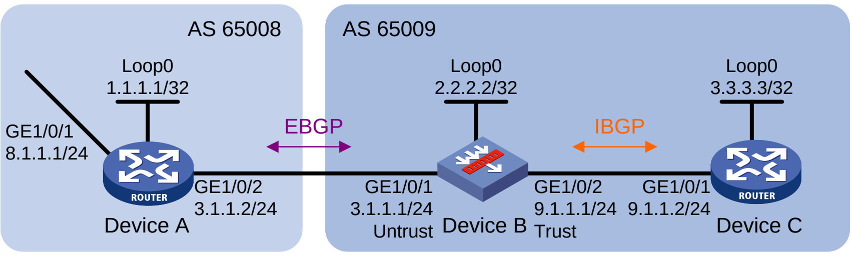
Basic IPv4 BGP network configuration examples

Example: Configuring basic BGP

Network configuration

As shown in Figure 10, all devices run BGP. Run EBGP between Device A and Device B, and run IBGP between Device B and Device C to allow Device C to access network 8.1.1.0/24 connected to Device A.

Figure 10 Network diagram



Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Add each interface on Device B to a security zone according to Figure 10.

```
<DeviceB> system-view
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

3. Configure security policies.
   a. Configure a security policy to allow EBGP session establishment between Device A and Device B by permitting traffic between security zone **untrust** and security zone **local**.

# Create security policy rule **ebgplocalin** and permit Device B to receive BGP packets from Device A.

```
[DeviceB] security-policy ip
[DeviceB-security-policy-ip] rule name ebgplocalin
[DeviceB-security-policy-ip-0-ebgplocalin] source-zone untrust
[DeviceB-security-policy-ip-0-ebgplocalin] destination-zone local
[DeviceB-security-policy-ip-0-ebgplocalin] service bgp
[DeviceB-security-policy-ip-0-ebgplocalin] action pass
[DeviceB-security-policy-ip-0-ebgplocalin] quit
```

# Create security policy rule **ebgplocalout** and permit Device B to send BGP packets to Device A.

```
[DeviceB-security-policy-ip] rule name ebgplocalout
[DeviceB-security-policy-ip-1-ebgplocalout] source-zone local
[DeviceB-security-policy-ip-1-ebgplocalout] destination-zone untrust
[DeviceB-security-policy-ip-1-ebgplocalout] service bgp
[DeviceB-security-policy-ip-1-ebgplocalout] action pass
[DeviceB-security-policy-ip-1-ebgplocalout] quit
```

b. Configure a security policy to allow IBGP session establishment between Device B and Device C by permitting traffic between security zone **trust** and security zone **local**.

# Create security policy rule **bgplocalout** and permit Device B to send BGP and OSPF packets to Device C.

```
[DeviceB-security-policy-ip] rule name bgplocalout
[DeviceB-security-policy-ip-2-bgplocalout] source-zone local
[DeviceB-security-policy-ip-2-bgplocalout] destination-zone trust
[DeviceB-security-policy-ip-2-bgplocalout] service bgp
[DeviceB-security-policy-ip-2-bgplocalout] service ospf
[DeviceB-security-policy-ip-2-bgplocalout] action pass
[DeviceB-security-policy-ip-2-bgplocalout] quit
```

# Create security policy rule **bgplocalin** and permit Device B to receive BGP and OSPF packets from Device C.

```
[DeviceB-security-policy-ip] rule name bgplocalin
[DeviceB-security-policy-ip-3-bgplocalin] source-zone trust
[DeviceB-security-policy-ip-3-bgplocalin] destination-zone local
[DeviceB-security-policy-ip-3-bgplocalin] service bgp
[DeviceB-security-policy-ip-3-bgplocalin] service ospf
[DeviceB-security-policy-ip-3-bgplocalin] action pass
[DeviceB-security-policy-ip-3-bgplocalin] quit
```

c. Configure a security policy to permit traffic between security zone **untrust** and security zone **trust** so that Device C can access network 8.1.1.0/24 connected to Device A.

# Create security policy rule **trust-untrust** and permit packets from security zone **trust** to security zone **untrust** to pass.

```
[DeviceB-security-policy-ip] rule name trust-untrust
[DeviceB-security-policy-ip-4-trust-untrust] source-zone trust
[DeviceB-security-policy-ip-4-trust-untrust] destination-zone untrust
[DeviceB-security-policy-ip-4-trust-untrust] source-ip-subnet 9.1.1.0 24
[DeviceB-security-policy-ip-4-trust-untrust] destination-ip-subnet 8.1.1.0 24
[DeviceB-security-policy-ip-4-trust-untrust] action pass
[DeviceB-security-policy-ip-4-trust-untrust] quit
[DeviceB-security-policy-ip] quit
```

4. Configure IBGP:

   - To prevent route flapping caused by port state changes, this example uses loopback interfaces to establish IBGP connections.
   - Because loopback interfaces are virtual interfaces, you need to use the **peer connect-interface** command to specify the loopback interface as the source interface for BGP connection establishment.
   - Enable OSPF in AS 65009 to ensure that Device B can communicate with Device C through loopback interfaces.

# Configure Device B.

```
[DeviceB] bgp 65009
[DeviceB-bgp-default] router-id 2.2.2.2
[DeviceB-bgp-default] peer 3.3.3.3 as-number 65009
[DeviceB-bgp-default] peer 3.3.3.3 connect-interface loopback 0
[DeviceB-bgp-default] address-family ipv4 unicast
[DeviceB-bgp-default-ipv4] peer 3.3.3.3 enable
[DeviceB-bgp-default-ipv4] quit
[DeviceB-bgp-default] quit
[DeviceB] ospf 1
[DeviceB-ospf-1] area 0
[DeviceB-ospf-1-area-0.0.0.0] network 2.2.2.2 0.0.0.0
[DeviceB-ospf-1-area-0.0.0.0] network 9.1.1.0 0.0.0.255
[DeviceB-ospf-1-area-0.0.0.0] quit
[DeviceB-ospf-1] quit
```

# Configure Device C.

```
<DeviceC> system-view
[DeviceC] bgp 65009
[DeviceC-bgp-default] router-id 3.3.3.3
[DeviceC-bgp-default] peer 2.2.2.2 as-number 65009
[DeviceC-bgp-default] peer 2.2.2.2 connect-interface loopback 0
[DeviceC-bgp-default] address-family ipv4 unicast
[DeviceC-bgp-default-ipv4] peer 2.2.2.2 enable
[DeviceC-bgp-default-ipv4] quit
[DeviceC-bgp-default] quit

[DeviceC-ospf-1-area-0.0.0.0] quit
[DeviceC-ospf-1] quit
[DeviceC] display bgp peer ipv4

 BGP local router ID : 3.3.3.3
 Local AS number : 65009
 Total number of peers : 1                 Peers in established state : 1

  * - Dynamically created peer
  Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

  2.2.2.2              65009        2        2    0       0 00:00:13 Established
```

The output shows that Device C has established an IBGP peer relationship with Device B.

5. Configure EBGP:
    - The EBGP peers (usually in different ISPs) are located in different ASs. Typically, their loopback interfaces are not reachable to each other, so directly connected interfaces are used for establishing EBGP sessions.
    - To enable Device C to access the network 8.1.1.0/24 connected directly to Device A, inject network 8.1.1.0/24 to the BGP routing table of Device A.

# Configure Device A.

```
<DeviceA> system-view
[DeviceA] bgp 65008
[DeviceA-bgp-default] router-id 1.1.1.1
[DeviceA-bgp-default] peer 3.1.1.1 as-number 65009
[DeviceA-bgp-default] address-family ipv4 unicast
[DeviceA-bgp-default-ipv4] peer 3.1.1.1 enable
[DeviceA-bgp-default-ipv4] network 8.1.1.0 24
[DeviceA-bgp-default-ipv4] quit
[DeviceA-bgp-default] quit
```

# Configure Device B.

```
[DeviceB] bgp 65009
[DeviceB-bgp-default] peer 3.1.1.2 as-number 65008
[DeviceB-bgp-default] address-family ipv4 unicast
[DeviceB-bgp-default-ipv4] peer 3.1.1.2 enable
[DeviceB-bgp-default-ipv4] quit
[DeviceB-bgp-default] quit
```

# Display BGP peer information on Device B.

```
[DeviceB] display bgp peer ipv4

 BGP local router ID : 2.2.2.2
 Local AS number : 65009
 Total number of peers : 2                 Peers in established state : 2

  * - Dynamically created peer
  Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

  3.3.3.3              65009        4        4    0       0 00:02:49 Established
  3.1.1.2              65008        2        2    0       0 00:00:05 Established
```

The output shows that Device B has established an IBGP peer relationship with Device C and an EBGP peer relationship with Device A.

# Display the BGP routing table on Device A.

```
[DeviceA] display bgp routing-table ipv4

 Total number of routes: 1

 BGP local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               Origin: i - IGP, e - EGP, ? - incomplete
```

```
     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >  8.1.1.0/24         8.1.1.1         0                     32768   i
```

# Display the BGP routing table on Device B.

```
[DeviceB] display bgp routing-table ipv4

 Total number of routes: 1

 BGP local router ID is 2.2.2.2
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >e 8.1.1.0/24         3.1.1.2         0                     0       65008i
```

# Display the BGP routing table on Device C.

```
[DeviceC] display bgp routing-table ipv4

 Total number of routes: 1

 BGP local router ID is 3.3.3.3
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

   i 8.1.1.0/24         3.1.1.2         0          100        0       65008i
```

The outputs show that Device A has no route to AS 65009, and Device C has learned network 8.1.1.0, but the next hop 3.1.1.2 is unreachable. As a result, the route is invalid.

6. Redistribute direct routes:

# Configure BGP to redistribute direct routes on Device B, so Device A can obtain the route to 9.1.1.0/24, and Device C can obtain the route to 3.1.1.0/24.

```
[DeviceB] bgp 65009
[DeviceB-bgp-default] address-family ipv4 unicast
[DeviceB-bgp-default-ipv4] import-route direct
[DeviceB-bgp-default-ipv4] quit
[DeviceB-bgp-default] quit
```

# Display the BGP routing table on Device A.

```
[DeviceA] display bgp routing-table ipv4

 Total number of routes: 4

 BGP local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               Origin: i - IGP, e - EGP, ? - incomplete
```

```
     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >e 2.2.2.2/32         3.1.1.1         0                     0       65009?
* >e 3.1.1.0/24         3.1.1.1         0                     0       65009?
* >  8.1.1.0/24         8.1.1.1         0                     32768   i
* >e 9.1.1.0/24         3.1.1.1         0                     0       65009?
```

Two routes 2.2.2.2/32 and 9.1.1.0/24 have been added in Device A's routing table.

# Display the BGP routing table on Device C.

```
[DeviceC] display bgp routing-table ipv4

 Total number of routes: 4

 BGP local router ID is 3.3.3.3
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >i 2.2.2.2/32         2.2.2.2         0          100        0       ?
* >i 3.1.1.0/24         2.2.2.2         0          100        0       ?
* >i 8.1.1.0/24         3.1.1.2         0          100        0       65008i
* >i 9.1.1.0/24         2.2.2.2         0          100        0       ?
```

The output shows that the route 8.1.1.0 has become valid and the next hop is Device A.

Verifying the configuration

# Verify that Device C can ping 8.1.1.1.

```
[DeviceC] ping 8.1.1.1
Ping 8.1.1.1 (8.1.1.1): 56 data bytes, press CTRL+C to break
56 bytes from 8.1.1.1: icmp_seq=0 ttl=255 time=2.000 ms
56 bytes from 8.1.1.1: icmp_seq=1 ttl=255 time=0.000 ms
56 bytes from 8.1.1.1: icmp_seq=2 ttl=255 time=0.000 ms
56 bytes from 8.1.1.1: icmp_seq=3 ttl=255 time=0.000 ms
56 bytes from 8.1.1.1: icmp_seq=4 ttl=255 time=1.000 ms

--- Ping statistics for 8.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 0.000/0.600/2.000/0.800 ms
```

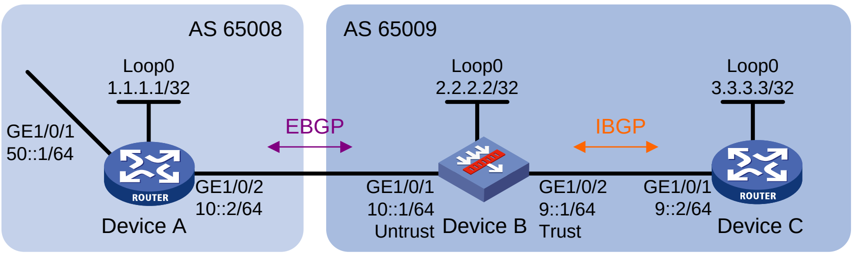
Basic IPv6 BGP network configuration examples

Example: Configuring IPv6 basic BGP

Network configuration

As shown in Figure 11, all devices run BGP. Run EBGP between Device A and Device B, and run IBGP between Device B and Device C to allow Device C to access network 50::/64 connected to Device A.

Figure 11 Network diagram



Procedure

1. Configure IPv6 addresses for interfaces and IPv4 addresses for Loopback interfaces. (Details not shown.)
2. Add each interface on Device B to a security zone according to Figure 11.

```
<DeviceB> system-view
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

3. Configure security policies.

   a. Configure a security policy to allow EBGP session establishment between Device A and Device B by permitting traffic between security zone **untrust** and security zone **local**.

   # Create security policy rule **ebgplocalin** and permit Device B to receive BGP packets from Device A.

```
[DeviceB] security-policy ipv6
[DeviceB-security-policy-ipv6] rule name ebgplocalin
[DeviceB-security-policy-ipv6-0-ebgplocalin] source-zone untrust
[DeviceB-security-policy-ipv6-0-ebgplocalin] destination-zone local
[DeviceB-security-policy-ipv6-0-ebgplocalin] service bgp
[DeviceB-security-policy-ipv6-0-ebgplocalin] action pass
[DeviceB-security-policy-ipv6-0-ebgplocalin] quit
```

   # Create security policy rule **ebgplocalout** and permit Device B to send BGP packets to Device A.

```
[DeviceB-security-policy-ipv6] rule name ebgplocalout
[DeviceB-security-policy-ipv6-1-ebgplocalout] source-zone local
[DeviceB-security-policy-ipv6-1-ebgplocalout] destination-zone untrust
[DeviceB-security-policy-ipv6-1-ebgplocalout] service bgp
[DeviceB-security-policy-ipv6-1-ebgplocalout] action pass
[DeviceB-security-policy-ipv6-1-ebgplocalout] quit
```

   b. Configure a security policy to allow IBGP session establishment between Device B and Device C by permitting traffic between security zone **trust** and security zone **local**.

   # Create security policy rule **bgplocalout** and permit Device B to send BGP packets to Device C.

```
[DeviceB-security-policy-ipv6] rule name bgplocalout
[DeviceB-security-policy-ipv6-2-bgplocalout] source-zone local
[DeviceB-security-policy-ipv6-2-bgplocalout] destination-zone trust
[DeviceB-security-policy-ipv6-2-bgplocalout] service bgp
```

```
[DeviceB-security-policy-ipv6-2-bgplocalout] action pass
[DeviceB-security-policy-ipv6-2-bgplocalout] quit
```

c. Configure a security policy to permit traffic between security zone **untrust** and security zone **trust** so that Device C can access network 50::/64 connected to Device A.

# Create security policy rule **trust-untrust** and permit packets from security zone **trust** to security zone **untrust** to pass.

```
[DeviceB-security-policy-ipv6] rule name trust-untrust
[DeviceB-security-policy-ipv6-3-trust-untrust] source-zone trust
[DeviceB-security-policy-ipv6-3-trust-untrust] destination-zone untrust
[DeviceB-security-policy-ipv6-3-trust-untrust] source-ip-subnet 9:: 64
[DeviceB-security-policy-ipv6-3-trust-untrust] destination-ip-subnet 50:: 64
[DeviceB-security-policy-ipv6-3-trust-untrust] action pass
[DeviceB-security-policy-ipv6-3-trust-untrust] quit
[DeviceB-security-policy-ipv6] quit
```

4. Configure IBGP:

# Configure Device B.

```
［DeviceB］ bgp 65009
［DeviceB-bgp-default］ router-id 2.2.2.2
［DeviceB-bgp-default］ peer 9::2 as-number 65009
［DeviceB-bgp-default］ address-family ipv6
［DeviceB-bgp-default-ipv6］ peer 9::2 enable
［DeviceB-bgp-default-ipv6］ quit
```

# Configure Device C.

```
<DeviceC> system-view
［DeviceC］ bgp 65009
［DeviceC-bgp-default］ router-id 3.3.3.3
［DeviceC-bgp-default］ peer 9::1 as-number 65009
［DeviceC-bgp-default］ address-family ipv6
［DeviceC-bgp-default-ipv6］ peer 9::1 enable
```

5. Configure EBGP:

# Configure Device A.

```
<DeviceA> system-view
［DeviceA］ bgp 65008
［DeviceA-bgp-default］ router-id 1.1.1.1
［DeviceA-bgp-default］ peer 10::1 as-number 65009
［DeviceA-bgp-default］ address-family ipv6
［DeviceA-bgp-default-ipv6］ peer 10::1 enable
```

# Configure Device B.

```
［DeviceB-bgp-default］ peer 10::2 as-number 65008
［DeviceB-bgp-default］ address-family ipv6
［DeviceB-bgp-default-ipv6］ peer 10::2 enable
```

6. Inject network routes to the BGP routing table:

# Configure Device A.

```
［DeviceA-bgp-default-ipv6］ network 10:: 64
［DeviceA-bgp-default-ipv6］ network 50:: 64
［DeviceA-bgp-default-ipv6］ quit
［DeviceA-bgp-default］ quit
```

# Configure Device B.

```
[DeviceB-bgp-default-ipv6] network 10:: 64
[DeviceB-bgp-default-ipv6] network 9:: 64
[DeviceB-bgp-default-ipv6] quit
[DeviceB-bgp-default] quit
```

# Configure Device C.

```
[DeviceC-bgp-default-ipv6] network 9:: 64
[DeviceC-bgp-default-ipv6] quit
[DeviceC-bgp-default] quit
```

Verifying the configuration

# Display IPv6 BGP peer information on Device B.

```
[DeviceB] display bgp peer ipv6

 BGP local router ID: 2.2.2.2
 Local AS number: 65009
 Total number of peers: 2                  Peers in established state: 2

  * - Dynamically created peer
  Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

  9::2                 65009       41       43    0       1 00:29:00 Established
  10::2                65008       38       38    0       2 00:27:20 Established
```

The output shows that Device A and Device B have established an EBGP connection, and Device B and Device C have established an IBGP connection.

# Display IPv6 BGP routing table information on Device A.

```
[DeviceA] display bgp routing-table ipv6

 Total number of routes: 4

 BGP local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               Origin: i - IGP, e - EGP, ? - incomplete

* >e Network : 9::                                      PrefixLen : 64

56 bytes from 50::1, icmp_seq=1 hlim=63 time=1.000 ms
56 bytes from 50::1, icmp_seq=2 hlim=63 time=2.000 ms
56 bytes from 50::1, icmp_seq=3 hlim=63 time=1.000 ms
56 bytes from 50::1, icmp_seq=4 hlim=63 time=1.000 ms

--- Ping6 statistics for 50::1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 1.000/1.200/2.000/0.400 ms
```

Troubleshooting BGP

State of the connection to a peer cannot become established

Symptom

The **display bgp peer ipv4 unicast** or **display bgp peer ipv6 unicast** command output shows that the state of the connection to a peer cannot become established.

Analysis

To become BGP peers, any two routers must establish a TCP connection using port 179 and exchange OPEN messages successfully.

Solution

1. To resolve the problem:
   a. Use the **display current-configuration** command to verify the current configuration, and verify that the peer's AS number is correct.
   b. Use the **display bgp peer ipv4 unicast** or **display bgp peer ipv6 unicast** command to verify that the peer's IP/IPv6 address is correct.
   c. If a loopback interface is used, verify that the loopback interface is specified with the **peer connect-interface** command.
   d. If the peer is a non-direct EBGP peer, verify that the **peer ebgp-max-hop** command is configured.
   e. If the **peer ttl-security hops** command is configured, verify that the command is configured on the peer. Verify that the *hop-count* values configured on them are greater than the number of hops between them.
   f. Verify that a valid route to the peer is available.
   g. Use the **ping** command to verify the connectivity to the peer.
   h. Use the **display tcp verbose** or **display ipv6 tcp verbose** command to verify the TCP connection.
   i. Verify that no ACL rule is applied to disable TCP port 179.
2. If the problem persists, contact NSFOCUS Support.

Configuring large-scale BGP networks

Large-scale BGP network configuration tasks at a glance

To configure large-scale BGP networks, perform the following tasks:

- Configuring BGP route dampening
- Configuring BGP communities
- Configuring BGP route reflection
- Configuring BGP confederation settings
  - Configuring a BGP confederation
  - (Optional.) Configuring confederation compatibility

Configuring BGP route dampening

About this task

Route dampening enables BGP to not select unstable routes as optimal routes.

Restrictions and guidelines

This feature applies to EBGP routes but not to IBGP routes.

If an EBGP peer goes down after you configure this feature, routes coming from the peer are dampened but not deleted.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Configure BGP route dampening.

   dampening [*half-life-reachable half-life-unreachable reuse suppress ceiling* | **route-policy** *route-policy-name*] *

By default, BGP route dampening is not configured.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Configure IPv6 BGP route dampening.

   dampening [*half-life-reachable half-life-unreachable reuse suppress ceiling* | **route-policy** *route-policy-name*] *

   By default, IPv6 BGP route dampening is not configured.

Configuring BGP communities

About this task

By default, a router does not advertise the COMMUNITY or extended community attribute to its peers or peer groups. When the router receives a route carrying the COMMUNITY or extended community attribute, it removes the attribute before advertising the route to other peers or peer groups.

Perform this task to enable a router to advertise the COMMUNITY or extended community attribute to its peers for route filtering and control. You can also use a routing policy to add or modify the COMMUNITY or extended community attribute for specific routes. For more information about routing policy, see "Configuring routing policies."

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

```
bgp as-number [ instance instance-name ]
ip vpn-instance vpn-instance-name
address-family ipv4 [ unicast ]
```

- Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

  ```
  bgp as-number [ instance instance-name ]
  address-family ipv4 multicast
  ```

3. Advertise the COMMUNITY attribute to a peer or peer group.

   ```
   peer { group-name | ipv4-address [ mask-length ] } advertise-community
   ```

   By default, the COMMUNITY attribute is not advertised.

4. Advertise the extended community attribute to a peer or peer group.

   ```
   peer { group-name | ipv4-address [ mask-length ] }
   advertise-ext-community
   ```

   By default, the extended community attribute is not advertised.

5. (Optional.) Apply a routing policy to routes advertised to a peer or peer group.

   ```
   peer { group-name | ipv4-address [ mask-length ] } route-policy
   route-policy-name export
   ```

   By default, no routing policy is applied.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   ```
   system-view
   ```

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     ```
     bgp as-number [ instance instance-name ]
     address-family ipv6 [ unicast ]
     ```

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     ```
     bgp as-number [ instance instance-name ]
     ip vpn-instance vpn-instance-name
     address-family ipv6 [ unicast ]
     ```

   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     ```
     bgp as-number [ instance instance-name ]
     address-family ipv6 multicast
     ```

3. Advertise the COMMUNITY attribute to a peer or peer group.

   ```
   peer { group-name | ipv6-address [ prefix-length ] }
   advertise-community
   ```

   By default, the COMMUNITY attribute is not advertised.

4. Advertise the extended community attribute to a peer or peer group.

   ```
   peer { group-name | ipv6-address [ prefix-length ] }
   advertise-ext-community
   ```

   By default, the extended community attribute is not advertised.

5. (Optional.) Apply a routing policy to routes advertised to a peer or peer group.

peer { *group-name* | *ipv6-address* [*prefix-length*] } **route-policy** *route-policy-name* **export**

By default, no routing policy is applied.

Configuring BGP route reflection

Configuring a BGP route reflector

About this task

Perform this task to configure a BGP route reflector and its clients. The route reflector and its clients automatically form a cluster identified by the router ID of the route reflector. The route reflector forwards route updates among its clients.

To improve availability, you can specify multiple route reflectors for a cluster. The route reflectors in the cluster must have the same cluster ID to avoid routing loops.

When a route reflector connects to multiple clusters, you can configure different cluster IDs for different peers or peer groups.

You only need to configure BGP route reflection on the device that acts as a route reflector. Other devices do not need to know the role of the local device in route reflection.

After you configure a device as a route reflector, it advertises routes as follows:

- Advertises routes received from a non-client IBGP peer to all clients.
- Advertises routes received from an IBGP peer that acts as a client to all peers.
- Advertises routes received from an EBGP peer to all peers.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Configure the router as a route reflector and specify a peer or peer group as its client.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **reflect-client**

   By default, no route reflector or client is configured.

4. (Optional.) Enable route reflection between clients.

   reflect between-clients

By default, route reflection between clients is enabled.

5. (Optional.) Configure the cluster ID of the route reflector.

   reflector cluster-id { *cluster-id* | *ipv4-address* }

   By default, a route reflector uses its own router ID as the cluster ID.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Configure the router as a route reflector and specify a peer or peer group as its client.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **reflect-client**

   By default, no route reflector or client is configured.

4. (Optional.) Enable route reflection between clients.

   reflect between-clients

   By default, route reflection between clients is enabled.

5. (Optional.) Configure the cluster ID of the route reflector.

   reflector cluster-id { *cluster-id* | *ipv4-address* }

   By default, a route reflector uses its own router ID as the cluster ID.

Ignoring the ORIGINATOR_ID attribute

About this task

By default, BGP drops incoming route updates whose ORIGINATOR_ID attribute is the same as the local router ID. Some special networks such as firewall networks require BGP to accept such route updates. To meet the requirement, you must configure BGP to ignore the ORIGINATOR_ID attribute.

Restrictions and guidelines

Make sure this command does not result in a routing loop.

After you execute this command, BGP also ignores the CLUSTER_LIST attribute.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

3. Ignore the ORIGINATOR_ID attribute.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **ignore-originatorid**

   By default, BGP does not ignore the ORIGINATOR_ID attribute.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Ignore the ORIGINATOR_ID attribute.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **ignore-originatorid**

   By default, BGP does not ignore the ORIGINATOR_ID attribute.

Configuring BGP confederation settings

About BGP confederation

BGP confederation provides another way to reduce IBGP connections in an AS.

A confederation contains sub-ASs. In each sub-AS, IBGP peers are fully meshed. Sub-ASs establish EBGP connections in between.

Configuring a BGP confederation

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Configure a confederation ID.

   confederation id *as-number*

   By default, no confederation ID is configured.

   From an outsider's perspective, the sub-ASs of the confederation is a single AS, which is identified by the confederation ID.

4. Specify confederation peer sub-ASs in the confederation.

   confederation peer-as *as-number-list*

   By default, no confederation peer sub-ASs are specified.

   A confederation can contain a maximum of 32 sub-ASs. The AS number of a sub-AS is effective only in the confederation.

   If the router needs to establish EBGP connections to other sub-ASs, you must specify the peering sub-ASs in the confederation.

Configuring confederation compatibility

About this task

If any routers in the confederation do not comply with RFC 3065, enable confederation compatibility to allow the router to work with those routers.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Enable confederation compatibility.
   confederation nonstandard
   By default, confederation compatibility is disabled.

Display and maintenance commands for large-scale BGP network configuration

Execute **display** commands in any view.

Displaying BGP (IPv4 unicast address family)

Task	Command
Display BGP IPv4 unicast route dampening parameter information.	**display bgp** [**instance** *instance-name*] **dampening parameter ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Display BGP IPv4 unicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**group-name** *group-name*]
Display BGP IPv4 unicast peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address* *mask-length* | { *ipv4-address* | **group-name** *group-name* } **log-info** | [*ipv4-address*] **verbose**]
Display dampened BGP IPv4 unicast route information.	**display bgp** [**instance** *instance-name*] **routing-table dampened ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Display BGP IPv4 unicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | **as-path-acl** *as-path-acl-number*]

Displaying BGP (IPv6 unicast address family)

Task	Command
Display BGP IPv6 unicast route dampening parameter information.	**display bgp** [**instance** *instance-name*] **dampening parameter ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Display BGP IPv6 unicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**group-name** *group-name*]
Display BGP IPv6 unicast peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv6-address* *prefix-length* | { *ipv6-address* | **group-name** *group-name* } **log-info** | [*ipv6-address*] **verbose**] **display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] [*ipv4-address* *mask-length* | *ipv4-address* **log-info** | [*ipv4-address*] **verbose**]
Display dampened BGP IPv6 unicast route information.	**display bgp** [**instance** *instance-name*] **routing-table dampened ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Display BGP IPv6 unicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv6-address* *prefix-length* | **as-path-acl** *as-path-acl-number*]

Displaying BGP (IPv4 multicast address family)

Task	Command
Display BGP IPv4 multicast route dampening parameter information.	**display bgp** [**instance** *instance-name*] **dampening parameter ipv4 multicast**
Display BGP IPv4 multicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv4 multicast** [**group-name** *group-name*]
Display BGP IPv4 multicast peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer ipv4 multicast** [*ipv4-address* *mask-length* | { *ipv4-address* | **group-name** *group-name* } **log-info** | [*ipv4-address*] **verbose**]
Display dampened BGP IPv4 multicast route information.	**display bgp** [**instance** *instance-name*] **routing-table dampened ipv4 multicast**
Display BGP IPv4 multicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv4 multicast** [*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | **as-path-acl** *as-path-acl-number*]

Displaying BGP (IPv6 multicast address family)

Task	Command
Display BGP IPv6 multicast route dampening parameter information.	**display bgp** [**instance** *instance-name*] **dampening parameter ipv6 multicast**
Display BGP IPv6 multicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv6 multicast** [**group-name** *group-name*]
Display BGP IPv6 multicast peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer ipv6 multicast** [*ipv6-address prefix-length* | { *ipv6-address* | **group-name** *group-name* } **log-info** | [*ipv6-address*] **verbose**]
Display dampened BGP IPv6 multicast route information.	**display bgp** [**instance** *instance-name*] **routing-table dampened ipv6 multicast**
Display BGP IPv6 multicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv6 multicast** [*ipv6-address prefix-length* | **as-path-acl** *as-path-acl-number*]

Controlling BGP path selection

BGP path selection control tasks at a glance

By configuring BGP path attributes, you can control BGP path selection.

To control BGP path selection, perform the following tasks:

1. Configuring preferences for BGP routes
2. Configuring the NEXT_HOP attribute
3. Setting a preferred value for received routes
4. Configuring the default local preference
5. Configuring the AS_PATH attribute
    - Permitting local AS number to appear in routes from a peer or peer group
    - Ignoring the AS_PATH attribute during optimal route selection
    - Advertising a fake AS number to a peer or peer group
    - Configuring AS number substitution
    - Removing private AS numbers from sent updates
    - Ignoring the first AS number of EBGP route updates
6. Configuring the MED attribute
    - Configuring the default MED value
    - Enabling MED comparison for routes from different ASs
    - Enabling MED comparison for routes on a per-AS basis
    - Enabling MED comparison for routes from confederation peers
7. Ignoring IGP metrics during optimal route selection
8. Ignoring router IDs during optimal route selection

Configuring preferences for BGP routes

About this task

Routing protocols each have a default preference. If they find multiple routes destined for the same network, the route found by the routing protocol with the highest preference is selected as the optimal route.

You can use the **preference** command to modify preferences for EBGP, IBGP, and local BGP routes, or use a routing policy to set a preference for matching routes. For routes not matching the routing policy, the default preference applies.

If a device has an EBGP route and a local BGP route to reach the same destination, it does not select the EBGP route because the EBGP route has a lower preference than the local BGP route by default. You can use the **network short-cut** command to configure the EBGP route as a shortcut route that has the same preference as the local BGP route. The EBGP route will more likely become the optimal route.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

- Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv4 multicast

3. Configure preferences for EBGP, IBGP, and local BGP routes.

   preference { *external-preference internal-preference local-preference* | **route-policy** *route-policy-name* }

   By default, the preferences for EBGP, IBGP, and local BGP routes are 255, 255, and 130, respectively.

4. (Optional.) Configure an EBGP route as a shortcut route.

   network *ipv4-address* [*mask-length* | *mask*] **short-cut**

   By default, an EBGP route has a preference of 255.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Configure preferences for EBGP, IBGP, and local BGP routes.

   preference { *external-preference internal-preference local-preference* | **route-policy** *route-policy-name* }

   By default, the preferences for EBGP, IBGP, and local BGP routes are 255, 255, and 130, respectively.

4. (Optional.) Configure an EBGP route as a shortcut route.

   network *ipv6-address prefix-length* **short-cut**

By default, an EBGP route has a preference of 255.

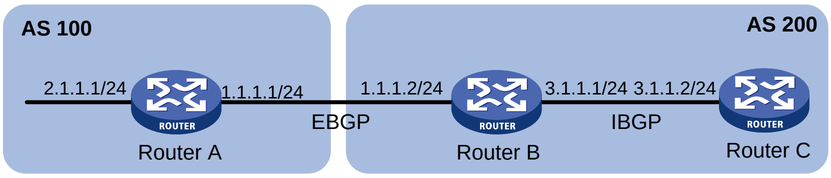
Configuring the NEXT_HOP attribute

About this task

By default, a BGP router does not set itself as the next hop for routes advertised to an IBGP peer or peer group. In some cases, however, you must configure the advertising router as the next hop to ensure that the BGP peer can find the correct next hop.

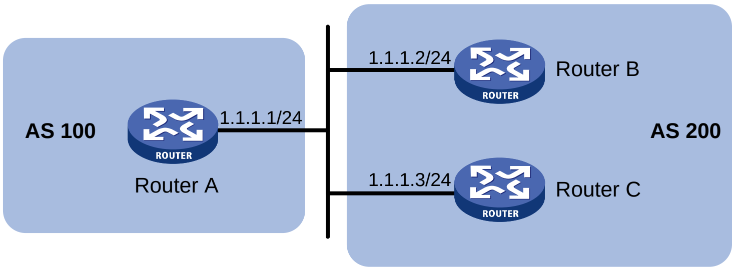
For example, as shown in Figure 12, Router A and Router B establish an EBGP neighbor relationship, and Router B and Router C establish an IBGP neighbor relationship. If Router C has no route destined for IP address 1.1.1.1/24, you must configure Router B to set itself 3.1.1.1/24 as the next hop for the network 2.1.1.1/24 advertised to Router C.

Figure 12 NEXT_HOP attribute configuration



If a BGP router has two peers on a broadcast network, it does not set itself as the next hop for routes sent to an EBGP peer by default. As shown in Figure 13, Router A and Router B establish an EBGP neighbor relationship, and Router B and Router C establish an IBGP neighbor relationship. They are on the same broadcast network 1.1.1.0/24. When Router B sends EBGP routes to Router A, it does not set itself as the next hop by default. However, you can configure Router B to set it (1.1.1.2/24) as the next hop for routes sent to Router A by using the **peer next-hop-local** command as needed.

Figure 13 NEXT_HOP attribute configuration



Restrictions and guidelines

If you have configured BGP load balancing, the router sets itself as the next hop for routes sent to an IBGP peer or peer group regardless of whether the **peer next-hop-local** command is configured.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.
   system-view
2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:
     bgp *as-number* [**instance** *instance-name*]

address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv4 [**unicast**]
- Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv4 multicast

3. Specify the router as the next hop for routes sent to a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **next-hop-local**

   By default, the router sets itself as the next hop for routes sent to an EBGP peer or peer group. However, it does not set itself as the next hop for routes sent to an IBGP peer or peer group.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Specify the router as the next hop for routes sent to a peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **next-hop-local**

   By default, the router sets itself as the next hop for routes sent to an EBGP peer or peer group. However, it does not set itself as the next hop for routes sent to an IBGP peer or peer group.

Setting a preferred value for received routes

About this task

Perform this task to set a preferred value for specific routes to control BGP path selection.

Among multiple routes that have the same destination/mask and are learned from different peers, the one with the greatest preferred value is selected as the optimal route.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast
3. Set a preferred value for routes received from a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **preferred-value** *value*

   By default, the preferred value is 0 for routes received from a peer or peer group.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Set a preferred value for routes received from a peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **preferred-value** *value*

   By default, the preferred value is 0 for routes received from a peer or peer group.

Configuring the default local preference

About this task

The local preference is used to determine the optimal route for traffic leaving the local AS. When a BGP router obtains from several IBGP peers multiple routes to the same destination, but with different next hops, it selects the route with the highest local preference as the optimal route.

This task allows you to specify the default local preference for routes sent to IBGP peers.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Configure the default local preference.

   default local-preference *value*

   The default local preference is 100.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

address-family ipv6 multicast

3. Configure the default local preference.

   default local-preference *value*

   The default local preference is 100.

Configuring the AS_PATH attribute

Permitting local AS number to appear in routes from a peer or peer group

About this task

In general, BGP checks whether the AS_PATH attribute of a route from a peer contains the local AS number. If yes, it discards the route to avoid routing loops.

In certain network environments, however, the AS_PATH attribute of a route from a peer must be allowed to contain the local AS number. Otherwise, the route cannot be advertised correctly.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Permit the local AS number to appear in routes from a peer or peer group and set the appearance times.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **allow-as-loop** [*number*]

   By default, the local AS number is not allowed in routes from a peer or peer group.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

bgp *as-number* [**instance** *instance-name*]

address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv6 multicast

3. Permit the local AS number to appear in routes from a peer or peer group and set the appearance times.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **allow-as-loop** [*number*]

   By default, the local AS number is not allowed in routes from a peer or peer group.

Ignoring the AS_PATH attribute during optimal route selection

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure BGP to ignore the AS_PATH attribute during optimal route selection.

   bestroute as-path-neglect [**all-instance**]

   By default, BGP includes the AS_PATH attribute in optimal route selection.

   The **all-instance** keyword is supported only in BGP instance view.

Advertising a fake AS number to a peer or peer group

About this task

After you move a BGP router from an AS to another AS (from AS 2 to AS 3 for example), you have to modify the AS number of the router on all its EBGP peers. To avoid such modifications, you can configure the router to advertise a fake AS number 2 to its EBGP peers so that the EBGP peers still think that Router A is in AS 2.

Restrictions and guidelines

This command applies only to EBGP peers or EBGP peer groups.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     ```
     bgp as-number [ instance instance-name ]
     ```
   - Execute the following commands in sequence to enter BGP-VPN instance view:
     ```
     bgp as-number [ instance instance-name ]
     ip vpn-instance vpn-instance-name
     ```
3. Advertise a fake AS number to a peer or peer group.
   ```
   peer { group-name | ipv4-address [ mask-length ] } fake-as as-number
   ```
   By default, no fake AS number is advertised to a peer or peer group.

Procedure (IPv6 unicast/multicast address family)

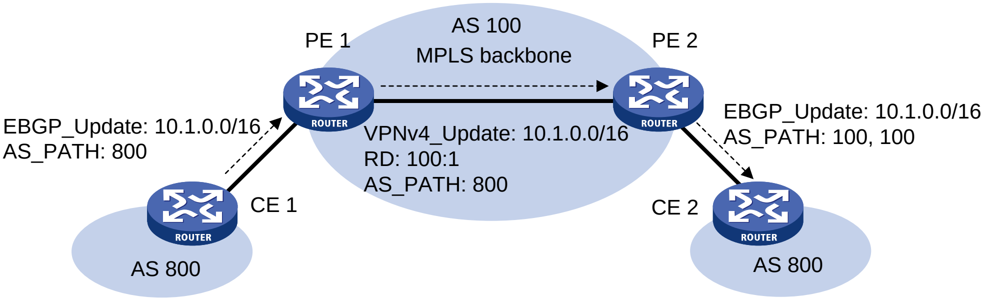
1. Enter system view.
   ```
   system-view
   ```
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     ```
     bgp as-number [ instance instance-name ]
     ```
   - Execute the following commands in sequence to enter BGP-VPN instance view:
     ```
     bgp as-number [ instance instance-name ]
     ip vpn-instance vpn-instance-name
     ```
3. Advertise a fake AS number to a peer or peer group.
   ```
   peer { group-name | ipv6-address [ prefix-length ] } fake-as as-number
   ```
   By default, no fake AS number is advertised to a peer or peer group.

Configuring AS number substitution

About this task

To use EBGP between PE and CE in MPLS L3VPN, VPN sites in different geographical areas should have different AS numbers. Otherwise, BGP discards route updates containing the local AS number. If two CEs connected to different PEs use the same AS number, you must configure AS number substitution on each PE. This substitution can replace the AS number in route updates originated by the remote CE as its own AS number before advertising them to the connected CE.

Figure 14 AS number substitution configuration (in an IPv4 network)



As shown in Figure 14, CE 1 and CE 2 use the same AS number 800. To ensure bidirectional communication between the two sites, configure AS number substitution on PE 2. PE 2 replaces AS 800 with AS 100 for the BGP route update originated from CE 1 before advertising it to CE 2. Perform the same configuration on PE 1.

Restrictions and guidelines

Do not configure AS number substitution in normal circumstances. Otherwise, routing loops might occur.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure AS number substitution for a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **substitute-as**

   By default, AS number substitution is not configured.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure AS number substitution for a peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **substitute-as**

   By default, AS number substitution is not configured.

Removing private AS numbers from sent updates

About this task

Private AS numbers are typically used in test networks, and should not be transmitted in public networks. The range of private AS numbers is from 64512 to 65535.

Perform this task to enable BGP to remove private AS numbers from the AS_PATH attribute of updates sent to a peer or peer group.

Restrictions and guidelines

This feature is applicable only to EBGP peers or peer groups.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

- Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv4 [**unicast**]
- Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv4 [**unicast**]
- Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv4 multicast

3. Configure BGP to remove private AS numbers from the AS_PATH attribute of updates sent to an EBGP peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **public-as-only**

   By default, BGP updates sent to an EBGP peer or peer group can carry both public and private AS numbers.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Configure BGP to remove private AS numbers from the AS_PATH attribute of updates sent to an EBGP peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **public-as-only**

   By default, BGP updates sent to an EBGP peer or peer group can carry both public and private AS numbers.

Ignoring the first AS number of EBGP route updates

About this task

By default, BGP checks the first AS number of an EBGP-learned route update. If the first AS number is neither the AS number of the BGP peer nor a private AS number, the BGP router disconnects the BGP session to the peer.

Ignoring the first AS number of all EBGP route updates

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enable BGP to ignore the first AS number of EBGP route updates.

   ignore-first-as

   By default, BGP checks the first AS number of EBGP-learned route updates.

Ignoring the first AS number of EBGP route updates received from a peer or peer group (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable BGP to ignore the first AS number of EBGP route updates received from a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **ignore-first-as**

   By default, BGP checks the first AS number of EBGP-learned route updates.

Ignoring the first AS number of EBGP route updates received from a peer or peer group (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable BGP to ignore the first AS number of EBGP route updates received from a peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **ignore-first-as**

   By default, BGP checks the first AS number of EBGP-learned route updates.

Configuring the MED attribute

About the MED attribute

BGP uses MED to determine the optimal route for traffic going into an AS. When a BGP router obtains multiple routes with the same destination but with different next hops, it selects the route with the smallest MED value as the optimal route if other conditions are the same.

Configuring the default MED value

Configuring the default MED value (IPv4 unicast/multicast address family)

1. Enter system view.

   `system-view`

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Configure the default MED value.

   default med *med-value*

   The default MED value is 0.

Configuring the default MED value (IPv6 unicast/multicast address family)

1. Enter system view.

   `system-view`

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

  ```
  bgp as-number [ instance instance-name ]
  address-family ipv6 multicast
  ```

3. Configure the default MED value.

   ```
   default med med-value
   ```

   The default MED value is 0.

Enabling MED comparison for routes from different ASs

About this task

By default, BGP only compares the MEDs of routes from the same AS. This task enables BGP to compare the MEDs of routes from different ASs.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     ```
     bgp as-number [ instance instance-name ]
     ```

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     ```
     bgp as-number [ instance instance-name ]
     ip vpn-instance vpn-instance-name
     ```

3. Enable MED comparison for routes from different ASs.

   ```
   compare-different-as-med
   ```

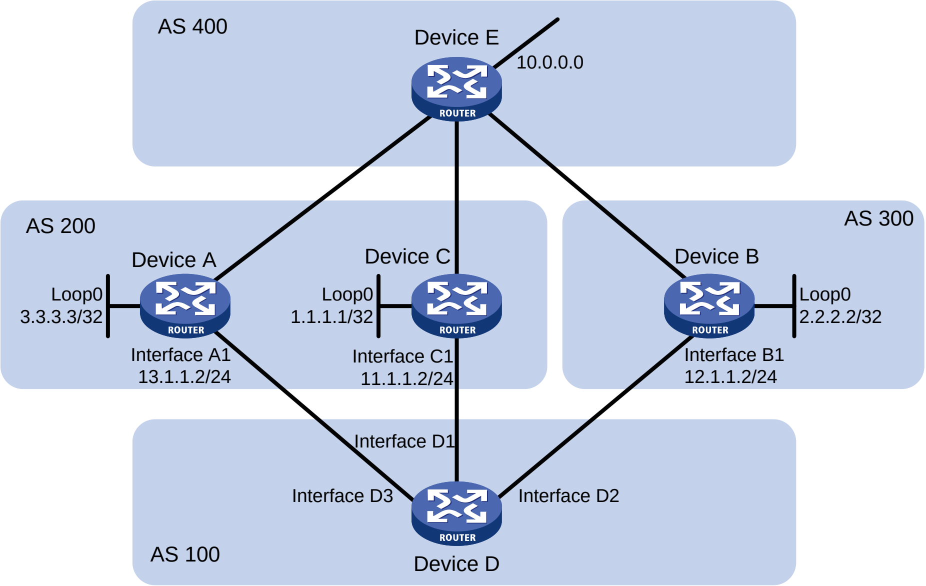
   By default, MED comparison for routes from different ASs is disabled.

Enabling MED comparison for routes on a per-AS basis

About this task

This task enables BGP to compare the MEDs of routes from an AS.

Figure 15 Route selection based on MED (in an IPv4 network)



As shown in Figure 15, Device D establishes indirect EBGP peer relationships with Device A, Device B, and Device C, and learns addresses 1.1.1.1/32, 2.2.2.2/32, and 3.3.3.3/32 through OSPF. The following output shows the routing information on Device D.

```
Destination/Mask   Proto   Pre Cost        NextHop         Interface
1.1.1.1/32         O_INTRA 10  10          11.1.1.2        Interface D1
2.2.2.2/32         O_INTRA 10  20          12.1.1.2        Interface D2
3.3.3.3/32         O_INTRA 10  30          13.1.1.2        Interface D3
```

Device D learns network 10.0.0.0 from both Device A and Device B. Because the route learned from Device B has a smaller IGP metric, the route is optimal. The following output shows the BGP routing table on Device D.

```
     Network             NextHop          MED         LocPrf      PrefVal Path/Ogn
 *>e  10.0.0.0           2.2.2.2          50                      0       300 400e
 * e                     3.3.3.3          50                      0       200 400e
```

When Device D learns network 10.0.0.0 from Device C, it compares the route with the optimal route in its routing table. Because Device C and Device B reside in different ASs, BGP does not compare the MEDs of the two routes. The route from Device C has a smaller IGP metric than the route from Device B, so the route from Device C becomes optimal. The following output shows the BGP routing table on Device D.

```
     Network             NextHop          MED         LocPrf      PrefVal Path/Ogn
 *>e  10.0.0.0           1.1.1.1          60                      0       200 400e
 * e  10.0.0.0           2.2.2.2          50                      0       300 400e
 * e                     3.3.3.3          50                      0       200 400e
```

However, Device C and Device A reside in the same AS, and Device C has a greater MED, so network 10.0.0.0 learned from Device C should not be optimal.

To avoid this problem, you can configure the **bestroute compare-med** command to enable MED comparison for routes from the same AS on Device D. After that, Device D puts the routes received from each AS into a group, selects the route with the lowest MED from each group, and compares routes from different groups. Network 10.0.0.0 learned from Device B is the optimal route. The following output shows the BGP routing table on Device D.

```
     Network             NextHop          MED         LocPrf      PrefVal Path/Ogn
 *>e  10.0.0.0           2.2.2.2          50                      0       300 400e
 * e                    3.3.3.3         50                     0       200 400e
 * e                    1.1.1.1         60                     0       200 400e
```

Procedure

1. Enter system view.

   `system-view`

2. Enter BGP instance view or BGP-VPN instance view.

   - Enter BGP instance view.

     `bgp` *`as-number`* `[` **`instance`** *`instance-name`* `]`

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     `bgp` *`as-number`* `[` **`instance`** *`instance-name`* `]`

     `ip vpn-instance` *`vpn-instance-name`*

3. Enable MED comparison for routes on a per-AS basis.

   `bestroute compare-med` `[` **`all-instance`** `]`

   By default, MED comparison for routes on a per-AS basis is disabled.

   The **`all-instance`** keyword is supported only in BGP instance view.

Enabling MED comparison for routes from confederation peers

About this task

This task enables BGP to compare the MEDs of routes received from confederation peers. However, if a route received from a confederation peer has an AS number that does not belong to the confederation, BGP does not compare the route with other routes. For example, a confederation has three AS numbers 65006, 65007, and 65009. BGP receives three routes from different confederation peers. The AS_PATH attributes of these routes are 65006 65009, 65007 65009, and 65008 65009, and the MED values of them are 2, 3, and 1. Because the third route's AS_PATH attribute contains AS number 65008 that does not belong to the confederation, BGP does not compare it with other routes. As a result, the first route becomes the optimal route.

Procedure

1. Enter system view.

   `system-view`

2. Enter BGP instance view or BGP-VPN instance view.

   - Enter BGP instance view.

     `bgp` *`as-number`* `[` **`instance`** *`instance-name`* `]`

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     `bgp` *`as-number`* `[` **`instance`** *`instance-name`* `]`

     `ip vpn-instance` *`vpn-instance-name`*

3. Enable MED comparison for routes from confederation peers.

   `bestroute med-confederation` `[` **`all-instance`** `]`

   By default, MED comparison for routes from confederation peers is disabled.

   The **`all-instance`** keyword is supported only in BGP instance view.

Ignoring IGP metrics during optimal route selection

About this task

By default, BGP includes IGP metrics in optimal route selection. If multiple routes to the same destination are available, BGP selects the route with the smallest IGP metric as the optimal route.

Perform this task to enable BGP to ignore IGP metrics during optimal route selection.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure BGP to ignore IGP metrics during optimal route selection.

   bestroute igp-metric-ignore [**all-instance**]

   By default, BGP includes IGP metrics in optimal route selection.

   The **all-instance** keyword is supported only in BGP instance view.

Ignoring router IDs during optimal route selection

About this task

By default, BGP compares router IDs during optimal route selection. If multiple routes to the same destination are available, BGP selects the route with the smallest router ID as the optimal route.

Perform this task to enable BGP to ignore router IDs during optimal route selection.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable BGP to ignore router IDs during optimal route selection.

   bestroute router-id-ignore [**all-instance**]

   By default, BGP compares router IDs during optimal route selection.

   The **all-instance** keyword is supported only in BGP instance view.

Display and maintenance commands for BGP path selection control

Execute **display** commands in any view.

Displaying BGP (IPv4 unicast address family)

Task	Command
Display BGP path attribute information.	**display bgp** [**instance** *instance-name*] **paths** [*as-regular-expression*]

Displaying BGP (IPv6 unicast address family)

Task	Command
Display BGP path attribute information.	**display bgp** [**instance** *instance-name*] **paths** [*as-regular-expression*]

Displaying BGP (IPv4 multicast address family)

Task	Command
Display BGP path attribute information.	**display bgp** [**instance** *instance-name*] **paths** [*as-regular-expression*]

Displaying BGP (IPv6 multicast address family)

Task	Command
Display BGP path attribute information.	**display bgp** [**instance** *instance-name*] **paths** [*as-regular-expression*]

Tuning and optimizing BGP networks

BGP network tuning and optimization tasks at a glance

To tune and optimize BGP networks, perform the following tasks:

- Establishing and resetting EBGP sessions
  - Enabling BGP to establish an EBGP session over multiple hops
  - Enabling immediate re-establishment of direct EBGP connections upon link failure
- Establishing, terminating, and resetting BGP sessions
  - Enabling 4-byte AS number suppression
  - Disabling BGP session establishment
  - Configuring BGP soft-reset
- Configuring BGP load balancing
- Protecting an EBGP peer when memory usage reaches level 2 threshold
- Flushing the suboptimal BGP route to the RIB
- Specifying a label allocation mode
- Recursing unlabeled public BGP routes to LSPs

Enabling BGP to establish an EBGP session over multiple hops

About this task

To establish an EBGP session, two routers must have a direct physical link and use directly connected interfaces. If no direct link is available, you must use the **peer ebgp-max-hop** command to enable BGP to establish an EBGP session over multiple hops and specify the maximum hops.

Restrictions and guidelines

When the BGP GTSM feature is enabled, two peers can establish an EBGP session after passing GTSM check, regardless of whether the maximum number of hops is reached.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Enable BGP to establish an EBGP session to an indirectly connected peer or peer group and specify the maximum hop count.

peer { *group-name* | *ipv4-address* [*mask-length*] } **ebgp-max-hop** [*hop-count*]

By default, BGP cannot establish an EBGP session to an indirectly connected peer or peer group.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Enable BGP to establish an EBGP session to an indirectly connected peer or peer group and specify the maximum hop count.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **ebgp-max-hop** [*hop-count*]

   By default, BGP cannot establish an EBGP session to an indirectly connected peer or peer group.

Enabling immediate re-establishment of direct EBGP connections upon link failure

About this task

By default, when the link to a directly connected EBGP peer goes down, the router does not re-establish a session to the peer until the hold time timer expires. This feature enables BGP to immediately recreate the session in that situation. When this feature is disabled, route flapping does not affect EBGP session state.

Procedure

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Enable immediate re-establishment of direct EBGP connections upon link failure.

   ebgp-interface-sensitive

   By default, immediate re-establishment of direct EBGP connections is enabled.

Enabling 4-byte AS number suppression

About this task

BGP supports 4-byte AS numbers. The 4-byte AS number occupies four bytes, in the range of 1 to 4294967295. By default, a device sends an OPEN message to the peer device for session establishment. The OPEN message indicates that the device supports 4-byte AS numbers. If the peer device supports 2-byte AS numbers instead of 4-byte AS numbers, the session cannot be established. To resolve this issue, enable the 4-byte AS number suppression feature. The device then sends an OPEN message to inform the peer that it does not support 4-byte AS numbers, so the BGP session can be established.

Restrictions and guidelines

If the peer device supports 4-byte AS numbers, do not enable the 4-byte AS number suppression feature. Otherwise, the BGP session cannot be established.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable 4-byte AS number suppression.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **capability-advertise suppress-4-byte-as**

   By default, 4-byte AS number suppression is disabled.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable 4-byte AS number suppression.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **capability-advertise suppress-4-byte-as**

   By default, 4-byte AS number suppression is disabled.

Disabling BGP session establishment

About disabling BGP session establishment

This task enables you to temporarily tear down BGP sessions to a peer/peer group. You can perform network upgrade and maintenance without needing to delete and reconfigure the peers and peer groups. To recover the sessions, execute the **undo peer ignore** command.

Disabling BGP session establishment with a peer or peer group (IPv4 unicast/multicast address family)

1. Enter system view.

system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Disable BGP session establishment with a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **ignore**

   By default, BGP can establish a session to a peer or peer group.

CAUTION:

- If a session has been established to a peer, executing the **peer ignore** command for the peer tears down the session and clears all related routing information.
- If sessions have been established to a peer group, executing the **peer ignore** command for the peer group tears down the sessions to all peers in the group and clears all related routing information.

Disabling BGP session establishment with a peer or peer group (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Disable BGP session establishment with a peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **ignore**

   By default, BGP can establish a session to a peer or peer group.

CAUTION:

- If a session has been established to a peer, executing the **peer ignore** command for the peer tears down the session and clears all related routing information.
- If sessions have been established to a peer group, executing the **peer ignore** command for the peer group tears down the sessions to all peers in the group and clears all related routing information.

Configuring BGP soft-reset

About BGP soft-reset

After you modify the route selection policy, for example, modify the preferred value, you must reset BGP sessions to apply the new policy. The reset operation tears down and re-establishes BGP sessions.

To avoid tearing down BGP sessions, you can use one of the following soft-reset methods to apply the new policy:

- **Enabling route refresh**—The BGP router advertises a ROUTE-REFRESH message to the specified peer, and the peer resends its routing information to the router. After receiving the routing information, the router filters the routing information by using the new policy.

  This method requires that both the local router and the peer support route refresh.
- **Saving updates**—Use the **`peer keep-all-routes`** command to save all route updates from the specified peer. After modifying the route selection policy, filter routing information by using the new policy.

  This method does not require that the local router and the peer support route refresh but it uses more memory resources to save routes.
- **Manual soft-reset**—Use the **`refresh bgp`** command to enable BGP to send local routing information or advertise a ROUTE-REFRESH message to the specified peer. The peer then resends its routing information. After receiving the routing information, the router filters the routing information by using the new policy.

  This method requires that both the local router and the peer support route refresh.

Enabling route refresh (IPv4 unicast/multicast address family)

1. Enter system view.

   ```
   system-view
   ```
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     ```
     bgp as-number [ instance instance-name ]
     ```
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     ```
     bgp as-number [ instance instance-name ]
     ip vpn-instance vpn-instance-name
     ```
3. Enable BGP route refresh for a peer or peer group.
   - Enable BGP route refresh for the specified peer or peer group.

     ```
     peer { group-name | ipv4-address [ mask-length ] }
     capability-advertise route-refresh
     ```
   - Enable the BGP route refresh, multi-protocol extension, and 4-byte AS number features for the specified peer or peer group.

     ```
     undo peer { group-name | ipv4-address [ mask-length ] }
     capability-advertise conventional
     ```

   By default, the BGP route refresh, multi-protocol extension, and 4-byte AS number features are enabled.

Enabling route refresh (IPv6 unicast/multicast address family)

1. Enter system view.

   ```
   system-view
   ```
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     ```
     bgp as-number [ instance instance-name ]
     ```

- Execute the following commands in sequence to enter BGP-VPN instance view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

3. Enable BGP route refresh for a peer or peer group.
   - Enable BGP route refresh for the specified peer or peer group.

     peer { *group-name* | *ipv6-address* [*prefix-length*] } **capability-advertise route-refresh**
   - Enable the BGP route refresh, multi-protocol extension, and 4-byte AS number features for the specified peer or peer group.

     undo peer { *group-name* | *ipv6-address* [*prefix-length*] } **capability-advertise conventional**

   By default, the BGP route refresh, multi-protocol extension, and 4-byte AS number features are enabled.

Saving updates (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast
3. Save all route updates from the peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **keep-all-routes**

   By default, route updates from peers and peer groups are not saved.

   This command takes effect only for the routes received after this command is executed.

Saving updates (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv6 multicast

3. Save all route updates from the peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **keep-all-routes**

   By default, route updates from peers and peer groups are not saved.

   This command takes effect only for the routes received after this command is executed.

Configuring manual soft-reset (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable BGP route refresh for a peer or peer group.
   - Enable BGP route refresh for the specified peer or peer group.

     peer { *group-name* | *ipv4-address* [*mask-length*] } **capability-advertise route-refresh**

   - Enable the BGP route refresh, multi-protocol extension, and 4-byte AS number features for the specified peer or peer group.

     undo peer { *group-name* | *ipv4-address* [*mask-length*] } **capability-advertise conventional**

   By default, the BGP route refresh, multi-protocol extension, and 4-byte AS number features are enabled.

4. Perform manual soft-reset:

   a. Return to system view.

      quit

   b. Return to user view.

      quit

   c. Perform manual soft-reset.

      refresh bgp [**instance** *instance-name*] { *ipv4-address* [*mask-length*] | **all** | **external** | **group** *group-name* | **internal** } { **export** | **import** } **ipv4** [**multicast** | [**unicast**] [**vpn-instance** *vpn-instance-name*]]

Configuring manual soft-reset (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable BGP route refresh for a peer or peer group.
   - Enable BGP route refresh for the specified peer or peer group.

     peer { *group-name* | *ipv6-address* [*prefix-length*] } **capability-advertise route-refresh**
   - Enable the BGP route refresh, multi-protocol extension, and 4-byte AS number features for the specified peer or peer group.

     undo peer { *group-name* | *ipv6-address* [*prefix-length*] } **capability-advertise conventional**

   By default, the BGP route refresh, multi-protocol extension, and 4-byte AS number features are enabled.

4. Perform manual soft-reset:

   a. Return to system view.

      quit

   b. Return to user view.

      quit

   c. Perform manual soft-reset.

      refresh bgp [**instance** *instance-name*] { *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } { **export** | **import** } **ipv6** [**multicast** | [**unicast**] [**vpn-instance** *vpn-instance-name*]]

Configuring BGP load balancing

About this task

Perform this task to specify the maximum number of BGP ECMP routes for load balancing.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

3. (Optional.) Enable BGP to ignore IGP metrics during optimal route selection.

   bestroute igp-metric-ignore

   By default, BGP compares IGP metrics during optimal route selection, and selects the route with the smallest IGP metric as the optimal route.

   BGP cannot use routes with different IGP metrics to implement load balancing. To resolve this issue, you can use this command.

4. Return to system view.
   - In BGP instance view:

     quit
   - In BGP-VPN instance view:

     quit

     quit

5. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

6. Specify the maximum number of BGP ECMP routes for load balancing.

   balance [**ebgp** | **eibgp** | **ibgp**] *number*

   By default, load balancing is disabled.

7. (Optional.) Enable BGP to ignore the AS_PATH attribute when it implements load balancing.

   balance as-path-neglect

   By default, BGP does not ignore the AS_PATH attribute when it implements load balancing.

8. (Optional.) Enable BGP to perform load balancing for routes that have different AS_PATH attributes of the same length.

   balance as-path-relax

   By default, BGP cannot perform load balancing for routes that have different AS_PATH attributes of the same length.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. (Optional.) Enable BGP to ignore IGP metrics during optimal route selection.

   bestroute igp-metric-ignore

   By default, BGP compares IGP metrics during optimal route selection, and selects the route with the smallest IGP metric as the optimal route.

   BGP cannot use routes with different IGP metrics to implement load balancing. To resolve this issue, you can use this command.

4. Return to system view.
   - In BGP instance view:

     quit
   - In BGP-VPN instance view:

     quit

     quit

5. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

6. Specify the maximum number of BGP ECMP routes for load balancing.

   balance [**ebgp** | **eibgp** | **ibgp**] *number*

   By default, load balancing is disabled.

7. (Optional.) Enable BGP to ignore the AS_PATH attribute when it implements load balancing.

   balance as-path-neglect

   By default, BGP does not ignore the AS_PATH attribute when it implements load balancing.

8. (Optional.) Enable BGP to perform load balancing for routes that have different AS_PATH attributes of the same length.

   balance as-path-relax

   By default, BGP cannot perform load balancing for routes that have different AS_PATH attributes of the same length.

Protecting an EBGP peer when memory usage reaches level 2 threshold

About this task

Memory usage includes the following threshold levels: normal, level 1, level 2, and level 3. When the level 2 threshold is reached, BGP periodically tears down an EBGP session to release memory resources until the memory usage falls below the level 2 threshold. You can configure this feature to avoid tearing down the EBGP session to an EBGP peer when the memory usage reaches the level 2 threshold.

For more information about memory usage thresholds, see device management configuration in *Fundamentals Configuration Guide*.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure BGP to protect an EBGP peer or peer group when the memory usage reaches level 2 threshold.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **low-memory-exempt**

   By default, BGP periodically tears down an EBGP session to release memory resources when level 2 threshold is reached.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure BGP to protect an EBGP peer or peer group when the memory usage reaches level 2 threshold.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **low-memory-exempt**

   By default, BGP tears down an EBGP session to release memory resources periodically when level 2 threshold is reached.

Flushing the suboptimal BGP route to the RIB

About this task

This feature flushes the suboptimal BGP route to the RIB when the following conditions are met:

- The optimal route is generated by the **network** command or is redistributed by the **import-route** command.
- The suboptimal route is received from a BGP peer.

After the suboptimal route is flushed to the RIB on a network, BGP immediately switches traffic to the suboptimal route when the optimal route fails.

For example, the device has a static route to the subnet 1.1.1.0/24 that has a higher priority than a BGP route. BGP redistributes the static route and receives a route to 1.1.1.0/24 from a peer. After the **flush suboptimal-route** command is executed, BGP flushes the received BGP route to the RIB as the suboptimal route. When the static route fails, BGP immediately switches traffic to the suboptimal route if inter-protocol FRR is enabled. For more information about inter-protocol FRR, see "Configuring basic IP routing."

Procedure

1. Enter system view.
   system-view
2. Enter BGP view.
   bgp *as-number* [**instance** *instance-name*]
3. Flush the suboptimal BGP route to the RIB.
   flush suboptimal-route

   By default, BGP is disabled from flushing the suboptimal BGP route to the RIB, and only the optimal route is flushed to the RIB.

Specifying a label allocation mode

About this task

BGP supports the following label allocation modes:

- **Per-prefix**—Allocates a label to each route prefix.
- **Per-next-hop**—Allocates a label to each next hop. This mode is applicable when the number of labels required by the per-prefix mode exceeds the maximum number of labels supported by the device.
- **Per-VPN-instance**—Allocates a label to each VPN instance. This mode is applicable when the number of labels required by the per-next-hop mode exceeds the maximum number of labels supported by the device.

Restrictions and guidelines

When you specify the per-prefix or per-next-hop label allocation mode, you can execute the **vpn popgo** command to specify the POPGO forwarding mode on an egress PE. The egress PE will pop the label for each packet and forward the packet out of the interface corresponding to the label.

When you specify the per-VPN instance label allocation mode, do not execute the **vpn popgo** command because it is mutually exclusive with the **label-allocation-mode per-vrf** command. The egress PE will pop the label for each packet and forward the packet through the FIB table.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Specify a label allocation mode.

label-allocation-mode { **per-prefix** | **per-vrf** }

By default, BGP allocates labels on a per-next-hop basis.

△ **CAUTION:**

A change to the label allocation mode enables BGP to re-advertise all routes, which will cause temporary service interruption. Use this feature with caution.

Recursing unlabeled public BGP routes to LSPs

About this task

To perform IP forwarding on customer packets, carrier network devices must learn a large number of routes. To reduce workload and save resources on carrier network devices, configure this feature to recurse unlabeled public BGP routes to LSPs on user access devices. This feature allows the carrier network devices to forward customer packets based on labels, without the need to learn customer network routes.

After you configure this feature, unlabeled public BGP routes will be preferentially recursed to LSPs. If a route fails to be recursed to an LSP, the route will be recursed to the IP next hop.

Restrictions and guidelines

To recurse unlabeled public IPv6 BGP routes to IPv4 tunnels, you must configure the egress node to assign a non-null label to the penultimate hop.

Procedure (IPv4 unicast)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enter BGP IPv4 unicast address family view.

   address-family ipv4 [**unicast**]

4. Recurse unlabeled public BGP routes to LSPs.

   unicast-route recursive-lookup tunnel [**prefix-list** *ipv4-prefix-list-name*] [**tunnel-policy** *tunnel-policy-name*]

   By default, unlabeled public BGP routes are recursed to IP next hops instead of LSPs.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enter BGP IPv6 unicast address family view.

   address-family ipv6 [**unicast**]

4. Recurse unlabeled public BGP routes to LSPs.

   unicast-route recursive-lookup tunnel [**prefix-list** *ipv6-prefix-list-name*] [**tunnel-policy** *tunnel-policy-name*]

   By default, unlabeled public BGP routes are recursed to IP next hops instead of LSPs.

Display and maintenance commands for BGP network tuning and optimization

Resetting BGP sessions

△ **CAUTION:**

A reset operation tears down BGP sessions for a short period of time.

Execute **reset** commands in user view.

Task	Command
Reset BGP sessions for IPv4 unicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv4-address* [*mask-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Reset BGP sessions for IPv4 multicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv4-address* [*mask-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv4 multicast**
Reset BGP sessions for IPv6 unicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] **reset bgp** *ipv4-address* [*mask-length*] **ipv6** [**unicast**]
Reset BGP sessions for IPv6 multicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv6 multicast**
Reset all BGP sessions.	**reset bgp** [**instance** *instance-name*] **all**

Configuring BGP security features

BGP security feature configuration tasks at a glance

To configure BGP security features, perform the following tasks:

- Enabling MD5 authentication for BGP peers
- Enabling keychain authentication for BGP peers
- Configuring GTSM for BGP
- Configuring IPsec for IPv6 BGP

Enabling MD5 authentication for BGP peers

About this task

MD5 authentication provides the following benefits:

- Peer authentication ensures that only BGP peers that have the same password can establish TCP connections.
- Integrity check ensures that BGP packets exchanged between peers are intact.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.

   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable MD5 authentication for a BGP peer group or peer.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **password** { **cipher** | **simple** } *password*

   By default, MD5 authentication is disabled.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.

   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable MD5 authentication for a BGP peer group or peer.

peer { *group-name* | *ipv6-address* [*prefix-length*] } **password** { **cipher** | **simple** } *password*

By default, MD5 authentication is disabled.

Enabling keychain authentication for BGP peers

About this task

Keychain authentication enhances the security of BGP in the following ways:

- BGP peers can establish TCP connections only when they are both enabled with keychain authentication.
- The keys used by the BGP peers at the same time must have the same ID.
- The keys with the same ID must use the same authentication algorithm and key string.

For more information about keychains, see *Security Configuration Guide*.

Restrictions and guidelines

Follow these restrictions and guidelines when you configure the algorithm and key ID in keychain authentication:

- BGP supports the HMAC-MD5, HMAC-SHA-256, HMAC-SM3, SM3, and MD5 algorithms. To configure an algorithm, execute the **authentication-algorithm** command.
- BGP supports key IDs in the range of 0 to 63. To configure a key ID, execute the **key** command.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable keychain authentication for a BGP peer or peer group.

   peer { *group-name* | *ip-address* [*mask-length*] } **keychain** *keychain-name*

   By default, keychain authentication is disabled.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable keychain authentication for a BGP peer or peer group.

peer { *group-name* | *ipv6-address* [*prefix-length*] } **keychain** *keychain-name*

By default, keychain authentication is disabled.

Configuring GTSM for BGP

About this task

The Generalized TTL Security Mechanism (GTSM) protects a BGP session by comparing the TTL value in the IP header of incoming BGP packets against a valid TTL range. If the TTL value is within the valid TTL range, the packet is accepted. If not, the packet is discarded.

The valid TTL range is from 255 – the configured hop count + 1 to 255.

When GTSM is configured, the BGP packets sent by the device have a TTL of 255.

GTSM provides best protection for directly connected EBGP sessions, but not for multihop EBGP or IBGP sessions because the TTL of packets might be modified by intermediate devices.

Restrictions and guidelines

When GTSM is configured, the local device can establish an EBGP session to the peer after both devices pass GTSM check, regardless of whether the maximum number of hops is reached.

To use GTSM, you must configure GTSM on both the local and peer devices. You can specify different *hop-count* values for them.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure GTSM for the specified BGP peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **ttl-security hops** *hop-count*

   By default, GTSM is disabled.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure GTSM for the specified BGP peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **ttl-security hops** *hop-count*

By default, GTSM is disabled.

Configuring IPsec for IPv6 BGP

About this task

Perform this task to configure IPsec for IPv6 BGP. IPsec can provide privacy, integrity, and authentication for IPv6 BGP packets exchanged between BGP peers.

When two IPv6 BGP peers are configured with IPsec (for example, Device A and Device B), Device A encapsulates an IPv6 BGP packet with IPsec before sending it to Device B. If Device B successfully receives and de-encapsulates the packet, it establishes an IPv6 BGP peer relationship with Device A and learns IPv6 BGP routes from Device A. If Device B receives but fails to de-encapsulate the packet, or receives a packet not protected by IPsec, it discards the packet.

Procedure

1. Enter system view.

   system-view

2. Configure an IPsec transform set and a manual IPsec profile.

   See *Security Configuration Guide*.

3. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

4. Apply the IPsec profile to an IPv6 BGP peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **ipsec-profile** *profile-name*

   By default, no IPsec profile is configured for any IPv6 BGP peer or peer group.

   This command supports only IPsec profiles in manual mode.

Improving BGP network reliability

BGP network reliability improvement tasks at a glance

To improve the BGP network reliability, perform the following tasks:

- Configuring BGP GR
- Configuring BGP NSR
- Configuring BFD for BGP
- Configuring BGP FRR

Configuring BGP GR

About this task

Graceful Restart (GR) ensures forwarding continuous when a routing protocol restarts or an active/standby switchover occurs. Two routers are required to complete a GR process. The following are router roles in a GR process:

- **GR restarter**—Performs GR upon a BGP restart or active/standby switchover.
- **GR helper**—Helps the GR restarter to complete the GR process.

A device can act as a GR restarter and GR helper at the same time.

BGP GR works as follows:

1. The BGP GR restarter and helper exchange OPEN messages for GR capability negotiation. If both parties have the GR capability, they establish a GR-capable session. The GR restarter sends the GR timer set by the **`graceful-restart timer restart`** command to the GR helper in an OPEN message.
2. When an active/standby switchover occurs or BGP restarts, the GR restarter does not remove existing BGP routes from Routing Information Base (RIB) and Forwarding Information Base (FIB). It still uses these routes for packet forwarding, and it starts the RIB purge timer (set by the **`graceful-restart timer purge-time`** command). The GR helper marks all routes learned from the GR restarter as stale instead of deleting them. It continues to use these routes for packet forwarding. During the GR process, packet forwarding is not interrupted.
3. After the active/standby switchover or BGP restart completes, the GR restarter re-establishes a BGP session to the GR helper. If the BGP session fails to be established within the GR timer advertised by the GR restarter, the GR helper removes the stale routes.
4. If the BGP session is established, routing information is exchanged for the GR restarter to retrieve route entries and for the GR helper to recover stale routes.
5. Both the GR restarter and the GR helper start the End-Of-RIB marker waiting timer.

   The End-Of-RIB marker waiting time is set by the **`graceful-restart timer wait-for-rib`** command. If routing information exchange is not completed within the time, the GR restarter does not receive new routes. The GR restarter updates the RIB with the BGP routes already learned, and removes the aged routes from the RIB. The GR helper removes the stale routes.
6. The GR restarter quits the GR process if routing information exchange is not completed within the RIB purge timer. It updates the RIB with the BGP routes already learned, and removes the aged routes.

Restrictions and guidelines

Follow these guidelines when you configure BGP GR:

- The End-Of-RIB indicates the end of route updates.
- The maximum time to wait for the End-of-RIB marker configured on the local end is not advertised to the peer. It controls the time for the local end to receive updates from the peer. Set a large value for the maximum time to wait for the End-of-RIB marker when a large number of routes need to be exchanged.
- As a best practice, perform the BGP GR configuration on both the GR restarter and GR helper.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enable GR capability for BGP.

   graceful-restart

   By default, GR capability is disabled for BGP.

4. Configure the GR timer.

   graceful-restart timer restart *timer*

   The default setting is 150 seconds.

   The time that a peer waits to re-establish a session must be less than the hold time.

5. Configure the maximum time to wait for the End-of-RIB marker.

   graceful-restart timer wait-for-rib *timer*

   The default setting is 180 seconds.

6. Configure the RIB purge timer.

   graceful-restart timer purge-time *timer*

   The default setting is 480 seconds.

Configuring BGP NSR

About this task

To use BGP nonstop routing (NSR), the system must have a minimum of two IRF member devices.

NSR ensures nonstop services when BGP has redundant processes on multiple IRF member devices. In contrast to GR, NSR does not require a neighbor device to recover routing information.

BGP NSR backs up BGP state and data information from the active BGP process to the standby BGP process. The standby BGP process takes over when any of the following events occurs:

- The active BGP process restarts.
- The MPU that runs the active BGP process fails.
- An ISSU starts on the MPU that runs the active BGP process.

Restrictions and guidelines

When both GR and NSR are configured for BGP, NSR has a higher priority than GR. The device will not act as the GR restarter. If the device acts as a GR helper, it cannot help the restarter to complete GR.

Procedure

1. Enter system view.

system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enable BGP NSR.

   non-stop-routing

   By default, BGP NSR is disabled.

Configuring BFD for BGP

About this task

BGP maintains neighbor relationships based on the keepalive timer and hold timer in seconds. It requires that the hold time must be at least three times the keepalive interval. This mechanism slows down link failure detection. Once a failure occurs on a high-speed link, a large quantity of packets will be dropped before routing convergence completes. BFD for BGP can solve this problem by fast detecting link failures to reduce convergence time.

Before you enable BFD for a BGP peer or peer group, you must establish a BGP session between the local router and the peer or peer group.

For more information about BFD, see BFD configuration in *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

If you have enabled GR, use BFD with caution because BFD might detect a failure before the system performs GR, which will result in GR failure. If you have enabled both BFD and GR for BGP, do not disable BFD during a GR process to avoid GR failure.

For BGP sessions established with link-local addresses, you can use only single-hop BFD to detect the link between BGP peers.

To establish a BFD session to a BGP peer, you must configure the same BFD detection mode (multi-hop or single-hop) on the local router and the BGP peer.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable BFD to detect the link to the specified BGP peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **bfd** [**multi-hop** | **single-hop**]

   By default, BFD is disabled.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

bgp *as-number* [**instance** *instance-name*]

- Execute the following commands in sequence to enter BGP-VPN instance view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

3. Enable BFD to detect the link to the specified IPv6 BGP peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **bfd** [**multi-hop** | **single-hop**]

   By default, BFD is disabled.

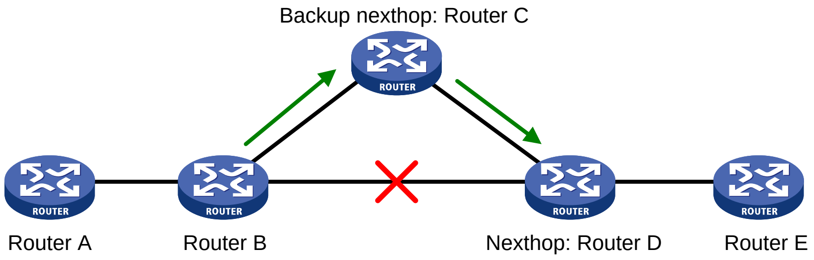
Configuring BGP FRR

About BGP FRR

When a link fails, the packets on the link are discarded, and a routing loop might occur until BGP completes routing convergence based on the new network topology.

You can enable BGP fast reroute (FRR) to resolve this issue.

Figure 16 Network diagram for BGP FRR



After you configure FRR on Router B as shown in Figure 16, BGP generates a backup next hop Router C for the primary route. BGP uses ARP or BFD echo packet mode in an IPv4 network or ND in an IPv6 network to detect the connectivity to Router D. When the link to Router D fails, BGP directs packets to the backup next hop. At the same time, BGP calculates a new optimal route, and forwards packets over the optimal route.

You can use the following methods to configure BGP FRR:

- **Method 1**—Execute the **pic** command in BGP address family view. BGP calculates a backup next hop for each BGP route in the address family if there are two or more unequal-cost routes that reach the destination.
- **Method 2**—Execute the **fast-reroute route-policy** command to use a routing policy in which a backup next hop is specified by using the command **apply** [**ipv6**] **fast-reroute backup-nexthop**. The backup next hop calculated by BGP must be the same as the specified backup next hop. Otherwise, BGP does not generate a backup next hop for the primary route. You can also configure **if-match** clauses in the routing policy to identify the routes protected by FRR.

If both methods are configured, Method 2 takes precedence over Method 1.

BGP supports FRR for IPv4 and IPv6 unicast routes, but not for IPv4 and IPv6 multicast routes.

Configuring BGP FRR by using a routing policy (IPv4 unicast address family)

1. Enter system view.

   `system-view`

2. Configure the source address of echo packets.

   `bfd echo-source-ip` *`ipv4-address`*

   By default, no source address is specified for echo packets.

   This step is required when BFD echo packet mode is used to detect the connectivity to the next hop of the primary route.

   Specify a source IP address that does not belong to any local network.

   For more information about this command, see BFD commands in *Network Management and Monitoring Command Reference*.

3. Create a routing policy and enter routing policy view.

   `route-policy` *`route-policy-name`* **`permit node`** *`node-number`*

   For more information about this command, see routing policy commands in *Layer 3—IP Routing Command Reference*.

4. Set the backup next hop for FRR.

   `apply fast-reroute backup-nexthop` *`ipv4-address`*

   By default, no backup next hop is set.

   For more information about this command, see routing policy commands in *Layer 3—IP Routing Command Reference*.

5. Return to system view.

   `quit`

6. Enter BGP instance view.

   `bgp` *`as-number`* [**`instance`** *`instance-name`*]

7. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.

   - Enter BGP IPv4 unicast address family view.

     `address-family ipv4` [**`unicast`**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     `ip vpn-instance` *`vpn-instance-name`*

     `address-family ipv4` [**`unicast`**]

8. Apply a routing policy to FRR for the address family.

   `fast-reroute route-policy` *`route-policy-name`*

   By default, no routing policy is applied.

   The **`apply fast-reroute backup-nexthop`** command and **`apply ipv6 fast-reroute backup-nexthop`** command can take effect in the applied routing policy. Other **`apply`** commands do not take effect.

Configuring BGP FRR by using a routing policy (IPv6 unicast address family)

1. Enter system view.

   `system-view`

2. Create a routing policy and enter routing policy view.

   route-policy *route-policy-name* **permit node** *node-number*

   For more information about this command, see routing policy commands in *Layer 3—IP Routing Command Reference*.

3. Set the backup next hop for FRR.

   apply ipv6 fast-reroute backup-nexthop *ipv6-address*

   By default, no backup next hop is set.

   For more information about this command, see routing policy commands in *Layer 3—IP Routing Command Reference*.

4. Return to system view.

   quit

5. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

6. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.

   address-family ipv6 [**unicast**]

7. Apply a routing policy to FRR for the address family.

   fast-reroute route-policy *route-policy-name*

   By default, no routing policy is applied.

   The **apply fast-reroute backup-nexthop** and **apply ipv6 fast-reroute backup-nexthop** commands can take effect in the applied routing policy. Other **apply** commands do not take effect.

Configuring BGP FRR through PIC (IPv4 unicast address family)

Restrictions and guidelines

This feature might result in routing loops. Use it with caution.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.

   address-family ipv4 [**unicast**]

4. Enable BGP FRR through PIC.

   pic

By default, BGP FRR is disabled.

Configuring BGP FRR through PIC (IPv6 unicast address family)

Restrictions and guidelines

This feature might result in routing loops. Use it with caution.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.

   address-family ipv6 [**unicast**]

4. Enable BGP FRR through PIC.

   pic

   By default, BGP FRR is disabled.

Enabling BGP FRR to detect next hop connectivity of the primary route through BFD

About this task

By default, BGP FRR uses ARP to detect the next hop connectivity of the primary route, featuring low detection speed. If the primary link fails, service traffic might not immediately switched over to the backup path, resulting in packet loss.

With this feature configured, the device automatically creates a BFD session of the IP FRR type for detecting next hop of the primary route. Upon detecting a failure, traffic immediately switches over to the backup next hop to ensure fast convergence.

Restrictions and guidelines

This feature takes effect and automatically creates a BFD session only when a backup next hop is available for the primary route.

In the current software version, BGP does not support calculating next hops for ECMP routes. The command cannot detect next hop connectivity for an ECMP route used as the primary route.

When using echo mode BFD session to detect next hop connectivity of the primary route, you only need to configure this feature on the local router.

If another protocol (for example, OSPF and IS-IS) also uses BFD to detect next hop connectivity for the primary route, the protocol automatically creates a BFD session. If the detected link is the same as the link attached to the next hop of the BGP primary route, BGP reuses the BFD session created by the protocol, instead of creating a BFD session.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Enable BGP FRR to detect next hop connectivity of the primary route through BFD.
   primary-path-detect bfd echo
   By default, BGP FRR uses ARP to detect next hop connectivity of the primary route.

Display and maintenance commands for BGP network reliability improvement

Execute **display** commands in any view.

Displaying BGP (IPv4 unicast address family)

Task	Command
Display BGP NSR status information.	**display bgp** [**instance** *instance-name*] **non-stop-routing status**

Displaying BGP (IPv6 unicast address family)

Task	Command
Display BGP NSR status information.	**display bgp** [**instance** *instance-name*] **non-stop-routing status**

Displaying BGP (IPv4 multicast address family)

Task	Command
Display BGP NSR status information.	**display bgp** [**instance** *instance-name*] **non-stop-routing status**

Displaying BGP (IPv6 multicast address family)

Task	Command
Display BGP NSR status information.	**display bgp** [**instance** *instance-name*] **non-stop-routing status**

Configuring extended BGP features

Extended BGP feature configuration tasks at a glance

To configure extended BGP features, perform the following tasks:

- Configuring BGP LS
  - Configuring basic BGP LS
  - (Optional.) Configuring BGP LS route reflection
  - (Optional.) Specifying an AS number and a router ID for BGP LS messages
  - (Optional.) Performing manual soft-reset for BGP sessions of LS address family

Configuring BGP LS

About BGP LS

The BGP Link State (LS) feature implements inter-domain and inter-AS advertisement of link state database (LSDB) and TE database (TEDB) information.

The device sends the collected link state information to the controller, which implements end-to-end traffic management and scheduling and meets the requirements of intended applications.

Configuring basic BGP LS

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Specify an AS number for an LS peer or peer group.

   peer { *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **as-number** *as-number*

   By default, no AS number is specified.

4. Create the BGP LS address family and enter its view.

   address-family link-state

5. Enable the device to exchange LS information with the peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **enable**

   By default, the device cannot exchange LS information with the peer or peer group.

Configuring BGP LS route reflection

About this task

Perform this task to configure a BGP route reflector and its clients. The route reflector and its clients automatically form a cluster identified by the router ID of the route reflector. The route reflector forwards route updates among its clients.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enter BGP LS address family view.

   address-family link-state

4. Configure BGP LS route reflection.

   - Configure the device as a route reflector and specify a peer or peer group as its client.

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **reflect-client**

     By default, no route reflector or client is configured.

   - (Optional.) Enable route reflection between clients.

     reflect between-clients

     By default, route reflection between clients is enabled.

     This command can reduce the number of IBGP connections in an AS.

   - (Optional.) Configure the cluster ID of the route reflector.

     reflector cluster-id { *cluster-id* | *ipv4-address* }

     By default, a route reflector uses its own router ID as the cluster ID.

Specifying an AS number and a router ID for BGP LS messages

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enter BGP LS address family view.

   address-family link-state

4. Specify an AS number and a router ID for BGP LS messages.

   domain-distinguisher *as-number:router-id*

   By default, the AS number and router ID of the current BGP process are used.

   Configure this command to ensure that LS messages sent by devices in the same AS have the same AS number and router ID.

Performing manual soft-reset for BGP sessions of LS address family

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Enable BGP route refresh.
   - Enable BGP route refresh for a peer or peer group.
     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **capability-advertise route-refresh**
   - Enable the BGP route refresh, multi-protocol extension, and 4-byte AS number features for a peer or peer group.
     undo peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **capability-advertise conventional**

   By default, the BGP route refresh, multi-protocol extension, and 4-byte AS number features are enabled.
4. Perform manual soft-reset for BGP sessions of LS address family:
   a. Return to system view.
      quit
   b. Return to user view.
      quit
   c. Perform manual soft-reset for BGP sessions of LS address family.
      refresh bgp [**instance** *instance-name*] { *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } { **export** | **import** } **link-state**

Display and maintenance commands for extended BGP features

Displaying BGP

Execute **display** commands in any view.

Displaying BGP (LS address family)

Task	Command
Display BGP LS peer group information.	**display bgp** [**instance** *instance-name*] **group link-state** [**group-name** *group-name*]
Display BGP LS information.	**display bgp** [**instance** *instance-name*] **link-state** [*ls-prefix* | **peer** { *ipv4-address* | *ipv6-address* } { **advertised** | **received** } [**statistics**] | **statistics**]
Display BGP LS peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer link-state**

Task	Command
	[*ipv4-address* *mask-length* | *ipv6-address* *prefix-length* | { *ipv4-address* | *ipv6-address* | **group-name** *group-name* } **log-info** | [*ipv4-address* | *ipv6-address*] **verbose**]
Display BGP LS address family update group information.	**display bgp** [**instance** *instance-name*] **update-group link-state** [*ipv4-address* | *ipv6-address*]

Resetting BGP sessions

CAUTION:

A reset operation tears down BGP sessions for a short period of time.

Execute **reset** commands in user view.

Task	Command
Reset BGP sessions for LS address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } **link-state**

Contents

Configuring PBR

About PBR

Policy-based routing (PBR) uses user-defined policies to route packets. A policy can specify parameters for packets that match specific criteria such as ACLs or that have specific lengths. The parameters include the next hop, output interface, default next hop, and default output interface.

Packet forwarding process

When the device receives a packet, the device searches the PBR policy for a matching node to forward that packet.

- If a matching node is found and its match mode is **permit**, the device performs the following operations:
  - **a.** Uses the next hops or output interfaces specified on the node to forward the packet.
  - **b.** Searches the routing table for a route (except the default route) to forward the packet if one of the following conditions exists:
    - – No next hops or output interfaces are specified on the node.
    - – Forwarding failed based on the next hops or output interfaces.
  - **c.** Uses the default next hop or default output interface specified on the node to forward the packet if one of the following conditions exists:
    - – No matching route was found in the routing table.
    - – The routing table-based forwarding failed.
  - **d.** Uses the default route to forward the packet if one of the following conditions exists:
    - – No default next hops or default output interfaces are specified on the node.
    - – The forwarding failed based on the default next hops or default output interfaces.
- The device perfoms routing table lookup to forward the packet in either of the following conditions:
  - o No matching node is found.
  - o A matching node is found, but its match mode is **deny**.

PBR types

PBR includes the following types:

- **Local PBR**—Guides the forwarding of locally generated packets, such as ICMP packets generated by using the **`ping`** command.
- **Interface PBR**—Guides the forwarding of packets received on an interface.

Policy

A policy includes match criteria and actions to be taken on the matching packets. A policy can have one or multiple nodes as follows:

- Each node is identified by a node number. A smaller node number has a higher priority.
- A node contains **`if-match`** and **`apply`** clauses. An **`if-match`** clause specifies a match criterion, and an **`apply`** clause specifies an action.

- A node has a match mode of **permit** or **deny**.

A policy compares packets with nodes in priority order. If a packet matches the criteria on a node, it is processed by the action on the node. If the packet does not match any criteria on the node, it goes to the next node for a match. If the packet does not match the criteria on any node, the device performs a routing table lookup.

Relationship between if-match clauses

On a node, you can specify multiple types of **if-match** clauses but only one **if-match** clause for each type.

To match a node, a packet must match all types of the **if-match** clauses for the node but only one **if-match** clause for each type.

Relationship between apply clauses

You can specify multiple **apply** clauses for a node, but some of them might not be executed. For more information about relationship between **apply** clauses, see "Configuring actions for a node."

Relationship between the match mode and clauses on the node

Does a packet match all the if-match clauses on the node?	Match mode	
	Permit	**Deny**
Yes.	• If the node contains **apply** clauses, PBR executes the **apply** clauses on the node. ○ If PBR-based forwarding succeeds, PBR does not compare the packet with the next node. ○ If PBR-based forwarding fails and the **apply continue** clause is not configured, PBR does not compare the packet with the next node. ○ If PBR-based forwarding fails and the **apply continue** clause is configured, PBR compares the packet with the next node. • If the node does not contain **apply** clauses, the device performs a routing table lookup for the packet.	The device performs a routing table lookup for the packet.
No.	PBR compares the packet with the next node.	PBR compares the packet with the next node.

NOTE:

A node that has no **if-match** clauses matches any packet.

PBR and Track

PBR can work with the Track feature to dynamically adapt the availability status of an **apply** clause to the link status of a tracked object. The tracked object can be a next hop, output interface, default next hop, or default output interface.

- When the track entry associated with an object changes to **Negative**, the **apply** clause is invalid.
- When the track entry changes to **Positive** or **NotReady**, the **apply** clause is valid.

For more information about Track-PBR collaboration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines: PBR configuration

If the device performs forwarding in software, PBR does not process IP packets destined for the local device.

If the device performs forwarding in hardware and a packet destined for it matches a PBR policy, PBR will execute the apply clauses in the policy, including the clause for forwarding. When you configure a PBR policy, be careful to avoid this situation.

PBR tasks at a glance

To configure PBR, perform the following tasks:

1. Configuring a policy
   a. Creating a node
   b. Setting match criteria for a node
   c. Configuring actions for a node
2. Specifying a policy for PBR

   Choose the following tasks as needed:
   - Specifying a policy for local PBR
   - Specifying a policy for interface PBR

Configuring a policy

Creating a node

1. Enter system view.

   system-view
2. Create a node for a policy, and enter its view.

   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

Setting match criteria for a node

1. Enter system view.

   system-view
2. Enter policy node view.

   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*
3. Set match criteria.
   - Set an ACL match criterion.

     if-match acl { *acl-number* | **name** *acl-name* }

     By default, no ACL match criterion is set.

The ACL match criterion cannot match Layer 2 information.

- Set a packet length match criterion.

  if-match packet-length *min-len max-len*

  By default, no packet length match criterion is set.

- Set a source IP address match criterion for local PBR.

  if-match source-ip { **interface** *interface-type interface-number* | [**vpn-instance** *vpn-instance-name*] *ip-address* }

  By default, no source IP address match criterion is set for local PBR.

  Support for this command depends on the device model. For more information, see the command reference.

- Set application group match criteria.

  if-match app-group *app-group-name*&<1-6>

  By default, no application group match criteria are set.

  Application group match criteria apply only to interface PBR.

  For more information about application groups, see APR configuration in *Security Configuration Guide*.

  Support for this command depends on the device model. For more information, see the command reference.

- Set service object group match criteria.

  if-match object-group service *object-group-name*&<1-6>

  By default, no service object group match criteria are set.

  For more information about service object groups, see object group configuration in *Security Configuration Guide*.

  Support for this command depends on the device model. For more information, see the command reference.

Configuring actions for a node

About this task

The **apply** clauses allow you to specify the actions to be taken on matching packets on a node.

The following **apply** clauses determine the packet forwarding paths in a descending order:

- **apply access-vpn**
- **apply next-hop**
- **apply output-interface**
- **apply default-next-hop**
- **apply default-output-interface**

PBR supports the **apply** clauses in Table 1.

Table 1 Apply clauses supported in PBR

Clause	Meaning	Remarks
apply precedence	Sets an IP precedence.	This clause is always executed.
apply ip-df *df-value*	Sets the Don't Fragment (DF) bit in the IP header.	This clause is always executed.

apply loadshare { **next-hop** | **output-interface** | **default-next-hop** | **default-output-interface** }	Enables load sharing among multiple next hops, output interfaces, default next hops, or default output interfaces.	Multiple next hop, output interface, default next hop, or default output interface options operate in either primary/backup or load sharing mode. • **Primary/backup mode**—One option is selected from all options in configuration order for packet forwarding, with all remaining options as backups. For example, if multiple output interfaces are configured, the first configured output interface is selected. When the selected output interface fails, the next available output interface takes over. • **Load sharing mode**—Matching traffic is distributed across the available options, as follows: ○ **Multiple output interface, default next hop, or default output interface options**—Load share traffic in round robin manner, starting from the first configured option. They perform per-packet load sharing for traffic that does not match any fast forwarding entry, and perform per-flow load sharing for traffic that matches a fast forwarding entry. ○ **Multiple next hops**—Load share traffic in proportion to their weight. By default, all next hops have the same weight and traffic is evenly distributed among them. By default, the primary/backup mode applies. For the load sharing mode to take effect, make sure multiple next hops, output interfaces, default next hops, or default output interfaces are set in the policy.
apply access-vpn	Specifies the forwarding tables that can be used for the matching packets.	Use this clause only in special scenarios that require sending packets received from one network to another network, for example, from a VPN to the public network, or from one VPN to another VPN. If a packet matches the forwarding table for a specified VPN instance, it is forwarded in the VPN.
apply remark-vpn	Enables VPN remark action.	VPN remark action marks the matching packets as belonging to the VPN instance to which they are forwarded based on the **apply access-vpn vpn-instance** command. All subsequent service modules of PBR handle the packets as belonging to the re-marked VPN instance. If the VPN remark action is not enabled, the forwarded matching packets are marked as belonging to the VPN instance or the public network from which they were received. VPN remark action applies only to packets

		that have been successfully forwarded based on the **apply access-vpn vpn-instance** command.
apply next-hop and **apply output-interface**	Sets next hops and sets output interfaces.	If both clauses are configured, only the **apply next-hop** clause is executed.
apply default-next-hop and **apply default-output-interface**	Sets default next hops and sets default output interfaces.	If both clauses are configured, only the **apply default-next-hop** clause is executed. The clauses take effect only in the following cases: • No next hops or output interfaces are set or the next hops and output interfaces are invalid. • The packet does not match any route in the routing table.
apply continue	Compares packets with the next node upon failure on the current node.	The **apply continue** clause applies when either of the the following conditions exist: • None of the following clauses is configured for packet forwarding: ○ **apply access-vpn vpn-instance** ○ **apply next-hop** ○ **apply output-interface** ○ **apply default-next-hop** ○ **apply default-output-interface** • A clause listed above is configured, but it has become invalid. Then, a routing table lookup also fails for the matching packet. **NOTE:** A clause might become invalid because the specified next hop is unreachable, packets cannot be forwarded in the specified VPN instance, or the specified output interface is down.

Restrictions and guidelines

For outbound PBR, you can specify only one next hop and the next hop must be directly connected.

If you specify a next hop or default next hop, PBR periodically performs a lookup in the FIB table to determine its availability. Temporary service interruption might occur if PBR does not update the route immediately after its availability status changes.

Configuring actions to modify packet fields

1. Enter system view.

   system-view

2. Enter policy node view.

   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Configure actions.

   - Set an IP precedence.

apply precedence { *type* | *value* }

By default, no IP precedence is specified.

- Set the DF bit in the IP header.

  apply ip-df *df-value*

  By default, the DF bit in the IP header is not set.

Configuring actions to direct packet forwarding

1. Enter system view.

   system-view

2. Enter policy node view.

   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Configure actions.
   - Specify the forwarding tables that can be used for the matching packets.

     apply access-vpn { **public** | **vpn-instance** *vpn-instance-name*&<1-4> }

     By default, the device forwards matching packets by using the forwarding table for the network from which the packets are received.

     You can repeat this command to specify the forwarding tables for the public network and VPN instances. The device forwards the matching packets by using the first available forwarding table selected in the order in which they are specified.

   - Enable VPN remark action to mark the matching packets as belonging to the VPN instance to which they are forwarded based on the **apply access-vpn vpn-instance** command.

     apply remark-vpn

     By default, VPN remark action is not configured.

   - Set next hops.

     apply next-hop [**vpn-instance** *vpn-instance-name* | **inbound-vpn**] { *ip-address* [**direct**] [**track** *track-entry-number*] [**weight** *weight-value*] }&<1-4>

     By default, no next hops are specified.

     On a node, you can specify a maximum of four next hops for backup or load sharing in one command line or by executing this command multiple times.

     If multiple next hops on the same subnet are specified for backup, the device first uses the subnet route for the next hops to forward packets when the primary next hop fails. If the subnet route is not available, the device selects a backup next hop.

     The value for n varies by device model. For more information, see the command reference.

   - Enable load sharing among multiple next hops.

     apply loadshare next-hop

     By default, the next hops operate in primary/backup mode.

   - Set output interfaces.

     apply output-interface { *interface-type interface-number* [**track** *track-entry-number*] }&<1-4>

     By default, no output interfaces are specified.

     On a node, you can specify a maximum of four output interfaces for backup or load sharing in one command line or by executing this command multiple times.

   - Enable load sharing among multiple output interfaces.

     apply loadshare output-interface

     By default, the output interfaces operate in primary/backup mode.

- Set default next hops.

  apply default-next-hop [**vpn-instance** *vpn-instance-name* | **inbound-vpn**] { *ip-address* [**direct**] [**track** *track-entry-number*] }&<1-4>

  By default, no default next hops are specified.

  On a node, you can specify a maximum of four default next hops for backup or load sharing in one command line or by executing this command multiple times.

  The value for n varies by device model. For more information, see the command reference.

- Enable load sharing among multiple default next hops.

  apply loadshare default-next-hop

  By default, the default next hops operate in primary/backup mode.

- Set default output interfaces.

  apply default-output-interface { *interface-type interface-number* [**track** *track-entry-number*] }&<1-4>

  By default, no default output interfaces are specified.

  On a node, you can specify a maximum of four default output interfaces for backup or load sharing in one command line or by executing this command multiple times.

- Enable load sharing among multiple default output interfaces.

  apply loadshare default-output-interface

  By default, the default output interfaces operate in primary/backup mode.

Comparing packets with the next node upon match failure on the current node

1. Enter system view.

   system-view

2. Enter policy node view.

   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Compare packets with the next node upon match failure on the current node.

   apply continue

   By default, PBR does not compare packets with the next node upon match failure on the current node.

   This command takes effect only when the match mode of the node is **permit**.

Specifying a policy for PBR

Specifying a policy for local PBR

About this task

Perform this task to specify a policy for local PBR to guide the forwarding of locally generated packets.

Restrictions and guidelines

You can specify only one policy for local PBR and must make sure the specified policy already exists. Before you apply a new policy, you must first remove the current policy.

Local PBR might affect local services such as ping and Telnet. When you use local PBR, make sure you fully understand its impact on local services of the device.

Procedure

1. Enter system view.

```
system-view
```

2. Specify a policy for local PBR.

   ```
   ip local policy-based-route policy-name
   ```

   By default, local PBR is not enabled.

Specifying a policy for interface PBR

About this task

Perform this task to apply a policy to an interface to guide the forwarding of packets received on the interface.

Restrictions and guidelines

You can apply only one policy to an interface and must make sure the specified policy already exists. Before you can apply a new interface PBR policy to an interface, you must first remove the current policy from the interface.

You can apply a policy to multiple interfaces.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Specify a policy for interface PBR.

   ```
   ip policy-based-route policy-name
   ```

   By default, no policy is applied to an interface.

Display and maintenance commands for PBR

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display PBR policy information.	**display ip policy-based-route** [**policy** *policy-name*]
Display interface PBR configuration and statistics.	**display ip policy-based-route interface** *interface-type interface-number* [**slot** *slot-number*]

Task	Command
Display local PBR configuration and statistics.	**display ip policy-based-route local** [**slot** *slot-number*]
Display PBR configuration.	**display ip policy-based-route setup**
Clear PBR statistics.	**reset ip policy-based-route statistics** [**policy** *policy-name*]

Contents

Configuring IPv6 PBR

About IPv6 PBR

IPv6 policy-based routing (PBR) uses user-defined policies to route IPv6 packets. A policy can specify parameters for packets that match specific criteria such as ACLs or that have specific lengths. The parameters include the next hop, output interface, default next hop, and default output interface.

IPv6 packet forwarding process

When the device receives an IPv6 packet, the device searches the IPv6 PBR policy for a matching node to forward that packet.

- If a matching node is found and its match mode is **permit**, the device performs the following operations:
  - **a.** Uses the next hops or output interfaces specified on the node to forward the packet.
  - **b.** Searches the routing table for a route (except the default route) to forward the packet if one of the following conditions exists:
    - No next hops or output interfaces are specified on the node.
    - Forwarding failed based on the next hops or output interfaces.
  - **c.** Uses the default next hop or default output interface specified on the node to forward the packet if one of the following conditions exists:
    - No matching route was found in the routing table.
    - The routing table-based forwarding failed.
  - **d.** Uses the default route to forward the packet if one of the following conditions exists:
    - No default next hops or default output interfaces are specified on the node.
    - The forwarding failed based on the default next hops or default output interfaces.
- The device perfoms routing table lookup to forward the packet in either of the following conditions:
  - No matching node is found.
  - A matching node is found, but its match mode is **deny**.

IPv6 PBR types

IPv6 PBR includes the following types:

- **Local PBR**—Guides the forwarding of locally generated packets, such as the ICMP packets generated by using the **`ping`** command.
- **Interface PBR**—Guides the forwarding of packets received on an interface only.

Policy

An IPv6 policy includes match criteria and actions to be taken on the matching packets. A policy can have one or multiple nodes as follows:

- Each node is identified by a node number. A smaller node number has a higher priority.
- A node contains **`if-match`** and **`apply`** clauses. An **`if-match`** clause specifies a match criterion, and an **`apply`** clause specifies an action.

- A node has a match mode of **permit** or **deny**.

An IPv6 policy compares packets with nodes in priority order. If a packet matches the criteria on a node, it is processed by the action on the node. If the packet does not match any criteria on the node, it goes to the next node for a match. If the packet does not match the criteria on any node, the device performs a routing table lookup for the packet.

Relationship between if-match clauses

On a node, you can specify multiple **`if-match`** clauses, but only one **`if-match`** clause for each type. A packet that matches all the **`if-match`** clauses of a node matches the node.

Relationship between apply clauses

You can specify multiple **`apply`** clauses for a node, but some of them might not be executed. For more information about the relationship between the **`apply`** clauses, see "Configuring actions for an IPv6 node."

Relationship between the match mode and clauses on the node

Does a packet match all the if-match clauses on the node?	Match mode	
	In permit mode	**In deny mode**
Yes	• If the node contains **`apply`** clauses, IPv6 PBR executes the **`apply`** clauses on the node. ○ If IPv6 PBR-based forwarding succeeds, IPv6 PBR does not compare the packet with the next node. ○ If IPv6 PBR-based forwarding fails and the **`apply continue`** clause is not configured, IPv6 PBR does not compare the packet with the next node. ○ If IPv6 PBR-based forwarding fails and the **`apply continue`** clause is configured, IPv6 PBR compares the packet with the next node. • If the node does not contain **`apply`** clauses, the device performs a routing table lookup for the packet.	The device performs a routing table lookup for the packet.
No	IPv6 PBR compares the packet with the next node.	IPv6 PBR compares the packet with the next node.

NOTE:

A node that has no **`if-match`** clauses matches any packet.

IPv6 PBR and Track

IPv6 PBR can work with the Track feature to dynamically adapt the availability status of an **apply** clause to the link status of a tracked object. The tracked object can be a next hop, output interface, default next hop, or default output interface.

- When the track entry associated with an object changes to **Negative**, the **apply** clause is invalid.
- When the track entry changes to **Positive** or **NotReady**, the **apply** clause is valid.

For more information about Track and IPv6 PBR collaboration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines: IPv6 PBR configuration

If the device performs forwarding in software, IPv6 PBR does not process IP packets destined for the local device.

If the device performs forwarding in hardware and a packet destined for it matches an IPv6 PBR policy, IPv6 PBR will execute the apply clauses in the policy, including the clause for forwarding. When you configure an IPv6 PBR policy, be careful to avoid this situation.

IPv6 PBR tasks at a glance

To configure IPv6 PBR, perform the following tasks:

1. Configuring an IPv6 policy
   a. Creating an IPv6 node
   b. Setting match criteria for an IPv6 node
   c. Configuring actions for an IPv6 node
2. Specifying a policy for IPv6 PBR

   Choose the following tasks as needed:
   - Specifying an IPv6 policy for IPv6 local PBR
   - Specifying an IPv6 policy for IPv6 interface PBR

Configuring an IPv6 policy

Creating an IPv6 node

1. Enter system view.

   system-view
2. Create an IPv6 policy or policy node and enter its view.

   ipv6 policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

Setting match criteria for an IPv6 node

1. Enter system view.

   system-view

2. Enter IPv6 policy node view.

   ```
   ipv6 policy-based-route policy-name [ deny | permit ] node node-number
   ```

3. Set match criteria.
   - Set an ACL match criterion.

     ```
     if-match acl { ipv6-acl-number | name ipv6-acl-name }
     ```

     By default, no ACL match criterion is set.

     The ACL match criterion cannot match Layer 2 information.
   - Set a packet length match criterion.

     ```
     if-match packet-length min-len max-len
     ```

     By default, no packet length match criterion is set.

Configuring actions for an IPv6 node

About this task

The **apply** clauses allow you to specify actions to take on matching packets on a node.

The following **apply** clauses determine the packet forwarding paths in a descending order:

- **apply access-vpn**
- **apply next-hop**
- **apply output-interface**
- **apply default-next-hop**
- **apply default-output-interface**

IPv6 PBR supports the **apply** clauses in Table 1.

Table 1 Apply clauses supported in IPv6 PBR

Clause	Meaning	Remarks
apply precedence	Sets an IP precedence.	This clause is always executed.
apply loadshare { **next-hop** | **output-interface** | **default-next-hop** | **default-output-interface** }	Enables load sharing among multiple next hops, output interfaces, default next hops, or default output interfaces.	Multiple next hop, output interface, default next hop, or default output interface options operate in either primary/backup or load sharing mode. • **Primary/backup mode**—One option is selected from all options in configuration order for packet forwarding, with all remaining options as backups. For example, if multiple output interfaces are configured, the first configured output interface is selected. When the selected output interface fails, the next available output interface takes over. • **Load sharing mode**—Matching traffic is distributed across the available options, as follows: ○ **Multiple output interface, default next hop, or default output interface options**—Load share traffic in round robin manner, starting from the first configured option. They perform per-packet

		load sharing for traffic that does not match any fast forwarding entry, and perform per-flow load sharing for traffic that matches a fast forwarding entry. ○ **Multiple next hops**—Load share traffic in proportion to their weight. By default, all next hops have the same weight and traffic is evenly distributed among them. By default, the primary/backup mode applies. For the load sharing mode to take effect, make sure multiple next hops, output interfaces, default next hops, or default output interfaces are set in the policy.
`apply access-vpn`	Specifies the forwarding tables that can be used for the matching packets.	Use this clause only in special scenarios that require sending packets received from one network to another network, for example, from a VPN to the public network, or from one VPN to another VPN. If a packet matches the forwarding table for a specified VPN instance, it is forwarded in the VPN.
`apply remark-vpn`	Enables VPN remark action.	VPN remark action marks the matching packets as belonging to the VPN instance to which they are forwarded based on the **`apply access-vpn vpn-instance`** command. All subsequent service modules of IPv6 PBR handle the packets as belonging to the re-marked VPN instance. If the VPN remark action is not enabled, the forwarded matching packets are marked as belonging to the VPN instance or the public network from which they were received. VPN remark action applies only to packets that have been successfully forwarded based on the **`apply access-vpn vpn-instance`** command.
`apply next-hop` and **`apply output-interface`**	Sets next hops and sets output interfaces.	If both clauses are configured, only the **`apply next-hop`** clause is executed.
`apply default-next-hop` and **`apply default-output-interface`**	Sets default next hops and sets default output interfaces.	If both clauses are configured, only the **`apply default-next-hop`** clause is executed. The clauses take effect only in the following cases: • No next hops or output interfaces are set or the next hops and output interfaces are invalid. • The IPv6 packet does not match any route in the routing table.
`apply continue`	Compares packets with the next node upon failure on the current node.	The **`apply continue`** clause applies when either of the the following conditions exist: • None of the following clauses is

		configured for packet forwarding: ○ **apply access-vpn vpn-instance** ○ **apply next-hop** ○ **apply output-interface** ○ **apply default-next-hop** ○ **apply default-output-interface** • A clause listed above is configured, but it has become invalid. Then, a routing table lookup also fails for the matching packet. **NOTE:** A clause might become invalid because the specified next hop is unreachable, packets cannot be forwarded in the specified VPN instance, or the specified output interface is down.

Restrictions and guidelines for action configuration

If you specify a next hop or default next hop, IPv6 PBR periodically performs a lookup in the FIB table to determine its availability. Temporary service interruption might occur if IPv6 PBR does not update the route immediately after its availability status changes.

Setting an IP precedence

1. Enter system view.

   system-view

2. Enter IPv6 policy node view.

   ipv6 policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Set an IP precedence.

   apply precedence { *type* | *value* }

   By default, no IP precedence is specified.

Configuring actions to direct packet forwarding

1. Enter system view.

   system-view

2. Enter IPv6 policy node view.

   ipv6 policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Configure actions for a node.
   - Specify the forwarding tables that can be used for the matching packets.

     apply access-vpn { **public** | **vpn-instance** *vpn-instance-name*&<1-4> }

     By default, the device forwards matching packets by using the forwarding table for the network from which the packets are received.

     You can repeat this command to specify the forwarding tables for the public network and VPN instances. The device forwards the matching packets by using the first available forwarding table selected in the order in which they are specified.
   - Enable VPN remark action to mark the matching packets as belonging to the VPN instance to which they are forwarded based on the **apply access-vpn vpn-instance** command.

     apply remark-vpn

By default, VPN remark action is not configured.

- Set next hops for permitted IPv6 packets.

  apply next-hop [**vpn-instance** *vpn-instance-name* | **inbound-vpn**] { *ipv6-address* [**direct**] [**track** *track-entry-number*] [**weight** *weight-value*] } &<1-4>

  By default, no next hops are specified.

  You can specify multiple next hops for backup or load sharing in one command line or by executing this command multiple times. You can specify a maximum of four next hops for a node.

  If multiple next hops on the same subnet are specified for backup, the device first uses the subnet route for the next hops to forward packets when the primary next hop fails. If the subnet route is not available, the device selects a backup next hop.

  The value for n varies by device model. For more information, see the command reference.

- Enable load sharing among multiple next hops.

  apply loadshare next-hop

  By default, the next hops operate in primary/backup mode.

- Set output interfaces.

  apply output-interface { *interface-type interface-number* [**track** *track-entry-number*] }&<1-4>

  By default, no output interfaces are specified.

  You can specify multiple output interfaces for backup or load sharing in one command line or by executing this command multiple times. You can specify a maximum of four output interfaces for a node.

- Enable load sharing among multiple output interfaces.

  apply loadshare output-interface

  By default, the output interfaces operate in primary/backup mode.

- Set default next hops.

  apply default-next-hop [**vpn-instance** *vpn-instance-name* | **inbound-vpn**] { *ipv6-address* [**direct**] [**track** *track-entry-number*] }&<1-4>

  By default, no default next hops are specified.

  You can specify multiple default next hops for backup or load sharing in one command line or by executing this command multiple times. You can specify a maximum of four default next hops for a node.

  The value for n varies by device model. For more information, see the command reference.

- Enable load sharing among multiple default next hops.

  apply loadshare default-next-hop

  By default, the default next hops operate in primary/backup mode.

- Set default output interfaces.

  apply default-output-interface { *interface-type interface-number* [**track** *track-entry-number*] }&<1-4>

  By default, no default output interfaces are specified.

  You can specify multiple default output interfaces for backup or load sharing in one command line or by executing this command multiple times. You can specify a maximum of four default output interfaces for a node.

- Enable load sharing among multiple default output interfaces.

  apply loadshare default-output-interface

  By default, the default output interfaces operate in primary/backup mode.

Comparing packets with the next node upon match failure on the current node

1. Enter system view.

   `system-view`

2. Enter IPv6 policy node view.

   ipv6 policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Compare packets with the next node upon match failure on the current node.

   `apply continue`

   By default, IPv6 PBR does not compare packets with the next node upon match failure on the current node.

   This command takes effect only when the match mode of the node is **permit**.

Specifying a policy for IPv6 PBR

Specifying an IPv6 policy for IPv6 local PBR

About this task

Perform this task to specify an IPv6 policy for IPv6 local PBR to guide the forwarding of locally generated packets.

Restrictions and guidelines

You can specify only one policy for IPv6 local PBR and must make sure the specified policy already exists. Before you apply a new policy, you must first remove the current policy.

IPv6 local PBR might affect local services, such as ping and Telnet. When you use IPv6 local PBR, make sure you fully understand its impact on local services of the device.

Procedure

1. Enter system view.

   `system-view`

2. Specify an IPv6 policy for IPv6 local PBR.

   ipv6 local policy-based-route *policy-name*

   By default, IPv6 local PBR is not enabled.

Specifying an IPv6 policy for IPv6 interface PBR

About this task

Perform this task to apply an IPv6 policy to an interface to guide the forwarding of packets received on the interface only.

Restrictions and guidelines

You can apply only one policy to an interface and must make sure the specified policy already exists. Before you apply a new policy, you must first remove the current policy from the interface.

You can apply a policy to multiple interfaces.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

interface *interface-type interface-number*

3. Specify an IPv6 policy for IPv6 interface PBR.

   ipv6 policy-based-route *policy-name*

   By default, no IPv6 policy is applied to the interface.

Display and maintenance commands for IPv6 PBR

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display IPv6 PBR policy information.	**display ipv6 policy-based-route** [**policy** *policy-name*]
Display IPv6 interface PBR configuration and statistics.	**display ipv6 policy-based-route interface** *interface-type interface-number* [**slot** *slot-number*]
Display IPv6 local PBR configuration and statistics.	**display ipv6 policy-based-route local** [**slot** *slot-number*]
Display IPv6 PBR configuration.	**display ipv6 policy-based-route setup**
Clear IPv6 PBR statistics.	**reset ipv6 policy-based-route statistics** [**policy** *policy-name*]

Contents

Configuring routing policies

About routing policies

Routing policies control routing paths by filtering and modifying routing information.

Routing policies can filter advertised, received, and redistributed routes, and modify attributes for specific routes.

Implementation of a routing policy

To configure a routing policy:

1. Configure filters based on route attributes.
2. Create a routing policy and apply filters to the routing policy.

Filters

Routing policies can use the following filters to match routes.

ACL

An ACL can match the destination or next hop of routes.

For more information about ACLs, see *ACL and QoS Configuration Guide*.

IP prefix list

An IP prefix list matches the destination address of routes.

An IP prefix list can contain multiple items that specify prefix ranges. Each destination IP address prefix of a route is compared with these items in ascending order of their index numbers. A prefix matches the IP prefix list if it matches one item in the list.

AS path list

An AS path list matches the AS_PATH attribute of BGP routes. The AS_PATH attribute identifies the ASs through which a route has passed.

For more information about AS path lists, see "Configuring BGP."

Community list

A community list matches the COMMUNITY attribute of BGP routes. The COMMUNITY attribute identifies the community of BGP routes.

For more information about community lists, see "Configuring BGP."

Extended community list

An extended community list matches the extended community attribute (Route-Target for VPN and Site of Origin) of BGP routes.

RD list

A route distinguisher (RD) list matches the RD of routes.

An RD list is identified by an RD list number and can contain multiple items that specify RD ranges. Each item is identified by an index number. The RD of a route is compared with these items in ascending order of their index numbers. An RD matches the RD list if it matches one item in the list.

Tag list

A tag list matches the tag of IGP routes.

Routing policy

A routing policy can contain multiple nodes, which are in a logical OR relationship. A node with a smaller number is matched first. A route matches the routing policy if it matches one node (except the node configured with the **continue** clause) in the routing policy.

Each node has a match mode of **permit** or **deny**.

- **permit**—Specifies the **permit** match mode for a routing policy node. If a route meets all the **if-match** clauses of the node, it is handled by the **apply** clauses of the node. The route is not compared with the next node unless the **continue** clause is configured. If a route does not meet all the **if-match** clauses of the node, it is compared with the next node.
- **deny**—Specifies the **deny** match mode for a routing policy node. The **apply** and **continue** clauses of a deny node are never executed. If a route meets all the **if-match** clauses of the node, it is denied without being compared with the next node. If a route does not meet all the **if-match** clauses of the node, it is compared with the next node.

A node can contain a set of **if-match**, **apply**, and **continue** clauses.

- **if-match** clauses—Specify the match criteria that match the attributes of routes. The **if-match** clauses of different types are in a logical AND relationship and the **if-match** clauses of the same type are in a logical OR relationship. A route must meet **if-match** clauses of all types to match the node.
- **apply** clauses—Specify the actions to be taken on permitted routes, such as modifying a route attribute.
- **continue** clause—Specifies the next node. A route that matches the current node (permit node) must match the specified next node in the same routing policy. The **continue** clause combines the **if-match** and **apply** clauses of the two nodes to improve flexibility of the routing policy. After you configure a **continue** clause, a route can pass the routing policy even if it does not match the specified next node. To reject such a route, add a **deny** node without clauses.

Follow these guidelines when you configure **if-match**, **apply**, and **continue** clauses:

- If you only want to filter routes, do not configure **apply** clauses.
- If you do not configure any **if-match** clauses for a permit node, the node will permit all routes.
- Configure a permit node containing no **if-match** or **apply** clauses following multiple deny nodes to allow unmatched routes to pass.

Routing policy tasks at a glance

To configure a routing policy, perform the following tasks:

1. (Optional.) Configure filters:
   - Configuring an IPv4 prefix list
   - Configuring an IPv6 prefix list
   - Configuring an AS path list
   - Configuring a community list
   - Configuring an extended community list
   - Configuring an RD list
   - Configuring a tag list
2. Configuring a routing policy:
   a. Creating a routing policy
   b. Configuring if-match clauses

c. Configuring apply clauses
d. Configuring the continue clause

Configuring an IPv4 prefix list

Restrictions and guidelines

If all the items are set to **deny** mode, no routes can pass the IPv4 prefix list. To permit unmatched IPv4 routes, you must configure the **permit** 0.0.0.0 0 **less-equal** 32 item following multiple **deny** items.

Procedure

1. Enter system view.
   `system-view`
2. Configure an IPv4 prefix list.
   `ip prefix-list` *`prefix-list-name`* [**`index`** *`index-number`*] { **`deny`** | **`permit`** } *`ip-address mask-length`* [**`greater-equal`** *`min-mask-length`*] [**`less-equal`** *`max-mask-length`*]

Configuring an IPv6 prefix list

Restrictions and guidelines

If all items are set to **deny** mode, no routes can pass the IPv6 prefix list. To permit unmatched IPv6 routes, you must configure the **permit** :: 0 **less-equal** 128 item following multiple **deny** items.

Procedure

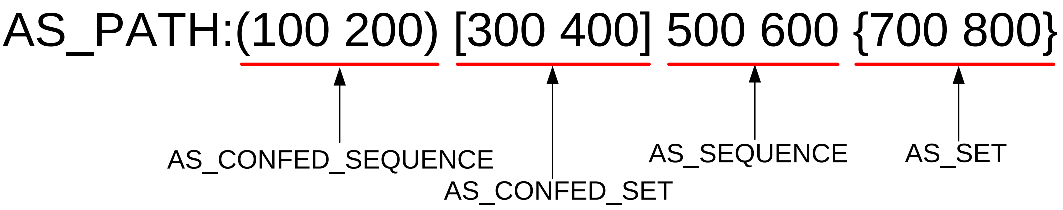
1. Enter system view.
   `system-view`
2. Configure an IPv6 prefix list.
   `ipv6 prefix-list` *`prefix-list-name`* [**`index`** *`index-number`*] { **`deny`** | **`permit`** } *`ipv6-address`* { **`inverse`** *`inverse-prefix-length`* | *`prefix-length`* [**`greater-equal`** *`min-prefix-length`*] [**`less-equal`** *`max-prefix-length`*] }

Configuring an AS path list

About this task

The AS_PATH attribute identifies the ASs through which a BGP route has passed. Figure 1 shows the AS_PATH attribute format in the BGP routing table.

Figure 1 AS_PATH attribute



The AS_PATH attribute value is a character string containing digits, parentheses, brackets, braces, and spaces. It is a sequence of the following AS path segments:

- **AS_CONFED_SEQUENCE**—Ordered set of member AS numbers in the local confederation that the UPDATE message has traversed.
- **AS_CONFED_SET**—Unordered set of member AS numbers in the local confederation that the UPDATE message has traversed.
- **AS_SEQUENCE**—Ordered set of ASs a route in the UPDATE message has traversed.
- **AS_SET**—Unordered set of ASs a route in the UPDATE message has traversed.

NOTE:

The AS_PATH attribute of a BGP route might not contain all of the four AS path segments.

An AS path list consists of regular expressions used for filtering BGP routes by their AS_PATH attributes. A regular expression can contain the special characters described in Table 1.

Table 1 Special characters supported in a regular expression

Character	Description	Example
^	Matches the beginning of a line.	Match a local route if its AS_PATH attribute is null: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } ^$
$	Matches the end of a line.	Match a route if it is originated from AS 100: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } 100$
.	Matches any single character.	Match a route if it has passed AS 100 but is not originated or received from AS 100: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } **._100_.**
*	Matches the preceding character or string zero, one, or multiple times.	Match a route if it has an AS_PATH attribute: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } **.***
+	Matches the preceding character or string one or multiple times.	Match a route if its AS_PATH attribute value contains **5**: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } 5+
x|y	Matches the preceding or succeeding string.	Match a route if it is originated from AS 100 or AS 200: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } 100$\|200$
( )	Matches the string in the parentheses, usually used together with the plus sign (+) or asterisk sign (*).	Match a route if its AS_PATH attribute value contains **123**: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } (123)+
[xyz]	Matches a single character in the brackets.	Match a route if it is received from AS 10 through AS 19: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } ^1[0-9]$

Character	Description	Example
[^xyz]	Matches a single character that is not in the brackets.	Match a route if its originating AS number does not end with **2** or **4**: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } [^24]$
{n}	Matches the preceding character *n* times. The number *n* must be a nonnegative integer.	Match a route if its AS_PATH attribute value contains two **5**: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } 5{2}
{n,}	Matches the preceding character *n* times or more. The number *n* must be a nonnegative integer.	Match a route if its AS_PATH attribute value contains two or more consecutive **5**: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } 5{2,}
{n,m}	Matches the preceding character *n* to *m* times or more. The numbers *n* and *m* must be nonnegative integers and *n* cannot be greater than *m*.	Match a route if its AS_PATH attribute value contains one or more consecutive **5**: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } 5{1,2}
[a-z]	Matches a single character within the specified range for only once.	Match a route if its AS_PATH attribute value contains **0**, **1**, or **2**: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** }[0-2]
[^a-z]	Matches a single character that is not in the specified range.	Match a route if its AS_PATH attribute value contains digits other than **0**, **1**, or **2**: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** }^ [^0-2]$
_	Matches a punctuation. The expression can begin or end with _.	Match a route if it has passed AS101 100: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } 101_100_
\b	Matches a word that starts with the pattern following \b or ends with the pattern preceding \b.	Match a route if it is originated from AS 100: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } \b100$
\B	Matches a word that contains the pattern but does not start or end with the pattern.	Match a route if its AS_PATH attribute value starts with **1**: **ip as-path** { *as-path-number* | *as-path-name* } { **deny** | **permit** } ^1\B
\	Escape character. If a special character listed in this table follows \, the specific meaning of the character is removed.	N/A
\w	Same as [A-Za-z0-9_], matches a digit, letter, or underscore.	Match a route if its AS_PATH attribute value contains double digits: **ip as-path** { *as-path-number* | *as-path-name* } \w{2}

Character	Description	Example
\W	Same as [^A-Za-z0-9_], matches a character that is not a digit, letter, or underscore.	N/A
\index	Matches the specified string in the parentheses followed by \ twice. Each string in the parentheses is numbered from 1 in order. The *index* argument represents the sequence number of the string you want to match. If the parentheses contain *n* strings, you can specify the sequence number of the string in the range of 1 to *n*.	Match a route if its AS_PATH attribute value contains two consecutive **1**: **ip as-path** { *as-path-number* | *as-path-name* } (1)\1

NOTE:

The regular expressions shown in Table 1 are used for illustration only. Other regular expressions might be available to achieve the same effect.

Restrictions and guidelines

You can configure multiple items for an AS path list that is identified by a number. The relationship between the items is logical OR. A route matches the AS path list if it matches one item in the list.

Procedure

1. Enter system view.
   system-view
2. Configure an AS path list.
   ip as-path *as-path-number* { **deny** | **permit** } *regular-expression*

Configuring a community list

About this task

You can configure multiple items for a community list that is identified by a number. The relationship between the items is logical OR. A route matches the community list if it matches one item in the list.

An advanced community list matches the community attributes of BGP routes based on the regular expressions described in "Configuring an AS path list."

Procedure

1. Enter system view.
   system-view
2. Configure a community list.
   - Configure a basic community list.
     ip community-list { *basic-comm-list-num* | **basic** *basic-comm-list-name* } { **deny** | **permit** } [*community-number*&<1-32> | *aa*:*nn*&<1-32>] [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] *
   - Configure an advanced community list.
     ip community-list { *adv-comm-list-num* | **advanced** *adv-comm-list-name* } { **deny** | **permit** } *regular-expression*

Configuring an extended community list

About this task

You can configure multiple items for an extended community list that is identified by a number. The relationship between the items is logical OR. A route matches the extended community list if it matches one item in the list.

Procedure

1. Enter system view.

   system-view

2. Configure an extended community list.

   ip extcommunity-list *ext-comm-list-number* [**index** *index-number*] { **deny** | **permit** } { **rt** *route-target* | **soo** *site-of-origin* }&<1-32>

Configuring an RD list

About this task

You can configure multiple items for an RD list that is identified by a number. The relationship between the items is logical OR. A route matches the RD list if it matches one item in the list.

Procedure

1. Enter system view.

   system-view

2. Configure an RD list.

   ip rd-list *rd-list-number* [**index** *index-number*] { **deny** | **permit** } **route-distinguisher**&<1-10>

Configuring a tag list

About this task

You can configure multiple items for a tag list. The relationship between the items is logical OR. A route matches the tag list if it matches one item in the list.

Procedure

1. Enter system view.

   system-view

2. Configure a tag list.

   route tag-list *tag-list-number* [**index** *index-number*] { **deny** | **permit** } *tag-value*&<1-32>

Configuring a routing policy

Creating a routing policy

About this task

A routing policy must have a minimum of one permit node. If all the nodes are in **deny** mode, no routes can pass the routing policy.

Procedure

1. Enter system view.

   system-view

2. Create a routing policy and a node, and enter routing policy node view.

   route-policy *route-policy-name* { **deny** | **permit** } **node** *node-number*

3. (Optional.) Configure a description for the routing policy node.

   description *text*

Configuring if-match clauses

About this task

You can either specify no **if-match** clauses or multiple **if-match** clauses for a routing policy node. If no **if-match** clause is specified for a permit node, all routes can pass the node. If no **if-match** clause is specified for a deny node, no routes can pass the node.

Restrictions and guidelines

When you configure **if-match** clauses, follow these restrictions and guidelines:

- The **if-match** clauses of a routing policy node have a logical AND relationship. A route must meet all **if-match** clauses before it can be executed by the **apply** clauses of the node. If an **if-match** command exceeds the maximum length, multiple **if-match** clauses of the same type are generated. These clauses have a logical OR relationship. A route only needs to meet one of them.
- All IPv4 routes match a node if the **if-match** clauses of the node use only IPv6 ACLs. All IPv6 routes match a node if the **if-match** clauses of the node use only IPv4 ACLs.
- If the ACL used by an **if-match** clause does not exist, the clause is always matched. If no rules of the specified ACL are matched or the match rules are inactive, the clause is not matched.
- If the prefix list, community list, or extended community list used by an **if-match** clause does not exist, the clause is always matched. If no rules of the specified prefix list, community list, or extended community list are matched, the clause is not matched.

Procedure

1. Enter system view.

   system-view

2. Enter routing policy node view.

   route-policy *route-policy-name* { **deny** | **permit** } **node** *node-number*

3. Match routes whose destination, next hop, or source address matches an ACL or prefix list.

   IPv4:

   if-match ip { **address** | **next-hop** | **route-source** } { **acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **prefix-list** *prefix-list-name* }

   IPv6:

   if-match ipv6 { **address** | **next-hop** | **route-source** } { **acl** { *ipv6-acl-number* | **name** *ipv6-acl-name* } | **prefix-list** *prefix-list-name* }

   By default, no ACL or prefix list match criterion is configured.

   The ACL specified in an **if-match** clause must be a non-VPN ACL.

4. Configure BGP route match criteria.

   ○ Match BGP routes whose AS_PATH attribute matches a specified AS path list.

   if-match as-path *as-path-number*&<1-32>

- Match BGP routes whose COMMUNITY attribute matches a specified community list.

  if-match community { { *basic-community-list-number* | **name** *comm-list-name* } [**whole-match**] | *adv-community-list-number* }&<1-32>

- Match BGP routes whose extended community attribute matches a specified extended community list.

  if-match extcommunity *ext-comm-list-number*&<1-32>

- Match BGP routes having the specified local preference.

  if-match local-preference *preference*

By default, no BGP route match criteria are configured.

5. Configure route match criteria.

   - Match routes having the specified cost.

     if-match cost *cost-value*

   - Match routes having the specified output interface.

     if-match interface { *interface-type interface-number* }&<1-16>

     This command is not supported by BGP.

   - Match routes having the specified route type.

     if-match route-type { **bgp-evpn-imet** | **bgp-evpn-ip-prefix** | **bgp-evpn-mac-ip** | **external-type1** | **external-type1or2** | **external-type2** | **internal** | **is-is-level-1** | **is-is-level-2** | **nssa-external-type1** | **nssa-external-type1or2** | **nssa-external-type2** } *

   - Match IGP routes having the specified tag value.

     if-match tag *tag-value*

   - Match IGP routes whose tag matches the specified tag list.

     if-match tag-list *tag-list-number*

   By default, no route match criteria are configured.

6. Match routes whose RD matches the specified RD list.

   if-match rd-list *rd-list-number*

   By default, no RD match criterion is configured.

Configuring apply clauses

1. Enter system view.

   system-view

2. Enter routing policy node view.

   route-policy *route-policy-name* { **deny** | **permit** } **node** *node-number*

3. Configure BGP route attributes.

   - Set the AS_PATH attribute for BGP routes.

     apply as-path *as-number*&<1-32> [**replace**]

   - Delete the specified COMMUNITY attribute for BGP routes.

     apply comm-list { *comm-list-number* | *comm-list-name* } **delete**

     By default, no COMMUNITY attribute is deleted for BGP routes.

   - Set the specified COMMUNITY attribute for BGP routes.

apply community { **none** | **additive** | { *community-number*&<1-32> | *aa:nn*&<1-32> | **internet** | **no-advertise** | **no-export** | **no-export-subconfed** } * [**additive**] }

- Set the extended community attribute for BGP routes.

  apply extcommunity { **rt** *route-target* }&<1-32> [**additive**]
- Set a local preference for BGP routes.

  apply local-preference *preference*
- Set the ORIGIN attribute for BGP routes.

  apply origin { **egp** *as-number* | **igp** | **incomplete** }
- Set a preferred value for BGP routes.

  apply preferred-value *preferred-value*
- Set a traffic index for BGP routes.

  apply traffic-index { *value* | **clear** }

By default, no BGP route attributes are configured.

4. Configure the route cost and cost type.
   - Set a cost for routes.

     apply cost [**+** | **-**] *cost-value*

     By default, no cost is set for routes.
   - Set a cost type for routes.

     apply cost-type { **external** | **internal** | **type-1** | **type-2** }

     By default, no cost type is set for routes.
5. Set the next hop for routes.

   IPv4:

   apply ip-address next-hop *ip-address* [**public** | **vpn-instance** *vpn-instance-name*]

   IPv6:

   apply ipv6 next-hop *ipv6-address*

   By default, no next hop is set for routes.

   The configuration does not apply to redistributed routes.
6. Configure route priorities.
   - Set an IP precedence for matching routes.

     apply ip-precedence { *value* | **clear** }

     By default, no IP precedence is set.
   - Set a preference.

     apply preference *preference*

     By default, no preference is set.
   - Set a prefix priority.

     apply prefix-priority { **critical** | **high** | **medium** }

     By default, the prefix priority is low.
7. Redistribute routes to the specified IS-IS level.

   apply isis { **level-1** | **level-1-2** | **level-2** }

   By default, routes are not redistributed into the specified IS-IS level.
8. Set a local QoS ID for matching routes.

   apply qos-local-id { *local-id-value* | **clear** }

By default, no local QoS ID is set.

9. Set a tag value for IGP routes.

   apply tag *tag-value*

   By default, no tag value is set for IGP routes.

10. Set a backup link for fast reroute (FRR).

    IPv4:

    apply fast-reroute { **backup-interface** *interface-type interface-number* [**backup-nexthop** *ip-address*] | **backup-nexthop** *ip-address* }

    IPv6:

    apply ipv6 fast-reroute { **backup-interface** *interface-type interface-number* [**backup-nexthop** *ipv6-address*] | **backup-nexthop** *ipv6-address* }

    By default, no backup link is set for FRR.

Configuring the continue clause

Restrictions and guidelines

When you configure the **continue** clause to combine multiple nodes, follow these restrictions and guidelines:

- If you configure an **apply** clause that sets different attribute values on all the nodes, the **apply** clause of the node configured most recently takes effect.
- If you configure the following **apply** clauses on all the nodes, the **apply** clause of each node takes effect:
  - **apply as-path** without the **replace** keyword.
  - **apply cost** with the **+** or **–** keyword.
  - **apply community** with the **additive** keyword.
  - **apply extcommunity** with the **additive** keyword.
- The **apply comm-list delete** clause configured on the current node cannot delete the community attributes set by the **apply community** clauses of the preceding nodes.

Procedure

1. Enter system view.

   system-view

2. Enter routing policy node view.

   route-policy *route-policy-name* { **deny** | **permit** } **node** *node-number*

3. Specify the next node to be matched.

   continue [*node-number*]

   By default, no continue clause is configured.

   The specified next node must have a larger number than the current node.

Display and maintenance commands for routing policies

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display BGP AS path list information.	**display ip as-path** [*as-path-number*]

Configuring guard routes

About guard routes

A guard route directs traffic to the guard device for filtering and cleaning. You can manually configure a guard route on the guard device, or use a script to automatically configure a guard route upon receipt of a notification.

Guard route characteristics

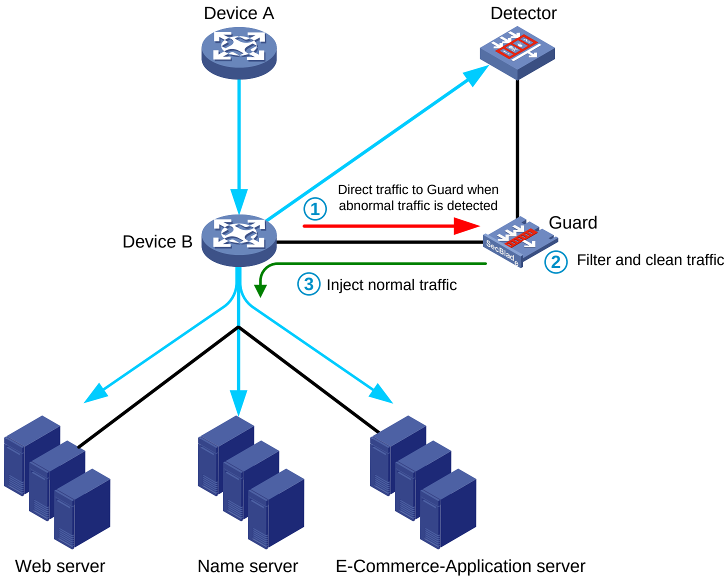
Guard routes use Null 0 as the outgoing interface.

Guard routes are inactive routes and will not be installed into the FIB.

You must configure a routing protocol, such as BGP, OSPF, or OSPFv3, to redistribute and advertise guard routes for directing traffic to the guard device.

Guard route mechanism

Figure 1 Guard route network diagram



As shown in Figure 1, Device B uses port mirroring to mirror traffic destined for the application servers to the detector for monitoring. It uses a routing protocol to redistribute guard routes from the guard device.

When no abnormal traffic is detected, Device B forwards traffic without the participation of the guard device.

When abnormal traffic is detected, the detector performs one of the following tasks:

- Sends a notification to the guard device. The guard device then automatically generates a guard route.
- Generates an alarm to notify the network administrator. The administrator then manually configures a guard route on the guard device.

The destination address of the guard route is the address to which the abnormal traffic is destined.

After the guard route is configured, the guard device advertises the route to Device B. Device B directs all traffic destined to the destination address of the guard route to the guard device. The guard device filters and cleans the traffic and then sends the normal traffic back to Device B.

Restrictions and guidelines: guard route configuration

A guard device is typically used for traffic filtering and cleaning. To avoid system consumption, configure a routing policy on the guard device or its connected device to disable receiving and advertising non-guard routes. For more information about routing policies, see "Configuring routing policies."

Configuring a guard route

1. Enter system view.

   system-view

2. Configure a guard route.

   IPv4:

   ip route-guard *ip-address* { *mask-length* | *mask* }

   By default, no IPv4 guard routes exist.

   IPv6:

   ipv6 route-guard *ipv6-address prefix-length*

   By default, no IPv6 guard routes exist.

Display and maintenance commands for guard routes

Execute **display** commands in any view.

Task	Commands
Display IPv4 guard route information.	**display ip routing-table protocol guard** [**inactive** | **verbose**]
Display IPv6 guard route information.	**display ipv6 routing-table protocol guard** [**inactive** | **verbose**]

Configuring RIR

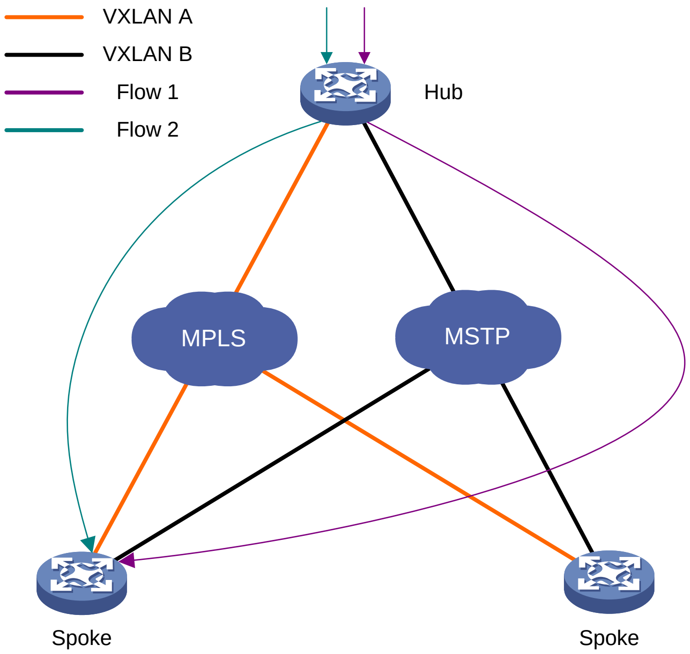
About RIR

Resilient Intelligent Routing (RIR) dynamically selects the most suitable links for traffic forwarding based on service requirements (for example, link quality and link bandwidth). RIR not only can select the optimal link from a specific type of transport network, but also can perform automatic link switchover when the current link becomes unqualified.

Application scenario

As shown in Figure 1, RIR is used in a VXLAN-based hub-spoke network. The feature can select different VXLAN tunnels to forward traffic for different services, depending on parameters including the link preference, link primary/backup role, link quality, and link bandwidth. RIR can perform link selection not only for traffic from a hub to a spoke, but also for traffic from a spoke to a hub. The feature might select different links for bidirectional traffic between a hub and a spoke.

Figure 1 RIR application scenario



Flow template

A flow template defines link selection policies for a type of service flow. A flow ID uniquely identifies a flow template.

The device applies the link selection policies under a flow template to the service flow marked with the flow ID of the flow template.

The device supports using QoS policies to mark flow IDs for service flows. After QoS identifies the service of a packet based on the quintuple and DSCP of the packet, it assigns a flow ID to the packet. Then, RIR will perform link selection for the packet based on the flow template that uses the flow ID.

The flow ID is marked only in the RIR process, and it will not be added to any outgoing packets.

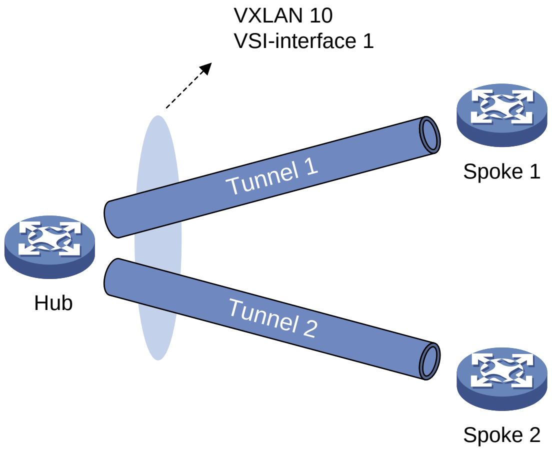
For more information about QoS marking, see QoS overview, QoS policies, and marking configuration in *ACL and QoS Configuration Guide*.

Link type

RIR uses the link type to identify the network type of a link and uses the link index to distinguish links of the same network type. RIR supports 4G, Internet, MPLS, and MSTP link types. The link type is used only for identifying links, and it does not affect packet encapsulation.

As shown in Figure 2, assign a link type and link index to the VSI interface to identify the VXLAN tunnels between the hub and the spokes in the VXLAN. To uniquely identify a VXLAN tunnel between a hub and a spoke, VXLAN-based RIR allows the hub and spoke to have only one VXLAN tunnel for each VSI interface.

Figure 2 Links in a VXLAN network



Preference-based link selection

Link preference

You can assign a preference to a link based on factors such as the service requirements, the link conditions, and the link cost. RIR preferentially selects links with higher preference.

VXLAN-based RIR supports assigning a link preference to a type of links with a specific link index in flow template view. The link type and link index identify a VSI interface. As VXLAN-based RIR allows a hub and spoke to have only one VXLAN tunnel for a VSI interface, the link preference of the VSI interface is the link preference of the VXLAN tunnel between the hub and spoke.

Link selection rules

You can assign the same preference value to different links in the same flow template.

RIR selects a link for a type of service flows from the links in the flow template in descending order of link preference. If the links with the highest preference cannot meet the service requirements, RIR tries the links with the second highest preference, and so forth to the links with the lowest preference.

If the flow template has two or more links with the same preference, RIR performs link selection based on RIR link load sharing criteria.

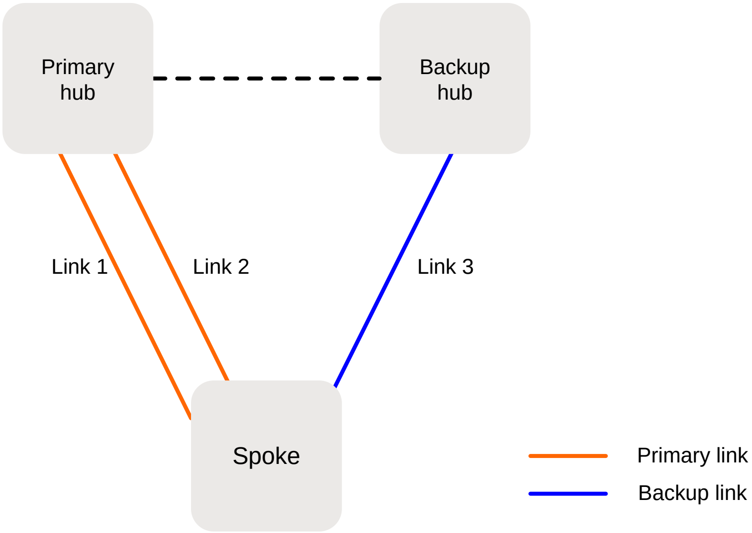
Redundant link selection

To ensure service high availability, redundant hubs are deployed. Typically, use the links between a spoke and the primary hub as primary links, and use the links between a spoke and the backup hub as backup links. When no link is available to reach the primary hub, the spoke can switch traffic to the backup hub to ensure service continuity.

A VXLAN tunnel is a primary link by default after it is assigned a link preference based on the link type and index on its VSI interface. To specify a VXLAN tunnel associated with a VSI interface as a backup link, specify that VXLAN tunnel as an RIR backup tunnel.

As shown in Figure 3, when primary links 1 and 2 are not available, the spoke uses backup link 3 to forward traffic to the backup hub.

Figure 3 Primary and backup links



Quality-based link selection

RIR server and RIR client

About the RIR server and RIR client

In a hub-spoke network, a hub is typically connected to multiple spokes. To avoid the hub from consuming too many resources on link quality detection by Network Quality Analyzer (NQA) probes, RIR provides the following roles:

- **RIR server**—An RIR server does not perform NQA link probes. It performs link selection based on the link quality probe results synchronized from RIR clients.
- **RIR client**—An RIR client performs NQA link probes to detect the link quality and synchronizes the link quality probe results to RIR servers.

Configure a hub as an RIR server and spokes as RIR clients, so the hub can perform link selection based on the link quality probe results synchronized from the RIR clients.

RIR server function

You can enable the RIR server globally or on an interface, as shown in Figure 4.

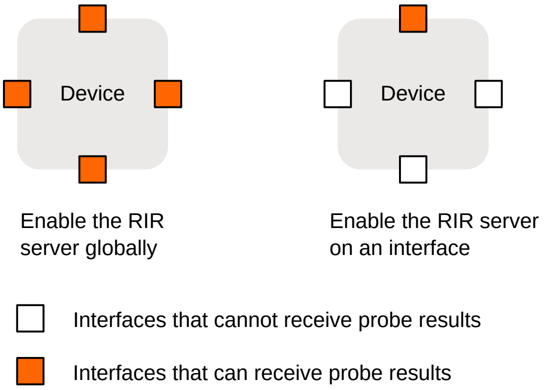
- If you enable the RIR server globally, the RIR server is also enabled on all interfaces on the device. The interfaces can receive RIR link quality probe results from RIR clients.

- If you enable the RIR server on an interface, only that interface can receive RIR link quality probe results from RIR clients.

IMPORTANT:

In a VXLAN network, only tunnel interfaces support enabling the RIR server. The RIR server uses the tunnel interfaces to receive RIR link quality probe results from RIR clients.

Figure 4 Enabling the RIR server



Device
Device
Enable the RIR server globally
Enable the RIR server on an interface
□ Interfaces that cannot receive probe results
■ Interfaces that can receive probe results

RIR client function

The RIR client synchronizes link quality probe results to RIR servers. Enabling the RIR client is the same as enabling the RIR server.

RIR server and client enabling policy

Enable the RIR server or RIR client, or use them in combination, depending on the role of the device in the network.

- If the device acts only as a hub, you can enable the RIR server globally.
- If the device acts only as a spoke, you can enable the RIR client globally.
- If the device acts as both a hub and a spoke, you can enable the RIR server and RIR client on the corresponding interfaces.

The RIR server and RIR client cannot be both enabled on the same interface. If the enabled role (RIR server or client) on an interface is different from the globally enabled role, the interface-specific role takes effect on that interface.

As shown in Figure 5, enable the global and interface-specific RIR server and RIR client in combination as follows:

- **Device A**—Enable the RIR server globally.
- **Device B**—Enable the RIR client globally and enable the RIR server on an interface.
- **Device C**—Enable the RIR client on an interface and enable the RIR server on an interface.
- **Device D**—Enable the RIR client globally.
- **Device E**—Enable the RIR client on an interface.

NQA link probes

RIR uses NQA to detect the status of candidate links and selects the most suitable link based on the NQA link quality probe results. For more information about NQA, see *Network Management and Monitoring Configuration Guide*.

A hub performs link selection based on the link quality probe results synchronized from spokes. RIR uses spokes as NQA clients and hubs as NQA servers. The following types of NQA link probe operations are defined:

- **NQA link connectivity probe operation**—Performs ICMP echo probes to check the connectivity of each link. If a link is disconnected, RIR does not perform NQA link quality probes on that link. You can configure only one NQA link connectivity probe operation.
- **NQA link quality probe operations**—Also referred to as NQA link quality operations, perform UDP jitter probes to detect the link delay, jitter, and packet loss ratio for links that pass NQA link connectivity check. You can configure multiple NQA link quality operations. The operations might offer different link quality probe results for the same link.

The device performs NQA probes only for links that are assigned link types and link indexes.

SLA

To meet the differentiated requirements of services on link quality, configure a Service Level Agreement (SLA) for each service. An SLA contains a set of link quality evaluation thresholds, including the link delay threshold, packet loss threshold, and jitter threshold.

The quality policy of a flow template contains an SLA and an NQA link quality operation. By comparing the NQA link quality probe results with the thresholds in the SLA, the device determines whether a link meets the quality requirements of the service. If all parameter values in the probe results of a link are lower than or equal to the thresholds in the SLA, the link is qualified for the service.

Quality policy

Link quality probe results

As shown in Figure 6, if a flow template is configured with a quality policy, the spoke determines whether a link is qualified for that type of service flow based on the NQA link quality probe results. In addition, the spoke synchronizes the link quality probe results to the hub. The hub performs link selection based on the link quality probe results synchronized from the spoke. You only need to configure the quality policy on the spoke.

RIR uses the following rules to determine whether a link is qualified for a type of service flow:

- If the link fails NQA link connectivity check, RIR determines that the link is unqualified.
- If the link passes NQA link connectivity check, RIR checks the NQA link quality probe results for the link.
    - If all link quality parameter values in the probe results are lower than or equal to the link quality thresholds in the SLA, RIR determines that the link is qualified.
    - If any link quality parameter value in the probe results is higher than the corresponding link quality threshold in the SLA, RIR determines that the link is unqualified.

Quality-based link selection on a hub and a spoke

When a spoke performs quality-based link selection, it considers only the quality policy configured on the spoke. If a quality policy has been configured in a flow template on the spoke, the spoke calculates link quality probe results based on the NQA link quality operation and SLA in the quality policy. Then, the spoke performs link selection for the flow that matches the flow template based on the link quality probe results. If no quality policy is configured in a flow template on the spoke, the spoke does not consider the quality factor when it performs link selection. All links in the flow template meet the service requirements in quality.

When a hub performs quality-based link selection for traffic sent to a spoke, it considers the quality policies both on the hub and spoke. Table 1 shows the link selection rules for a flow that matches a flow template on a hub.

Table 1 Quality-based link selection rules on a hub

Whether a quality policy is configured on the hub	Whether a quality policy is configured on the spoke	Quality-based link selection rules on the hub
Yes	Yes	The hub performs link selection based on the link quality probe results synchronized from the spoke.
Yes	No	The spoke does not synchronize link quality probe results to the hub. The hub determines that no link in the flow template meets the quality requirements.
No	Yes	The spoke synchronizes link quality probe results to the hub. The hub determines that all links in the flow template are qualified for packets that match the flow template.
No	No	The spoke does not synchronize link quality probe results to the hub. The hub determines that all links in the flow template are qualified for packets that match the flow template.

As a best practice, configure a quality policy both on the hub and spoke for a type of service flow or do not configure any quality policy on the hub or spoke for the type of service flow.

Bandwidth-based link selection

About bandwidth-based link selection

Bandwidth-based link selection not only can select links that meet the service bandwidth requirements, but also can load share service traffic among multiple links. This manner can avoid a link from being overwhelmed or congested.

Bandwidth-based link selection policy

Bandwidth-based link selection enables the device to select a suitable link for service traffic based on the used bandwidth of the link, the total link bandwidth, and the per-session expected bandwidth. The device can automatically obtain the used bandwidth of the link. The total bandwidth of the link and the per-session expected bandwidth are manually configured or calculated based on the user configuration.

The device uses sessions as the minimum granularity and performs bandwidth-based link selection to achieve refined link bandwidth management. A session is uniquely defined by a quintuple including the source IP address, destination IP address, source port, destination port, and transport layer protocol.

When the device selects links for traffic of a session, it first performs bandwidth detection based on the per-session expected bandwidth in the flow template to which the session belongs. If the used bandwidth plus the per-session expected bandwidth of a candidate link is less than 80% of its total bandwidth, the available bandwidth of the link meets the session bandwidth requirements. The link passes the bandwidth detection.

When different sessions of the same service type use the same link selection policy, the link selection results might be different.

Load balancing

Load balancing modes

If multiple links are available for sessions that match a flow template, the device distributes the traffic of the sessions to these links for load balancing based on the link bandwidths. RIR supports the following load balancing modes:

- **Per-session weight-based link selection mode**—RIR global link load balancing mode that takes effect on all RIR flows. This mode can distribute the sessions that match the same flow template to different links according to the weights of the links. RIR selects only one link to transmit a session.
- **Per-session periodic link adjustment mode**—RIR global link load balancing mode that takes effect on all RIR flows. This mode not only can distribute the sessions that match the same flow template to different links, but also can periodically adjust links for the sessions. Within one adjustment period, RIR selects only one link to transmit a session.
- **Per-packet mode**—Flow-specific link load balancing mode that takes effect only on traffic that matches the flow template where this mode is enabled. This mode can distribute the same session to different links for transmission.

The per-packet mode takes precedence over the per-session modes.

Load balancing concepts

Bandwidth weight

The bandwidth of a link is used as the weight of the link. If the total bandwidth of a link is used as the link weight, the weight is called the total bandwidth weight. If the remaining bandwidth of a link is used as the link weight, the weight is called the remaining bandwidth weight.

To select links from multiple links based on their bandwidth weights, the probability that each link is selected equals to the ratio of the bandwidth of a single link to the bandwidth sum of all the links. The bandwidth sum of all the links is the weight sum.

For example, the total bandwidths of links 1, 2, and 3 are 10 Mbps, 10 Mbps, and 20 Mbps, respectively. The remaining bandwidths of links 1, 2, and 3 are 8 Mbps, 4 Mbps, and 8 Mbps, respectively. All the links meet the service requirements. To select links based on the total bandwidth weights, the probabilities that links 1, 2, and 3 are selected are 25%, 25%, and 50%, respectively. To select links based on the remaining bandwidth weights, the probabilities that links 1, 2, and 3 are selected are 40%, 20%, and 40% ,respectively.

Remaining bandwidth ratio

The remaining bandwidth ratio refers to the ratio of the remaining bandwidth of a link compared to the total bandwidth of the link. If the remaining bandwidth ratio of a link is the largest among multiple links, this remaining bandwidth ratio is called the largest remaining bandwidth ratio. If the remaining bandwidth ratio of a link is the smallest among multiple links, this remaining bandwidth ratio is called the smallest remaining bandwidth ratio.

Per-session weight-based link selection mode

The mechanisms of the per-session weight-based link selection mode are as follows:

- **For preference-based primary link selection, preference-based backup link selection, and quality tolerant link selection**—If multiple links with the same preference meet the requirements of a flow template, RIR selects one optimal link for each session of the flow template from these links. In this mode, RIR performs link selection based on the remaining bandwidth weight of each link. The used bandwidth is the actually used bandwidth plus the per-session expected bandwidth.
- **For bandwidth tolerant link selection**—If multiple links meet the requirements of a flow template, RIR selects one optimal link for each session of the flow template from these links. In this scenario, RIR performs link selection based on the total bandwidth weight of each link.

For more information about the preference-based primary or backup link selection, quality tolerant link selection, and bandwidth tolerant link selection, see "RIR working mechanisms."

Per-session periodic link adjustment mode

The mechanisms of the per-session periodic link adjustment mode are as follows:

- **For preference-based primary link selection, preference-based backup link selection, and quality tolerant link selection**—If multiple links with the same preference meet the requirements of a flow template, RIR selects one optimal link for each session of the flow template from these links. RIR preferentially selects the link with the lowest bandwidth usage for a session. The used bandwidth is the actually used bandwidth plus the per-session expected bandwidth.
- **For bandwidth tolerant link selection**—If multiple links meet the requirements of a flow template, RIR selects one optimal link for each session of the flow template from these links. The link selected the last time for a session takes precedence over the other links for that session. If RIR performs link selection for a session for the first time, it selects a link based on the remaining bandwidth weights of the available links.

In per-session periodic link adjustment mode, the device periodically detects the bandwidth usage of all links that have RIR sessions at the configured adjustment intervals. RIR reselect links for sessions that match a flow template if the links in the flow template meet the following requirements: The difference between the largest remaining bandwidth ratio and the smallest remaining bandwidth ratio becomes larger than or equal to the periodic adjustment upper threshold. The link adjustment might be last for several adjustment intervals. RIR stops link adjustment if one of the following requirements is met:

- The difference between the largest remaining bandwidth ratio and the smallest remaining bandwidth ratio of the links becomes smaller than the periodic adjustment lower threshold.
- The adjustment interval is the 20th interval after link reselection is triggered.

Per-packet mode

The mechanisms of the per-packet mode are as follows:

- **For preference-based primary link selection, preference-based backup link selection, and quality tolerant link selection**—If multiple links with the same preference meet the requirements of a session, all these links are candidate optimal links for this session. When forwarding traffic for the session, the device distributes the traffic to these links packet by packet according to the remaining bandwidth weight of each link.

  For example, the device needs 10 Mbps of bandwidth to transmit traffic for a session with flow ID 1. Links 1 and 2 are available. The remaining bandwidth of link 1 is 20 Mbps and the remaining bandwidth of link 2 is 30 Mbps. Finally, the traffic of this session uses 4 Mbps of bandwidth on link 1 and 6 Mbps of bandwidth on link 2.

- **For bandwidth tolerant link selection**—If multiple links meet the requirements of a session, all these links are candidate optimal links for this session. When forwarding traffic for the session, the device distributes the traffic to these links packet by packet. Each link has the same probability to be selected.

Link selection delay and suppression

To improve packet forwarding efficiency, the device does not repeatedly perform link selection for traffic of the same session. After the device performs link selection for traffic of a session, it forwards the subsequent traffic of that session according to the previous link selection result. Link reselection is triggered when any link in the session's flow template has one of the following changes:

- The quality of a link becomes qualified from unqualified or the quality of a link becomes unqualified from qualified.
- The bandwidth usage of a link has reached the maximum.

To avoid frequent link selection caused by link flapping, RIR defines a link selection delay and link selection suppression period.

After the device performs link selection, it starts the link selection suppression period if the period has been configured. Within the link selection suppression period, the device does not perform link reselection, but it maintains the link state data. When the link selection suppression period ends, the link selection delay timer starts. If the link state still meets the conditions that can trigger link reselection when the delay timer expires, the device performs link reselection. If the link state changes to not meet the conditions that can trigger link reselection within the delay time, the device does not perform link reselection.

RIR collaboration

About RIR collaboration

RIR collaboration enables multiple RIR-capable devices to share link data, load share traffic, and realize distributed link schedule through establishing RIR dedicated links between each pair of them.

Network structure

As shown in Figure 7, RIR collaboration has the following concepts:

- **RIR collaboration device group**—Contains a group of devices that collaboratively select links. Each pair of devices in an RIR collaboration device group are peer devices to each other. They share links for RIR.

  Typically, devices in the same RIR collaboration device group are deployed in the same physical area, for example, the same equipment room or campus.

  - A group of hubs can form an RIR collaboration hub group.
  - A group of spokes can form an RIR collaboration spoke group.

  An RIR collaboration device group acts as a logical device. The logical device can form a hub-spoke network with RIR collaboration device groups or physical devices.

- **RIR collaboration link group**—Contains a group of links that connect an RIR collaboration device group and another RIR collaboration device group or a physical device (hub or spoke). As shown in Figure 7, RIR collaboration link groups 1 and 2 connect the RIR collaboration hub group to a spoke and an RIR collaboration spoke group, respectively.
- **Local packets and peer packets**—In RIR collaboration, the packets firstly processed by the local device are called local packets and the packets firstly processed by the peer device are called peer packets. Devices in an RIR collaboration device group use different link selection

policies to process local packets and peer packets. If a device does not belong to an RIR collaboration device group, all service packets received by the device are local packets.

Figure 7 RIR collaboration network structure

Spoke
RIR collaboration spoke group

Working mechanism

The RIR collaboration mechanism is as follows:

1. After each pair of devices in an RIR collaboration device group establish RIR collaboration relationship, the device with a lower IP address acts as the client. The client initiates a TCP connection to the peer device.
2. Through TCP connections, a device synchronizes the configuration and status data of local links that meet the service requirements to its peer devices. The data does not include the link data synchronized from other devices in the same RIR collaboration device group. As a result, the devices in the RIR collaboration device group can obtain link information from one another, and can update link information in real time.
3. When a device in the RIR collaboration device group receives a service packet for a session, it handles the packets as shown in Table 2.

Table 2 Collaborative link selection policies

Packet condition	Are routes available to forward the packet	Collaborative link selection policies
Local packet and received for the first time	Yes	If the optimal link information exists for the session, the local device forwards the packet according to the information. If no optimal link information exists for the session, the local device examines all links in the same flow template on the local device and peer devices. Then, the local device selects the most suitable link for the packet. • If the selected link is a link on the local device, the local device directly forwards the packet.

Packet condition	Are routes available to forward the packet	Collaborative link selection policies
		• If the selected link is a link on a peer device, the local device forwards the packet to the peer device.
Local packet and received for the first time	No	The local device selects a peer device in the same RIR collaboration device group and forwards the packet to the peer device.
Local packet but not received for the first time	Yes	The packet is forwarded to a peer device, and then the peer device returns the packet back to the local device because it does not have a route to forward the packet. After the packet is returned back, the local device only examines the local links in order to find the most suitable link to forward the packet. The local device performs link reselection for the session every 60 seconds. This ensures that the traffic of the session can be switched to the peer device in time after the routes on the peer device recover.
Local packet but not received for the first time	No	The local device selects a peer device to which it has never forwarded the traffic of the session and forwards the packet to the peer device. If no such a peer device is available, the local device discards the packet.
Peer packet	Yes	If the optimal link information exists for the session, the local device forwards the packet according to the information. If no optimal link information exists for the session, the local device selects the most suitable link from the local links to forward the packet.
Peer packet	No	The local device returns the packet back to the original peer device.

RIR working mechanisms

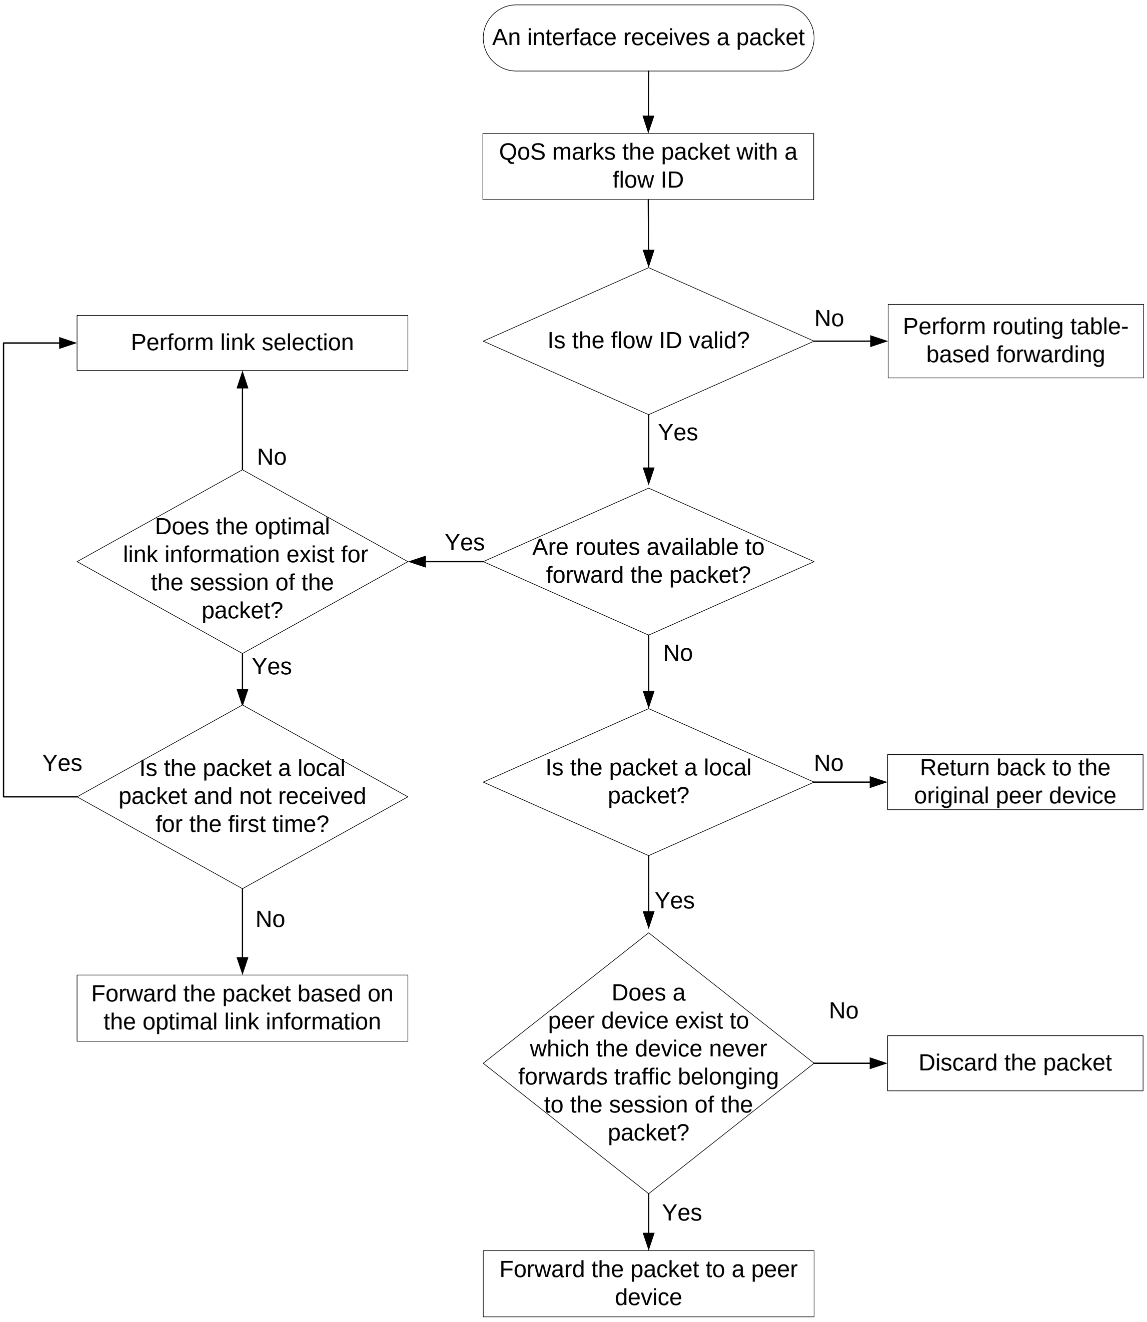
Preparation

When the device receives a packet on an interface, it handles the packet as follows:

1. Uses QoS to mark the packet with a flow ID based on the quintuple and DSCP of the packet.
2. Identifies whether the flow ID of the packet is valid.
   - If the flow ID is invalid, the device performs routing table-based forwarding for the packet.
   - If the flow ID is valid, go to the next step.
3. Performs a routing table lookup to identify whether routes are available to forward the packet.
   - If no route is available, the device identifies whether the packet is a local packet.
     - If the packet is not a local packet, the device returns the packet back to the original peer device.
     - If the packet is a local packet, the device selects a peer device to which it has never forwarded traffic for the packet's session and forwards the packet to the peer device. If no such a peer device is available, the device discards the packet.
   - If routes are available, go to the next step.
4. Examines whether the optimal link information exists for the session of the packet.

- If the optimal link information exists, the device forwards the packet based on the information.
- If no optimal link information exists, the device performs link selection for the packet.

Figure 8 RIR preparation



An interface receives a packet
QoS marks the packet with a flow ID
Is the flow ID valid?
No
Perform routing table-based forwarding
Yes
Are routes available to forward the packet?
Yes
Does the optimal link information exist for the session of the packet?
No
Perform link selection
Yes
Is the packet a local packet and not received for the first time?
Yes
No
Forward the packet based on the optimal link information
No
Is the packet a local packet?
No
Return back to the original peer device
Yes
Does a peer device exist to which the device never forwards traffic belonging to the session of the packet?
No
Discard the packet
Yes
Forward the packet to a peer device

Link selection workflow summary

RIR uses the following workflow to select a link to forward a packet:

1. Selects the flow template that has the same flow ID as the packet.
2. Selects the most suitable link from the links in the flow template by using the following criteria in order:
   a. Preference-based primary link selection.

   b. Preference-based backup link selection.
   c. Quality tolerant link selection.
   d. Bandwidth tolerant link selection.

   If the packet is a local packet and is received for the first time, the candidate links also include the links synchronized from RIR collaboration peer devices in the same flow template.

   If the packet is a peer packet or the packet is a local packet but is not received for the first time, the candidate links only include links on the local device.

3. If a link is found suitable, RIR returns the link selection result and stops searching other links. If no link is found suitable for a criterion, RIR uses the next criterion to select links. If RIR fails to find a suitable link by using all criteria, it determines that no link is suitable and returns the link selection result.
4. If no suitable link is found, the device performs forwarding based on the routing table. If a suitable link is found, RIR forwards the packet based on the link selection result.
   - If the most suitable link belongs to the local device, the device directly forwards the packet through the link.
   - If the most suitable link belongs to a peer device in the RIR collaboration device group, the device forwards the packet to the peer device.

After finishing link selection, the device associates the quintuple of the packet with the most suitable link and records the association as the optimal link information for the session. The device forwards the subsequent packets of the same session based on the optimal link information. If no traffic is received for the session for a period of time, the device will delete the optimal link information.

Figure 9 RIR link selection workflow

Link selection workflow

Preference-based primary link selection

RIR preferentially selects primary links that meet both the quality and bandwidth requirements for a service flow that matches a flow template. As shown in Figure 10, the device selects a primary link from the primary links in the flow template by examining the links in descending order of link preference. The device uses the following process to examine links with the same preference:

1. The device examines all links with the preference and identifies whether a link forms ECMP routes with other links. If a link forms ECMP routes with other links, the device further identifies whether the link is a primary link that meets both the quality and bandwidth requirements of the service.
    - If yes, the device adds the link to the available suitable link list of that preference.
    - If no, the device further identifies whether the link is a primary link that meets the bandwidth requirements of the service.
        - If yes, the device adds the link to the quality tolerant link list for quality tolerant link selection. Then, the device continues to examine other links with the same preference.
        - If no, the device continues to examine other links with the same preference.

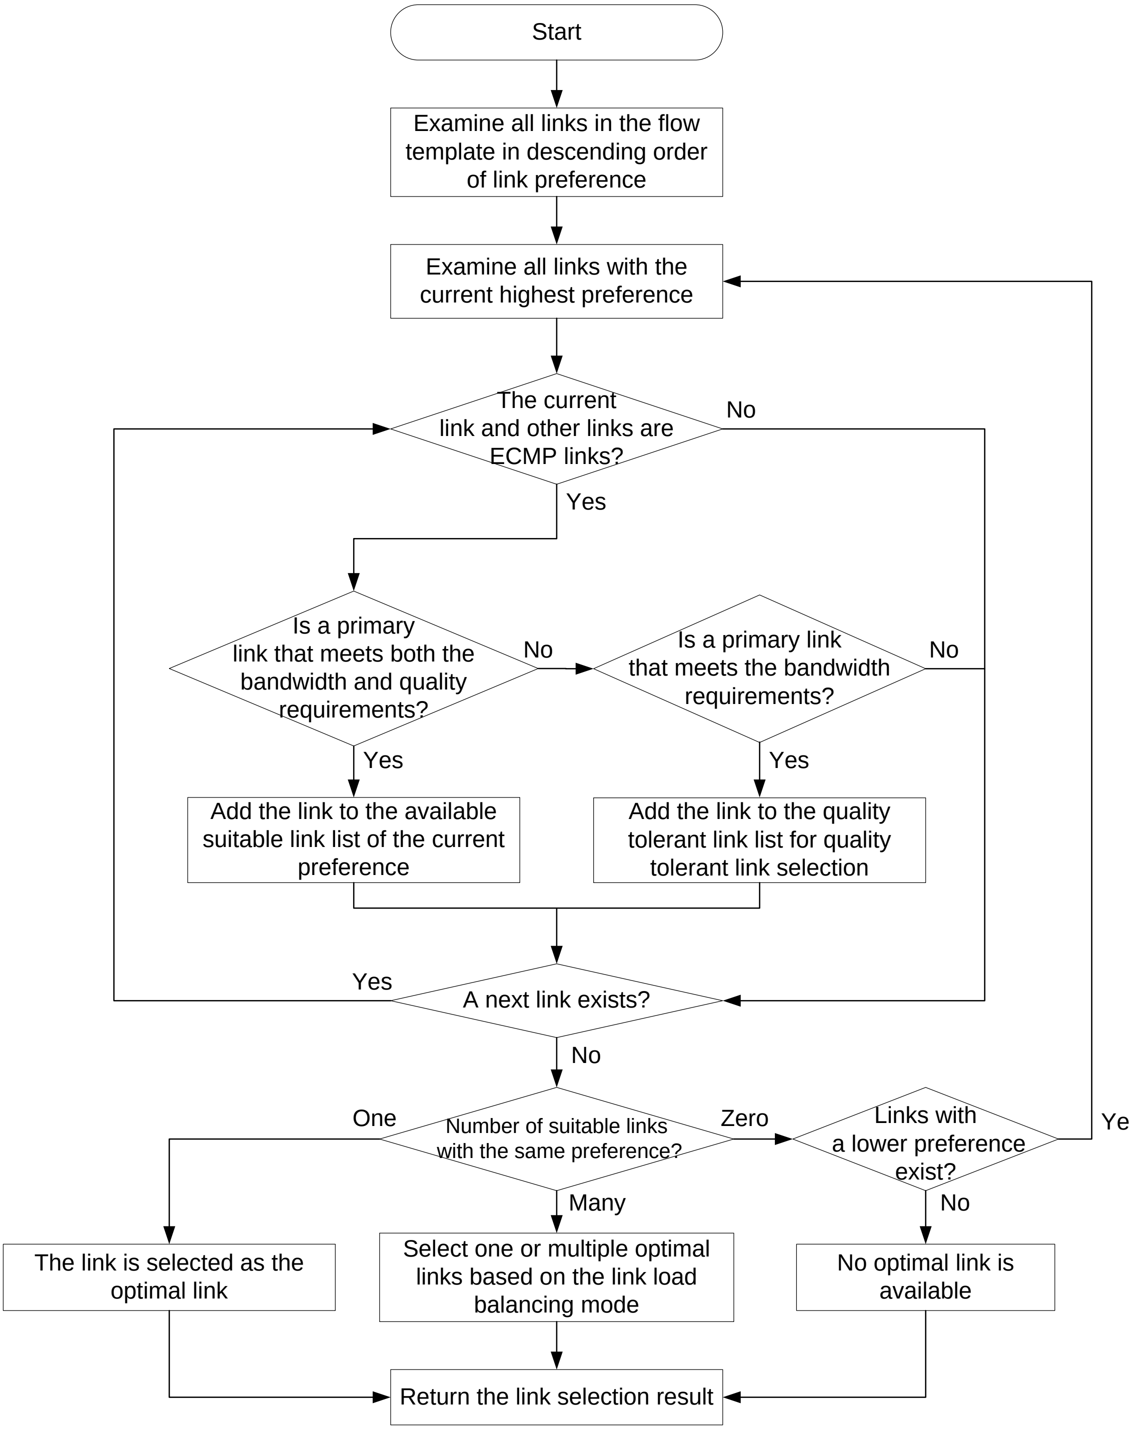
    If a link does not form ECMP routes with other links, the device continues to examine other links with the same preference.
2. When the device finishes examining all links with the preference, it identifies how many suitable links are available for the service flow.

- If only one suitable link is available, the device selects that link as the optimal link.
- If multiple suitable links are available, the device selects one or multiple optimal links from them based on the link load balancing mode. In a per-session load balancing mode, the device selects only one link as the optimal link of a session. In the per-packet load balancing mode, the device can select multiple links as the optimal links of a session.
- If no suitable link is available, the device examines the links that have a preference value lower than the links with the current preference.

If no primary links in the flow template are suitable, the device determines that no optimal primary link is found for the service flow.

For more information about identifying whether a link meets the quality requirements, see "Quality-based link selection." For more information about identifying whether a link meets the bandwidth requirements, see "Bandwidth-based link selection."

Figure 10 Preference-based primary link selection workflow



Start
Examine all links in the flow template in descending order of link preference
Examine all links with the current highest preference
The current link and other links are ECMP links?
No
Yes
Is a primary link that meets both the bandwidth and quality requirements?
No
Is a primary link that meets the bandwidth requirements?
No
Yes
Yes
Add the link to the available suitable link list of the current preference
Add the link to the quality tolerant link list for quality tolerant link selection

Zero
Links with a lower preference exist?
Yes
Many
No
The link is selected as the optimal link
Select one or multiple optimal links based on the link load balancing mode
No optimal link is available
Return the link selection result

Preference-based backup link selection

If no primary link is suitable for a service flow, the device tries to find a backup link that meets both the quality and bandwidth requirements for the flow in the flow template. The link selection process is the same as that for selecting a primary link.

Quality tolerant link selection

If preference-based link selection fails to select a suitable link from both primary and backup links, the device performs quality tolerant link selection.

The links that meet the quality tolerant link selection criterion are those added to the quality tolerant link list during preference-based primary and backup link selection. These links do not meet the quality requirements of the service, but they meet the bandwidth requirements of the service. Quality tolerant link selection selects a link from the links that meet only the bandwidth requirements of the service.

If multiple quality tolerant links are available, the device selects one or multiple optimal links from them based on the link load balancing mode.

Bandwidth tolerant link selection

If quality tolerant link selection still cannot find a suitable link for a service flow, the device performs bandwidth tolerant link selection. Bandwidth tolerant link selection selects one link from ECMP routes in the flow template as the optimal link.

If multiple links are available, the device selects one or multiple optimal links from them based on the link load balancing mode.

Restrictions: Hardware compatibility with RIR

Models	RIR compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB1180, NFNX3-HDB1480	No

Restrictions and guidelines: RIR configuration

When a link has a large amount of traffic, do not change the link selection policy for that link. For example, change the link preference. If you change the link selection policy, the system might fail to perform link selection as expected. As a best practice, change the link selection policy for a link when the link does not have traffic or when the link has a small amount of traffic.

RIR tasks at a glance

Spoke configuration tasks at a glance

To configure RIR on a spoke, perform the following tasks:

1. Enabling the RIR process
2. Configuring a spoke
   - Enabling the RIR client
   - Specifying an RIR client synchronization port
   - Enabling the NQA client
   - (Optional.) Configuring NQA link connectivity probe parameters

- Configuring an NQA link quality operation
- Configuring an SLA

3. Configuring link attributes
   - Assigning a link type and index to a VSI interface
   - Configuring the link bandwidth of a VXLAN tunnel interface
   - (Optional.) Configuring RIR backup links
4. Configuring a flow template
   - Creating a flow template
   - Configuring a quality policy for the flow template
   - (Optional.) Specifying the per-session expected bandwidth
   - Specifying link preference values for links
5. (Optional.) Configuring the link load balancing mode
   - Setting the per-session periodic link adjustment mode
   - Setting the per-packet load balancing mode

   By default, the per-session weight-based link selection mode is used.
6. (Optional.) Configuring flow priority-based traffic scheduling
7. (Optional.) Setting the link selection delay and link selection suppression period
8. Configuring a QoS policy to mark matching packets with a flow ID
   a. Creating a traffic class and defining packet match criteria
   b. Creating a traffic behavior and configuring a flow ID marking action
   c. Configuring a QoS policy
   d. Applying the QoS policy to an interface
9. (Optional.) Configuring RIR collaboration
   a. Setting up RIR dedicated links between local and peer devices
   b. Applying QoS policies to interfaces interconnecting local and peer devices
   c. Assigning links to an RIR collaboration link group
   d. Establishing RIR collaboration relationship for each pair of local and peer devices
   e. Configuring RIR packet redirection
10. (Optional.) Enabling RIR logging
11. (Optional.) Configuring flow ID-based traffic rate statistics for tunnels

Hub configuration tasks at a glance

To configure RIR on a hub, perform the following tasks:

1. Enabling the RIR process
2. Configuring a hub
   - Enabling the RIR server
   - Specifying an RIR server synchronization port
   - Configuring the NQA server
   - (Optional.) Creating an SLA and an NQA link quality operation
3. Configuring link attributes
   - Assigning a link type and index to a VSI interface
   - Configuring the link bandwidth of a VXLAN tunnel interface
   - (Optional.) Configuring RIR backup links

4. Configuring a flow template
   - Creating a flow template
   - Configuring a quality policy for the flow template
   - (Optional.) Specifying the per-session expected bandwidth
   - Specifying link preference values for links
5. (Optional.) Configuring the link load balancing mode
   - Setting the per-session periodic link adjustment mode
   - Setting the per-packet load balancing mode

   By default, the per-session weight-based link selection mode is used.
6. (Optional.) Configuring flow priority-based traffic scheduling
7. (Optional.) Setting the link selection delay and link selection suppression period
8. Configuring a QoS policy to mark matching packets with a flow ID
   a. Creating a traffic class and defining packet match criteria
   b. Creating a traffic behavior and configuring a flow ID marking action
   c. Configuring a QoS policy
   d. Applying the QoS policy to an interface
9. (Optional.) Configuring RIR collaboration
   a. Setting up RIR dedicated links between local and peer devices
   b. Applying QoS policies to interfaces interconnecting local and peer devices
   c. Assigning links to an RIR collaboration link group
   d. Establishing RIR collaboration relationship for each pair of local and peer devices
   e. Configuring RIR packet redirection
10. (Optional.) Enabling RIR logging
11. (Optional.) Configuring flow ID-based traffic rate statistics for tunnels

Prerequisites for RIR configuration

Make sure the hub and each spoke have a minimum of two ECMP routes to reach each other.

Enabling the RIR process

1. Enter system view.
   ```
   system-view
   ```
2. Enable the RIR process and enter RIR view.
   ```
   rir
   ```
   By default, the RIR process is disabled.

Configuring a spoke

Enabling the RIR client

About this task

To avoid NQA probes from occupying too many resources on a hub in a hub-spoke network, configure the hub as an RIR server and configure the spokes as RIR clients.

You can enable the RIR client globally or on an interface.

- Enabling the RIR client globally also enables the RIR client for all interfaces on the device. The interfaces can send link quality probe results for the RIR client.
- Enabling the RIR client on an interface allows only that interface to send link quality probe results for the RIR client.

Restrictions and guidelines

When you enable the RIR client, follow these restrictions and guidelines:

- In a VXLAN network, only tunnel interfaces support enabling the RIR client. The RIR client uses the tunnel interfaces to send link quality probe results.
- The RIR server and RIR client cannot be both enabled on the same interface.
- If the enabled role (RIR server or client) on an interface is different from the globally enabled role, the interface-specific role takes effect on that interface.

Procedure

1. Enter system view.

   system-view

2. Enable the RIR client. Perform the following tasks as needed:
   - Execute the following commands in sequence to enable the RIR client globally:

     rir

     client enable
   - Execute the following commands in sequence to enable the RIR client on a VXLAN tunnel interface:

     interface tunnel *tunnel-number*

     rir role client

   By default, the RIR client is disabled globally and on an interface.

Specifying an RIR client synchronization port

About this task

Perform this task to specify a port for an RIR client to synchronize link quality probe results to RIR servers.

Restrictions and guidelines

Specify the same synchronization port on the RIR client and server for successful synchronization of link quality probe results.

Procedure

1. Enter system view.

   system-view

2. Enter RIR view.

   rir

3. Specify a port for the RIR client to synchronize probe information to RIR servers.

   probe sync-port *port-number*

   By default, no port is specified for an RIR client to synchronize probe information to RIR servers.

Enabling the NQA client

About this task

An RIR client also acts as an NQA client. You must enable the NQA client on a spoke to ensure that NQA link connectivity probes and link quality probes can be performed correctly.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable the NQA client.

   ```
   nqa agent enable
   ```

   By default, the NQA client is disabled.

   For more information about this command, see NQA commands in *Network Management and Monitoring Command Reference*.

Configuring NQA link connectivity probe parameters

About this task

An NQA client starts NQA link connectivity probes on all links configured on flow templates after RIR is enabled. A spoke (NQA client) performs consecutive probes at intervals as configured and waits for responses for the packets. If the client does not receive any responses when the probe packet timeout timer expires, a link connectivity issue exists.

In a VXLAN network, the NQA link connectivity probe targets are the VXLAN tunnel interfaces enabled with the RIR client.

A link connectivity probe packet uses the source IP address of a VXLAN tunnel as its source IP address and uses the tunnel destination IP address as its destination IP address.

Restrictions and guidelines

Setting a shorter probe interval obtains more precise probe results but requires more system resources.

Set a shorter probe packet timeout time if the requirement for link quality is high.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter RIR view.

   ```
   rir
   ```

3. Configure NQA link connectivity probe parameters.

   ```
   probe connect interval interval timeout timeout
   ```

   By default, the NQA probe interval is 100 milliseconds and the NQA packet timeout time is 3000 milliseconds.

Configuring an NQA link quality operation

About this task

An NQA link quality operation allows a flow template to start UDP jitter probes based on the probe parameters in the operation in order to detect the quality of links.

You can configure a quality policy for a flow template to associate the flow template with an SLA and an NQA link quality operation. The device monitors the quality of links in the flow template based on the NQA link quality operation and compares the NQA probe results with the thresholds in the SLA. If all parameter values in the probe results of a link are lower than or equal to the thresholds in the SLA, the link is qualified for the flow.

To differentiate service flows that have different link quality requirements, associate the flow templates with NQA link quality operations that contain different probe parameter values. Two NQA link quality operations with different probe parameter values might offer different probe results for the same link.

In a VXLAN network, the NQA link quality probe targets are the VXLAN tunnel interfaces enabled with the RIR client.

A link quality probe packet uses the source IP address of a VXLAN tunnel as its source IP address and uses the tunnel destination IP address as its destination IP address.

Restrictions and guidelines

NQA link quality probes are used in conjunction with the NQA server and client features. For a spoke (NQA client) to perform NQA link quality probes, make sure UDP listening services have been configured on the NQA server.

Procedure

1. Enter system view.
   system-view
2. Enter RIR view.
   rir
3. Create an NQA link quality operation and enter its view.
   nqa *nqa-id*
4. Configure NQA link quality probe parameters.
   - Set the intervals at which the NQA client performs consecutive probes.
     probe interval *interval*

     By default, the NQA link quality probe interval is 100 milliseconds.
   - Set the DSCP value of NQA link quality probe packets.
     probe packet-dscp *dscp-value*

     By default, the DSCP value of NQA link quality probe packets is 63.
   - Set the number of NQA link quality probe packets sent per probe.
     probe packet-number *number*

     By default, 100 NQA link quality probe packets are sent per probe.
   - Set the intervals at which NQA link quality probe packets are sent.
     probe packet-interval *interval*

     By default, NQA link quality probe packets are sent at intervals of 20 milliseconds.
   - Set the timeout time for waiting for a response to an NQA link quality probe packet.
     probe packet-timeout *packet-timeout*

     By default, the timeout time is 3000 milliseconds.
   - Specify a destination port for NQA link quality probes.
     probe port *port-number*

     By default, no destination port is specified for NQA link quality probes.

     To correctly perform NQA link quality probes, the destination port number must be the same as the listening port on the NQA server.

Configuring an SLA

About this task

You can specify an SLA and NQA link quality operation for a flow template. The device monitors the quality of links in the flow template based on the NQA link quality operation and compares the NQA probe results with the thresholds in the SLA. The device selects only links that meet the quality requirements of the SLA for traffic that matches the flow template.

Perform this task to create an SLA and configure its link quality thresholds. Two SLAs might offer different quality results for the same NQA link quality operation.

Procedure

1. Enter system view.
   `system-view`
2. Enter RIR view.
   `rir`
3. Create an SLA and enter its view.
   `sla` *`sla-id`*
4. Configure NQA link quality thresholds.
   - Configure the link delay threshold.
     `delay threshold` *`threshold-value`*
     By default, the link delay threshold is 10 milliseconds.
   - Configure the link jitter threshold.
     `jitter threshold` *`threshold-value`*
     By default, the link jitter threshold is 100 milliseconds.
   - Configure the packet loss threshold.
     `packet-loss threshold` *`threshold-value`*
     By default, the packet loss threshold is 100‰.

Configuring a hub

Enabling the RIR server

About this task

To avoid NQA probes from occupying too many resources on a hub in a hub-spoke network, configure the hub as an RIR server and configure the spokes as RIR clients.

You can enable the RIR server globally or on an interface.

- Enabling the RIR server globally also enables the RIR server for all interfaces on the device. The interfaces can receive link quality probe results synchronized from RIR clients.
- Enabling the RIR server on an interface allows only that interface to receive link quality probe results synchronized from RIR clients.

Restrictions and guidelines

When you enable the RIR server, follow these restrictions and guidelines:

- In a VXLAN network, only tunnel interfaces support enabling the RIR server. The RIR server uses the tunnel interfaces to receive link quality probe results synchronized from RIR clients.
- The RIR server and RIR client cannot be both enabled on the same interface.

- If the enabled role (RIR server or client) on an interface is different from the globally enabled role, the interface-specific role takes effect on that interface.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable the RIR server. Perform the following tasks as needed:
   - Execute the following commands in sequence to enable the RIR server globally:
     ```
     rir
     server enable
     ```
   - Execute the following commands in sequence to enable the RIR server on a VXLAN tunnel interface:
     ```
     interface tunnel tunnel-number
     rir role server
     ```

   By default, the RIR server is disabled globally and on an interface.

Specifying an RIR server synchronization port

About this task

Perform this task to specify a port for an RIR server to receive link quality probe results synchronized from RIR clients.

Restrictions and guidelines

Specify the same synchronization port on the RIR client and server for successful synchronization of link quality probe results.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enter RIR view.
   ```
   rir
   ```
3. Specify a port for receiving probe information synchronized from RIR clients.
   ```
   probe sync-port port-number
   ```
   By default, no port is specified for receiving probe information synchronized from RIR clients.

Configuring the NQA server

About this task

A hub that acts as an RIR server also acts as an NQA server. To ensure that NQA link connectivity probes can be performed correctly, you must enable the NQA server on the hub. To ensure that NQA link quality probes can be performed correctly, configure UDP listening services.

Restrictions and guidelines

The listening port specified on the hub (NQA server) must be the same as the destination port number specified in NQA link quality operations on the spokes (NQA clients). In addition, make sure the port is not used by any other services.

Procedure

1. Enter system view.

```
system-view
```

2. Enable the NQA server.

   ```
   nqa server enable
   ```

   By default, the NQA server is disabled.

   For more information about this command, see NQA commands in *Network Management and Monitoring Command Reference*.

3. Configure a UDP listening service for the NQA server to listen to a port on an IP address.

   ```
   nqa server udp-echo ip-address port-number [ vpn-instance
   vpn-instance-name ] [ tos tos ]
   ```

   For more information about this command, see NQA commands in *Network Management and Monitoring Command Reference*.

Creating an SLA and an NQA link quality operation

About this task

When you configure the quality policy of a flow template on a hub, you must specify an SLA and an NQA link quality operation. Perform this task to create the SLA and NQA link quality operation specified in the quality policy. On the hub, you do not need to configure the parameters in the SLA and NQA link quality operation. If you configure these parameters, the configuration does not take effect. For more information about quality policy configuration, see "Configuring a quality policy for the flow template."

Restrictions and guidelines

If you do not plan to configure the quality policy of a flow template on a hub, you do not need to create an SLA and NQA link quality operation.

The hub and spoke can have different SLA and NQA link quality operation settings in the quality policy of the same flow template. The difference does not affect the execution and application of the quality policy. As a best practice to identify the quality policy, configure the same SLA and NQA link quality operation on the hub and spoke.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter RIR view.

   ```
   rir
   ```

3. Create an SLA and enter its view.

   ```
   sla sla-id
   ```

4. Return to RIR view.

   ```
   quit
   ```

5. Create an NQA link quality operation and enter its view.

   ```
   nqa nqa-id
   ```

Configuring link attributes

Assigning a link type and index to a VSI interface

About this task

The link type and link index together uniquely identify a link between a hub and a spoke. For a flow template to use a link, you must assign a link type and index to the link. Perform this task to configure the link type as 4G, Internet, MPLS, or MSTP. The link type only marks the network type of the link and it does not affect packet encapsulation.

VXLAN-based RIR allows a hub and a spoke to have only one VXLAN tunnel for a VSI interface (a VXLAN). By assigning a link type and index to the VSI interface, RIR can identify the VXLAN tunnel between the hub and spoke.

A VSI interface on a hub (or spoke) can have a VXLAN tunnel to each spoke (or hub). The VXLAN tunnels of the same VSI interface are assigned the same link type and link index.

Restrictions and guidelines

Only 4G, Internet, MPLS, and MSTP link types are supported.

The link type is used only for identifying links, and it does not affect packet encapsulation.

A VSI interface can be associated only with one link type.

You must assign different link indexes to the same type of links on different VSI interfaces.

Procedure

1. Enter system view.

   system-view

2. Enter VSI interface view.

   interface vsi-interface *vsi-interface-id*

3. Assign a link type and index to the VSI interface.

   rir link-type { **4g** | **internet** | **mpls** | **mstp** } **index** *link-index*

   By default, no link type or index is assigned to a VSI interface.

Configuring the link bandwidth of a VXLAN tunnel interface

1. Enter system view.

   system-view

2. Enter VXLAN tunnel interface view.

   interface tunnel *tunnel-number*

3. Configure the expected link bandwidth of the VXLAN tunnel interface.

   bandwidth *bandwidth-value*

   The default expected bandwidth (in kbps) is the interface maximum rate divided by 1000.

   The expected bandwidth is an informational parameter used only by higher-layer protocols for calculation. You cannot adjust the actual bandwidth of an interface by using this command.

   For more information about this command, see tunneling commands in *Layer 3—IP Services Command Reference*.

Configuring RIR backup links

About this task

The links between a spoke and a primary hub are typically primary links, and the links between a spoke and a backup hub are typically backup links. RIR selects qualified primary links prior to qualified backup links.

In a VXLAN network, the links (VXLAN tunnels) that are assigned link preference values are primary links by default. If you configure a VXLAN tunnel as an RIR backup tunnel, RIR uses the VXLAN tunnel as an RIR backup link.

Restrictions and guidelines

Configure VXLAN tunnels as backup links depending on the network requirements. You can configure a VXLAN tunnel between a spoke and a primary hub as a backup link.

Procedure

1. Enter system view.

   `system-view`

2. Enter VXLAN tunnel interface view.

   `interface tunnel` *`number`*

3. Configure the tunnel as an RIR backup tunnel.

   `rir backup`

   By default, a tunnel is an RIR primary tunnel.

Configuring a flow template

About flow template configuration

Configure a flow template to determine the link selection policies for a type of service flow.

Creating a flow template

About this task

To define link selection policies for a type of service flow, you can create a flow template and configure link selection policies in the flow template. By marking the type of service flow with the flow ID of the flow template, the device can use the link selection policies in the flow template to select links for that type of service flow.

Procedure

1. Enter system view.

   `system-view`

2. Enter RIR view.

   `rir`

3. Create a flow template and enter its view.

   `flow` *`flow-id`*

Configuring a quality policy for the flow template

About this task

If you configure the quality policy of a flow template on a hub, the hub performs link quality detection based on the link quality probe results synchronized from spokes. If you do not configure the quality policy on the spokes for the same flow template, the hub cannot obtain link quality probe results from any spokes. Because the hub does not perform link quality probe on its own, it determines that all links in the flow template fail quality detection.

If you do not configure the quality policy of a flow template on a hub, the hub determines that all links in the flow template meet the service quality requirements.

Procedure

1. Enter system view.

   `system-view`

2. Enter RIR view.

   `rir`

3. Enter flow template view.

   `flow` *`flow-id`*

4. Configure a quality policy for the flow template.

   `quality-policy sla` *`sla-id`* **`nqa`** *`nqa-id`*

   By default, no quality policy is configured for a flow template.

   The specified SLA and NQA link quality operation must already exist.

Specifying the per-session expected bandwidth

About this task

To select a link for traffic of a session, a device first performs bandwidth detection based on the per-session expected bandwidth in the flow template to which the session belongs. If the used bandwidth plus the per-session expected bandwidth of a candidate link is less than 80% of its total bandwidth, the current available bandwidth of the candidate link meets the session bandwidth requirements. The link passes the bandwidth detection.

The per-session expected bandwidth is not the actual bandwidth of a session. It is only a value estimated based on the user services.

Procedure

1. Enter system view.

   `system-view`

2. Enter RIR view.

   `rir`

3. Enter flow template view.

   `flow` *`flow-id`*

4. Specify the per-session expected bandwidth.

   `expect-bandwidth` *`bandwidth`*

   By default, the per-session expected bandwidth is 0 kbps.

Specifying link preference values for links

About this task

RIR preferentially selects links with higher preference for a type of service flow.

VXLAN-based RIR supports assigning a link preference to a type of links with a specific link index in flow template view. The link type and link index identify links on a VSI interface. As VXLAN-based RIR allows a hub and spoke to have only one VXLAN tunnel for a VSI interface, the link preference configured on the VSI interface is the link preference of the VXLAN tunnel between the hub and spoke.

Restrictions and guidelines

You can assign the same link preference value to links with different link types and indexes in the same flow template.

Procedure

1. Enter system view.

   system-view

2. Enter RIR view.

   rir

3. Enter flow template view.

   flow *flow-id*

4. Configure a link preference for the specified type of links with the specified link index.

   path link-type { **4g** | **internet** | **mpls** | **mstp** } **index** *link-index* **preference** *preference*

   By default, no link preference is configured for a type of links with a specific link index in a flow template.

Configuring the link load balancing mode

Restrictions and guidelines for link load balancing mode configuration

For a flow template, the per-packet load balancing mode takes precedence over the global per-session periodic link adjustment mode. If the per-packet load balancing mode is not enabled for a flow template, the flow template uses the global link load balancing mode.

Setting the per-session periodic link adjustment mode

1. Enter system view.

   system-view

2. Enter RIR view.

   rir

3. Set the link load balancing mode to the per-session periodic link adjustment mode.

   load-balance per-session periodic-adjust enable

   By default, the link load balancing mode is per-session weight-based link selection mode.

4. Set the adjustment interval for the per-session periodic link adjustment mode.

load-balance per-session periodic-adjust adjust-interval *interval-value*

By default, the adjustment interval for the per-session periodic link adjustment mode is 30 seconds.

5. Set the periodic adjustment thresholds in per-session periodic link adjustment mode.

   load-balance per-session periodic-adjust threshold upper *upper-threshold-value* **lower** *lower-threshold-value*

   By default, the periodic adjustment upper threshold is 50% and the periodic adjustment lower threshold is 20%.

   The periodic adjustment upper threshold must be greater than or equal to the periodic adjustment lower threshold.

Setting the per-packet load balancing mode

Restrictions and guidelines

Because packets of the same session are distributed to multiple links, the receiver might receive out-of-order packets. As a best practice, do not enable per-packet load balancing for order-sensitive services (except the services that use protocols to maintain a correct packet order, for example, TCP).

Procedure

1. Enter system view.

   system-view

2. Enter RIR view.

   rir

3. Enter flow template view.

   flow *flow-id*

4. Set the link load balancing mode to the per-packet mode.

   load-balance per-packet enable

   By default, the RIR global link load balancing mode applies.

Configuring flow priority-based traffic scheduling

About this task

To ensure that services with higher priority preferentially use link resources, enable flow priority-based traffic scheduling.

The priority of a flow that matches a flow template is determined by the ID of the SLA associated with that flow template. The greater the SLA ID is, the higher the flow priority. To specify an SLA for a flow template, use the **quality-policy** command. If the command is not configured in a flow template, flows that match the flow template have the lowest priority.

If flow priority-based traffic scheduling is enabled, traffic scheduling is triggered when the bandwidth usage of a link exceeds the upper threshold. The scheduling might be last for several scheduling periods. Within each scheduling period, RIR redistributes the current lowest priority flow on this link to other links. The scheduling does not stop until the bandwidth usage of all links for the current lowest priority flow is below the lower threshold or only the highest priority flow is left on this link.

Procedure

1. Enter system view.

   system-view

2. Enter RIR view.

   `rir`

3. Enable flow priority-based traffic scheduling.

   `flow priority-based-schedule enable`

   By default, flow priority-based traffic scheduling is disabled.

4. Set the scheduling period for flow priority-based traffic scheduling.

   `flow priority-based-schedule schedule-period` *`schedule-period-value`*

   By default, the scheduling period for flow priority-based traffic scheduling is 30 seconds.

5. Set the bandwidth usage thresholds for flow priority-based traffic scheduling.

   `flow priority-based-schedule bandwidth-threshold upper` *`upper-threshold`* **`lower`** *`lower-threshold`*

   By default, the bandwidth usage upper threshold is 90% and the bandwidth usage lower threshold is 20%.

   The upper threshold must be greater than or equal to the lower threshold.

Setting the link selection delay and link selection suppression period

1. Enter system view.

   `system-view`

2. Enter RIR view.

   `rir`

3. Set the link selection delay.

   `link-select delay` *`delay`*

   By default, the link selection delay is 60 seconds.

4. Set the link selection suppression period.

   `link-select suppress-period` *`period-value`*

   By default, no link selection suppression period is configured. The device does not start the link selection suppression period after a link selection.

   As a best practice, set the link selection suppression period to a multiple of the link selection delay time. Make sure the suppression period is at least double of the link selection delay time.

Configuring a QoS policy to mark matching packets with a flow ID

About configuring a QoS policy to mark matching packets with a flow ID

Apply a QoS policy to an interface to mark matching packets on the interface with a flow ID. RIR processes packets marked with a flow ID based on the flow template that uses the flow ID. For more information about QoS marking, see QoS overview, QoS policies, and marking configuration in *ACL and QoS Configuration Guide*.

Creating a traffic class and defining packet match criteria

1. Enter system view.

   system-view

2. Create a traffic class and enter its view.

   traffic classifier *classifier-name* [**operator** { **and** | **or** }]

3. Define packet match criteria, including the quintuple and DSCP.

   if-match [**not**] *match-criteria*

   By default, no packet match criteria are defined.

Creating a traffic behavior and configuring a flow ID marking action

1. Enter system view.

   system-view

2. Create a traffic behavior and enter its view.

   traffic behavior *behavior-name*

3. Configure the traffic behavior to mark matching traffic with the specified flow ID.

   remark flow-id *flow-id*

   By default, no flow ID marking action is configured.

Configuring a QoS policy

1. Enter system view.

   system-view

2. Create a QoS policy and enter its view.

   qos policy *policy-name*

3. Associate the traffic behavior with the traffic class in the QoS policy.

   classifier *classifier-name* **behavior** *behavior-name*

   By default, no traffic behavior is associated with a traffic class.

Applying the QoS policy to an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Apply the QoS policy to the inbound direction of the interface.

   qos apply policy *policy-name* **inbound**

   By default, no QoS policy is applied to an interface.

Configuring RIR collaboration

Restrictions and guidelines for RIR collaboration configuration

All devices that form an RIR collaboration device group must have independent RIR capabilities. They must mark the same type of service traffic with the same flow ID.

Perform the RIR collaboration tasks in this section on both the local and peer devices in an RIR collaboration device group.

Setting up RIR dedicated links between local and peer devices

Use RIR dedicated links to ensure that packets can be correctly forwarded between local and peer devices. You can configure direct routes or GRE tunnels as dedicated links as follows:

- For directly-connected peer devices, you can configure multiple physical interfaces or subinterfaces on the devices. The interfaces or subinterfaces will generate direct routes for packets in the public network and each VPN instance. For more information, see Ethernet interface configuration in *Interface Configuration Guide*.
- For indirectly-connected peer devices, manually configure GRE tunnels between them for packets in the public network and each VPN instance. For more information about GRE configuration, see *Layer 3—IP Services Configuration Guide*.

Applying QoS policies to interfaces interconnecting local and peer devices

Outgoing packets do not carry the flow ID marked in the RIR process. To mark a flow ID for received packets, apply a QoS policy to the interfaces interconnecting the local and peer devices. For more information, see "Configuring a QoS policy to mark matching packets with a flow ID."

Assigning links to an RIR collaboration link group

About this task

The local device can discover and select links synchronized from peer devices only after the links are assigned to an RIR collaboration link group. In the RIR collaboration link group, both local links and links synchronized from peer devices have the same destination.

Restrictions and guidelines

In an RIR collaboration device group, make sure all links to the same device or RIR collaboration device group are assigned to the same RIR collaboration link group.

In an RIR collaboration device group, make sure the links to different devices or RIR collaboration device groups are assigned to different RIR collaboration link groups.

In different RIR collaboration device groups, the links to the same device or RIR collaboration device group can be assigned to the same RIR collaboration link group. As a best practice to identify links, assign the links to different RIR collaboration link groups.

Procedure

1. Enter system view.

```
system-view
```

2. Enter VXLAN tunnel interface view.

```
interface tunnel number
```

3. Assign the VXLAN tunnel to an RIR collaboration link group.

```
rir collaboration-link-group group-id
```

By default, a VXLAN tunnel belongs to RIR collaboration link group 0.

Establishing RIR collaboration relationship for each pair of local and peer devices

About this task

Each pair of devices in an RIR collaboration device group must establish RIR collaboration relationship with each other for link data synchronization. After a pair of devices establish RIR collaboration relationship, the device with a lower IP address acts as the client to initiate a TCP connection to the other device. Through the TCP connection, the local device can synchronize the configuration and status data of links that meet the service requirements to the peer device. The data does not include the link data synchronized from other devices in the same RIR collaboration device group.

Restrictions and guidelines

The local and peer IP addresses used to establish RIR collaboration relationship must belong to the public network or the same VPN instance.

A pair of RIR collaboration devices can establish only one TCP connection to synchronize link data.

Procedure

1. Enter system view.

```
system-view
```

2. Enter RIR view.

```
rir
```

3. Enable the local device to establish RIR collaboration relationship with a peer device.

```
collaboration peer [ vpn-instance vpn-instance-name ]
peer-ipv4-address local local-ipv4-address sync-port port-number
```

By default, the local device does not establish RIR collaboration relationship with any device.

Configuring RIR packet redirection

About this task

For the local device to select links from a peer device, you must configure RIR packet redirection. Perform this task to specify the redirect IP address for packets redirected to the peer device on the public network or a VPN instance. When the local device selects links from the peer device to forward packets on the public network or a VPN instance, it performs the following operations:

1. Looks up the routing table of the public network or VPN instance based on the redirect IP address.
2. Forwards the packets to the peer device through the RIR dedicated link.

Procedure

1. Enter system view.

```
system-view
```

2. Enter RIR view.

rir

3. Specify the IP address to which the local device redirects packets forwarded to an RIR collaboration peer.

   collaboration peer [**vpn-instance** *vpn-instance-name*] **peer-ipv4-address redirect** [**vpn-instance** *redirect-vpn-instance-name*] *redirect-ipv4-address*

   By default, no IP address is specified for the local device to redirect packets forwarded to an RIR collaboration peer.

   The **vpn-instance** *vpn-instance-name* option specifies the VPN instance on which the local and peer devices establish RIR collaboration relationship. The **vpn-instance** *redirect-vpn-instance-name* option specifies a redirect VPN instance. When the local device selects a link from a peer device for forwarding traffic in the redirect VPN instance, the local device redirects the packets to the redirect IPv4 address.

Enabling RIR logging

About this task

RIR logs record events occurred during the RIR process, such as link selection and reselection, quality change, bandwidth change, configuration change, and link fault events. The logs help the administrator analyze, maintain, and adjust the RIR network.

RIR logs are flow logs. To output RIR logs, you must also configure flow log features. For more information about flow logs, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter RIR view.

   rir

3. Enable RIR logging.

   log enable

   By default, RIR logging is disabled.

Configuring flow ID-based traffic rate statistics for tunnels

About this task

This feature enables the device to periodically collect traffic rate statistics for tunnels on a flow ID basis.

Procedure

1. Enter system view.

   system-view

2. Enable flow ID-based traffic rate statistics for tunnels.

   tunnel flow-statistics enable

   By default, flow ID-based traffic rate statistics for tunnels is disabled.

3. (Optional.) Set the intervals at which the device collects flow ID-based traffic rate statistics for tunnels.

tunnel flow-statistics interval *interval*

By default, the device collects flow ID-based traffic rate statistics for tunnels at intervals of 300 seconds.

Display and maintenance commands for RIR

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display flow ID-based traffic rate statistics for tunnels.	**display tunnel flow-statistics** [**flow** *flow-id* [**interface tunnel** *number*]]
Clear flow ID-based traffic rate statistics for tunnels.	**reset tunnel flow-statistics** [**flow** *flow-id* [**interface tunnel** *number*]]

NSFOCUS Firewall Series

NF ACL and QoS

Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for ACL and QoS features, including ACL, QoS, and time range.
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
❗ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Configuring ACLs

About ACLs

An access control list (ACL) is a set of rules for identifying traffic based on criteria such as source IP address, destination IP address, and port number. The rules are also called permit or deny statements.

ACLs are primarily used for packet filtering. You can also use ACLs in QoS, security, routing, and other modules for identifying traffic. The packet drop or forwarding decisions depend on the modules that use ACLs.

Numbering and naming ACLs

When creating an ACL, you must assign it a number or name for identification. You can specify an existing ACL by its number or name. Each ACL type has a unique range of ACL numbers.

For basic or advanced ACLs with the same number, you must use the **`ipv6`** keyword to distinguish them. For ACLs with the same name, you must use the **`ipv6`** and **`mac`** keywords to distinguish them.

ACL types

Type	ACL number	IP version	Match criteria
Basic ACLs	2000 to 2999	IPv4	Source IPv4 address.
		IPv6	Source IPv6 address.
Advanced ACLs	3000 to 3999	IPv4	Source IPv4 address, destination IPv4 address, packet priority, protocol number, and other Layer 3 and Layer 4 header fields.
		IPv6	Source IPv6 address, destination IPv6 address, packet priority, protocol number, and other Layer 3 and Layer 4 header fields.
Layer 2 ACLs	4000 to 4999	IPv4 and IPv6	Layer 2 header fields, such as source and destination MAC addresses, 802.1p priority, and link layer protocol type.

Match order

The rules in an ACL are sorted in a specific order. When a packet matches a rule, the device stops the match process and performs the action defined in the rule. If an ACL contains overlapping or conflicting rules, the matching result and action to take depend on the rule order.

The following ACL match orders are available:

- **config**—Sorts ACL rules in ascending order of rule ID. A rule with a lower ID is matched before a rule with a higher ID. If you use this method, check the rules and their order carefully.
- **auto**—Sorts ACL rules in depth-first order. Depth-first ordering makes sure any subset of a rule is always matched before the rule. Table 1 lists the sequence of tie breakers that depth-first ordering uses to sort rules for each type of ACL.

Table 1 Sort ACL rules in depth-first order

ACL type	Sequence of tie breakers
IPv4 basic ACL	**1.** VPN instance. **2.** More 0s in the source IPv4 address wildcard (more 0s means a narrower IPv4 address range). **3.** Rule configured earlier.
IPv4 advanced ACL	**1.** VPN instance. **2.** Specific protocol number. **3.** More 0s in the source IPv4 address wildcard mask. **4.** More 0s in the destination IPv4 address wildcard. **5.** Narrower TCP/UDP service port number range. **6.** Rule configured earlier.
IPv6 basic ACL	**1.** VPN instance. **2.** Longer prefix for the source IPv6 address (a longer prefix means a narrower IPv6 address range). **3.** Rule configured earlier.
IPv6 advanced ACL	**1.** VPN instance. **2.** Specific protocol number. **3.** Longer prefix for the source IPv6 address. **4.** Longer prefix for the destination IPv6 address. **5.** Narrower TCP/UDP service port number range. **6.** Rule configured earlier.
Layer 2 ACL	**1.** More 1s in the source MAC address mask (more 1s means a smaller MAC address). **2.** More 1s in the destination MAC address mask. **3.** Rule configured earlier.

A wildcard mask, also called an inverse mask, is a 32-bit binary number represented in dotted decimal notation. In contrast to a network mask, the 0 bits in a wildcard mask represent "do care" bits, and the 1 bits represent "don't care" bits. If the "do care" bits in an IP address are identical to the "do care" bits in an IP address criterion, the IP address matches the criterion. All "don't care" bits are ignored. The 0s and 1s in a wildcard mask can be noncontiguous. For example, 0.255.0.255 is a valid wildcard mask.

Rule numbering

ACL rules can be manually numbered or automatically numbered. This section describes how automatic ACL rule numbering works.

Rule numbering step

If you do not assign an ID to the rule you are creating, the system automatically assigns it a rule ID. The rule numbering step sets the increment by which the system automatically numbers rules. For example, the default ACL rule numbering step is 5. If you do not assign IDs to rules you are creating, they are automatically numbered 0, 5, 10, 15, and so on. The wider the numbering step, the more rules you can insert between two rules.

By introducing a gap between rules rather than contiguously numbering rules, you have the flexibility of inserting rules in an ACL. This feature is important for a config-order ACL, where ACL rules are matched in ascending order of rule ID.

The rule numbering step sets the increment by which the system numbers rules automatically. If you do not specify a rule ID when creating an ACL rule, the system automatically assigns it a rule ID. This rule ID is the nearest higher multiple of the numbering step to the current highest rule ID, starting from the start rule ID. For example, if the rule numbering step is 5 and the current highest rule ID is 12, the rule is numbered 15.

The wider the numbering step, the more rules you can insert between two rules. Whenever the step changes, the rules are renumbered, starting from the start rule ID. For example, if there are five rules numbered 0, 5, 9, 10, and 15, changing the step from 5 to 2 causes the rules to be renumbered 0, 2, 4, 6, and 8.

Automatic rule numbering and renumbering

The ID automatically assigned to an ACL rule takes the nearest higher multiple of the numbering step to the current highest rule ID, starting with 0.

For example, if the step is 5, and there are five rules numbered 0, 5, 9, 10, and 12, the newly defined rule is numbered 15. If the ACL does not contain a rule, the first rule is numbered 0.

Whenever the step changes, the rules are renumbered, starting from 0. For example, changing the step from 5 to 2 renumbers rules 5, 10, 13, and 15 as rules 0, 2, 4, and 6.

For an ACL of the match order **auto**, rules are sorted in depth-first order, and are renumbered based on the match order. For example, rules are in the match order of 0, 10, and 5. Changing the numbering step to 2 renumbers rules 0, 10, and 5 (not 0, 5, and 10) as rules 0, 2, 4

Fragment filtering with ACLs

Traditional packet filtering matches only first fragments of packets, and allows all subsequent non-first fragments to pass through. Attackers can fabricate non-first fragments to attack networks.

To avoid risks, the ACL feature is designed as follows:

- Filters all fragments by default, including non-first fragments.
- Allows for matching criteria modification for efficiency. For example, you can configure the ACL to filter only non-first fragments.

Restrictions and guidelines: ACL configuration

- If you create a numbered ACL, you can enter the view of the ACL by using the following commands:
  - **acl** [**ipv6**] **number** *acl-number*
  - **acl** { [**ipv6**] { **advanced** | **basic** } | **mac** } *acl-number*
- If you create a ACL by specifying both a number and a name, you can enter the view of the ACL by using the following commands:
  - **acl** [**ipv6**] **number** *acl-number* (only for basic and advanced ACLs)
  - **acl** [**ipv6**] **number** *acl-number* [**name** *acl-name*]
  - **acl** { [**ipv6**] { **advanced** | **basic** } | **mac** } **name** *acl-name*
- If you create a named ACL by using the **acl** { [**ipv6**] { **advanced** | **basic** } | **mac** } **name** *acl-name* command, you can enter the view of the ACL by using the following commands:
  - **acl** [**ipv6**] **name** *acl-name*
  - **acl** { [**ipv6**] { **advanced** | **basic** } | **mac** } **name** *acl-name*
- Matching packets are forwarded through slow forwarding if an ACL rule contains match criteria or has functions enabled in addition to the following match criteria and functions:
  - Source and destination IP addresses.
  - Source and destination ports.
  - Transport layer protocol.
  - ICMP or ICMPv6 message type, message code, and message name.
  - VPN instance.

  - Logging.
  - Time range.

  Slow forwarding requires packets to be sent to the control plane for forwarding entry calculation, which affects the device forwarding performance.
- As a best practice to ensure device performance during peak hours, do not modify an ACL and the address object group that references it.

ACL tasks at a glance

To configure an ACL, perform the following tasks:

- Configure ACLs according to the characteristics of the packets to be matched
  - Configuring a basic ACL
  - Configuring an advanced ACL
  - Configuring a Layer 2 ACL
- (Optional.) Copying an ACL
- (Optional.) Enabling ACL acceleration
- (Optional.) Configuring packet filtering with ACLs

Configuring a basic ACL

About basic ACLs

Basic ACLs match packets based only on source IP addresses.

Restrictions and guidelines for basic ACL configuration

The **logging** keyword specified in an ACL rule enables the ACL module to send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output ACL logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view ACL logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Configuring an IPv4 basic ACL

1. Enter system view.

   system-view
2. Create an IPv4 basic ACL and enter its view. Choose one option as needed:
   - Create an IPv4 basic ACL by specifying an ACL number.

     acl number *acl-number* [**name** *acl-name*] [**match-order** { **auto** | **config** }]

- Create an IPv4 basic ACL by specifying the **basic** keyword.

  acl basic { *acl-number* | **name** *acl-name* } [**match-order** { **auto** | **config** }]

3. (Optional.) Configure a description for the IPv4 basic ACL.

   description *text*

   By default, an IPv4 basic ACL does not have a description.
4. (Optional.) Enable rule ID preemption.

   rule insert-only enable

   By default, rule ID preemption is disabled.
5. (Optional.) Set the rule numbering step.

   step *step-value*

   By default, the rule numbering step is 5 and the start rule ID is 0.
6. Create or edit a rule.

   rule [*rule-id*] { **deny** | **permit** } [**counting** | **fragment** | **logging** | **source** { **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

   The **logging** keyword takes effect only when the module (for example, packet filtering) that uses the ACL supports logging.
7. (Optional.) Add or edit a rule comment.

   rule *rule-id* **comment** *text*

   By default, no rule comment is configured.

Configuring an IPv6 basic ACL

1. Enter system view.

   system-view
2. Create an IPv6 basic ACL view and enter its view. Choose one option as needed:
   - Create an IPv6 basic ACL by specifying an ACL number.

     acl ipv6 number *acl-number* [**name** *acl-name*] [**match-order** { **auto** | **config** }]
   - Create an IPv6 basic ACL by specifying the **basic** keyword.

     acl ipv6 basic { *acl-number* | **name** *acl-name* } [**match-order** { **auto** | **config** }]
3. (Optional.) Configure a description for the IPv6 basic ACL.

   description *text*

   By default, an IPv6 basic ACL does not have a description.
4. (Optional.) Enable rule ID preemption.

   rule insert-only enable

   By default, rule ID preemption is disabled.
5. (Optional.) Set the rule numbering step.

   step *step-value*

   By default, the rule numbering step is 5 and the start rule ID is 0.
6. Create or edit a rule.

   rule [*rule-id*] { **deny** | **permit** } [**counting** | **fragment** | **logging** | **routing** [**type** *routing-type*] | **source** { **object-group** *address-group-name* |

source-address source-prefix | *source-address/source-prefix* | **any** } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

The **logging** keyword takes effect only when the module (for example, packet filtering) that uses the ACL supports logging.

7. (Optional.) Add or edit a rule comment.

   rule *rule-id* **comment** *text*

   By default, no rule comment is configured.

Configuring an advanced ACL

About advanced ACLs

Advanced ACLs match packets based on the following criteria:

- Source IP addresses.
- Destination IP addresses.
- Packet priorities.
- Protocol types.
- Other protocol header information, such as TCP/UDP source and destination port numbers, TCP flags, ICMP message types, and ICMP message codes.

Compared to basic ACLs, advanced ACLs allow more flexible and accurate filtering.

Restrictions and guidelines for advanced ACL configuration

The **logging** keyword specified in an ACL rule enables the ACL module to send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output ACL logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view ACL logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

To prevent device performance from degrading, do not configure an advanced ACL rule to match the DSCP field.

Configuring an IPv4 advanced ACL

1. Enter system view.

   system-view

2. Create an IPv4 advanced ACL and enter its view. Choose one option as needed:
   - Create a numbered IPv4 advanced ACL by specifying an ACL number.

     acl number *acl-number* [**name** *acl-name*] [**match-order** { **auto** | **config** }]
   - Create an IPv4 advanced ACL by specifying the **advanced** keyword.

acl advanced { *acl-number* | **name** *acl-name* } [**match-order** { **auto** | **config** }]

3. (Optional.) Configure a description for the IPv4 advanced ACL.

   description *text*

   By default, an IPv4 advanced ACL does not have a description.

4. (Optional.) Enable rule ID preemption.

   rule insert-only enable

   By default, rule ID preemption is disabled.

5. (Optional.) Set the rule numbering step.

   step *step-value*

   By default, the rule numbering step is 5 and the start rule ID is 0.

6. Creaete or edit a rule.

   rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | **logging** | **source** { **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

   The **logging** keyword takes effect only when the module (for example, packet filtering) that uses the ACL supports logging.

7. (Optional.) Add or edit a rule comment.

   rule *rule-id* **comment** *text*

   By default, no rule comment is configured.

Configuring an IPv6 advanced ACL

1. Enter system view.

   system-view

2. Create an IPv6 advanced ACL and enter its view. Choose one option as needed:
   - Create a numbered IPv6 advanced ACL by specifying an ACL number.

     acl ipv6 number *acl-number* [**name** *acl-name*] [**match-order** { **auto** | **config** }]
   - Create an IPv6 advanced ACL by specifying the **advanced** keyword.

     acl ipv6 advanced { *acl-number* | **name** *acl-name* } [**match-order** { **auto** | **config** }]

3. (Optional.) Configure a description for the IPv6 advanced ACL.

   description *text*

   By default, an IPv6 advanced ACL does not have a description.

4. (Optional.) Enable rule ID preemption.

   rule insert-only enable

   By default, rule ID preemption is disabled.

5. (Optional.) Set the rule numbering step.

step *step-value*

By default, the rule numbering step is 5 and the start rule ID is 0.

6. Create or edit a rule.

   rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **object-group** *address-group-name* | *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **dscp** *dscp* | **flow-label** *flow-label-value* | **fragment** | **icmp6-type** { *icmp6-type icmp6-code* | *icmp6-message* } | **logging** | **routing** [**type** *routing-type*] | **hop-by-hop** [**type** *hop-type*] | **source** { **object-group** *address-group-name* | *source-address source-prefix* | *source-address/source-prefix* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

   The **logging** keyword takes effect only when the module (for example, packet filtering) that uses the ACL supports logging.

7. (Optional.) Add or edit a rule comment.

   rule *rule-id* **comment** *text*

   By default, no rule comment is configured.

Configuring a Layer 2 ACL

About this task

Layer 2 ACLs, also called Ethernet frame header ACLs, match packets based on Layer 2 Ethernet header fields, such as:

- Source MAC address.
- Destination MAC address.
- 802.1p priority (VLAN priority).
- Link layer protocol type.
- Encapsulation type.

Procedure

1. Enter system view.

   system-view

2. Create a Layer 2 ACL and enter its view. Choose one option as needed:
   - Create a Layer 2 ACL by specifying an ACL number.

     acl number *acl-number* [**name** *acl-name*] [**match-order** { **auto** | **config** }]
   - Create a Layer 2 ACL by specifying the **mac** keyword.

     acl mac { *acl-number* | **name** *acl-name* } [**match-order** { **auto** | **config** }]

3. (Optional.) Configure a description for the Layer 2 ACL.

   description *text*

   By default, a Layer 2 ACL does not have a description.

4. (Optional.) Enable rule ID preemption.

   rule insert-only enable

   By default, rule ID preemption is disabled.

5. (Optional.) Set the rule numbering step.

   step *step-value*

   By default, the rule numbering step is 5 and the start rule ID is 0.

6. Create or edit a rule.

   rule [*rule-id*] { **deny** | **permit** } [**cos** *dot1p* | **counting** | **dest-mac** *dest-address dest-mask* | { **lsap** *lsap-type lsap-type-mask* | **type** *protocol-type protocol-type-mask* } | **source-mac** *source-address source-mask* | **time-range** *time-range-name*] *

7. (Optional.) Add or edit a rule comment.

   rule *rule-id* **comment** *text*

   By default, no rule comment is configured.

Copying an ACL

About this task

You can create an ACL by copying an existing ACL (source ACL). The new ACL (destination ACL) has the same properties and content as the source ACL, but uses a different number or name than the source ACL.

Restrictions and guidelines

To successfully copy an ACL, make sure:

- The destination ACL is the same type as the source ACL.
- The source ACL already exists, but the destination ACL does not.

Procedure

1. Enter system view.

   system-view

2. Copy an existing ACL to create a new ACL.

   acl [**ipv6** | **mac**] **copy** { *source-acl-number* | **name** *source-acl-name* } **to** { *dest-acl-number* | **name** *dest-acl-name* }

Enabling ACL acceleration

About this task

ACL acceleration speeds up ACL rule lookup. The acceleration effect increases with the number of ACL rules. For example, when a large ACL is used for a session-based service, such as NAT or ASPF, ACL acceleration can avoid session timeouts caused by ACL processing delays.

ACL acceleration is delayed for a period after an ACL rule is added, deleted, or modified. If additional rule changes occur during the delay period, the delay period starts to count again. If an ACL contains 100 or less rules, the delay period is 2 seconds. If an ACL contains more than 100 rules, the delay period is 20 seconds.

Procedure

1. Enter system view.

   system-view

2. Create an ACL and enter ACL view.

   acl { [**ipv6**] { **advanced** | **basic** } { *acl-number* | **name** *acl-name* } | **mac** { *acl-number* | **name** *acl-name* } } [**match-order** { **auto** | **config** }]

3. Enable ACL acceleration for the ACL.

   `accelerate`

   By default, ACL acceleration is disabled.

> △ **CAUTION:**
>
> When there are a large number of ACLs on the device, executing the **`undo accelerate`** command might cause the CPU usage of the device to reach the upper threshold and cause service processing exceptions.

Configuring packet filtering with ACLs

About packet filtering with ACLs

This section describes procedures for using an ACL to filtering packets. For example, you can apply an ACL to an interface to filter incoming or outgoing packets.

Applying an ACL to an interface for packet filtering

Restrictions and guidelines

You can apply a maximum of 32 ACLs to the same direction of an interface.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Apply an ACL to the interface to filter packets.

   `packet-filter` [**`ipv6`** | **`mac`**] { *`acl-number`* | **`name`** *`acl-name`* } **`inbound`**

   By default, an interface does not filter packets.

Applying an ACL to a zone pair for packet filtering

Restrictions and guidelines

You can apply a maximum of 32 ACLs to the same zone pair. For more information about zone pairs, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter zone pair view.

   `zone-pair security source` *`source-zone-name`* **`destination`** *`destination-zone-name`*

3. Apply an ACL to the zone pair to filter packets.

   `packet-filter` [**`ipv6`**] { *`acl-number`* | **`name`** *`acl-name`* }

   By default, a zone pair does not filter packets.

Configuring logging and SNMP notifications for packet filtering

About this task

You can configure the ACL module to generate log entries or SNMP notifications for packet filtering and output them to the information center or SNMP module at the output interval. The log entry or notification records the number of matching packets and the matched ACL rules. When the first packet of a flow matches an ACL rule, the output interval starts, and the device immediately outputs a log entry or notification for this packet. When the output interval ends, the device outputs a log entry or notification for subsequent matching packets of the flow.

For more information about the information center, see *Network Management and Monitoring Configuration Guide.*

For more information about SNMP, see *Network Management and Monitoring Configuration Guide.*

Procedure

1. Enter system view.

   `system-view`

2. Set the interval for outputting packet filtering logs or notifications.

   `acl` { **`logging`** | **`trap`** } **`interval`** *`interval`*

   The default setting is 0 minutes. By default, the device does not generate log entries or SNMP notifications for packet filtering.

Setting the packet filtering default action

About this task

By default, the packet filter permits packets that do not match any ACL rule to pass. Perform this task to deny packets that do not match any ACL rule. The packet filtering default action does not take effect on zone pair packet filtering. The default action for zone pair packet filtering is always **deny**.

Procedure

1. Enter system view.

   `system-view`

2. Set the packet filtering default action to deny.

   `packet-filter default deny`

   By default, the packet filter permits packets that do not match any ACL rule to pass.

Display and maintenance commands for ACL

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display ACL configuration and match statistics.	**display acl** [**ipv6** | **mac**] { *acl-number* | **all** | **name** *acl-name* }
Display ACL acceleration status.	**display acl accelerate** { **summary** [**ipv6** | **mac**] | **verbose** [**ipv6** | **mac**] { *acl-number* | **name** *acl-name* } **slot** *slot-number* }
Display ACL application information	**display packet-filter** { **interface**

Task	Command
for packet filtering.	[*interface-type interface-number*] [**inbound**] | **zone-pair security** [**source** *source-zone-name* **destination** *destination-zone-name*] } [**slot** *slot-number*]
Display match statistics for packet filtering ACLs.	**display packet-filter statistics** { **interface** *interface-type interface-number* **inbound** [**default** | [**ipv6** | **mac**] { *acl-number* | **name** *acl-name* }] | **zone-pair security source** *source-zone-name* **destination** *destination-zone-name* [[**ipv6**] { *acl-number* | **name** *acl-name* }] } [**brief**]
Display the accumulated statistics for packet filtering ACLs.	**display packet-filter statistics sum inbound** [**ipv6** | **mac**] { *acl-number* | **name** *acl-name* } [**brief**]
Display detailed ACL packet filtering information.	**display packet-filter verbose** { **interface** *interface-type interface-number* **inbound** [[**ipv6** | **mac**] { *acl-number* | **name** *acl-name* }] | **zone-pair security source** *source-zone-name* **destination** *destination-zone-name* [[**ipv6**] { *acl-number* | **name** *acl-name* }] } [**slot** *slot-number*]
Clear ACL statistics.	**reset acl** [**ipv6** | **mac**] **counter** { *acl-number* | **all** | **name** *acl-name* }
Clear match statistics for packet filtering ACLs.	**reset packet-filter statistics** { **interface** [*interface-type interface-number*] **inbound** [**default** | [**ipv6** | **mac**] { *acl-number* | **name** *acl-name* }] | **zone-pair security** [**source** *source-zone-name* **destination** *destination-zone-name*] [**ipv6**] { *acl-number* | **name** *acl-name* } }

ACL configuration examples

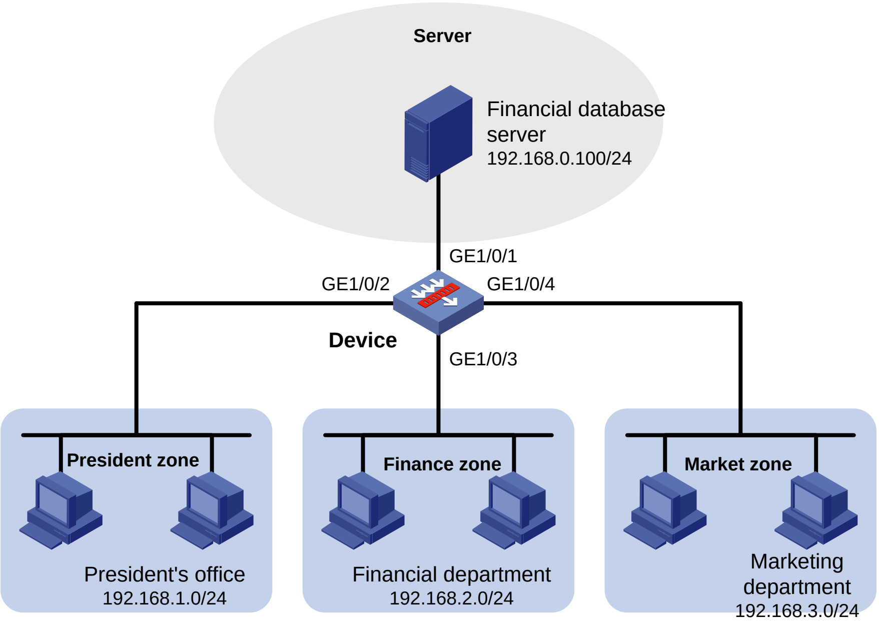
Example: Configuring a zone pair-based packet filter

Network configuration

A company interconnects its departments through the device. The financial database server, President's office, Financial department, and Marketing department belong to different security zones. Configure a packet filter to:

- Permit access from the President's office at any time to the financial database server.
- Permit access from the Financial department to the financial database server only during working hours (from 8:00 to 18:00) on working days.
- Deny access from any other department to the financial database server.

Figure 1 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   # Assign an IP address to GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.0.1 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [Device] security-zone name Server
   [Device-security-zone-Server] import interface gigabitethernet 1/0/1
   [Device-security-zone-Server] quit
   [Device] security-zone name President
   [Device-security-zone-President] import interface gigabitethernet 1/0/2
   [Device-security-zone-President] quit
   [Device] security-zone name Finance
   [Device-security-zone-Finance] import interface gigabitethernet 1/0/3
   [Device-security-zone-Finance] quit
   [Device] security-zone name Market
   [Device-security-zone-Market] import interface gigabitethernet 1/0/4
   [Device-security-zone-Market] quit
   ```

3. Create a periodic time range from 8:00 to 18:00 on working days.

   ```
   [Device] time-range work 08:0 to 18:00 working-day
   ```

4. Configure ACLs:

   # Configure ACL 3000 to permit access from the President's office at any time to the financial database server.

   ```
   [Device] acl advanced 3000
   [Device-acl-ipv4-adv-3000] rule permit ip source 192.168.1.0 0.0.0.255 destination
   192.168.0.100 0
   ```

```
[Device-acl-ipv4-adv-3000] quit
```

# Configure ACL 3001 to permit access from the Financial department to the financial database server only during working hours on working days.

```
[Device] acl advanced 3001
[Device-acl-ipv4-adv-3001] rule permit ip source 192.168.2.0 0.0.0.255 destination
192.168.0.100 0 time-range work
[Device-acl-ipv4-adv-3001] quit
```

# Configure ACL 3002 to deny access from any other department to the financial database server.

```
[Device] acl advanced 3002
[Device-acl-ipv4-adv-3002] rule deny ip source any destination 192.168.0.100 0
[Device-acl-ipv4-adv-3002] quit
```

5. Applying ACLs to zone pairs for packet filtering:

# Create a zone pair with the source security zone **President** and destination security zone **Server**. Apply ACL 3000 to the zone pair for packet filtering.

```
[Device] zone-pair security source president destination server
[Device-zone-pair-security-President-Server] packet-filter 3000
[Device-zone-pair-security-President-Server] quit
```

# Create a zone pair with the source security zone **Finance** and destination security zone **Server**. Apply ACL 3001 to the zone pair for packet filtering.

```
[Device] zone-pair security source finance destination server
[Device-zone-pair-security-Finance-Server] packet-filter 3001
[Device-zone-pair-security-President-Server] quit
```

# Create a zone pair with the source security zone **Market** and destination security zone **Server**. Apply ACL 3002 to the zone pair for packet filtering.

```
[Device] zone-pair security source market destination server
[Device-zone-pair-security-Market-Server] packet-filter 3002
[Device-zone-pair-security-Market-Server] quit
```

Verifying the configuration

# Verify that a PC in the Financial department can ping the database server during working hours. (All PCs in this example use Windows XP).

```
C:\> ping 192.168.0.100

Pinging 192.168.0.100 with 32 bytes of data:

Reply from 192.168.0.100: bytes=32 time=1ms TTL=255
Reply from 192.168.0.100: bytes=32 time<1ms TTL=255
Reply from 192.168.0.100: bytes=32 time<1ms TTL=255
Reply from 192.168.0.100: bytes=32 time<1ms TTL=255
Ping statistics for 192.168.0.100:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 0ms, Maximum = 1ms, Average = 0ms
```

# Verify that a PC in the Marketing department cannot ping the database server during working hours.

```
C:\> ping 192.168.0.100

Pinging 192.168.0.100 with 32 bytes of data:
```

```
Request timed out.
Request timed out.
Request timed out.
Request timed out.

Ping statistics for 192.168.0.100:
    Packets: Sent = 4, Received = 0, Lost = 4 (100% loss),
```

# Display configuration and match statistics for IPv4 advanced ACL 3001 and 3002 on the device during working hours.

```
[Device] display acl 3001
Advanced IPv4 ACL 3001, 1 rule,
ACL's step is 5
 rule 0 permit ip source 192.168.2.0 0.0.0.255 destination 192.168.0.100 0 time-range work
(4 times matched) (Active)
[Device] display acl 3002
Advanced IPv4 ACL 3002, 1 rule,
ACL's step is 5
 rule 0 deny ip destination 192.168.0.100 0 (4 times matched)
```

The output shows that the rule in ACL 3001 is active. ACL 3001 and ACL 3002 both have been matched four times as the result of the ping operations.

Contents

QoS overview

In data communications, Quality of Service (QoS) provides differentiated service guarantees for diversified traffic in terms of bandwidth, delay, jitter, and drop rate, all of which can affect QoS.

QoS manages network resources and prioritizes traffic to balance system resources.

The following section describes typical QoS service models and widely used QoS techniques.

QoS service models

This section describes several typical QoS service models.

Best-effort service model

The best-effort model is a single-service model. The best-effort model is not as reliable as other models and does not guarantee delay-free delivery.

The best-effort service model is the default model for the Internet and applies to most network applications. It uses the First In First Out (FIFO) queuing mechanism.

IntServ model

The integrated service (IntServ) model is a multiple-service model that can accommodate diverse QoS requirements. This service model provides the most granularly differentiated QoS by identifying and guaranteeing definite QoS for each data flow.

In the IntServ model, an application must request service from the network before it sends data. IntServ signals the service request with the RSVP. All nodes receiving the request reserve resources as requested and maintain state information for the application flow.

The IntServ model demands high storage and processing capabilities because it requires all nodes along the transmission path to maintain resource state information for each flow. This model is suitable for small-sized or edge networks. However, it is not suitable for large-sized networks, for example, the core layer of the Internet, where billions of flows are present.

DiffServ model

The differentiated service (DiffServ) model is a multiple-service model that can meet diverse QoS requirements. It is easy to implement and extend. DiffServ does not signal the network to reserve resources before sending data, as IntServ does.

QoS techniques in a network

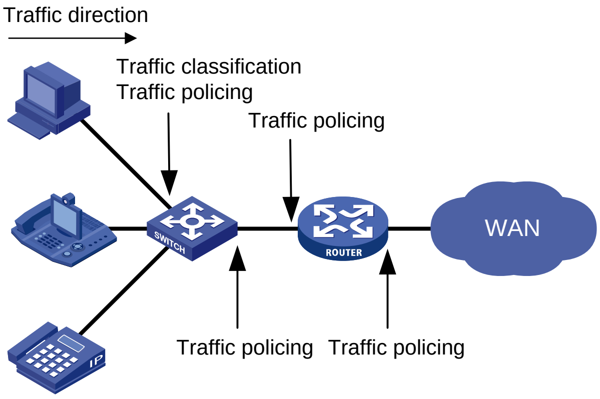
The QoS techniques include the following features:

- Traffic classification.
- Traffic policing.
- Traffic shaping.
- Rate limit.
- Congestion management.
- Congestion avoidance.

The following section briefly introduces these QoS techniques.

All QoS techniques in this document are based on the DiffServ model.

Figure 1 Position of the QoS techniques in a network



As shown in Figure 1, traffic classification, traffic shaping, traffic policing, congestion management, and congestion avoidance mainly implement the following functions:

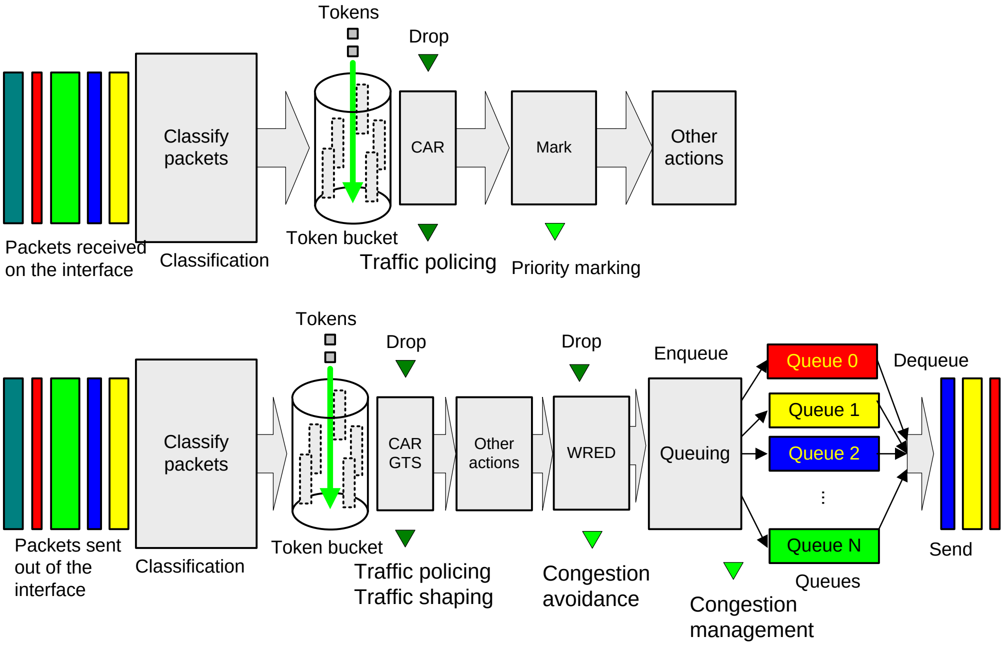
- **Traffic classification**—Uses match criteria to assign packets with the same characteristics to a traffic class. Based on traffic classes, you can provide differentiated services.
- **Traffic policing**—Polices flows and imposes penalties to prevent aggressive use of network resources. You can apply traffic policing to both incoming and outgoing traffic of a port.
- **Traffic shaping**—Adapts the output rate of traffic to the network resources available on the downstream device to eliminate packet drops. Traffic shaping usually applies to the outgoing traffic of a port.
- **Congestion management**—Provides a resource scheduling policy to determine the packet forwarding sequence when congestion occurs. Congestion management usually applies to the outgoing traffic of a port.
- **Congestion avoidance**—Monitors the network resource usage. It is usually applied to the outgoing traffic of a port. When congestion worsens, congestion avoidance reduces the queue length by dropping packets.

QoS processing flow in a device

Figure 2 briefly describes how the QoS module processes traffic.

1. Traffic classifier identifies and classifies traffic for subsequent QoS actions.
2. The QoS module takes various QoS actions on classified traffic as configured, depending on the traffic processing phase and network status. For example, you can configure the QoS module to perform the following operations:
   - Traffic policing for incoming traffic.
   - Traffic shaping for outgoing traffic.
   - Congestion avoidance before congestion occurs.
   - Congestion management when congestion occurs.

Figure 2 QoS processing flow



QoS configuration approaches

You can configure QoS by using the MQC approach or non-MQC approach.

In the modular QoS configuration (MQC) approach, you configure QoS service parameters by using QoS policies. A QoS policy defines QoS actions to take on different classes of traffic and can be applied to an object (such as an interface) to control traffic.

In the non-MQC approach, you configure QoS service parameters without using a QoS policy.

Some features support both approaches, but some support only one.

Configuring a QoS policy

About QoS policies

A QoS policy has the following components:

- **Traffic class**—Defines criteria to match packets.
- **Traffic behavior**—Defines QoS actions to take on matching packets.

By associating a traffic class with a traffic behavior, a QoS policy can perform the QoS actions on matching packets.

A QoS policy can have multiple class-behavior associations.

QoS policy tasks at a glance

To configure a QoS policy, perform the following tasks:

1. Defining a traffic class
2. Defining a traffic behavior
3. Defining a QoS policy
4. (Optional.) Configuring policy nesting
5. Applying the QoS policy
   - Applying the QoS policy to an interface
   - Applying the QoS policy to a control plane
   - Applying the QoS policy in control-plane management view
6. (Optional.) Setting the QoS policy-based traffic rate statistics collection period for an interface

Defining a traffic class

1. Enter system view.
   `system-view`
2. Create a traffic class and enter traffic class view.
   `traffic classifier` *`classifier-name`* [**`operator`** { **`and`** | **`or`** }]
3. Configure a match criterion.
   `if-match` [**`not`**] *`match-criteria`*

   By default, no match criterion is configured.

   For more information, see the **`if-match`** command in *ACL and QoS Command Reference*.

Defining a traffic behavior

1. Enter system view.
   `system-view`
2. Create a traffic behavior and enter traffic behavior view.
   `traffic behavior` *`behavior-name`*
3. Configure an action in the traffic behavior.

By default, no action is configured for a traffic behavior.

For more information about configuring an action, see the subsequent chapters for traffic policing, traffic filtering, priority marking, and so on.

Defining a QoS policy

1. Enter system view.

   system-view

2. Create a QoS policy and enter QoS policy view.

   qos policy *policy-name*

3. Associate a traffic class with a traffic behavior to create a class-behavior association in the QoS policy.

   classifier *classifier-name* **behavior** *behavior-name* [**insert-before** *before-classifier-name*]

   By default, a traffic class is not associated with a traffic behavior.

   Repeat this step to create more class-behavior associations.

Configuring policy nesting

About this task

A QoS policy configuration can contain a parent policy and a child policy.

Policy nesting allows you to create a child policy in the view of a traffic behavior of the parent policy.

You can nest a QoS policy in a traffic behavior to reclassify the traffic class associated with the behavior. Then the system performs the actions defined in the QoS policy on the reclassified traffic. The QoS policy nested in the traffic behavior is called the child policy. The QoS policy that nests the behavior is called the parent policy.

Prerequisites

Before configuring policy nesting, define a child policy (see "Defining a QoS policy").

Procedure

1. Enter system view.

   system-view

2. Define a traffic class for the parent policy.

   a. Create a traffic class for the parent policy and enter traffic class view.

      traffic classifier *classifier-name* [**operator** { **and** | **or** }]

   b. Configure a match criterion.

      if-match [**not**] *match-criteria*

      By default, no match criterion is configured.

      For more information about configuring match criteria, see *ACL and QoS Command Reference*.

   c. Return to system view.

      quit

3. Nest the child QoS policy in the traffic behavior of the parent policy.

   a. Create a traffic behavior for the parent policy and enter traffic behavior view.

      traffic behavior *behavior-name*

   b. Nest the child QoS policy.

      traffic-policy *policy-name*

      By default, policy nesting is not configured.

   c. Return to system view.

      quit

4. Create the parent policy and enter parent policy view.

   qos policy *policy-name*

5. Associate the class with the behavior in the parent policy.

   classifier *classifier-name* **behavior** *behavior-name*

   By default, a class is not associated with a behavior.

Applying the QoS policy

Application destinations

You can apply a QoS policy to the following destinations:

- **Interface**—The QoS policy can be applied to the traffic sent or received on the interface.
- **Control plane**—The QoS policy can be applied to the traffic received on the control plane.
- **Management interface control plane**—The QoS policy can be applied to the traffic sent from the management interface to the control plane.

Restrictions and guidelines for applying a QoS policy

You can modify traffic classes, traffic behaviors, and class-behavior associations in a QoS policy even after it is applied. If a traffic class uses an ACL for traffic classification, you can delete or modify the ACL.

If an action in a traffic behavior cannot take effect, all other actions in the traffic behavior do not take effect.

Applying the QoS policy to an interface

Restrictions and guidelines

A QoS policy can be applied to multiple interfaces. However, only one QoS policy can be applied to one direction (inbound or outbound) of an interface.

The QoS policy applied to the outgoing traffic on an interface does not regulate local packets. Local packets refer to critical protocol packets sent by the local system for operation maintenance. The most common local packets include link maintenance, RIP, and SSH packets.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Apply the QoS policy to the interface.

   qos apply policy *policy-name* { **inbound** | **outbound** }

   By default, no QoS policy is applied to an interface.

Applying the QoS policy to a control plane

About this task

A device provides the user plane and the control plane.

- **User plane**—The units at the user plane are responsible for receiving, transmitting, and switching (forwarding) packets, such as various dedicated forwarding chips. They deliver super processing speeds and throughput.
- **Control plane**—The units at the control plane are processing units running most routing and switching protocols. They are responsible for protocol packet resolution and calculation, such as CPUs. Compared with user plane units, the control plane units allow for great packet processing flexibility but have lower throughput.

When the user plane receives packets that it cannot recognize or process, it transmits them to the control plane. If the transmission rate exceeds the processing capability of the control plane, the control plane will be busy handling undesired packets. As a result, the control plane will fail to handle legitimate packets correctly or timely. As a result, protocol performance is affected.

To address this problem, apply a QoS policy to the control plane to take QoS actions, such as traffic filtering or traffic policing, on inbound traffic. This ensures that the control plane can correctly receive, transmit, and process packets.

A predefined control plane QoS policy uses the protocol type or protocol group type to identify the type of packets sent to the control plane. You can use protocol types or protocol group types in **`if-match`** commands in traffic class view for traffic classification. Then you can reconfigure traffic behaviors for these traffic classes as required. You can use the **`display qos policy control-plane pre-defined`** command to display predefined control plane QoS policies.

Procedure

1. Enter system view.

   `system-view`

2. Enter control plane view.

   `control-plane slot` *`slot-number`*

3. Apply the QoS policy to the control plane.

   `qos apply policy` *`policy-name`* **`inbound`**

   By default, no QoS policy is applied to a control plane.

Applying the QoS policy in control-plane management view

About this task

If the rate of packets from the management interface to the control plane exceeds the processing capability, the control plane will fail to handle the packets correctly or timely. As a result, protocol performance is affected.

This feature allows you to rate limit the packets sent from the management interface to the control plane. This ensures that the control plane can correctly receive, transmit, and process packets from the management interface.

By default, a predefined QoS policy is applied in control-plane management view. To display the predefined QoS policy, use the **`display qos policy control-plane management pre-defined`** command. The predefined QoS policy uses the protocol type or protocol group type to identify the type of packets sent from the management interface to the control plane. You can use protocol types or protocol group types in **`if-match`** commands in traffic class view for traffic classification. Then, you can reconfigure traffic behaviors for these traffic classes as required.

Procedure

1. Enter system view.

   system-view

2. Enter control-plane management view.

   control-plane management

3. Apply the QoS policy.

   qos apply policy *policy-name* **inbound**

   By default, no QoS policy is applied in control-plane management view.

Setting the QoS policy-based traffic rate statistics collection period for an interface

About this task

You can enable collection of per-class traffic statistics over a period of time, including the average forwarding rate and drop rate. For example, if you set the statistics collection period to n minutes, the system performs the following operations:

- Collects traffic statistics for the most recent n minutes.
- Refreshes the statistics every n/5 minutes.

You can use the **display qos policy interface** command to view the collected traffic rate statistics.

A subinterface uses the statistics collection period configured on the main interface.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the traffic rate statistics collection period for the interface.

   qos flow-interval *interval*

   The default setting is 5 minutes.

Display and maintenance commands for QoS policies

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display QoS policy configuration.	**display qos policy user-defined** [*policy-name* [**classifier** *classifier-name*]] [**slot** *slot-number*]
Display QoS policies applied to hub-spoke tunnels on a tunnel interface.	**display qos policy advpn tunnel** *number* [*ipv4-address* | *ipv6-address*] [**outbound**]
Display information about QoS policies	**display qos policy control-plane slot**

Task	Command
applied to the control plane.	*slot-number*
Display information about the predefined QoS policy applied in control-plane management view.	**display qos policy control-plane management pre-defined**
Display information about the predefined QoS policy applied to the control plane.	**display qos policy control-plane pre-defined** [**slot** *slot-number*]
Display information about QoS policies applied to interfaces.	**display qos policy interface** [*interface-type interface-number*] [**slot** *slot-number*] [**inbound** | **outbound**]
Display traffic behavior configuration.	**display traffic behavior user-defined** [*behavior-name*] [**slot** *slot-number*]
Display traffic class configuration.	**display traffic classifier user-defined** [*classifier-name*] [**slot** *slot-number*]
Clear the statistics for the QoS policy applied to the control plane.	**reset qos policy control-plane slot** *slot-number*
Clear the statistics for QoS policies applied to hub-spoke tunnels on a tunnel interface.	**reset qos policy advpn tunnel** *number* [*ipv4-address* | *ipv6-address*] [**outbound**]

Configuring traffic policing, GTS, and rate limit

About traffic policing, GTS, and rate limit

Traffic limit helps assign network resources (including bandwidth) and increase network performance. For example, you can configure a flow to use only the resources committed to it in a certain time range. This avoids network congestion caused by burst traffic.

Traffic policing, Generic Traffic Shaping (GTS), and rate limit control the traffic rate and resource usage according to traffic specifications. You can use token buckets for evaluating traffic specifications.

Traffic evaluation and token buckets

Token bucket features

A token bucket is analogous to a container that holds a certain number of tokens. Each token represents a certain forwarding capacity. The system puts tokens into the bucket at a constant rate. When the token bucket is full, the extra tokens cause the token bucket to overflow.

Evaluating traffic with the token bucket

A token bucket mechanism evaluates traffic by looking at the number of tokens in the bucket. If the number of tokens in the bucket is enough for forwarding the packets:

- The traffic conforms to the specification (called conforming traffic).
- The corresponding tokens are taken away from the bucket.

Otherwise, the traffic does not conform to the specification (called excess traffic).

A token bucket has the following configurable parameters:

- Mean rate at which tokens are put into the bucket, which is the permitted average rate of traffic. It is usually set to the committed information rate (CIR).
- Burst size or the capacity of the token bucket. It is the maximum traffic size permitted in each burst. It is usually set to the committed burst size (CBS). The set burst size must be greater than the maximum packet size.

Each arriving packet is evaluated.

Complicated evaluation

You can set two token buckets, bucket C and bucket E, to evaluate traffic in a more complicated environment and achieve more policing flexibility. The following are main mechanisms used for complicated evaluation:

- **Single rate two color**—Uses one token bucket and the following parameters:
    - **CIR**—Rate at which tokens are put into bucket C. It sets the average packet transmission or forwarding rate allowed by bucket C.
    - **CBS**—Size of bucket C, which specifies the transient burst of traffic that bucket C can forward.

  When a packet arrives, the following rules apply:

    - If bucket C has enough tokens to forward the packet, the packet is colored green.
    - Otherwise, the packet is colored red.
- **Single rate three color**—Uses two token buckets and the following parameters:

    - **CIR**—Rate at which tokens are put into bucket C. It sets the average packet transmission or forwarding rate allowed by bucket C.
    - **CBS**—Size of bucket C, which specifies the transient burst of traffic that bucket C can forward.
    - **EBS**—Size of bucket E minus size of bucket C, which specifies the transient burst of traffic that bucket E can forward. The EBS cannot be 0. The size of E bucket is the sum of the CBS and EBS.

    When a packet arrives, the following rules apply:

    - If bucket C has enough tokens, the packet is colored green.
    - If bucket C does not have enough tokens but bucket E has enough tokens, the packet is colored yellow.
    - If neither bucket C nor bucket E has sufficient tokens, the packet is colored red.
- **Two rate three color**—Uses two token buckets and the following parameters:
    - **CIR**—Rate at which tokens are put into bucket C. It sets the average packet transmission or forwarding rate allowed by bucket C.
    - **CBS**—Size of bucket C, which specifies the transient burst of traffic that bucket C can forward.
    - **PIR**—Rate at which tokens are put into bucket E, which specifies the average packet transmission or forwarding rate allowed by bucket E.
    - **EBS**—Size of bucket E, which specifies the transient burst of traffic that bucket E can forward.

    When a packet arrives, the following rules apply:

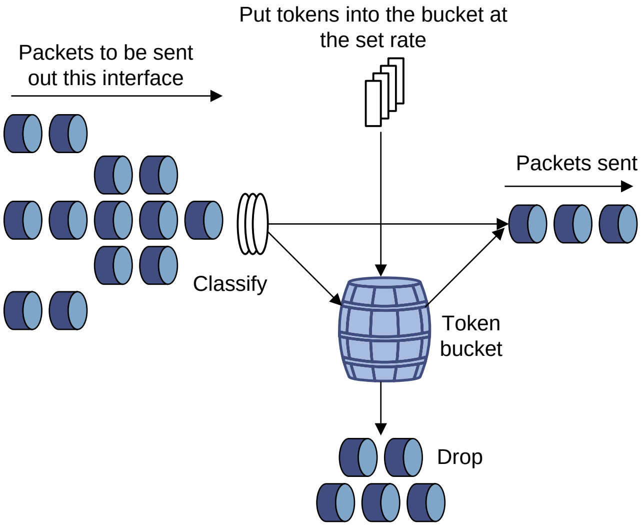
    - If bucket C has enough tokens, the packet is colored green.
    - If bucket C does not have enough tokens but bucket E has enough tokens, the packet is colored yellow.
    - If neither bucket C nor bucket E has sufficient tokens, the packet is colored red.

Traffic policing

Traffic policing supports policing the inbound traffic and the outbound traffic.

A typical application of traffic policing is to supervise the specification of traffic entering a network and limit it within a reasonable range. Another application is to "discipline" the extra traffic to prevent aggressive use of network resources by an application. For example, you can limit bandwidth for HTTP packets to less than 50% of the total. If the traffic of a session exceeds the limit, traffic policing can drop the packets or set the precedence of the packets. Figure 3 shows an example of policing outbound traffic on an interface.

Figure 3 Traffic policing



Put tokens into the bucket at the set rate
Packets to be sent out this interface
Packets sent
Classify
Token bucket
Drop

Traffic policing is widely used in policing traffic entering the ISP networks. It can classify the policed traffic and take predefined policing actions on each packet depending on the evaluation result:

- Forwarding the packet if the evaluation result is "conforming."
- Dropping the packet if the evaluation result is "excess."
- Forwarding the packet with its precedence re-marked if the evaluation result is "conforming."
- Delivering the packet to next-level traffic policing with its precedence re-marked if the evaluation result is "conforming."
- Entering the next-level policing (you can set multiple traffic policing levels, each focused on objects at different levels).

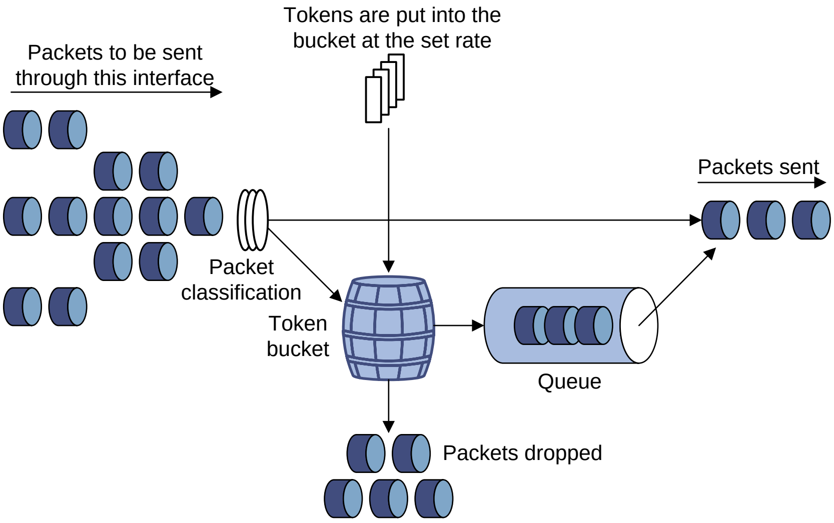
GTS

GTS supports shaping only outbound traffic. GTS limits the outbound traffic rate by buffering exceeding traffic. You can use GTS to adapt the traffic output rate on a device to the input traffic rate of its connected device to avoid packet loss.

The differences between traffic policing and GTS are as follows:

- Packets to be dropped with traffic policing are retained in a buffer or queue with GTS, as shown in Figure 4. When enough tokens are in the token bucket, the buffered packets are sent at an even rate.
- GTS can result in additional delay and traffic policing does not.

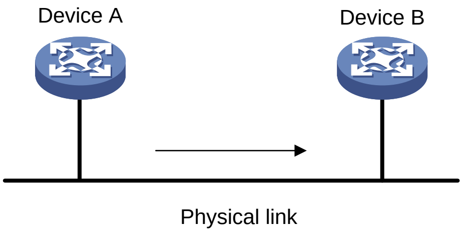
Figure 4 GTS



Tokens are put into the bucket at the set rate
Packets to be sent through this interface
Packets sent
Packet classification
Token bucket
Queue
Packets dropped

For example, in Figure 5, Device B performs traffic policing on packets from Device A and drops packets exceeding the limit. To avoid packet loss, you can perform GTS on the outgoing interface of Device A so that packets exceeding the limit are cached in Device A. Once resources are released, GTS takes out the cached packets and sends them out.

Figure 5 GTS application



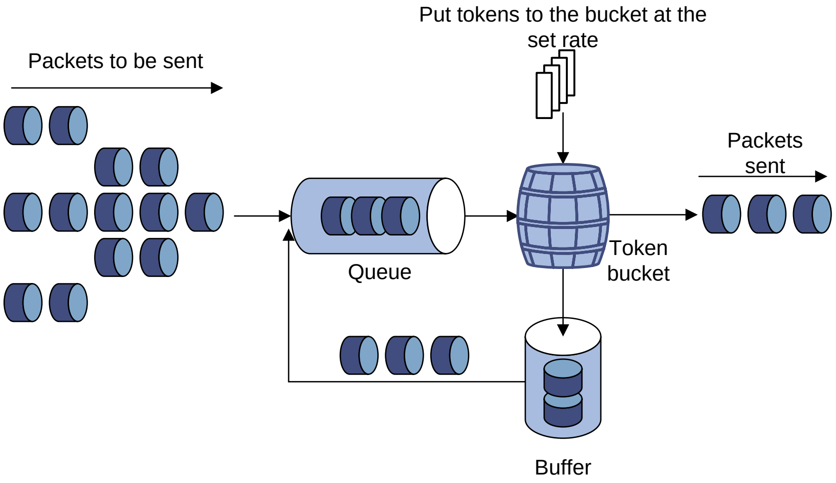
Rate limit

Rate limit controls the rates of inbound and outbound traffic.

The rate limit of an interface or PW specifies the maximum rate for forwarding packets (excluding critical packets).

Rate limit also uses token buckets for traffic control. When rate limit is configured on an interface, a token bucket handles all packets to be sent through the interface for rate limiting. If enough tokens are in the token bucket, packets can be forwarded. Otherwise, packets are put into QoS queues for congestion management. In this way, the traffic passing the interface is controlled.

Figure 6 Rate limit implementation



The token bucket mechanism limits traffic rate when accommodating bursts. It allows bursty traffic to be transmitted if enough tokens are available. If tokens are scarce, packets cannot be transmitted until efficient tokens are generated in the token bucket. It restricts the traffic rate to the rate for generating tokens.

Rate limit controls the total rate of all packets on an interface. It is easier to use than traffic policing in controlling the total traffic rate.

Configuring traffic policing

Traffic policing configuration approaches

You can configure traffic policing by using the MQC approach or the non-MQC approach. If both approaches are used, the MQC configuration takes effect.

You can configure the following types of traffic policing by using the non-MQC approach:

- CAR-list-based traffic policing.
- ACL-based traffic policing.
- Traffic policing for all traffic.

If traffic policing is configured by using both the MQC approach and non-MQC approach, the configuration in MQC approach takes effect.

Configuring traffic policing by using the MQC approach

Restrictions and guidelines

The device supports the following application destinations for traffic policing:

- Interface.
- Control plane.
- Control-plane management view.

Procedure

1. Enter system view.

```
system-view
```

2. Define a traffic class.
   a. Create a traffic class and enter traffic class view.

      traffic classifier *classifier-name* [**operator** { **and** | **or** }]
   b. Configure a match criterion.

      if-match [**not**] *match-criteria*

      By default, no match criterion is configured.

      For more information about the **if-match** command, see *ACL and QoS Command Reference*.
   c. Return to system view.

      quit
3. Define a traffic behavior.
   a. Create a traffic behavior and enter traffic behavior view.

      traffic behavior *behavior-name*
   b. Configure a traffic policing action.
   - In absolute value:

     car cir *committed-information-rate* [**cbs** *committed-burst-size* [**ebs** *excess-burst-size*]] [**green** *action* | **red** *action* | **yellow** *action*] *

     car cir *committed-information-rate* [**cbs** *committed-burst-size*] **pir** *peak-information-rate* [**ebs** *excess-burst-size*] [**green** *action* | **red** *action* | **yellow** *action*] *
   - In percentage:

     car cir percent *cir-percent* [**cbs** *cbs-time* [**ebs** *ebs-time*]] [**green** *action* | **red** *action* | **yellow** *action*] *

     car cir percent *cir-percent* [**cbs** *cbs-time*] **pir percent** *pir-percent* [**ebs** *ebs-time*] [**green** *action* | **red** *action* | **yellow** *action*] *

     By default, no traffic policing action is configured.

     Support for this command depends on the device model. For more information, see the command reference.
   c. Return to system view.

      quit
4. Define a QoS policy.
   a. Create a QoS policy and enter QoS policy view.

      qos policy *policy-name*
   b. Associate the traffic class with the traffic behavior in the QoS policy.

      classifier *classifier-name* **behavior** *behavior-name*

      By default, a traffic class is not associated with a traffic behavior.
   c. Return to system view.

      quit
5. Apply the QoS policy.

   For more information, see "Applying the QoS policy."

   By default, no QoS policy is applied.

Configuring CAR-list-based static traffic policing

1. Enter system view.

   system-view

2. Configure a CAR list.

   qos carl *carl-index* { **dscp** *dscp-list* | **mac** *mac-address* | **mpls-exp** *mpls-exp-value* | **precedence** *precedence-value* | { **destination-ip-address** | **source-ip-address** } { **range** *start-ip-address* **to** *end-ip-address* | **subnet** *ip-address mask-length* } [**per-address** [**shared-bandwidth**]] }

3. Enter interface view.

   interface *interface-type interface-number*

4. Apply a CAR-list-based CAR policy to the interface.

   qos car { **inbound** | **outbound** } **carl** *carl-index* **cir** *committed-information-rate* [**cbs** *committed-burst-size* [**ebs** *excess-burst-size*]] [**green** *action* | **red** *action* | **yellow** *action*] *

   qos car { **inbound** | **outbound** } **carl** *carl-index* **cir** *committed-information-rate* [**cbs** *committed-burst-size*] **pir** *peak-information-rate* [**ebs** *excess-burst-size*] [**green** *action* | **red** *action* | **yellow** *action*] *

   By default, no CAR policy is applied to an interface.

Configuring ACL-based traffic policing

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure an ACL-based CAR policy on the interface.

   qos car { **inbound** | **outbound** } **acl** [**ipv6**] *acl-number* **cir** *committed-information-rate* [**cbs** *committed-burst-size* [**ebs** *excess-burst-size*]] [**green** *action* | **red** *action* | **yellow** *action*] *

   qos car { **inbound** | **outbound** } **acl** [**ipv6**] *acl-number* **cir** *committed-information-rate* [**cbs** *committed-burst-size*] **pir** *peak-information-rate* [**ebs** *excess-burst-size*] [**green** *action* | **red** *action* | **yellow** *action*] *

   By default, no CAR policy is configured on an interface.

Configuring traffic policing for all traffic

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure a CAR policy for all traffic on the interface.

   qos car { **inbound** | **outbound** } **any** **cir** *committed-information-rate* [**cbs** *committed-burst-size* [**ebs** *excess-burst-size*]] [**green** *action* | **red** *action* | **yellow** *action*] *

   qos car { **inbound** | **outbound** } **any** **cir** *committed-information-rate* [**cbs** *committed-burst-size*] **pir** *peak-information-rate* [**ebs** *excess-burst-size*] [**green** *action* | **red** *action* | **yellow** *action*] *

   By default, no CAR policy is configured on an interface.

Configuring GTS

GTS configuration approaches

You can configure GTS by using either the MQC approach or non-MQC approach.

You can configure the following types of GTS by using the non-MQC approach:

- ACL-based GTS.
- GTS for all traffic.

If GTS is configured by using both the MQC approach and non-MQC approach, the configuration in MQC approach takes effect.

Hardware compatibility with GTS

Models	**Feature compatibility**
NFNX5-HD6480, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No

Configuring GTS by using the MQC approach

Restrictions and guidelines

The device supports the following application destinations for GTS:

- **Interface.**
- **Control plane**.

Procedure

1. Enter system view.
   system-view
2. Define a traffic class.
   a. Create a traffic class and enter traffic class view.
      traffic classifier *classifier-name* [**operator** { **and** | **or** }]
   b. Configure a match criterion.
      if-match [**not**] *match-criteria*
      By default, no match criterion is configured.
      For configurable match criteria, see the **if-match** command in *ACL and QoS Command Reference*.
   c. Return to system view.
      quit
3. Define a traffic behavior.
   a. Create a traffic behavior and enter traffic behavior view.
      traffic behavior *behavior-name*
   b. Configure a GTS action.

- In absolute value:

  gts cir *committed-information-rate* [**cbs** *committed-burst-size* [**ebs** *excess-burst-size*]] [**queue-length** *queue-length*]

- In percentage:

  gts percent cir *cir-percent* [**cbs** *cbs-time* [**ebs** *ebs-time*]] [**queue-length** *queue-length*]

By default, no GTS action is configured.

c. Return to system view.

quit

4. Define a QoS policy.

a. Create a QoS policy and enter QoS policy view.

qos policy *policy-name*

b. Associate the class with the traffic behavior in the QoS policy.

classifier *classifier-name* **behavior** *behavior-name*

By default, a traffic class is not associated with a traffic behavior.

c. Return to system view.

quit

5. Apply the QoS policy.

For more information, see "Applying the QoS policy."

By default, no QoS policy is applied.

Configuring ACL-based GTS

1. Enter system view.

system-view

2. Enter interface view.

interface *interface-type interface-number*

3. Configure ACL-based GTS on the interface.

qos gts acl [**ipv6**] *acl-number* **cir** *committed-information-rate* [**cbs** *committed-burst-size* [**ebs** *excess-burst-size*]] [**queue-length** *queue-length*]

By default, GTS is not configured on an interface.

Configuring GTS for all traffic

1. Enter system view.

system-view

2. Enter interface view.

interface *interface-type interface-number*

3. Configure GTS on the interface.

qos gts any cir *committed-information-rate* [**cbs** *committed-burst-size* [**ebs** *excess-burst-size*]] [**queue-length** *queue-length*]

By default, GTS is not configured on an interface.

Configuring the rate limit

Hardware compatibility with rate limit

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No

Configuring the rate limit for an interface

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure the rate limit for the interface.

   `qos lr outbound cir` *`committed-information-rate`* [**`cbs`** *`committed-burst-size`* [**`ebs`** *`excess-burst-size`*]]

   By default, no rate limit is configured on an interface.

Including the physical layer header in calculating the packet length for rate limiting

About this task

By default, the device calculates the packet length for rate limiting based on the data link layer frame. This feature allows the device to include a 24-byte physical layer header in calculating the packet length for rate limiting.

Restrictions and guidelines

This feature takes effect only on Layer 3 Ethernet interfaces and Layer 3 aggregate interfaces.

Procedure

1. Enter system view.

   `system-view`

2. Include the physical layer header in calculating the packet length for rate limiting.

   `qos overhead layer physical`

   By default, the device calculates the packet length for rate limiting based on the data link layer frame.

Display and maintenance commands for traffic policing, GTS, and rate limit

Execute **`display`** commands in any view.

Task	Command
Display CAR configuration and statistics on an interface.	**display qos car interface** [*interface-type interface-number*]
Display CAR list information.	**display qos carl** [*carl-index*] [**slot** *slot-number*]
Display GTS configuration and statistics for interfaces.	**display qos gts interface** [*interface-type interface-number*]
Display rate limit configuration and statistics.	**display qos lrinterface** [*interface-type interface-number*]
Display traffic behavior configuration.	**display traffic behavior user-defined** [*behavior-name*] [**slot** *slot-number*]

Configuring traffic filtering

About traffic filtering

You can filter in or filter out traffic of a class by associating the class with a traffic filtering action. For example, you can filter packets sourced from an IP address according to network status.

Restrictions and guidelines: Traffic filtering configuration

The device supports applying traffic filtering to an interface or control plane.

Procedure

1. Enter system view.

   `system-view`

2. Define a traffic class.

   a. Create a traffic class and enter traffic class view.

      traffic classifier *classifier-name* [**operator** { **and** | **or** }]

   b. Configure a match criterion.

      if-match [**not**] *match-criteria*

      By default, no match criterion is configured.

      For more information about configuring match criteria, see *ACL and QoS Command Reference*.

   c. Return to system view.

      `quit`

3. Define a traffic behavior.

   a. Create a traffic behavior and enter traffic behavior view.

      traffic behavior *behavior-name*

   b. Configure the traffic filtering action.

      filter { **deny** | **permit** }

      By default, no traffic filtering action is configured.

      If a traffic behavior has the **filter deny** action, all other actions in the traffic behavior do not take effect.

   c. Return to system view.

      `quit`

4. Define a QoS policy.

   a. Create a QoS policy and enter QoS policy view.

      qos policy *policy-name*
