NSFOCUS Firewall Series

NF Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

About the NSFOCUS firewall series configuration guides

The NSFOCUS firewall series configuration guides describe the software features for the NSFOCUS firewall series, and guide you through the software configuration procedures. These configuration guides also provide configuration examples to help you apply the software features to different network scenarios.

Applicable hardware and software versions

To obtain software version information for a device, use the **`display version`** command in any view on the device. The configuration guides use the RXX60P28 versions as examples to illustrate feature configuration. For information about feature changes in other software versions, see the release notes for your device.

Contents

Table 1 lists features included in each configuration guide. Support for the features depends on the device model.

Table 1 Configuration guide content

Configuration guide	Content
Fundamentals Configuration Guide	Covers information about using the command line interface, logging in to and setting up the device, and using the basic management features. This guide includes: • CLI (command line interface overview and how to use the CLI) • RBAC • Login management • License management • Device management • FTP and TFTP • File system management • Configuration file management • Software upgrade • ISSU • Automatic • Tcl • Python
Virtual Technologies Configuration Guide	Covers the configuration of virtual technologies. This guide includes: • IRF • Context • Reth interface and redundancy group
Security Configuration Guide	Covers identity authentication, access security, secure management, SSL, and attack protection features. This guide includes: • Security zone • Security policy • ASPF • Session management

Configuration guide	Content
	• Object group • IP source guard • AAA • 802.1X • User identification • Password control • Portal • MAC authentication • IPoE • Public key configuration • PKI • SSH • SSL • Connection limit • Attack detection and prevention • Server connection detection • ARP attack protection • ND attack defense • uRPF • IP-MAC binding • APR • Keychain • Crypto engine • MAC learning through a Layer 3 device • SMS
DPI Configuration Guide	Covers fundamentals and configuration of deep packet inspection. This guide includes: • DPI overview • DPI engine • IPS • URL filtering • Data filtering • File filtering • Anti-virus • Data analysis center • Proxy policy
NAT Configuration Guide	Covers fundamentals and configuration of NAT and AFT. This guide includes: • NAT • NAT66 • AFT
VPN Configuration Guide	Covers VPN-related features. This guide includes: • SSL VPN • IPsec • Tunneling • GRE • L2TP • ADVPN
Internet Access Behavior Management Configuration Guide	Covers Internet access behavior management features. This guide includes:

Configuration guide	Content
	• Bandwidth management • Application audit and management • NetShare control
Load Balancing Configuration Guide	Covers fundamentals, configuration procedures, and configuration examples of load balancing features.
High Availability Configuration Guide	Describes high availability technologies and features available on the device for failure detection and failover.
Interface Configuration Guide	Covers the configuration of various interfaces. This guide includes: • Bulk interface • Ethernet interface • Loopback, null, and inloopback interfaces
Layer 2—LAN Switching Configuration Guide	Covers Layer 2 technologies and features used on a LAN switched network. This guide includes: • MAC address table • Ethernet link aggregation • VLAN • VLAN termination • Spanning tree • LLDP • Layer 2 forwarding
Layer 2—WAN Access Configuration Guide	Covers the Layer 2 WAN access features. This guide includes: • PPP • Mobile communication modem
Layer 3—IP Services Configuration Guide	Covers IP addressing (including static and dynamic IPv4 and IPv6 address assignment), network performance optimization, ARP, and interoperation between IPv4 and IPv6. This guide includes: • IP addressing • IP forwarding basics • Fast forwarding • ARP (including proxy ARP) • IPv6 basics • IPv6 fast forwarding • DHCP • DHCPv6 • DNS • IP performance optimization • Multi-CPU packet distribution • Adjacency table • Web caching
Layer 3—IP Routing Configuration Guide	Covers the routing technologies for IPv4 and IPv6 networks of different sizes, route filtering, route control, and policy based routing. This guide includes: • Basic IP routing • Static routing • IPv6 static routing • RIP • RIPng • OSPF • OSPFv3

Configuration guide	Content
	• IS-IS • BGP • Policy-based routing • IPv6 policy-based routing • Routing policy • Guard route • RIR
ACL and QoS Configuration Guide	Covers information about classifying traffic with ACLs, and controlling traffic and allocating network resources with QoS technologies to improve network performance and network use efficiency. This guide includes: • ACL • QoS (including QoS overview, QoS policy, traffic policing, traffic filtering, and priority marking) • Time range
IP Multicast Configuration Guide	Covers the IP multicast features. This guide includes: • Multicast overview • Multicast routing and forwarding • IGMP • PIM • IPv6 multicast routing and forwarding • MLD
Network Management and Monitoring Configuration Guide	Covers features that help you manage and monitor your network, for example, manage system events, collect traffic statistics, sample packets, assess network performance, and test network connectivity. This guide includes: • Information center • Flow log • Fast log output • NetStream • Cloud connection • Mirroring • Packet capture • NQA • Track • BFD • Monitor Link • Smart Link • Interface backup • Interface collaboration • System maintenance and debugging (ping, tracert, and system debugging) • NTP • EAA • Process monitoring and maintenance • NETCONF • CWMP • SNMP (including the MIB style configuration) • RMON • Event MIB • Process placement

Configuration guide	Content
VPN Instance Configuration Guide	Covers VPN instance fundamentals and configuration procedures.
VXLAN Configuration Guide	Describes the fundamentals and configuration of VXLAN features.
Service Chain Configuration Guide	Describes the fundamentals and configuration of *Service Chain* features.
Acronyms	Lists the significant acronyms in the configuration guides.

NSFOCUS Firewall Series

NF Fundamentals Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes features and tasks that help you get started with the device, iIt includes the following feature modules:
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
❗ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Using the CLI

About the CLI

At the command-line interface (CLI), you can enter text commands to configure, manage, and monitor the device.

You can use different methods to log in to the CLI. For example, you can log in through the console port or Telnet. For more information about login methods, see "Login overview."

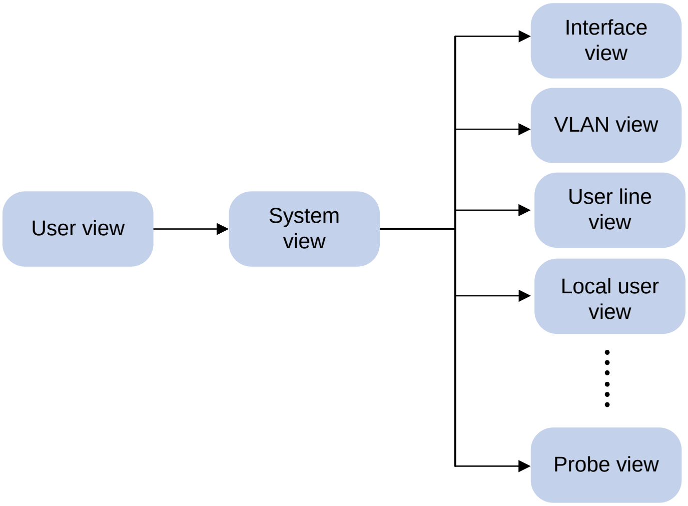
Using CLI views

About CLI views

Commands are grouped in different views by feature. To use a command, you must enter its view.

CLI views are hierarchically organized, as shown in Figure 1. Each view has a unique prompt, from which you can identify where you are and what you can do. For example, the prompt [Sysname-vlan100] shows that you are in VLAN 100 view and can configure attributes for that VLAN.

Figure 1 CLI views



You are placed in user view immediately after you log in to the CLI.

In user view, you can perform the following tasks:

- Perform basic operations including display, debug, file management, FTP, Telnet, clock setting, and reboot.
- Enter system view.

In system view, you can perform the following tasks:

- Configure settings that affect the device as a whole, such as the daylight saving time, banners, and hotkeys.
- Enter feature views.

  For example, you can perform the following tasks:

  - Enter interface view to configure interface parameters.

- Enter VLAN view to add ports to the VLAN.
- Enter user line view to configure login user attributes.

A feature view might have child views. For example, NQA operation view has the child view HTTP operation view.

- Enter probe view by using the **probe** command.

  The probe view provides display, debugging, and maintenance commands, which are mainly used by developers and testers for system fault diagnosis and system operation monitoring.

  For more information about the commands in probe view, see the probe commands manual for each feature.

△ **CAUTION:**

Use the commands in probe view under the guidance of engineers to avoid system exceptions caused by misoperations.

To display all commands available in a view, enter a question mark (?) at the view prompt.

Entering system view from user view

To enter system view from user view, execute the following command:

```
system-view
```

Returning to the upper-level view from a view

Restrictions and guidelines

Executing the **quit** command in user view terminates your connection to the device.

To return from public key view to system view, you must use the **peer-public-key end** command.

Procedure

To return to the upper-level view from a view, execute the following command:

```
quit
```

Returning to user view

About this task

This feature enables you to return to user view from any view except Tcl configuration view and Python shell view by performing a single operation. You do not need to execute the **quit** command multiple times.

To return to user view from Tcl configuration view, use the **tclquit** command. To return to user view from Python shell view, use the **exit()** command.

Procedure

To return directly to user view from any other view except Tcl configuration view and Python shell view, use one of the following methods:

- Execute the **return** command.
- Press **Ctrl+Z**.

Accessing the CLI online help

The CLI online help is context sensitive. Enter a question mark at any prompt or in any position of a command to display all available options.

To access the CLI online help, use one of the following methods:

- Enter a question mark at a view prompt to display the first keyword of every command available in the view. For example:

  ```
  <Sysname> ?
  User view commands:
    archive             Archive configuration
    backup              Backup operation
    boot-loader         Software image file management
  ...
  ```

- Enter a space and a question mark after a command keyword to display all available keywords and arguments.
  - If the question mark is in the place of a keyword, the CLI displays all possible keywords, each with a brief description. For example:

    ```
    <Sysname> terminal ?
      debugging  Enable to display debugging logs on the current terminal
      logging    Display logs on the current terminal
      monitor    Enable to display logs on the current terminal
    ```

  - If the question mark is in the place of an argument, the CLI displays the description for the argument. For example:

    ```
    <Sysname> system-view
    [Sysname] interface vlan-interface ?
      <1-4094>  Vlan-interface interface number
    [Sysname] interface vlan-interface 1 ?
      <cr>
    [Sysname] interface vlan-interface 1
    ```

    <1-4094> is the value range for the argument. **<cr>** indicates that the command is complete and you can press **Enter** to execute the command.

- Enter an incomplete keyword string followed by a question mark to display all keywords starting with that string. The CLI also displays the descriptions for the keywords. For example:

  ```
  <Sysname> f?
    fdisk     Partition a storage medium
    firmware  Firmware management
    fixdisk   Check and repair a storage medium
    format    Format a storage medium
    free      Release a connection
    ftp       Open an FTP connection
    fuser     Display processes that are using a file system, directory, or file
  <Sysname> display ftp?
    ftp         FTP module
    ftp-server  FTP server information
    ftp-user    FTP user information
  ```

Using the undo form of a command

Most configuration commands have an **undo** form for the following tasks:

- Canceling a configuration.
- Restoring the default.
- Disabling a feature.

For example, the **`info-center enable`** command enables the information center. The **`undo info-center enable`** command disables the information center.

Entering a command

When you enter a command, you can perform the following tasks:

- Use keys or hotkeys to edit the command line.
- Use abbreviated keywords or keyword aliases.

Editing a command line

To edit a command line, use the keys listed in Table 1 or the hotkeys listed in Table 4. When you are finished, you can press **Enter** to execute the command.

Table 1 Command line editing keys

Keys	Function
Common keys	If the edit buffer is not full, pressing a common key inserts a character at the cursor and moves the cursor to the right. The edit buffer can store up to 511 characters. Unless the buffer is full, all common characters that you enter before pressing **Enter** are saved in the edit buffer.
Backspace	Deletes the character to the left of the cursor and moves the cursor back one character.
Left arrow key (←)	Moves the cursor one character to the left.
Right arrow key (→)	Moves the cursor one character to the right.
Up arrow key (↑)	Displays the previous command in the command history buffer.
Down arrow key (↓)	Displays the next command in the command history buffer.
Tab	If you press **Tab** after typing part of a keyword, the system automatically completes the keyword. • If a unique match is found, the system displays the complete keyword. • If there is more than one match, press **Tab** multiple times to pick the keyword you want to enter. • If there is no match, the system does not modify what you entered but displays it again in the next line.

The device supports the following special commands:

- **#**–Used by the system in a configuration file as separators for adjacent sections.
- **`version`**–Used by the system in a configuration file to indicate the software version information. For example, **`version 7.1. xxx`**, **`Release xxx`**.

These commands are special because of the following reasons:

- These commands are not intended for you to use at the CLI.

- You can enter the **#** command in any view or the **version** command in system view, or enter any values for them. For example, you can enter **# abc** or **version abc**. However, the settings do not take effect.
- The device does not provide any online help information for these commands.

Entering a text or string type value for an argument

A text type argument value can contain any characters except question marks (?).

A string type argument value can contain any printable characters except question marks (?).

- To include a quotation mark (") or backward slash (\) in a string type argument value, prefix the character with an escape key (\), for example, \" and \\.
- To include a blank space in a string type argument value, enclose the value in quotation marks, for example, "my device".

A specific argument might have more requirements. For more information, see the relevant command reference.

To enter a printable character, you can enter the character or its ASCII code in the range of 32 to 126.

Entering an interface type

You can enter an interface type in one of the following formats:

- Full spelling of the interface type.
- An abbreviation that uniquely identifies the interface type.
- Acronym of the interface type.

For a command line, all interface types are case insensitive. The following table shows the full spellings and acronyms of interface types.

For example, to use the **interface** command to enter the view of interface GigabitEthernet 1/0/1, you can enter the command line in the following formats:

- **interface gigabitethernet 1/0/1**
- **interface g 1/0/1**
- **interface ge 1/0/1**

Spaces between the interface types and interfaces are not required.

Table 2 Full spellings and acronyms of interface types

Full spelling	Acronym
Analogmodem	AM
Async	Asy
IMA-group	IMA-G
Bridge-template	Bridge
Dialer	Dia
Virtual-Access	VA
Inner-Ethernet	I-E
InLoopBack	InLoop
LoopBack	Loop

Full spelling	Acronym
Encrypt	Encry
Ethernet	Eth
GigabitEthernet	GE
VE-Bridge	VEB
Ten-GigabitEthernet	XGE
Virtual-Ethernet	VEth
M-Ethernet	ME
M-GigabitEthernet	MGE
Serial	Ser
subscriber-line	line
Tunnel	Tun
Vlan-interface	Vlan-int
Virtual-Template	VT
InAsync	InAsy
Bridge-Aggregation	BAGG
Register-Tunnel	REG
Route-Aggregation	RAGG
FortyGigE	FGE
HundredGigE	HGE
SAN-Aggregation	SAGG
S-Channel	S-Ch
Virtual-PPP	VPPP
Schannel-Aggregation	SCH-AGG
TwentyGigE	TGE
Twenty-FiveGigE	WGE
Tunnel-Bundle	Tunnel-B
VE-L2VPN	L2VE
VE-L3VPN	L3VE
Blade-Aggregation	BLAGG
Eth-channel	E-Ch
Beth-redundancy	BEth
Reth-redundancy	Reth
Circuit-Emulation	CEM
LoRa-Radio	Lor

Abbreviating commands

You can enter a command line quickly by entering incomplete keywords that uniquely identify the complete command. In user view, for example, commands starting with an **s** include **startup saved-configuration** and **system-view**. To enter the command **system-view**, you need to type only **sy**. To enter the command **startup saved-configuration**, type **st s**.

You can also press **Tab** to complete an incomplete keyword.

Configuring and using command aliases

About this task

You can configure one or more aliases for a command or the starting keywords of commands. Then, you can use the aliases to execute the command or commands. If the command or commands have **undo** forms, you can also use the aliases to execute the **undo** command or commands.

For example, if you configure the **shiprt** alias for **display ip routing-table**, you can enter **shiprt** to execute the **display ip routing-table** command. If you configure the **ship** alias for **display ip**, you can use **ship** to execute all commands starting with **display ip**, including:

- Enter **ship routing-table** to execute the **display ip routing-table** command.
- Enter **ship interface** to execute the **display ip interface** command.

The device provides a set of system-defined command aliases, as listed in Table 3.

Table 3 System-defined command aliases

Command alias	Command or command keyword
access-list	**acl**
end	**return**
erase	**delete**
exit	**quit**
hostname	**sysname**
logging	**info-center**
no	**undo**
show	**display**
write	**save**

Restrictions and guidelines

A command alias can be used only as the first keyword of a command or the second keyword of the **undo** form of a command.

After you successfully execute a command by using an alias, the system saves the command, instead of the alias, to the running configuration.

The command string can include up to nine parameters. Each parameter starts with the dollar sign ($) and a sequence number in the range of 1 to 9. For example, you can configure the alias **shinc** for the **display ip $1 | include $2** command. Then, to execute the **display ip routing-table | include Static** command, you need to enter only **shinc routing-table Static**.

To use an alias for a command that has parameters, you must specify a value for each parameter. If you fail to do so, the system informs you that the command is incomplete and displays the command string represented by the alias.

System-defined command aliases cannot be deleted.

Procedure

1. Enter system view.

   `system-view`

2. Configure a command alias.

   `alias` *`alias command`*

   By default, the device has a set of command aliases, as listed in Table 3.

3. (Optional.) Display command aliases.

   `display alias` `[` *`alias`* `]`

   This command is available in any view.

Configuring and using hotkeys

About this task

The system defines the hotkeys shown in Table 4 and provides a set of configurable command hotkeys. Pressing a command hotkey is the same as entering a command.

Table 4 System-reserved hotkeys

Hotkey	Function
Ctrl+A	Moves the cursor to the beginning of a line.
Ctrl+B	Moves the cursor one character to the left.
Ctrl+C	Stops the current command.
Ctrl+D	Deletes the character at the cursor.
Ctrl+E	Moves the cursor to the end of a line.
Ctrl+F	Moves the cursor one character to the right.
Ctrl+H	Deletes the character to the left of the cursor.
Ctrl+K	Aborts the connection request.
Ctrl+N	Displays the next command in the history buffer.
Ctrl+P	Displays the previous command in the history buffer.
Ctrl+R	Redisplays the current line.
Ctrl+V	Pastes text from the clipboard.
Ctrl+W	Deletes the word to the left of the cursor.
Ctrl+X	Deletes all characters to the left of the cursor.
Ctrl+Y	Deletes all characters from the cursor to the end of the line.
Ctrl+Z	Returns to user view.
Ctrl+]	Terminates the current connection.
Esc+B	Moves the cursor back one word.
Esc+D	Deletes all characters from the cursor to the end of the word.

Hotkey	Function
Esc+F	Moves the cursor forward one word.
Esc+N	Moves the cursor down one line. You can use this hotkey before pressing **Enter**.
Esc+P	Moves the cursor up one line. You can use this hotkey before pressing **Enter**.
Esc+<	Moves the cursor to the beginning of the clipboard.
Esc+>	Moves the cursor to the end of the clipboard.

Restrictions and guidelines

A hotkey can correspond to only one command or function. If you assign multiple commands or functions to the same hotkey, the most recently assigned command or function takes effect.

A command or function can be assigned to multiple hotkeys. You can use any of the hotkeys to execute the command or function.

If a hotkey is also defined by the terminal software you are using to interact with the device, the terminal software definition takes effect.

Procedure

1. Enter system view.

   `system-view`

2. Assign a command to a configurable command hotkey.

   `hotkey` { **`ctrl_g`** | **`ctrl_l`** | **`ctrl_o`** | **`ctrl_t`** | **`ctrl_u`** } *command*

   The following are the defaults:

   - **Ctrl+G** is assigned the **`display current-configuration`** command.
   - **Ctrl+L** is assigned the **`display ip routing-table`** command.
   - **Ctrl+O** is assigned the **`undo debugging all`** command.
   - No command is assigned to **Ctrl+T** or **Ctrl+U**.

3. (Optional.) Display hotkeys.

   `display hotkey`

   This command is available in any view.

Enabling redisplaying entered-but-not-submitted commands

About this task

Your input might be interrupted by system information output. If redisplaying entered-but-not-submitted commands is enabled, the system redisplays your input after finishing the output. You can then continue entering the command line.

Procedure

1. Enter system view.

   `system-view`

2. Enable redisplaying entered-but-not-submitted commands.

   `info-center synchronous`

   By default, the system does not redisplay entered-but-not-submitted commands.

   For more information about this command, see *Network Management and Monitoring Command Reference*.

Understanding command-line syntax error messages

After you press **Enter** to submit a command, the command line interpreter examines the command syntax.

- If the command passes syntax check, the CLI executes the command.
- If the command fails syntax check, the CLI displays an error message.

Table 5 Common command-line syntax error messages

Error message	Cause
% Unrecognized command found at '^' position.	The keyword in the marked position is invalid.
% Incomplete command found at '^' position.	One or more required keywords or arguments are missing.
% Ambiguous command found at '^' position.	The entered character sequence matches more than one command.
% Too many parameters found at '^' position.	The entered character sequence contains excessive keywords or arguments.
% Wrong parameter found at '^' position.	The argument in the marked position is invalid.

Using the command history feature

About command history buffers

The system automatically saves commands successfully executed by a login user to the following two command history buffers:

- Command history buffer for the user line.
- Command history buffer for all user lines.

Table 6 Comparison between the two types of command history buffers

Item	Command history buffer for a user line	Command history buffer for all user lines
Which commands are saved in the buffer?	Commands successfully executed by the current user of the user line.	Commands successfully executed by all login users.
Can commands in the buffer be displayed?	Yes.	Yes.
Can commands in the buffer be recalled?	Yes.	No.
Are buffered commands cleared when the user logs out?	Yes.	No.
Is the buffer size adjustable?	Yes.	No. The buffer size is fixed at 1024.

Command buffering rules

The system follows these rules when buffering commands:

- If you use incomplete keywords when entering a command, the system buffers the command in the exact form that you used.
- If you use an alias when entering a command, the system transforms the alias to the represented command or command keywords before buffering the command.
- If you enter a command in the same format multiple times in succession, the system buffers the command only once. If you enter a command in different formats multiple times, the system buffers each command format. For example, **`display cu`** and **`display current-configuration`** are buffered as two entries but successive repetitions of **`display cu`** create only one entry.
- To buffer a new command when a buffer is full, the system deletes the oldest command entry in the buffer.

Managing and using the command history buffers

Displaying the commands in command history buffers

To display the commands in command history buffers, execute the following commands in any view:

- Display the commands in command history buffers for a user line.

  ```
  display history-command
  ```

- Display the commands in command history buffers for all user lines.

  ```
  display history-command all
  ```

Recalling commands in the command history buffer for a user line

Use up and down arrow keys to navigate to the command and press **Enter**.

Setting the size of the command history buffer for a user line

Use the **`history-command max-size`** command in user line or user line class view. For more information, see *Fundamentals Command Reference*.

Repeating commands in the command history buffer for a user line

About this task

You can recall and execute commands in the command history buffer for the current user line multiple times.

Restrictions and guidelines

The **`repeat`** command is available in any view. However, to repeat a command, you must first enter the view for the command. To repeat multiple commands, you must first enter the view for the first command.

The **`repeat`** command executes commands in the order they were executed.

The system waits for your interaction when it repeats an interactive command.

Procedure

To repeat commands in the command history buffer for the current user line, execute the following command:

```
repeat [ number ] [ count times ] [ delay seconds ]
```

Controlling the CLI output

This section describes the CLI output control features that help you identify the desired output.

Pausing between screens of output

About this task

The device can automatically pause after displaying a specific number of lines if the output is too long to fit on one screen. At a pause, the device displays **----more----**. You can use the keys described in Table 7 to display more information or stop the display.

You can also disable pausing between screens of output for the current session. Then, all output is displayed at one time and the screen is refreshed continuously until the final screen is displayed.

Table 7 Output controlling keys

Keys	Function
Space	Displays the next screen.
Enter	Displays the next line.
Ctrl+C	Stops the display and cancels the command execution.
<PageUp>	Displays the previous page.
<PageDown>	Displays the next page.

Disabling pausing between screens of output

To disable pausing between screens of output, execute the following command in user view:

```
screen-length disable
```

The default depends on the settings of the **screen-length** command in user line view. The following are the default settings for the **screen-length** command:

- Pausing between screens of output is enabled.
- The maximum number of lines to be displayed at a time is 24.

For more information about the **screen-length** command, see *Fundamentals Command Reference*.

This command is a one-time command and takes effect only for the current CLI session.

Numbering each output line from a display command

About this task

For easy identification, you can use the **| by-linenum** option to display a number for each output line from a **display** command.

Each line number is displayed as a 5-character string and might be followed by a colon (:) or hyphen (-). If you specify both **| by-linenum** and **| begin** *regular-expression* for a **display** command, a hyphen is displayed for all lines that do not match the regular expression.

Procedure

To number each output line from a **display** command, execute the following command in any view:

display *command* **| by-linenum**

Example

# Display information about VLAN 999, numbering each output line.

```
<Sysname> display vlan 999 | by-linenum
    1:  VLAN ID: 999
    2:  VLAN type: Static
    3:  Route interface: Configured
    4:  IPv4 address: 192.168.2.1
    5:  IPv4 subnet mask: 255.255.255.0
    6:  Description: For LAN Access
    7:  Name: VLAN 0999
    8:  Tagged ports:   None
    9:  Untagged ports: None
```

Filtering the output from a display command

About this task

You can use the **|** { **begin** | **exclude** | **include** } *regular-expression* option to filter the output from a **display** command.

- **begin**—Displays the first line matching the specified regular expression and all subsequent lines.
- **exclude**—Displays all lines not matching the specified regular expression.
- **include**—Displays all lines matching the specified regular expression.
- *regular-expression*—A case-sensitive string of 1 to 256 characters, which can contain the special characters described in Table 8.

Table 8 Special characters supported in a regular expression

Characters	Meaning	Examples
^	Matches the beginning of a line.	"^u" matches all lines beginning with "u". A line beginning with "Au" is not matched.
$	Matches the end of a line.	"u$" matches all lines ending with "u". A line ending with "uA" is not matched.
. (period)	Matches any single character.	".s" matches "as" and "bs".
*	Matches the preceding character or string zero, one, or multiple times.	"zo*" matches "z" and "zoo", and "(zo)*" matches "zo" and "zozo".
+	Matches the preceding character or string one or multiple times.	"zo+" matches "zo" and "zoo", but not "z".
|	Matches the preceding or succeeding string.	"def|int" matches a line containing "def" or "int".
( )	Matches the string in the parentheses, usually used together with the plus sign (+) or asterisk sign (*).	"(123A)" matches "123A". "408(12)+" matches "40812" and "408121212", but not "408".
\N	Matches the preceding strings in parentheses, with the *N*th string repeated once.	"(string)\1" matches a string containing "stringstring". "(string1)(string2)\2" matches a string containing

Characters	Meaning	Examples
		"string1string2string2". "(string1)(string2)\1\2" matches a string containing " string1string2string1string2".
[ ]	Matches a single character in the brackets.	"[16A]" matches a string containing 1, 6, or A; "[1-36A]" matches a string containing 1, 2, 3, 6, or A (- is a hyphen). To match the character "]", put it immediately after "[", for example, [ ]abc]. There is no such limit on "[".
[^]	Matches a single character that is not in the brackets.	"[^16A]" matches a string that contains one or more characters except for 1, 6, or A, such as "abc". A match can also contain 1, 6, or A (such as "m16"), but it cannot contain these three characters only (such as 1, 16, or 16A).
{n}	Matches the preceding character *n* times. The number *n* must be a nonnegative integer.	"o{2}" matches "food", but not "Bob".
{n,}	Matches the preceding character *n* times or more. The number *n* must be a nonnegative integer.	"o{2,}" matches "foooood", but not "Bob".
{n,m}	Matches the preceding character *n* to *m* times or more. The numbers *n* and *m* must be nonnegative integers and *n* cannot be greater than *m*.	" o{1,3}" matches "fod", "food", and "foooood", but not "fd".
\<	Matches a string that starts with the pattern following \<. A string that contains the pattern is also a match if the characters preceding the pattern are not digits, letters, or underscores.	"\<do" matches "domain" and "doa".
\>	Matches a string that ends with the pattern preceding \>. A string that contains the pattern is also a match if the characters following the pattern are not digits, letters, or underscores.	"do\>" matches "undo" and "cdo".
\b	Matches a word that starts with the pattern following \b or ends with the pattern preceding \b.	"er\b" matches "never", but not "verb" or "erase". "\ber" matches "erase", but not "verb" or "never".
\B	Matches a word that contains the pattern but does not start or end with the pattern.	"er\B" matches "verb", but not "never" or "erase".
\w	Same as [A-Za-z0-9_], matches a digit, letter, or underscore.	"v\w" matches "vlan" and "service".
\W	Same as [^A-Za-z0-9_], matches a character that is not a digit, letter, or underscore.	"\Wa" matches "-a", but not "2a" or "ba".
\	Escape character. If a special character listed in this table follows \, the specific meaning of the character is removed.	"\\" matches a string containing "\", "\^" matches a string containing "^", and "\\b" matches a string containing "\b".

Restrictions and guidelines

The required filtering time increases with the complexity of the regular expression. To abort the filtering process, press **Ctrl+C**.

Examples

# Display the running configuration, starting from the first configuration line that contains **line**.

```
<Sysname> display current-configuration | begin line
line class console
user-role network-admin
#
line class vty
user-role network-operator
#
line console 0
user-role network-admin
#
line vty 0 31
authentication-mode scheme
user-role network-operator
#
...
```

# Display brief information about interfaces in up state.

```
<Sysname> display interface brief | exclude DOWN
Brief information on interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Protocol: (s) - spoofing
Interface            Link Protocol Primary IP      Description
InLoop0              UP   UP(s)    --
NULL0                UP   UP(s)    --
Vlan1                UP   UP       192.168.1.83
```

# Display SNMP-related running configuration lines.

```
<Sysname> display current-configuration | include snmp
snmp-agent
 snmp-agent community write private
 snmp-agent community read public
 snmp-agent sys-info version all
 snmp-agent target-host trap address udp-domain 192.168.1.26 params securityname public
```

Saving the output from a display command to a file

About this task

A **display** command shows certain configuration and operation information of the device. Its output might vary over time or with user configuration or operation. You can save the output to a file for future retrieval or troubleshooting.

Use one of the following methods to save the output from a **display** command:

- Save the output to a separate file. Use this method if you want to use one file for a single **display** command.

- Append the output to the end of a file. Use this method if you want to use one file for multiple **display** commands.

Procedure

To save the output from a **display** command to a file, use one of the following commands in any view:

- Save the output from a **display** command to a separate file.

  display *command* **>** *filename*

- Append the output from a **display** command to the end of a file.

  display *command* **>>** *filename*

Examples

# Save the VLAN 1 settings to a separate file named **vlan.txt**.

```
<Sysname> display vlan 1 > vlan.txt
```

# Verify that the VLAN 1 settings are saved to the file **vlan.txt**.

```
<Sysname> more vlan.txt
VLAN ID: 1
 VLAN type: Static
 Route interface: Not configured
 Description: VLAN 0001
 Name: VLAN 0001
 Tagged ports:   None
 Untagged ports: None
```

# Append the VLAN 999 settings to the end of the file **vlan.txt**.

```
<Sysname> display vlan 999 >> vlan.txt
```

# Verify that the VLAN 999 settings are appended to the end of the file **vlan.txt**.

```
<Sysname> more vlan.txt
VLAN ID: 1
 VLAN type: Static
 Route interface: Not configured
 Description: VLAN 0001
 Name: VLAN 0001
 Tagged ports:   None
 Untagged ports: None

 VLAN ID: 999
 VLAN type: Static
 Route interface: Configured
 IPv4 address: 192.168.2.1
 IPv4 subnet mask: 255.255.255.0
 Description: For LAN Access
 Name: VLAN 0999
 Tagged ports:   None
 Untagged ports: None
```

Viewing and managing the output from a display command effectively

You can use the following methods in combination to filter and manage the output from a **display** command:

- Numbering each output line from a display command
- Filtering the output from a display command
- Saving the output from a display command to a file

Procedure

To use multiple measures to view and manage the output from a **display** command effectively, execute the following command in any view:

display *command* [**|** [**by-linenum**] { **begin** | **exclude** | **include** } *regular-expression*] [**>** *filename* | **>>** *filename*]

Examples

# Save the running configuration to a separate file named **test.txt**, with each line numbered.

```
<Sysname> display current-configuration | by-linenum > test.txt
```

# Append lines including **snmp** in the running configuration to the file **test.txt**.

```
<Sysname> display current-configuration | include snmp >> test.txt
```

# Display the first line that begins with **user-group** in the running configuration and all the following lines.

```
<Sysname> display current-configuration | by-linenum begin user-group
  114:  user-group system
  115-  #
  116-  return
```

// The colon (:) following a line number indicates that the line contains the string user-group. The hyphen (-) following a line number indicates that the line does not contain the string **user-group**.

Contents

Configuring RBAC

About RBAC

Role-based access control (RBAC) controls access permissions of users based on user roles.

RBAC assigns access permissions to user roles that are created for different job functions. Users are given permission to access a set of items and resources based on the users' user roles. Separating permissions from users enables simple permission authorization management.

Permission assignment

Use the following methods to assign permissions to a user role:

- Define a set of rules to determine accessible or inaccessible items for the user role. (See "User role rules.")
- Configure resource access policies to specify which resources are accessible to the user role. (See "Resource access policies.")

To use a command related to a system resource, a user role must have access to both the command and the resource.

For example, a user role has access to the **vlan** command and access only to VLAN 10. When the user role is assigned, you can use the **vlan** command to create VLAN 10 and enter its view. However, you cannot create any other VLANs. If the user role has access to VLAN 10 but does not have access to the **vlan** command, you cannot use the command to enter the view of VLAN 10.

When a user logs in to the device with any user role and enters **<?>** in a view, help information is displayed for the system-defined command aliases in the view. However, the user might not have the permission to access the command aliases. Whether the user can access the command aliases depends on the user role's permission to the commands corresponding to the aliases. For information about command aliases, see "Using the CLI."

A user that logs in to the device with any user role has access to the **system-view**, **quit**, and **exit** commands.

User role rules

User role rules permit or deny access to the items, including commands, Web pages, XML elements, or MIB nodes. You can define the following types of rules for different access control granularities:

- **Command rule**—Controls access to a command or a set of commands that match a regular expression.
- **Feature rule**—Controls access to the commands of a feature by command type.
- **Feature group rule**—Controls access to the commands of features in a feature group by command type.
- **Web menu rule**—Controls access to Web pages used for configuring the device. These Web pages are called Web menus.
- **XML element rule**—Controls access to XML elements used for configuring the device.
- **OID rule**—Controls SNMP access to a MIB node and its child nodes. An OID is a dotted numeric string that uniquely identifies the path from the root node to a leaf node.

The items (commands, Web menus, XML elements, and MIB nodes) are controlled based on the following types:

- **Read**—Items that display configuration and maintenance information. For example, the **display** commands and the **dir** command.

- **Write**—Items that configure the features in the system. For example, the **info-center enable** command and the **debugging** command.
- **Execute**—Items that execute specific functions. For example, the **ping** command and the **ftp** command.

A user role can access the set of permitted items specified in the user role rules. The user role rules include predefined (identified by sys-*n*) and user-defined user role rules. For more information about the user role rule priority, see "Configuring user role rules."

Resource access policies

Resource access policies control access of a user role to system resources and include the following types:

- **Interface policy**—Controls access to interfaces.
- **VLAN policy**—Controls access to VLANs.
- **VPN instance policy**—Controls access to VPN instances.
- **Security zone policy**—Controls access to security zones.

Resource access policies do not control access to the VLAN, VPN instance, security zone, or interface options in the **display** commands. You can specify these options in the **display** commands if the options are permitted by any user role rule.

Predefined user roles

The system provides predefined user roles. These user roles have access to all system resources. However, their access permissions differ, as shown in Table 1.

Among all of the predefined user roles, only network-admin, context-admin, and level-15 can create, modify, and delete local users and local user groups. The other user roles can only modify their own passwords if they have permissions to configure local users and local user groups.

All the predefined user roles are available for the default context. The network-admin and network-operator user roles are not available for non-default contexts. For more information about contexts, see *Virtual Technologies Configuration Guide*.

The access permissions of the level-0 to level-14 user roles can be modified through user role rules and resource access policies. However, you cannot make changes on the predefined access permissions of these user roles. For example, you cannot change the access permission of these user roles to the **display history-command all** command.

Table 1 Predefined roles and permissions matrix

User role name	Permissions
network-admin	Accesses all features and resources in the system, except for the **display security-logfile summary**, **info-center security-logfile directory**, and **security-logfile save** commands.
network-operator	• Accesses the **display** commands for features and resources in the system. To display all accessible commands of the user role, use the **display role** command. • Enables local authentication login users to change their own passwords. • Accesses the command used for entering XML view. • Accesses all read-type Web menu items. • Accesses all read-type XML elements. • Accesses all read-type MIB nodes.
level-*n* (*n* = 0 to 15)	• **level-0**—Has access to commands including **ping**, **tracert**, **ssh2**, **telnet**, and **super**. Level-0 access rights are

User role name	Permissions
	configurable. • **level-1**—Has access to the **`display`** commands of features and resources in the system. The **level-1** user role also has all access rights of the level-0 user role. Level-1 access rights are configurable. • **level-2 to level-8, and level-10 to level-14**—Have no access rights by default. Access rights are configurable. • **level-9**—Has access to most of the features and resources in the system. If you are logged in with a local user account that has a level-9 user role, you can change the password in the local user account. The following are the major features and commands that the level-9 user role cannot access: ○ RBAC non-debugging commands. ○ Local users. ○ File management. ○ Device management. ○ The **`display history-command all`** command. • **level-15**—Has the same rights as network-admin on the default context, and has the same rights as context-admin on non-default contexts.
security-audit	Security log manager. The user role has the following access rights to security log files: • Accesses the commands for displaying and maintaining security log files (for example, the **`dir`**, **`display security-logfile summary`**, and **`more`** commands). • Accesses the commands for managing security log files and security log file system (for example, the **`info-center security-logfile directory`**, **`mkdir`**, and **`security-logfile save`** commands). For more information about security log management commands, see information center commands in *Network Management and Monitoring Command Reference*. For more information about file system management commands, see *Fundamentals Command Reference*. **IMPORTANT:** Only the security-audit user role has access to security log files. You cannot assign the security-audit user role to non-AAA authentication users.
guest-manager	Accesses only guest-related web pages, and has no access to commands.
context-admin	Accesses all features and resources in the context, except for the **`display security-logfile summary`**, **`info-center security-logfile directory`**, and **`security-logfile save`** commands.
context-operator	• Accesses the **`display`** commands for features and resources available in the context. To display all accessible commands of the user role, use the **`display role`** command. • Enables local authentication login users to change their own passwords. • Accesses the command used for entering XML view. • Accesses all read-type Web menu items. • Accesses all read-type XML elements. • Accesses all read-type MIB nodes.
system-admin	System manager. The user role has the following access permissions:

User role name	Permissions
	• Has read, write, and execute access permissions to the Web menus under the Summary category. • Has read, write, and execute access permissions to the System Logs Web menu under the Monitoring category. • Has the following access permissions under the System category: ○ Has read access permissions to the Administrators and Roles Web menus. ○ Has read, write, and execute access permissions to other Web menus. • Accesses the **`ping`** and **`tracert`** commands. To display the detailed access permissions of this user role, use the **`display role`** command. **IMPORTANT:** You cannot assign the system-admin user role to non-AAA authentication users.
security-admin	Security manager. The user role has the following access permissions: • Has read, write, and execute access permissions to Web menus under the Policies, Objects, and Network categories. • Has the following access permissions under the Monitoring category: ○ Has no access permissions to the System Logs and Operation Logs Web menus. ○ Has read, write, and execute access permissions to other Web menus. • Accesses the **`ping`** and **`tracert`** commands. To display the detailed access permissions of this user role, use the **`display role`** command. **IMPORTANT:** You cannot assign the security-admin user role to non-AAA authentication users.
audit-admin	Audit manager. The user role has the following access permissions: • Has read, write, and execute access permissions to the Operation Logs Web menu under the Monitoring category. • Accesses the **`ping`** and **`tracert`** commands. To display the detailed access permissions of this user role, use the **`display role`** command. **IMPORTANT:** You cannot assign the audit-admin user role to non-AAA authentication users.

User role assignment

You assign access rights to a user by assigning a minimum of one user role. The user can use the collection of items and resources accessible to all user roles assigned to the user. For example, you can access any interface to use the **`qos apply policy`** command if you are assigned the following user roles:

- User role A denies access to the **`qos apply policy`** command and permits access only to interface GigabitEthernet 1/0/1.
- User role B permits access to the **`qos apply policy`** command and all interfaces.

Depending on the authentication method, user role assignment has the following methods:

- **AAA authorization**—If scheme authentication is used, the AAA module handles user role assignment.
  - If the user passes local authorization, the device assigns the user roles specified in the local user account.
  - If the user passes remote authorization, the remote AAA server assigns the user roles specified on the server. The AAA server can be a RADIUS or HWTACACS server.
- **Non-AAA authorization**—When the user accesses the device without authentication or by passing password authentication on a user line, the device assigns user roles specified on the user line. This method also applies to SSH clients that use publickey or password-publickey authentication. User roles assigned to these SSH clients are specified in their respective device management user accounts.

For more information about AAA, see *Security Configuration Guide*. For more information about user lines, see "Login overview" and "Configuring CLI login."

RBAC tasks at a glance

To configure RBAC, perform the following tasks:

1. Creating a user role
2. Configuring user role rules
3. (Optional.) Configuring a feature group
4. Configuring resource access policies
   - Configuring the user role interface policy
   - Configuring the user role VLAN policy
   - Configuring the user role VPN instance policy
   - Configuring the user role security zone policy
5. Assigning user roles
   - Enabling the default user role feature
   - Assigning user roles to remote AAA authentication users
   - Assigning user roles to local AAA authentication users
   - Assigning user roles to non-AAA authentication users on user lines
6. Configuring temporary user role authorization
   a. Setting the authentication mode for temporary user role authorization
   b. Specifying the default target user role for temporary user role authorization
   c. Setting an authentication password for temporary user role authorization
   d. (Optional.) Automatically obtaining the login username for temporary user role authorization
   e. Obtaining temporary user role authorization

Creating a user role

About this task

In addition to the predefined user roles, you can create a maximum of 64 custom user roles for granular access control.

Procedure

1. Enter system view.

```
system-view
```

2. Create a user role and enter its view.

   role name *role-name*

   By default, the system has the following predefined user roles:

   - network-admin.
   - network-operator.
   - context-admin.
   - context-operator.
   - level-*n* (where *n* equals an integer in the range of 0 to 15).
   - security-audit.
   - guest-manager.
   - system-admin.
   - security-admin.
   - audit-admin.

   Among these user roles, only the permissions and descriptions of the level-0 to level-14 user roles are configurable.

3. (Optional.) Configure a description for the user role.

   description *text*

   By default, a user role does not have a description.

Configuring user role rules

About this task

You can configure user role rules to permit or deny the access of a user role to specific commands, Web pages, XML elements, and MIB nodes.

The following guidelines apply to non-OID rules:

- If two user-defined rules of the same type conflict, the rule with the higher ID takes effect. For example, a user role can use the **tracert** command but not the **ping** command if the user role contains rules configured by using the following commands:
  - **rule** *1* **permit command** *ping*
  - **rule** *2* **permit command** *tracert*
  - **rule** *3* **deny command** *ping*
- If a predefined user role rule and a user-defined user role rule conflict, the user-defined user role rule takes effect.

The following guidelines apply to OID rules:

- The system compares an OID with the OIDs specified in user role rules, and it uses the longest match principle to select a rule for the OID. For example, a user role cannot access the MIB node with OID 1.3.6.1.4.1.25506.141.3.0.1 if the user role contains rules configured by using the following commands:
  - **rule** *1* **permit read write oid** *1.3.6*
  - **rule** *2* **deny read write oid** *1.3.6.1.4.1*
  - **rule** *3* **permit read write oid** *1.3.6.1.4*
- If the same OID is specified in multiple rules, the rule with the higher ID takes effect. For example, a user role can access the MIB node with OID 1.3.6.1.4.1.25506.141.3.0.1 if the user role contains rules configured by using the following commands:
  - **rule** *1* **permit read write oid** *1.3.6*
  - **rule** *2* **deny read write oid** *1.3.6.1.4.1*

  - **rule** *3* **permit read write oid** *1.3.6.1.4.1*

Restrictions and guidelines

- Context-related rules take effect only if they are configured in views of the following user roles: network-admin, network-operator, context-admin, context-operator, and level-15.
- Only the network-admin, context-admin, and level-15 user roles have access to the following commands:
  - The **display history-command all** command.
  - All commands that start with the **display role**, **display license**, **reboot**, **startup saved-configuration**, and **undo startup saved-configuration** keywords.
  - All commands that start with the **role**, **undo role**, **super**, **undo super**, **license**, **password-recovery**, and **undo password-recovery** keywords in system view.
  - All commands that start with the **snmp-agent community**, **undo snmp-agent community**, **snmp-agent usm-user**, **undo snmp-agent usm-user**, **snmp-agent group**, and **undo snmp-agent group** keywords in system view.
  - All commands that start with the **user-role**, **undo user-role**, **authentication-mode**, **undo authentication-mode**, **set authentication password**, and **undo set authentication password** keywords in user line view or user line class view.
  - All commands that start with the **user-role** and **undo user-role** keywords in schedule view or in CLI-defined policy view.
  - All commands of the event MIB feature.
- You can configure a maximum of 256 user-defined rules for a user role. The total number of user-defined user role rules cannot exceed 1024.
- Any rule modification, addition, or removal for a user role takes effect only on users who are logged in with the user role after the change.

Procedure

1. Enter system view.

   system-view

2. Enter user role view.

   role name *role-name*

3. Configure rules for the user role. Choose the options to configure as needed:
   - Configure a command rule.

     rule *number* { **deny** | **permit** } **command** *command-string*
   - Configure a feature rule.

     rule *number* { **deny** | **permit** } { **execute** | **read** | **write** } * **feature** [*feature-name*]
   - Configure a feature group rule.

     rule *number* { **deny** | **permit** } { **execute** | **read** | **write** } * **feature-group** *feature-group-name*

     A feature group rule takes effect only after the feature group is created.
   - Configure a Web menu rule.

     rule *number* { **deny** | **permit** } { **execute** | **read** | **write** } * **web-menu** [*web-string*]
   - Configure an XML element rule.

rule *number* { **deny** | **permit** } { **execute** | **read** | **write** } * **xml-element** [*xml-string*]

- Configure an OID rule.

  rule *number* { **deny** | **permit** } { **execute** | **read** | **write** } * **oid** *oid-string*

Configuring a feature group

About this task

Use feature groups to bulk assign command access permissions to sets of features. In addition to the predefined feature groups, you can create a maximum of 64 custom feature groups and assign a feature to multiple feature groups.

Procedure

1. Enter system view.

   system-view

2. Create a feature group and enter its view.

   role feature-group name *feature-group-name*

   By default, the system has the following predefined feature groups, which cannot be deleted or modified:

   - **L2**—Includes all Layer 2 commands.
   - **L3**—Includes all Layer 3 commands.

3. Add a feature to the feature group.

   feature *feature-name*

   By default, a feature group does not have any feature.

Configuring resource access policies

About resource access policies

Every user role has one VLAN policy, VPN instance policy, security zone policy, and interface policy. By default, these policies permit a user role to access any system resources. You can configure the policies of a user-defined user role or a predefined level-*n* user role to limit its access to any resources.

Restrictions and guidelines for resource access policy configuration

The policy configuration takes effect only on users who are logged in with the user role after the configuration.

Configuring the user role interface policy

1. Enter system view.

   system-view

2. Enter user role view.

   role name *role-name*

3. Enter user role interface policy view.

```
interface policy deny
```

By default, the interface policy of the user role permits access to all interfaces.

△ **CAUTION:**

This command denies the user role access to any interfaces if you do not specify accessible interfaces by using the **`permit interface`** command.

4. (Optional.) Specify a list of interfaces accessible to the user role.

   `permit interface` *`interface-list`*

   By default, no accessible interfaces are configured in user role interface policy view.

   Repeat this step to add multiple accessible interfaces.

Configuring the user role VLAN policy

1. Enter system view.

   `system-view`

2. Enter user role view.

   `role name` *`role-name`*

3. Enter user role VLAN policy view.

   `vlan policy deny`

   By default, the VLAN policy of the user role permits access to all VLANs.

△ **CAUTION:**

This command denies the user role access to any VLANs if you do not specify accessible VLANs by using the **`permit vlan`** command.

4. (Optional.) Specify a list of VLANs accessible to the user role.

   `permit vlan` *`vlan-id-list`*

   By default, no accessible VLANs are configured in user role VLAN policy view.

   Repeat this step to add multiple accessible VLANs.

Configuring the user role VPN instance policy

1. Enter system view.

   `system-view`

2. Enter user role view.

   `role name` *`role-name`*

3. Enter user role VPN instance policy view.

   `vpn-instance policy deny`

   By default, the VPN instance policy of the user role permits access to all VPN instances.

△ **CAUTION:**

This command denies the user role access to any VPN instances if you do not specify accessible VPN instances by using the **`permit vpn-instance`** command.

4. (Optional.) Specify a list of VPN instances accessible to the user role.

   `permit vpn-instance` *`vpn-instance-name`*`&<1-10>`

By default, no accessible VPN instances are configured in user role VPN instance policy view.

Repeat this step to add multiple accessible VPN instances.

Configuring the user role security zone policy

1. Enter system view.

   system-view

2. Enter user role view.

   role name *role-name*

3. Enter user role security zone policy view.

   security-zone policy deny

   By default, the security zone policy of the user role permits access to all security zones.

> △ **CAUTION:**
>
> This command denies the user role access to any security zones if you do not specify accessible security zones by using the **permit security-zone** command.

4. (Optional.) Specify a list of security zones accessible to the user role.

   permit security-zone *security-zone-name*&<1-10>

   By default, no accessible security zones are configured in user role security zone policy view.

   Repeat this step to add multiple accessible security zones.

Assigning user roles

Restrictions and guidelines for user role assignment

To control user access to the system, you must assign a minimum of one user role. Make sure a minimum of one user role among the user roles assigned by the server exists on the device.

Enabling the default user role feature

About this task

The default user role feature assigns the default user role to AAA-authenticated users if the authentication server (local or remote) does not assign any user roles to the users. These users are allowed to access the system with the default user role.

You can specify any user role existing in the system as the default user role.

Procedure

1. Enter system view.

   system-view

2. Enable the default user role feature.

   role default-role enable [*role-name*]

   By default, the default user role feature is disabled.

   If you do not use the **authorization-attribute** command to assign user roles to local users, you must enable the default user role feature. For information about the **authorization-attribute** command, see AAA commands in *Security Command Reference*.

Assigning user roles to remote AAA authentication users

For remote AAA authentication users, user roles are specified on the remote authentication server. For information about specifying user roles for RADIUS users on the RADIUS server, see the RADIUS server documentation. For HWTACACS users, the user roles must be specified in the **roles="***role-1 role-2 … role-n***"** format, where user roles are space separated. For example, specify **roles="level-0 level-1 level-2"** to assign the level-0, level-1, and level-2 user roles to an HWTACACS user.

For information about configuring the device to cooperate with the remote AAA server for user role assignment, see AAA configuration in *Security Configuration Guide*.

If the AAA server assigns the security-audit user role and other user roles to the same user, only the security-audit user role takes effect.

If the AAA server assigns different admin roles (system-admin, security-admin, and audit-admin) to a user, only the first admin role takes effect.

Assigning user roles to local AAA authentication users

About this task

Configure user roles for local AAA authentication users in their local user accounts. For information about AAA and local user configuration, see AAA configuration in *Security Configuration Guide*.

Restrictions and guidelines

- Every local user has a default user role. If this default user role is not suitable, remove it.
- If a local user is the only user with the security-audit user role, the user cannot be deleted.
- The system-admin, security-admin, and audit-admin user roles are mutually exclusive with other user roles in a user account.
- The system-admin, security-admin, and audit-admin user roles are mutually exclusive in a user account.
- When you assign user roles to a user, the system prompts you to confirm the deletion of the user roles that are mutually exclusive with the new user roles.
- You can assign a maximum of 64 user roles to a local user.

Procedure

1. Enter system view.

`system-view`

2. Create a local user and enter its view.

`local-user` *`user-name`* **`class`** { **`manage`** | **`network`** }

3. Assign a user role to the local user.

`authorization-attribute user-role` *`role-name`*

The following default settings apply:

- The network-operator user role is assigned to local users created by a network-admin or level-15 user on the default context.
- The context-operator user role is assigned to local users created by a context-admin or level-15 user on a non-default context.

Assigning user roles to non-AAA authentication users on user lines

About this task

Specify user roles for the following two types of login users on the user lines:

- Non-SSH users that use password authentication or no authentication.
- SSH clients that use publickey or password-publickey authentication. User roles assigned to these SSH clients are specified in their respective device management user accounts.

For more information about user lines, see "Login overview" and "Configuring CLI login." For more information about SSH, see *Security Configuration Guide*.

Restrictions and guidelines

- You can assign a maximum of 64 user roles to a non-AAA authentication user on a user line.
- The device cannot assign the security-audit user role to non-AAA authentication users.
- The device cannot assign the following user roles to non-AAA authentication users:
    - system-admin.
    - security-admin.
    - audit-admin..

Procedure

1. Enter system view.

   `system-view`

2. Enter user line view or user line class view.
    - Enter user line view.

      line { *first-num1* [*last-num1*] | { **console** | **vty** } *first-num2* [*last-num2*] }
    - Enter user line class view.

      line class { **console** | **vty** }

   For information about the priority order and application scope of the settings in user line view and user line class view, see "Configuring CLI login."

3. Specify a user role on the user line.

   user-role *role-name*

   The following default settings apply:
    - The network-admin user role is specified on the console user line for default-context login users. The network-operator user role is specified on any other user line for default-context login users.
    - The network-admin user role of default-context login users changes to context-admin after the users use the **switchto context** command to log in to non-default contexts.
    - The context-operator user role is specified on user lines for other non-default context login users.

Configuring temporary user role authorization

About temporary user role authorization

Temporary user role authorization allows you to obtain another user role without reconnecting to the device. This feature is useful when you want to use a user role temporarily to configure a feature.

Temporary user role authorization is effective only on the current login. This feature does not change the user role settings in the user account that you have been logged in with. The next time you are logged in with the user account, the original user role settings take effect.

To enable a user to obtain another user role without reconnecting to the device, you must configure user role authentication. Table 2 describes the available authentication modes and configuration requirements.

Table 2 User role authentication modes

Keywords	Authentication mode	Description
local	Local password authentication only (local-only)	The device uses the locally configured password for authentication. If no local password is configured for a user role in this mode, a console user can obtain the user role by either entering a string or not entering anything.
scheme	Remote AAA authentication through HWTACACS or RADIUS (remote-only)	The device sends the username and password to the HWTACACS or RADIUS server for remote authentication. To use this mode, you must perform the following configuration tasks: • Configure the required HWTACACS or RADIUS scheme, and configure the ISP domain to use the scheme for the user. For more information, see AAA in *Security Configuration Guide*. • Add the user account and password on the HWTACACS or RADIUS server.
local scheme	Local password authentication first, and then remote AAA authentication (local-then-remote)	Local password authentication is performed first. If no local password is configured for the user role in this mode, the device performs remote AAA authentication for VTY users. A console user can obtain another user role by either entering a string or not entering anything.
scheme local	Remote AAA authentication first, and then local password authentication (remote-then-local)	Remote AAA authentication is performed first. Local password authentication is performed in either of the following situations: • The HWTACACS or RADIUS server does not respond. • The remote AAA configuration on the device is invalid.

Restrictions and guidelines for temporary user role authorization

If HWTACACS authentication is used, the following rules apply:

- If the device is not enabled to automatically obtain the login username as the authentication username, you must enter a username for role authentication.

- The device sends the username to the server in the *username or username@domain-name* format. Whether the domain name is included in the username depends on the **`user-name-format`** command in the HWTACACS scheme.
- To obtain a level-*n* user role, the user account on the server must have the target user role level or a level higher than the target user role. A user account that obtains the level-*n* user role can obtain any user role among level-0 through level-*n*.
- To obtain a non-level-*n* user role, make sure the user account on the server meets the following requirements:
  - The account has a user privilege level.
  - The HWTACACS custom attribute is configured for the account in the form of **allowed-roles="***role***"**. The variable *role* represents the target user role.

If RADIUS authentication is used, the following rules apply:

- The device does not use the username you enter or the automatically obtained login username to request user role authentication. It uses a username in the **$enab***n***$** format. The variable *n* represents a user role level, and a domain name is not included in the username. You can always pass user role authentication when the password is correct.
- To obtain a level-*n* user role, you must create a user account for the level-*n* user role in the **$enabn$** format on the RADIUS server. The variable *n* represents the target user role level. For example, to obtain the authorization of the level-3 user role, you can enter any username. The device uses the username **$enab3$** to request user role authentication from the server.
- To obtain a non-level-*n* user role, you must perform the following tasks:
  - Create a user account named **$enab0$** on the server.
  - Configure the cisco-av-pair attribute for the account in the form of **allowed-roles="***role***"**. The variable *role* represents the target user role.

The device selects an authentication domain for user role authentication in the following order:

1. The ISP domain included in the entered username.
2. The default ISP domain.

If you execute the **`quit`** command after obtaining user role authorization, you are logged out of the device.

Setting the authentication mode for temporary user role authorization

1. Enter system view.

   ```
   system-view
   ```

2. Set the authentication mode.

   ```
   super authentication-mode { local | scheme } *
   ```

   By default, local-only authentication applies.

Specifying the default target user role for temporary user role authorization

1. Enter system view.

   ```
   system-view
   ```

2. Specify the default target user role for temporary user role authorization.

   ```
   super default role role-name
   ```

   The following default settings apply:

- For default-context login users, the default target user role is network-admin.
- For non-default-context login users, the default target user role is context-admin.

Setting an authentication password for temporary user role authorization

About this task

Authentication passwords are required only for local password authentication.

Procedure

1. Enter system view.

   system-view

2. Set a local authentication password for a user role.

   super password [**role** *role-name*] [{ **hash** | **simple** } *string*]

   By default, no password is set.

   If you do not specify the **role** *role-name* option, the command sets a password for the default target user role.

Automatically obtaining the login username for temporary user role authorization

About this task

This feature is applicable only to the login from a user line that uses scheme authentication, which requires a username for login. This feature enables the device to automatically obtain the login username when the login user requests a temporary user role authorization from a remote authentication server.

Restrictions and guidelines

If the user was logged in from a user line that uses password authentication or no authentication, the device cannot obtain the login username. The request for temporary user role authorization from a remote authentication server will fail.

This feature does not take effect on local password authentication for temporary user role authorization.

Procedure

1. Enter system view.

   system-view

2. Enable the device to automatically obtain the login username when a login user requests temporary user role authorization from a remote authentication server.

   super use-login-username

   By default, the device prompts for a username when a login user requests temporary user role authorization from a remote authentication server.

Obtaining temporary user role authorization

Restrictions and guidelines

Enter the username (if any) and password within 60 seconds after you enter the **super** command. If you fail to do so, the command will time out. To obtain the role, you will need to re-execute the command.

The operation of obtaining temporary user role authorization fails after three consecutive unsuccessful authentication attempts.

You might fail to switch to a non-level-*n* user role if both of the following conditions exist:

- User role switching authentication is performed in the same ISP domain as the current login user.
- User role switching authentication uses a different AAA method than the login authorization method configured for the ISP domain.

To resolve this issue, make sure the AAA methods configured by using the **authentication super** command are consistent with those configured by using the **authorization login** command for the ISP domain.

For more information about AAA, see *Security Configuration Guide*.

Prerequisites

Before you obtain temporary user role authorization, make sure the current user account has the permission to execute the **super** command to obtain temporary user role authorization.

Procedure

To obtain the temporary authorization to use a user role, execute the following command in user view:

super [*role-name*]

If you do not specify the *role-name* argument, you obtain the default target user role for temporary user role authorization.

Display and maintenance commands for RBAC

Execute **display** commands in any view.

Task	Command
Display user role information.	**display role** [**name** *role-name*]
Display user role feature information.	**display role feature** [**name** *feature-name* | **verbose**]
Display user role feature group information.	**display role feature-group** [**name** *feature-group-name*] [**verbose**]

Troubleshooting RBAC

This section describes several typical RBAC issues and their solutions.

Local users have more access permissions than intended

Symptom

A local user can use more commands than should be permitted by the assigned user roles.

Analysis

The local user might have been assigned to user roles without your knowledge. For example, the local user is automatically assigned the default user role when you create the user.

Solution

To resolve the issue:

1. Use the **`display local-user`** command to examine the local user accounts for undesirable user roles, and remove them.
2. If the issue persists, contact NSFOCUS Support.

Login attempts by RADIUS users always fail

Symptom

Attempts by a RADIUS user to log in to the network access device always fail, even though the following conditions exist:

- The network access device and the RADIUS server can communicate with one another.
- All AAA settings are correct.

Analysis

RBAC requires that a login user have a minimum of one user role. If the RADIUS server does not authorize the login user to use any user role, the user cannot log in to the device.

Solution

To resolve the issue:

1. Use one of the following methods:
   - Configure the **`role default-role enable`** command. A RADIUS user can log in with the default user role when no user role is assigned by the RADIUS server.
   - Add the user role authorization attributes on the RADIUS server.
2. If the issue persists, contact NSFOCUS Support.

Contents

Login overview

The device supports the following types of login methods:

- **CLI login**—At the CLI, you can enter text commands to configure and manage the device.

  To log in to the CLI, you can use one of the following methods:

  - Connect to the console port.
  - Use Telnet.
  - Use SSH.
- **Web login**—Through the Web interface, you can configure and manage the device visually.
- **SNMP access**—You can run SNMP on an NMS to access the device MIB, and perform Get and Set operations to configure and manage the device.
- **RESTful access**—You can use RESTful API operations to configure and manage the device.

The first time you access the device, you can use one of the following methods:

- Connect to the console port and enter **admin** as both the username and password to log in to the CLI of the default context.
- Enter 192.168.0.1 in the address bar of the Web browser and enter **admin** as both the username and password to log in to the Web interface of the default context.

After login, you can change console or Web login parameters, configure other access methods, or create non-default contexts.

Non-default contexts do not have console ports. To log in to a non-default context for the first time, you must perform the following tasks:

1. Log in to the default context.
2. Switch to the non-default context by using the **`switchto context`** command.

After you log in to a non-default context, you can configure other access methods. Then, administrators of the default context and the non-default contexts can use the methods to access the non-default contexts. For more information about contexts, see *Virtual Technologies Configuration Guide*.

In login management related descriptions, it is assumed that the device does not enter the automatic configuration process at startup.

The first time you access the device, the default username and password are both **admin** for console login and Web login. The default IP address of the management interface on the device is 192.168.0.1/24.

Using the console port for the first device access

About this task

Console login is the fundamental login method.

Prerequisites

To log in through the console port, prepare a console terminal, for example, a PC. Make sure the console terminal has a terminal emulation program, such as HyperTerminal or PuTTY. For information about how to use terminal emulation programs, see the programs' user guides.

Procedure

1. Turn off the PC.

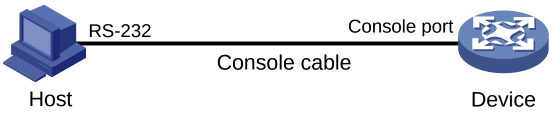
   The serial ports on PCs do not support hot swapping. Before connecting a cable to or disconnecting a cable from a serial port on a PC, you must turn off the PC.

2. Find the console cable shipped with the device and connect the DB-9 female connector of the console cable to the serial port of the PC.
3. Identify the console port of the device carefully and connect the RJ-45 connector of the console cable to the console port.

IMPORTANT:

To connect a PC to an operating device, first connect the PC end. To disconnect a PC from an operating device, first disconnect the device end.

Figure 1 Connecting a terminal to the console port



4. Turn on the PC.
5. On the PC, launch the terminal emulation program, and create a connection that uses the serial port connected to the device. Set the port properties so the port properties match the following console port default settings:
   - **Bits per second**—9600 bps.
   - **Flow control**—None.
   - **Parity**—None.
   - **Stop bits**—1.
   - **Data bits**—8.
6. Power on the device and press **Enter** as prompted.

   The user view prompt appears. You can enter commands to configure or manage the device. To get help, enter a question mark (?).

Configuring CLI login

About CLI login

The device uses user lines (also called user interfaces) to manage CLI sessions and monitor user behavior. For a user line, you can configure access control settings, including the login authentication method and user roles.

User lines

User line types

The device supports the following types of user lines, and different user lines require different login methods:

- **Console line**—Login through the console port.
- **Virtual type terminal (VTY) line**—Login through Telnet or SSH.

User line numbering

A user line has an absolute number and a relative number.

An absolute number uniquely identifies a user line among all user lines. The user lines are numbered starting from 0 and incrementing by 1, in the sequence of console and VTY lines. You can use the **`display line`** command without any parameters to view supported user lines and their absolute numbers.

A relative number uniquely identifies a user line among all user lines of the same type. The number format is *user line type* + *number*. All types of user lines are numbered starting from 0 and incrementing by 1. For example, the first VTY line is VTY 0.

User line assignment

The device assigns user lines to CLI login users depending on their login methods. When a user logs in, the device checks the idle user lines for the login method, and assigns the lowest numbered user line to the user. For example, if VTY 0 and VTY 3 are idle when a user Telnets to the device, the device assigns VTY 0 to the user.

Each user line can be assigned only to one user at a time. If no user line is available, a CLI login attempt will be rejected.

Login authentication modes

You can configure login authentication to prevent illegal access to the device CLI.

The device supports the following login authentication modes:

- **None**—Disables authentication. This mode allows access without authentication and is insecure.
- **Password**—Requires password authentication. A user must provide the correct password at login.
- **Scheme**—Uses the AAA module to provide local or remote login authentication. A user must provide the correct username and password at login.

Different login authentication modes require different user line configurations, as shown in Table 1.

Table 1 Configuration required for different login authentication modes

Authentication mode	Configuration tasks
None	Set the authentication mode to none.
Password	**1.** Set the authentication mode to password. **2.** Set a password.
Scheme	**1.** Set the authentication mode to scheme. **2.** Configure login authentication methods in ISP domain view. For more information, see *Security Configuration Guide*.

User roles

A user is assigned user roles at login. The user roles control the commands available for the user. For more information about user roles, see "Configuring RBAC."

The device assigns user roles based on the login authentication mode and user type.

- In none or password authentication mode, the device assigns the user roles specified for the user line.
- In scheme authentication mode, the device uses the following rules to assign user roles:
    - For an SSH login user who uses publickey or password-publickey authentication, the device assigns the user roles specified for the local device management user with the same name.
    - For other users, the device assigns user roles according to the user role configuration of the AAA module. If the AAA server does not assign any user roles and the default user role feature is disabled, a remote AAA authentication user cannot log in.

Restrictions and guidelines: CLI login configuration

For commands that are available in both user line view and user line class view, the following rules apply:

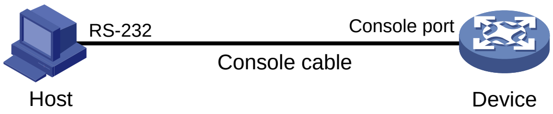
- A setting in user line view applies only to the user line. A setting in user line class view applies to all user lines of the class.
- A non-default setting in either view takes precedence over the default setting in the other view. A non-default setting in user line view takes precedence over the non-default setting in user line class view.
- A setting in user line class view takes effect only on users who log in after the setting is made. It does not affect users who are already online when the setting is made.

Configuring console login

About console login

You can connect a terminal to the console port of the device to log in and manage the device, as shown in Figure 2. For information about the login procedure, see "Using the console port for the first device access."

Figure 2 Logging in through the console port



By default, console login is enabled and the authentication mode is **`scheme`**. The username and password are both **admin**. The default user role is **network-admin** for a console user.

Restrictions and guidelines

A console login configuration change takes effect only on users who log in after the change is made. It does not affect users who are already online when the change is made.

Console login configuration tasks at a glance

To configure console login, perform the following tasks:

1. Configuring console login authentication
   - Disabling authentication for console login
   - Configuring password authentication for console login
   - Configuring scheme authentication for console login
2. (Optional.) Configuring common console login settings

Configuring console login authentication

Disabling authentication for console login

1. Enter system view.

   `system-view`

2. Enter console line view or class view.
   - Enter console line view.

     `line console` *`first-number`* `[` *`last-number`* `]`

   - Enter console line class view.

     `line class console`

3. Disable authentication.

   `authentication-mode none`

   By default, scheme authentication is enabled for console login.

CAUTION:

When authentication is disabled, users can log in to the device through the line or line class without authentication. For security purpose, disable authentication with caution.

4. Assign a user role.

   `user-role` *`role-name`*

   By default, a console user of the default context is assigned the **network-admin** user role. Non-default contexts do not support console login.

Configuring password authentication for console login

1. Enter system view.

system-view

2. Enter console line view or class view.
   - Enter Console line view.
     line console *first-number* [*last-number*]
   - Enter Console class view.
     line class console
3. Enable password authentication.
   authentication-mode password
   By default, scheme authentication is enabled for console login.
4. Set a password.
   set authentication password { **hash** | **simple** } *string*
   By default, no password is set.
5. Assign a user role.
   user-role *role-name*
   By default, a console user of the default context is assigned the **network-admin** user role. Non-default contexts do not support console login.

Configuring scheme authentication for console login

1. Enter system view.
   system-view
2. Enter console line view or class view.
   - Enter console line view.
     line console *first-number* [*last-number*]
   - Enter console line class view.
     line class console
3. Enable scheme authentication.
   authentication-mode scheme
   By default, scheme authentication is enabled for console login.

△ **CAUTION:**

When you enable scheme authentication, make sure an authentication user account is available. If no authentication user account is available, you cannot log in to the device through the line or line class at the next time.

4. Configure user authentication parameters in ISP domain view.
   To use local authentication, configure a local user and set the relevant attributes. To use remote authentication, configure a RADIUS, LDAP, or HWTACACS scheme. For more information, see AAA in *Security Configuration Guide*.

Configuring common console login settings

Restrictions and guidelines

Some common console login settings take effect immediately and can interrupt the current session. Use a login method different from console login to log in to the device before you change console login settings.

After you change console login settings, adjust the settings on the configuration terminal accordingly for a successful login.

Procedure

1. Enter system view.

   `system-view`

2. Enter console line view or class view.
   - Enter console line view.

     `line console` *`first-number`* `[` *`last-number`* `]`

   - Enter console line class view.

     `line class console`

3. Configure transmission parameters.
   - Set the transmission rate.

     `speed` *`speed-value`*

     By default, the transmission rate is 9600 bps.

     This command is not available in user line class view.

   - Specify the parity mode.

     `parity` `{` **`even`** `|` **`mark`** `|` **`none`** `|` **`odd`** `|` **`space`** `}`

     By default, a user line does not use parity.

     This command is not available in user line class view.

   - Configure flow control.

     `flow-control` `{` **`hardware`** `|` **`none`** `|` **`software`** `}`

     By default, the device does not perform flow control.

     This command is not available in user line class view.

   - Specify the number of data bits for a character.

     `databits` `{` **`7`** `|` **`8`** `}`

     The default is 8.

     This command is not available in user line class view.

Parameter	Description
7	Uses standard ASCII characters.
8	Uses extended ASCII characters.

   - Specify the number of stop bits for a character.

     `stopbits` `{` **`1`** `|` **`1.5`** `|` **`2`** `}`

     The default is 1.

     Stop bits indicate the end of a character. The more the stop bits, the slower the transmission.

     This command is not available in user line class view.

4. Configure terminal attributes.
   - Enable the terminal service.

     `shell`

     Be default, the terminal service is enabled on all user lines.

     The **`undo shell`** command is not available in console line view.

   - Specify the terminal display type.

     `terminal type` `{` **`ansi`** `|` **`vt100`** `}`

     By default, the terminal display type is ANSI.

The device supports ANSI and VT100 terminal display types. As a best practice, specify VT100 type on both the device and the configuration terminal. You can also specify the ANSI type for both sides, but a display problem might occur if a command line has more than 80 characters.

- Set the maximum number of lines of command output to send to the terminal at a time.

  `screen-length` *`screen-length`*

  By default, the device sends a maximum of 24 lines to the terminal at a time.

  To disable pausing between screens of output, set the value to 0.

- Set the size for the command history buffer.

  `history-command max-size` *`value`*

  By default, the buffer size is 10. The buffer for a user line can save a maximum of 10 history commands.

- Set the CLI connection idle-timeout timer.

  `idle-timeout` *`minutes`* `[` *`seconds`* `]`

  By default, the CLI connection idle-timeout timer is 10 minutes.

  If no interaction occurs between the device and the user within the idle-timeout interval, the system automatically terminates the user connection on the user line.

  If you set the timeout timer to 0, the connection will not be aged out.

5. Specify the command to be automatically executed for login users on the lines.

`auto-execute command` *`command`*

By default, no command is specified for auto execution.

△ **CAUTION:**

Use this command with caution. If this command is used on a user line, users that log in to the device through this user line might fail to configure the system.

The device will automatically execute the specified command when a user logs in through the user line, and close the user connection after the command is executed.

This command is not available in console line view or console line class view.

6. Configure shortcut keys.

- Specify the terminal session activation key.

  `activation-key` *`character`*

  By default, pressing **Enter** starts the terminal session.

- Specify the escape key.

  `escape-key` { *`key-string`* | **`default`** }

  By default, pressing **Ctrl+C** terminates a command.

- Set the user line locking key.

  `lock-key` *`key-string`*

  By default, no user line locking key is set.

Configuring Telnet login

About Telnet login

The device can act as a Telnet server to allow Telnet login, or as a Telnet client to Telnet to other devices.

Restrictions and guidelines

A Telnet login configuration change takes effect only on users who log in after the change is made. It does not affect users who are already online when the change is made.

Configuring the device as a Telnet server

Telnet server configuration tasks at a glance

To configure the device as a Telnet server, perform the following tasks:

1. Enabling the Telnet server
2. Configuring Telnet login authentication
   - Disabling authentication for Telnet login
   - Configuring password authentication for Telnet login
   - Configuring scheme authentication for Telnet login
3. (Optional.) Configuring common Telnet server settings
4. (Optional.) Configuring common VTY line settings

Enabling the Telnet server

1. Enter system view.

   `system-view`

2. Enable the Telnet server.

   `telnet server enable`

   By default, the Telnet server is disabled.

Disabling authentication for Telnet login

1. Enter system view.

   `system-view`

2. Enter VTY line view or class view.
   - Enter VTY line view.

     `line vty` *`first-number`* `[` *`last-number`* `]`

   - Enter VTY line class view.

     `line class vty`

3. Disable authentication.

   `authentication-mode none`

   By default, scheme authentication is enabled for Telnet login.

   > △ **CAUTION:**
   >
   > When authentication is disabled, users can log in to the device through the line or line class without authentication. For security purpose, disable authentication with caution.

   In VTY line view, this command is associated with the **`protocol inbound`** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

4. (Optional.) Assign a user role.

   `user-role` *`role-name`*

   By default, a Telnet user of the default context is assigned the **network-operator** user role, and a Telnet user of a non-default context is assigned the **context-operator** user role.

Configuring password authentication for Telnet login

1. Enter system view.

   `system-view`

2. Enter VTY line view or class view.
   - Enter VTY line view.

     `line vty` *`first-number`* `[` *`last-number`* `]`
   - Enter VTY line class view.

     `line class vty`

3. Enable password authentication.

   `authentication-mode password`

   By default, scheme authentication is enabled for Telnet login.

   > △ **CAUTION:**
   >
   > When you enable password authentication, you must also configure an authentication password for the line or line class. If no authentication password is configured, you cannot log in to the device through the line or line class at the next time.

   In VTY line view, this command is associated with the **`protocol inbound`** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

4. Set a password.

   `set authentication password` `{` **`hash`** `|` **`simple`** `}` *`password`*

   By default, no password is set.

5. (Optional.) Assign a user role.

   `user-role` *`role-name`*

   By default, a Telnet user of the default context is assigned the **network-operator** user role, and a Telnet user of a non-default context is assigned the **context-operator** user role.

Configuring scheme authentication for Telnet login

1. Enter system view.

   `system-view`

2. Enter VTY line view or class view.
   - Enter VTY line view.

     `line vty` *`first-number`* `[` *`last-number`* `]`
   - Enter VTY line class view.

     `line class vty`

3. Enable scheme authentication.

   `authentication-mode scheme`

   By default, scheme authentication is enabled for Telnet login.

   > △ **CAUTION:**
   >
   > When you enable scheme authentication, make sure an authentication user account is available. If no authentication user account is available, you cannot log in to the device through the line or line class at the next time.

   In VTY line view, this command is associated with the **`protocol inbound`** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

4. Configure user authentication parameters in ISP domain view.

   To use local authentication, configure a local user and set the relevant attributes.

   To use remote authentication, configure a RADIUS, LDAP, or HWTACACS scheme. For more information, see AAA in *Security Configuration Guide*.

Configuring common Telnet server settings

1. Enter system view.

   `system-view`

2. Set the DSCP value for outgoing Telnet packets.

   IPv4:

   `telnet server dscp` *`dscp-value`*

   IPv6:

   `telnet server ipv6 dscp` *`dscp-value`*

   By default, the DSCP value is 48.

3. Specify the Telnet service port number.

   IPv4:

   `telnet server port` *`port-number`*

   IPv6:

   `telnet server ipv6 port` *`port-number`*

   By default, the Telnet service port number is 23.

4. Set the maximum number of concurrent Telnet users.

   `aaa session-limit telnet` *`max-sessions`*

   By default, the maximum number of concurrent Telnet users is 32.

   Changing this setting does not affect users who are currently online. If the new limit is less than the number of online Telnet users, no additional users can Telnet in until the number drops below the new limit.

   For more information about this command, see *Security Command Reference*.

Configuring common VTY line settings

1. Enter system view.

   `system-view`

2. Enter VTY line view or class view.
   - Enter VTY line view.

     `line vty` *`first-number`* `[` *`last-number`* `]`
   - Enter VTY line class view.

     `line class vty`

3. Configure VTY terminal attributes.
   - Enable the terminal service.

     `shell`

     By default, the terminal service is enabled on all user lines.
   - Specify the terminal display type.

     `terminal type` `{` **`ansi`** `|` **`vt100`** `}`

     By default, the terminal display type is ANSI.
   - Set the maximum number of lines of command output to send to the terminal at a time.

     `screen-length` *`screen-length`*

     By default, the device sends a maximum of 24 lines to the terminal at a time.

To disable pausing between screens of output, set the value to 0.

- Set the size for the command history buffer.

  history-command max-size *value*

  By default, the buffer size is 10. The buffer for a user line can save a maximum of 10 history commands.

- Set the CLI connection idle-timeout timer.

  idle-timeout *minutes* [*seconds*]

  By default, the CLI connection idle-timeout timer is 10 minutes.

  If no interaction occurs between the device and the user within the idle-timeout interval, the system automatically terminates the user connection on the user line.

  If you set the timeout timer to 0, the connection will not be aged out.

4. Specify the supported protocols.

   protocol inbound { **all** | **ssh** | **telnet** }

   By default, Telnet and SSH are supported.

   A protocol change takes effect only on users who log in after the setting is made. It does not affect users who are already online when the setting is made.

   In VTY line view, this command is associated with the **authentication-mode** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

5. Specify the command to be automatically executed for login users on the user lines.

   auto-execute command *command*

   By default, no command is specified for auto execution.

   IMPORTANT:

   Before you use this command and save the configuration, make sure you can access the CLI to modify the configuration through other VTY lines.

   For a VTY line, you can specify a command that is to be automatically executed when a user logs in. After executing the specified command, the system automatically disconnects the Telnet session.

6. Configure shortcut keys.

   - Specify the shortcut key for terminating a task.

     escape-key { *character* | **default** }

     The default setting is **Ctrl+C**.

   - Set the user line locking key.

     lock-key *key-string*

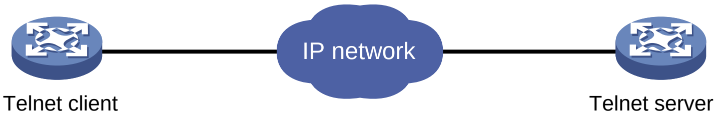
     By default, no user line locking key is set.

Using the device to log in to a Telnet server

About this task

You can use the device as a Telnet client to log in to a Telnet server.

Figure 3 Telnetting from the device to a Telnet server



Prerequisites

Assign an IP address to the device and obtain the IP address of the Telnet server. If the device resides on a different subnet than the Telnet server, make sure the device and the Telnet server can reach each other.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Specify the source IPv4 address or source interface for outgoing Telnet packets.

   telnet client source { **interface** *interface-type interface-number* | **ip** *ip-address* }

   By default, no source IPv4 address or source interface is specified. The device uses the primary IPv4 address of the output interface as the source address for outgoing Telnet packets.

3. Return to user view.

   quit

4. Use the device to log in to a Telnet server.

   IPv4:

   telnet *remote-host* [*service-port*] [**vpn-instance** *vpn-instance-name*] [**source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] [**dscp** *dscp-value*] [**escape** *character*]

   IPv6:

   telnet ipv6 *remote-host* [**-i** *interface-type interface-number*] [*port-number*] [**vpn-instance** *vpn-instance-name*] [**source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] [**dscp** *dscp-value*] [**escape** *character*]

Configuring SSH login

About SSH login

SSH offers a secure remote login method. By providing encryption and strong authentication, it protects devices against attacks such as IP spoofing and plaintext password interception. For more information, see *Security Configuration Guide*.

The device can act as an SSH server to allow Telnet login, or as an SSH client to log in to an SSH server.

Configuring the device as an SSH server

About this task

This section provides the SSH server configuration procedure used when the SSH client authentication method is password. For more information about SSH and publickey authentication configuration, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create local key pairs.

   public-key local create { **dsa** | **ecdsa secp256r1** | **rsa** }

3. Enable the SSH server.

   ssh server enable

   By default, the SSH server is enabled.

4. (Optional.) Create an SSH user and specify the authentication mode.

   ssh user *username* **service-type stelnet authentication-type password**

5. Enter VTY line view or class view.
   - Enter VTY line view.

     line vty *first-number* [*last-number*]
   - Enter VTY line class view.

     line class vty

6. Enable scheme authentication.

   authentication-mode scheme

   By default, scheme authentication is enabled for VTY lines.

   In VTY line view, this command is associated with the **protocol inbound** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

△ **CAUTION:**

When you enable scheme authentication, make sure an authentication user account is available. If no authentication user account is available, you cannot log in to the device through the line or line class at the next time.

7. (Optional.) Specify the protocols for the user lines to support.

   protocol inbound { **all** | **ssh** | **telnet** }

   By default, Telnet and SSH are supported.

   A protocol change takes effect only on users who log in after the setting is made. It does not affect users who are already online when the setting is made.

   In VTY line view, this command is associated with the **authentication-mode** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

8. (Optional.) Set the maximum number of concurrent SSH users.

   aaa session-limit ssh *max-sessions*

   By default, the maximum number of concurrent SSH users is 32.

   Changing this setting does not affect users who are currently online. If the new limit is less than the number of online SSH users, no additional SSH users can log in until the number drops below the new limit.

   For more information about this command, see *Security Command Reference*.

9. (Optional.) Configure common settings for VTY lines:

   a. Return to system view.

      quit

   b. Configure common settings for VTY lines.

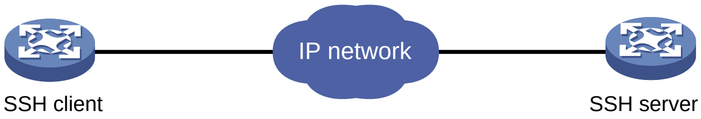
See "Configuring common VTY line settings."

Using the device to log in to an SSH server

About this task

You can use the device as an SSH client to log in to an SSH server.

Figure 4 Logging in to an SSH server from the device



Prerequisites

Assign an IP address to the device and obtain the IP address of the SSH server. If the device resides on a different subnet than the SSH server, make sure the device and the SSH server can reach each other.

Procedure

To use the device to log in to an SSH server, execute one of the following commands in user view:

IPv4:

ssh2 *server*

IPv6:

ssh2 ipv6 *server*

To work with the SSH server, you might need to specify a set of parameters. For more information, see *Security Configuration Guide*.

Display and maintenance commands for CLI login

Execute **display** commands in any view.

Task	Command	Remarks
Display user line information.	**display line** [*num1* | { **console** | **vty** } *num2*] [**summary**]	N/A
Display the packet source setting for the Telnet client.	**display telnet client**	N/A
Display online CLI users.	**display users** [**all**]	N/A
Release a user line.	**free line** { *num1* | { **console** | **vty** } *num2* }	Multiple users can log in to the device to simultaneously configure the device. When necessary, you can execute this command to release some connections. You cannot use this command to release the connection you are using. This command is available in user view.
Lock the current user line and set the password for unlocking the line.	**lock**	By default, the system does not lock any user lines.

Task	Command	Remarks
		This command is available in user view.
Lock the current user line and enable unlocking authentication.	**lock reauthentication**	By default, the system does not lock any user lines or initiate reauthentication. To unlock the locked user line, you must press **Enter** and provide the login password to pass reauthentication. This command is available in any view.
Send messages to user lines.	**send** { **all** | *num1* | { **console** | **vty** } *num2* }	This command is available in user view.

Configuring Web login

About Web login

The device provides a built-in Web server that supports HTTP 1.0, HTTP 1.1, and HTTPS. You can use a Web browser to log in to and configure the device.

HTTPS uses SSL to ensure the integrity and security of data exchanged between the client and the server, and is more secure than HTTP. You can define a certificate-based access control policy to allow only legal clients to access the Web interface.

IMPORTANT:

On a PC, a Web browser allows only one user to log in to the device. If multiple users use the same Web browser to log in to the device, the most recent login takes effect.

Restrictions and guidelines: Web login configuration

To improve device security, the system automatically enables the HTTPS service when you enable the HTTP service. When the HTTP service is enabled, you cannot disable the HTTPS service.

Web login configuration tasks at a glance

To configure Web login, perform the following tasks:

1. Configuring Web login
   - Configuring HTTP login
   - Configuring HTTPS login
2. Configuring a Web login local user
3. Managing Web connections

Prerequisites for Web login

Before logging in to the Web interface of the device, log in to the device by using any other method and assign an IP address to the device. Make sure the configuration terminal and the device can communicate over the IP network.

Configuring HTTP login

1. (Optional.) Specify a fixed verification code for Web login.

   ```
   web captcha verification-code
   ```

   By default, no fixed verification code is specified. A Web user must enter the verification code displayed on the login page at login.

   Execute this command in user view.

2. Enter system view.

   ```
   system-view
   ```

3. Enable the HTTP service.

   ```
   ip http enable
   ```

   By default, the HTTP service is disabled.

4. (Optional.) Specify the HTTP service port number.

   ```
   ip http port port-number
   ```

   The default HTTP service port number is 80.

5. (Optional.) Specify the HTTP methods to be added to the reply to an OPTIONS request.

   ```
   http method { delete | get | head | options | post | put } *
   ```

   By default, no HTTP methods are specified.

Configuring HTTPS login

About this task

The device supports the following HTTPS login modes:

- **Simplified mode**—Using this mode is easy in configuration but has low security. The device uses a self-signed certificate (a certificate that is generated and signed by the device itself) and the default SSL settings. The device operates in simplified mode after you enable HTTPS service on the device. You do not need to configure an SSL server policy with the HTTPS service. However, a self-signed certificate is not signed by a CA, so it is not trusted by a browser. The browser will prompt a security risk message when you access the device through HTTPS. If you do not have high security requirements and can accept the security risk with a self-signed certificate, you can choose to ignore this message and continue browsing the webpage.
- **Secure mode**—Using this mode is complicated in configuration but has high security. The device uses a certificate signed by a CA and a set of user-defined security protection settings to ensure security. For the device to operate in secure mode, you must perform the following tasks:
  - Obtain a CA certificate and apply a local certificate from the CA.
  - Enable HTTPS service on the device.
  - Specify an SSL server policy for the service.
  - Configure PKI domain-related parameters.

IMPORTANT:

To use secure mode for HTTPS login, first purchase a local certificate for SSL from an official third-party CA organization. NSFOCUS does not provide the device with a CA certificate issued by an authoritative organization.

For more information about SSL, self-signed certificates, CA-signed certificates, and PKI, see *Security Configuration Guide*.

Restrictions and guidelines

- If the HTTPS service and the SSL VPN service use the same port number, they must use the same SSL server policy. If they use different SSL server policies, only one of them can be enabled.

  To modify the SSL server policy used by both the HTTPS service and the SSL VPN service, you must perform the following tasks:

  a. Disable the two services before you modify the SSL server policy.

  b. Enable the two services again after the modification.

  If you fail to complete the required tasks, the new settings do not take effect.

- To associate a different SSL server policy with the HTTPS service, you must perform the following tasks:
  a. Disable the HTTP service and HTTPS service before you associate the new SSL server policy.
  b. Enable the HTTP service and HTTPS service again after the association.

  If you fail to complete the required tasks, the new SSL server policy does not take effect.
- For the HTTP service to use its self-signed certificate after you associate an SSL server policy with the HTTPS service, you must follow these steps:
  a. Disable the HTTP service and HTTPS service.
  b. Execute the **`undo ip https ssl-server-policy`** command to remove the existing SSL server policy association.
  c. Enable the HTTP service and HTTPS service again.
- Enabling the HTTPS service triggers the SSL handshake negotiation process.
  - If the device has a local certificate, the SSL handshake negotiation succeeds and the HTTPS service starts up.
  - If the device does not have a local certificate, the certificate application process starts. Because the certificate application process takes a long time, the SSL handshake negotiation might fail and the HTTPS service might not be started. To solve the problem, execute the **`ip https enable`** command again until the HTTPS service is enabled.
- To use a certificate-based access control policy to control HTTPS access, you must perform the following tasks:
  - Use the **`client-verify enable`** command in the SSL server policy that is associated with the HTTPS service.
  - Configure a minimum of one **permit** rule in the certificate-based access control policy.

  If you fail to complete the required tasks, HTTPS clients cannot log in.

Procedure

1. (Optional.) Specify a fixed verification code for Web login.

`web captcha` *`verification-code`*

By default, no fixed verification code is configured. A Web user must enter the verification code displayed on the login page at login.

2. Enter system view.

`system-view`

3. (Optional.) Apply policies to the HTTPS service.

- Apply an SSL server policy.

  `ip https ssl-server-policy` *`policy-name`*

  By default, no SSL server policy is associated. The HTTP service uses a self-signed certificate.
- Apply a certificate-based access control policy to control HTTPS access.

  `ip https certificate access-control-policy` *`policy-name`*

  By default, no certificate-based access control policy is applied.

  For more information about certificate-based access control policies, see PKI in *Security Configuration Guide*.

4. Enable the HTTPS service.

`ip https enable`

By default, the HTTPS service is enabled.

5. (Optional.) Specify the HTTPS service port number.

ip https port *port-number*

The default HTTPS service port number is 443.

6. (Optional.) Set the authentication and authorization mode for HTTPS login.

   web https-authorization mode { **auto** | **certificate** | **certificate-manual** | **manual** }

   By default, manual mode is used for HTTPS login authentication and authorization.

7. (Optional.) Specify the certificate field to be used as the username for certificate-based authentication.

   web https-authorization username { **cn** | **email-prefix** | **oid** *oid-value* }

   By default, the CN field in the certificate is used as the username for certificate-based authentication.

Configuring a Web login local user

1. Enter system view.

   system-view

2. Create a local user and enter local user view.

   local-user *user-name* [**class manage**]

3. (Optional.) Configure a password for the local user.

   password [{ **hash** | **simple** } *password*]

   By default, no password is configured for a local user. The local user can pass authentication after entering the correct username and passing attribute checks.

4. Configure user attributes.

   - Assign a user role to the local user.

     authorization-attribute user-role *user-role*

     The default user role is network-operator for a Web user.

   - Specify the service type for the local user.

     service-type { **http** | **https** }

     By default, no service type is specified for a local user.

Managing Web connections

Setting the Web connection idle-timeout timer

1. Enter system view.

   system-view

2. Set the Web connection idle-timeout timer.

   web idle-timeout *minutes*

   By default, the Web connection idle-timeout timer is 10 minutes.

Specifying the maximum number of online HTTP or HTTPS users

1. Enter system view.

   system-view

2. Specify the maximum number of online HTTP or HTTPS users.

   aaa session-limit { **http** | **https** } *max-sessions*

By default, the device supports a maximum number of 32 online HTTP users and 32 online HTTPS users.

Changing this setting does not affect users who are currently online. If the new setting is less than the number of online HTTP or HTTPS users, no additional HTTP or HTTPS users can log in until the number drops below the new limit. For more information about this command, see *Security Command Reference*.

Logging off Web users

To log off Web users, execute the following command in user view:

free web users { **all** | **user-id** *user-id* | **user-name** *user-name* }

Display and maintenance commands for Web login

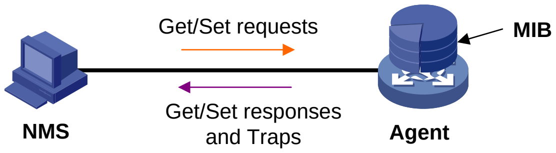
Execute **display** commands in any view and the **free web users** command in user view.

Task	Command
Display HTTP service configuration and status information.	**display ip http**
Display HTTPS service configuration and status information.	**display ip https**
Display Web interface navigation tree information.	**display web menu** [**chinese**]
Display online Web users.	**display web users**
Log off online Web users.	**free web users** { **all** | **user-id** *user-id* | **user-name** *user-name* }

Accessing the device through SNMP

You can run SNMP on an NMS to access the device MIB and perform Get and Set operations to configure and manage the device.

Figure 5 SNMP access diagram



For more information about SNMP, see *Network Management and Monitoring Configuration Guide*.

Configuring RESTful access

About RESTful access

The device provides the Representational State Transfer application programming interface (RESTful API). Based on this API, you can use programming languages such as Python, Ruby, or Java to write programs to perform the following tasks:

- Send RESTful requests to the device to pass authentication.
- Use RESTful API operations to configure and manage the device. RESTful API operations include Get, Put, Post, and Delete.

The device supports using HTTP or HTTPS to transfer RESTful packets.

Configuring RESTful access over HTTP

1. Enter system view.

   system-view

2. (Optional.) Specify the service port number for RESTful access over HTTP.

   restful http port *port-number*

   By default, the service port number for RESTful access over HTTP is 80.

3. Enable RESTful access over HTTP.

   restful http enable

   By default, RESTful access over HTTP is disabled.

4. Create a local user and enter local user view.

   local-user *user-name* [**class manage**]

5. Configure a password for the local user.

   password [{ **hash** | **simple** } *password*]

6. (Optional.) Assign a user role to the local user.

   authorization-attribute user-role *user-role*

   The default user role is network-operator for a RESTful access user.

7. Specify the HTTP service for the local user.

   service-type http

   By default, no service type is specified for a local user.

Configuring RESTful access over HTTPS

1. Enter system view.

   system-view

2. (Optional.) Apply an SSL server policy to the RESTful access over HTTPS service.

   restful https ssl-server-policy *policy-name*

   By default, no SSL server policy is applied to the RESTful access over HTTPS service.

   The RESTful access over HTTPS service will use the SSL server policy to enhance service security. For more information about SSL server policies, see SSL configuration in *Security Configuration Guide*.

3. (Optional.) Specify the service port number for RESTful access over HTTPS.

   restful https port *port-number*

   By default, the service port number for RESTful access over HTTPS is 443.

4. Enable RESTful access over HTTPS.

   restful https enable

   By default, RESTful access over HTTPS is disabled.

5. Create a local user and enter local user view.

   local-user *user-name* [**class manage**]

6. Configure a password for the local user.

   password [{ **hash** | **simple** } *password*]

7. (Optional.) Assign a user role to the local user.

   authorization-attribute user-role *user-role*

   The default user role is network-operator for a RESTful access user.

8. Specify the HTTPS service for the local user.

   service-type https

   By default, no service type is specified for a local user.

Controlling user access to the device

About login user access control

Use ACLs to prevent unauthorized access, and configure command authorization and accounting to monitor and control user behavior.

To control user access, specify an ACL that has rules so only users permitted by the ACL can access the device.

- If no ACL is applied, all users can access the device.
- If the ACL for Web user access control does not exist or does not have rules, all Web users can access the device.
- If the ACL for Telnet, SSH, or SNMP access control does not exist or does not have rules, no Telnet, SSH, or SNMP users can access the device.
- If a VPN instance is specified in an ACL rule, the rule applies only to the packets of the VPN instance. If no VPN instance is specified in an ACL rule, the rule applies only to the packets on the public network.

For more information about ACLs, see *ACL and QoS Configuration Guide.*

Controlling Telnet and SSH logins

Controlling Telnet logins

1. Enter system view.

   `system-view`

2. Apply an ACL to control Telnet logins.

   IPv4:

   `telnet server acl` `[` **`mac`** `]` *`acl-number`*

   IPv6:

   `telnet server ipv6 acl` `{` **`ipv6`** `|` **`mac`** `}` *`acl-number`*

   By default, no ACL is used to control Telnet logins.

3. (Optional.) Enable logging for Telnet login attempts that are denied by the Telnet login control ACL.

   `telnet server acl-deny-log enable`

   By default, logging is disabled for Telnet login attempts that are denied by the Telnet login control ACL.

Controlling SSH logins

1. Enter system view.

   `system-view`

2. Apply an ACL to control SSH logins.

   IPv4:

   `ssh server acl` `{` *`advanced-acl-number`* `|` *`basic-acl-number`* `|` **`mac`** *`mac-acl-number`* `}`

IPv6:

```
ssh server ipv6 acl { ipv6 { advanced-acl-number | basic-acl-number }
| mac mac-acl-number }
```

By default, no ACL is used to control SSH logins.

3. (Optional.) Enable logging for SSH login attempts that are denied by the SSH login control ACL.

```
ssh server acl-deny-log enable
```

By default, logging is disabled for SSH login attempts that are denied by the SSH login control ACL.

For more information about **ssh** commands, see SSH in *Security Command Reference*.

Controlling Web logins

Configuring source IP-based Web login control

1. Enter system view.

```
system-view
```

2. Apply a basic ACL to control Web logins.
   - Control HTTP logins.

```
ip http acl [ ipv6 ] [ advanced ] { acl-number | name acl-name }
ip http acl mac { acl-number | name acl-name }
```

   - Control HTTPS logins.

```
ip https acl [ ipv6 ] [ advanced ] { acl-number | name acl-name }
ip https acl mac { acl-number | name acl-name }
```

By default, no ACL is applied to control Web logins.

Configuring command authorization

About command authorization

By default, commands available for a user depend only on the user's user roles. When the authentication mode is scheme, you can configure the command authorization feature to further control access to commands.

After you enable command authorization, a user can use only commands that are permitted by both the AAA scheme and user roles.

Restrictions and guidelines

When command authorization is enabled, commands available for a user vary by the user's login authentication mode.

- If authentication is disabled or password authentication is enabled, command authorization does not take effect, and the user cannot use any commands.
- If scheme authentication is enabled, commands available for a user vary by the user's access authentication method.
  - If local authentication is used, the device uses the user roles assigned to the user to perform command authorization.

- If remote authentication is used, the remote authorization server performs command authorization to determine whether a command entered by a login user is permitted. If remote authorization fails, the device uses the user roles of a local user with the same name as the login user to determine whether the command can be used. If the authorization also fails, the login user cannot use the command.

Command authorization configuration changes in user line class view do not take effect on the current session. The changes take effect only on subsequent login sessions. Command authorization configuration changes in user line view take effect immediately on all users that access the user line.

If the remote server performs command authorization, you must configure a command authorization method in ISP domain view. The command authorization method can be different from the user login authorization method. For more information, see AAA in *Security Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter user line view or user line class view.

   - Enter user line view.

     `line` { *`first-number1`* [*`last-number1`*] | { **`console`** | **`vty`** } *`first-number2`* [*`last-number2`*] }

   - Enter user line class view.

     `line class` { **`console`** | **`vty`** }

   A setting in user line view applies only to the user line. A setting in user line class view applies to all user lines of the class. A non-default setting in either view takes precedence over the default setting in the other view. A non-default setting in user line view takes precedence over the non-default setting in user line class view.

   A setting in user line class view takes effect only on users who log in after the setting is made. It does not affect users who are already online when the setting is made.

3. Enable scheme authentication.

   `authentication-mode scheme`

   By default, scheme authentication is enabled for console login and VTY login.

   In VTY line view, this command is associated with the **`protocol inbound`** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

   △ **CAUTION:**

   When you enable scheme authentication, make sure an authentication user account is available. If no authentication user account is available, you cannot log in to the device through the line or line class at the next time.

4. Enable command authorization.

   `command authorization`

   By default, command authorization is disabled, and the commands available for a user only depend on the user role.

   If the **`command authorization`** command is used in user line class view, command authorization is enabled on all user lines in the class. You cannot use the **`undo command authorization`** command in the view of a user line in the class.

Configuring command accounting

About command accounting

Command accounting uses the HWTACACS server to record all executed commands to monitor user behavior on the device.

If command accounting is enabled but command authorization is not, every executed command is recorded. If both command accounting and command authorization are enabled, only authorized commands that are executed are recorded.

Restrictions and guidelines

The command accounting method can be the same as or different from the command authorization method and user login authorization method.

For the command accounting feature to take effect, you must configure a command accounting method in ISP domain view. For more information, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter user line view or user line class view.
   - Enter user line view.

     ```
     line { first-number1 [ last-number1 ] | { console | vty }
     first-number2 [ last-number2 ] }
     ```

   - Enter user line class view.

     ```
     line class { console | vty }
     ```

   A setting in user line view applies only to the user line. A setting in user line class view applies to all user lines of the class. A non-default setting in either view takes precedence over the default setting in the other view. A non-default setting in user line view takes precedence over the non-default setting in user line class view.

   A setting in user line class view takes effect only on users who log in after the setting is made. It does not affect users who are already online when the setting is made.

3. Enable scheme authentication.

   ```
   authentication-mode scheme
   ```

   By default, scheme authentication is enabled for console login and VTY login.

   In VTY line view, this command is associated with the **protocol inbound** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

> △ **CAUTION:**
>
> When you enable scheme authentication, make sure an authentication user account is available. If no authentication user account is available, you cannot log in to the device through the line or line class at the next time.

4. Enable command accounting.

   ```
   command accounting
   ```

By default, command accounting is disabled. The accounting server does not record the commands executed by users.

If the **command accounting** command is used in user line class view, command accounting is enabled on all user lines in the class. You cannot use the **undo command accounting** command in the view of a user line in the class.

Contents

Managing licenses

About licenses

To obtain information about license-based features, their licensing status, and license availability, execute the **`display license feature`** command on the device. Then, you can purchase and install licenses as needed.

License types

NSFOCUS offers trial (or temporary), preinstalled, and formal licenses. For more information about the license options available for a product, see the license matrixes document for that product.

Preinstalled licenses

Preinstalled licenses are built into a system and are available for use on initial startup of the system. Users do not need to activate them.

A preinstalled license is typically time limited and cannot be uninstalled or transferred.

When a preinstalled license expires, the license-based feature becomes unavailable. To continue to use the feature, you must purchase and install a formal license for it.

Trial licenses

Trial licenses are provided for you to verify the functionality of premium features so you can make an educated purchase decision.

A trial license is time limited and cannot be uninstalled or transferred.

When a trial license expires, the license-based feature becomes unavailable. To continue to use the feature, you must purchase and install a formal license for it.

To obtain a trial license for a feature:

1. Contact your NSFOCUS sales representative or technical support.to obtain a trial license key and an activation file.
2. Install the activation file to activate the feature.

Formal licenses

To gain most from a license-based feature, purchase a formal license for it.

Formal licenses are available with different validity periods and their support for uninstallation and transfer of formal licenses depends on product model. For more information, see the license matrixes document for the product.

To install a formal license for a feature:

1. Purchase a software license certificate through an official channel.
2. Provide the license key in the software license certificate to NSFOCUS sales representative or technical support to obtain an activation file.
3. Install the activation file in the target system.

Basic concepts

The following information describes the basic concepts that you might encounter when you register, install, and manage licenses.

Software license certificate

A software license certificate allows users to use a license-based feature. It contains license key, license capacity, and other information.

License key

A license key uniquely identifies a license.

- To obtain a formal license key, purchase a software license certificate. The authorization serial number in the software license certificate is the license key.
- To obtain a trial license key, contact your NSFOCUS sales representative or NSFOCUS technical support. Support for trial licenses depends on the device model. For more information, contact NSFOCUS sales representative or NSFOCUS technical support.

Device serial number

A device serial number (SN or S/N) is a barcode that uniquely identifies a device. It comes with the device and must be provided when you contact NSFOCUS to request a license.

Device ID (DID) and DID file

A DID is a string of characters that uniquely identifies a hardware device. A DID file stores the DID and other information. The device comes with a DID or DID file. You must provide the DID or DID file when you contact NSFOCUS to request a license.

Activation file

An activation file binds a license to a system.

To use a license-based feature on a system, you must perform the following tasks:

1. Use the license key and the required device information to obtain an activation file from NSFOCUS.
2. Install the activation file on the system.

Uninstall key and Uninstall file

When you uninstall a license, an Uninstall file that contains an Uninstall key is created. The Uninstall key is required for transferring the license.

License storage

License storage is a persistent storage of fixed size for storing licensing information. This information includes the licensing state, validity period, Uninstall key or Uninstall file, and other related information.

Data in the license storage persists through reboot. This ensures licensing accuracy and continuity.

Restrictions and guidelines: License management

Management operation restrictions

- Purchase licenses from NSFOCUS official channels.
- For licenses that have been installed on the device, execute the **`display license`** command to view the license validity period. To use a license-based feature continuously, install a new license for the feature before the old license expires.
- Licenses are typically device locked. To ensure a successful licensing, use the following licensing guidelines:
  - **a.** When you purchase a license certificate, verify the following items:
    - Make sure the license is compatible with the target device.

    - Make sure its licensed functionality and capacity meet your requirements.

  b. When you obtain an activation file, make sure the provided license key and hardware information are correct.

  c. Install the activation file on the correct target device.

- Make sure no one else is performing license management tasks while you are managing licenses on the device.
- You can manage licenses only on the default context. Any license operation performed on the default context takes effect on all contexts. For information about contexts, see *Virtual Technologies Configuration Guide.*

File operation restrictions

When you manage DID files, activation files, or Uninstall files, follow these restrictions and guidelines:

- To avoid licensing error, do not modify the name of a DID file, activation file, or Uninstall file, or edit the file content.
- Before you install an activation file, download the activation file to the storage media of the device such as flash memory. When installing an activation file, the device automatically copies the activation file to the **license** folder in the root directory of the storage media. The **license** folder stores important files for licensing. For licensed features to function correctly, do not delete or modify the **license** folder or the files in this folder.

License consolidation

License consolidation combines multiple licenses to create one activation file. It delivers the following benefits:

- **Ease of license installation and management**—This feature enables you to install one activation file to activate multiple licenses, without having to install one activation file for each of them.
- **Storage conservation**—This feature enables the device to store one activation file for multiple licenses, which conserves the license storage space on the device. Licenses that support consolidation are called consolidable licenses.

Configuring local licensing

About local licensing

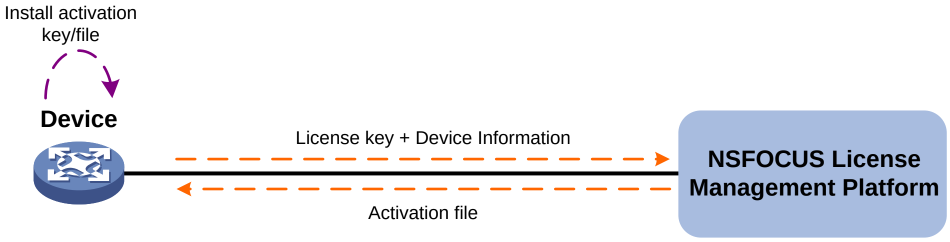
Local licensing requires license activation device by device. It is applicable to small-sized networks.

To install a license on a device:

1. Obtain the license key and the required device information.
2. Contact NSFOCUS sales representatives or technical support to obtain an activation file based on the license key and the device information.
3. Install the activation file on the device to activate the license.

The activation file for a license is device locked. You cannot install the activation file for one device to activate the license on another device.

Figure 1 Local licensing procedure



Install activation key/file
Device
License key + Device Information
Activation file
NSFOCUS License Management Platform

Installing a license

The procedures for installing formal licenses and trial licenses are the same .

Identifying the license storage

To identify the free space of the license storage, execute the following command in any view:

```
display license feature
```

From the command output, view the **Total** and **Usage** fields to examine whether the remaining license storage is sufficient for installing new licenses. If the remaining license storage is not sufficient, compress the license storage.

Compressing the license storage

About this task

The license storage stores licensing information and has a fixed size.

You can compress the license storage to delete expired and uninstalled license information to ensure sufficient storage space for installing new licenses.

If no license has been installed on the device, you do not need to compress the license storage.

Prerequisites

Back up the Uninstall keys or Uninstall files for the uninstalled licenses for subsequent license transfer or license uninstallation.

If uninstalled licenses or expired licenses exist on the device, the compression operation will make the DID change. You will be unable to install the activation file obtained by using the old DID on the device. As a best practice, install all activation files registered with the old DID before performing a compression.

If you have not installed an activation file registered with the old DID, take the following actions:

- If the license storage is sufficient, install the activation file on the device. For more information, see the licensing guide for the device.
- If the license storage is insufficient and the activation file cannot be installed after the compression, contact NSFOCUS Support.

Procedure

1. Enter system view.

   `system-view`

2. Compress the license storage.

   `license compress slot` *`slot-number`*

Obtaining required information for license registration

To obtain SN and DID information, execute the following command in any view:

`display license device-id slot` *`slot-number`*

Installing an activation file

About this task

△ **CAUTION:**

Back up an activation file before you install it. If the activation file is inadvertently deleted or becomes unavailable for some other reason, you can use the backup activation file to restore the license.

To obtain a license, install an activation file for the license on the device.

Prerequisites

Use FTP or TFTP to upload the activation file to be installed to the device. If FTP is used to transfer the activation file, set it in binary mode.

Installing an activation file

1. Enter system view.

   `system-view`

2. Install an activation file.

   `license activation-file install` *`license-file`* **`slot`** *`slot-number`*

   You can install a single .ak file or multiple .ak files through one operation. To install multiple .ak files, save all activation files in the same directory and specify the directory as the value of the *`license-file`* argument

Display and maintenance commands for license management

Execute **`display`** commands in any view.

Task	Command
Display detailed license information.	**display license** [**activation-file**] [**slot** *slot-number*]
Display the SN and DID information.	**display license device-id slot** *slot-number*
Display brief feature license information.	**display license feature**

Contents

Managing the device

About device management

This chapter describes how to configure basic device parameters and manage the device.

Device management tasks at a glance

All device management tasks are optional. You can perform any of the tasks in any order.

- Configuring basic parameters
  - Configuring the device name
  - Configuring the system ID
  - Configuring the system time
  - Enabling displaying the copyright statement
  - Configuring banners
- Configuring security parameters
  - Disabling password recovery capability
  - Disabling USB interfaces
- Adjusting device capacities
  - Setting the port status detection timer
- Monitoring the device
  - Monitoring CPU usage
  - Monitoring CPU core usage
  - Setting memory alarm thresholds
  - Configuring resource monitoring
  - Setting the temperature alarm thresholds
- Managing resources
  - Verifying and diagnosing transceiver modules
- Maintaining the device
  - Scheduling a task
  - Locating devices
  - Rebooting the device
  - Restoring the factory-default configuration

Configuring the device name

About this task

A device name (also called hostname) identifies a device in a network and is used in CLI view prompts. For example, if the device name is **Sysname**, the user view prompt is <Sysname>.

Procedure

1. Enter system view.

```
system-view
```

2. Configure the device name.

```
sysname sysname
```

By default, the device name is NSFOCUS.

Configuring the system ID

About this task

You can use the system ID to indicate the position or functionality of the device or any other information.

Procedure

1. Enter system view.

```
system-view
```

2. Configure the system ID.

```
sysid system-id
```

By default, the device does not have a system ID.

Configuring the system time

About the system time

Correct system time is essential to network management and communication. Configure the system time correctly before you run the device on the network.

The device can use one of the following methods to obtain the system time:

- Uses the locally set system time, and then uses the clock signals generated by its built-in crystal oscillator to maintain the system time.
- Periodically obtains the UTC time from an NTP source, and uses the UTC time, time zone, and daylight saving time to calculate the system time. For more information about NTP, see *Network Management and Monitoring Configuration Guide*.

The system time calculated by using the UTC time from a time source is more precise.

Restrictions and guidelines for configuring the system time

After you execute the **clock protocol none** command, the **clock datetime** command determines the system time, whether or not the time zone or daylight saving time has been configured.

If you configure or change the time zone or daylight saving time after the device obtains the system time, the device recalculates the system time. To view the system time, execute the **display clock** command.

This feature is supported only on the default context. All contexts on the device use the same system time.

System time configuration tasks at a glance

To configure the system time, perform the following tasks:

1. Configuring the system time

Choose one of the following tasks:

- Setting the system time at the CLI
- Obtaining the UTC time through a time protocol

2. (Optional.) Setting the time zone

   Make sure each network device uses the time zone of the place where the device resides.

3. (Optional.) Setting the daylight saving time

   Make sure each network device uses the daylight saving time parameters of the place where the device resides.

Setting the system time at the CLI

1. Enter system view.

   `system-view`

2. Configure the device to use the local system time.

   `clock protocol none`

   By default, the device uses the NTP time source specified on the default context.

   If you execute the **`clock protocol`** command multiple times, the most recent configuration takes effect.

3. Return to user view.

   `quit`

4. Set the local system time.

   `clock datetime` *`time date`*

   By default, the system time is UTC time 00:00:00 01/01/2011.

△ **CAUTION:**

This command changes the system time, which affects the execution of system time-related features (for example, scheduled tasks) and collaborative operations of the device with other devices (for example, log reporting and statistics collection). Before executing this command, make sure you fully understand its impact on your live network.

Obtaining the UTC time through a time protocol

Restrictions and guidelines

If the NTP signals are lost, the device uses the clock signals generated by its built-in crystal oscillator to maintain the system time. After the NTP signals recover, the device obtains the UTC time again through NTP.

Procedure

1. Enter system view.

   `system-view`

2. Specify the protocol for obtaining the UTC time.

   `clock protocol ntp context` *`context-id`*

   By default, the device uses the NTP time source specified on the default context.

   If you execute the **`clock protocol`** command multiple times, the most recent configuration takes effect.

   Support for the **`context`** *`context-id`* option depends on the device model. For more information, see device management in *Fundamentals Command Reference*.

3. Configure time protocol parameters.

   For more information about NTP configuration, see *Network Management and Monitoring Configuration Guide*.

Setting the time zone

1. Enter system view.

   `system-view`

2. Set the time zone.

   `clock timezone` *`zone-name`* { **`add`** | **`minus`** } *`zone-offset`*

   By default, the system uses the UTC time zone.

Setting the daylight saving time

1. Enter system view.

   `system-view`

2. Set the daylight saving time.

   `clock summer-time` *`name start-time start-date end-time end-date add-time`*

   By default, the daylight saving time is not set.

Enabling displaying the copyright statement

About this task

This feature enables the device to display the copyright statement in the following situations:

- When a Telnet or SSH user logs in.
- When a console user quits user view. This is because the device automatically tries to restart the user session.

If you disable displaying the copyright statement, the device does not display the copyright statement in any situations.

Procedure

1. Enter system view.

   `system-view`

2. Enable displaying the copyright statement.

   `copyright-info enable`

   By default, displaying the copyright statement is enabled.

Configuring banners

About this task

Banners are messages that the system displays when a user logs in.

The system supports the following banners:

- **Legal banner**—Appears after the copyright statement. To continue login, the user must enter **Y** or press **Enter**. To quit the process, the user must enter **N**. **Y** and **N** are case insensitive.

- **Message of the Day (MOTD) banner**—Appears after the legal banner and before the login banner.
- **Login banner**—Appears only when password or scheme authentication is configured.
- **Shell banner**—Appears before the user enters user view.

The system displays the banners in the following order: legal banner, MOTD banner, login banner, and shell banner.

Banner input methods

You can configure a banner by using one of the following methods:

- Input the entire command line in a single line.

  The banner cannot contain carriage returns. The entire command line, including the command keywords, the banner, and the delimiters, can have a maximum of 511 characters. The delimiters for the banner can be any printable character but must be the same. You cannot press **Enter** before you input the end delimiter.

  For example, you can configure the shell banner "Have a nice day." as follows:

  ```
  <System> system-view
  [System] header shell %Have a nice day.%
  ```

- Input the command line in multiple lines.

  The banner can contain carriage returns. A carriage return is counted as two characters.

  To input a banner configuration command line in multiple lines, use one of the following methods:

  - Press **Enter** after the final command keyword, type the banner, and end the final line with the delimiter character %. The banner plus the delimiter can have a maximum of 1999 characters.

    For example, you can configure the banner "Have a nice day." as follows:

    ```
    <System> system-view
    [System] header shell
    Please input banner content, and quit with the character '%'.
    Have a nice day.%
    ```

  - After you type the final command keyword, type any printable character as the start delimiter for the banner and press **Enter**. Then, type the banner and end the final line with the same delimiter. The banner plus the end delimiter can have a maximum of 1999 characters.

    For example, you can configure the banner "Have a nice day." as follows:

    ```
    <System> system-view
    [System] header shell A
    Please input banner content, and quit with the character 'A'.
    Have a nice day.A
    ```

  - After you type the final command keyword, type the start delimiter and part of the banner. Make sure the final character of the final string is different from the start delimiter. Then, press **Enter**, type the rest of the banner, and end the final line with the same delimiter. The banner plus the start and end delimiters can have a maximum of 2002 characters.

    For example, you can configure the banner "Have a nice day." as follows:

    ```
    <System> system-view
    [System] header shell AHave a nice day.
    Please input banner content, and quit with the character 'A'.
    A
    ```

Procedure

1. Enter system view.

```
system-view
```

2. Configure the legal banner.

   header legal *text*

3. Configure the MOTD banner.

   header motd *text*

4. Configure the login banner.

   header login *text*

5. Configure the shell banner.

   header shell *text*

Disabling password recovery capability

About this task

Password recovery capability controls console user access to the device configuration and SDRAM from BootWare menus. For more information about BootWare menus, see the release notes.

If password recovery capability is enabled, a console user can access the device configuration without authentication to configure a new password.

If password recovery capability is disabled, console users must restore the factory-default configuration before they can configure new passwords. Restoring the factory-default configuration deletes the next-startup configuration files.

To enhance system security, disable password recovery capability.

Restrictions and guidelines

This feature is supported only on the default context.

To access the device configuration without authentication, you must connect to the master device and access the BootWare menu while the master device is starting up.

Procedure

1. Enter system view.

   system-view

2. Disable password recovery capability.

   undo password-recovery enable

   By default, password recovery capability is enabled.

Disabling USB interfaces

About this task

You can upload or download files or use 3G or 4G capabilities on the device through USB interfaces. By default, all USB interfaces are enabled. You can disable USB interfaces as needed. If USB interfaces are disabled, file upload and download and 3G/4G capabilities are not available.

Restrictions and guidelines

This feature is supported only on the default context.

Procedure

1. Enter system view.

   system-view

2. Disable USB interfaces.

   `usb disable`

   By default, all USB interfaces are enabled.

Setting the port status detection timer

About this task

The device starts a port status detection timer when a port is shut down by a protocol. Once the timer expires, the device brings up the port so the port status reflects the port's physical status.

Procedure

1. Enter system view.

   `system-view`

2. Set the port status detection timer.

   `shutdown-interval` *`time`*

   The default setting is 30 seconds.

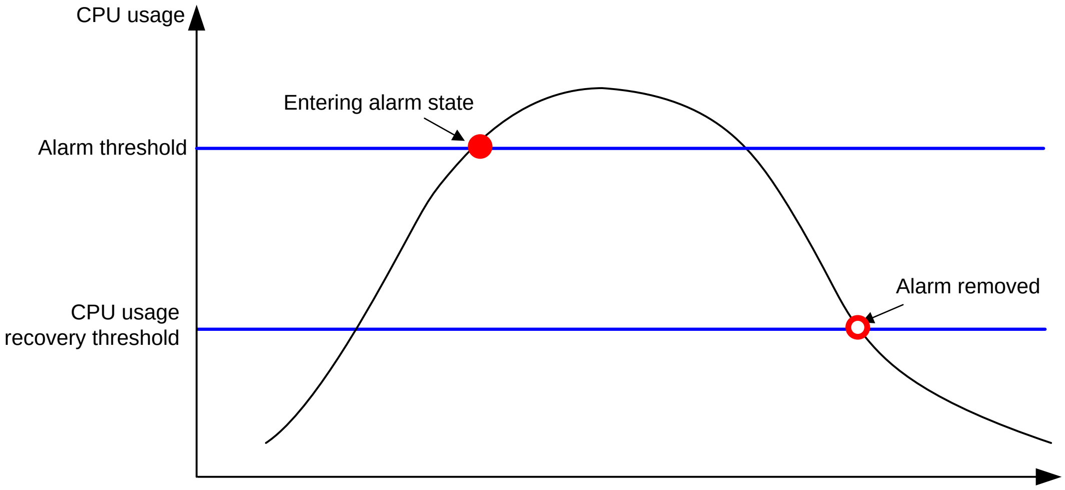
Monitoring CPU usage

About this task

To monitor CPU usage, the device performs the following operations:

- Samples CPU usage at 1-minute intervals and compares the samples with the CPU usage threshold and the CPU usage recovery threshold.
  - If a sample is greater than or equal to the CPU usage threshold, the device determines the CPU usage is high and sends traps to affected service modules and processes.
  - If a sample decreases to or below the CPU usage recovery threshold, the device determines the CPU usage has recovered and sends traps to affected service modules and processes.
- Samples and saves CPU usage at a configurable interval if CPU usage tracking is enabled. You can use the **`display cpu-usage history`** command to display the historical CPU usage statistics in a coordinate system.

Figure 1 CPU alarms and alarm-removed notifications



Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Set the CPU usage alarm thresholds.

   ```
   monitor cpu-usage threshold severe-threshold recovery-threshold
   recovery-threshold [ slot slot-number [ cpu cpu-number ] ]
   ```

   By default, the CPU usage alarm threshold is 70%, and the CPU usage recovery threshold is 30%.

   CAUTION:

   If you set the severe CPU usage alarm threshold to a too low value, the device will reach the threshold easily. Normal services will be affected.

3. Set the sampling interval for CPU usage tracking.

   ```
   monitor cpu-usage interval interval [ slot slot-number [ cpu
   cpu-number ] ]
   ```

   By default, the sampling interval for CPU usage tracking is 1 minute.

4. Enable CPU usage tracking.

   ```
   monitor cpu-usage enable [ slot slot-number [ cpu cpu-number ] ]
   ```

   By default, CPU usage tracking is enabled.

5. Enable periodic CPU usage logging.

   ```
   monitor cpu-usage logging slot slot-number cpu cpu-number interval
   interval-time
   ```

   By default, periodic CPU usage logging is disabled.

Monitoring CPU core usage

About this task

The device samples CPU core usage at 5-second intervals and calculates the average value during each CPU core usage statistics interval. If the value during an interval is greater than the CPU core usage threshold, the device issues an alarm and logs the event.

Restrictions and guidelines

As a best practice, set this argument to a multiple of the sampling interval, which is fixed at 5 seconds. If you do not do so, the actual statistics interval is the biggest multiple of the sampling interval that is smaller than the setting. For example, if you set this argument to 12 seconds, the actual statistics interval is 10 seconds.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Set CPU core usage statistics intervals.

   ```
   monitor cpu-usage statistics-interval interval slot slot-number cpu
   cpu-number core core-id-list
   ```

   By default, the CPU core usage statistics interval is 60 seconds.

3. Set CPU core alarm resending intervals.

   ```
   monitor resend cpu-usage core-interval core-interval [ slot
   slot-number [ cpu cpu-number ] ]
   ```

By default, the CPU core alarm resending interval is 300 seconds.

Setting memory alarm thresholds

About memory alarm thresholds

To ensure correct operation and improve memory efficiency, the system performs the following operations:

- Samples memory usage at 1-minute intervals. If the sample is equal to or greater than the memory usage threshold, the device sends a trap.
- Monitors the amount of free memory space in real time. If the amount of free memory space reaches the minor, severe, or critical alarm threshold, the system issues an alarm to affected service modules and processes.

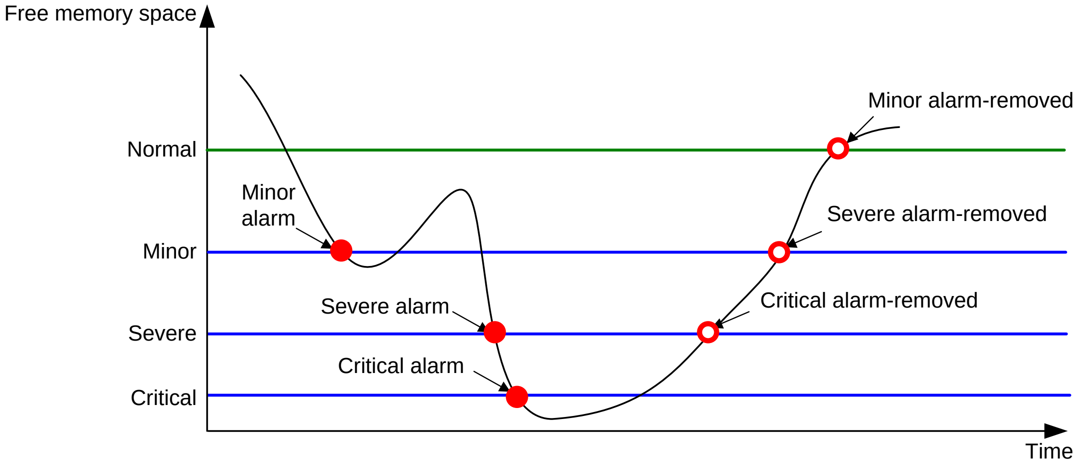
As shown in Table 1 and Figure 2, the system supports the following free-memory thresholds:

- Normal state threshold.
- Minor alarm threshold.
- Severe alarm threshold.
- Critical alarm threshold.

Table 1 Memory alarm notifications and memory alarm-removed notifications

Notification	Triggering condition	Remarks
Minor alarm notification	The amount of free memory space decreases below the minor alarm threshold.	After generating and sending a minor alarm notification, the system does not generate and send any additional minor alarm notifications until the minor alarm is removed.
Severe alarm notification	The amount of free memory space decreases below the severe alarm threshold.	After generating and sending a severe alarm notification, the system does not generate and send any additional severe alarm notifications until the severe alarm is removed.
Critical alarm notification	The amount of free memory space decreases below the critical alarm threshold.	After generating and sending a critical alarm notification, the system does not generate and send any additional critical alarm notifications until the critical alarm is removed.
Critical alarm-removed notification	The amount of free memory space increases above the severe alarm threshold.	N/A
Severe alarm-removed notification	The amount of free memory space increases above the minor alarm threshold.	N/A
Minor alarm-removed notification	The amount of free memory space increases above the normal state threshold.	N/A

Figure 2 Memory alarm notifications and alarm-removed notifications



Restrictions and guidelines

Restrictions and guidelines

This feature is supported only on the default context.

If a memory alarm occurs, delete unused configuration items or disable some features to increase the free memory space. Because the memory space is insufficient, some configuration items might not be able to be deleted.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Set the memory usage threshold.

   ```
   memory-threshold [ slot slot-number [ cpu cpu-number ] ] usage memory-threshold
   ```

   By default, the memory usage threshold is 95%.

3. Set the free-memory thresholds.

   ```
   memory-threshold [ slot slot-number [ cpu cpu-number ] ] [ ratio ] minor minor-value severe severe-value critical critical-value normal normal-value
   ```

   The default settings vary by device model. To view the default settings, use the **undo memory-threshold** command to restore the default settings and then execute the **display memory-threshold** command.

4. Enable periodic memory usage logging.

   ```
   monitor memory-usage logging slot slot-number cpu cpu-number interval interval-time
   ```

   By default, periodic memory usage logging is disabled.

Configuring resource monitoring

Monitoring the total inbound bandwidth usage

About this task

If the total inbound traffic remains greater than or equal to the total inbound bandwidth usage threshold for the specified duration, the device sends an alarm. If the alarm state persists, the device resends the alarm at 5-second intervals.

Restrictions and guidelines

This feature is supported only on the default context.

Procedure

1. Enter system view.

   system-view

2. Set the total inbound bandwidth usage threshold.

   monitor resource-usage bandwidth inbound threshold *threshold-value* [**duration** *duration-value*]

   By default, the total inbound bandwidth usage threshold is not set. The bandwidth usage alarm feature is disabled.

Monitoring the aggregate interface usage

About this task

When the number of created Layer 2 or Layer 3 aggregate interfaces reaches the aggregate interface usage threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 3-hour intervals.

Procedure

1. Enter system view.

   system-view

2. Set aggregate interface usage thresholds.

   monitor resource-usage { **bridge-aggregation** | **route-aggregation** } **threshold** *threshold-value*

   By default, no aggregate interface usage thresholds are set. The aggregate interface usage alarm feature is disabled.

Monitoring the inner interface throughput

About this task

When the inner interface throughput reaches the threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 10-minute intervals.

Restrictions and guidelines

This feature is supported only on the default context.

Procedure

1. Enter system view.

   system-view

2. Set the inner interface throughput threshold.

   monitor resource-usage blade-throughput threshold *threshold-value*

   By default, the inner interface throughput threshold is not set. The inner interface throughput alarm feature is disabled.

Monitoring the number of contexts

About this task

When the total number of contexts created on the device reaches the global context usage threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 6-hour intervals.

Restrictions and guidelines

This feature is supported only on the default context.

Procedure

1. Enter system view.

   system-view

2. Set the global context usage threshold.

   monitor resource-usage context threshold *threshold-value*

   By default, the global context usage threshold is not set. The global context usage alarm feature is disabled.

Monitoring the number of NAT mappings

About this task

When the number of NAT mappings reaches the NAT mapping threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 3-hour intervals.

In the current software version, this feature counts only static NAT mappings and effective NAT server mappings. To display the status of NAT server mappings, execute the **display nat server** command.

Procedure

1. Enter system view.

   system-view

2. Set the NAT mapping threshold.

   monitor resource-usage nat threshold *threshold-value*

   By default, the NAT mapping threshold is not set. The NAT mapping alarm feature is disabled.

Monitoring the number of security policy rules

About this task

When the number of created security policy rules reaches the security policy rule usage threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 6-hour intervals.

Procedure

1. Enter system view.

   system-view

2. Set security policy rule usage thresholds.

   monitor resource-usage security-policy { **ip** | **ipv6** } **threshold** *threshold-value*

   By default, no security policy rule thresholds are set. The security policy rule alarm feature is disabled.

Monitoring the number of sessions

About this task

When the number of sessions reaches the session usage threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 10-minute intervals.

Procedure

1. Enter system view.

   system-view

2. Set the session usage threshold.

   monitor resource-usage session-count [**slot** *slot-number*] **threshold** *threshold-value*

   By default, no session usage thresholds are set. The session usage alarm feature is disabled.

Monitoring the session establishment rate

About this task

When the session establishment rate reaches the threshold, the device sends an alarm. If the alarm state persists, the device resends the alarm at 10-minute intervals.

Procedure

1. Enter system view.

   system-view

2. Set the session establishment rate threshold.

   monitor resource-usage session-rate [**slot** *slot-number*] **threshold** *threshold-value*

   By default, no session establishment rate thresholds are set. The session establishment rate alarm feature is disabled.

Setting the temperature alarm thresholds

About this task

The device monitors its temperature based on the following thresholds:

- Low-temperature threshold.
- High-temperature warning threshold.
- High-temperature alarming threshold.

When the device temperature drops below the low-temperature threshold or reaches the high-temperature warning or alarming threshold, the device performs the following operations:

- Sends log messages and traps.
- Sets LEDs on the device panel.

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Restrictions and guidelines

This feature is supported only on the default context.

Procedure

1. Enter system view.

   `system-view`

2. Configure the temperature alarm thresholds.

   `temperature-limit slot` *`slot-number`* { **`hotspot`** | **`inflow`** | **`outflow`** } *`sensor-number lowlimit warninglimit`* [*`alarmlimit`*]

   The defaults vary by temperature sensor model. To view the defaults, execute the **`undo temperature-limit`** and **`display environment`** commands in turn.

   The high-temperature alarming threshold must be higher than the high-temperature warning threshold, and the high-temperature warning threshold must be higher than the low-temperature threshold.

   Support for the command depends on the device model. For more information, see the command reference.

Verifying and diagnosing transceiver modules

Verifying transceiver modules

About this task

You can use one of the following methods to verify the genuineness of a transceiver module:

- Display the key parameters of a transceiver module, including its transceiver type, connector type, central wavelength of the transmit laser, transfer distance, and vendor name.
- Display its electronic label. The electronic label is a profile of the transceiver module and contains the permanent configuration, including the serial number, manufacturing date, and vendor name. The data was written to the transceiver module or the device's storage component during debugging or testing of the transceiver module or device.

The device regularly checks transceiver modules for their vendor names. If a transceiver module does not have a vendor name or the vendor name is not NSFOCUS, the device repeatedly outputs traps and log messages. For information about logging rules, see information center in *Network Management and Monitoring Configuration Guide*.

Procedure

To verify transceiver modules, execute the following commands in any view:

- Display the key parameters of transceiver modules.

  `display transceiver interface` [*`interface-type interface-number`*]

- Display the electrical label information of transceiver modules.

display transceiver manuinfo { **controller** [*controller-type controller-number*] | **interface** [*interface-type interface-number*] }

Diagnosing transceiver modules

About this task

The device provides the alarm and digital diagnosis functions for transceiver modules. When a transceiver module fails or is not operating correctly, you can perform the following tasks:

- Check the alarms that exist on the transceiver module to identify the fault source.
- Examine the key parameters monitored by the digital diagnosis function, including the temperature, voltage, laser bias current, TX power, and RX power.

Procedure

To diagnose transceiver modules, execute the following commands in any view:

- Display transceiver alarms.

  display transceiver alarm { **controller** [*controller-type controller-number*] | **interface** [*interface-type interface-number*] }
- Display the current values of the digital diagnosis parameters on transceiver modules.

  display transceiver diagnosis { **controller** [*controller-type controller-number*] | **interface** [*interface-type interface-number*] }

Support for the **controller** keyword depends on the device model. For more information, see device management commands in *Fundamentals Command Reference*.

Scheduling a task

About task scheduling

You can schedule the device to automatically execute a command or a set of commands without administrative interference.

You can configure a periodic schedule or a non-periodic schedule. A non-periodic schedule is not saved to the configuration file and is lost when the device reboots. A periodic schedule is saved to the startup configuration file and is automatically executed periodically.

Restrictions and guidelines

- To assign a command (command A) to a job, you must first assign the job the command or commands for entering the view of command A.
- Make sure all commands in a schedule are compliant to the command syntax. The system does not check the syntax when you assign a command to a job.
- A schedule cannot contain any one of these commands: **telnet**, **ftp**, **ssh2**, and **monitor process**.
- A schedule does not support user interaction. If a command requires a yes or no answer, the system always assumes that a **Y** or **Yes** is entered. If a command requires a character string input, the system assumes that either the default character string (if any) or a null string is entered.
- A schedule is executed in the background, and no output (except for logs, traps, and debug information) is displayed for the schedule.

Procedure

1. Enter system view.

   system-view

2. Create a job.

   scheduler job *job-name*

3. Assign a command to the job.

   command *id command*

   By default, no command is assigned to a job.

   You can assign multiple commands to a job. A command with a smaller ID is executed first.

4. Exit to system view.

   quit

5. Create a schedule.

   scheduler schedule *schedule-name*

6. Assign a job to the schedule.

   job *job-name*

   By default, no job is assigned to a schedule.

   You can assign multiple jobs to a schedule. The jobs will be executed concurrently.

7. Assign user roles to the schedule.

   user-role *role-name*

   By default, a schedule has the user role of the schedule creator.

   You can assign a maximum of 64 user roles to a schedule. A command in a schedule can be executed if it is permitted by one or more user roles of the schedule.

8. Specify the execution time for the schedule.

   Choose one option as needed:

   - Execute the schedule at specific points of time.

     time at *time date*

     time once at *time* [**month-date** *month-day* | **week-day** *week-day*&<1-7>]

   - Execute the schedule after a period of time.

     time once delay *time*

   - Execute the schedule at the specified time on every specified day in a month or week.

     time repeating at *time* [**month-date** [*month-day* | **last**] | **week-day** *week-day*&<1-7>]

   - Execute the schedule periodically from the specified time on.

     time repeating [**at** *time* [*date*]] **interval** *interval*

   By default, no execution time is specified for a schedule.

   The **time** commands overwrite each other. The most recently executed command takes effect.

9. (Optional.) Set the size of the job execution log file.

   scheduler logfile size *value*

   By default, the size of the job execution log file is 16 KB.

   The job execution log file stores the execution information of jobs. If the file is full, old records are deleted to make room for new records. If the size of the log information to be written to the file is greater than the file size, the excessive information is not written to the file.

Locating devices

About device locating

The device provides SYS LEDs for device locating. The **locator blink** *blink-time* command flashes the LEDs quickly for a specified period of time unless you execute the **locator blink stop** command.

Restrictions and guidelines

This feature is supported only on the default context.

Starting LED flashing

To start LED flashing, execute one of the following commands in user view:

locator [**slot** *slot-number*] **blink** *blink-time*

Stopping LED flashing

To stop LED flashing, execute one of the following commands in user view:

locator [**slot** *slot-number*] **blink stop**

Rebooting the device

About device reboot

The following device reboot methods are available:

- Schedule a reboot at the CLI, so the device automatically reboots at the specified time or after the specified period of time.
- Immediately reboot the device at the CLI.

  During the reboot process, the device performs the following operations:

  a. Resets all of its chips.

  b. Uses the BootWare to verify the startup software package, decompress the package, and load the images.

  c. Initializes the system.
- Power off and then power on the device. This method might cause data loss, and is the least-preferred method.

Using the CLI, you can reboot the device from a remote host.

Restrictions and guidelines for device reboot

For data security, the device does not reboot while it is performing file operations.

Rebooting devices immediately at the CLI

Prerequisites

Perform the following steps in any view:

1. Verify that the next-startup configuration file is correctly specified.

   `display startup`

   For more information about the **`display startup`** command, see *Fundamentals Command Reference*.

2. Verify that the startup image files are correctly specified.

   `display boot-loader`

   If one main startup image file is damaged or does not exist, you must specify another main startup image file before rebooting the device.

   For more information about the **`display boot-loader`** command, see *Fundamentals Command Reference*.

3. Save the running configuration to the next-startup configuration file.

   `save`

   To avoid configuration loss, save the running configuration before a reboot.

   For more information about the **`save`** command, see *Fundamentals Command Reference*.

Procedure

To reboot the device immediately at the CLI, execute one of the following commands in user view:

`reboot` `[` **`slot`** *`slot-number`* `] [` **`force`** `]`

CAUTION:

- A device reboot might result in service interruption. Before using this command, make sure you fully understand its impact on your live network.
- Use the **`force`** keyword to reboot the device only when the system is faulty or fails to start up normally. A forced device reboots might cause file system damage. Before using the **`force`** keyword to reboot the device, make sure you understand its impact.

Scheduling a device reboot

Restrictions and guidelines

The automatic reboot configuration takes effect on all member devices. It will be canceled if a master/subordinate switchover occurs.

The device supports only one device reboot schedule. If you execute the **`scheduler reboot`** command multiple times, the most recent configuration takes effect.

Procedure

To schedule a reboot, execute one of the following commands in user view:

- **`scheduler reboot at`** *`time`* `[` *`date`* `]`
- **`scheduler reboot delay`** *`time`*

By default, no device reboot time is specified.

CAUTION:

This command enables the device to reboot at a scheduled time, which causes service interruption.

Before using this command, make sure you fully understand its impact on your live network.

Restoring the factory-default configuration

About this task

If you want to use the device in a different scenario or you cannot troubleshoot the device by using other methods, use this task to restore the factory-default configuration.

This task does not delete **.bin** files and license files.

Restrictions and guidelines

This feature is supported only on the default context.

Procedure

To restore the factory-default configuration for the device, execute the following command in user view:

`restore factory-default`

△ **CAUTION:**

This command restores the device to the factory default settings. Before using this command, make sure you fully understand its impact on your live network.

Display and maintenance commands for device management configuration

ⓘ **IMPORTANT:**

- Support for the **`display alarm`**, **`display environment`**, **`display fan`**, and **`display power`** commands depends on the device model.
- Support for the **`cf-card`**, **`harddisk`**, and **`usb`** keywords in the **`display device`** command depends on the device model.
- Support for the **`context`** keyword in the **`display diagnostic-information`** command depends on the device model.
- Support for the *`fan-id`* argument in the **`display fan`** command depends on the device model.
- Support for the *`power-id`* argument in the **`display power`** command depends on the device model.
- Support for the **`context`** keyword in the **`display system stable state`** command depends on the device model.
- Support for the **`controller`** keyword in the following commands depends on the device model: **`display transceiver alarm`**, **`display transceiver diagnosis`**, and **`display transceiver manuinfo`**.

For more information, see device management commands in *Fundamentals Command Reference*.

Execute **`display`** commands in any view. Execute the **`reset scheduler logfile`** command in user view. Execute the **`reset version-update-record`** command in system view.

Task	Command
Display device alarm information.	**`display alarm`** [**`slot`** *`slot-number`*]

Display the system time, date, time zone, and daylight saving time.	**display clock**
Display the copyright statement.	**display copyright**
Display CPU usage statistics.	**display cpu-usage** [**summary**] [**slot** *slot-number* [**cpu** *cpu-number* [**core** { *core-number* | **all** }]]] **display cpu-usage** [**control-plane** | **data-plane**] [**summary**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display CPU usage monitoring settings.	**display cpu-usage configuration** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display the historical CPU usage statistics in a coordinate system.	**display cpu-usage history** [**job** *job-id*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display hardware information.	**display device** [**harddisk** | **usb**] [**slot** *slot-number* [**subslot** *subslot-number*] | **verbose**]
Display electronic label information for the device.	**display device manuinfo** [**slot** *slot-number*]
Display or save operating information for features and hardware modules.	**display diagnostic-information** [**hardware** | **infrastructure** | **l2** | **l3** | **service**] [**key-info**] [*filename*]
Display device temperature information.	**display environment** [**slot** *slot-number*]
Display the operating states of fan trays.	**display fan** [**slot** *slot-number* [*fan-id*]]
Display memory usage statistics.	**display memory** [**summary**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory alarm thresholds and statistics.	**display memory-threshold** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display power supply information.	**display power** [**slot** *slot-number* [*power-id*]]
Display job configuration information.	**display scheduler job** [*job-name*]
Display job execution log information.	**display scheduler logfile**
Display the automatic reboot schedule.	**display scheduler reboot**
Display schedule information.	**display scheduler schedule** [*schedule-name*]
Display system stability and status information.	**display system stable state**
Display system version information.	**display version**
Display startup software image upgrade records.	**display version-update-record**
Clear job execution log information.	**reset scheduler logfile**
Clear startup software image upgrade records.	**reset version-update-record**

NOTE:

- Executing the **display cpu-usage**, **display cpu-usage configuration**, **display cpu-usage history**, or **display memory** command on a context displays information for the context.
- The **display device** command displays device information about the physical devices, whether you execute the command on the default context or on a non-default context.

NOTE:

The following commands are supported only on the default context:

- **display alarm**
- **display device manuinfo**
- **display environment**
- **display fan**
- **display memory-threshold**
- **display power**
- **display version-update-record**
- **reset scheduler logfile**
- **reset version-update-record**

Contents

Configuring FTP

About FTP

File Transfer Protocol (FTP) is an application layer protocol for transferring files from one host to another over an IP network. It uses TCP port 20 to transfer data and TCP port 21 to transfer control commands.

FTP is based on the client/server model. The device can act as the FTP server or FTP client.

FTP file transfer modes

FTP supports the following transfer modes:

- **Binary mode**—Used to non-text files, such as **.app**, **.bin**, and **.btm** files.
- **ASCII mode**—Used to transfer text files, such as **.txt**, **.bat**, and **.cfg** files.

When the device acts as the FTP client, you can set the transfer mode (**binary** by default). When the device acts as the FTP server, the transfer mode is determined by the FTP client.

FTP operation modes

FTP can operate in either of the following modes:

- **Active mode (PORT)**—The FTP server initiates the TCP connection. This mode is not suitable when the FTP client is behind a firewall, for example, when the FTP client resides in a private network.
- **Passive mode (PASV)**—The FTP client initiates the TCP connection. This mode is not suitable when the server does not allow the client to use a random unprivileged port greater than 1024.

FTP operation mode varies depending on the FTP client program.

Using the device as an FTP server

To use the device as an FTP server, you must enable the FTP server and configure authentication and authorization on the device. Other commands are optional.

FTP server configuration tasks at a glance

To use the device as an FTP server, perform the following tasks:

1. Enabling the FTP server
2. Configuring client authentication and authorization
3. (Optional.) Configuring FTP server access control
4. (Optional.) Setting connection management parameters
5. (Optional.) Specifying an SSL server policy for SFTP connections
6. (Optional.) Setting the DSCP value for outgoing FTP packets
7. (Optional.) Manually releasing FTP connections

Enabling the FTP server

1. Enter system view.

   ```
   system-view
   ```

2. Enable the FTP server.

   ```
   ftp server enable
   ```

   By default, the FTP server is disabled.

Configuring client authentication and authorization

Perform this task on the FTP server to authenticate FTP clients and set the authorized directories that authenticated clients can access.

The following authentication modes are available:

- **Local authentication**—The device looks up the client's username and password in the local user account database. If a match is found, authentication succeeds.
- **Remote authentication**—The device sends the client's username and password to a remote authentication server for authentication. The user account is configured on the remote authentication server rather than the device.

The following authorization modes are available:

- **Local authorization**—The device assigns authorized directories to FTP clients based on the locally configured authorization attributes.
- **Remote authorization—**A remote authorization server assigns authorized directories on the device to FTP clients.

For more information about configuring authentication and authorization, see AAA in *Security Configuration Guide*.

Configuring FTP server access control

About this task

Use ACLs to prevent unauthorized access. If an applied ACL does not exist or does not have any rules, no user login restriction is applied. If the ACL exists and has rules, only FTP clients permitted by the ACL can access the device.

Restrictions and guidelines

When no ACL is applied, all FTP clients can access the FTP server. To control FTP access, specify an ACL that exists and has rules so only FTP clients permitted by the ACL can access the FTP server. If you specify an ACL that does not exist or does not have rules, no FTP clients can access the FTP server.

If a VPN instance is specified in an ACL rule, the ACL rule applies only to the packets of the VPN instance. If no VPN instance is specified in an ACL rule, the ACL rule applies only to the packets on the public network.

The ACL takes effect only for FTP connections to be established. It does not impact existing FTP connections.

For more information about ACL, see *ACL and QoS Configuration Guide.*

If you configure FTP server access control multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.

system-view

2. (Optional.) Use an ACL to control access to the FTP server.

   IPv4:

   ftp server acl { *advanced-acl-number* | *basic-acl-number* | *mac mac-acl-number* }

   IPv6:

   ftp server acl ipv6 { *advanced-acl-number* | *basic-acl-number* | **mac** *mac-acl-number* }

   By default, no ACL is used for access control.

3. (Optional.) Enable logging for FTP login attempts that are denied by the FTP login control ACL.

   ftp server acl-deny-log enable

   By default, logging is disabled for FTP login attempts that are denied by the FTP login control ACL.

Setting connection management parameters

1. Enter system view.

   system-view

2. Set the FTP connection idle-timeout timer.

   ftp timeout *minutes*

   By default, the FTP connection idle-timeout timer is 30 minutes.

   If no data transfer occurs on an FTP connection before the idle-timeout timer expires, the FTP server closes the FTP connection.

3. Set the maximum number of concurrent FTP users.

   aaa session-limit ftp *max-sessions*

   By default, the maximum number of concurrent FTP users is 32.

   Changing this setting does not affect users who are currently online. If the new limit is less than the number of online FTP users, no additional FTP users can log in until the number drops below the new limit.

   For more information about this command, see *Security Command Reference*.

Specifying an SSL server policy for SFTP connections

About this task

After you associate an SSL server policy with the device, a client that supports SFTP will establish a secure connection to the device to ensure data security.

Procedure

1. Enter system view.

   system-view

2. Associate an SSL server policy with the FTP server to ensure data security.

   ftp server ssl-server-policy *policy-name*

   By default, no SSL server policy is associated with the FTP server.

Setting the DSCP value for outgoing FTP packets

1. Enter system view.

```
system-view
```

2. Set the DSCP value for outgoing FTP packets.

   IPv4:

   ftp server dscp *dscp-value*

   IPv6:

   ftp server ipv6 dscp *dscp-value*

   By default, the DSCP value is 0.

Manually releasing FTP connections

To manually release FTP connections, execute the following commands in user view:

- Release the FTP connection established by using a specific user account:

  free ftp user *username*

- Release the FTP connection to a specific IP address:

  free ftp user-ip [**ipv6**] *ip-address* [**port** *port*]

Display and maintenance commands for the FTP server

Execute **display** commands in any view.

Task	Command
Display FTP server configuration and status information.	**display ftp-server**
Display detailed information about online FTP users.	**display ftp-user**

Using the device as an FTP client

FTP client configuration tasks at a glance

To use the device as an FTP server, perform the following tasks:

1. Establishing an FTP connection
2. (Optional.) Displaying command help information
3. (Optional.) Displaying directories and files on the FTP server
4. (Optional.) Managing directories on the FTP server
5. (Optional.) Working with files on the FTP server
6. (Optional.) Changing to another user account
7. (Optional.) Maintaining and troubleshooting the FTP connection
8. (Optional.) Terminating the FTP connection

Establishing an FTP connection

FTP connection establishment task list

To establish an FTP connection, perform the following tasks:

1. (Optional.) Specifying a source IP address for outgoing FTP packets

2. Establishing an FTP connection
3. Setting the FTP file transfer mode and operation mode

Restrictions and guidelines

The source IP address specified in the **ftp** command takes precedence over the one set by the **ftp client source** command.

The source IP address specified in the **ftp ipv6** command takes precedence over the one set by the **ftp client ipv6 source** command.

Specifying a source IP address for outgoing FTP packets

1. Enter system view.
   system-view
2. Specify a source IP address for outgoing FTP packets.
   IPv4:
   ftp client source { **interface** *interface-type interface-number* | **ip** *source-ip-address* }
   By default, no source IP address is specified. The device uses the primary IP address of the output interface as the source IP address.
   IPv6:
   ftp client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *source-ipv6-address* }
   By default, no source IPv6 address is specified. The source address is automatically selected as defined in RFC 3484.

Establishing an FTP connection

- Log in to the FTP server from user view.
  IPv4:
  ftp [*ftp-server* [*service-port*] [**vpn-instance** *vpn-instance-name*] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ip** *source-ip-address* }]] *
  IPv6:
  ftp ipv6 [*ftp-server* [*service-port*] [**vpn-instance** *vpn-instance-name*] [**dscp** *dscp-value* | **source** { **ipv6** *source-ipv6-address* | **interface** *interface-type interface-number* }] * [**-i** *interface-type interface-number*]]
- Log in to the FTP server from FTP client view.
  a. Enter FTP client view.
     ftp [**ipv6**]
  b. Log in to the FTP server.
     open *server-address* [*service-port*]

Setting the FTP file transfer mode and operation mode

1. Enter FTP client view from user view.
   ftp
2. Set the file transfer mode.
   - Set the file transfer mode to ASCII.
     ascii
   - Set the file transfer mode to binary.

binary

The default file transfer mode is binary.

3. Change the FTP operation mode.

   passive

   The default FTP operation mode is passive.

Displaying command help information

1. Enter FTP client view from user view.

   ftp

2. Display command help information.
   - **help** [*command-name*]
   - **?** [*command-name*]

Displaying directories and files on the FTP server

1. Enter FTP client view from user view.

   ftp

2. Display directories and files on the FTP server.
   - **dir** [*remotefile* [*localfile*]]
   - **ls** [*remotefile* [*localfile*]]

Managing directories on the FTP server

Prerequisites

Use the **dir** or **ls** command to display the directories and files on the FTP server.

Procedure

1. Enter FTP client view from user view.

   ftp

2. Manage directories on the FTP server.
   - Display the working directory that is being accessed on the FTP server.

     pwd
   - Change the working directory on the FTP server.

     cd { *directory* | **..** | **/** }
   - Return to the upper level directory on the FTP server.

     cdup
   - Create a directory on the FTP server.

     mkdir *directory*
   - Delete a directory from the remote FTP server.

     rmdir *directory*

CAUTION:

Delete a directory from the FTP server with caution. When you delete a directory from the FTP server, make sure the directory is no longer in use.

Managing directories on the FTP client

1. Enter FTP client view from user view.

   ftp

2. Display or change the local working directory of the FTP client.

   lcd [*directory* | **/**]

   To upload a file, use this command to change to the directory where the file resides. Downloaded files are saved in the working directory.

Working with files on the FTP server

Prerequisites

Use the **dir** or **ls** command to display the directories and files on the FTP server.

Procedure

1. Enter FTP client view from user view.

   ftp

2. Work with files on the FTP server.
   - Delete a file from the FTP server permanently.

     delete *remotefile*

     △ **CAUTION:**

     Permanently delete a file from the FTP server with caution. When you delete a file from the FTP server permanently, make sure the file is no longer in use.

     This command requires that you have the delete right.
   - Rename a file.

     rename [*oldfilename* [*newfilename*]]
   - Upload a file to the FTP server.

     put *localfile* [*remotefile*]
   - Download a file from the FTP server.

     get *remotefile* [*localfile*]
   - Add the content of a file on the FTP client to a file on the FTP server.

     append *localfile* [*remotefile*]
   - Specify the retransmit marker.

     restart *marker*

     Use this command together with the **put**, **get**, or **append** command.
   - Update a local file.

     newer *remotefile*
   - Get the missing part of a file.

     reget *remotefile* [*localfile*]

Changing to another user account

About this task

If you tried to access an FTP server but failed to pass the authentication, you can use this command to try again before the connection to the FTP server expires.

Restrictions and guidelines

For successful account change, you must enter the new username and password correctly. A wrong username or password can cause the FTP connection to be disconnected.

Procedure

1. Enter FTP client view from user view.

   `ftp`

2. Initiate an FTP authentication on the current FTP connection.

   `user` *`username`* `[` *`password`* `]`

Maintaining and troubleshooting the FTP connection

About this task

After you use the device to establish an FTP connection to the FTP server, use the commands in this section to locate and troubleshoot problems about the FTP connection.

Procedure

1. Enter FTP client view from user view.

   `ftp`

2. Maintain and troubleshoot the FTP connection.
   - Display FTP commands supported by the FTP server.

     `rhelp`
   - Display help information about an FTP command that is supported by the FTP server.

     `rhelp` *`protocol-command`*
   - Display FTP server status.

     `rstatus`
   - Display detailed information about a directory or file on the FTP server.

     `rstatus` *`remotefile`*
   - Display FTP connection status.

     `status`
   - Display the system information of the FTP server.

     `system`
   - Enable or disable FTP operation information display.

     `verbose`

     By default, this function is enabled.
   - Enable FTP client debugging.

     `debug`

     By default, FTP client debugging is disabled.
   - Clear the reply information in the buffer.

     `reset`

Terminating the FTP connection

1. Enter FTP client view from user view.

   ```
   ftp
   ```

2. Terminate the connection.
   - Terminate the connection to the FTP server without exiting FTP client view.

     ```
     disconnect
     close
     ```

   - Terminate the connection to the FTP server and return to user view.

     ```
     bye
     quit
     ```

Display and maintenance commands for the FTP client

Execute the **display** command in any view.

Task	Command
Display source IP address information on the FTP client.	**display ftp client source**

Configuring TFTP

About TFTP

Trivial File Transfer Protocol (TFTP) is a simplified version of FTP for file transfer over secure reliable networks. TFTP uses UDP port 69 for data transmission. In contrast to TCP-based FTP, TFTP does not require authentication or complex message exchanges, and is easier to deploy. TFTP is suited for reliable network environments.

The device can act as the TFTP server or TFTP client.

Restrictions and guidelines: TFTP configuration

You can upload a file from a TFTP client to the TFTP server or download a file from the TFTP server to a TFTP client. As a best practice, specify a file name that has not been used in the destination directory. If the destination file name has been used in the destination directory, the device deletes the existing file before saving the new file.

Configuring the device as a TFTP server

1. Enter system view.

`system-view`

2. Enable the TFTP server.

`tftp server enable`

By default, the TFTP server is disabled.

The device can act as the TFTP server on both IPv4 and IPv6 networks.

3. Set the TFTP server working directory.

`tftp server work-directory` *`directory`*

By default, the TFTP server working directory is the root directory of the default file system.

Configuring and using the IPv4 TFTP client

1. Enter system view.

`system-view`

2. (Optional.) Use an ACL to control the client's access to TFTP servers.

`tftp-server acl` *`acl-number`*

By default, no ACL is used for access control.

3. Specify the source IP address for TFTP packets sent by the TFTP client.

`tftp client source` { **`interface`** *`interface-type interface-number`* | **`ip`** *`source-ip-address`* }

By default, no source IP address is specified. The device uses the primary IP address of the output interface as the source IP address.

4. Return to user view.

`quit`

5. Download or upload a file in an IPv4 network.

tftp *tftp-server* { **get** | **put** | **sget** } *source-filename* [*destination-filename*] [**vpn-instance** *vpn-instance-name*] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ip** *source-ip-address* }] *

The source IP address specified in this command takes precedence over the source IP address set by using the **tftp client source** command.

Configuring and using the IPv6 TFTP client

1. Enter system view.

   system-view

2. (Optional.) Use an ACL to control the client's access to TFTP servers.

   tftp-server ipv6 acl *ipv6-acl-number*

   By default, no ACL is used for access control.

3. Specify the source IPv6 address for TFTP packets sent by the TFTP client.

   tftp client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *source-ipv6-address* }

   By default, no source IPv6 address is specified. The source address is automatically selected as defined in RFC 3484.

4. Return to user view.

   quit

5. Download or upload a file in an IPv6 network.

   tftp ipv6 *tftp-server* [**-i** *interface-type interface-number*] { **get** | **put** | **sget** } *source-filename* [*destination-filename*] [**vpn-instance** *vpn-instance-name*] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ipv6** *source-ipv6-address* }] *

   The source IP address specified in this command takes precedence over the one set by the **tftp client ipv6 source** command.

Contents

Managing file systems

This chapter describes how to manage file systems.

About file system management

Storage media and file systems

The device supports both fixed (the flash memory) and hot swappable (USB disk and hard disk) storage media.

- The fixed storage medium has one file system.
- The hot swappable storage media can be partitioned. Each unpartitioned storage medium has one file system. On a partitioned storage medium, each partition has one file system.

Storage medium and file system naming conventions

The file system on the flash memory has the same name as the flash memory. The name has the following parts:

- Storage medium type **flash**.
- Colon (:).

A hard disk or USB disk name and the file system names share the following parts:

- Storage medium type, for example, **usb** for the USB disk.
- Sequence number, a lower-case English letter such as a, b, or c.
- Partition number, a digit that starts at 0 and increments by 1. If the storage medium is not partitioned, the system determines that the storage medium has one partition. (A storage medium name does not contain a partition number.)
- Colon (:).

IMPORTANT:

File system names are case sensitive and must be entered in lower case.

File system location

To identify a file system on the master device, you do not need to specify the file system location. To identify a file system on a subordinate member device, you must specify the file system location in the **slot***n***#** format. The *n* argument represents the IRF member ID of the member device. For example, the location is **slot2#** for a file system that resides on member device 2.

IMPORTANT:

The file system location string is case sensitive and must be entered in lower case.

Default file system

You are working with the default file system by default after you log in. To specify a file or directory on the default file system, you do not need to specify the file system name. For example, you do not need to specify any location information if you want to save the running configuration to the root directory of the default file system.

To change the default file system, use the BootWare or Boot ROM menu. For more information, see the software release notes.

Directories

Directories in a file system are structured in a tree form.

Root directory

The root directory is represented by a forwarding slash (/). For example, **flash:/** represents the root directory of the flash memory.

Working directory

The working directory is also called the current directory.

Directory naming conventions

When you specify a name for a directory, follow these conventions:

- A directory name can contain letters, digits, and special characters except for asterisks (*), vertical bars (|), forward slashes (/), backward slashes (\), question marks (?), left angle brackets (<), right angle brackets (>), quotation marks ("), and colons (:).
- A directory whose name starts with a dot character (.) is a hidden directory. To prevent the system from hiding a directory, make sure the directory name does not start with a dot character.

Commonly used directories

The device has some factory-default directories. The system automatically creates directories during operation. These directories include:

- **diagfile**—Stores diagnostic information files.
- **license**—Stores license files.
- **logfile**—Stores log files.
- **seclog**—Stores security log files.
- **versionInfo**—Stores software version information files.

Files

File naming conventions

When you specify a name for a file, follow these conventions:

- A file name can contain letters, digits, and special characters except for asterisks (*), vertical bars (|), forward slashes (/), backward slashes (\), question marks (?), left angle brackets (<), right angle brackets (>), quotation marks ("), and colons (:).
- A file whose name starts with a dot character (.) is a hidden file. To prevent the system from hiding a file, make sure the file name does not start with a dot character.

Common file types

The device has some factory-default files and might create some files automatically during operation. The types of these files include:

- **.ipe file**—Compressed software image package file.
- **.bin file**—Software image file.
- **.cfg file**—Configuration file.
- **.mdb file**—Binary configuration file.
- **.log file**—Log file.

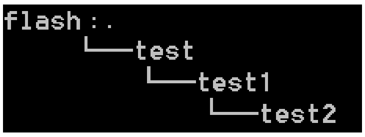
Specifying a directory name or file name

Specifying a directory name

To specify a directory, you can use the absolute path or a relative path. For example, the working directory is **flash:/**. To specify the **test2** directory in Figure 1, you can use the following methods:

- **flash:/test/test1/test2** (absolute path)
- **flash:/test/test1/test2/** (absolute path)
- **test/test1/test2** (relative path)
- **test/test1/test2/** (relative path)

Figure 1 Sample directory hierarchy



```
flash:.
    └──test
         └──test1
              └──test2
```

Specifying a file name

To specify a file, use the following methods:

- Enter the absolute path of the file and the file name in the format of *filesystem/directory1/directory2/…/directoryn/filename*, where *directoryn* is the directory in which the file resides.
- Enter the relative path of the file and the file name.

For example, the working directory is **flash:/**. The **samplefile.cfg** file is in the **test2** directory shown in Figure 1. To specify the file, you can use the following methods:

- **flash:/test/test1/test2/samplefile.cfg**
- **test/test1/test2/samplefile.cfg**

Restrictions and guidelines: File system management

To avoid file system corruption, do not perform the following tasks during file system management:

- Install or remove storage media.
- Perform a master/subordinate switchover.

If you remove a storage medium while a directory or file on the medium is being accessed, the device might not recognize the medium when you reinstall it. To reinstall this kind of storage medium, first complete one of the following tasks:

- If you were accessing a directory on the storage medium, change the working directory.
- If you were accessing a file on the storage medium, close the file.
- If another administrator was accessing the storage medium, unmount all partitions on the storage medium.

Make sure a USB disk is not write protected before an operation that requires the write right on the disk.

For the device to recognize a new hard disk or USB disk, you must first partition and format the hard disk or USB disk. To partition a disk, use the **`fdisk`** command. To format a disk, use the **`format`** command.

You cannot access a storage medium that is being partitioned, or a file system that is being formatted or repaired.

Before managing file systems, directories, and files, make sure you know the possible impact.

Managing storage media and file systems

Partitioning a storage medium

About this task

A storage medium can be divided into logical devices called partitions. Operations on one partition do not affect the other partitions.

Restrictions and guidelines

IMPORTANT:

Partitioning a storage medium clears all data on the medium.

The flash memory does not support partitioning.

Before partitioning a storage medium, make sure no other users are accessing the medium.

To partition a USB disk, make sure the disk is not write protected. If the disk is write protected, the partition operation will fail. To restore access to the USB disk, you must reinstall the disk or remount the file systems on the disk.

A partition must have a minimum of 32 MB of storage space.

The actual partition size and the specified partition size might have a difference of less than 5% of the storage medium's total size.

Prerequisites

Back up the files in the storage medium.

Procedure

To partition a storage medium, execute the following command in user view:

`fdisk` *`medium`* `[` *`partition-number`* `]`

This command is supported only on the default context.

To partition a storage medium evenly, specify the *`partition-number`* argument. To customize the sizes of partitions, do not specify the *`partition-number`* argument. The command will require you to specify a size for each partition.

Mounting or unmounting a file system

Restrictions and guidelines

You can mount or unmount only a file system that is on a hot-swappable storage medium.

You can unmount a file system only when no other users are accessing the file system.

To prevent a USB disk and the USB interface from being damaged, make sure the following requirements are met before unmounting file systems on the USB disk:

- The system has recognized the USB disk.
- The USB disk LED is not blinking.

Mounting a file system

To mount a file system, execute the following command in user view:

```
mount filesystem
```

This command is supported only on the default context.

File systems on a hot-swappable storage medium are automatically mounted when the storage medium is connected to the device. If the system cannot recognize a file system, you must mount the file system before you can access it.

Unmounting a file system

To unmount a file system, execute the following command in user view:

```
umount filesystem
```

This command is supported only on the default context.

To remove a hot-swappable storage medium from the device, you must first unmount all file systems on the storage medium to disconnect the medium from the device. Removing a connected hot-swappable storage medium might damage files on the storage medium or even the storage medium itself.

Formatting a file system

Restrictions and guidelines

You can format a file system only when no other users are accessing the file system.

Procedure

To format a file system, execute the following command in user view:

```
format filesystem [ ext4 | vfat ]
```

△ **CAUTION:**

Formatting a file system permanently deletes all files and directories in the file system. You cannot restore the deleted files or directories. If a startup configuration file exists in the file system, back up the file if necessary.

This command is supported only on the default context.

Repairing a file system

Restrictions and guidelines

If part of a file system is inaccessible, use this task to examine and repair the file system.

You can repair a file system only when no other users are accessing the file system.

Procedure

To repair a file system, execute the following command in user view:

```
fixdisk filesystem
```

This command is supported only on the default context.

Managing files and directories

Setting the operation mode for files and directories

About this task

The device supports the following operation modes:

- **alert**—The system prompts for confirmation when your operation might cause problems such as file corruption or data loss. This mode provides an opportunity for you to cancel a disruptive operation.
- **quiet**—The system does not prompt for confirmation when you perform a file or directory operation except the recycle bin emptying operation.

Procedure

1. Enter system view.

   `system-view`

2. Set the operation mode for files and directories.

   `file prompt` { **`alert`** | **`quiet`** }

   The default mode is alert.

Displaying file and directory information

To display file and directory information, execute the following command in user view:

`dir` [**`/all`**] [*`file`* | *`directory`* | **`/all-filesystems`**]

If multiple users perform file operations (for example, creating or deleting files or directories) at the same time, the output from this command might be incorrect.

Displaying the contents of a text file

To display the contents of a text file, execute the following command in user view:

`more` *`file`*

Displaying the working directory

To display the working directory, execute the following command in user view:

`pwd`

Changing the working directory

About this task

The default working directory is the root directory of the default file system on the master device.

Procedure

To change the working directory, execute the following command in user view:

`cd` { *`directory`* | **`..`** }

Creating a directory

To create a directory, execute the following command in user view:

mkdir *directory*

Renaming a file or directory

To rename a file or directory, execute the following command in user view:

rename { *source-file* | *source-directory* } { *dest-file* | *dest-directory* }

Copying a file

About this task

You can copy a file as follows:

- Copy a local file and save it locally.
- Copy a local file and save it to a remote file server.
- Copy a file from a remote file server and save it locally.

The remote file server can be an FTP, TFTP, or HTTP server.

Restrictions and guidelines

To specify a file or directory on a remote file server, use the following guidelines:

Location	Name format	Remarks
On an FTP server	Enter the URL in the format of **ftp://***FTP username*[**:***password*]**@***server address*[**:***port number*]**/***file path*[**/***file name*].	The username and password must be the same as the username and password configured on the FTP server. If the server authenticates users only by the username, you are not required to enter the password. For example, to use the username **a** and password **1** and specify the **startup.cfg** file in the authorized working directory on the FTP server 1.1.1.1, enter **ftp://a:1@1.1.1.1/startup.cfg**.
On a TFTP server	Enter the URL in the format of **tftp://***server address*[**:***port number*]**/***file path*[**/***file name*].	For example, to specify the **startup.cfg** file in the working directory on TFTP server 1.1.1.1, enter the URL **tftp://1.1.1.1/startup.cfg**.
On an HTTP server	Enter the URL in the format of **http://**[*HTTP username*[**:***password*]@]*server address*[**:***port number*]**/***filepath*[**/***file name*].	The username and password in the URL must be the same as the username and password configured on the server. If only the username is required for authentication, you do not need to enter the password. If authentication is not required, you do not need to enter the username or password. For example, the **startup.cfg** file is saved in the authorized directory on the HTTP server at 1.1.1.1. The HTTP account username and password are **a** and **1**, respectively. To copy the file, enter the URL **http://a:1@1.1.1.1/startup.cfg**. If authentication is not required, enter the URL **http://1.1.1.1/startup.cfg**.

To specify an IPv6 address, enclose the IPv6 address in square brackets ([ ]), for example, **ftp://test:test@[2001::1]:21/test.cfg**.

Procedure

To copy a file, execute the command in user view.

copy *source-file* { *dest-file* | *dest-directory* } [**vpn-instance** *vpn-instance-name*] [**source interface** *interface-type interface-number*] [**append**]

Moving a file

To move a file, execute the following command in user view:

move *source-file* { *dest-file* | *dest-directory* }

Deleting and restoring files

About this task

You can delete a file permanently or move it to the recycle bin of the file system. A file moved to the recycle bin can be restored, but a permanently deleted file cannot.

Each file system has a recycle bin. A recycle bin is a directory named **.trash** in the root directory of the file system.

Restrictions and guidelines

Files in the recycle bin occupy storage space. To release the occupied storage space, delete files from the recycle bin.

To delete files from the recycle bin, use the **reset recycle-bin** command. If you use the **delete** command, the recycle bin might not be able to operate correctly.

To display files in a recycle bin, use one of the following methods:

- Access the root directory of the file system and execute the **dir /all .trash** command.
- Access the recycle bin directory of the file system and execute the **dir** command.

Deleting a file

To delete a file, execute one of the following commands in user view:

- Delete a file by moving it to the recycle bin.
  delete *file*
- Delete a file permanently.
  delete /unreserved *file*

△ **CAUTION:**

The **delete /unreserved** *file* command deletes a file permanently. The file cannot be restored.

- Delete files from the recycle bin.
  reset recycle-bin [**/force**]

△ **CAUTION:**

The files in a recycle bin can be restored by using the **undelete** command. If you delete a file from the recycle bin, that file cannot be restored. Before you delete files from a recycle bin, make sure the files are no longer in use.

Restoring a file

To restore a file from the recycle bin, execute the following command in user view:

undelete *file*

Deleting a directory

To delete a directory, execute the following command in user view:

rmdir *directory*

△ **CAUTION:**

To delete a directory, you must first delete all files and subdirectories in the directory permanently or move them to the recycle bin. If you move them to the recycle bin, executing the **rmdir** command to delete the directory will delete them permanently. Before you use the **rmdir** command to delete a directory, you must make sure the directory and its files and subdirectories are no longer in use.

Archiving files and directories

About this task

You can archive files and directories to a single file for purposes such as file backup. The original files and directories still exist.

When you archive files and directories, you can choose to compress the archive files so the archive files use less storage space.

Procedure

To archive files and directories, execute the following command in user view:

tar create [**gz**] **archive-file** *dest-file* [**verbose**] **source** { *source-file* | *source-directory* }&<1-5>

Extracting files and directories

About this task

Use this feature to extract files and directories from archive files.

Restrictions and guidelines

To specify the **screen** keyword for the **tar extract** command, first use the **tar list** command to identify the types of the archived files. As a best practice, specify the keyword only if all archived files are text files. Displaying the content of an archived non-text file that contains terminal control characters might result in garbled characters and even cause the terminal unable to operate correctly. To use the terminal again, you must close the current connection and log in to the device again.

Procedure

To extract files and directories, execute the following commands in user view:

1. (Optional.) Display archived files and directories.

   tar list archive-file *file*

2. Extract files and directories.

   tar extract archive-file *file* [**verbose**] [**screen** | **to** *directory*]

Compressing a file

To compress a file, execute the following command in user view:

gzip *file*

Decompressing a file

To decompress a file, execute the following command in user view:

gunzip *file*

Calculating the file digest

About this task

File digests are used to verify file integrity.

Procedure

To calculate the digest of a file, execute one of the following commands in user view:

- Use the SHA-256 algorithm.

  sha256sum *file*
- Use the MD5 algorithm.

  md5sum *file*

Displaying processes that are using a file system, directory, or file

About this task

Execute this command if you fail to execute a command such as **fdisk**, **fixdisk**, **format**, **umount**, **rmdir**, **rename**, **delete**, or **copy** command for a file system, directory, or file. View the command output to identify whether a process is using the file system, directory, or file.

Procedure

To display processes that are using a file system, directory, or file, execute the following command in user view:

fuser { *directory* | *file* | *filesystem* }

Contents

Managing configuration files

About configuration file management

You can manage configuration files from the CLI or the BootWare menu. The following information explains how to manage configuration files from the CLI.

A configuration file saves a set of commands for configuring software features on the device. You can save any configuration to a configuration file so the configuration can survive a reboot. You can also back up configuration files to a host for future use.

Configuration types

Initial configuration

Initial configuration is the collection of initial default settings for the configuration commands in software.

The device starts up with the initial configuration if you access the BootWare menu and select the **Skip Current System Configuration** option. In this situation, the device might also be described as starting up with empty configuration.

No commands are available to display the initial configuration. To view the initial default settings for the configuration commands, see the Default sections in the command references.

Factory defaults

Factory defaults are custom basic settings that came with the device. Factory defaults vary by device models and might differ from the initial default settings for the commands.

The device starts up with the factory defaults if no next-startup configuration files are available.

To display the factory defaults, use the **`display default-configuration`** command.

Startup configuration

The device uses startup configuration to configure software features during startup. After the device starts up, you can specify the configuration file to be loaded at the next startup. This configuration file is called the next-startup configuration file. The configuration file that has been loaded is called the current startup configuration file.

You can display the startup configuration by using one of the following methods:

- To display the contents of the current startup configuration file, execute the **`display current-configuration`** command before changing the configuration after the device reboots.
- To display the contents of the next-startup configuration file, use the **`display saved-configuration`** command.
- Use the **`display startup`** command to display names of the current startup configuration file and next-startup configuration files. Then, you can use the **`more`** command to display the contents of the specified startup configuration file.

Running configuration

The running configuration includes unchanged startup settings and new settings. The running configuration is stored in memory and is cleared at a device reboot or power off. To use the running configuration after a power cycling or reboot, save it to a configuration file.

To display the running configuration, use the **`display current-configuration`** command.

Configuration file types and file selection process at startup

When you save the configuration, the system saves the settings to a .cfg configuration file and to an .mdb file.

- A .cfg configuration file is a human-readable text file and its contents can be displayed by using the **more** command. Configuration files you specify for saving the configuration must use the .cfg extension.
- An .mdb file is a user-inaccessible binary file that has the same name as the .cfg file. The device loads an .mdb file faster than loading a .cfg file.

At startup, the device uses the following procedure to identify the configuration file to load:

1. The device searches for a valid .cfg next-startup configuration file. For more information about the file selection rules, see "Next-startup configuration file redundancy."
2. If a valid .cfg next-startup configuration file is found, the device searches for an .mdb file that has the same name and checksum as the .cfg file.
3. If a matching .mdb file is found, the device starts up with the .mdb file. If none is found, the device starts up with the .cfg file.

If no .cfg next-startup configuration files are available, the device starts up with the factory defaults.

Unless otherwise stated, the term "configuration file" in this document refers to a .cfg configuration file.

Next-startup configuration file redundancy

You can specify one main next-startup configuration file and one backup next-startup configuration file for redundancy.

At startup, the device tries to select the .cfg startup configuration in the following order:

1. The main next-startup configuration file.
2. The backup next-startup configuration file if the main next-startup configuration file does not exist or is corrupt.

If no next-startup configuration files are available, the device starts up with the factory defaults.

Configuration file content organization and format

IMPORTANT:

To run on the device, a configuration file must meet the content and format requirements. To ensure a successful configuration load at startup, use a configuration file created on the device. If you edit the configuration file, make sure all edits are compliant with the requirements.

A configuration file must meet the following requirements:

- All commands are saved in their complete form.
- Commands are sorted into sections by different command views, including system view, interface views, protocol views, and user line views.
- Two adjacent sections are separated by a pound sign (#).
- The configuration file ends with the word **return**.

The following is a sample configuration file excerpt:

```
#
local-user root class manage
```

```
 password hash
$h$6$Twd73mLrN8O2vvD5$Cz1vgdpR4KoTiRQNE9pg33gU14Br2p1VguczLSVyJLO2huV5Syx/LfDIf8ROLtV
ErJ/C31oq2rFtmNuyZf4STw==
 service-type ssh telnet terminal
 authorization-attribute user-role network-admin
 authorization-attribute user-role network-operator
#
interface Vlan-interface1
 ip address 192.168.1.84 255.255.255.0
#
```

Configuration rollback

Configuration rollback allows you to replace the running configuration with the configuration in a configuration file without rebooting the device. You can use this feature for the following purposes:

- Reverting to a previous configuration state.
- Adapting the running configuration to different network environments.

Restrictions and guidelines: Configuration file management

For the device to load the configuration correctly at startup, do not save the factory defaults or startup configuration files on a removable hard disk.

Enabling configuration encryption

About this task

Configuration encryption enables the device to encrypt a startup configuration file automatically when it saves the running configuration. All devices running NF software use the same method to encrypt configuration files.

Restrictions and guidelines

Any devices running NF software can decrypt the encrypted configuration files. To prevent an encrypted file from being decoded by unauthorized users, make sure the file is accessible only to authorized users.

You cannot use the **more** command to view the contents of an encrypted configuration file.

You cannot compare an encrypted configuration file with any configuration for their differences.

Procedure

1. Enter system view.

   system-view

2. Enable configuration encryption.

   configuration encrypt { **private-key** | **public-key** }

   By default, configuration encryption is disabled.

Saving the running configuration

About this task

When you save the running configuration to a .cfg configuration file, you can specify the file as a next-startup configuration file or not.

If you are specifying the file as a .cfg next-startup configuration file, use one of the following methods to save the configuration:

- **Fast mode**—Use the **save** command without the **safely** keyword. In this mode, the device directly overwrites the target next-startup configuration file. If a reboot or power failure occurs during this process, the next-startup configuration file is lost. You must specify a new startup configuration file after the device reboots (see "Specifying a next-startup configuration file").
- **Safe mode**—Use the **save** command with the **safely** keyword. Safe mode is slower than fast mode, but more secure. In safe mode, the system saves the configuration in a temporary file and starts overwriting the target next-startup configuration file after the save operation is complete. If a reboot or power failure occurs during the save operation, the next-startup configuration file is still retained. Use the safe mode if the power source is not reliable or you are remotely configuring the device.

Restrictions and guidelines

To prevent the loss of next-startup configuration, make sure no one reboots or power cycles the device while the device is saving the running configuration.

When an IRF member device splits from the IRF fabric, its settings are retained in memory but removed from the running configuration on the IRF fabric. Saving the running configuration before the IRF fabric recovers will remove the member device's settings from the next-startup configuration file.

If you have saved the running configuration before the member device rejoins the IRF fabric, perform the following steps to restore the member device settings to the next-startup configuration file:

1. Resolve the split issue.
2. Reboot the member device to rejoin the IRF fabric.
3. After the member device rejoins the IRF fabric, execute the **display current-configuration** command to verify that the member device's settings have been restored from memory to the running configuration.
4. Save the running configuration to the next-startup configuration file on the IRF fabric.

IMPORTANT:

To ensure a successful configuration restoration, make sure the IRF fabric has not rebooted after the member device left.

Procedure

To save the running configuration, perform one of the following tasks in any view:

- Save the running configuration to a configuration file without specifying the file as a next-startup configuration file.

  save *file-url* [**all** | **slot** *slot-number*]
- Save the running configuration to a configuration file in the root directory of the storage medium on each IRF member device, and specify the file as a next-startup configuration file.

  save [**safely**] [**backup** | **main**] [**force**] [**context-all** | **changed**]

  As a best practice, specify the **safely** keyword for reliable configuration saving.

CAUTION:

Use caution when you save the running configuration. This operation will overwrite the settings in the target configuration file. When you perform this operation, carefully read the messages displayed by the system and make sure you fully understand the impact of the operation on services.

Comparing configurations for their differences

About this task

You can compare configuration files or compare a configuration file with the running configuration for their differences.

If you specify the next-startup configuration for a comparison, the system selects the next-startup configuration file to be compared with in the following order:

1. The main next-startup configuration file.
2. The backup next-startup configuration file if the main next-startup configuration file is unavailable.

If both configuration files are unavailable, the system displays a message indicating that no next-startup configuration files exist.

Restrictions and guidelines

If you specify a configuration file for a comparison, the configuration file must be a .cfg configuration file.

Procedure

To compare configurations for their differences, perform one of the following tasks in any view:

- Display the differences that a configuration file, the running configuration, or the next-startup configuration has as compared with the specified source configuration file.

  display diff configfile *file-name-s* { **configfile** *file-name-d* | **current-configuration** | **startup-configuration** }
- Display the differences that a configuration file or next-startup configuration has as compared with the running configuration.

  display diff current-configuration { **configfile** *file-name-d* | **startup-configuration** }
- Display the differences that a configuration file has as compared with the next-startup configuration.

  display diff startup-configuration configfile *file-name-d*
- Display the differences that the running configuration has as compared with the next-startup configuration.
  - Method 1:

    display diff startup-configuration current-configuration
  - Method 2:

    display current-configuration diff

Archiving the running configuration

About running configuration archiving

You can perform local or remote configuration archiving to archive the running configuration to a directory on the device or to a remote server, respectively.

The remote server can be an FTP, TFTP, or SCP server.

The following are methods for archiving the running configuration:

- **Automatic configuration archiving**—The system automatically archives the running configuration at intervals as configured.
- **Manual configuration archiving**—You can disable automatic configuration archiving and manually archive the running configuration if the configuration will be rarely changed. You can also use this method to back up configuration before performing complicated configuration tasks.

Restrictions and guidelines for archiving the running configuration

Local archiving (the **`archive configuration location`** command) and remote archiving (the **`archive configuration server`** command) are mutually exclusive. You cannot use the two features at the same time.

If you configure parameters multiple times for an archiving method, the most recent configuration takes effect.

Configuring local configuration archiving

About this task

Local configuration archives are named in the format of *prefix_serial number*.**cfg** (for example, **archive_1.cfg** and **archive_2.cfg**). The serial number is automatically assigned from 1 to 1000, increasing by 1. After the serial number reaches 1000, it restarts from 1.

If you change the file directory or file name prefix, the following events occur:

- The old configuration archives change to common configuration files.
- The configuration archive counter is reset. The serial number for new configuration archives starts at 1.
- The **`display archive configuration`** command no longer displays the old configuration archives.

The configuration archive counter does not restart when you delete configuration archives from the archive directory. However, if the device reboots after all configuration archives have been deleted, the configuration archive counter restarts. The serial number for new configuration archives starts at 1.

If an archiving has started based on the existing archive parameters when an archive parameter is changed, the archive will still be retained in the old directory. However, the **`display archive configuration`** command will not display the record about this archiving.

Restrictions and guidelines

After the maximum number of configuration archives is reached, the system deletes the oldest archive to make room for the new archive.

The **`undo archive configuration location`** command removes the local configuration archive directory and file name prefix settings, but it does not delete the configuration archives on the device. In addition, the command performs the following operations:

- Disables both the manual and automatic configuration archiving features.
- Restores the default settings for the **`archive configuration interval`** and **`archive configuration max`** commands.

- Clears the configuration archive information displayed by using the **display archive configuration** command.

The local archiving feature saves the running configuration only on the master device. To make sure the system can archive the running configuration after a master/subordinate switchover, create the configuration archive directory on all IRF members.

Procedure

1. Enter system view.

   system-view

2. Set the directory and file name prefix for archiving the running configuration to the local device.

   archive configuration location *directory* **filename-prefix** *filename-prefix*

   By default, no path or file name prefix is set for configuration archives on the device, and the system does not regularly archive the running configuration.

   In an IRF fabric, the configuration archive directory must already exist on the master device and cannot include a member ID.

3. (Optional.) Set the maximum number of configuration archives that can be stored on the device.

   archive configuration max *file-number*

   The default number is 5.

   Change the setting depending on the amount of storage available on the device.

4. Archive the running configuration to the configuration archive directory. Choose one of the following methods:

   - Enable automatic configuration archiving and set the archiving interval.

     archive configuration interval *interval*

     By default, automatic configuration archiving is disabled.

   - Execute the following commands in sequence to manually archive the running configuration in user view:

     quit

     archive configuration

Configuring remote configuration archiving

About this task

If you archive the running configuration to a remote server, configuration archives are named in the format of *prefix_YYYYMMDD_HHMMSS***.cfg** (for example, **archive_20170526_203430.cfg**).

Restrictions and guidelines

The **undo archive configuration server** command removes the remote configuration archive directory and file name prefix settings from the device, but it does not delete the configuration archives on the server. In addition, the command performs the following operations:

- Disables both the manual and automatic configuration archiving features.
- Restores the default setting for the **archive configuration server user** and **archive configuration server password** commands.
- Clears the configuration archive information displayed by using the **display archive configuration** command.

When you modify parameters (for example, the username or password) for remote archiving, make sure the changes are consistent between the device and the server. A manual or automatic remote archiving will fail if it has started before you change the device and the server settings to be consistent.

Procedure

1. Enter system view.

   system-view

2. Configure parameters for archiving the running configuration to a remote server.

   archive configuration server { **ftp** | **tftp** | **scp** } { *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**vpn-instance** *vpn-instance-name*] [**directory** *directory*] **filename-prefix** *filename-prefix* [**interval** *interval*]

   By default, no parameters are configured for archiving the running configuration to a remote server.

   To automatically archive the running configuration regularly to the server, specify the **interval** *interval* option.

3. If an FTP or SCP server is used, configure the username and password for accessing the server.

   a. Configure the username.

      archive configuration server user *user-name*

      By default, no username is configured for accessing the FTP or SCP server.

   b. Configure the password.

      archive configuration server password { **cipher** | **simple** } *string*

      By default, no password is configured for accessing the FTP or SCP server.

   Make sure the username and password are the same as the FTP or SCP account settings on the FTP or SCP server.

4. To manually archive the running configuration to the remote server:

   a. Return to user view.

      quit

   b. Manually archive the running configuration to the remote server.

      archive configuration

Rolling back the running configuration

About configuration rollback

Configuration rollback allows you to replace the running configuration with the configuration in a replacement configuration file without rebooting the device. The replacement configuration file can be saved on the local device or on an FTP or TFTP server.

The configuration rollback feature compares the running configuration with the specified replacement configuration file and handles configuration differences as follows:

- If a command in the running configuration is not in the replacement file, the rollback feature executes the **undo** form of the command.
- If a command in the replacement file is not in the running configuration, the rollback feature adds the command to the running configuration.
- If a command has different settings in the running configuration and the replacement file, the rollback feature replaces the running command setting with the setting in the replacement file.

Restrictions and guidelines for configuration rollback

△ **CAUTION:**

A configuration rollback might cause service disruption.

To ensure a successful rollback, do not install or remove expansion interface cards or perform a master/subordinate switchover while the system is rolling back the configuration.

Make sure the replacement configuration file is created by using the configuration archive feature or the **save** command on the device. If the configuration file is not created on the device, make sure the command lines in the configuration file are fully compatible with the device.

If configuration rollback fails for some command lines, the system outputs a rollback failure message. To identify those command lines, use the **display diff current-configuration configfile** *file-name-d* command, with the replacement file specified for the *file-name-d* argument. The command lines that have failed to roll back are displayed as configuration differences between the running configuration and the replacement configuration file.

The configuration rollback feature might fail to reconfigure some commands in the running configuration for one of the following reasons:

- A command cannot be undone because prefixing the **undo** keyword to the command does not result in a valid **undo** command. For example, if the **undo** form designed for the **A** [**B**] **C** command is **undo A C**, the configuration rollback feature cannot undo the **A B C** command. This is because the system does not recognize the **undo A B C** command.
- A command (for example, a hardware-dependent command) cannot be deleted, overwritten, or undone due to system restrictions.
- The commands in different views are dependent on each other.
- Commands or command settings that the device does not support cannot be added to the running configuration.

In an HA group environment, you must execute the **configuration manual-sync** command to back up the configuration on the primary device to the secondary device for configuration consistency. For more information about HA groups, see *High Availability Configuration Guide*.

Performing a local configuration rollback

Restrictions and guidelines

The replacement configuration file must be stored unencrypted on the local system.

Procedure

1. Enter system view.

   system-view

2. Roll the running configuration back to the configuration in a configuration file.

   configuration replace file *filename*

   △ **CAUTION:**

   This operation will cause settings not in the replacement configuration file to be lost, which might cause service interruption. When you perform configuration rollback, make sure you fully understand its impact on your network.

Scheduling or performing a remote configuration rollback

About this task

You can roll back the running configuration by using a configuration file stored on an FTP or TFTP server.

When you perform this task, you can roll back the running configuration immediately or schedule a rollback for a future date and time.

The device performs a remote rollback as follows:

1. Downloads a replacement configuration file from a remote server.
2. Saves the downloaded file as a temporary file.
3. Replaces the running configuration with the configuration in the temporary file.
4. Deletes the temporary file after the configuration rollback finishes.

Restrictions and guidelines

The **undo configuration replace server** command performs the following operations:

- Disables the running configuration remote rollback feature.
- Restores the default settings for the **configuration replace server user** and **configuration replace server password** commands.
- Clears the configuration rollback information displayed by using the **display configuration replace server** command.

You can cancel a configuration rollback schedule anytime before its scheduled date and time. When you schedule a rollback, you can specify the date and time or specify only the time to execute the rollback.

- If you specify a rollback date with the rollback time, the specified date must be the same or later than the current system date. If the specified date is the same as the current system date, the specified time must be later than the current system time. After you create the rollback schedule, be careful with changing the system clock backward. The rollback schedule will be canceled automatically if it expires before it could be executed because the system date or time is changed backward.
- If you do not specify a rollback date with the rollback time, the device compares the specified rollback time with the current system time.
  - If the specified rollback time is later than the current system time, the device performs a rollback at the specified time on the current day.
  - If the specified rollback time is earlier than the current system time, the device performs a rollback at the specified time on the next day.

Procedure

1. Enter system view.

   system-view

2. Configure server parameters for remote configuration rollback.

   configuration replace server { **ftp** | **tftp** } { *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**vpn-instance** *vpn-instance-name*] [**directory** *directory*] **file** *filename*

   By default, no server parameters are configured for remote configuration rollback.

   The configuration file specified by using this command will be used for rollback if no configuration file is specified when you perform or schedule a remote rollback.

3. If an FTP server is used, configure the username and password for accessing the remote FTP server.

a. Configure the username.

   configuration replace server user *user-name*

   By default, no username is configured for accessing the FTP server.

   If no username is configured, the username will be **anonymous**.

b. Configure the password.

   configuration replace server password { **cipher** | **simple** } *string*

   By default, no password is configured for accessing the FTP server.

Make sure the username and password are the same as the FTP account settings on the FTP server.

4. Roll the running configuration back to the configuration in a replacement configuration file.
   - Roll the running configuration back immediately.

     configuration replace server file [*filename*]
   - Schedule a configuration rollback.

     configuration replace server file [*filename*] **at** *time* [*date*]

   If no replacement configuration file is specified, the configuration file specified by using the **configuration replace server** command is used for rollback.

△ **CAUTION:**

This operation will cause settings not in the replacement configuration file to be lost, which might cause service interruption. When you perform configuration rollback, make sure you fully understand its impact on your network.

Specifying a next-startup configuration file

Restrictions and guidelines

△ **CAUTION:**

Using the **undo startup saved-configuration** command can cause an IRF split after the IRF fabric or an IRF member reboots. When you execute this command, make sure you understand its impact on your network.

As a best practice, specify different files as the main and backup next-startup configuration files.

The **undo startup saved-configuration** command changes the attribute of the main or backup next-startup configuration file to NULL instead of deleting the file.

Prerequisites

In an IRF fabric, make sure the specified configuration file is valid and has been saved to the root directory of a storage medium on each member device. In addition, make sure the storage media are the same type across all IRF member devices.

Procedure

1. Specify a next-startup configuration file. Choose one of the following methods:
   - Execute the following command in user view to specify a next-startup configuration file:

     startup saved-configuration *cfgfile* [**backup** | **main**]

     By default, no next-startup configuration files are specified.
   - Execute the following command in any view to save the running configuration to a file and specify the file as a next-startup configuration file:

     save [**safely**] [**backup** | **main**] [**force**]

For more information about this command, see "Saving the running configuration."

If you do not specify the **backup** or **main** keyword, this command specifies the configuration file as the main next-startup configuration file.

2. (Optional.) Verify the configuration. Use one of the following commands in any view:
   - Display the names of the configuration files for this startup and the next startup.
     display startup
   - Display the contents of the configuration file for the next system startup.
     display saved-configuration

Backing up and restoring the main next-startup configuration file

About backing up and restoring the main next-startup configuration file

You can back up the main next-startup configuration file to a TFTP server or restore the main next-startup configuration file from a TFTP server.

Prerequisites for configuration backup and restoration

Before you back up or restore the main next-startup configuration file, perform the following tasks:

- Make sure the following requirements are met:
  - The server is reachable.
  - The server is enabled with TFTP service.
  - You have read and write permissions to the server.
- For configuration backup, use the **display startup** command to verify that the main next-startup configuration file has been specified in user view. If no next-startup configuration file has been specified or the specified configuration file does not exist, the backup operation will fail.

Backing up the main next-startup configuration file to a TFTP server

To back up the main next-startup configuration file to a TFTP server, execute the following command in user view:

backup startup-configuration to { *ipv4-server* | **ipv6** *ipv6-server* } [*dest-filename*] [**vpn-instance** *vpn-instance-name*]

Restoring the main next-startup configuration file from a TFTP server

1. Restore the main next-startup configuration file from a TFTP server in user view.
   restore startup-configuration from { *ipv4-server* | **ipv6** *ipv6-server* } *src-filename* [**vpn-instance** *vpn-instance-name*]

2. (Optional.) Verify that the specified configuration file has been set as the main next-startup configuration file. Use one of the following commands in any view:
   - Display the names of the configuration files for this startup and the next startup.

     `display startup`
   - Display the contents of the configuration file for the next system startup.

     `display saved-configuration`

Deleting a next-startup configuration file

About this task

You can perform this task to delete a next-startup configuration file.

If both the main and backup next-startup configuration files are deleted, the device uses the factory defaults at the next startup.

To delete a file that is set as both main and backup next-startup configuration files, you must execute both the **`reset saved-configuration backup`** command and the **`reset saved-configuration main`** command. Using only one of the commands removes the specified file attribute instead of deleting the file.

For example, if the **`reset saved-configuration backup`** command is executed, the backup next-startup configuration file setting is set to NULL. However, the file is still used as the main file. To delete the file, you must also execute the **`reset saved-configuration main`** command.

Restrictions and guidelines

△ **CAUTION:**

This task permanently deletes a next-startup configuration file from all IRF member devices. As a best practice, make sure you have a configuration backup before you perform this task.

If you do not specify the **`backup`** or **`main`** keyword when you perform this task, the main next-startup configuration is deleted.

Procedure

To delete a next-startup configuration file, execute the following command in user view:

`reset saved-configuration` [**`backup`** | **`main`**]

Display and maintenance commands for configuration files

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display configuration archive information.	**`display archive configuration`**
Display information about remote configuration rollback.	**`display configuration replace server`**
Display the running configuration.	**`display current-configuration`** [**`configuration`** [*`module-name`*] | **`interface`** [*`interface-type`* [*`interface-number`*]] | **`vpn-instance`** [*`vpn-instance-name`*]]

Task	Command
Display the differences that the running configuration has as compared with the next-startup configuration.	**display current-configuration diff**
Display the factory defaults.	**display default-configuration**
Display the differences between configurations.	• **display diff configfile** *file-name-s* { **configfile** *file-name-d* | **current-configuration** | **startup-configuration** } • **display diff current-configuration** { **configfile** *file-name-d* | **startup-configuration** } • **display diff startup-configuration** { **configfile** *file-name-d* | **current-configuration** }
Display the contents of the configuration file for the next system startup.	**display saved-configuration**
Display the names of the configuration files for this startup and the next startup.	**display startup**
Display the valid configuration in the current view.	**display this**
Delete next-startup configuration files.	**reset saved-configuration** [**backup** | **main**]

Contents

Upgrading software

About software upgrade

Software upgrade enables you to upgrade a software version, add new features, and fix software bugs. This chapter describes software types and release forms, compares software upgrade methods, and provides the procedures for upgrading software from the CLI.

Software types

The following software types are available:

- **BootWare image**—Also called the Boot ROM image. This image contains a basic segment and an extended segment.
    - The basic segment is the minimum code that bootstraps the system.
    - The extended segment enables hardware initialization and provides system management menus. When the device cannot start up correctly, you can use the menus to load software and the startup configuration file or manage files.

  Typically, the BootWare image is integrated into the Boot image to avoid software compatibility errors.
- NF **image**—Includes the following image subcategories:
    - **Boot image**—A .bin file that contains the Linux operating system kernel. It provides process management, memory management, and file system management.
    - **System image**—A .bin file that contains the NF kernel and standard features, including device management, interface management, configuration management, and routing.
    - **Feature image**—A .bin file that contains advanced or customized software features. You can purchase feature images as needed.
    - **Patch image**—A .bin file that is released for fixing bugs without rebooting the device. A patch image does not add or remove features.

      Patch images have the following types:
        - **Incremental patch images**—A new incremental patch image can cover all, part, or none of the functions provided by an old incremental patch image. A new incremental patch image can coexist with an old incremental patch image on the device only when the former covers none of the functions provided by the latter.
        - **Non-incremental patch images**—A new non-incremental patch image covers all functions provided by an old non-incremental patch image. Each of the boot, system, and feature images can have one non-incremental patch image, and these patch images can coexist on the device. The device uninstalls the old non-incremental patch image before installing a new non-incremental patch image.

      An incremental patch image and a non-incremental patch image can coexist on the device.

  NF images that have been loaded are called current software images. NF images specified to load at the next startup are called startup software images.

BootWare image, boot image, and system image are required for the device to operate.

You can install up to 32 .bin files on the device, including one boot image file, one system image file, and up to 30 feature and patch image files.

Software release forms

Software images are released in one of the following forms:

- Separate .bin files. You must verify compatibility between software images.
- As a whole in one .ipe package file. The images in an .ipe package file are compatible. The system decompresses the file automatically, loads the .bin images and sets them as startup software images.

NOTE:

Software image file names use the *model-comware version-im*age *type-release* format. This document uses **boot.bin** and **system.bin** as boot and system image file names.

Upgrade methods

Upgrade method	Software types	Remarks
Upgrading from the CLI by using the boot loader method	• BootWare image • NF images (excluding patches)	This method is disruptive. You must reboot the entire device to complete the upgrade.
Performing an ISSU from the CLI	NF images	This method enables a software upgrade with a minimum amount of downtime. Use this method if possible. For more information about ISSU, see "Performing an ISSU."
Upgrading from the BootWare menu	• BootWare image • NF images	Use this method when the device cannot start up correctly. To use this method, first connect to the console port and power cycle the device. Then, press **Ctrl+B** at prompt to access the BootWare menu. For more information about upgrading software from the BootWare menu, see the release notes for the software version. **IMPORTANT:** Use this method only when you do not have any other choice.

This chapter covers only upgrading software from the CLI by using the boot loader method.

Software image loading

Startup software images

To upgrade software, you must specify the upgrade files as the startup software images for the device to load at next startup. You can specify two lists of software images: one main and one backup. The device first loads the main startup software images. If the main startup software images are not available, the devices loads the backup startup software images.

Image loading process at startup

At startup, the device performs the following operations after loading and initializing BootWare:

1. Loads main images.

2. If any main image does not exist or is invalid, loads the backup images.
3. If any backup image does not exist or is invalid, checks the main or backup boot image.
4. If both the main and backup boot images do not exist or are invalid, the device cannot start up.

Digitally signed software images

The software images for the device are digitally signed for authenticity and integrity verification. This mechanism ensures that the software installed on the system is from a trusted source and has not been tampered with in the transfer, storage, or installation phase.

The system performs software digital signature verification for authenticity and integrity in the following situations:

- Before the system loads a software image during startup. If the digital signature verification fails, the system will not load the image and you will receive a digital signature verification failure message.
- When you specify a software image to upgrade the device from the BootWare menu. If the digital signature verification fails, the system will not set the image for upgrade and you will receive a digital signature verification failure message.
- Before the system loads a BootWare image to the Normal area of BootWare. If the digital signature verification fails, the system will not load the image and you will receive a digital signature verification failure message.
- When you specify a software image as a startup image through the boot loader. The system will verify the digital signature of the image before it updates the startup image list with the specified image. If the digital signature verification fails, the system will not update the startup image list and you will receive a digital signature verification failure message.
- When you specify startup images for an ISSU. The system verifies the digital signature of a software image for authenticity and integrity before it sets and loads that image as a main startup image. If the digital signature verification fails, the system will not set or load the image as a main startup image and you will receive a digital signature verification failure message. For more information about ISSU, see "Performing an ISSU."
- Before the system activates a feature or patch image. If the digital signature verification fails, the system will not activate the image and you will receive a digital signature verification failure message.

Restrictions and guidelines: Software upgrade

As a best practice, store the startup images in a fixed storage medium. If you store the startup images in a hot swappable storage medium, do not remove the hot swappable storage medium during the startup process.

Software upgrade is supported only on the default context.

Upgrading device software by using the boot loader method

Software upgrade tasks at a glance

To upgrade software, perform one of the following tasks:

- Upgrade the IRF fabirc:
  a. (Optional.) Preloading the BootWare image to BootWare

If a BootWare upgrade is required, you can perform this task to shorten the subsequent upgrade time. This task helps reduce upgrade problems caused by unexpected power failure. If you skip this task, the device upgrades the BootWare automatically when it upgrades the startup software images.

  b. Specifying startup images and completing the upgrade

- (Optional.) Synchronizing startup images from the master device to subordinate devices

  Perform this task when the startup images on subordinate devices are not the same version as those on the master device.

Prerequisites

1. Use the **display version** command to verify the current BootWare image version and startup software version.
2. Use the release notes for the upgrade software version to evaluate the upgrade impact on your network and verify the following items:
   - Software and hardware compatibility.
   - Version and size of the upgrade software.
   - Compatibility of the upgrade software with the current BootWare image and startup software image.
3. Use the release notes to verify whether the software images require a license. If licenses are required, register and activate licenses for each license-based software image. For more information about licensing, see "Managing licenses."
4. Use the **dir** command to verify that all IRF member devices have sufficient storage space for the upgrade images. If the storage space is not sufficient, delete unused files by using the **delete** command. For more information, see "Managing file systems."
5. Use FTP or TFTP to transfer the upgrade image file to the root directory of a file system. For more information about FTP and TFTP, see "Configuring FTP" or "Configuring TFTP." For more information about file systems, see "Managing file systems."

Preloading the BootWare image to BootWare

1. Enter system view.

   system-view

2. (Optional.) Enable BootWare image validity check.

   bootrom-update security-check enable

   By default, this feature is enabled.

   This feature examines BootWare images for file type errors, file corruption, and hardware incompatibility. As a best practice, enable it to ensure a successful upgrade.

3. Return to user view.

   quit

4. (Optional.) Back up the current BootWare image in the Normal area of BootWare.
   - Back up the image to the Backup area of BootWare:

     bootrom backup slot *slot-number-list* [**all** | **part**]

   - Back up the image to the default file system:

     bootrom read slot *slot-number-list* [**all** | **part**]

     The **bootrom read** command creates two BootWare image files on the default file system: **basicbtm.bin** for the basic segment and **extendbtm.bin** for the extended section.

Use either command to back up the BootWare image for a future version rollback or image restoration.

5. Load the upgrade BootWare image to the Normal area of BootWare.

   bootrom update file *file* **slot** *slot-number-list* [**all** | **part**]

   Specify the downloaded software image file for the *file* argument.

   NOTE:

   The system will verify the digital signature of a BootWare image before it loads it to the Normal area of BootWare. If the digital signature verification fails, the system will not load the image and you will receive a digital signature verification failure message.

   The new BootWare image takes effect at a reboot.

Specifying startup images and completing the upgrade

Perform the following steps in user view:

1. Specify main or backup startup images for all member devices.
   - Use an .ipe file:

     boot-loader file *ipe-filename* { **all** | **slot** *slot-number* } { **backup** | **main** }
   - Use .bin files:

     boot-loader file boot *filename* **system** *filename* [**feature** *filename*&<1-30>] { **all** | **slot** *slot-number* } { **backup** | **main** }

   As a best practice in a multichassis IRF fabric, specify the **all** keyword for the command. If you use the **slot** *slot-number* option to upgrade member devices one by one, version inconsistencies occur among the member devices during the upgrade.

   NOTE:

   The system will verify the digital signature of the specified images before it updates the startup image list with the specified images. If the digital signature verification fails, the system will not update the startup image list and you will receive a digital signature verification failure message.

2. Save the running configuration.

   save

   This step ensures that any configuration you have made can survive a reboot.

3. Reboot the IRF fabric.

   reboot

4. (Optional.) Verify the software image settings.

   display boot-loader [**slot** *slot-number*]

   Verify that the current software images are the same as the startup software images.

Synchronizing startup images from the master device to subordinate devices

About this task

Perform this task when the startup images on subordinate devices are not the same version as those on the master device.

This task synchronizes startup images that are running on the master device to subordinate devices. If any of the startup images does not exist or is invalid, the synchronization fails.

The startup images synchronized to subordinate devices are set as main startup images, regardless of whether the source startup images are main or backup.

Restrictions and guidelines

If an ISSU or patch installation has been performed on the master device, use the **install commit** command to update the set of main startup images on the master device before software synchronization. This command ensures startup image consistency between the master and subordinate devices.

Procedure

Perform the following steps in user view:

1. Synchronize startup images from the master to subordinate devices.
   boot-loader update { **all** | **slot** *slot-number* }
2. Reboot the subordinate devices.
   reboot slot *slot-number* [**force**]

Restoring the BootWare image

About this task

Use this task to restore the BootWare image when the BootWare image in the Normal area is corrupted or a version rollback is required.

Restrictions and guidelines

Make sure you have used the **bootrom backup** command to back up the image to the BootWare Backup area.

Procedure

Perform the following steps in user view:

1. Restore the BootWare image in the Normal area of BootWare.
   bootrom restore slot *slot-number-list* [**all** | **part**]
2. Reboot the device.
   reboot
   At startup, the system runs the new BootWare image to complete the restoration.

Display and maintenance commands for software images

Execute **display** commands in any view.

Task	Command
Display running software images and startup software images.	**display boot-loader** [**slot** *slot-number*]

Contents

Performing an ISSU

About ISSU

The In-Service Software Upgrade (ISSU) feature upgrades the NF software with a minimum amount of downtime.

Unless otherwise stated, the term "upgrade" refers to both software upgrade and downgrade in ISSU.

ISSU advantages

The NF software includes the boot image, the system image, and feature images. ISSU supports upgrading the images individually.

When you use ISSU to upgrade a feature, only the related feature images are affected. Other features can continue to provide services.

ISSU supports installing patch images to fix system bugs without a system reboot.

ISSU methods

ISSU methods are determined at software release depending on the compatibility between software versions.

ISSU supports the following upgrade types:

- **Compatible upgrade**—The new software version is compatible with the running software version. This upgrade type supports the ISSU methods in Table 1.
- **Incompatible upgrade**—The new software version is incompatible with the running software version. The two versions cannot run concurrently.

  This upgrade type supports only one upgrade method (also called incompatible upgrade). This method requires a cold reboot to upgrade both control and data planes. Incompatible upgrade disrupts service if hardware redundancy is not available.

For information about identifying the ISSU method, see "Identifying the ISSU methods."

Table 1 ISSU methods for compatible upgrade

ISSU method	Description
Incremental upgrade: • Service Upgrade • File Upgrade	Upgrades only user mode processes that have differences between the new and old software versions. Backup processes and a main/backup process switchover are required for service continuity. • **Service upgrade**—Upgrades service features. The upgrade does not affect the operation of the features that are not being upgraded. • **File upgrade**—Upgrades hidden system program files. The system can provide services during the upgrade.
Reboot	⚠ **CAUTION:** The Reboot method disrupts service if hardware redundancy is not available. As a best practice, schedule the downtime carefully to minimize the upgrade impact on the services. Reboots member devices to complete the software upgrade. While one member device is rebooting, the other member devices can provide services.

ISSU commands

ISSU includes the **`install`** and **`issu`** command sets. After you identify the recommended ISSU method, use Table 2 to choose the command set you want to use.

Table 2 Command set comparison

Item	issu commands	install commands
Upgrade types	• Compatible. • Incompatible.	Compatible.
Impact on the system	Large.	Small.
Technical skill requirements	Low. As a best practice, use this command set.	High. Administrators must have extensive system knowledge and understand the impact of each upgrade task on the network.

Restrictions and guidelines: ISSU

IMPORTANT:

- For a successful ISSU, you must remove all commands that the new version does not support and save the running configuration. To identify the feature changes between the current version and the new version, read the release notes for the device.
- To ensure correct system operation, you must remove the commands configured for features to be uninstalled and save the running configuration before uninstalling the features.

During an ISSU, follow these restrictions and guidelines:

- Do not perform any of the following tasks:
  - Reboot member devices.
  - Perform tasks that are irrelevant to the ISSU, such as modifying the configuration and displaying information.
  - Modify, delete, or rename image files.
- You cannot use both **`install`** and **`issu`** commands for the same ISSU.
- For better service continuity, strictly follow the recommended ISSU procedure. Make sure a step is completed before you proceed to the next step.
- Before executing the following commands, use the **`display system stable state`** command to verify that the system is stable:
  - **issu commands**—**`issu load`** and **`issu commit`**.
  - **install commands**—**`install activate`** and **`install deactivate`**.

  If the **System State** field displays **Stable**, the system is stable.
- You may use **`issu`** commands to upgrade all or some of the software images. If you are upgrading only some of the images, make sure the new images are compatible with the images that are not to be upgraded. The upgrade will fail if a conflict exists.
- You can install up to 32 .bin files on the device, including one boot image file, one system image file, and up to 30 feature and patch image files.
- A patch image file can be incremental or non-incremental. You can install up to 30 incremental patch image files. Because each boot, system, or feature image can have one non-incremental patch image file, you can install up to 16 non-incremental patch image files. For more

information about incremental and non-incremental patch image files, see "Upgrading software."

After an ISSU, you must log in to the device again before you can use the changed or added commands.

Prerequisites for ISSU

To perform a successful ISSU, make sure all the preparation requirements are met.

Logging in to the device through the console port

Log in to the device through the console port. If you use Telnet or SSH, you might be disconnected from the device before the ISSU is completed.

In a multiuser environment, make sure no other administrators access the device while you are performing the ISSU.

Identifying availability of ISSU and licensing requirements

Read the software release notes to identify the following items:

- Support of the device for ISSU between the current software version and the new software version.
- Licensing requirements for the upgrade software images. If the upgrade software images require licenses, make sure the device has the required licenses. For more information about license installation, see "Managing licenses."

Verifying the device operating status

Use the **display device** command to verify that all components are operating correctly.

Preparing the upgrade images

1. Use the **dir** command to verify that every file system has sufficient free storage space for the upgrade images. If the storage space is not sufficient, delete unused files by using the **delete /unreserved** *file-url* command. If the files to be deleted will be used, back up the files before deleting them. You will be unable to restore a deleted file if the **/unreserved** keyword is used. For more information, see "Managing file systems."
2. Use FTP or TFTP to transfer upgrade image files (in .bin or .ipe) to the root directory of a file system on the master device.

Identifying the ISSU methods

1. Execute the **display version comp-matrix file** command to identify the recommended ISSU methods.
    - For a compatible upgrade, check the **Upgrade Way** field to identify the recommended ISSU methods.
    - For an incompatible upgrade, check the end of command output for the **Incompatible upgrade** string.

   For more information about ISSU methods, see Table 1.

Verifying the device configuration

For a successful ISSU reboot or incompatible upgrade and the IRF fabric integrity during the ISSU, a set of features must have the same configuration as expected after the upgrade. The following are the features and the commands for you to change and verify feature settings:

- System operating mode.

  system-working-mode

  display system-working-mode
- Maximum number of ECMP routes.

  max-ecmp-num

  display max-ecmp-num
- IPv4 enhanced ECMP mode.

  ecmp mode enhanced

  display ecmp mode

For more information about system operating mode, see device management in *Fundamentals Configuration Guide*.

For more information about ECMP routes and IPv4 enhanced ECMP mode, see basic IP routing configuration in *Layer 3—IP Routing Configuration Guide*.

Verifying feature status

For service continuity during an ISSU, configure the following feature settings:

Feature	Setting requirements
GR and NSR	Enable GR or NSR for protocols including OSPF, IS-IS, BGP, and FSPF.
BFD	Disable BFD for protocols including OSPF, IS-IS, RIP, BGP, VRRP, and NQA.
Ethernet link aggregation	Use the long LACP timeout interval (the **lacp period short** command is not configured) on all member ports in dynamic aggregation groups.
IRF	Configure IRF bridge MAC persistence as follows: • **Compatible upgrade**—Configure the **irf mac-address persistent timer** or **irf mac-address persistent always** command. • **Incompatible upgrade**—Configure the **irf mac-address persistent always** command if the bridge MAC address is the MAC address of the device for which you want to execute the **issu load** command.

Determining the upgrade procedure

1. Use Table 2 to choose an upgrade command set, depending on the ISSU method.
2. Identify the hardware redundancy condition.

   ISSU can maintain service continuity only when the following conditions are met:

   - The IRF fabric has multiple members and uses the ring topology.

IMPORTANT:

If hardware redundancy is not available, service discontinuity is not avoidable during a reboot upgrade or an incompatible upgrade. Make sure you understand the impact of the upgrade on the network.

3. Choose the correct procedure from the procedures described in "Performing an ISSU by using issu commands" or "Performing an ISSU by using install commands."

Adjusting and saving the running configuration

1. Remove all commands that the new software version does not support from the running configuration. To identify all feature changes between the current version and the new version, read the release notes for the device.
2. To uninstall a feature image, remove the commands configured for the feature.
3. Use the **save** command to save the running configuration.

Performing an ISSU by using issu commands

Performing a compatible upgrade on a multichassis IRF fabricRestrictions and guidelines

Restrictions and guidelines

Upgrade a subordinate member device first. Then, upgrade the remaining member devices, including the original master.

Procedure

1. (Optional.) Configure automatic rollback:
   a. Enter system view.
      system-view
   b. Set the automatic rollback timer.
      issu rollback-timer *minutes*

      By default, the automatic rollback timer is set to 45 minutes.

      The automatic rollback timer starts when you execute the **issu run switchover** command.
   c. Return to user view.
      quit
2. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step.
3. Load the upgrade images as startup images on a subordinate member.
   - Use .bin files:

     issu load file { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> | **patch** *filename*&<1-30> } * **slot** *slot-number*&<1-9> [**reboot**]

- Use an .ipe file:

  issu load file ipe *ipe-filename* [**patch** *filename*&<1-30>] **slot** *slot-number*&<1-9> [**reboot**]

NOTE:

The software images for the device are digitally signed. The system verifies the digital signature of a software image for authenticity and integrity before it sets and loads that image as a main startup image. If the digital signature verification fails, the system will not set or load the image as a main startup image and you will receive a digital signature verification failure message.

4. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step. If the system reported an error in the previous step, verify that the system is stable and then use the **issu rollback** command to roll back the upgrade.
5. Perform an ISSU switchover.

   issu run switchover

   This command also starts the automatic rollback timer. If the timer expires, the system automatically rolls back to the original software images.
6. (Optional.) Accept the upgrade and delete the automatic rollback timer.

   issu accept

   Execute this command before the automatic rollback timer expires.
7. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step. If the system reported an error in the previous two steps, verify that the system is stable and then use the **issu rollback** command to roll back the upgrade.
8. Upgrade the remaining members to complete the ISSU.

   issu commit slot *slot-number*

   Execute this command before the automatic rollback timer expires.

△ **CAUTION:**

Repeat the previous step and this step to upgrade the remaining member devices, including the original master device. After you execute this command for one member device, wait for the member device to start up and join the IRF fabric again before you upgrade another member device. This practice ensures a successful ISSU.

9. Verify that the ISSU is finished.

   display issu state

   If the **ISSU state** field displays **Init**, the ISSU is finished.

Performing an incompatible upgrade on a multichassis IRF fabric

Restrictions and guidelines

Upgrade one or more subordinate member devices first. Then, upgrade the remaining member devices, including the original master.

Procedure

To perform an incompatible upgrade on a multichassis IRF fabric, execute the following commands in user view:

1. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step.

2. Load the upgrade images as startup images on subordinate members.

   - Use .bin files:

     issu load file { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> | **patch** *filename*&<1-30> } * **slot** *slot-number*&<1-9> [**reboot**]

   - Use an .ipe file:

     issu load file ipe *ipe-filename* [**patch** *filename*&<1-30>] **slot** *slot-number*&<1-9> [**reboot**]

   As a best practice on a ring-topology IRF fabric, specify half of the subordinate members for this command to reduce service interruption. Make sure the specified subordinate members are physically connected.

   NOTE:

   The software images for the device are digitally signed. The system verifies the digital signature of a software image for authenticity and integrity before it sets and loads that image as a main startup image. If the digital signature verification fails, the system will not set or load the image as a main startup image and you will receive a digital signature verification failure message.

3. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step. If the system reported an error in the previous step, verify that the system is stable and then use the **issu rollback** command to roll back the upgrade.

4. Perform an ISSU switchover to complete the ISSU process.

   issu run switchover

   This command upgrades the remaining members.

5. Verify that the ISSU is finished.

   display issu state

   If the **ISSU state** field displays **Init**, the ISSU is finished.

Performing an incremental upgrade on a single-chassis IRF fabric

To perform an incremental upgrade on a single-chassis IRF fabric, execute the following commands in user view:

1. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step.

2. Load the upgrade images as startup images.

- Use .bin files:

  issu load file { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> | **patch** *filename*&<1-30> } * **slot** *slot-number* [**reboot**]

- Use an .ipe file:

  issu load file ipe *ipe-filename* [**patch** *filename*&<1-30>] **slot** *slot-number* [**reboot**]

NOTE:

The software images for the device are digitally signed. The system verifies the digital signature of a software image for authenticity and integrity before it sets and loads that image as a main startup image. If the digital signature verification fails, the system will not set or load the image as a main startup image and you will receive a digital signature verification failure message.

3. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step. If the system reported an error in the previous step, verify that the system is stable and then use the **issu rollback** command to roll back the upgrade.

4. Complete the ISSU process.

   issu commit slot *slot-number*

CAUTION:

The ISSU process cannot be rolled back automatically or manually after you execute this command. When the ISSU commit operation is completed, the ISSU status changes to Init.

5. Verify that the ISSU is finished.

   display issu state

   If the **ISSU state** field displays **Init**, the ISSU is finished.

Performing a reboot or incompatible upgrade on a single-chassis IRF fabric

1. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step.

2. Load the parent device's upgrade images as startup images on subordinate members.

   - Use .bin files:

     issu load file { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> | **patch** *filename*&<1-30> } * **slot** *slot-number* [**reboot**]

   - Use an .ipe file:

     issu load file ipe *ipe-filename* [**patch** *filename*&<1-30>] **slot** *slot-number* [**reboot**]

NOTE:

The software images for the device are digitally signed. The system verifies the digital signature of a software image for authenticity and integrity before it sets and loads that image as a main startup image. If the digital signature verification fails, the system will not set or load the image as a main startup image and you will receive a digital signature verification failure message.

3. Verify that the ISSU is finished.

   ```
   display issu state
   ```

   If the **ISSU state** field displays **Init**, the ISSU is finished.

Performing an ISSU by using install commands

ISSU tasks at a glance

1. (Optional.) Decompressing an .ipe file
2. Installing and upgrading software images
3. (Optional.) Deactivating software images
4. (Optional.) Rolling back the running software images
5. (Optional.) Aborting a software activate or deactivate operation
6. (Optional.) Verifying software images
7. Committing software changes
8. (Optional.) Deleting inactive software images

Decompressing an .ipe file

1. (Optional.) Identify images that are included in the .ipe file.

   ```
   display install ipe-info
   ```

2. Decompress the .ipe file.

   ```
   install add ipe-filename filesystem
   ```

Installing and upgrading software images

About this task

Use this task to install new features and patch images or upgrade the running boot, system, or feature images.

Software image installation and upgrade methods

Use one of the following methods to install or upgrade software images:

- **Slot by slot**—Activate all the images on one slot, and then move to the next slot.
- **Image by image**—Activate one image on all slots before activating another image.

Restrictions and guidelines

To install an image, you must begin with the master device. To upgrade an image, you must begin with a subordinate device.

The activate operation for an incremental upgrade or patch images only updates the current software image list. For the image changes to take effect after a reboot, you must perform a commit operation to update the main startup image list.

Installing or upgrading boot, system, and feature images

To install or upgrade boot, system, and feature images, execute the following commands in user view:

1. Verify that the system is stable.

display system stable state

The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step.

2. (Optional.) Identify the recommended ISSU method and the possible impact of the upgrade.

   install activate { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> } * **slot** *slot-number* **test**

3. Activate images.

   install activate { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> } * **slot** *slot-number*

Installing patch images

To install patch images, execute the following commands in user view:

1. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful installation, you must make sure the system is stable before you proceed to the next step.

2. Activate patch images.

   install activate patch *filename* { **all** | **slot** *slot-number* }

   The **install activate patch** *filename* **all** command installs the specified patch images on all hardware and the images can survive a reboot. You do not need to execute the **install commit** command for the installation.

   You can specify only one patch image file for the command at a time. However, you can execute the command multiple times to activate multiple patch image files.

Deactivating software images

Restrictions and guidelines

You can deactivate only feature and patch images.

The deactivate operation only removes images from the current software image list. For the image changes to take effect after a reboot, you must perform a commit operation to remove the images from the main startup image list.

Deactivated images are still stored on the storage medium. To permanently delete the images, execute the **install remove** command. For more information, see "Deleting inactive software images."

Deactivating feature images

To deactivate feature images, execute the following commands in user view:

1. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful deactivate operation, you must make sure the system is stable before you proceed to the next step.

2. Deactivate feature images.

   install deactivate feature *filename*&<1-30> **slot** *slot-number*

Deactivating patch images

To deactivate patch images, execute the following commands in user view:

1. Verify that the system is stable.

   display system stable state

The system is stable if the **System State** field displays **Stable**. For a successful deactivate operation, you must make sure the system is stable before you proceed to the next step.

2. Deactivate patch images.

install deactivate patch *filename* { **all** | **slot** *slot-number* }

The **install deactivate patch** *filename* **all** command deactivates the specified patch images on all hardware and the image changes can survive a reboot. You do not need to execute the **install commit** command for the deactivation.

You can specify only one patch image file for the command at a time. However, you can execute the command multiple times to deactivate multiple patch image files.

Rolling back the running software images

About this task

During an incremental upgrade, the system creates a rollback point for each activate or deactivate operation of a boot, system, or feature image. The system can maintain a maximum of 50 rollback points. If this limit has been reached when a rollback point is created, the system removes the earliest rollback point. You can roll back the software to any of the rollback points.

During a reboot upgrade, the system does not create rollback points. After a reboot upgrade, you can roll back the software only to the status before any activate or deactivate operations were performed.

Restrictions and guidelines

You can perform this task only before committing software changes. A commit operation deletes all rollback points.

For an incremental upgrade rollback to take effect after a reboot, you must perform a commit operation to update the main startup image list.

Procedure

To roll back the running software images, execute the following commands in user view:

1. (Optional.) Display available rollback points.

display install rollback

2. Roll back the software.

install rollback to { *point-id* | **original** }

Aborting a software activate or deactivate operation

About this task

While the system is activating or deactivating a software image for a service upgrade or file upgrade, you can abort the activate or deactivate operation. After an operation is aborted, the system runs with the software images that it was running with before the operation.

Procedure

To abort a software activate or deactivate operation, use one of the following methods:

- Execute the **install abort** [*job-id*] command in user view.
- Press **Ctrl+C**.

Committing software changes

About this task

When you activate or deactivate images for an incremental upgrade, or activate or deactivate patch images, the main startup image list does not update with the changes. The software changes are lost at reboot. For the changes to take effect after a reboot, you must commit the changes.

Procedure

To commit software changes, execute the following command in user view:

install commit

Verifying software images

About this task

Perform this task to verify the following items:

- **Integrity**—Verify that the boot, system, and feature images are integral.
- **Consistency**—Verify that the same active images are running across the entire system.
- **Software commit status**—Verify that the active images are committed as needed.

Procedure

To verify software images, execute the following commands in user view:

1. Verify software images.
   install verify
2. Activate or deactivate images as required.
   install { **activate** | **deactivate** }
3. Commit the software changes.
   install commit

Deleting inactive software images

About this task

After completing an ISSU, you can use this task to delete old image files permanently.

Restrictions and guidelines

This task deletes image files permanently. You cannot use the **install rollback to** command to revert the operation, or use the **install abort** command to abort the operation.

Procedure

To delete inactive software image files, execute the following command in user view:

install remove [**slot** *slot-number*] { *filename* | **inactive** }

Terminating the ongoing ISSU process forcibly

About this task

Use this feature to terminate the ISSU process if one of the following exceptions occurs and you cannot perform an upgrade or rollback:

- The ISSU status is not **Init** but the upgrade has stopped.

- The ISSU status is **Init** but the upgrade has not completed.

Procedure

1. Enter system view.
   system-view
2. Terminate the ongoing ISSU process forcibly.
   issu quit

Display and maintenance commands for ISSU

△ **CAUTION:**

The **reset install rollback oldest** command clears the specified rollback point and all rollback points earlier than the specified rollback point. You will be unable to roll back the configuration to the status when any of these rollback points was created.

Unless otherwise stated, the **display** and **reset** commands can be used during an ISSU, regardless of whether the **install** or **issu** commands are used.

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display active software images.	**display install active** [**slot** *slot-number*] [**verbose**]
Display backup startup software images.	**display install backup** [**slot** *slot-number*] [**verbose**]
Display main startup software images.	**display install committed** [**slot** *slot-number*] [**verbose**]
Display inactive software images in the root directories of file systems.	**display install inactive** [**slot** *slot-number*] [**verbose**]
Display the software images included in an .ipe file.	**display install ipe-info** *ipe-filename* N/A
Display ongoing ISSU activate, deactivate, and rollback operations.	**display install job** N/A
Display ISSU log entries.	**display install log** [*log-id*] [**verbose**] N/A
Display software image file information.	**display install package** { *filename* | **all** } [**verbose**] N/A
Display rollback point information. (The system does not record rollback points during an ISSU that uses **issu** commands.)	**display install rollback** [*point-id*]
Display the software image file that includes a specific component or file.	**display install which** { **component** *name* | **file** *filename* } [**slot** *slot-number*] N/A
Display automatic rollback timer	**display issu rollback-timer**

Task	Command
information.	
Display ISSU status information. (This command applies only to an ISSU that uses **issu** commands.)	**display issu state**
Display the ISSU methods.	**display version comp-matrix file** { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> } * **display version comp-matrix file ipe** *ipe-filename*
Clear ISSU log entries.	**reset install log-history oldest** *log-number*
Clear ISSU rollback points.	**reset install rollback oldest** *point-id*

Examples of using issu commands for ISSU

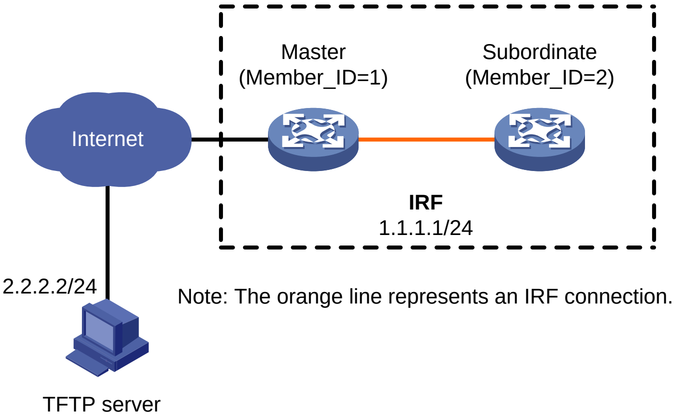
Example: Upgrading the system software to a compatible version

Network configuration

As shown in Figure 1, the IRF fabric has two members.

Upgrade the boot, system, and feature images from T0001015 to T0001016. The two versions are compatible.

Figure 1 Network diagram



Procedure

# Download the upgrade image files from the TFTP server.

```
<Sysname> tftp 2.2.2.2 get boot-t0001016.bin
  % Total     % Received % Xferd  Average Speed   Time    Time     Time  Current

Using automatic configuration

About automatic configuration

With the automatic configuration feature, the device can automatically obtain a set of configuration settings at startup. You only need to save the configuration file on a specific storage medium. This feature simplifies network configuration and maintenance.

The device supports only USB-based automatic configuration. USB-based automatic configuration applies to the following scenarios:

- Small networks where the devices reside near to each other and no host can be used as a file server.
- Large networks where only a few devices require automatic configuration or configuration update.

Restrictions and guidelines: Automatic configuration

USB disk-based automatic configuration supports configuring the default context but does not support configuring non-default contexts.

The device performs USB disk-based automatic configuration at startup only if it does not have a configuration file.

Using USB-based automatic configuration

About USB-based automatic configuration

USB-based automatic configuration enables the device to obtain a configuration file from a connected USB disk at startup.

After obtaining a configuration file, the device compares the file with its main startup configuration file. If the two files have the same settings, the device loads its main startup configuration file. If the two files have different settings, the device performs the following operations:

1. Identifies whether its main startup configuration file is using the same name as the obtained configuration file.
   - If yes, the device renames its main startup configuration file by adding **_bak** to the base name of the file, and copies the obtained configuration file.
   - If not, the system uses the obtained configuration file to overwrite its main startup configuration file.
2. Loads the obtained configuration file.
   - If all commands in the obtained configuration file are successfully loaded, the device sets the obtained configuration file as the main startup configuration file.
   - If a command in the obtained configuration file fails, the device removes all loaded settings and searches for a local configuration file.
     - If a configuration file is found, the device loads the configuration file.
     - If no configuration file is found, the device finishes the automatic configuration process without loading any configurations.

Preparing the USB disk for automatic configuration

1. Prepare a USB disk that has only one partition.
2. Display the serial number of the device.

   ```
   display device manuinfo
   ```

   For more information about this command, see *Fundamentals Command Reference*.
3. Create a configuration file named *Device serial number***.cfg** or **autodeploy.cfg**, and save the file to the root directory of the file system on the USB disk.

   If a configuration file named *Device serial number***.cfg** coexists with configuration file **autodeploy.cfg**, configuration file *Device serial number***.cfg** is used.

Configuring and using USB-based automatic configuration

1. Enable USB-based automatic configuration on the device:
   a. Enter system view.

      ```
      system-view
      ```

   b. Enable USB-based automatic configuration.

      ```
      autodeploy udisk enable
      ```

      By default, USB-based automatic configuration is enabled.

   c. Save the running configuration.

      ```
      save
      ```

      A device reboot is required for USB-based automatic configuration. Save the running configuration to ensure that the USB-based automatic configuration feature takes effect after a reboot.
2. If the IRF fabric has two or more member devices, shut down the IRF physical interfaces by using the **shutdown** command to split the IRF fabric.
3. Connect the USB disk to the USB1 interface on the master device of the original IRF fabric.

   The USB disk will be identified as usba0.
4. Reboot the device and observe the LEDs of the device.

   If the device finds no configuration files to load at startup, it performs the following operations:

   a. Copies the configuration file on the USB disk.

   b. Specifies the file as the startup configuration file.

   c. Reboots to load the configuration file.

   - If the SYS LED flashes green quickly for 5 seconds, the automatic configuration succeeded. Proceed to step 5.
   - If the SYS LED flashes yellow quickly for 10 seconds, the automatic configuration failed. Display the log file named *Fully qualified configuration file name***.log** in the USB disk root directory to locate and resolve the problem.

   For more information about the LEDs, see the installation guide.
5. If the automatic configuration succeeded, use the **display current-configuration** command to verify that the configuration file has been loaded correctly.
6. Rebuild the IRF fabric.

   The subordinate members automatically synchronize their configurations with the master at startup.

Contents

Using Tcl

About Tcl

NF provides a built-in tool command language (Tcl) interpreter. From user view, you can use the **`tclsh`** command to enter Tcl configuration view to execute the following commands:

- Tcl 8.5 commands.
- NF commands.

The Tcl configuration view is equivalent to the user view. You can use NF commands in Tcl configuration view in the same way they are used in user view.

Restrictions and guidelines: Tcl

To return from a subview under Tcl configuration view to the upper-level view, use the **`quit`** command.

To return from a subview under Tcl configuration view to the Tcl configuration view, press **Ctrl+Z**.

Using Tcl commands to configure the device

Restrictions and guidelines

When you use Tcl to configure the device, follow these restrictions and guidelines:

- You can apply Tcl environment variables to NF commands.
- No online help information is provided for Tcl commands.
- You cannot press **Tab** to complete an abbreviated Tcl command.
- Make sure the Tcl commands can be executed correctly.
- As a best practice, log in through Telnet or SSH. You cannot stop Tcl commands by using a shortcut key or a CLI command. If a problem occurs when the Tcl commands are being executed, you can terminate the process by closing the connection if you logged in through Telnet or SSH. If you logged in from the console port, you must perform one of the following tasks:
    - Restart the device.
    - Log in to the device by using a different method, and use the **`free line`** command to release the console line. For more information about the command, see *Fundamentals Command Reference*.
- You can press **Ctrl+D** to abort Tcl command **`read stdin`**.

Procedure

1. Enter Tcl configuration view from user view.
   `tclsh`
2. Execute a Tcl command.
   `Tcl command`
3. Return from Tcl configuration view to user view.

- **tclquit**
- **quit**

Executing NF commands in Tcl configuration view

About executing NF commands in Tcl configuration view

To execute a NF command in Tcl configuration view, use one of the following methods:

- Enter the NF command directly. If a Tcl command uses the same command string as the NF command, the Tcl command is executed.
- Prefix the NF command with the **cli** keyword. If a Tcl command uses the same command string as the NF command, the NF command is executed.

Restrictions and guidelines

Follow these restrictions and guidelines when you execute NF commands in Tcl configuration view:

- To specify a string enclosed in quotation marks (") or braces ({ and }), you must use the escape character (\) before the quotation marks or braces. For example, to specify **"a"** as the description for an interface, you must enter **description \"a\"**. If you enter **description "a"**, the description is **a**.
- For NF commands, you can enter **?** to obtain online help or press **Tab** to complete an abbreviated command. For more information, see "Using the CLI."
- The **cli** command is a Tcl command, so you cannot enter **?** to obtain online help or press **Tab** to complete an abbreviated command.
- Successfully executed NF commands are saved to command history buffers. You can use the upper arrow or lower arrow key to obtain executed commands.
- To execute multiple NF commands in one operation:
  - Enter multiple NF commands separated by semi-colons to execute the commands in the order they are entered. For example, **ospf 100**; **area 0**.
  - Specify multiple NF commands for the **cli** command, quote them, and separate them by a space and a semicolon. For example, **cli** "**ospf 100** ; **area 0**".
  - Specify one NF command for each **cli** command and separate them by a space and a semicolon. For example, **cli ospf 100** ; **cli area 0**.

Procedure

1. Enter Tcl configuration view

   tclsh

2. Execute NF commands.
   - Execute NF commands directly.

     Command
   - Execute NF commands by using the **cli** command.

     cli *command*
3. Return from Tcl configuration view to user view.
   - **tclquit**
   - **quit**

Contents

Using Python

About Python

NF provides a built-in Python interpreter. You can use Python to perform the following tasks:

- Execute Python scripts to implement automatic device configuration.
- Enter Python shell to configure the device by using the following items:
  - Python 2.7 commands.
  - Python 2.7 standard API.
  - Extended API. For more information about the extended API, see "NF extended Python API."

Executing a Python script

To execute a Python script, use the following command in user view:

python *filename*

Entering the Python shell

To enter the Python shell from user view, execute the following command:

python

Importing and using the extended Python API

To use the extended Python API, you must first import the API to Python.

Importing the entire extended API and using the API

Procedure

1. Enter the Python shell from user view.
   python
2. Import the entire extended API.
   import platformtools
3. Execute an extended API function.
   platformtools.*api*

Example

# Use extended API function **Transfer** to download the **test.cfg** file from TFTP server 192.168.1.26.

```
<Sysname> python
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import platformtools
>>> platformtools.Transfer('tftp', '192.168.1.26', 'test.cfg', 'flash:/test.cfg',
user='', password='')
<platformtools.Transfer object at 0xb7eab0e0>
```

Importing an extended API function and using the function

Procedure

1. Enter the Python shell from user view.
   `python`
2. Import an extended API function.
   `from platformtools import` *`api-name`*
3. Execute an extended API function.
   `api-function`

Example

# Use extended API function **`Transfer`** to download the **test.cfg** file from TFTP server 192.168.1.26.

```
<Sysname> python
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> from platformtools import Transfer
>>> Transfer('tftp', '192.168.1.26', 'test.cfg', 'flash:/test.cfg', user='',
password='')
<platformtools.Transfer object at 0xb7e5e0e0>
```

Exiting the Python shell

To exit the Python shell, execute the following command in the Python shell.

`exit()`

NF extended Python API

The NF extended Python API is compatible with the Python syntax.

CLI

Use **`CLI`** to execute NF CLI commands and create CLI objects.

Syntax

`CLI`(*`command`*=‘’, *`do_print`*=True)

Parameters

`command`: Specifies the commands to be executed. To enter multiple commands, use a space and a semicolon (;) as the delimiter. To enter a command in a view other than user view, you must first enter the commands used to enter the view. For example, you must enter **`’system-view ;local-user test class manage’`** to execute the **`local-user test class manage`** command.

`do_print`: Specifies whether to output the execution result:

- **True**—Outputs the execution result. This value is the default.
- **False**—Does not output the execution result.

Usage guidelines

This API function supports only NF commands. It does not support Linux, Python, or Tcl commands.

Returns

CLI objects

Examples

# Add a local user named **test**.

```
<Sysname> python
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import platformtools
>>> platformtools.CLI('system-view ;local-user test class manage')
```

Sample output

```
<Sysname> system-view
System View: return to User View with Ctrl+Z.
[Sysname] local-user test class manage
New local user added.
<platformtools.CLI object at 0xb7f680a0>
```

get_error

Use **`get_error`** to get the error information from the download operation.

Syntax

`Transfer.get_error()`

Returns

Error information (if there is no error information, the return is null)

Examples

# Download file **test.cfg** from TFTP server 1.1.1.1 and get the error information from the operation.

```
<Sysname> python
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import platformtools
>>> c = platformtools.Transfer('tftp', '1.1.1.1', 'test.cfg', 'flash:/test.cfg', user='',
password='')
>>> c.get_error()
```

Sample output

```
"Timeout was reached”
```

get_output

Use **`get_output`** to get the output from executed commands.

Syntax

`CLI.get_output()`

Returns

Output from executed commands

Examples

# Add a local user and get the output from the command.

```
<Sysname> python
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import platformtools
>>> c = platformtools.CLI('system-view ;local-user test class manage', False)
>>> c.get_output()
```

Sample output

```
['<Sysname>system-view', 'System View: return to User View with Ctrl+Z.',
'[Sysname]local-user test class manage', 'New local user added.']
```

get_self_slot

Use **`get_self_slot`** to get the member ID of the master device.

Syntax

`get_self_slot()`

Returns

A list object in the format of `[`-1,*slot-number*`]`. The *slot-number* indicates the member ID of the master device.

Examples

# Get the member ID of the master device.

```
<Sysname> python
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import platformtools
>>> platformtools.get_self_slot()
```

Sample output

```
[-1,1]
```

get_slot_info

Use **`get_slot_info`** to get information about a member device.

Syntax

`get_slot_info()`

Returns

A dictionary object in the format of {'Slot': *slot-number*, 'Status': '*status*', 'Chassis': *chassis-number*, 'Role': '*role*', 'Cpu': *CPU-number* }. The *slot-number* argument indicates the member ID of the device. The *status* argument indicates the status of the member device. The *chassis-number* and *CPU-number* arguments are fixed at 0. The *role* argument indicates the role of the member device.

Examples

# Get information about the device, a card, or a member device.

```
<Sysname> python
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import platformtools
>>> platformtools.get_slot_info(1)
```

Sample output

```
{'Slot': 1, 'Status': 'Normal', 'Chassis': 0, 'Role': 'Master', 'Cpu': 0}
```

get_slot_range

Use **`get_slot_range`** to get the supported IRF member ID range.

Syntax

`get_slot_range()`

Returns

A dictionary object in the format of {'MaxSlot': *max-slot-number*, 'MinSlot': *min-slot-number* }. The *max-slot-number* argument indicates the maximum member ID. The *min-slot-number* argument indicates the minimum member ID.

Examples

# Get the supported IRF member ID range.

```
<Sysname> python
```

```
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import platformtools
>>> platformtools.get_slot_range()
```

Sample output

{'MaxSlot': 2, 'MinSlot': 1}

get_standby_slot

Use **`get_standby_slot`** to get the member IDs of the subordinate devices.

Syntax

`get_standby_slot()`

Returns

A list object in one of the following formats:

- `[ ]`—The IRF fabric does not have a subordinate device.
- `[[`-1,*slot-number*`]]`—The IRF fabric has only one subordinate device.
- `[[`-1,*slot-number1*`]`,`[`-1,*slot-number2*`]`,...`]`—The IRF fabric has multiple subordinate devices.

The *slot-number* arguments indicate the member IDs of the subordinate devices.

Examples

# Get the member IDs of the subordinate devices.

```
<Sysname> python
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import platformtools
>>> platformtools.get_standby_slot()
```

Sample output

```
[[-1, 1], [-1, 2]]
```

Transfer

Use **`Transfer`** to download a file from a server.

Syntax

`Transfer`(*`protocol`*=‘’, *`host`*=‘’, *`source`*=‘’, *`dest`*=‘’, *`vrf`*=‘’,*`login_timeout`*=10, *`user`*=‘’, *`password`*=‘’)

Parameters

`protocol`: Specifies the protocol used to download a file:

- **`ftp`**—Uses FTP.
- **`tftp`**—Uses TFTP.
- **`http`**—Uses HTTP.

`host`: Specifies the IP address of the remote server.

source: Specifies the name of the file to be downloaded from the remote server.

dest: Specifies a name for the downloaded file.

vrf: Specifies the MPLS L3VPN instance to which the remote server belongs. This argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the server belongs to the public network, do not specify this argument.

login_timeout: Specifies the timeout for the operation, in seconds. The default is 10.

user: Specifies the username for logging in to the server.

password: Specifies the login password.

Returns

Transfer object

Examples

# Download file **test.cfg** from TFTP server 192.168.1.26.

```
<Sysname> python
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import platformtools
>>> platformtools.Transfer('tftp', '192.168.1.26', 'test.cfg', 'flash:/test.cfg',
user='', password='')
```

Sample output

```
<platformtools.Transfer object at 0xb7f700e0>
```

send

Use **send** to generate and send a log message.

Syntax

SYSLOG.send(*digest*=‘’, *info*=‘’, *priority*=‘’)

Parameters

digest: Specifies a mnemonic for the log message. The mnemonic is a case-sensitive string of 1 to 32 characters.

info: Specifies the content of the log message, a case-sensitive string of 1 to 1024 characters.

priority: Specifies a priority for the log message, in the range of 0 to 4294967295.

Returns

None.

Usage guidelines

You must use the **SYSLOG** function to create a syslog object before you can generate and send a log message.

To display the generated log messages on the current terminal, first execute the **terminal monitor** command in user view.

For more information about the log message format, see information center configuration in *Network Management and Monitoring Configuration Guide*.

Examples

# Enable the current terminal to display log messages, and then generate and send a log message for the SNMP module. Set the mnemonic to **Test**, the content to **Try to send one message.**, and the priority to 1000.

```
<Sysname> terminal monitor
<Sysname> python
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import platformtools
>>> a = platformtools.SYSLOG('snmp')
>>> a.send('Test','Try to send one message.',1000)
```

Sample output

```
>>> %Jan  1 06:24:17:908 2019 Sysname SNMP/0/Test: Try to send one message.
```

SYSLOG

Use **SYSLOG** to create a syslog object.

Syntax

SYSLOG(*module*=‘’)

Parameters

module: Specifies the name of the feature module for which the Syslog object is created. The name is a case-insensitive string of 1 to 8 characters.

Returns

None.

Usage guidelines

You must create a syslog object for a feature module before you can generate and send a log message for that object.

Examples

# Create a syslog object named **SNMP** and assign the object to variable **a**.

```
<Sysname> python
Python 2.7.3 (default)
[GCC 4.4.1] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import platformtools
>>> a = platformtools.SYSLOG('snmp')
>>> a
```

Sample output

```
<platformtools.SYSLOG object at 0xb7e180e0>
```

NSFOCUS Firewall Series

NF Virtual Technologies

Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for virtual technologies features, including IRF, context and Reth interface and redundancy group.
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
ⓘ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Configuring an IRF fabric

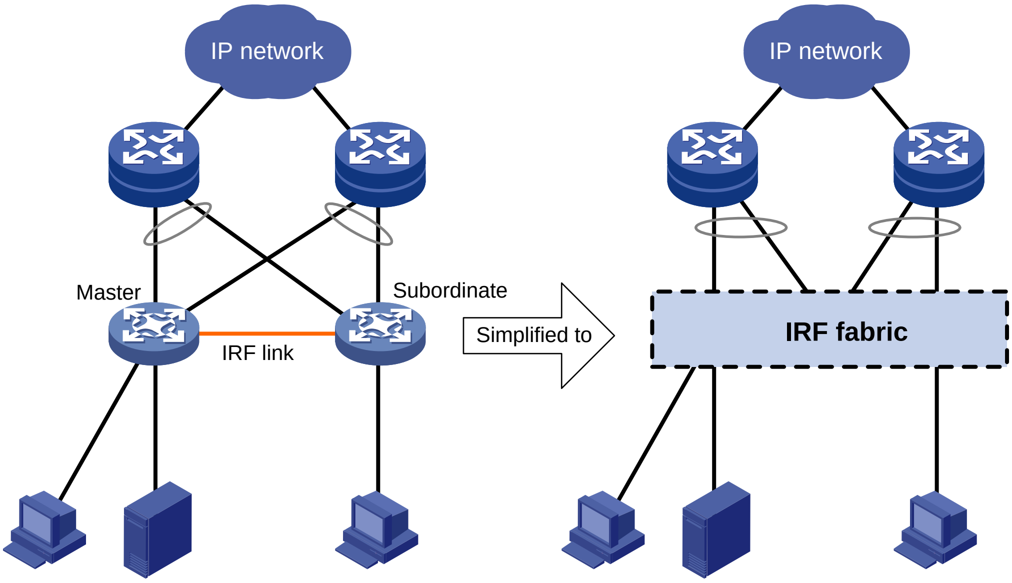
About IRF

The Intelligent Resilient Framework (IRF) technology virtualizes multiple physical devices at the same layer into one virtual fabric to provide data center class availability and scalability. IRF virtualization technology offers processing power, interaction, unified management, and uninterrupted maintenance of multiple devices.

IRF network model

Figure 1 shows an IRF fabric that has two devices, which appear as a single node to the upper-layer and lower-layer devices.

Figure 1 IRF application scenario



IRF benefits

IRF provides the following benefits:

- **Simplified topology and easy management**—An IRF fabric appears as one node and is accessible at a single IP address on the network. You can use this IP address to log in at any member device to manage all the members of the IRF fabric. In addition, you do not need to run the spanning tree feature among the IRF members.
- **1:N redundancy**—In an IRF fabric, one member acts as the master to manage and control the entire IRF fabric. All the other members process services while backing up the master. When the master fails, all the other member devices elect a new master from among them to take over without interrupting services.
- **IRF link aggregation**—You can assign several physical links between neighboring members to their IRF ports to create a load-balanced aggregate IRF connection with redundancy.
- **Multichassis link aggregation**—You can use the Ethernet link aggregation feature to aggregate the physical links between the IRF fabric and its upstream or downstream devices across the IRF members.

- **Network scalability and resiliency**—Processing capacity of an IRF fabric equals the total processing capacities of all the members. You can increase ports, network bandwidth, and processing capacity of an IRF fabric simply by adding member devices without changing the network topology.

Basic concepts

IRF member roles

IRF uses two member roles: master and standby (called subordinate throughout the documentation).

When devices form an IRF fabric, they elect a master to manage and control the IRF fabric, and all the other devices back up the master. When the master device fails, the other devices automatically elect a new master. For more information about master election, see "Master election."

IRF member ID

An IRF fabric uses member IDs to uniquely identify and manage its members. This member ID information is included as the first part of interface numbers and file paths to uniquely identify interfaces and files in an IRF fabric. Two devices cannot form an IRF fabric if they use the same member ID. A device cannot join an IRF fabric if its member ID has been used in the fabric.

Member priority

Member priority determines the possibility of a member device to be elected the master. A member with higher priority is more likely to be elected the master.

IRF port

An IRF port is a logical interface that connects IRF member devices. Every IRF-capable device has two IRF ports.

The IRF ports are named IRF-port *n*/1 and IRF-port *n*/2, where *n* is the member ID of the device. The two IRF ports are referred to as IRF-port 1 and IRF-port 2.

To use an IRF port, you must bind a minimum of one physical interface to it. The physical interfaces assigned to an IRF port automatically form an aggregate IRF link. An IRF port goes down when all its IRF physical interfaces are down.

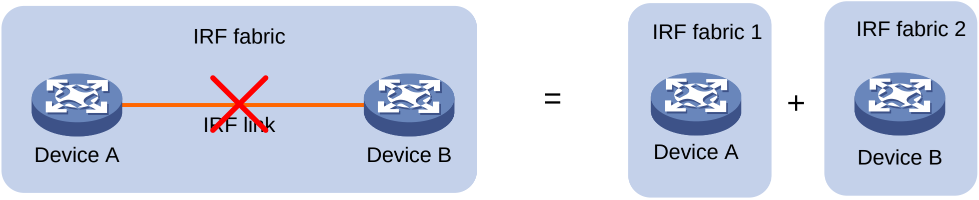
IRF physical interface

IRF physical interfaces connect IRF member devices and must be bound to an IRF port. They forward traffic between member devices, including IRF protocol packets and data packets that must travel across IRF member devices.

IRF split

IRF split occurs when an IRF fabric breaks up into multiple IRF fabrics because of IRF link failures, as shown in Figure 2. The split IRF fabrics operate with the same IP address. IRF split causes routing and forwarding problems on the network. To quickly detect a multi-active collision, configure a minimum of one MAD mechanism (see "Configuring MAD").

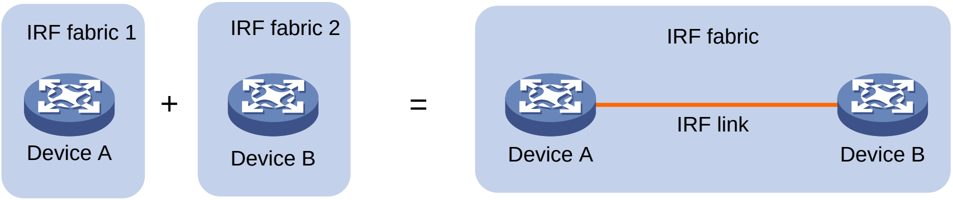
Figure 2 IRF split



IRF merge

IRF merge occurs when two split IRF fabrics reunite or when two independent IRF fabrics are united, as shown in Figure 3.

Figure 3 IRF merge



MAD

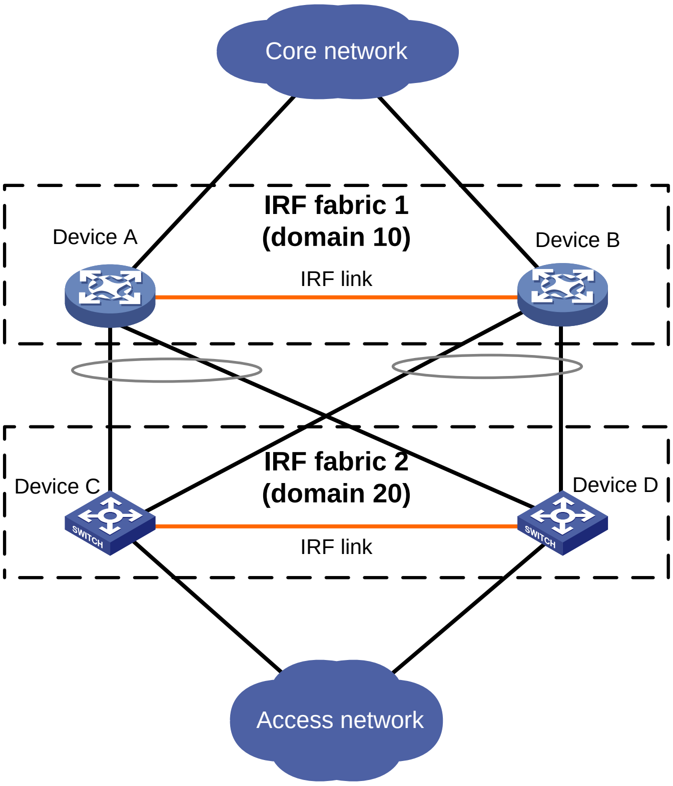
An IRF link failure causes an IRF fabric to split in two IRF fabrics operating with the same Layer 3 settings, including the same IP address. To avoid IP address collision and network problems, IRF uses multi-active detection (MAD) mechanisms to detect the presence of multiple identical IRF fabrics, handle collisions, and recover from faults.

IRF domain ID

One IRF fabric forms one IRF domain. IRF uses IRF domain IDs to uniquely identify IRF fabrics and prevent IRF fabrics from interfering with one another.

As shown in Figure 4, IRF fabric 1 contains Device A and Device B, and IRF fabric 2 contains Device C and Device D. Both fabrics use the LACP aggregate links between them for MAD. When a member device receives an extended LACPDU for MAD, it checks the domain ID to determine whether the packet is from the local IRF fabric. Then, the member device can handle the packet correctly.

Figure 4 A network that contains two IRF domains



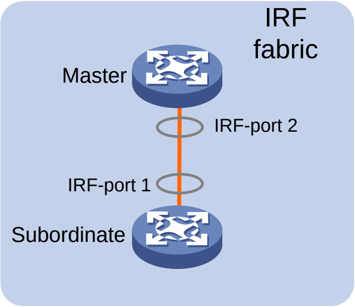
IRF network topology

An IRF fabric can use a daisy-chain topology, as shown in Figure 5.

IMPORTANT:

No relay devices are allowed between IRF member devices.

Figure 5 Daisy-chain topology



Master election

Master election occurs each time the IRF fabric topology changes in the following situations:

- The IRF fabric is established.
- The master device fails or is removed.
- The IRF fabric splits.
- Independent IRF fabrics merge.

NOTE:

Master election does not occur when split IRF fabrics merge. For information about the master device of the merged IRF fabric, see "Failure recovery."

Master election selects a master in descending order:

1. Current master, even if a new member has higher priority.

   When an IRF fabric is being formed, all members consider themselves as the master. This rule is skipped.
2. Member with higher priority.
3. Member with the longest system uptime.

   Two members are considered to start up at the same time if the difference between their startup times is equal to or less than 10 minutes. For these members, the next tiebreaker applies.
4. Member with the lowest CPU MAC address.

For the setup of a new IRF fabric, the subordinate devices must reboot to complete the setup after the master election.

For an IRF merge, devices must reboot if they are in the IRF fabric that fails the master election.

Interface naming conventions

A physical interface is numbered in the *chassis-number/slot-number/interface-index* format.

- ***chassis-number***—Member ID of the device. The default value for this argument is 1. Any change to the member ID takes effect after a reboot.
- ***slot-number***—Slot number of the interface.
- ***interface-index***—Interface index on the device. Interface index depends on the number of physical interfaces available on the device. To identify the index of a physical interface, examine its index mark on the chassis.

For example, GigabitEthernet 2/0/1 represents the first fixed physical interface on member device 2. Set its link type to trunk, as follows:

```
<Sysname> system-view
[Sysname] interface gigabitethernet 2/0/1
[Sysname-GigabitEthernet2/0/1] port link-type trunk
```

File system naming conventions

On a single-chassis fabric, you can use its storage device name to access its file system.

On a multichassis IRF fabric, you can use the storage device name to access the file system of the master. To access the file system of any other member device, use the name in the **slot***member-ID#storage-device-name* format.

For more information about storage device naming conventions, see *Fundamentals Configuration Guide*.

For example:

- To create and access the **test** folder under the root directory of the flash memory on the master switch:

  ```
  <Master> mkdir test
  Creating directory flash:/test... Done.
  <Master> cd test
  <Master> dir
  Directory of flash:/test
  The directory is empty.

  524288 KB total (29832 KB free)
  ```

- To create and access the **test** folder under the root directory of the flash memory on member device 2:

  ```
  <Master> mkdir slot2#flash:/test
  Creating directory slot2#flash:/test... Done.
  <Master> cd slot2#flash:/test
  <Master> dir
  Directory of slot2#flash:/test
  The directory is empty.

  524288 KB total (128812 KB free)
  ```

Configuration synchronization

IRF uses a strict running-configuration synchronization mechanism. In an IRF fabric, all devices obtain and run the running configuration of the master. Configuration changes are automatically propagated from the master to the remaining devices. The configuration files of these devices are retained, but the files do not take effect. The devices use their own startup configuration files only after they are removed from the IRF fabric.

As a best practice, back up the next-startup configuration file on a device before adding the device to an IRF fabric as a subordinate.

A subordinate device's next-startup configuration file might be overwritten if the master and the subordinate use the same file name for their next-startup configuration files. You can use the backup file to restore the original configuration after removing the subordinate from the IRF fabric.

For more information about configuration management, see *Fundamentals Configuration Guide*.

Multi-active handling procedure

The multi-active handling procedure includes detection, collision handling, and failure recovery.

Detection

IRF provides MAD mechanisms by extending LACP, BFD, ARP, and IPv6 ND to detect multi-active collisions. As a best practice, configure a minimum of one MAD mechanism on an IRF fabric. For more information about the MAD mechanisms and their application scenarios, see "MAD mechanisms."

For information about LACP, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*. For information about BFD, see *Network Management and Monitoring Configuration Guide*. For information about ARP, see *Layer 3—IP Services Configuration Guide*. For information about ND, see IPv6 basics in *Layer 3—IP Services Configuration Guide*.

Collision handling

When MAD detects a multi-active collision, it sets all IRF fabrics except one to the Recovery state. The fabric that is not placed in Recovery state can continue to forward traffic. The Recovery-state IRF fabrics are inactive and cannot forward traffic.

LACP MAD and BFD MAD use the following process to handle a multi-active collision:

1. Compare the number of members in each fabric.
2. Set all fabrics to the Recovery state except the one that has the most members.
3. Compare the member IDs of the masters if all IRF fabrics have the same number of members.
4. Set all fabrics to the Recovery state except the one that has the lowest numbered master.
5. Shut down all common network interfaces in the Recovery-state fabrics except for the following interfaces:
   - Interfaces automatically excluded from being shut down by the system.
   - Interfaces specified by using the **`mad exclude interface`** command.

ARP MAD and ND MAD use the following process to handle a multi-active collision:

1. Compare the member IDs of the masters in the IRF fabrics.
2. Set all fabrics to the Recovery state except the one that has the lowest numbered master.
3. Take the same action on the network interfaces in Recovery-state fabrics as LACP MAD and BFD MAD.

Failure recovery

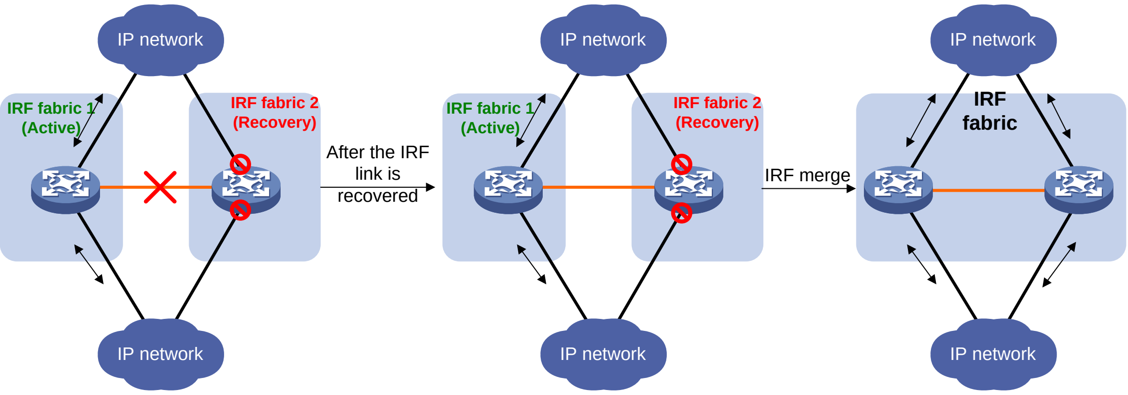
To merge two split IRF fabrics, first repair the failed IRF link and remove the IRF link failure.

After the failed IRF link between two split IRF fabrics is recovered, reboot the member devices in the inactive IRF fabric. The member devices in the inactive IRF fabric join the active IRF fabric as subordinate devices. The network interfaces that have been shut down by MAD automatically restore their original state, as shown in Figure 6.

△ **CAUTION:**

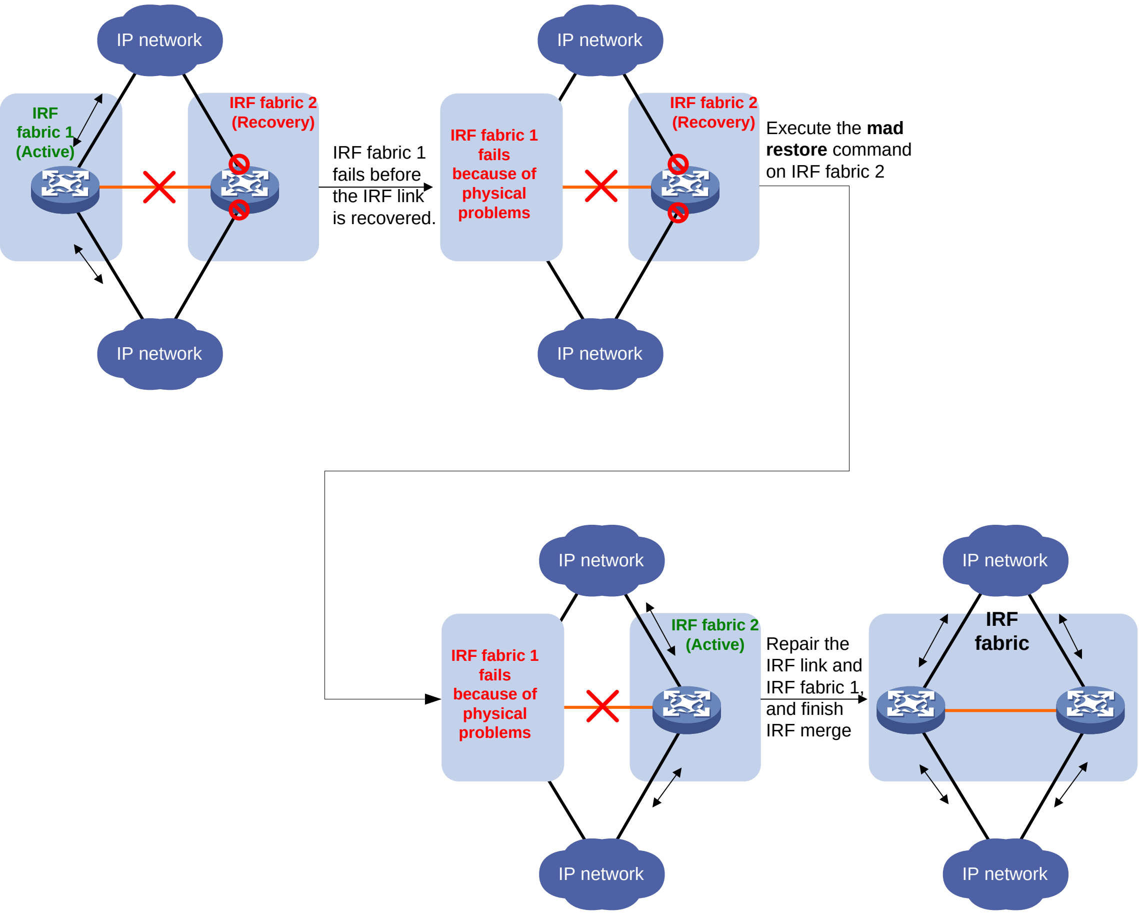
If you inadvertently reboot the active IRF fabric after the failed IRF link recovers, its member devices will join the inactive IRF fabric with their network interfaces being shut down by MAD. To restore the original states of the network interfaces in the merged IRF fabric, use the **`mad restore`** command.

Figure 6 Recovering the IRF fabric



If the active IRF fabric fails before the IRF link is recovered (see Figure 7), use the **`mad restore`** command on the inactive IRF fabric to recover the inactive IRF fabric. This command brings up all network interfaces that were shut down by MAD. After the IRF link is repaired, merge the two parts into a unified IRF fabric.

Figure 7 Active IRF fabric fails before the IRF link is recovered



IP network

MAD mechanisms

IRF provides MAD mechanisms by extending LACP, BFD, ARP, and IPv6 ND.

Table 1 compares the MAD mechanisms and their application scenarios.

Table 1 Comparison of MAD mechanisms

MAD mechanism	Advantages	Disadvantages	Application scenarios
LACP MAD	• Detection speed is fast. • Runs on existing aggregate links without requiring MAD-dedicated physical links or Layer 3 interfaces.	Requires an intermediate device that supports extended LACP for MAD.	Link aggregation is used between the IRF fabric and its upstream or downstream device.
BFD MAD	• Detection speed is fast. • Intermediate device, if used, can come from any vendor.	Requires MAD dedicated physical links and Layer 3 interfaces, which cannot be used for transmitting user traffic.	• No special requirements for network scenarios. • If no intermediate device is used, this mechanism is only suitable for IRF fabrics that have only two members that are geographically close to one another.
ARP MAD	• No intermediate device is required. • Intermediate device, if used, can come from any vendor. • Does not require MAD dedicated ports.	• Detection speed is slower than BFD MAD and LACP MAD. • The spanning tree feature must be enabled.	Spanning tree-enabled non-link aggregation IPv4 network scenarios.
ND MAD	• No intermediate device is required. • Intermediate device, if used, can come from any vendor. • Does not require MAD dedicated ports.	• Detection speed is slower than BFD MAD and LACP MAD. • The spanning tree feature must be enabled.	Spanning tree-enabled non-link aggregation IPv6 network scenarios.

LACP MAD

As shown in Figure 8, LACP MAD has the following requirements:

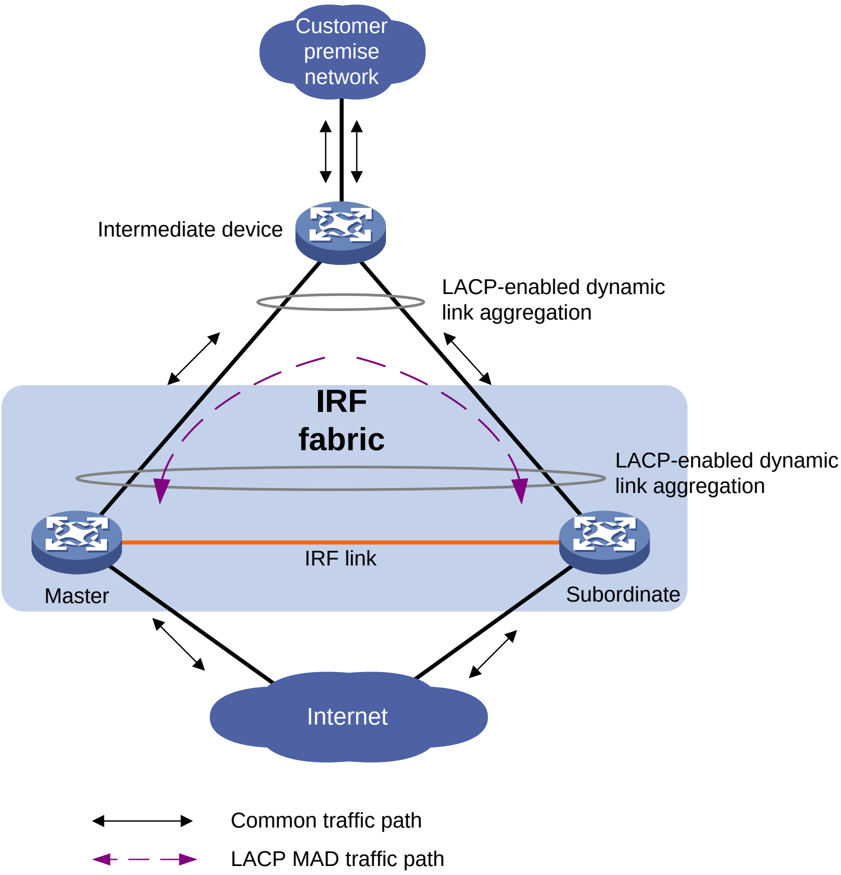
- Every IRF member must have a link with an intermediate device.
- All the links form a dynamic link aggregation group.
- The intermediate device must be a device that supports extended LACP for MAD.

The IRF member devices send extended LACPDUs that convey a domain ID and an active ID (the member ID of the master). The intermediate device transparently forwards the extended LACPDUs received from one member device to all the other member devices.

- If the domain IDs and active IDs sent by all the member devices are the same, the IRF fabric is integrated.

- If the extended LACPDUs convey the same domain ID but different active IDs, a split has occurred. LACP MAD handles this situation as described in "Collision handling."

Figure 8 LACP MAD scenario



BFD MAD

BFD MAD detects multi-active collisions by using BFD.

You can use common Ethernet ports for BFD MAD.

If management Ethernet ports are used, BFD MAD has the following requirements:

- An intermediate device is required and each IRF member device must have a BFD MAD link to the intermediate device.
- Each member device is assigned a MAD IP address on the master's management Ethernet port.

If common Ethernet ports are used, BFD MAD has the following requirements:

- If an intermediate device is used, each member device must have a BFD MAD link to the intermediate device. If no intermediate device is used, all member devices must have a BFD MAD link to each other. As a best practice, use an intermediate device to connect IRF member devices if the IRF fabric has more than two member devices. A full mesh of IRF members might cause broadcast loops.
- Ports on BFD MAD links are assigned to a VLAN (or Layer 3 aggregate interface) used for BFD MAD. Each member device is assigned a MAD IP address on the VLAN interface (or Layer 3 aggregate interface).

As a best practice, preferentially use management Ethernet ports for BFD MAD.

The BFD MAD links and BFD MAD VLAN (or Layer 3 aggregate interface) must be dedicated. Do not use BFD MAD links or BFD MAD VLAN (or Layer 3 aggregate interface) for any other purposes.

When you use a Layer 3 aggregate interface for BFD MAD, make sure its member ports do not exceed the maximum number of Selected ports allowed for an aggregation group. If the number of member ports exceeds the maximum number of Selected ports, some member ports cannot become Selected. BFD MAD will be unable to work correctly and its state will change to Faulty. For more information about setting the maximum number of Selected ports for an aggregation group, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*.

NOTE:

- The MAD addresses identify the member devices and must belong to the same subnet.
- Of all management Ethernet ports on an IRF fabric, only the master's management Ethernet port is accessible.

Figure 9 shows a typical BFD MAD scenario that uses an intermediate device. On the intermediate device, assign the ports on the BFD MAD links to the same VLAN.

Figure 10 shows a typical BFD MAD scenario that does not use an intermediate device.

With BFD MAD, the master attempts to establish BFD sessions with other member devices by using its MAD IP address as the source IP address.

- If the IRF fabric is integrated, only the MAD IP address of the master takes effect. The master cannot establish a BFD session with any other member. If you execute the **`display bfd session`** command, the state of the BFD sessions is **Down**.
- When the IRF fabric splits, the IP addresses of the masters in the split IRF fabrics take effect. The masters can establish a BFD session. If you execute the **`display bfd session`** command, the state of the BFD session between the two devices is **Up**.

Figure 9 BFD MAD scenario with an intermediate device

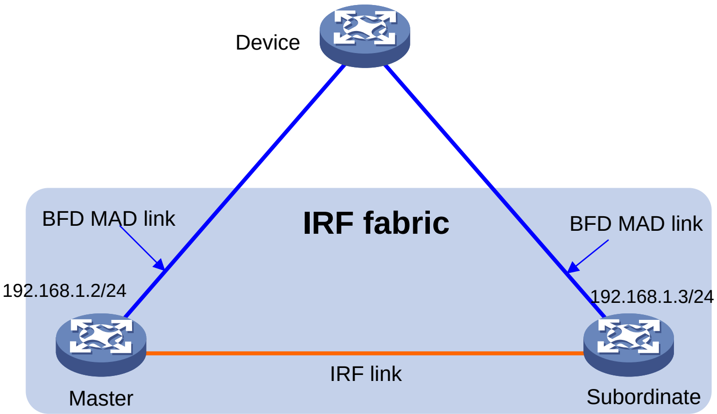


Figure 10 BFD MAD scenario without an intermediate device

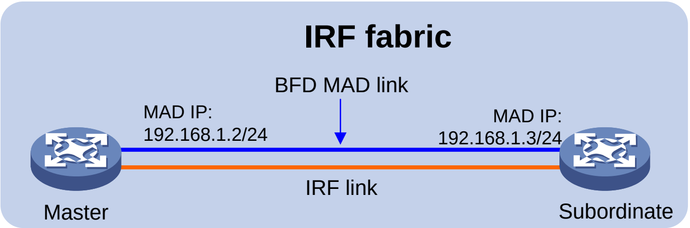


ARP MAD

ARP MAD detects multi-active collisions by using extended ARP packets that convey the IRF domain ID and the active ID.

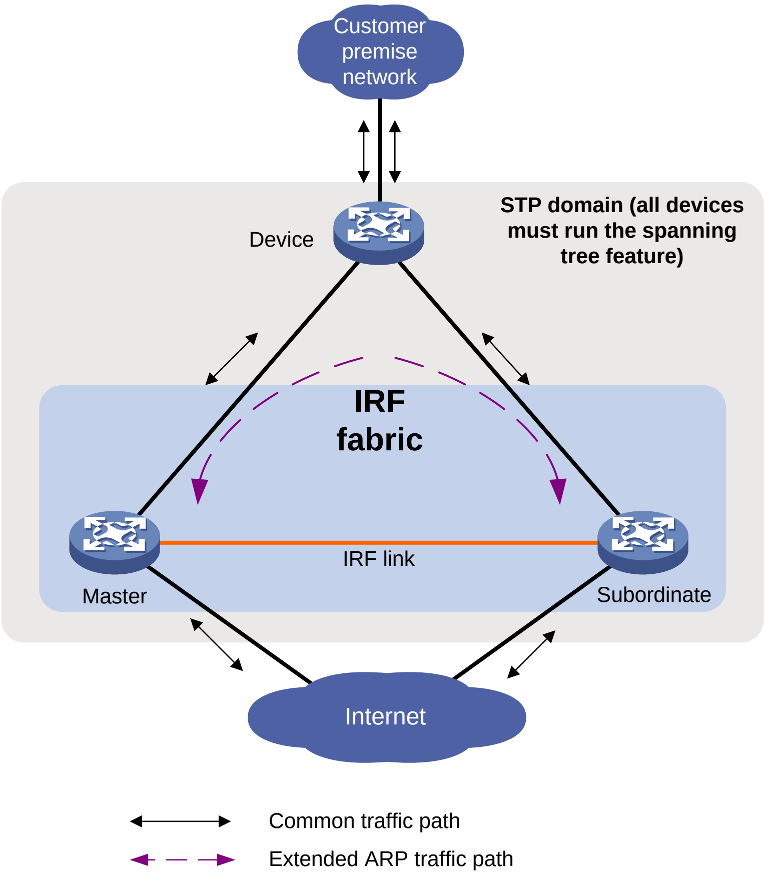
ARP MAD can work with or without an intermediate device. Make sure the following requirements are met:

- If an intermediate device is used, connect each IRF member device to the intermediate device, as shown in Figure 11. Run the spanning tree feature between the IRF fabric and the intermediate device. In this situation, data links can be used.
- If no intermediate device is used, connect each IRF member device to all other member devices. In this situation, IRF links cannot be used for ARP MAD.

Each IRF member compares the domain ID and the active ID (the member ID of the master) in incoming extended ARP packets with its domain ID and active ID.

- If the domain IDs are different, the extended ARP packet is from a different IRF fabric. The device does not continue to process the packet with the MAD mechanism.
- If the domain IDs are the same, the device compares the active IDs.
  - If the active IDs are different, the IRF fabric has split.
  - If the active IDs are the same, the IRF fabric is integrated.

Figure 11 ARP MAD scenario



ND MAD

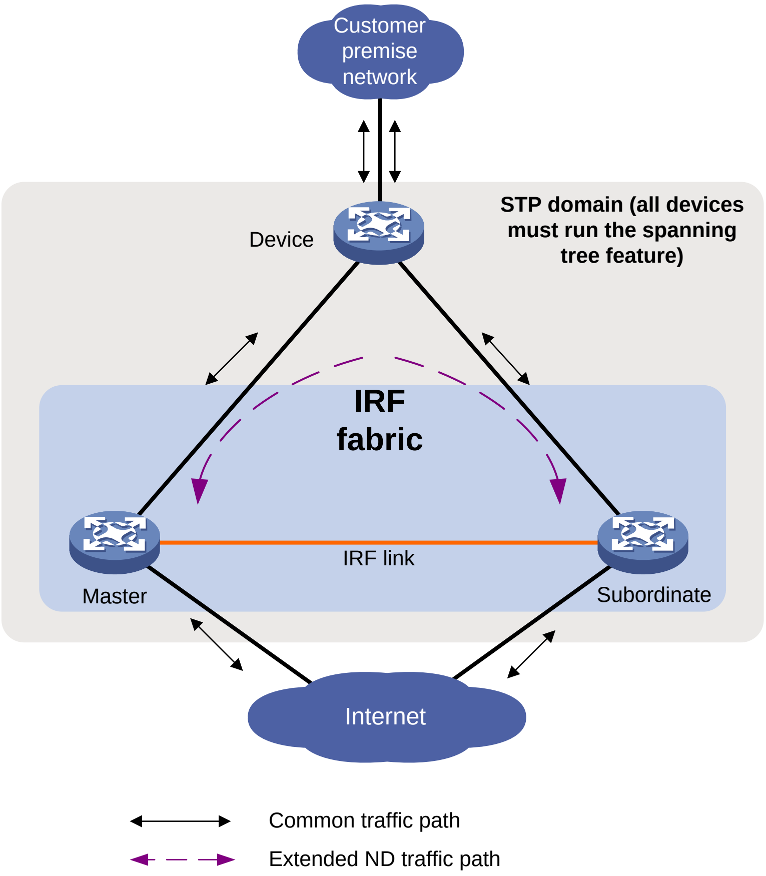
ND MAD detects multi-active collisions by using NS packets to transmit the IRF domain ID and the active ID.

You can set up ND MAD links between neighbor IRF member devices or between each IRF member device and an intermediate device (see Figure 12). If an intermediate device is used, you must also run the spanning tree protocol between the IRF fabric and the intermediate device.

Each IRF member device compares the domain ID and the active ID (the member ID of the master) in incoming NS packets with its domain ID and active ID.

- If the domain IDs are different, the NS packet is from a different IRF fabric. The device does not continue to process the packet with the MAD mechanism.
- If the domain IDs are the same, the device compares the active IDs.
  - If the active IDs are different, the IRF fabric has split.
  - If the active IDs are the same, the IRF fabric is integrated.

Figure 12 ND MAD scenario



Restrictions: Hardware compatibility with IRF

Models	IRF compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Restrictions and guidelines: IRF configuration

Support for Web-based configuration

You can configure only basic IRF settings from the Web interface. To configure IRF parameters not available on the Web interface, access the CLI.

Hardware compatibility with IRF

The device can form an IRF fabric only with devices of the same model.

Software requirements for IRF

All IRF member devices must run the same software image version. Make sure the software auto-update feature is enabled on all member devices.

IRF fabric size

An IRF fabric can contain a maximum of two member devices.

Candidate IRF physical interfaces

As a best practice, use high-speed ports as IRF physical interfaces.

Do not use the following ports as IRF physical interfaces:

- Console ports.
- Management ports. The interface type identifier for management ports is M-GigabitEthernet. The port identifier for a management port has a suffix of "/MGMT" on the panel.
- A port that has been assigned by default or manually to a bridge instance enabled with security service bypass..

As a best practice, do not bind a Ten-GigabitEthernet (XGE) fiber port to an IRF port if a gigabit fiber transceiver module is installed in it. The port identifier for a Ten-GigabitEthernet fiber port is **10GBASE-R** on the panel.

To use a port as an IRF physical interface, use the **`port group interface`** command to bind the port to an IRF port.

Use Table 2 to identify which ports on your device or module can act as IRF physical interfaces.

Table 2 NFNX series and candidate IRF physical interfaces matrix

Models	Candidate IRF physical interfaces
NFNX5-HD6480	• XGE 1/0/14 to XGE 1/0/17. • XGE 1/0/20. • XGE 1/0/21.
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280	• GE 1/0/0 to GE 1/0/23. • XGE 1/0/24 to XGE 1/0/29.
NFNX3-HDB1780, NFNX3-HDB3080	• GE 1/0/0 to GE 1/0/25. • XGE 1/0/26. • XGE 1/0/27.
NFNX3-HDB1180, NFNX3-HDB1480	• GE 1/0/4 to GE 1/0/21. • XGE 1/0/30. • XGE 1/0/31.
NFNX3-HDB680, NFNX3-HDB1080	IRF not supported.

Transceiver modules and cables selection for IRF

When you select transceiver modules and cables, follow these restrictions and guidelines:

- Use Category 5 (or above) twisted-pair cables to connect 10/100/1000Mbps Ethernet ports for a short-distance connection.
- Use SFP or SFP+ DAC cables to connect SFP or SFP+ ports for a short-distance connection.
- Use SFP or SFP+ transceiver modules and fibers to connect SFP or SFP+ ports for a long-distance connection.
- The transceiver modules at the two ends of an IRF link must be the same type.

For more information about the transceiver modules and DAC cables, see the device installation guide and *NSFOCUS Transceiver Modules User Guide*.

NOTE:

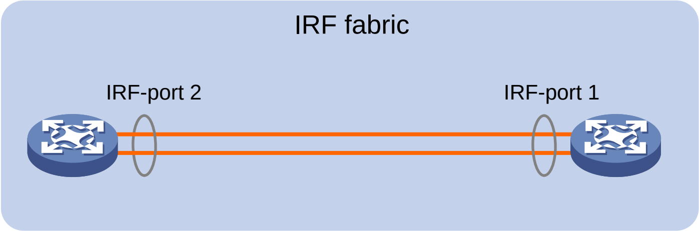
The transceiver modules and DAC cables available for the device are subject to change over time. For the most up-to-date list of transceiver modules and DAC cables, contact your NSFOCUS sales representative.

IRF port connection

When you connect two neighboring IRF members, follow these restrictions and guidelines:

- You must connect the physical interfaces of IRF-port 1 on one member to the physical interfaces of IRF-port 2 on the other.
- For high availability, bind multiple physical interfaces to an IRF port.
- No relay devices are allowed between neighboring members.

Figure 13 Connecting IRF physical interfaces



IRF physical interface configuration restrictions and guidelines

Command configuration restrictions

On a physical interface bound to an IRF port, you can execute only the following commands:

- Interface commands, including:
  - **`description`**.
  - **`flow-interval`**.
  - **`shutdown`**.

  For more information about these commands, see Ethernet interface configuration in *Interface Command Reference*.
- LLDP commands, including:

- ○ **lldp admin-status**.
- ○ **lldp check-change-interval**.
- ○ **lldp enable**.
- ○ **lldp encapsulation snap**.
- ○ **lldp notification remote-change enable**.
- ○ **lldp tlv-enable**.

For more information about these commands, see *Layer 2—LAN Switching Command Reference*.

- The **mirroring-group reflector-port** command, which specifies the physical interface as a reflector port for remote mirroring. For more information about this command, see port mirroring in *Network Management and Monitoring Command Reference*.

IMPORTANT:

Do not execute the **mirroring-group reflector-port** command on an IRF physical interface if that interface is the only member interface of an IRF port. Doing so will split the IRF fabric, because this command also removes the binding of the physical interface and IRF port.

Feature compatibility and configuration restrictions with IRF

ACL

To form an IRF fabric, all member devices in the IRF fabric must have the same settings for the ACL hardware mode. For more information about hardware-based ACLs, see *ACL and QoS Configuration Guide*.

Licensing requirements for IRF

For a license-based feature to run correctly on an IRF fabric, make sure the licenses installed for the feature on all member devices are the same. For more information about feature licensing, see *Fundamentals Configuration Guide*.

Configuration rollback restrictions

The configuration rollback feature cannot roll back the following IRF settings:

- Member device description (set by using the **irf member description** command).
- Member device priority (set by using the **irf member priority** command).
- IRF physical interface and IRF port bindings (set by using the **port group interface** command).

For more information about the configuration rollback feature, see configuration file management in *Fundamentals Configuration Guide*.

IRF tasks at a glance

To configure IRF, perform the following tasks:

1. Setting up an IRF fabric
2. Configuring MAD

   Configure a minimum of one MAD mechanism on an IRF fabric.

   - Configuring LACP MAD
   - Configuring BFD MAD
   - Configuring ARP MAD
   - Configuring ND MAD
   - Excluding interfaces from the shutdown action upon detection of multi-active collision

     This feature excludes an interface from the shutdown action for management or other special purposes when an IRF fabric transits to the Recovery state.
   - Recovering an IRF fabric
3. (Optional.) Optimizing IRF settings for an IRF fabric
   - Configuring a member device description
   - Configuring IRF link load sharing mode
   - Configuring the IRF bridge MAC address
   - Enabling software auto-update for software image synchronization

     This feature automatically synchronizes the current software images of the master to devices that are attempting to join the IRF fabric.
   - Removing an expansion interface card that has IRF physical interfaces
   - Replacing an expansion interface card that has IRF physical interfaces

Planning the IRF fabric setup

Consider the following items when you plan an IRF fabric:

- Hardware compatibility and restrictions.
- IRF fabric size.
- Master device.
- Member ID and priority assignment scheme.
- Fabric topology and cabling scheme.
- IRF physical interfaces.

Setting up an IRF fabric

IRF setup tasks at a glance

To set up an IRF fabric, perform the following tasks:

1. Configure member IDs, priorities, and IRF physical interfaces separately.
   a. Assigning a member ID to each IRF member device
   b. (Optional.) Specifying a priority for each member device
   c. Binding physical interfaces to IRF ports

   Skip these tasks if you configure member IDs, priorities, domain ID, and IRF physical interfaces in bulk.
2. Bulk-configuring basic IRF settings for a member device

   Skip this task if you configure member IDs, priorities, domain ID, and IRF physical interfaces separately.
3. Connecting IRF physical interfaces
4. Accessing the IRF fabric

Assigning a member ID to each IRF member device

Restrictions and guidelines

To create an IRF fabric, you must assign a unique IRF member ID to each member device.

The new member ID of a device takes effect at a reboot. After the device reboots, the settings on all member ID-related physical resources (including common physical network interfaces) are removed, regardless of whether you have saved the configuration.

Procedure

1. Enter system view.

   `system-view`

2. Assign a member ID to a member device.

   `irf member` *`member-id`* **`renumber`** *`new-member-id`*

   The default IRF member ID is 1.

   △ **CAUTION:**

   An IRF member ID change can invalidate member ID-related settings and cause data loss. Make sure you fully understand its impact on the live network.

3. (Optional.) Save the configuration.

   `save`

   If you have bound physical interfaces to IRF ports or assigned member priority, you must perform this step for these settings to take effect after the reboot.

4. Return to user view.

   `quit`

5. Reboot the device.

   `reboot` `[` **`slot`** *`slot-number`* `] [` **`force`** `]`

Specifying a priority for each member device

About this task

IRF member priority represents the possibility for a device to be elected the master in an IRF fabric. A larger priority value indicates a higher priority.

A change to member priority affects the election result at the next master election, but it does not cause an immediate master re-election.

Procedure

1. Enter system view.

   `system-view`

2. Specify a priority for the device.

   `irf member` *`member-id`* **`priority`** *`priority`*

   The default IRF member priority is 1.

Binding physical interfaces to IRF ports

Restrictions and guidelines

Select qualified physical interfaces as IRF physical interfaces as described in "Candidate IRF physical interfaces."

Make sure the IRF physical interfaces of an IRF port use the same binding mode.

After binding physical interfaces to IRF ports for the first time, you must use the **irf-port-configuration active** command to activate the settings on the IRF ports.

The system activates the IRF port settings automatically only in the following situations:

- The configuration file that the device starts with contains IRF port bindings.
- You are adding physical interfaces to an IRF port (in UP state) after an IRF fabric is formed.

Procedure

1. Enter system view.

   system-view

2. Enter the interface view or interface range view of an IRF physical interface or a range of IRF physical interfaces, respectively.

   - Enter Layer 2 or Layer 3 Ethernet interface view.

     interface *interface-type interface-number*

   - Enter interface range view. Choose one of the following commands:

     interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

     interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

   To shut down a range of IRF physical interfaces, enter interface range view.

   To shut down one IRF physical interface, enter its interface view.

3. Shut down the physical interfaces.

   shutdown

   By default, a physical interface is not administratively down.

   You must always shut down a physical interface before binding it to an IRF port or removing the binding. If the system prevents you from shutting down an interface, follow the system instructions to disable its peer interface.

4. Return to system view.

   quit

5. Enter IRF port view.

   irf-port *member-id/irf-port-number*

6. Bind each physical interface to the IRF port.

   port group interface *interface-type interface-number*

   By default, no physical interfaces are bound to an IRF port.

   Repeat this step to assign multiple physical interfaces to the IRF port.

7. Return to system view.

   quit

8. Enter the interface view or interface range view of an IRF physical interface or a range of IRF physical interfaces, respectively.

   - Enter Layer 2 or Layer 3 Ethernet interface view.

interface *interface-type interface-number*

  - Enter interface range view. Choose one of the following commands:

    interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

    interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

9. Bring up the physical interfaces.

   undo shutdown

10. Return to system view.

    quit

11. Save the configuration.

    save

    Activating IRF port configurations causes IRF merge and reboot. To avoid data loss, save the running configuration to the startup configuration file before you perform the operation.

12. Activate the IRF port settings.

    irf-port-configuration active

Bulk-configuring basic IRF settings for a member device

About this task

Use the easy IRF feature to bulk-configure basic IRF settings for a member device, including the member ID, domain ID, priority, and IRF port bindings.

The easy IRF feature provides the following configuration methods:

- **Interactive method**—Enter the **easy-irf** command without parameters. The system will guide you to set the parameters step by step.
- **Non-interactive method**—Enter the **easy-irf** command with parameters.

As a best practice, use the interactive method if you are new to IRF.

Restrictions and guidelines

△ **CAUTION:**

- Use caution when you change the member ID of an IRF member device. An IRF member ID uniquely identifies a device in an IRF fabric . An IRF member ID change can invalidate member ID-related settings, including interface and file path settings, and cause data loss. Make sure you fully understand its impact on the live network.
- The member device reboots immediately after you specify a new member ID for it. Make sure you are aware of the impact of this operation on the network.

If you execute the **easy-irf** command multiple times, the following settings take effect:

- The most recent settings for the member ID, domain ID, and priority.
- IRF port bindings added through repeated executions of the command. To remove an IRF physical interface from an IRF port, you must use the **undo port group interface** command in IRF port view.

If you specify IRF physical interfaces by using the interactive method, you must also follow these restrictions and guidelines:

- Do not enter spaces between the interface type and interface number.
- Use a comma (,) to separate two physical interfaces. No spaces are allowed between interfaces.

Procedure

1. Enter system view.

   system-view

2. Bulk-configure basic IRF settings for the device.

   easy-irf [**member** *member-id* [**renumber** *new-member-id*] **domain** *domain-id* [**priority** *priority*] [**irf-port1** *interface-list1*] [**irf-port2** *interface-list2*]]

   Make sure the new member ID is unique in the IRF fabric to which the device will be added.

Connecting IRF physical interfaces

Follow the restrictions in "IRF port connection" to connect IRF physical interfaces as well as based on the topology and cabling scheme. The devices perform master election. The member devices that fail the master election automatically reboot to form an IRF fabric with the master device.

Accessing the IRF fabric

The IRF fabric appears as one device after it is formed. You configure and manage all IRF members at the CLI of the master. All settings you have made are automatically propagated to the IRF members.

The following methods are available for accessing an IRF fabric:

- **Local login**—Log in through the AUX or console port of any member device.
- **Remote login**—Log in at a Layer 3 interface on any member device by using methods including Telnet and SNMP.

When you log in to an IRF fabric, you are placed at the CLI of the master, regardless of at which member device you are logged in.

For more information, see login configuration in *Fundamentals Configuration Guide*.

Configuring MAD

Restrictions and guidelines for MAD configuration

VLAN interface compatibility

Do not configure MAD on VLAN interfaces.

MAD mechanism compatibility

As a best practice, configure a minimum of one MAD mechanism on an IRF fabric for prompt IRF split detection. Because MAD mechanisms use different collision handling processes, follow these restrictions and guidelines when you configure multiple MAD mechanisms on an IRF fabric:

- Do not configure LACP MAD together with ARP MAD or ND MAD.
- Do not configure BFD MAD together with ARP MAD or ND MAD.

Assigning IRF domain IDs

An IRF fabric has only one IRF domain ID.

You can change the IRF domain ID by using the following commands: **irf domain**, **mad enable**, **mad arp enable**, or **mad nd enable**. The IRF domain IDs configured by using these commands overwrite each other.

If LACP MAD, ARP MAD, or ND MAD runs between two IRF fabrics, assign each fabric a unique IRF domain ID. (For BFD MAD, this task is optional.)

Actions on interfaces shut down by MAD

To prevent a multi-active collision from causing network issues, avoid using the **undo shutdown** command to bring up the interfaces shut down by a MAD mechanism on a Recovery-state IRF fabric.

Configuring LACP MAD

1. Enter system view.

   system-view

2. Assign a domain ID to the IRF fabric.

   irf domain *domain-id*

   The default IRF domain ID is 0.

   ⚠ **CAUTION:**

   Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the remaining member devices in the IRF fabric.

3. Create an aggregate interface and enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.

     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.

     interface route-aggregation *interface-number*

   Perform this step also on the intermediate device.

4. Configure the aggregation group to operate in dynamic aggregation mode.

   link-aggregation mode dynamic

   By default, an aggregation group operates in static aggregation mode.

   LACP MAD takes effect only on dynamic aggregate interfaces.

   Perform this step also on the intermediate device.

5. Enable LACP MAD.

   mad enable

   By default, LACP MAD is disabled.

6. Return to system view.

   quit

7. Enter Ethernet interface view or interface range view.
   - Enter Ethernet interface view.

     interface *interface-type interface-number*
   - Enter interface range view. Choose one of the following commands:

     interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

     interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

   To assign a range of ports to the aggregation group, enter interface range view.

   To assign one port to the aggregation group, enter Ethernet interface view.

8. Assign the Ethernet port or the range of Ethernet ports to the specified aggregation group.

   port link-aggregation group *group-id*

   Multichassis link aggregation is allowed.

   Perform this step also on the intermediate device.

Configuring BFD MAD

Restrictions and guidelines for configuring BFD MAD

As a best practice, use the following procedure to set up BFD MAD:

1. Choose a BFD MAD link scheme as described in "BFD MAD."
2. Configure BFD MAD.
3. Connect the BFD MAD links.

When you configure BFD MAD on a Layer 3 aggregate interface, follow these restrictions and guidelines:

Category	Restrictions and guidelines
BFD MAD-enabled Layer 3 aggregate interface	• Make sure the Layer 3 aggregate interface operates in static aggregation mode. • Make sure the member ports in the aggregation group do not exceed the maximum number of Selected ports allowed for an aggregation group. If the number of member ports exceeds the maximum number of Selected ports, some member ports cannot become Selected. BFD MAD will be unable to work correctly and its state will change to Faulty.
BFD MAD VLAN	If a switch is used as the intermediate device, use a VLAN as the BFD MAD VLAN on the intermediate device. • If the intermediate device acts as a BFD MAD intermediate device for multiple IRF fabrics, assign different BFD MAD VLANs to the IRF fabrics. • Assign the ports on the BFD MAD links for the same IRF fabric to the same VLAN. Do not assign the ports to an aggregate interface. If the ports are hybrid ports, make sure these ports are untagged members of their PVIDs. • Do not use the BFD MAD VLAN on the intermediate device for any purposes other than BFD MAD. • Make sure the BFD MAD VLAN on the intermediate device contains only ports on the BFD MAD links. Exclude a port from the BFD MAD VLAN if that port is not on a BFD MAD link. If you have assigned that port to all VLANs by using the **port trunk permit vlan all** command, use the **undo port trunk permit** command to exclude that port from the BFD MAD VLAN.
BFD MAD-enabled Layer 3 aggregate interface and feature compatibility	Use only the **mad bfd enable** and **mad ip address** commands on the BFD MAD-enabled interface. If you configure other features, both BFD MAD and other features on the interface might run incorrectly.
MAD IP address	• To avoid network issues, only use the **mad ip address** command to configure IP addresses on the BFD MAD-enabled interface. Do not configure an IP address by using the **ip address** command on the BFD MAD-enabled interface. • Make sure all the MAD IP addresses are on the same subnet.

Configuring BFD MAD on a Layer 3 aggregate interface

1. Enter system view.

   system-view

2. (Optional.) Assign a domain ID to the IRF fabric.

   irf domain *domain-id*

   By default, the domain ID of an IRF fabric is 0.

> **CAUTION:**
>
> Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the remaining member devices in the IRF fabric.

3. Create a Layer 3 aggregate interface for BFD MAD.

   interface route-aggregation *interface-number*

4. Return to system view.

   quit

5. Enter interface view or interface range view.
   - Enter Ethernet interface view.

     interface *interface-type interface-number*
   - Enter interface range view. Choose one of the following commands:

     interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

     interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

   To assign a range of ports to the aggregation group for the aggregate interface, enter interface range view.

   To assign one port to the aggregation group for the aggregate interface, enter Ethernet interface view.

6. Assign the port or the range of ports to the aggregation group for the aggregate interface.

   port link-aggregation group *number*

7. Return to system view.

   quit

8. Enter Layer 3 aggregate interface view.

   interface route-aggregation *interface-number*

9. Enable BFD MAD.

   mad bfd enable

   By default, BFD MAD is disabled.

10. Assign a MAD IP address to a member device on the Layer 3 aggregate interface.

    mad ip address *ip-address* { *mask* | *mask-length* } **member** *member-id*

    By default, no MAD IP addresses are configured on aggregate interfaces.

    Repeat this step to assign a MAD IP address to each member device on the aggregate interface.

Configuring ARP MAD

Restrictions and guidelines

As a best practice, use the following procedure to set up ARP MAD:

1. Choose an ARP MAD link scheme as described in "ARP MAD."
2. Configure ARP MAD.

3. Connect the ARP MAD links if you are not using existing data links as ARP MAD links.

When you configure ARP MAD, follow these restrictions and guidelines:

Category	Restrictions and guidelines
ARP MAD VLAN	• Do not enable ARP MAD on VLAN-interface 1. • If you are using an intermediate device, perform the following tasks: ○ On the IRF fabric and the intermediate device, create a VLAN for ARP MAD. ○ On the IRF fabric and the intermediate device, assign the ports of ARP MAD links to the ARP MAD VLAN. ○ On the IRF fabric, create a VLAN interface for the ARP MAD VLAN. • Do not use the ARP MAD VLAN for any other purposes.
ARP MAD and feature configuration	If an intermediate device is used, make sure the following requirements are met: • Run the spanning tree feature between the IRF fabric and the intermediate device to ensure that there is only one ARP MAD link in forwarding state. For more information about the spanning tree feature and its configuration, see *Layer 2—LAN Switching Configuration Guide*. • Enable the IRF fabric to change its bridge MAC address as soon as the address owner leaves. • If the intermediate device is also an IRF fabric, assign the two IRF fabrics different domain IDs for correct split detection.

Procedure

1. Enter system view.

   `system-view`

2. Assign a domain ID to the IRF fabric.

   `irf domain` *`domain-id`*

   The default IRF domain ID is 0.

CAUTION:

Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the remaining member devices in the IRF fabric.

3. Configure the IRF bridge MAC address to change as soon as the address owner leaves.

   `undo irf mac-address persistent`

   By default, the IRF bridge MAC address remains unchanged for 6 minutes after the address owner leaves.

4. Create a VLAN dedicated to ARP MAD.

   `vlan` *`vlan-id`*

   By default, only VLAN 1 exists.

5. Return to system view.

   `quit`

6. Enter Ethernet interface view or interface range view.
   - Enter Ethernet interface view.

     `interface` *`interface-type interface-number`*

   - Enter interface range view. Choose one of the following commands:

interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

To assign a range of ports to the ARP MAD VLAN, enter interface range view.

To assign one port to the ARP MAD VLAN, enter Ethernet interface view.

7. Assign the port or the range of ports to the ARP MAD VLAN.
   - Assign the ports to the VLAN as access ports.

     port access vlan *vlan-id*
   - Assign the ports to the VLAN as trunk ports.

     port trunk permit vlan *vlan-id*
   - Assign the ports to the VLAN as hybrid ports.

     port hybrid vlan *vlan-id* { **tagged** | **untagged** }

   The link type of ARP MAD ports can be access, trunk, or hybrid.

   The default link type of a port is access.
8. Return to system view.

   quit
9. Enter VLAN interface view.

   interface vlan-interface *vlan-interface-id*
10. Assign the interface an IP address.

    ip address *ip-address* { *mask* | *mask-length* }

    By default, no IP addresses are assigned to any VLAN interfaces.
11. Enable ARP MAD.

    mad arp enable

    By default, ARP MAD is disabled.

Configuring ND MAD

Restrictions and guidelines

When you use ND MAD, follow these guidelines:

- If an intermediate device is used, you can use common data links as ND MAD links. If no intermediate device is used, set up dedicated ND MAD links between IRF member devices.
- If an intermediate device is used, make sure the following requirements are met:
  - Run the spanning tree feature between the IRF fabric and the intermediate device. Make sure there is only one ND MAD link in forwarding state. For more information about the spanning tree feature and its configuration, see *Layer 2—LAN Switching Configuration Guide*.
  - Enable the IRF fabric to change its bridge MAC address as soon as the address owner leaves.
  - If the intermediate device is also an IRF fabric, assign the two IRF fabrics different domain IDs for correct split detection.

Procedure

1. Enter system view.

   system-view
2. Assign a domain ID to the IRF fabric.

irf domain *domain-id*

The default IRF domain ID is 0.

CAUTION:

Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the remaining member devices in the IRF fabric.

3. Configure the IRF bridge MAC address to change as soon as the address owner leaves.

   undo irf mac-address persistent

   By default, the IRF bridge MAC address remains unchanged for 6 minutes after the address owner leaves.
4. Create a VLAN dedicated to ND MAD.

   vlan *vlan-id*

   By default, only VLAN 1 exists.

   Do not configure ND MAD on VLAN-interface 1.

   Do not use the VLAN configured for ND MAD for any other purposes.

   Perform this task also on the intermediate device (if any).
5. Return to system view.

   quit
6. Enter Ethernet interface view or interface range view.
   - Enter Ethernet interface view.

     interface *interface-type interface-number*
   - Enter interface range view. Choose one of the following commands:

     interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

     interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

   To assign a range of ports to the ND MAD VLAN, enter interface range view.

   To assign one port to the ND MAD VLAN, enter Ethernet interface view.
7. Assign the port or the range of ports to the ND MAD VLAN.
   - Assign the ports to the VLAN as access ports.

     port access vlan *vlan-id*
   - Assign the ports to the VLAN as trunk ports.

     port trunk permit vlan *vlan-id*
   - Assign the ports to the VLAN as hybrid ports.

     port hybrid vlan *vlan-id* { **tagged** | **untagged** }

   The link type of ND MAD ports can be access, trunk, or hybrid.

   The default link type of a port is access.

   Perform this task also on the intermediate device (if any).
8. Return to system view.

   quit
9. Enter VLAN interface view.

   interface vlan-interface *vlan-interface-id*
10. Assign the interface an IPv6 address.

```
ipv6 address { ipv6-address/prefix-length | ipv6-address
prefix-length }
```

By default, no IPv6 addresses are assigned to any VLAN interfaces.

11. Enable ND MAD.

```
mad nd enable
```

By default, ND MAD is disabled.

Excluding interfaces from the shutdown action upon detection of multi-active collision

About this task

When an IRF fabric transits to the Recovery state, the system automatically excludes the following network interfaces from being shut down:

- IRF physical interfaces.
- Member interfaces of an aggregate interface if the aggregate interface is excluded from being shut down.

You can exclude a network interface from the shutdown action for management or other special purposes. For example:

- Exclude a port from the shutdown action so you can Telnet to the port for managing the device.
- Exclude a VLAN interface and its Layer 2 ports from the shutdown action so you can log in through the VLAN interface.

Restrictions and guidelines

If the Layer 2 ports of a VLAN interface are distributed on multiple member devices, the exclusion operation might introduce IP collision risks. The VLAN interface might be up on both active and inactive IRF fabrics.

Procedure

1. Enter system view.

```
system-view
```

2. Configure a network interface to not shut down when the IRF fabric transits to the Recovery state.

```
mad exclude interface interface-type interface-number
```

By default, all network interfaces on a Recovery-state IRF fabric are shut down, except for the network interfaces automatically excluded by the system.

Recovering an IRF fabric

About this task

For split IRF fabrics, if the active IRF fabric fails before the IRF link is recovered, perform this task on the inactive IRF fabric to recover the inactive IRF fabric. The manual recovery operation brings up all interfaces that were shut down by MAD on the inactive IRF fabric.

Procedure

1. Enter system view.

```
system-view
```

2. Recover the inactive IRF fabric.

```
mad restore
```

Optimizing IRF settings for an IRF fabric

Configuring a member device description

1. Enter system view.

   system-view

2. Configure a description for a member device.

   irf member *member-id* **description** *text*

   By default, no member device description is configured.

Configuring IRF link load sharing mode

About IRF link load sharing mode

On an IRF port, traffic is balanced across its physical links.

You can configure the IRF port to distribute traffic based on any combination of the following criteria:

- IP addresses.
- MAC addresses.

The system displays an error message if a criteria combination is not supported.

The criteria can also be packet types, such as Layer 2, IPv4, and IPv6.

Restrictions and guidelines for configuring IRF link load sharing mode

Configure the IRF link load sharing mode for IRF links in system view or IRF port view:

- In system view, the configuration is global and takes effect on all IRF ports.
- In IRF port view, the configuration is port specific and takes effect only on the specified IRF port.

An IRF port preferentially uses the port-specific load sharing mode. If no port-specific load sharing mode is available, the IRF port uses the global load sharing mode.

Before you configure a port-specific load sharing mode, make sure you have bound a minimum of one physical interface to the IRF port.

Configuring the global load sharing mode

1. Enter system view.

   system-view

2. Configure the global IRF link load sharing mode.

   irf-port global load-sharing mode { **destination-ip** | **destination-mac** | **source-ip** | **source-mac** } *

   By default, packets are distributed based on the load sharing mode automatically selected depending on the packet type.

   If you execute this command multiple times, the most recent configuration takes effect.

Configuring a port-specific load sharing mode

1. Enter system view.

   system-view

2. Enter IRF port view.

   irf-port *member-id/irf-port-number*

3. Configure the port-specific load sharing mode.

irf-port load-sharing mode { **destination-ip** | **destination-mac** | **source-ip** | **source-mac** } *

By default, packets are distributed based on the load sharing mode automatically selected depending on the packet type.

If you execute this command multiple times, the most recent configuration takes effect.

Configuring the IRF bridge MAC address

About this task

The bridge MAC address of a system must be unique on a switched LAN. IRF bridge MAC address identifies an IRF fabric by Layer 2 protocols (for example, LACP) on a switched LAN.

By default, an IRF fabric uses the bridge MAC address of the master as the IRF bridge MAC address. After the master leaves, the IRF bridge MAC address persists for a period of time or permanently depending on the IRF bridge MAC persistence setting. When the IRF bridge MAC persistence timer expires, the IRF fabric uses the bridge MAC address of the current master as the IRF bridge MAC address.

If IRF fabric merge occurs, IRF determines the IRF bridge MAC address of the merged IRF fabric as follows:

1. When IRF fabrics merge, IRF ignores the IRF bridge MAC addresses and checks the bridge MAC address of each member device in the IRF fabrics. IRF merge fails if any two member devices have the same bridge MAC address.
2. After IRF fabrics merge, the merged IRF fabric uses the bridge MAC address of the merging IRF fabric that won the master election as the IRF bridge MAC address.

Restrictions and guidelines

△ **CAUTION:**

Bridge MAC address change will cause transient traffic disruption.

When you configure IRF bridge MAC persistence, follow these restrictions and guidelines:

- If ARP MAD or ND MAD is used with the spanning tree feature, you must disable IRF bridge MAC persistence by using the **undo irf mac-address persistent** command.
- If the IRF fabric has multichassis aggregate links, do not use the **undo irf mac-address persistent** command. Use of this command might cause traffic disruption.

An IRF bridge MAC change might cause the MAC addresses of logical interfaces such as VLAN interfaces to change, resulting in forwarding issues. To avoid this situation, configure IRF bridge MAC persistence to have the existing IRF bridge MAC address persists for a while or permanently after the address owner leaves the IRF fabric.

Configuring IRF bridge MAC persistence

1. Enter system view.

   system-view

2. Configure IRF bridge MAC persistence.
   - Retain the bridge MAC address permanently even if the address owner has left the fabric.

     irf mac-address persistent always
   - Retain the bridge MAC address for 6 minutes after the address owner leaves the fabric.

     irf mac-address persistent timer
   - Change the bridge MAC address as soon as the address owner leaves the fabric.

     undo irf mac-address persistent

By default, the IRF bridge MAC address remains unchanged for 6 minutes after the address owner leaves.

The **`irf mac-address persistent timer`** command avoids unnecessary bridge MAC address changes caused by device reboot, transient link failure, or purposeful link disconnection.

Enabling software auto-update for software image synchronization

About this task

The software auto-update feature automatically synchronizes the current software images of the master to devices that are attempting to join the IRF fabric.

To join an IRF fabric, a device must use the same software images as the master in the fabric.

When you add a device to the IRF fabric, software auto-update compares the startup software images of the device with the current software images of the IRF master. If the two sets of images are different, the device automatically performs the following operations:

1. Downloads the current software images of the master.
2. Sets the downloaded images as its main startup software images.
3. Reboots with the new software images to rejoin the IRF fabric.

You must manually update the new device with the software images running on the IRF fabric if software auto-update is disabled.

Restrictions and guidelines

To ensure a successful software auto-update in a multi-user environment, prevent anyone from rebooting member devices during the auto-update process. To inform administrators of the auto-update status, configure the information center to output the status messages to configuration terminals (see *Network Management and Monitoring Configuration Guide*).

Make sure the device you are adding to the IRF fabric has sufficient storage space for the new software images.

If sufficient storage space is not available, the device automatically deletes the current software images. If the reclaimed space is still insufficient, the device cannot complete the auto-update. You must reboot the device, and then access the Bootware menu to delete files.

Procedure

1. Enter system view.

```
system-view
```

2. Enable software auto-update.

```
irf auto-update enable
```

   By default, software auto-update is enabled.

Removing an expansion interface card that has IRF physical interfaces

To remove an expansion interface card that provides IRF physical interfaces:

1. Perform one of the following tasks to eliminate temporary packet loss:
   - Remove cables from the IRF physical interfaces on the card.
   - Shut down the IRF physical interfaces on the card by using the **`shutdown`** command.
2. Remove the card.

Replacing an expansion interface card that has IRF physical interfaces

Replacing the old card with a different model replacement card

1. Shut down the IRF physical interfaces on the old card by using the **shutdown** command.
2. Remove the IRF port bindings that contain the physical interfaces.
3. Remove the old card, and then install the replacement card.
4. Verify that the replacement card has been correctly installed by using the **display device** command.
5. Reconfigure the IRF port bindings, as described in "Binding physical interfaces to IRF ports."
6. Activate the IRF port settings by using the **irf-port-configuration active** command.

   You can skip this step if the IRF port is in UP state when you add bindings.

Replacing the old card with the same model replacement card

1. Shut down the IRF physical interfaces on the old card by using the **shutdown** command.
2. Remove the old card, and then install the replacement card.
3. Verify that the replacement card has been correctly installed by using the **display device** command.

   Bring up the physical interfaces by using the **undo shutdown** command after the interface card completes startup.

Display and maintenance commands for IRF

Execute **display** commands in any view.

Task	Command
Display information about all IRF members.	**display irf**
Display the IRF fabric topology.	**display irf topology**
Display IRF link information.	**display irf link**
Display IRF configuration.	**display irf configuration**
Display the load sharing mode for IRF links.	**display irf-port load-sharing mode** [**irf-port** [*member-id/irf-port-number*]]
Display MAD configuration.	**display mad** [**verbose**]

Contents

Configuring contexts

About contexts

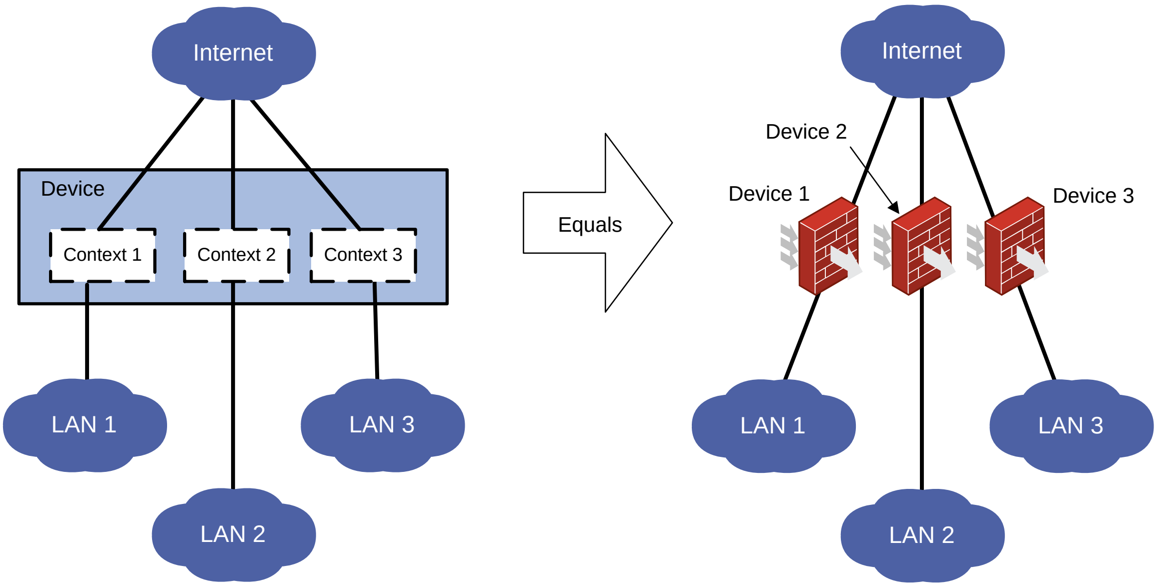
A physical device or an IRF fabric can be virtualized into multiple logical devices called contexts. Each context is assigned separate hardware and software resources, and operates independently of other contexts. From the user's perspective, a context is a standalone device.

Context applications

With context technology, you can meet device requirements from different branches or companies by using a single physical device.

As shown in Figure 1, LAN 1, LAN 2, and LAN 3 are connected to the Internet through the same device. To provide secure access services for the three LANs, you can deploy a single physical device and configure a context for each LAN on the device. The administrator of each LAN can only log in to and manage its own context without affecting other LANs. This has the same effect as deploying a separate device for each LAN.

Figure 1 Network diagram



Default context and non-default contexts

A device supporting contexts is considered to be a context. This context is called the default context (for example, Device in Figure 1). The default context always uses the name **Admin** and the ID 1. You cannot delete it or change its name or ID.

When you log in to the physical device, you are logged in to the default context. On the default context, you can perform the following tasks:

- Manage the entire physical device.
- Create and delete non-default contexts (for example, Context 1, Context 2, and Context 3 in Figure 1).
- Assign resources to non-default contexts. These resources include CPU resources, disk spaces, memory spaces, interfaces, and VLANs.

Administrators of non-default contexts can only use resources assigned to their own contexts. They cannot use free resources or create other contexts. Resources that are not assigned to any non-default context belong to the default context.

A non-default context does not support packet capture on shared interfaces. For more information about packet capture, see *Network Management and Monitoring Configuration Guide*.

Restrictions: Hardware compatibility with context configuration

Models	Context compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080	Yes
NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	No

Restrictions and guidelines: Context configuration

All commands in this chapter are supported on the default context. On a non-default context, only the **`display context interface`**, **`display context reboot`**, and **`reset context reboot`** commands are supported.

DPI services on non-default contexts use the DPI engine on the default context for packet matching. Creating, deleting, stopping, or restarting a non-default context re-activates the DPI engine on the default context. Before the DPI engine on the default context operates correctly, no contexts can provide DPI services.

Context tasks at a glance

To configure contexts, perform the following tasks:

1. Creating contexts
2. (Optional.) Assigning interfaces and VLANs to a context
   - Assigning interfaces to a context
   - Assigning VLANs to a context
3. (Optional.) Limiting resource use for a context

   - Setting the outbound throughput threshold
   - Setting the maximum number of security policy rules
   - Setting the maximum number of concurrent unicast sessions
   - Setting the upper limit of the session establishment rate
   - Setting the maximum number of SSL VPN users
4. Starting a context
5. (Optional.) Assigning CPU, disk, and memory resources to a context
   - Specifying a CPU weight for a context
   - Specifying a memory space percentage for a context
6. Accessing a context
7. (Optional.) Configuring inbound rate limiting for contexts
8. (Optional.) Setting the CPU usage threshold per CPU core for attack prevention
9. (Optional.) Archiving log messages for contexts
10. (Optional.) Configuring a context to support inter-VPC connectivity

Creating contexts

Restrictions and guidelines

When you create a context, you can assign it the VLAN-unshared attribute as required.

- A context with the VLAN-unshared attribute has its own VLAN resources (VLAN 2 through VLAN 4094). It does not share VLAN resources with any other context. To create VLANs for the context, log in to the context and use the **`vlan`** command. VLAN 1 is system defined. You cannot create or delete VLAN 1.
- All contexts without the VLAN-unshared attribute share the same VLAN resources (VLAN 1 through VLAN 4094). You can create VLANs on the default context and use the **`allocate vlan`** command to assign VLANs to the contexts. A VLAN can be assigned only to one context. VLAN 1 is system defined. It belongs to the default context. You cannot assign it to a non-default context.

  For a context without the VLAN-unshared attribute, you cannot perform the following tasks:

  - Change the link mode of Layer 3 Ethernet interfaces on the context to Layer 2.
  - Assign a Layer 2 Ethernet interface exclusively to the context.

Procedure

1. Enter system view.

   `system-view`

2. Create a context and enter context view.

   `context` *`context-name`* `[` **`id`** *`context-id`* `]` `[` **`vlan-unshared`** `]`

   By default, a default context exists. The context name is **Admin** and the context ID is 1.

3. Configure a description for the context.

   `description` *`text`*

   By default, the default context uses the description **DefaultContext**, and a non-default context does not have a description.

Assigning interfaces and VLANs to a context

Assigning interfaces to a context

About this task

By default, all interfaces belong to the default context. A non-default context cannot use any interfaces. To enable a non-default context to communicate, you must assign it interfaces.

You can assign interfaces to contexts in exclusive or shared mode:

- **Exclusive mode**—You assign an interface exclusively to a context, and only the context can use the interface. The administrator of the context can see the interface and use all commands supported on the interface.
- **Shared mode**—You assign an interface to multiple contexts in shared mode, and the system creates a virtual interface for each context. The virtual interfaces use the same name as the physical interface but have different MAC addresses and IP addresses. They forward and receive packets through the physical interface. The shared mode improves interface usage.

  You can see the physical interface and perform all commands supported on the interface from the default context. The administrator of a context can only see the context's virtual interface and use the shutdown, description, and network- and security-related commands.

Restrictions and guidelines

Do not assign IRF physical interfaces to a non-default context.

Do not assign member interfaces of an aggregate interface to a non-default context.

If a subinterface of a Layer 3 interface is a member interface of a Reth interface, do not assign the Layer 3 interface to a non-default context.

A logical interface (for example, a subinterface or aggregate interface) can be assigned to a context only in shared mode.

After assigning a subinterface to a context, you cannot assign its primary interface to a context. After assigning a primary interface to a context, you cannot assign its subinterfaces to a context.

After assigning an interface to contexts in shared mode, you cannot assign the interface to contexts in exclusive mode before reclaiming the interface.

For non-default contexts to communicate with each other, you must assign physical or logical interfaces to the non-default contexts in shared mode on the default context.

Procedure

1. Enter system view.

   `system-view`

2. Enter context view.

   `context` *`context-name`*

3. Assign interfaces to the context.
   - Assign individual interfaces to the context.

     `allocate interface` `{` *`interface-type interface-number`* `}&<1-24> [` **`share`** `]`
   - Assign a range of interfaces to the context.

     `allocate interface` *`interface-type interface-number1`* **`to`** *`interface-type interface-number2`* `[` **`share`** `]`

   By default, all interfaces belong to the default context. A non-default context cannot use any interfaces.

Assigning VLANs to a context

Restrictions and guidelines

For contexts without the VLAN-unshared attribute, you can only assign VLANs to them and cannot use the **vlan** command to create VLANs for them. Before the assignment, you must create the VLANs on the default context. A VLAN can be assigned only to one context.

You cannot assign the following VLANs to a context without the VLAN-unshared attribute:

- VLAN 1.
- Default VLANs of interfaces.
- VLANs for which you have created VLAN interfaces.

Procedure

1. Enter system view.

   system-view

2. Enter context view.

   context *context-name*

3. Assign VLANs to the context.
   - Assign individual VLANs to the context.

     allocate vlan *vlan-id*&<1-24>
   - Assign a range of VLANs to the context.

     allocate vlan *vlan-id1* **to** *vlan-id2*

   By default, no VLANs are assigned to a context.

Limiting resource use for a context

Setting the outbound throughput threshold

About this task

This feature limits the outbound throughput for a context to prevent it from occupying too many shared resources on a security engine.

Procedure

1. Enter system view.

   system-view

2. Enter context view.

   context *context-name*

3. Set the outbound throughput threshold on the context.

   capability throughput { **kbps** | **pps** } *value*

   By default, the outbound throughput is not limited on a context.

Setting the maximum number of security policy rules

About this task

A large number of rules occupy too much memory, affecting other features on the context. This feature limits the number of security policy rules for a context. When the maximum number is reached, you cannot add new rules. For information about security policies, see *Security Configuration Guide*.

Restrictions and guidelines

If the maximum number you set is smaller than the number of existing security policy rules, this setting takes effect. The context does not delete extra existing security policy rules and allows new security policy rules to be created only when the number of security policy rules drops below the maximum number.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter context view.

   ```
   context context-name
   ```

3. Set the maximum number of security policy rules.

   ```
   capability security-policy-rule maximum max-value
   ```

   By default, the number of security policy rules is not limited for a context.

Setting the maximum number of concurrent unicast sessions

About this task

A large number of sessions occupy too much memory, affecting establishment of sessions on other contexts. This feature limits the number of concurrent unicast sessions for a context. When the maximum number is reached, you cannot establish additional unicast sessions.

This feature does not affect local traffic, such as FTP traffic, Telnet traffic, SSH traffic, HTTP traffic, and HTTP-based load balancing traffic.

Restrictions and guidelines

If the maximum number you set is smaller than the number of existing concurrent unicast sessions, this setting takes effect. The context does not delete extra existing concurrent unicast sessions and allows new unicast sessions to be created only when the number of concurrent unicast sessions drops below the maximum number.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter context view.

   ```
   context context-name
   ```

3. Set the maximum number of concurrent unicast sessions.

   ```
   capability session maximum max-number
   ```

   By default, the number of concurrent unicast sessions is not limited.

Setting the upper limit of the session establishment rate

About this task

Establishing sessions too frequently consumes too much CPU resources. If a context establishes sessions too frequently, other contexts will not be able to establish sessions. This feature limits the number of sessions that can be established per second for a context. When the upper limit is reached for a context, no additional sessions can be established.

This feature does not affect local traffic, such as FTP traffic, Telnet traffic, SSH traffic, HTTP traffic, and HTTP-based load balancing traffic.

Procedure

1. Enter system view.

   `system-view`

2. Enter context view.

   `context` *`context-name`*

3. Set the upper limit of the session establishment rate.

   `capability session rate` *`max-value`*

   By default, the session establishment rate is not limited for a context.

Setting the maximum number of SSL VPN users

About this task

The maximum number of SSL VPN users allowed on the device is license-restricted. If the number of logged-in users in a context already reaches the total upper limit, other contexts cannot accept login requests. This feature limits the number of SSL VPN users that can log in to a context. When the maximum number is reached, the context will reject the login requests of new SSL VPN users.

Restrictions and guidelines

If the maximum number you set is smaller than the number of SSL VPN users that already have logged in to a context, this setting takes effect. The context does not log out the currently logged-in users and allows new users to log in only when the number of the logged-in users drops below the maximum number.

Procedure

1. Enter system view.

   `system-view`

2. Enter context view.

   `context` *`context-name`*

3. Set the maximum number of SSL VPN users.

   `capability sslvpn-user maximum` *`max-number`*

   By default, the number of SSL VPN users is not limited for a context. The number is determined by the usage of the SSL VPN licenses installed on the device.

Starting a context

About this task

You must perform this task to initialize a newly created context. You can configure a context only after it is started.

When a context starts, the device examines whether requirements for starting the context are met to ensure status consistency between the master and backup contexts and correct operation of the context.

In an IRF fabric, memory insufficiency might occur during master and backup switchover or configuration recovery. Some contexts will stay in updating or inactive status because of status inconsistency between master and backup processes although they can process services. Use the **`context start force`** command to forcibly start these contexts after the memory becomes sufficient. The device will recover the abnormal context processes without service interruption.

Restrictions and guidelines

Before using the **`context start force`** command, you can use the following commands to display the context running information:

- **`display context`**
- **`display system internal context configuration-status`**
- **`display system internal`** *`context id`* **`context-id running-status`**

Procedure

1. Enter system view.

   `system-view`
2. Enter context view.

   `context` *`context-name`*
3. Start the context.

   `context start` `[` **`force`** `]`

   By default, a context is not started.

Assigning CPU, disk, and memory resources to a context

About CPU, disk, and memory resources assignment

When you assign a context to a security engine group, the system automatically assigns CPU, disk space, and memory space resources on the security engines to the context. All contexts residing on the same security engine share and compete for the engine's free CPU, disk, and memory resources. To prevent one context from occupying too many resources, assign CPU, disk space resources, and memory space resources to the contexts. To assign resources to a context, specify a CPU weight, disk space percentage, and memory space percentage for the context.

Specifying a CPU weight for a context

About this task

When the CPU resources on a security engine cannot meet the processing requirements from contexts, the system allocates CPU resources on the engine as follows:

1. Identifies the CPU weights of all contexts on the engine.
2. Calculates the percentage of each context's CPU weight among the CPU weights of all contexts.
3. Allocates CPU resources to contexts based on their CPU weight percentages.

For example, three contexts share the same CPU. You can assign a weight of 2 to the key context and a weight of 1 to each of the other two contexts. When the system is running out of CPU resources, the key context can use approximately two times of the CPU resources that each of the other two contexts can use.

Procedure

1. Enter system view.

   `system-view`
2. Enter context view.

   `context` *`context-name`*

3. Specify a CPU weight for the context.

   limit-resource cpu weight *weight-value*

   By default, each context has a CPU weight of 10.

Specifying a memory space percentage for a context

Restrictions and guidelines

To prevent a context from start failures because of memory space insufficiency, specify a memory space percentage for the context after the context has started correctly.

After the context starts, make sure the configured memory space limit meets the memory space needs of the services provided by the context.

Procedure

1. Enter system view.

   system-view

2. Enter context view.

   context *context-name*

3. Display the amount of memory space that has been used by the context.

   display context resource memory

4. Specify a memory space percentage for the context.

   limit-resource memory slot *slot-number* **cpu** *cpu-number* **ratio** *limit-ratio*

   By default, all contexts share the memory space in the system. A context can use all free memory space.

Accessing a context

About this task

From the system view of the default context, you can log in to a non-default context and enter the context's user view.

You can also access a context by using Telnet and SSH.

Procedure

1. Enter system view.

   system-view

2. Log in to a context.

   switchto context *context-name*

   To return to the default context, use the **quit** command.

Configuring inbound rate limiting for contexts

Configuring inbound broadcast rate limiting

About this task

Inbound broadcast rate limiting controls the rates of incoming broadcast packets on contexts. This feature can prevent a context from using too many resources and degrading the service processing capabilities of other contexts.

Inbound broadcast rate limiting uses the following types of limits:

- **Per-context broadcast rate limit**—Limit on the rate of incoming broadcast packets on a single context.
- **Total broadcast rate limit**—Limit on the total rate of incoming broadcast packets on all contexts.

When both a per-context broadcast rate limit and the total broadcast rate limit are reached, the device drops subsequent broadcast packets that arrive at the context.

Restrictions and guidelines

This feature applies only to inbound broadcast packets.

This feature takes effect only on active contexts that share interfaces with other contexts.

Setting the total inbound broadcast rate limit to 0 disables the inbound broadcast rate limiting feature.

Procedure

1. Enter system view.
   system-view
2. Set the total inbound broadcast rate limit.
   context-capability inbound broadcast total pps *threshold*
   The default setting varies by device model. For more information, see the command reference.
3. Set the inbound broadcast rate limit for the default context.
   context-capability inbound broadcast single pps *threshold*
   By default, the inbound broadcast rate limit for the default context is the total rate limit divided by the number of active contexts that share interfaces with other contexts.
4. Enter the view of a non-default context.
   context *context-name*
5. Set the inbound broadcast rate limit for the context.
   context-capability inbound broadcast single pps *threshold*
   By default, the inbound broadcast rate limit for a non-default context is the total rate limit divided by the number of active contexts that share interfaces with other contexts.

Configuring inbound multicast rate limiting

About this task

Inbound multicast rate limiting controls the rates of incoming multicast packets on contexts. This feature can prevent a context from using too many resources and degrading the service processing capabilities of other contexts.

Inbound multicast rate limiting uses the following types of limits:

- **Per-context multicast rate limit**—Limit on the rate of incoming multicast packets on a single context.
- **Total multicast rate limit**—Limit on the total rate of incoming multicast packets on all contexts.

When both a per-context inbound multicast rate limit and the total inbound multicast rate limit are reached, the device drops subsequent multicast packets that arrive at the context.

Restrictions and guidelines

This feature applies only to inbound multicast packets.

This feature takes effect only on active contexts that share interfaces with other contexts.

Setting the total inbound multicast rate limit to 0 disables the inbound multicast rate limiting feature.

Procedure

1. Enter system view.
   system-view
2. Set the total inbound multicast rate limit.
   context-capability inbound multicast total pps *threshold*

   The default setting varies by device model. For more information, see the command reference.
3. Set the inbound multicast rate limit for the default context.
   context-capability inbound multicast single pps *threshold*

   By default, the inbound multicast rate limit for the default context is the total rate limit divided by the number of active contexts that share interfaces with other contexts.
4. Enter the view of a non-default context.
   context *context-name*
5. Set the multicast rate limit for the context.
   context-capability inbound multicast single pps *threshold*

   By default, the inbound multicast rate limit for a non-default context is the total rate limit divided by the number of active contexts that share interfaces with other contexts.

Enabling logging for packets dropped because of rate limiting

About this task

This logging feature generates and sends a log message to the information center when an incoming packet is dropped because of rate limiting on contexts. For more information about how the information center manages log messages, see information center configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enable logging for incoming packets dropped because of rate limiting on contexts.
   context-capability inbound drop-logging enable

   By default, logging is disabled for incoming packets that are dropped because of rate limiting on contexts.

Setting the CPU usage threshold per CPU core for attack prevention

About this task

Perform this task to set the CPU usage threshold per CPU core for all inbound packets from all contexts. The specified threshold applies to all inbound packets, including broadcast, unicast, and multicast packets.

If the shared queue in the driver is full when the total usage of a CPU core reaches the specified threshold, the system determines that an attack risk is present. Then, it takes the attack prevention action configured by using the **`attack-defense cpu-core action`** command until the attack risk is eliminated. For more information about the **`attack-defense cpu-core action`** command, see attack detection and prevention commands in *Security Command Reference*.

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280	Yes
NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	No

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Set the CPU usage threshold per CPU core for all inbound packets from all contexts for attack prevention.

   ```
   context-capability inbound unicast total cpu-usage threshold
   ```

   By default, the CPU usage threshold per CPU core is 95%.

Archiving log messages for contexts

About this task

This feature archives all files in the **logfile** directory and **diagfile** directory.

Procedure

To archive log messages for contexts, execute this command in the user view:

```
tar context [ name context-name ] log file filename
```

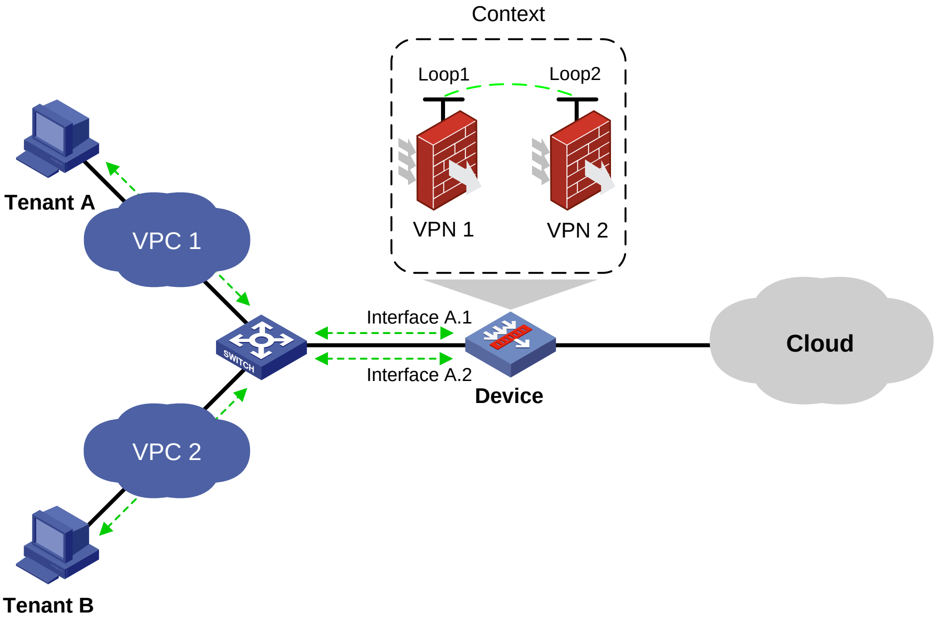
Configuring a context to support inter-VPC connectivity

About this task

In a virtual private cloud (VPC) scenario, the following tasks are required for tenant isolation and inter-VPC connectivity:

- Configure VPN instances, each of which corresponds to a VPC, thus isolating traffic of tenants in different VPCs.
- Configure static routes for the VPN instances to implement interconnectivity of VPCs. In the static routes, loopback interfaces are specified as the output interfaces.

Figure 2 Inter-VPC connectivity



Restrictions and guidelines

If a context is configured to support inter-VPC connectivity, make sure you configure only compatible related services on the context. Compatibility of related services with inter-VPC connectivity is as follows:

- Packet filtering services such as security policy are supported. However, services that will change the IP address of packets such as NAT and load balancing are not supported.
- Static routing is supported.

As a best practice, use subinterfaces for the device to communicate with tenants in VPCs.

Procedure

1. Enter system view.
   `system-view`
2. Create VPN instances and associate an interface with each VPN instance.
   For more information, see VPN instance configuration in *VPN Instance Configuration Guide*.
3. Configure static routes for the VPN instances and specify loopback interfaces as the output interfaces for the static routes.
   For more information, see static routing configuration and IPv6 static routing configuration in *Layer 3—IP Routing Configuration Guide*.

Display and maintenance commands for contexts

Execute **`display`** commands in any view on the default context.

Execute **`reset`** commands in user view on the default context.

Task	Command
Display contexts.	**display context** [**name** *context-name*] [**verbose**]
Display usage of allocable service resources for contexts.	**display context** [**name** *context-name*] **capability** [**security-policy** | **session** [**slot** *slot-number*] | **sslvpn-user**]
Display the inbound broadcast rate limit statitiscs for a context.	**display context name** *context-name* **capability inbound broadcast slot** *slot-number*
Display the inbound multicast rate limit statitiscs for a context.	**display context name** *context-name* **capability inbound multicast slot** *slot-number*
Display attack prevention statistics for CPU cores.	**display capability inbound unicast slot** *slot-number*
Display context configuration information.	**display context** [**name** *context-name*] **configuration** [**file** *filename*]
Display interfaces assigned to contexts.	**display context** [**name** *context-name*] **interface**
Display CPU, disk space, and memory usage of contexts.	**display context** [**name** *context-name*] **resource** [**cpu** | **disk** | **memory**] [**slot** *slot-number* **cpu** *cpu-number*]
Display resource statistics for contexts.	**display context** [**name** *context-name*] **statistics** [**file** *filename*]
Display non-default context reboot information.	**display context name** *context-name* **reboot** *show-number* [*offset*]
Display the number of online SSL VPN users on all contexts.	**display context online-users sslvpn**
Display VLAN lists for contexts.	**display context** [**name** *context-name*] **vlan**
Clear the inbound broadcast rate limit statistics for a context.	**reset context name** *context-name* **capability inbound broadcast slot** *slot-number*
Clear the inbound multicast rate limit statistics for a context.	**reset context name** *context-name* **capability inbound multicast slot** *slot-number*
Clear non-default context reboot information.	**reset context** [**name** *context-name*] **reboot**

Execute **display** commands in any view and **reset** commands in user view on a non-default context:

Task	Command
Display interfaces assigned to the context.	**display context** [**name** *context-name*] **interface**
Display reboot information about the current context.	**display context reboot** *show-number* [*offset*]
Clear reboot information about the current context.	**reset context reboot**

Context configuration examples

Example: Configuring contexts

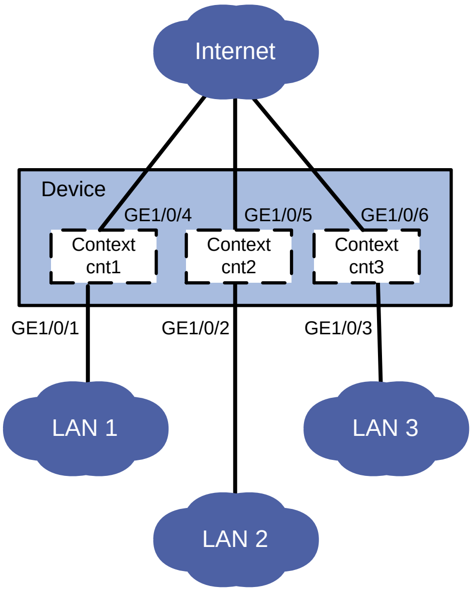
Network configuration

As shown in Figure 3, LAN 1, LAN 2, and LAN 3 use 192.168.1.0/24, 192.168.2.0/24, and 192.168.3.0/24, respectively.

Configure contexts for the LANs as follows:

- Configure context **cnt1** for LAN 1. Assign 60% disk space and 60% memory space to the context and set the CPU weight to 8.
- Configure context **cnt2** for LAN 2. Leave the context to use the default amount of disk space and the default amount of memory space.
- Configure context **cnt3** for LAN 3. Set the CPU weight to 2.

Figure 3 Network diagram



Procedure

1. Configure context **cnt1** for LAN 1.

   # Create a context named **cnt1** and configure a description for it.

   ```
   <Device> system-view
   [Device] context cnt1
   [Device-context-2-cnt1] description context-1
   ```

   # Set both the disk space percentage and memory space percentage to 60% and set the CPU weight to 8 for the context.

   ```
   [Device-context-2-cnt1] limit-resource disk slot 1 cpu 0 ratio 60

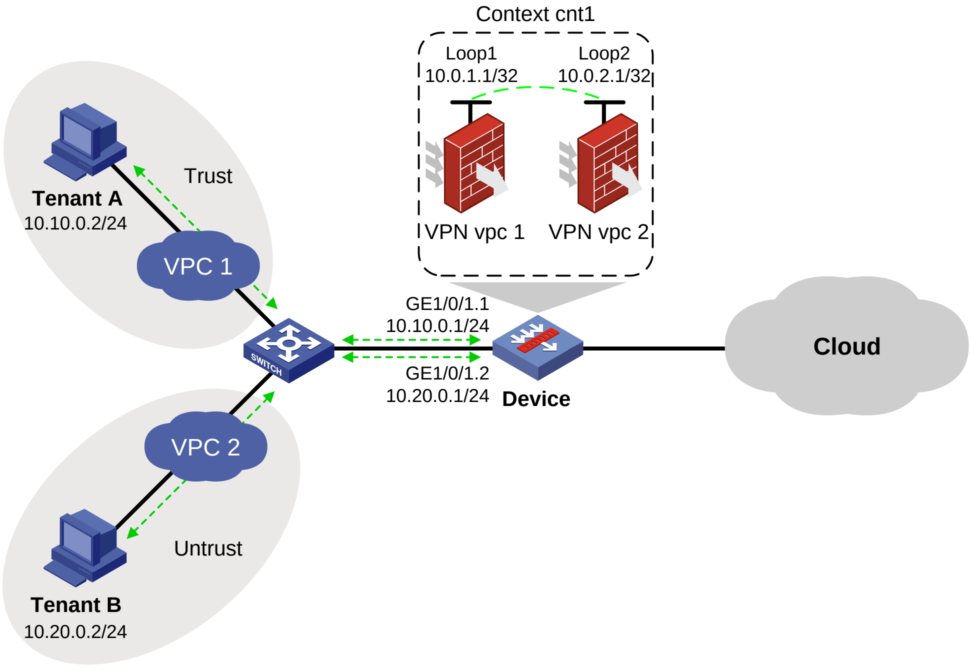
Example: Configuring a context to support inter-VPC connectivity

Network configuration

As shown in Figure 4, configure a context to provide security data access to the public cloud for tenants in VPCs as well as interconnectivity between the VPCs.

Figure 4 Network diagram



Procedure

1. Create a context.

   # Create context **cnt1**, and assign CPU, memory, disk space, and interface resources to the context. For more information, see "Example: Configuring contexts." (Details not shown.)

2. Log in to context **cnt1** from the default context.

   ```
   <Device> system-view
   [Device] switchto context cnt1
   ******************************************************************************
   * Copyright (c) 2004-2020 NSFOCUS. All rights reserved.                      *
   * Without the owner's prior written consent,                                 *
   * no decompiling or reverse-engineering shall be allowed.                    *
   ******************************************************************************

   <NSFOCUS> system-view
   ```

   # Configure Telnet to ensure that users can log in to the context. For more information, see login management configuration in *Fundamentals Configuration Guide*. (Details not shown.)

   # Set the name of context **cnt1** to **cnt1**.

   ```
   [NSFOCUS] sysname cnt1
   ```

3. Create VPN instances, and associate interfaces with the VPN instances.

   # Create VPN instances, configure loopback interfaces and Ethernet subinterfaces, and configure Ethernet subinterfaces to terminate VLAN-tagged packets with the specified outermost VLAN IDs.

   ```
   [cnt1] ip vpn-instance vpc1
   [cnt1-vpn-instance-vpc1] quit
   [cnt1] ip vpn-instance vpc2
   [cnt1-vpn-instance-vpc2] quit
   [cnt1] interface loopback 1
   [cnt1-LoopBack1] ip binding vpn-instance vpc1
   [cnt1-LoopBack1] ip address 10.0.1.1 255.255.255.255
   [cnt1-LoopBack1] quit
   [cnt1] interface loopback 2
   [cnt1-LoopBack2] ip binding vpn-instance vpc2
   [cnt1-LoopBack2] ip address 10.0.2.1 255.255.255.255
   [cnt1-LoopBack2] quit
   [cnt1] interface gigabitethernet 1/0/1.1
   [cnt1-GigabitEthernet 1/0/1.1] ip binding vpn-instance vpc1
   [cnt1-GigabitEthernet 1/0/1.1] ip address 10.10.0.1 255.255.255.0
   [cnt1-GigabitEthernet 1/0/1.1] vlan-type dot1q vid 10
   [cnt1-GigabitEthernet 1/0/1.1] quit
   [cnt1] interface gigabitethernet 1/0/1.2
   [cnt1-GigabitEthernet 1/0/1.2] ip binding vpn-instance vpc2
   [cnt1-GigabitEthernet 1/0/1.2] ip address 10.20.0.1 255.255.255.0
   [cnt1-GigabitEthernet 1/0/1.2] vlan-type dot1q vid 20
   [cnt1-GigabitEthernet 1/0/1.2] quit
   ```

4. Configure settings for routing.

   This example configures static routes to ensure that the VPCs can reach each other.

   ```
   [cnt1] ip route-static vpn-instance vpc1 10.20.0.0 24 loopback1 10.0.2.1
   [cnt1] ip route-static vpn-instance vpc2 10.10.0.0 24 loopback2 10.0.1.1
   ```

5. **Configure security zones.**

   # Add loopback interfaces and Ethernet subinterfaces to security zones.

```
[cnt1] security-zone name trust
[cnt1-security-zone-Trust] import interface loopback1
[cnt1-security-zone-Trust] import interface gigabitethernet 1/0/1.1
[cnt1-security-zone-Trust] quit
[cnt1] security-zone name untrust
[cnt1-security-zone-Untrust] import interface loopback2
[cnt1-security-zone-Untrust] import interface gigabitethernet 1/0/1.2
[cnt1-security-zone-Untrust] quit
```

6. **Configure a security policy to ensure that traffic can be forwarded between the VPCs.**

```
[cnt1] security-policy ip
[cnt1-security-policy-ip] rule name vpc1
[cnt1-security-policy-ip-0-vpc1] action pass
[cnt1-security-policy-ip-0-vpc1] vrf vpc1
[cnt1-security-policy-ip-0-vpc1] source-zone trust
[cnt1-security-policy-ip-0-vpc1] destination-zone untrust
[cnt1-security-policy-ip-0-vpc1] quit
[cnt1-security-policy-ip] rule name vpc2
[cnt1-security-policy-ip-1-vpc2] action pass
[cnt1-security-policy-ip-1-vpc2] vrf vpc2
[cnt1-security-policy-ip-1-vpc2] source-zone untrust
[cnt1-security-policy-ip-1-vpc2] destination-zone trust
[cnt1-security-policy-ip-1-vpc2] quit
[cnt1-security-policy-ip] quit
```

Verifying the configuration

# Ping Tenant B from Tenant A.

```
C:\> ping 10.20.0.2

Pinging 10.20.0.2 with 32 bytes of data:

Reply from 10.20.0.2: bytes=32 time=19ms TTL=254
Reply from 10.20.0.2: bytes=32 time<1ms TTL=254
Reply from 10.20.0.2: bytes=32 time<1ms TTL=254
Reply from 10.20.0.2: bytes=32 time<1ms TTL=254

Ping statistics for 10.20.0.2:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 0ms, Maximum = 19ms, Average = 4ms
```

The output shows that Tenant B can ping Tenant A.

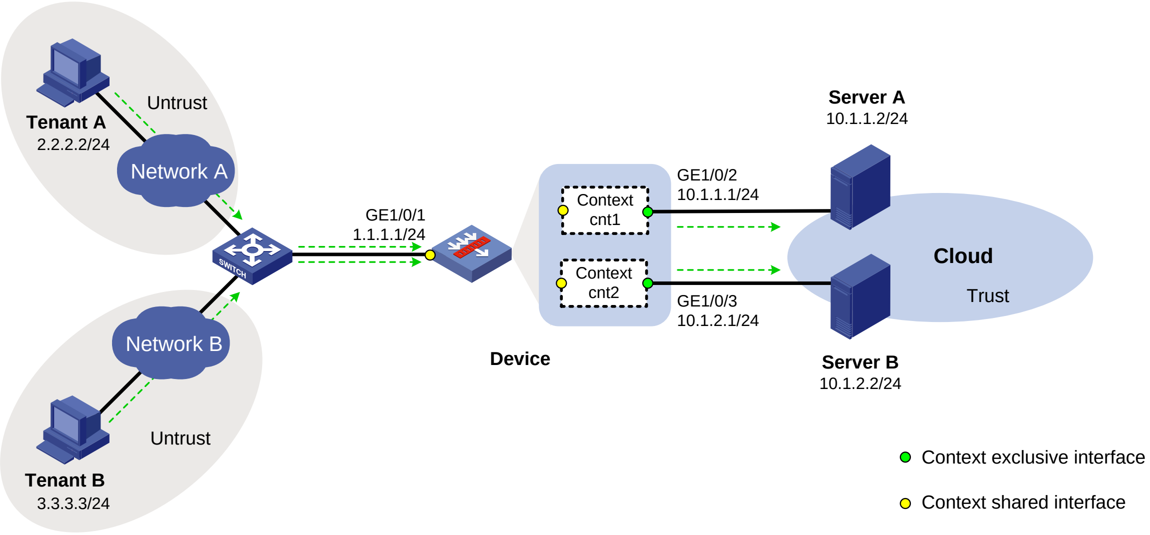
Example: Configuring contexts to act as gateways in a cloud computing center

Network configuration

As shown in Figure 5, Device is the gateway in the cloud computing center for internal information protection. The device has only one public network interface, which is GigabitEthernet 1/0/1. For Tenant A and Tenant B to independently access computing resources in the center, perform the following tasks:

- Create two contexts on the device, one is **cnt1** and the other is **cnt2**.
- Assign interfaces to the contexts for Tenant A and Tenant B to access the center.
  - Assign GigabitEthernet 1/0/1 to context **cnt1** in shared mode and GigabitEthernet 1/0/2 to the context in exclusive mode.
  - Assign GigabitEthernet 1/0/1 to context **cnt2** in shared mode and GigabitEthernet 1/0/3 to the context in exclusive mode.
- On the shared interface GigabitEthernet 1/0/1, configure a NAT internal server for Tenant A and Tenant B to use independent public IP addresses to access Server A and Server B, respectively.

Figure 5 Network diagram



Procedure

1. Assign an IP address to GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 1.1.1.1 24
[Device-GigabitEthernet1/0/1] quit
```

2. Create and configure context **cnt1** for Tenant A:

# Create context **cnt1** and configure a description for the context.

```
[Device] context cnt1
[Device-context-2-cnt1] description context-1
```

# Assign GigabitEthernet 1/0/1 to context **cnt1** in shared mode.

```
[Device-context-2-cnt1] allocate interface gigabitethernet 1/0/1 share
```

# Assign GigabitEthernet 1/0/2 to context **cnt1** in exclusive mode.

```
[Device-context-2-cnt1] allocate interface gigabitethernet 1/0/2
Configuration of the interfaces will be lost. Continue? [Y/N]:y
```

# Start context **cnt1**.

```
[Device-context-2-cnt1] context start
It will take some time to start the context...
Context started successfully.
[Device-context-2-cnt1] quit
```

# Log in to context **cnt1**.

```
[Device] switchto context cnt1
******************************************************************************
* Copyright (c) 2004-2021 NSFOCUS. All rights reserved.                      *
* Without the owner's prior written consent,                                 *
* no decompiling or reverse-engineering shall be allowed.                    *
******************************************************************************

<NSFOCUS> system-view
```

# Change the system name of the context to **cnt1**.

```
[NSFOCUS] sysname cnt1
```

# Assign IP address 10.1.1.1/24 to interface GigabitEthernet 1/0/2.

```
[cnt1] interface gigabitethernet 1/0/2
[cnt1-GigabitEthernet1/0/2] ip address 10.1.1.1 24
[cnt1-GigabitEthernet1/0/2] quit
```

# Assign interfaces GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to security zones **Untrust** and **Trust**, respectively.

```
[cnt1] security-zone name untrust
[cnt1-security-zone-Untrust] import interface gigabitethernet 1/0/1
[cnt1-security-zone-Untrust] quit
[cnt1] security-zone name trust
[cnt1-security-zone-Trust] import interface gigabitethernet 1/0/2
[cnt1-security-zone-Trust] quit
```

# Configure the IPv4 security policy to ensure that Tenant A can access Server A.

```
[cnt1] security-policy ip
[cnt1-security-policy-ip] rule name untrust-trust
[cnt1-security-policy-ip-0-untrust-trust] action pass
[cnt1-security-policy-ip-0-untrust-trust] source-zone untrust
[cnt1-security-policy-ip-0-untrust-trust] destination-zone trust
[cnt1-security-policy-ip-0-untrust-trust] source-ip-host 2.2.2.2
[cnt1-security-policy-ip-0-untrust-trust] destination-ip-host 10.1.1.2
[cnt1-security-policy-ip-0-untrust-trust] quit
[cnt1-security-policy-ip] quit
```

# Return to the default context from context **cnt1**.

```
[cnt1] quit
<cnt1> quit
[Device]
```

3. Create and configure context **cnt2** for Tenant B:

# Create context **cnt2** and configure a description for the context.

```
[Device] context cnt2
[Device-context-3-cnt2] description context-2
```

# Assign GigabitEthernet 1/0/1 to context **cnt2** in shared mode.

```
[Device-context-3-cnt2] allocate interface gigabitethernet 1/0/1 share
```

# Assign GigabitEthernet 1/0/3 to context **cnt2** in exclusive mode.

```
[Device-context-3-cnt2] allocate interface gigabitethernet 1/0/3
Configuration of the interfaces will be lost. Continue? [Y/N]:y
```

# Start context **cnt2**.

```
[Device-context-3-cnt2] context start
It will take some time to start the context...
Context started successfully.
[Device-context-3-cnt2] quit
```

# Log in to context **cnt2**.

```
[Device] switchto context cnt2
******************************************************************************
* Copyright (c) 2004-2021 NSFOCUS. All rights reserved.                      *
* Without the owner's prior written consent,                                 *
* no decompiling or reverse-engineering shall be allowed.                    *
******************************************************************************

<NSFOCUS> system-view
```

# Change the system name of the context to **cnt2**.

```
[NSFOCUS] sysname cnt2
```

# Assign IP address 10.1.2.1/24 to interface GigabitEthernet 1/0/3.

```
[cnt2] interface gigabitethernet 1/0/3
[cnt2-GigabitEthernet1/0/3] ip address 10.1.2.1 24
[cnt2-GigabitEthernet1/0/3] quit
```

# Assign interfaces GigabitEthernet 1/0/1 and GigabitEthernet 1/0/3 to security zones **Untrust** and **Trust**, respectively.

```
[cnt2] security-zone name untrust
[cnt2-security-zone-Untrust] import interface gigabitethernet 1/0/1
[cnt2-security-zone-Untrust] quit
[cnt2] security-zone name trust
[cnt2-security-zone-Trust] import interface gigabitethernet 1/0/3
[cnt2-security-zone-Trust] quit
```

# Configure the IPv4 security policy to ensure that Tenant B can access Server B.

```
[cnt2] security-policy ip
[cnt2-security-policy-ip] rule name untrust-trust
[cnt2-security-policy-ip-0-untrust-trust] action pass
[cnt2-security-policy-ip-0-untrust-trust] source-zone untrust
[cnt2-security-policy-ip-0-untrust-trust] destination-zone trust
[cnt2-security-policy-ip-0-untrust-trust] source-ip-host 3.3.3.3
[cnt2-security-policy-ip-0-untrust-trust] destination-ip-host 10.1.2.2
[cnt2-security-policy-ip-0-untrust-trust] quit
[cnt2-security-policy-ip] quit
```

# Return to the default context from context **cnt2**.

```
[cnt2] quit
<cnt2> quit
[Device]
```

4. On GigabitEthernet 1/0/1, configure a NAT internal server to allow the external network to access Server A by using address http://1.1.1.2:8080 and access Server B by using address http://1.1.1.3:8080.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] nat server protocol tcp global 1.1.1.2 8080 inside 10.1.1.2 http
[Device-GigabitEthernet1/0/1] nat server protocol tcp global 1.1.1.3 8080 inside 10.1.2.2 http
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

1. Verify that the contexts are created successfully and running correctly. The device has three contexts in active state.

```
[Device] display context
ID     Name             Status       Description
1      Admin            active       DefaultContext
2      cnt1             active       context-1
3      cnt2             active       context-2
```

2. Verify that Tenant A can access Server A by using address http://1.1.1.2:8080 and Tenant B can access Server B by using address http://1.1.1.3:8080.

Contents

Configuring Reth interfaces

About Reth interfaces

A redundant Ethernet (Reth) interface is a virtual Layer 3 interface that uses two member interfaces to ensure link availability. One member interface is active and the other is inactive. When the active interface fails, the inactive interface becomes active. The member interface switchover does not interrupt traffic.

Operating mechanism

A member interface of a Reth interface can be in either of the following states:

- **Active**—The interface can forward packets. A Reth interface can have only one active member interface.
- **Inactive**—The interface cannot forward packets.

A Reth interface determines the state of its member interfaces by using the following rules:

- When the member interfaces are physically up, the member interface with the higher priority is active. The other member interface is inactive. The priority of an interface is user configurable.
- When the member interfaces are physically down, both interfaces are inactive.
- When the active member interface goes down physically, the inactive interface automatically becomes active to forward packets.

If the Reth interface is added to a redundancy group, the member interface states are determined by the redundancy group. For more information, see "Configuring redundancy groups."

The switchover between the Reth member interfaces is not visible to the network and does not cause network topology changes. For the upstream and downstream devices, they are connected to the Reth interface and learn only the MAC address of the Reth interface.

Application scenario

The Reth interface feature is typically used with the redundancy group feature. For more information, see "Configuring redundancy groups."

Reth subinterfaces

To transmit and receive VLAN-tagged packets on a Reth interface, you can create subinterfaces for the Reth interface. A Reth subinterface is a Layer 3 logical interface and can be assigned an IP address. Packets from different VLANs can be forwarded by different Reth subinterfaces, which improves the interface efficiency and networking flexibility. For more information about VLAN-tagged packet processing on a Reth subinterface, see VLAN termination in *Layer 2—LAN Switching Configuration Guide*.

Restrictions: Hardware compatibility with Reth interface

Models	Reth interface compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Restrictions and guidelines: Reth interface configuration

During master/subordinate switchover in an IRF fabric, do not delete the aggregate interface from the Reth interface.

Configuring a Reth interface

Restrictions and guidelines: Reth interface configuration

Supported member interface types

A Reth interface can use the following interfaces and their subinterfaces as member interfaces:

- Layer 3 Ethernet interfaces.

IMPORTANT:

If a Layer 3 Ethernet interface is marked as a bypass interface on the panel or has the bypass feature enabled, do not use that interface as a member interface of a Reth interface. If you do so, communication errors will occur. For more information about the bypass feature, see "Configuring bridge forwarding."

- Layer 3 aggregate interfaces.

Member interface configuration

When you configure a Reth interface, follow these restrictions and guidelines:

- You can assign a maximum of two member interfaces to a Reth interface. The member interfaces must have different priorities.
- You cannot assign member interfaces to a Reth subinterface.
- You cannot assign subinterfaces or interfaces that have subinterfaces to a Reth interface if the Reth interface has Reth subinterfaces.
- You can assign an interface or subinterface to only one Reth interface.
- As a best practice, assign interfaces of the same type and speed to a Reth interface.
- If both member interfaces of a Reth interface are subinterfaces, make sure they are on different main interfaces and terminate the same VLAN ID. For more information about VLAN termination, see *Layer 2—LAN Switching Configuration Guide*.

- Do not specify a Reth interface as the outgoing interface in IPv6 static neighbor entries if its member interfaces contain subinterfaces. For more information about IPv6 static neighbor entries, see *Layer 3—IP Services Configuration Guide*.
- Settings made on the member interfaces of a Reth interface will not take effect until they are removed from the Reth interface.

Member interface deletion

Before you delete a Reth interface, make sure all its member interfaces have been removed.

Configuring basic parameters for a Reth interface

1. Enter system view.

   `system-view`

2. Create a Reth interface and enter its view.

   `interface reth` *`interface-number`*

   By default, no Reth interfaces exist.

3. Assign a member interface to the Reth interface.

   `member interface` *`interface-type interface-number`* **`priority`** *`priority`*

   By default, a Reth interface does not have member interfaces.

4. (Optional.) Configure the expected bandwidth for the Reth interface.

   `bandwidth` *`bandwidth-value`*

   By default, the expected bandwidth is 10000 kbps.

   The expected bandwidth is an informational parameter used only by higher-layer protocols for calculation. You cannot adjust the actual bandwidth of an interface by using this command.

5. (Optional.) Configure the description of the Reth interface.

   `description` *`text`*

   The default description of a Reth interface is *interface-name* **Interface** (for example, **Reth1 Interface**).

6. (Optional.) Set the MTU of the Reth interface.

   `mtu` *`size`*

   By default, the MTU of a Reth interface is 1500 bytes.

7. (Optional.) Assign a MAC address to the Reth interface.

   `mac-address` *`mac-address`*

   By default, Reth interfaces use the bridge MAC address of the device.

   Reth interfaces use the same default MAC address. To avoid communication errors, manually assign unique MAC addresses to the Reth interfaces.

8. Bring up the Reth interface.

   `undo shutdown`

   By default, a Reth interface is not manually shut down.

Setting the parameters for retransmitting advertisement messages after a Reth member interface switchover

About this task

After you configure the parameters for retransmitting advertisement messages, a Reth interface performs the following operations when a Reth member interface switchover occurs on it:

1. Sends advertisement messages (including gratuitous ARP messages and NA messages) to neighbors immediately.
2. Retransmits the advertisement messages according to the number of retransmissions and the retransmission interval you have configured.

Restrictions and guidelines

If a Reth interface has subinterfaces, the subinterfaces also send advertisement messages upon a Reth member interface switchover. To save CPU resources, the parameters for retransmitting advertisement messages take effect only on Reth interfaces. Reth subinterfaces are not controlled by these parameters.

Procedure

1. Enter system view.
   `system-view`
2. Set the parameters for retransmitting advertisement messages to neighbors after a Reth member interface switchover.
   `reth advertise retransmit` *`times`* **`interval`** *`seconds`*
   By default, after a Reth member interface switchover, a Reth interface retransmits advertisement messages to neighbors five times at an interval of 1 second.

Enabling fast traffic switchover on a Reth interface

About fast traffic switchover

IMPORTANT:

This feature introduces low possibility of forwarding traffic on the inactive member interface while the system is operating correctly. Make sure you understand this impact on your services when you use this feature.

This feature enables faster traffic switchover between Reth member interfaces than the standard switchover mechanism of Reth when the master device is powered off or reboots unexpectedly.

This feature implements fast switchover by allowing the inactive member interface to forward packets. In rare cases, the neighbor device might learn MAC address entries on the link connected to the inactive interface and sends traffic to the inactive interface.

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080	Yes
NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB680, NFNX3-HDB1080	No

Restrictions and guidelines

For this feature to take effect and operate effectively, follow these restrictions and guidelines:

- Make sure the Reth member interfaces are physical interfaces.
- Enable fast switchover on both the Reth interface for uplink traffic and the Reth interface for downlink traffic.
- Assign the downlink and uplink Reth interfaces to a redundancy group.

- Make sure the high-priority Reth member interfaces are on the master device (high-priority redundancy group node).
- To minimize the chance of receiving traffic on the inactive interface, use the **`arp timer aging`** command on the neighbor device to shorten the ARP entry aging timer.

Procedure

1. Enter system view.

   `system-view`

2. Enter Reth interface view.

   `interface reth` *`interface-number`*

3. Enable fast traffic switchover.

   `fast-switch enable`

   By default, fast traffic switchover is disabled.

Configuring a Reth subinterface

About this task

You can create Reth subinterfaces and configure VLAN termination on the Reth subinterfaces to process VLAN-tagged packets.

Restrictions and guidelines

When you configure a Reth subinterface, follow these restrictions and guidelines:

- To create a Reth subinterface, create the Reth interface first.
- You cannot create subinterfaces for a Reth interface in any of the following situations:
  - The members of the Reth interface are Layer 3 Ethernet subinterfaces or Layer 3 aggregate subinterfaces.
  - A minimum of one subinterface is created on the member interfaces of the Reth interface.

Procedure

1. Enter system view.

   `system-view`

2. Create a Reth subinterface and enter its view.

   `interface reth` *`interface-number.subnumber`*

   By default, no Reth subinterfaces exist.

   If the specified Reth subinterface already exists, this command enters the view of the Reth subinterface.

3. (Optional.) Configure the expected bandwidth for the Reth subinterface.

   `bandwidth` *`bandwidth-value`*

   By default, the expected bandwidth is 10000 kbps.

4. (Optional.) Configure a description for the Reth subinterface.

   `description` *`text`*

   The default description of a Reth subinterface is *interface-name* **Interface** (for example, **Reth1.1 Interface**).

5. (Optional.) Set the MTU of the Reth subinterface.

   `mtu` *`size`*

   By default, the MTU of a Reth subinterface is 1500 bytes.

6. Return to system view.

quit

7. Enter Reth interface view.
   interface reth *interface-number*
8. Enable subinterface rate statistics collection on the Reth interface.
   sub-interface rate-statistic

   By default, subinterface rate statistics collection is disabled on a Reth interface.

   After you execute this command, the device periodically refreshes subinterface rate statistics for the Reth interface. The statistics is displayed in the **Last 300 seconds input rate** and **Last 300 seconds output rate** fields of the command output from the **display interface reth** command.
9. Return to system view.
   quit
10. Enter Reth subinterface view.
    interface reth *interface-number.subnumber*
11. Bring up the Reth subinterface.
    undo shutdown

    By default, a Reth subinterface is not manually shut down.

Restoring default settings for a Reth interface or subinterface

Restrictions and guidelines

CAUTION:

The **default** command might interrupt ongoing network services. Make sure you are fully aware of the impacts of this command when you execute it on a live network.

This command might fail to restore the default settings for some commands for reasons such as command dependencies and system restrictions.

To resolve this issue:

1. Use the **display this** command in interface view to identify these commands.
2. Use their **undo** forms or follow the command reference to restore their default settings.
3. If the restoration attempt still fails, follow the error message instructions to resolve the issue.

Procedure

1. Enter system view.
   system-view
2. Enter a Reth interface or subinterface view.
   interface reth { *interface-number* | *interface-number.subnumber* }
3. Restore the default settings for the Reth interface.
   default

Displaying and maintaining Reth interfaces

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display Reth interface traffic statistics.	**display counters** { **inbound** | **outbound** } **interface** [**reth** [*interface-number*]]
Display traffic rate statistics for Reth interfaces in up state during the most recent statistics polling interval.	**display counters rate** { **inbound** | **outbound** } **interface** [**reth** [*interface-number*]]
Display Reth interface or subinterface information.	**display interface** [**reth** [*interface-number* | *interface-number.subnumber*]] [**brief** [**description** | **down**]]
Display information about the member interfaces of a Reth interface.	**display reth interface** *interface-type interface-number*
Clear statistics for Reth interfaces.	**reset counters interface** [**reth** [*interface-number*]]

Configuring redundancy groups

About redundancy groups

A redundancy group works on IRF fabrics. It allows traffic to enter and leave an IRF fabric through the same member device.

Operating mechanism of a redundancy group

As shown in Figure 1, a redundancy group has two redundancy group nodes. Each node is bound to an IRF member device.

A redundancy group node is a collection of objects on its bound IRF member device. The objects include member interfaces of Reth interfaces and individual physical Ethernet interfaces. The state of the objects is consistent with the state of the node.

In a redundancy group, one node is in primary state, and the other node is in secondary state. Only the primary node forwards traffic. When the primary node fails, the redundancy group switches over to the secondary node. This mechanism ensures path symmetry for traffic.

As shown in Figure 1, a redundancy group performs a switchover as follows:

1. When both IRF member devices are operating correctly, the redundancy group forwards traffic through Node 1 (Device A) and backs up services and data (such as NAT) to Node 2 (Device B).
2. When the upstream interface on Device A fails, the redundancy group shuts down the downstream interface on Device A and switches traffic over to Device B.

Figure 1 Redundancy group operating mechanism

IRF link
Device B
①
③ Downstream interface down(redundancy down)
①
④
IP network
Traffic forwarding path (upstream interface on Node 1 is up)
Traffic forwarding path (upstream interface on Node 1 is down)

Redundancy group node states

A redundancy group node can act as the primary or secondary node. Only the primary node can forward traffic.

When both nodes are operating correctly, the primary node is selected in the following order:

1. The node with higher node priority.
2. The node with smaller ID if the two nodes have the same priority.

When the primary node fails, the secondary node takes over the primary role to forward traffic. For more information about the state monitoring and switchover mechanisms, see "Redundancy group switchover."

Redundancy group members

Application scenarios of redundancy group members

Redundancy group members can be physical Ethernet interfaces and Reth interfaces that are located on the IRF member devices bound to the group's nodes.

You can assign physical Ethernet interfaces or Reth interfaces to a redundancy group for symmetric traffic forwarding, as shown in Table 1.

Table 1 Application scenarios of physical Ethernet interfaces and Reth interfaces

Member type	Application scenarios	Supported interfaces
Physical Ethernet interfaces	Dynamic routing protocols run between the IRF fabric and its upstream and downstream devices.	Layer 2 Ethernet interfaces. Later 3 Ethernet interfaces.
Reth interfaces	No dynamic routing protocol runs between the IRF fabric and its upstream and downstream devices.	A Reth interface can use the following interfaces and their subinterfaces as member interfaces: • Layer 3 Ethernet interfaces. • Layer 3 aggregate interfaces.

Using physical Ethernet interfaces in a redundancy group

You assign physical Ethernet interfaces to a redundancy group by binding them to their respective redundancy group nodes.

For symmetric traffic switchover, you must bind a minimum of one downlink interface and a minimum of one uplink interface with each node of the redundancy group.

The state of the member physical Ethernet interfaces changes with the state of the redundancy group nodes. Only the member interfaces on the primary node can forward traffic.

As shown in Figure 2, Interface A1 and Interface A2 are on Node 1, and Interface B1 and Interface B2 are on Node 2. When Node 1 is in primary state, Interface A1 and Interface A2 are up to forward traffic, while Interface B1 and Interface B2 do not forward traffic.

When Interface A1 goes down, the Reth module places Node 1 in secondary state. Node 2 changes to the primary state, and Interface B1 and Interface B2 take over to forward traffic, as shown in Figure 3.

Figure 2 States of the member interfaces when both nodes are operating correctly

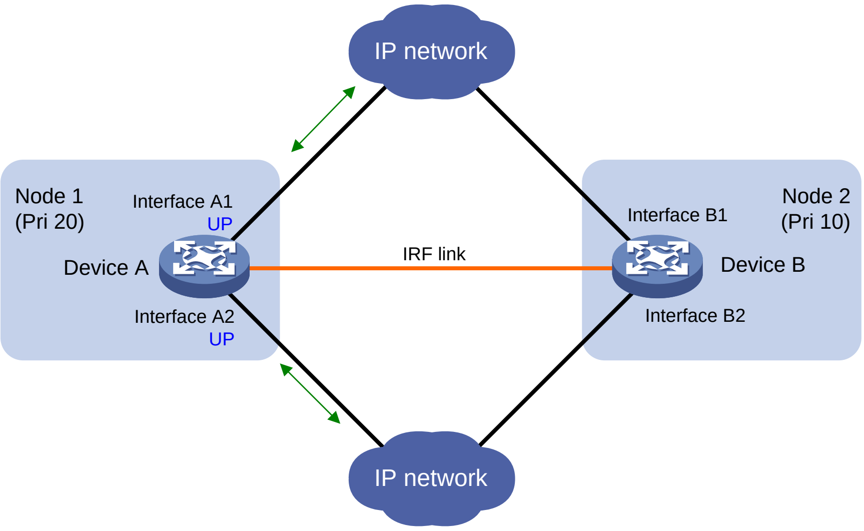

Figure 3 States of the member interfaces after a switchover

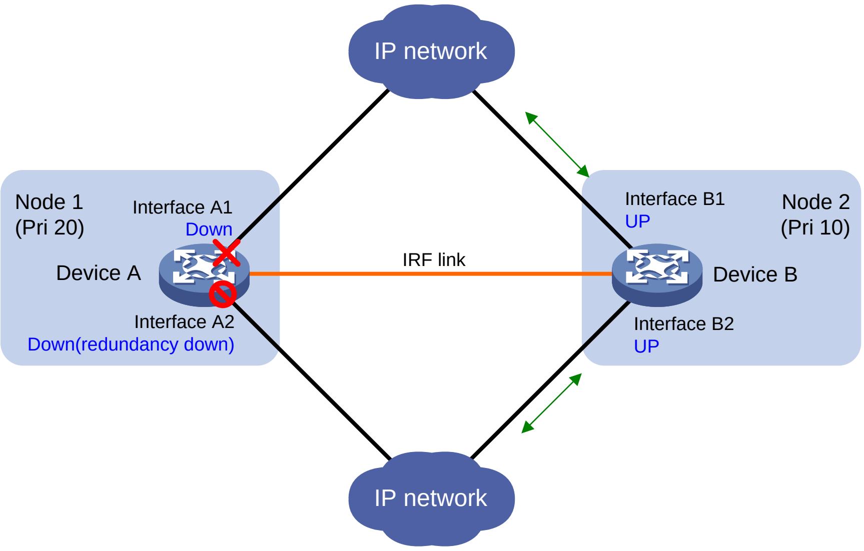

Using Reth interfaces in a redundancy group

To use Reth interfaces for symmetric forwarding, you must assign two Reth interfaces to a redundancy group: one for uplink traffic and the other for downlink traffic. The Reth interfaces must meet the following requirements:

- The Reth interface for uplink traffic contains one uplink port on each redundancy group node.
- The Reth interface for downlink traffic contains one downlink port on each redundancy group node.
- The high-priority member of each Reth interface belongs to the high-priority node.

The state of each Reth interface's members depends on the state of the redundancy group nodes.

- When the high-priority node is in primary state, the high-priority member is active.
- When the low-priority node is in primary state, the low-priority member is active.

As shown in Figure 4, redundancy group 1 contains Reth 1 for uplink traffic and Reth 2 for downlink traffic. Reth 1 contains Interface A1 (on Node 1) and Interface B1 (on Node 2). Reth 2 contains Interface A2 (on Node 1) and Interface B2 (on Node 2).

When Node 1 is in primary state, Interface A1 in Reth 1 and Interface A2 in Reth 2 are active to forward uplink and downlink traffic, respectively.

When Interface A1 fails, the Reth module places Node 1 in secondary state and shuts down Interface A2, as shown in Figure 5. Node 2 changes to the primary state, and Interface B1 and Interface B2 become active to forward uplink and downlink traffic.

Figure 4 States of each Reth interface's members when both nodes are operating correctly

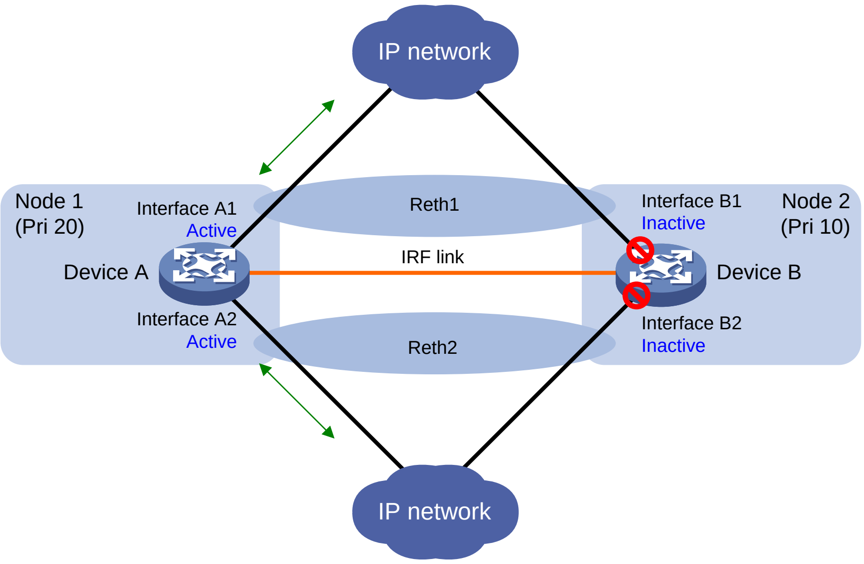

Figure 5 States of each Reth interface's members after a switchover

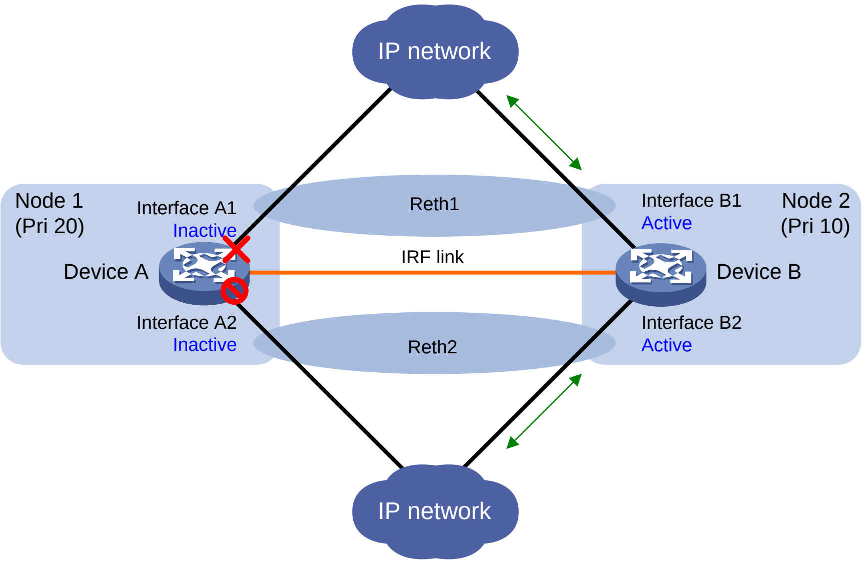


Redundancy group switchover

Switchover types

Redundancy group switchovers include automatic switchovers and manual switchovers.

Automatic switchover timers

Timers for automatic switchovers include the hold-down timer and the preemption delay timer.

- **Hold-down timer**—The hold-down timer specifies the minimum interval between two switchovers to prevent frequent switchovers. The timer starts when a switchover is finished. The redundancy group can perform the next switchover only after the hold-down timer expires.
- **Preemption delay timer**—The preemption delay timer specifies the delay for a switchover back to the high-priority node. The preemption delay timer starts when the switchover is triggered. The redundancy group performs the switchover only after the timer expires. The delay allows the system to process events (such as interface state changes) required for the switchover.

Automatic switchover

A redundancy group cooperates with the Track module to monitor link and interface status for automatic switchovers.

A redundancy group node has a weight of 255 (not configurable). Each redundancy group node is associated with one or multiple track entries that have a user-configurable weight decrement rate. When the state of a track entry changes, the weight of the associated node is reduced or increased, as follows:

- When the track entry changes to the **NotReady** or **Negative** state, the node weight is reduced by the weight decrement rate of the track entry.
- When the track entry changes to the **Positive** state, the node weight is increased by the weight decrement rate of the track entry.

When the node weight decreases to 0 or a lower value, a switchover request is triggered.

- Switchover to the low-priority node occurs when the hold-down timer expires.
- Switchover to the high-priority node occurs when the preemption delay timer expires.

Manual switchover

You can issue a manual switchover request in one of the following situations:

- An automatic switchover to the high-priority node cannot be performed when no tracked interfaces are excluded from the shutdown action by the Reth module.
- Switchovers are required when both redundancy group nodes operate correctly. For example, component replacement is required on the high-priority node.

Automatic switchover to the high-priority node is not allowed if the preemption delay timer is set to 0, even when both nodes are operating correctly. You can perform only manual switchover.

Restrictions: Hardware compatibility with redundancy group

Models	Redundancy group compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	Yes
NFNX3-HDB680, NFNX3-HDB1080	No

Redundancy group configuration tasks at a glance

To configure a redundancy group, perform the following tasks:

1. Creating a redundancy group

2. Configuring a redundancy group node
3. Assigning members to the redundancy group
   - Assigning physical Ethernet interfaces to a redundancy group

     This task is applicable to the network scenario where a dynamic routing protocol runs between the IRF fabric and its upstream and downstream devices.
   - Assigning Reth interfaces to a redundancy group

     This task is applicable to the network scenario where no dynamic routing protocol runs between the IRF fabric and its upstream and downstream devices.
4. Configuring the switchover timers
5. (Optional.) Performing a manual switchover
6. (Optional.) Performing a manual switchover back to the high-priority node
7. (Optional.) Enabling SNMP notifications for redundancy groups

Creating a redundancy group

Restrictions and guidelines

Before you delete a redundancy group, you must remove all its Reth interfaces and redundancy group nodes.

Procedure

1. Enter system view.

   `system-view`
2. Create a redundancy group and enter its view.

   `redundancy group` *`group-name`*

   By default, no redundancy groups exist.

Configuring a redundancy group node

Restrictions and guidelines

You can configure a maximum of two nodes for a redundancy group. Nodes in different redundancy groups can use the same ID.

You can bind a redundancy group node to one IRF member device. An IRF member device cannot be bound to multiple redundancy group nodes. You cannot change the binding for a node if it has member interfaces or is associated with track entries.

When you associate a track entry with a redundancy group node, follow these restrictions and guidelines:

- You cannot associate a track entry with both nodes in a redundancy group.
- For correct interface state recovery, you must exclude a tracked interface from the shutdown action by the Reth module if the interface has one of the following roles:
  - Member interface in the redundancy group.
  - Member of a Reth interface in the redundancy group.
- On the high-priority node, do not exclude a subinterface from the shutdown action by the Reth module if its main interface has one of the following roles:
  - Member interface of the redundancy group.
  - Member of a Reth interface in the redundancy group.

When the Reth module shuts down the main interface, the subinterface is also shut down. The shutdown subinterface cannot recover automatically to trigger an automatic switchover.

Prerequisites

Before you associate a track entry with a redundancy group, you must configure the track entry. For more information about configuring track entries, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter redundancy group view.

   redundancy group *group-name*

3. Create a redundancy group node and enter its view.

   node *node-id*

   By default, no redundancy group nodes exist.

4. Set the priority of the redundancy group node.

   priority *priority*

   By default, the priority of a redundancy group node is 1.

5. Bind the redundancy group node with an IRF member device.

   bind slot *slot-number*

   By default, a node is not bound with an IRF member device.

6. Associate an existing track entry with the redundancy group node.

   track *track-entry-number* [**reduced** *weight-reduced*] [**interface** *interface-type interface-number*]

   By default, a node is not associated with track entries.

Assigning physical Ethernet interfaces to a redundancy group

Restrictions and guidelines

For symmetric traffic switchover, you must bind a minimum of one uplink interface and a minimum of one downlink interface with each node of the redundancy group.

You can bind a physical Ethernet interface with only one redundancy group node.

You cannot bind a member of a Reth interface with a redundancy group node.

Procedure

1. Enter system view.

   system-view

2. Enter redundancy group view.

   redundancy group *group-name*

3. Enter redundancy group node view.

   node *node-id*

4. Bind a physical Ethernet interface with the redundancy group node.

   node-member interface *interface-type interface-number*

   By default, a physical Ethernet interface is not bound with a redundancy group node.

Assigning Reth interfaces to a redundancy group

Restrictions and guidelines

To use Reth interfaces for symmetric forwarding, you must assign two Reth interfaces to a redundancy group: one for uplink traffic and the other for downlink traffic. The Reth interfaces must meet the following requirements:

- The Reth interface for uplink traffic contains one uplink port on each redundancy group node.
- The Reth interface for downlink traffic contains one downlink port on each redundancy group node.
- The high-priority member of each Reth interface belongs to the high-priority node.

Procedure

1. Enter system view.

   `system-view`

2. Create a Reth interface and enter its view.

   `interface reth` *`interface-number`*

3. Assign a member interface to the Reth interface.

   `member interface` *`interface-type interface-number`* **`priority`** *`priority`*

   By default, a Reth interface does not have member interfaces.

   Repeat this step to assign two member interfaces to the Reth interface. Assign a higher priority for the *`priority`* argument to the member interface on the high-priority redundancy node.

4. Return to system view.

   `quit`

5. Enter redundancy group view.

   `redundancy group` *`group-name`*

6. Assign the Reth interface to the redundancy group.

   `member interface reth` *`interface-number`* `[` **`quick-fallback`** `]`

   By default, a redundancy group does not contain Reth interfaces.

Configuring the switchover timers

1. Enter system view.

   `system-view`

2. Enter redundancy group view.

   `redundancy group` *`group-name`*

3. Set the hold-down timer for the redundancy group.

   `hold-down-interval` *`second`*

   By default, the hold-down timer is 1 second.

4. Set the preemption delay timer for the redundancy group.

   `preempt-delay seconds` *`sec`*

   By default, the preemption delay timer is 1 minute (60 seconds).

   If you set this timer to 0 seconds, automatic switchover to the high-priority node is disabled. You can perform only manual switchover.

Performing a manual switchover to the low-priority node

1. Enter system view.
   `system-view`
2. Enter redundancy group view.
   `redundancy group` *`group-name`*
3. Request a switchover to the low-priority node.
   `switchover request`

Performing a manual switchover back to the high-priority node

1. Enter system view.
   `system-view`
2. Enter redundancy group view.
   `redundancy group` *`group-name`*
3. Request a switchover back to the high-priority node.
   `switchover reset`

Enabling SNMP notifications for redundancy groups

About this task

This feature enables SNMP notifications for the following events:

- A manual switchover is performed.
- An interface goes down.
- A faulty interface is recovered.

To send the event notifications to an NMS, you must also configure SNMP as described in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Enable SNMP notifications for redundancy groups.
   `snmp-agent trap enable rddc`
   By default, SNMP notifications are enabled for redundancy groups.

Displaying and maintaining redundancy groups

Execute **`display`** commands in any view.

Task	Command
Display redundancy group information.	**display redundancy group** [*group-name*]

Redundancy group configuration examples

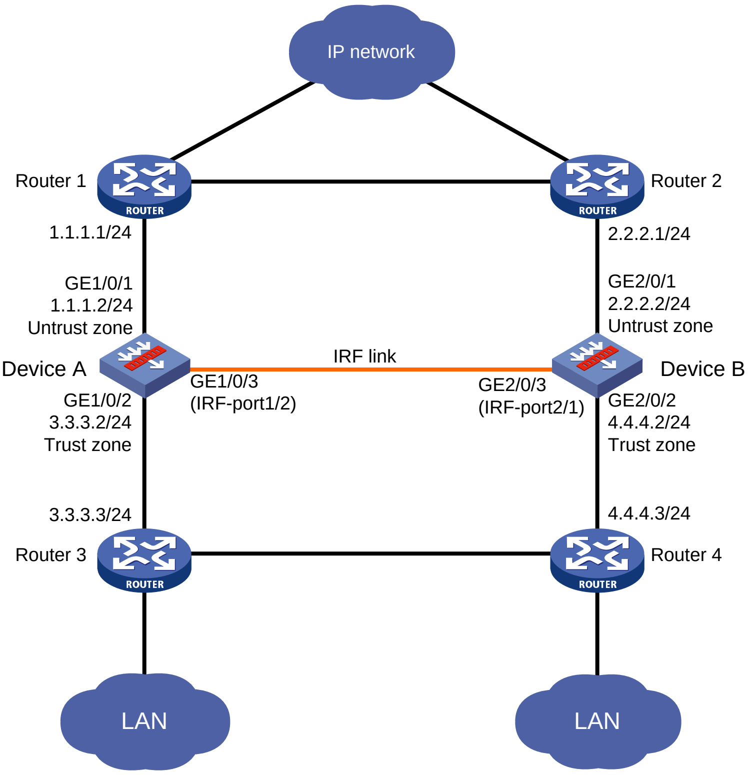
Example: Configuring a redundancy group with Layer 3 interface members

Network configuration

As shown in Figure 6, Device A (member ID 1) and Device B (member ID 2) form an IRF fabric.

Configure a redundancy group on the IRF fabric to ensure that traffic is forwarded along the Router 1—Device A—Router 3 path when the path is available. When a link or device failure occurs on the path, switch traffic to the Router 2—Device B—Router 4 path.

Figure 6 Network diagram



Procedure

1. Configure IRF:
   a. Configure Device A:

   # Bind GigabitEthernet 1/0/3 to IRF port 1/2, and save the configuration.

```
<DeviceA> system-view
[DeviceA] interface GigabitEthernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] shutdown
[DeviceA-GigabitEthernet1/0/3] quit
```

```
[DeviceA] irf-port 1/2
[DeviceA-irf-port1/2] port group interface GigabitEthernet 1/0/3
You must perform the following tasks for a successful IRF setup:
Save the configuration after completing IRF configuration.
Execute the "irf-port-configuration active" command to activate the IRF ports.
[DeviceA-irf-port1/2] quit
[DeviceA] interface GigabitEthernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] undo shutdown
[DeviceA-GigabitEthernet1/0/3] quit
[DeviceA] save
The current configuration will be written to the device. Are you sure? [Y/N]:y
Please input the file name(*.cfg)[flash:/startup.cfg]
(To leave the existing filename unchanged, press the enter key):irf-port-configu
ration active
The configuration file is invalid or not exist.
```

# Assign member priority 2 to Device A for it to becomes the IRF master, and activate the IRF port configuration.

```
[DeviceA] irf member 1 priority 2
[DeviceA] irf-port-configuration active
```

b. Configure Device B:

# Change the member ID of Device B to 2, and reboot the device to validate the change.

```
<DeviceB> system-view
[DeviceB] irf member 1 renumber 2
Renumbering the member ID may result in configuration change or loss. Continue?
[Y/N]:y
[DeviceB] quit
<DeviceB> reboot
Start to check configuration with next startup configuration file, please wait..
.......DONE!
This command will reboot the device. Continue? [Y/N]:y
```

# Connect Device B to Device A (see Figure 6).

# Log in to Device B. (Details not shown.)

# Bind GigabitEthernet 2/0/3 to IRF port 2/1, save the configuration, and activate the IRF port configuration.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 2/0/3
[DeviceB-GigabitEthernet2/0/3] shutdown
[DeviceB-GigabitEthernet2/0/3] quit
[DeviceB] irf-port 2/1
[DeviceB-irf-port2/1] port group interface GigabitEthernet 2/0/3
You must perform the following tasks for a successful IRF setup:
Save the configuration after completing IRF configuration.
Execute the "irf-port-configuration active" command to activate the IRF ports.
[DeviceB-irf-port2/1] quit
[DeviceB] interface GigabitEthernet 2/0/3
[DeviceB-GigabitEthernet2/0/3] undo shutdown
[DeviceB-GigabitEthernet2/0/3] quit
[DeviceB] save
```

```
[DeviceB] irf-port-configuration active
```

2. Create track entries to monitor the physical layer state of the interfaces.

```
<DeviceA> system-view
[DeviceA] track 1 interface gigabitethernet 1/0/1 physical
[DeviceA-track-1] quit
[DeviceA] track 2 interface gigabitethernet 1/0/2 physical
[DeviceA-track-2] quit
[DeviceA] track 3 interface gigabitethernet 2/0/1 physical
[DeviceA-track-3] quit
[DeviceA] track 4 interface gigabitethernet 2/0/2 physical
[DeviceA-track-4] quit
```

3. Configure a redundancy group:

# Create redundancy group **aaa** and create node 1 for the redundancy group.

```
[DeviceA] redundancy group aaa
[DeviceA] redundancy-group-aaa] node 1
```

# Bind node 1 to Device A.

```
[DeviceA-redundancy-group-aaa-node1] bind slot 1
```

# Set the priority of node 1 to 100.

```
[DeviceA-redundancy-group-aaa-node1] priority 100
```

# Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to node 1.

```
[DeviceA-redundancy-group-aaa-node1] node-member interface gigabitethernet 1/0/1
[DeviceA-redundancy-group-aaa-node1] node-member interface gigabitethernet 1/0/2
```

# Associate track entries 1 and 2 with node 1. Exclude GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 from the shutdown action by the Reth module.

```
[DeviceA-redundancy-group-aaa-node1] track 1 interface gigabitethernet 1/0/1
[DeviceA-redundancy-group-aaa-node1] track 2 interface gigabitethernet 1/0/2
[DeviceA-redundancy-group-aaa-node1] quit
```

# Create node 2 for redundancy group **aaa**.

```
[DeviceA] redundancy-group-aaa] node 2
```

# Bind node 2 to Device B.

```
[DeviceA-redundancy-group-aaa-node2] bind slot 2
```

# Set the priority of node 2 to 50.

```
[DeviceA-redundancy-group-aaa-node2] priority 50
```

# Assign GigabitEthernet 2/0/1 and GigabitEthernet 2/0/2 to node 2.

```
[DeviceA-redundancy-group-aaa-node2] node-member interface gigabitethernet 2/0/1
[DeviceA-redundancy-group-aaa-node2] node-member interface gigabitethernet 2/0/2
```

# Associate track entries 3 and 4 with node 2. Exclude GigabitEthernet 2/0/1 and GigabitEthernet 2/0/2 from the shutdown action by the Reth module.

```
[DeviceA-redundancy-group-aaa-node2] track 3 interface gigabitethernet 2/0/1
[DeviceA-redundancy-group-aaa-node2] track 4 interface gigabitethernet 2/0/2
[DeviceA-redundancy-group-aaa-node2] quit
[DeviceA-redundancy-group-aaa] quit
```

4. Assign IP addresses to interfaces:

# Assign an IP address to interface GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 1.1.1.2 255.255.255.0
[DeviceA-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

5. Configure settings for routing.

   This example configures static routes, and the next hops in the routes are 1.1.1.1, 2.2.2.1, 3.3.3.3, and 4.4.4.3.

```
[DeviceA] ip route-static 0.0.0.0 0 1.1.1.1
[DeviceA] ip route-static 0.0.0.0 0 2.2.2.1 preference 80
[DeviceA] ip route-static 5.5.5.0 24 3.3.3.3
[DeviceA] ip route-static 5.5.5.0 24 4.4.4.3 preference 80
```

6. Add interfaces to security zones.

```
[DeviceA] security-zone name untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] import interface gigabitethernet 2/0/1
[DeviceA-security-zone-Untrust] quit
[DeviceA] security-zone name trust
[DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceA-security-zone-Trust] import interface gigabitethernet 2/0/2
[DeviceA-security-zone-Trust] quit
```

7. Configure a security policy. Configure a rule named **trust-untrust** to permit the packets between the LANs and the external network.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-1-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-1-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-1-trust-untrust] source-ip-subnet 5.5.5.0 24
[DeviceA-security-policy-ip-1-trust-untrust] action pass
[DeviceA-security-policy-ip-1-trust-untrust] quit
[DeviceA-security-policy-ip] quit
```

Verifying the configuration

# Verify that node 1 is the primary node in redundancy group **aaa**. The member interfaces are up on both node 1 and node 2.

```
[DeviceA] display redundancy group aaa
Redundancy group aaa (ID 1):
  Node ID      Slot       Priority   Status        Track weight
  1            Slot1      100        Primary       255
  2            Slot2      50         Secondary     255

    4         Positive       255              GE2/0/2
```

Example: Configuring a redundancy group with Reth interface members

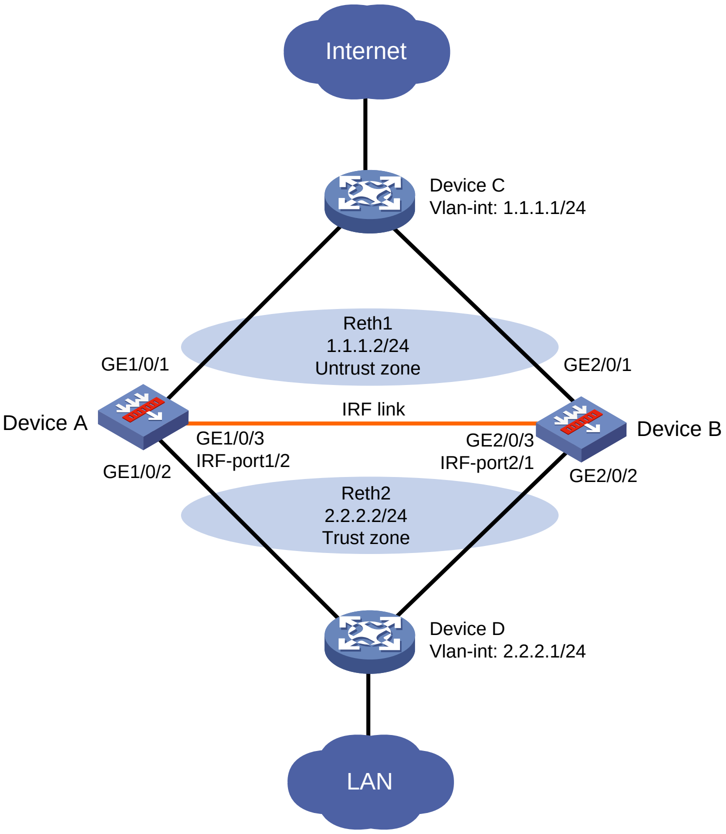
Network configuration

As shown in Figure 7, Device A (member ID 1) and Device B (member ID 2) form an IRF fabric. The IRF fabric connects to Device C and Device D through Reth 1 and Reth 2, respectively. Device C and Device D each use a VLAN interface to communicate with the IRF fabric.

Configure a redundancy group on the IRF fabric to ensure that traffic is forwarded along the Device C—Device A—Device D path when the path is available. When a link or device failure occurs on the path, traffic is switched to the Device C—Device B—Device D path.

This configuration example provides only redundancy group configuration. For more information about IRF fabric setup, see *Virtual Technologies Configuration Guide*.

Figure 7 Network diagram



Procedure

1. Configure IRF as described in "Example: Configuring a redundancy group with Layer 3 interface members."
2. Configure Reth interfaces:

   # Create Reth 1 and enter its view.

   ```
   <DeviceA> system-view
   [DeviceA] interface reth 1
   ```

   # Assign an IP address to Reth 1.

   ```
   [DeviceA-Reth1] ip address 1.1.1.2 24
   ```

# Assign GigabitEthernet 1/0/1 and GigabitEthernet 2/0/1 to Reth 1, and set their priority to 255 and 50, respectively.

```
[DeviceA-Reth1] member interface gigabitethernet 1/0/1 priority 255
[DeviceA-Reth1] member interface gigabitethernet 2/0/1 priority 50
[DeviceA-Reth1] quit
```

# Create Reth 2 and enter its view.

```
[DeviceA] interface reth 2
```

# Assign an IP address to Reth 2.

```
[DeviceA-Reth2] ip address 2.2.2.2 24
```

# Assign GigabitEthernet 1/0/2 and GigabitEthernet 2/0/2 to Reth 2, and set their priority to 255 and 50, respectively.

```
[DeviceA-Reth2] member interface gigabitethernet 1/0/2 priority 255
[DeviceA-Reth2] member interface gigabitethernet 2/0/2 priority 50
[DeviceA-Reth2] quit
```

3. Create track entries to monitor the link state of the interfaces.

```
[DeviceA] track 1 interface gigabitethernet 1/0/1 physical
[DeviceA-track-1] quit
[DeviceA] track 2 interface gigabitethernet 1/0/2 physical
[DeviceA-track-2] quit
[DeviceA] track 3 interface gigabitethernet 2/0/1 physical
[DeviceA-track-3] quit
[DeviceA] track 4 interface gigabitethernet 2/0/2 physical
[DeviceA-track-4] quit
```

4. Configure a redundancy group:

# Create redundancy group **aaa** and create node 1 for the redundancy group.

```
[DeviceA] redundancy group aaa
[DeviceA-redundancy-group-aaa] node 1
```

# Bind node 1 to Device A.

```
[DeviceA-redundancy-group-aaa-node1] bind slot 1
```

# Set the priority of node 1 to 100.

```
[DeviceA-redundancy-group-aaa-node1] priority 100
```

# Associate track entries 1 and 2 with node 1. Exclude GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 from the shutdown action by the Reth module.

```
[DeviceA-redundancy-group-aaa-node1] track 1 interface gigabitethernet 1/0/1
[DeviceA-redundancy-group-aaa-node1] track 2 interface gigabitethernet 1/0/2
[DeviceA-redundancy-group-aaa-node1] quit
```

# Create node 2 for redundancy group **aaa**.

```
[DeviceA-redundancy-group-aaa] node 2
```

# Bind node 2 to Device B.

```
[DeviceA-redundancy-group-aaa-node2] bind slot 2
```

# Set the priority of node 2 to 50.

```
[DeviceA-redundancy-group-aaa-node2] priority 50
```

# Associate track entries 3 and 4 with node 2. Exclude GigabitEthernet 2/0/1 and GigabitEthernet 2/0/2 from the shutdown action by the Reth module.

```
[DeviceA-redundancy-group-aaa-node2] track 3 interface gigabitethernet 2/0/1
[DeviceA-redundancy-group-aaa-node2] track 4 interface gigabitethernet 2/0/2
[DeviceA-redundancy-group-aaa-node2] quit
```

# Assign Reth 1 and Reth 2 to redundancy group **aaa**.

```
[DeviceA-redundancy-group-aaa] member interface reth 1
[DeviceA-redundancy-group-aaa] member interface reth 2
[DeviceA-redundancy-group-aaa] quit
```

5. Configure settings for routing.

   This example configures static routes, and the next hops in the routes are 1.1.1.1 and 2.2.2.1.

   ```
   [DeviceA] ip route-static 0.0.0.0 0 1.1.1.1
   [DeviceA] ip route-static 3.3.3.0 24 2.2.2.1
   ```

6. Add interfaces to security zones.

   ```
   [DeviceA] security-zone name untrust
   [DeviceA-security-zone-Untrust] import interface reth 1
   [DeviceA-security-zone-Untrust] quit
   [DeviceA] security-zone name trust
   [DeviceA-security-zone-Trust] import interface reth 2
   [DeviceA-security-zone-Trust] quit
   ```

7. Configure a security policy. Configure a rule named **trust-untrust** to permit the packets between the LAN and the external network.

   ```
   [DeviceA] security-policy ip
   [DeviceA-security-policy-ip] rule 1 name trust-untrust
   [DeviceA-security-policy-ip-1-trust-untrust] source-zone trust
   [DeviceA-security-policy-ip-1-trust-untrust] destination-zone untrust
   [DeviceA-security-policy-ip-1-trust-untrust] source-ip-subnet 3.3.3.0 24
   [DeviceA-security-policy-ip-1-trust-untrust] action pass
   [DeviceA-security-policy-ip-1-trust-untrust] quit
   [DeviceA-security-policy-ip] quit
   ```

Verifying the configuration

# Verify that node 1 is the primary node in redundancy group **aaa**.

```
[DeviceA] display redundancy group aaa
Redundancy group aaa (ID 1):
  Node ID   Slot     Priority  Status       Track weight
  Node1     Slot1    100       Primary      255
  Node2     Slot2    50        Secondary    255

Preempt delay time remained   : 0    min
Preempt delay timer setting   : 1    min
Remaining hold-down time      : 0    sec
Hold-down timer setting       : 300  sec
Manual switchover request     : No

Node 1:
  Track info:
    Track     Status        Reduced weight       Interface
    1         Positive      255                  GE1/0/1
    2         Positive      255                  GE1/0/2
Node 2:
  Track info:
    Track     Status        Reduced weight      Interface
    3         Positive      255                 GE2/0/1
    4         Positive      255                 GE2/0/2
```

# Verify that GigabitEthernet 1/0/1 of Reth 1 and GigabitEthernet 1/0/2 of Reth 2 are active.

```
[DeviceA] display reth interface reth 1
Reth1 :

NSFOCUS Firewall Series

NF Security Configuration Guide

NSFOCUS Technologies, Inc.

Document version: 6W600-20230221

Preface

- This configuration guide describes the fundamentals and configuration procedures for security features, including:
- Security zones, security policies, object groups, object policies, APR, and session management.
- User access and authentication features (such as AAA, portal, user identification, password control, and PKI).
- Data security features (such as public key management, SSL, SSH, and crypto engine).
- Attack protection features (such as ASPF, connection limit, IP source guard, ARP attack protection, ND attack defense, uRPF, attack detection and prevention, and IP-MAC binding).

This preface includes the following topics about the documentation:

- Audience.
- Conventions.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
(!) **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
💡 **TIP:**	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.

Convention	Description
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Contents

Configuring security zones

About security zones

You can configure security zones to implement security zone-based security management.

Basic concepts

The security zone feature includes the following basic concepts:

- **Security zone**—A security zone is a collection of interfaces that have the same security requirements.
- **System-defined security zones**—The device provides the following system-defined security zones: **Local**, **Trust**, **DMZ**, **Management**, and **Untrust**. The system creates these security zones automatically when one of following events occurs:
  - The first command for creating a security zone is executed.
  - The first command related to creating an interzone policy is executed.

  System-defined security zones cannot be deleted.
- **DMZ**—A demilitarized zone is a network that is separate from the internal network and the external network both logically and physically. Typically, a DMZ contains devices for the public to access, such as the Web servers and FTP servers.

Security zone-based packet processing rules

The following table describes how the device handles packets when security zone-based security management is configured:

Packets	**Action**
Packets between an interface that is in a security zone and an interface that is not in any security zone	Discard.
Packets between two interfaces that are in the same security zone	Discard by default.
Packets between two interfaces that belong to different security zones	Forward or discard, depending on the matching interzone policy. If no policy is applied or the policy does not exist or does not take effect, the packets are discarded. For more information, see "Creating a zone pair."
Packets between two interfaces that are not in any security zone	Discard.
Packets originated from or destined for the device itself	Forward or discard, depending on the matching interzone policy. By default, these packets are discarded.

Application scenarios

As a best practice, use security zone-based security management if the firewall is connected to multiple network segments or the network topology might change.

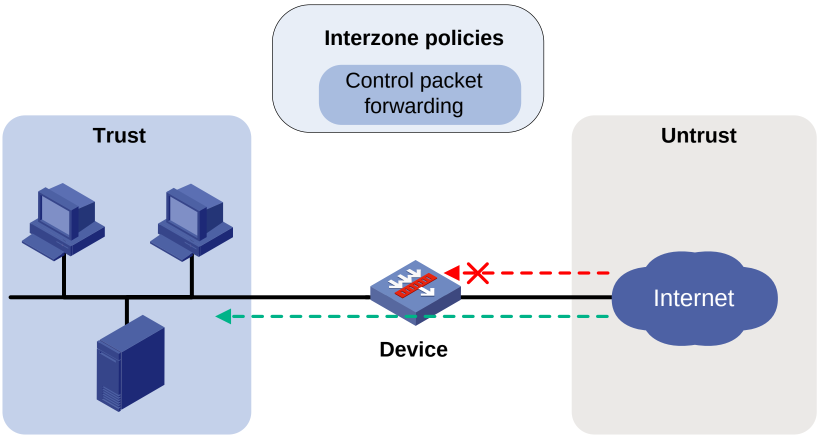
The traditional security management technology is based on interfaces. To filter packets, you must apply interzone policies on the inbound and outbound interfaces of a firewall. When the firewall is connected to multiple network segments, deploying interzone policies is time consuming and complicated. If the network topology changes, you might have to reconfigure interzone policies.

About interzone policies

Interzone policies identify data flows and control packet forwarding based on security zones, as shown in Figure 1. You can assign interfaces with the same security requirements to the same security zone, and assign interfaces with different security requirements to different security zones. For example, you can assign the interface connected to the internal network to security zone **trust**, and assign the interface connected to the Internet to security zone **Untrust**. Then, you can deploy interzone policies between the security zones to control packet forwarding.

If the network topology changes, you only need to change interface assignments. You do not need to modify the interzone policies.

Figure 1 Security zones and interzone policies



Interzone policy types

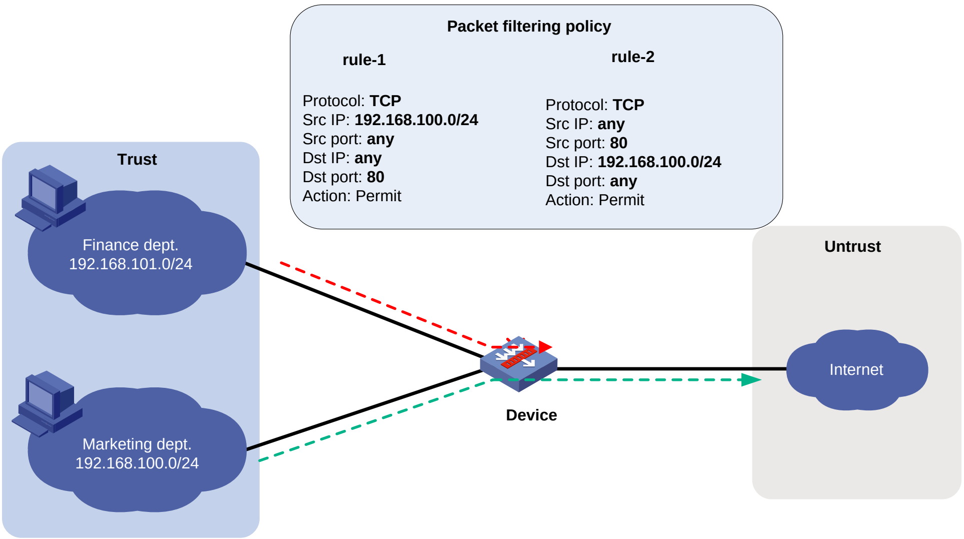
Interzone policies fall in to the following types: packet filtering, ASPF, and security policy. Packet filtering and ASPF can be applied on zone pairs. Security policies are based on security zones and are configured globally.

Packet filtering

Packet filtering controls packet forwarding between security zones by using packet quintuple information, including the source IP address, source port number, destination IP address, destination port number, and protocol number. For more information about packet filtering, see ACL configuration in *ACL and QoS Configuration Guide*.

As shown in Figure 2, to allow only employees in the Marketing department to access the Internet, configure **rule-1** and **rule-2**. The default rule denies access requests from the Finance department. Then, apply packet filtering policies to both directions of the **Trust**-**Untrust** zone pair.

Figure 2 Packet filtering

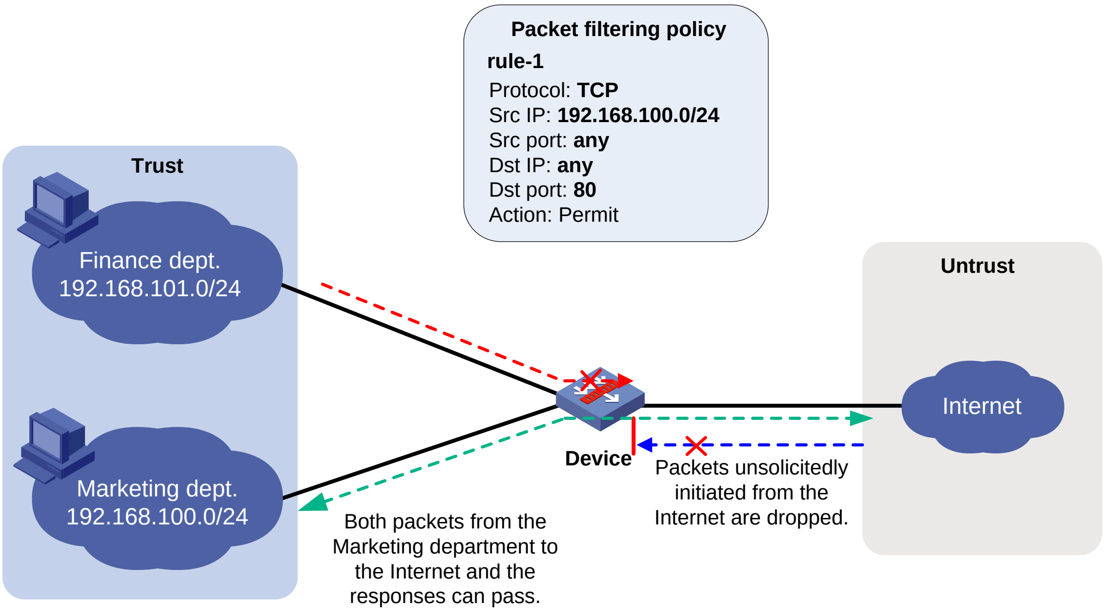


ASPF

Advanced Stateful Packet Filter (ASPF) records information about packets permitted by packet filtering policies to forward responses to the packets between security zones. For more information about ASPF, see "Configuring ASPF."

As shown in Figure 3, to allow only employees in the Marketing department to access the Internet, you can configure **rule-1** and ASPF. The default rule denies access requests from the Finance department but also denies responses to packets from the Marketing department. ASPF enables the device to forward responses to packets from the Marketing department to the Marketing department.

Figure 3 Packet filtering and ASPF

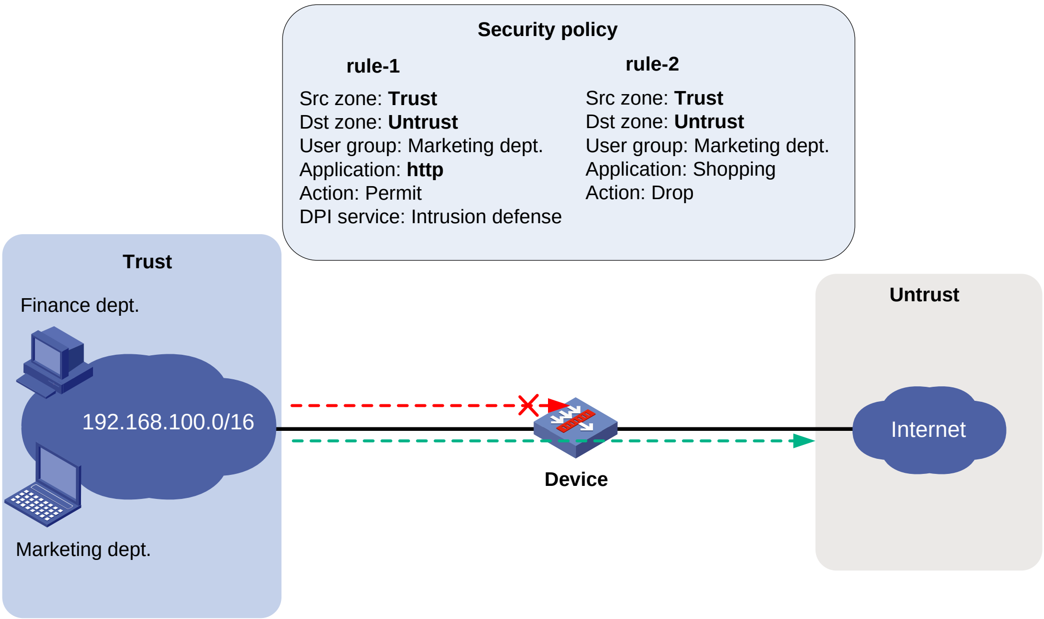


Security policy

Security policies are configured globally and take effect globally. They can be used not only to replace packet filtering, but also to control packet forwarding based on users and applications. Security policies can also use DPI application profiles to perform DPI for matching packets. For more information about security policies, see "Configuring security policies."

As shown in Figure 4, to allow only employees in the Marketing department to access the Internet and forbid access to shopping websites, configure a security policy. The security policy can also implement DPI on web pages. The default rule denies access requests from the Finance department.

Figure 4 Security policy application



Advantages of security policies

As described in "Interzone policy types," security policies have the following advantages over the other types of interzone policies:

- **More flexible and visible management**—Security policies can identify packets based on not only quintuple information but also users.
- **Precise and granular management**—Security policies can identify packets based on protocols (for example, HTTP) and applications (for example, webpage-based games, videos, and shopping).
- **DPI**—By partnering with DPI, it can also provide security protection services such as antivirus and intrusion protection.

Restrictions and guidelines: Security zone configuration

Security policies take precedence over packet filtering policies. Packets matching security policies are processed based on the security policies.

Security zone configuration tasks at a glance

To configure security zones, perform the following tasks:

- Creating a security zone
- Adding members to a security zone

- (Optional.) Specifying a permitted protocol
- Creating a zone pair
- (Optional.) Specifying the default action for packets between interfaces in the same security zone
- (Optional.) Enabling filtering based on virtual service IP address

Creating a security zone

1. Enter system view.
   system-view
2. Create a security zone and enter security zone view.
   security-zone name *zone-name*

   By default, the device has the following security zones: Local, Trust, DMZ, Management, and Untrust.

Adding members to a security zone

About this task

A security zone can include member types listed in Table 1.

Table 1 Security zone members and objects that the members identify

Security zone member	Objects that each member identifies
Layer 3 interface: • Layer 3 Ethernet interface • Layer 3 logical interface, such as a Layer 3 subinterface	All packets received or sent on the interface
Layer 2 interface-VLAN combination	All packets received or sent on the interface that carry the specified VLAN tag
VLAN	All packets that carry the specified VLAN tag. This type of security zones applies only to bridge forwarding. For more information about bridge forwarding, see bridge forwarding configuration in *Layer 2—LAN Switching Configuration Guide.*
IPv4 subnet	All packets sourced from or destined for the IPv4 subnet.
IPv6 subnet	All packets sourced from or destined for the IPv6 subnet.

If a security zone has multiple types of members, a packet is matched in the following order: subnet, interface, and VLAN. The match operation stops when the first matching member is found.

Hardware and feature compatibility

On the default context, only security zone Management has interfaces by default.

The following compatibility matrix shows the default interfaces for security zone Management:

Models	Default interfaces
NFNX5-HD6480, NFNX3-HDB1180, NFNX3-HDB1480	M-GigabitEthernet 1/0/0 M-GigabitEthernet 1/0/1

Models	Default interfaces
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080	M-GigabitEthernet 1/0/0
NFNX3-HDB680, NFNX3-HDB1080	GigabitEthernet 1/0/0 GigabitEthernet 1/0/2

Procedure

1. Enter system view.

   `system-view`

2. Enter security zone view.

   `security-zone name` *`zone-name`*

3. Add members to the security zone.

   Choose one option as needed:

   - Add a Layer 3 Ethernet interface.

     `import interface` *`layer3-interface-type layer3-interface-number`*

     By default, a security zone does not have Layer 3 Ethernet interface members.

     You can perform this step multiple times to add multiple Layer 3 Ethernet interface members.

   - Add Layer 2 interface-VLAN combinations.

     `import interface` *`layer2-interface-type layer2-interface-number`* **`vlan`** *`vlan-list`*

     By default, a security zone does not have Layer 2 interface-VLAN combination members.

     You can perform this step multiple times to add multiple Layer 2 interface-VLAN combination members.

   - Add VLANs.

     `import vlan` *`vlan-list`*

     By default, a security zone does not have VLAN members.

     You can perform this step multiple times to add multiple VLAN members.

   - Add an IPv4 subnet.

     `import ip` *`ip-address`* { *`mask-length`* | *`mask`* } [**`vpn-instance`** *`vpn-instance-name`*]

     By default, a security zone does not have IPv4 subnet members.

     You can perform this step multiple times to add multiple IPv4 subnet members.

   - Add an IPv6 subnet.

     `import ipv6` *`ipv6-address prefix-length`* [**`vpn-instance`** *`vpn-instance-name`*]

     By default, a security zone does not have IPv6 subnet members.

     You can perform this step multiple times to add multiple IPv6 subnet members.

Specifying a permitted protocol

About this task

By default, the device permits packets only between security zones **Local** and **Management**. It denies packets between security zone **Local** and other security zones. To permit packets of the specified protocols between security zone **Local** and other security zones, you can specify permitted protocols on interfaces or configure interzone policies.

After you specify a permitted protocol on an interface, the device will permit packets of the specified protocol from the device that is connected to the interface. The packets will not be limited based on security policies or traffic policies.

You can configure the **`manage`** command multiple times to specify multiple permitted protocols.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Specifying a permitted protocol.

   `manage` `{ {` **`http`** `|` **`https`** `|` **`ping`** `|` **`ssh`** `|` **`telnet`** `} {` **`inbound`** `|` **`outbound`** `} | {` **`netconf-http`** `|` **`netconf-https`** `|` **`netconf-ssh`** `|` **`snmp`** `}` **`inbound`** `}`

   By default, no permitted protocols are specified. The device permits packets only from other devices that are connected through interfaces in security zone **Management**.

Creating a zone pair

About this task

A zone pair has a source security zone and a destination security zone. The device examines received first data packets and uses zone pairs to identify data flows. Then, the device uses interzone policies applied to the matching zone pairs to process the data flows.

You can use the **`zone-pair security source any destination any`** command to define the any-to-any zone pair. This zone pair matches all packets from one security zone to another security zone. A zone pair between specific security zones has a higher priority than the any-to-any zone pair.

For packets between the **Management** and **Local** security zones, the device uses only interzone policies applied to the zone pairs of the two security zones. By default, the device forwards packets between the **Management** and **Local** zones.

Procedure

1. Enter system view.

   `system-view`

2. Create a zone pair and enter zone pair view.

   `zone-pair security source` `{` *`source-zone-name`* `|` **`any`** `}` **`destination`** `{` *`destination-zone-name`* `|` **`any`** `}`

Specifying the default action for packets between interfaces in the same security zone

About this task

The system uses the default action for packets that are exchanged between interfaces in the same security zone in the following situations:

- A zone pair from the security zone to the security zone itself is not configured.
- A zone pair from the security zone to the security zone itself is configured, but no interzone policy is applied to the zone pair.

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB680, NFNX3-HDB1080	Yes
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Specify the default action for packets exchanged between interfaces in the same security zone.
   - Set the default action to **permit**.

     ```
     security-zone intra-zone default permit
     ```

   - Set the default action to **deny**.

     ```
     undo security-zone intra-zone default permit
     ```

   By default, the default action is **deny**.

Enabling filtering based on virtual service IP address

About this task

This feature enables the device to filter packets from external networks to internal servers by virtual service IP address in scenarios where server load balancing is deployed. By default, this feature is disabled. Before matching each of the packets against ACLs, the device translates the destination IP address (the virtual service IP address) to the real server IP address. For more information about packet filtering, see ACL configuration in *ACL and QoS Configuration Guide*.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable filtering based on virtual service IP address for zone pairs.

   ```
   zone-pair vsip-filter enable
   ```

   By default, filtering based on virtual service IP address is disabled.

Display and maintenance commands for security zones

Execute **display** commands in any view.

Task	Command
Display security zone information.	**display security-zone** [**name** *zone-name*]
Display zone pair information.	**display zone-pair security**

Security zone configuration examples

Example: Configuring security zones

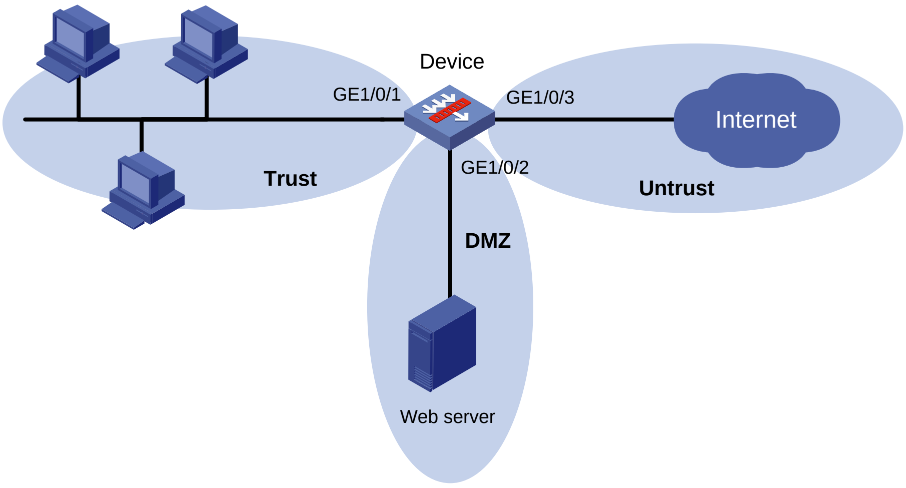
Network configuration

As shown in Figure 5, a security protection device (Device) connects the corporate network to the Internet. The corporate network needs to provide Web services for only internal users.

To ensure corporate network security, configure the device as follows:

- Assign GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 to security zones **Trust**, **DMZ**, and **Untrust**, respectively.
- Configure zone pairs and apply interzone policies to control access as follows:
  - Allow internal users to access the Web server and the Internet.
  - Forbid external users to access the internal network and the Web server.
  - Forbid the Web server to access the internal network.

Figure 5 Network diagram



Procedure

1. Assign IP address to the interfaces.

   # Assign an IP address to GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   ```

```
[Device-GigabitEthernet1/0/1] ip address 1.1.1.1 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/1
[Device-security-zone-Trust] quit
[Device] security-zone name dmz
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/2
[Device-security-zone-DMZ] quit
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/3
[Device-security-zone-Untrust] quit
```

3. Configure ACLs.

# Configure ACL 3001 to allow internal hosts to access the Internet.

```
[Device] acl advanced 3001
[Device-acl-ipv4-adv-3500] rule permit ip source 1.1.1.0 0.0.0.255 destination
3.3.3.0 0.0.0.255
[Device-acl-ipv4-adv-3500] quit
```

# Configure ACL 3002 to allow internal hosts to access the Web server.

```
[Device] acl advanced 3002
[Device-acl-ipv4-adv-3002] rule permit ip source 1.1.1.0 0.0.0.255 destination
2.2.2.0 0.0.0.255
[Device-acl-ipv4-adv-3500] quit
```

4. Configure zone pairs.

# Create a zone pair with the source security zone **Trust** and destination security zone **Untrust**. Apply ACL 3001 to the zone pair.

```
[Device] zone-pair security source trust destination untrust
[Device-zone-pair-security-Trust-Untrust] packet-filter 3001
[Device-zone-pair-security-Trust-Untrust] quit
```

# Create a zone pair with the source security zone **Trust** and destination security zone **DMZ**. Apply ACL 3002 to the zone pair.

```
[Device] zone-pair security source trust destination dmz
[Device-zone-pair-security-Trust-DMZ] packet-filter 3002
[Device-zone-pair-security-Trust-DMZ] quit
```

Verifying the configuration

# Verify that internal hosts can access the Internet and the Web server. (Details not shown.)

# Verify that access requests initiated from the Internet and the **DMZ** zone to the internal network are denied. (Details not shown.)

Contents

Configuring security policies

About security policies

A security policy defines a set of rules for forwarding control and Deep Packet Inspection (DPI). It matches packets against the rules and takes the action stated in the rules on the matched packets.

Security policy rules

A security policy contains one or multiple rules. Each security policy rule is a permit or deny, or DPI statement for identifying traffic based on criteria.

Rule numbering

Each rule is uniquely identified by a name and an ID. When you create a rule, the rule name must be manually configured, and the rule ID can be manually configured or automatically assigned by the system.

Rule match criteria

The rule match criteria include the following types: source security zone, destination security zone, source IP address and source MAC address, destination IP address, user and user group, application and application group, VPN instance, and service.

You can specify multiple criteria for each type, except VPN instance. For example, you can configure multiple source security zones for a rule.

Rule and session management

When a security policy is configured, the device generates session entries for permitted packets to record packet information.

You can set session aging times for protocol states, application layer protocols, or rules. The aging time configured for a rule takes precedence over the aging time configured for a protocol state or an application layer protocol. For more information about session management, see "Managing sessions."

Security policy mechanism

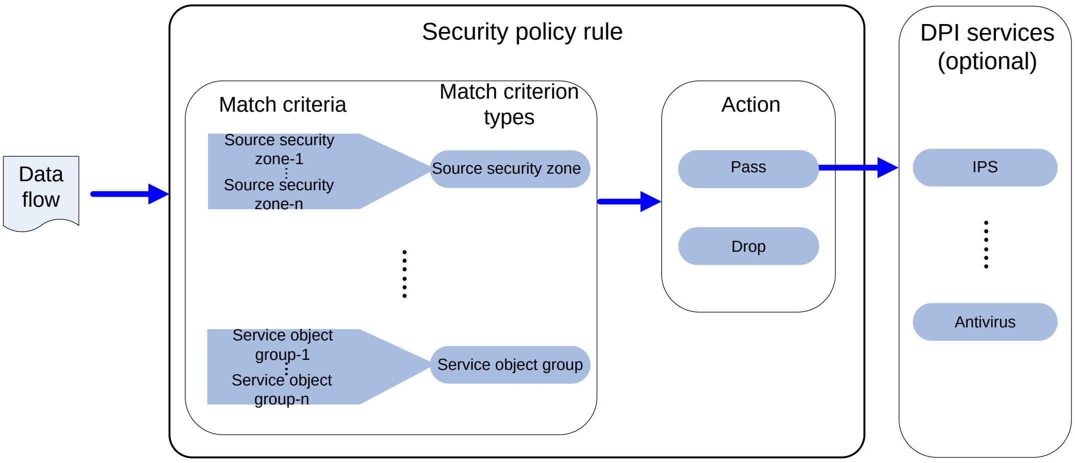
As shown in Figure 1, a security policy operates as follows:

1. After receiving a packet, the device matches the packet against the configured security policy rules.

   A security policy rule includes various match criterion types. A packet is considered matched if it matches all the criterion types in the rule. Each criterion type includes one or more criteria, and a packet matches a criterion type if it matches any criterion of the type. Source MAC address criteria and source IP address criteria belong to the same criterion type.

   - If no match is found, the device discards the packet.
   - If a match is found and the rule action is **drop**, the device discards the packet.
   - If a match is found and the rule action is **pass**, the device goes to the next step.
2. If a DPI application profile is configured for the matched rule, the device uses the specified profile to perform DPI on the packet. If no DPI application profile is specified, the device allows the packet to pass.

Figure 1 Security policy mechanism



Rule matching acceleration

This feature accelerates security policy rule matching to enhance connection establishment and packet forwarding performance, especially for a device using multiple rules to match packets from multiple users.

Security policy rule grouping

Security policy rule grouping allows users to enable, disable, delete, and move security policy rules in batches. A security policy rule in a security policy rule group takes effect only when both the rule and the group are enabled.

Application scenarios

Local device access

In a local access scenario, you must configure security policy rules for the following operations to be performed successfully:

- Local device access through a non-management local port, including ping, telnet, Web access, and FTP operations.
- Protocol packet exchange triggered by any other devices (such as packet exchanges of Dynamic Routing Protocol or VPN tunneling).

For example, as shown in Figure 2, for a PC (10.1.1.10) in the Trust security zone to access the Web interface of the local device (10.1.1.1) through HTTPS, you must configure a security policy rule as described in Table 1.

Figure 2 Local device access

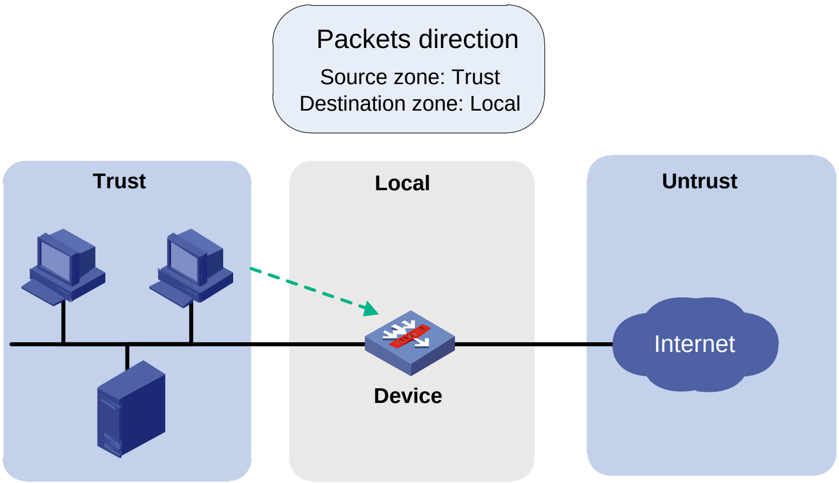


Table 1 Security policy rule configuration

Rule name	Source security zone	Destination security zone	Source IP address	Destination IP address	Service	Action
httpslocalin	Trust	Local	10.1.1.10	10.1.1.1	https	pass

For more information about permitting protocol packets, see "Common local services."

Remote device access

In a remote access scenario, you must configure security policy rules for the following operations to be performed successfully:

- Remote device access through a non-management local port, including ping, telnet, Web access, and FTP operations.
- Protocol packet exchange triggered by the local device (such as packet exchanges of Dynamic Routing Protocol or VPN tunneling).

For example, as shown in Figure 3, for the local device (10.1.1.1) to access the FTP service provided by the FTP server (10.1.1.20) in the Trust security zone, you must configure a security policy rule as described in Table 2.

Figure 3 Remote device access

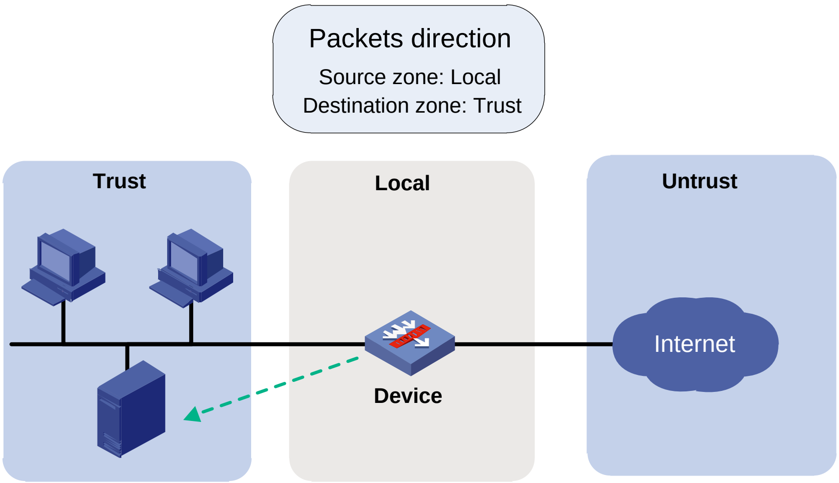

Table 2 Configuration of local device accessing other devices

Rule name	Source security zone	Destination security zone	Source IP address	Destination IP address	Service	Action
ftplocalout	Local	Trust	10.1.1.1	10.1.1.20	ftp	pass

Direct traffic forwarding

For the local device to forward traffic that is either sent from or destined to the local device, you must configure security policy rules to permit traffic from the corresponding security zones.

For example, as shown in Figure 4, for a PC (10.1.1.10) in the Trust zone to visit a website in the Untrust zone through HTTP, you must configure a security policy rule as shown in Table 3.

Figure 4 Direct traffic forwarding

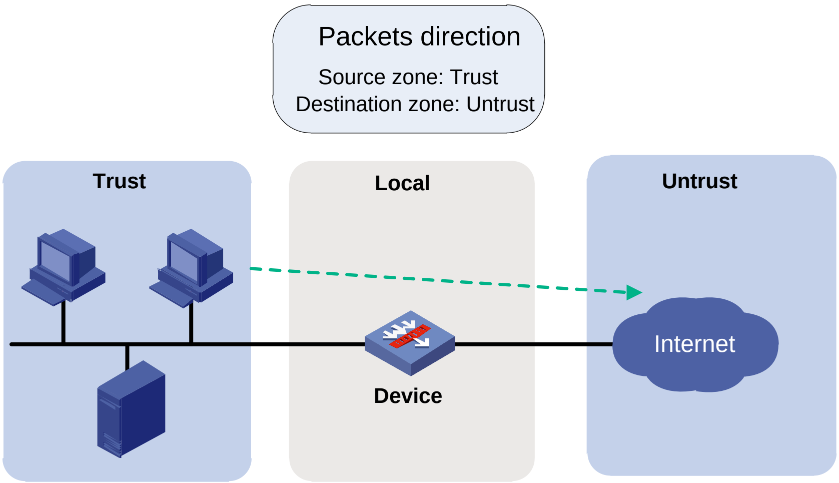

Table 3 Direct traffic forwarding

Rule name	Source security zone	Destination security zone	Source IP address	Service	Action
trust-untrust	Trust	Untrust	10.1.1.10	http	pass

Configuration principles

As a best practice to achieve the optimal performance, follow these principles when you configure security policy rules:

- Configure matching criteria as strict as possible.
- Follow the depth-first order during rule creation to create rules with stricter match criteria first because the system matches packets against rules in the order the rules were created.
- For packets from and to the same security zone, configure two rules to control packet exchanges between interfaces instead of using one rule that allows traffic between any interfaces in the zone to pass.
- Place security policy rules using the Local security zone as a matching criterion in front of all the other rules to ensure that local service packets can be correctly processed.

Common local services

You must configure security policy rules to permit local service traffic from or to specific security zones. Table 4 lists the common local services that require security policy permission. Support for the common local services varies by device.

Table 4 Common local services that require security policy permission

Service	Required security policy configuration
OSPF/IS-IS/RIP/BGP	Configure rules for the service traffic from or to the local zone.
IPsec/SSL/L2TP/MPLS/GRE	Configure rules for the service traffic from or to the local zone.
DNS/DHCP/FTP (client)	Configure rules only for the service traffic from the local zone.
DNS/DHCP/FTP (server)	Configure rules only for the service traffic to the local zone.
SSH/Telnet/Ping/Tracet (locally triggered)	Configure rules only for the service traffic from the local zone.
SSH/Telnet/SNMP/HTTP/HTTPS (local access)	Configure rules only for the service traffic to the local zone.
BFD	Configure rules for the service traffic from or to the local zone.
LB	Configure rules for the service traffic from or to the local zone.

Restrictions and guidelines: Security policy configuration

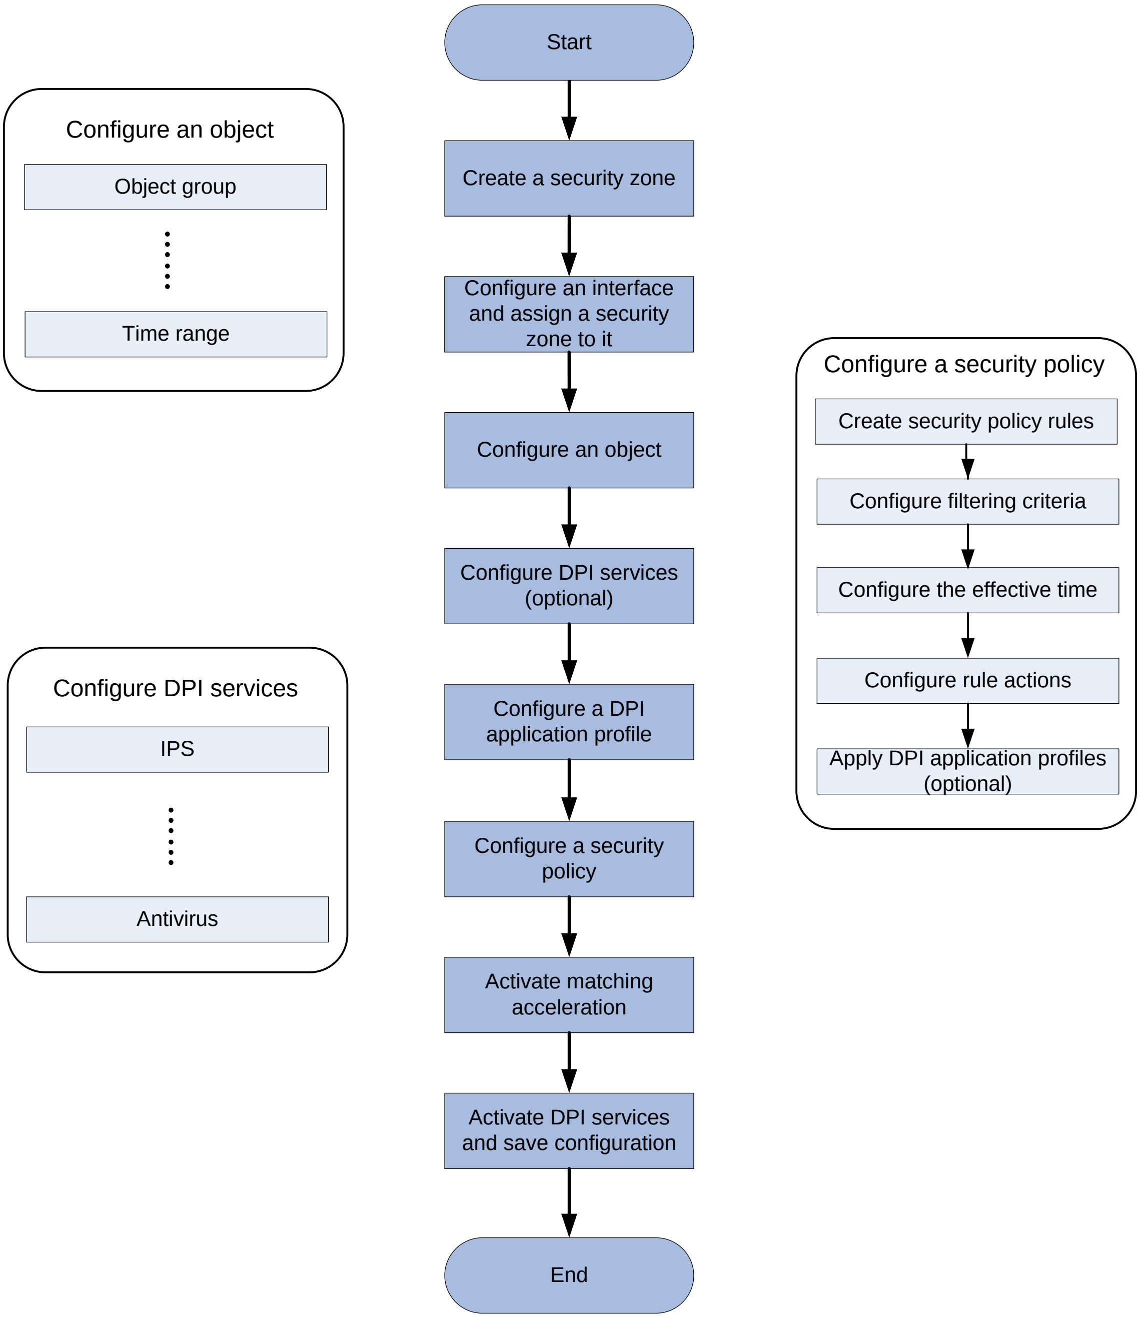
As a best practice, do not configure packet filtering and object policies at the same time. If you do so, some policies might fail to take effect, causing service interruption.

Before configuring security policies, verify if the device is configured with packet filtering. As a best practice, switch packet filtering and object policies to security policies because security policies take precedence over packet filtering. For more information, see "Switching packet filtering to security policy settings."

Configuration procedure diagram

Figure 5 shows how to configure a security policy.

Figure 5 Security policy configuration procedure



Start
Create a security zone
Configure an interface and assign a security zone to it
Configure an object
Configure DPI services (optional)
Configure a DPI application profile
Configure a security policy
Activate matching acceleration
Activate DPI services and save configuration
End
Configure an object
Object group
Time range
Configure DPI services
IPS
Antivirus
Configure a security policy
Create security policy rules
Configure filtering criteria
Configure the effective time
Configure rule actions
Apply DPI application profiles (optional)

Prerequisites for security policies

Before you configure security policies, perform the following tasks:

- Configure a time range. See time range configuration in *ACL and QoS Configuration Guide*.
- Configure IP address object groups and service object groups. See "Configuring object groups."
- Configure applications and application groups. See "Configuring APR."
- Configure user and user groups. See "Configuring user identification."
- Configure security zones. See "Configuring security zones.".

- Configure DPI. See *DPI Configuration Guide*.

Security policy tasks at a glance

To configure object policies, perform the following tasks:

1. (Optional.) Switching packet filtering to security policy settings
2. Enabling the security policy feature
3. Configuring IPv4 security policy rules
   a. Creating a security policy rule
   b. Configuring filtering criteria for a security policy rule
   c. Specifying the action for a security policy rule
   d. (Optional.) Specifying a time range for a security policy rule
   e. (Optional.) Applying a DPI application profile to a security policy rule
   f. (Optional.) Setting the session aging time for a security policy rule
   g. (Optional.) Associating a security policy rule with a track entry
   h. (Optional.) Enabling logging for matched packets
   i. (Optional.) Enabling statistics collection for matched packets
4. Configuring IPv6 security policy rules
   a. Creating a security policy rule
   b. Configuring filtering criteria for a security policy rule
   c. Specifying the action for a security policy rule
   d. (Optional.) Specifying a time range for a security policy rule
   e. (Optional.) Applying a DPI application profile to a security policy rule
   f. (Optional.) Setting the session aging time for a security policy rule
   g. (Optional.) Associating a security policy rule with a track entry
   h. (Optional.) Enabling logging for matched packets
   i. (Optional.) Enabling statistics collection for matched packets
5. (Optional.) Manage security policies
   a. Changing the rule match order
   b. Activating rule matching acceleration
   c. Disabling a security policy rule
   d. Renaming a security policy rule
6. (Optional.) Configuring security policy rule groups
   a. Creating a security policy rule group
   b. Specifying a security policy rule group for a security policy rule
   c. Moving a security policy rule group
   d. Renaming a security policy rule group
7. (Optional.) Setting the time for fast output of security policy settings as logs

Switching packet filtering to security policy settings

When security policies are configured, packet filtering is performed only on packets that do not match any security policy rule. As a best practice to avoid interruption of services permitted by packet filtering, do not configure packet filtering and security policies at the same time.

If packet filtering is configured, switch packet filtering to security policy settings as a best practice before enabling the security policy feature.

Switching packet filtering to security policy settings before security policies are configured

1. Execute the **`security-policy disable`** command to disable the security policy feature.
2. Enter security policy view, configure filtering criteria and actions for security policy rules based on the packet filtering configuration.
3. Execute the **`undo security-policy disable`** command to enable the security policy feature.
4. (Optional.) Delete the packet filtering configuration from the device.

Switching packet filtering to security policy settings after security policies are configured

You can perform this task from the Web interface (recommended) or CLI.

To perform this task from the CLI:

1. Access the CLI of the device. As a best practice, access the device through the Console port or interface of the Management security zone in case the connection is terminated by packet filtering.
2. Enter security policy view, and configure filtering criteria and actions for security policy rules based on the packet filtering configuration.

> △ **CAUTION:**
>
> After using the **`rule`** [*`rule-id`*] **name** *`rule-name`* command to create the first security policy rule, configure the filtering criteria and actions based on packet filtering as soon as possible to shorten service interruption. With no filtering criteria or action specified, the rule matches and drops all packets. You can configure other security policy settings when the service is not busy as a best practice.

3. (Optional.) Delete the packet filtering configuration from the device.

Enabling the security policy feature

Restrictions and guidelines

Security policy settings take effect only when the security policy feature is enabled.

Procedure

1. Enter system view.

   `system-view`

2. Enable the security policy feature.

   undo security-policy disable

   By default, the security policy feature is enabled.

△ **CAUTION:**

The **security-policy disable** command disables the security policy feature and might cause traffic interruption.

Configuring IPv4 security policy rules

Creating a security policy rule

About this task

By default, no rules exist in a security policy, and the device allows only packets exchanged between the Management security zone and the Local security zone to pass. For the device to process packets correctly, configure policy rules for each security policy.

If a configured feature, such as dynamic routing, requires exchanges with the device, configure security policy rules for the Local security zone to communicate with the specific zones.

Procedure

1. Enter system view.

   system-view

2. Enter IPv4 security policy view.

   security-policy ip

△ **CAUTION:**

- The **undo security-policy** { **ip** | **ipv6** } command directly deletes all security policy configurations and might cause network interruptions.

3. (Optional.) Configure a description for the policy.

   description *text*

   By default, a security policy does not have a description.

4. Create a security policy rule.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }

5. (Optional.) Configure a description for the rule.

   description *text*

   By default, a security policy rule does not have a description.

Configuring filtering criteria for a security policy rule

Restrictions and guidelines

A rule matches all packets if no criteria are specified for the rule. If no action is set for the rule, the device drops the matched packets by default.

If a specified object group has no objects, the rule cannot match any packets.

Packets exchanged between the Management and Local security zones are allowed to pass by default and can only match local-to-management or management-to-local security policy rules. To discard packets between the Management and Local security zones, configure local-to-management and management-to-local rules and specify the rule actions as **drop**.

Security policy rules specified with an IP address object group that uses a user or user group cannot match packets. To filter packets by user or user group, configure security policy rules specified with user or user group criteria.

Procedure

1. Enter system view.

   system-view

2. Enter IPv4 security policy view.

   security-policy ip

3. Enter security policy rule view.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }

4. Configure source filtering criteria:
   - Specify a source security zone as a filtering criterion.

     source-zone *source-zone-name*

     By default, no source security zone is specified as a filtering criterion.
   - Specify a source IPv4 address object group as a filtering criterion.

     source-ip *object-group-name*

     By default, no source IPv4 address object group is specified as a filtering criterion.
   - Specify a source IPv4 host address as a filtering criterion.

     source-ip-host *ip-address*

     By default, no source IPv4 host address is specified as a filtering criterion.
   - Specify a source IPv4 subnet as a filtering criterion.

     source-ip-subnet *ip-address* { *mask-length* | *mask* }

     By default, no source IPv4 subnet is specified as a filtering criterion.
   - Specify a source IPv4 address range as a filtering criterion.

     source-ip-range *ip-address1 ip-address2*

     By default, no source IPv4 address range is specified as a filtering criterion.
   - Specify a source MAC address object group as a filtering criterion.

     source-mac *object-group-name*

     By default, no source MAC address object group is specified as a filtering criterion.

5. Configure destination filtering criteria:
   - Specify a destination security zone as a filtering criterion.

     destination-zone *destination-zone-name*

     By default, no destination security zone is specified as a filtering criterion.
   - Specify a destination IPv4 address object group as a filtering criterion.

     destination-ip *object-group-name*

     By default, no destination IPv4 address object group is specified as a filtering criterion.
   - Specify a destination IPv4 host address as a filtering criterion.

     destination-ip-host *ip-address*

     By default, no destination IPv4 host address is specified as a filtering criterion.
   - Specify a destination IPv4 subnet as a filtering criterion.

     destination-ip-subnet *ip-address* { *mask-length* | *mask* }

     By default, no destination IPv4 subnet is specified as a filtering criterion.

- Specify a destination IPv4 address range as a filtering criterion.

  destination-ip-range *ip-address1 ip-address2*

  By default, no destination IPv4 address range is specified as a filtering criterion.

6. Specify a service object group as a filtering criterion.

   service { *object-group-name* | **any** }

   By default, no service object group is specified as a filtering criterion.

7. Specify a service port as a filtering criterion.

   service-port *protocol* [{ **destination** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } | **source** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } } * | *icmp-type icmp-code* | *icmpv6-type icmpv6-code*]

   By default, no service port is specified as a filtering criterion.

8. Configure application filtering criteria:
   - Specify an application as a filtering criterion.

     application *application-name*

     By default, no application is specified as a filtering criterion.

     For the application filtering criteria to be identified, you must permit the dependent applications to pass through.
   - Specify an application group as a filtering criterion.

     app-group *app-group-name*

     By default, no application group is specified as a filtering criterion.

9. Configure user filtering criterion:
   - Specify a user as a filtering criterion.

     user *username* [**domain** *domain-name*]

     By default, no user is specified as a filtering criterion.
   - Specify a user group as a filtering criterion.

     user-group *user-group-name* [**domain** *domain-name*]

     By default, no user group is specified as a filtering criterion.

10. Configure the rule to take effect on received packets of the specified VPN instance.

    vrf *vrf-name*

    By default, a security policy rule takes effect on received packets of the public network.

Specifying the action for a security policy rule

1. Enter system view.

   system-view

2. Enter IPv4 security policy view.

   security-policy ip

3. Enter security policy rule view.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }

4. Specify the action for the security policy rule.

   action { **drop** | **pass** }

   By default, the action for a security policy rule is **drop**.

Specifying a time range for a security policy rule

1. Enter system view.

   `system-view`

2. Enter IPv4 security policy view.

   `security-policy ip`

3. Enter security policy rule view.

   `rule` { *`rule-id`* | [*`rule-id`*] **name** *`rule-name`* }

4. Specify a time range during which the security policy rule is in effect.

   `time-range` *`time-range-name`*

   By default, a security policy rule is in effect at any time.

Applying a DPI application profile to a security policy rule

About this task

This feature enables the device to perform DPI on packets matching the specified rule. For more information about DPI, see *DPI Configuration Guide*.

Restrictions and guidelines

This feature takes effect only when the rule action is **pass**.

Procedure

1. Enter system view.

   `system-view`

2. Enter IPv4 security policy view.

   `security-policy ip`

3. Enter security policy rule view.

   `rule` { *`rule-id`* | [*`rule-id`*] **name** *`rule-name`* }

4. Specify the rule action as **pass**.

   `action` **pass**

   By default, the action for a security policy rule is **drop**.

5. Apply a DPI application profile to the rule.

   `profile` *`app-profile-name`*

   By default, no DPI application profile is applied to a rule.

Setting the session aging time for a security policy rule

About this task

Perform this task to specify the aging time for stable sessions and persistent sessions. The configuration takes effect only on sessions established afterwards.

The configured aging time for persistent sessions is effective only on TCP sessions in ESTABLISHED state.

The priorities of the session aging times configured by using the **`session persistent aging-time`**, **`session aging-time`**, and **`session persistent acl`** commands are in descending order.

Procedure

1. Enter system view.

   system-view

2. Enter IPv4 security policy view.

   security-policy ip

3. Enter security policy rule view.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }

4. Set the session aging time.

   session aging-time *time-value*

   By default, the session aging time is not configured.

5. Set the aging time for persistent sessions.

   session persistent aging-time *time-value*

   By default, the aging time for persistent sessions is not configured.

△ **CAUTION:**

Setting too long an aging time might cause persistent sessions to increase rapidly and therefore cause the CPU usage to be high.

Associating a security policy rule with a track entry

About this task

Perform this task to enable the collaboration between the track module and a security policy rule. The collaboration operates as follows:

- If a rule is associated with the Negative state of a track entry, the device:
  - Sets the rule state to Active if the track entry is in Negative state.
  - Sets the rule state to Inactive if the track entry is in Positive state.
- If a rule is associated with the Positive state of a track entry, the device:
  - Sets the rule state to Active if the track entry is in Positive state.
  - Sets the rule state to Inactive if the track entry is in Negative state.

For more information about track entries, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter IPv4 security policy view.

   security-policy ip

3. Enter security policy rule view.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }

4. Associate the rule with a track entry.

   track { **negative** | **positive** } *track-entry-number*

   By default, no track entry is associated with a rule.

Enabling logging for matched packets

About this task

This feature enables the device to log matching packets and send the log to the information center for processing or fast output the log. The log destinations and output rules are determined by the information center or fast log output settings. For more information about the information center and fast log output, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter IPv4 security policy view.

   `security-policy ip`

3. Enter security policy rule view.

   `rule` { *`rule-id`* | [*`rule-id`*] **name** *`rule-name`* }

4. Enable logging for matched packets.

   `logging enable`

   By default, logging for matched packets is disabled.

Enabling statistics collection for matched packets

About this task

Perform this task to enable the device to collect statistics about matched packets. The collected statistics can be viewed by executing the **`display security-policy statistics`** command.

If an enabling period is specified, the system disables the statistics collection feature and removes the configuration at period expiration. If no enabling period is specified, you must execute the **undo** command to disable the statistics collection feature.

Restrictions and guidelines

When inter-VLAN bridge forwarding is configured, this feature collects statistics only about packets discarded by security policies and DPI. Statistics about permitted packets are not collected. For more information about inter-VLAN bridge forwarding, see Layer 2 forwarding in *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter IPv4 security policy view.

   `security-policy ip`

3. Enter security policy rule view.

   `rule` { *`rule-id`* | [*`rule-id`*] **name** *`rule-name`* }

4. Enable statistics collection for matched packets.

   `counting enable` [**`period`** *`value`*]

   By default, the device does not collect statistics about matched packets.

Configuring IPv6 security policy rules

Creating a security policy rule

About this task

By default, no rules exist in a security policy, and the device allows only packets exchanged between the Management security zone and the Local security zone to pass. For the device to process packets correctly, configure policy rules for each security policy.

If a configured feature, such as dynamic routing, tunneling, and VPN, requires exchanges with the device, configure security policy rules for the Local security zone to communicate with the specific zones.

Procedure

1. Enter system view.

   `system-view`

2. Enter IPv6 security policy view.

   `security-policy ipv6`

> **CAUTION:**
>
> - The **`undo security-policy`** { **`ip`** | **`ipv6`** } command directly deletes all security policy configurations and might cause network interruptions.

3. (Optional.) Configure a description for the policy.

   `description` *`text`*

   By default, a security policy does not have a description.

4. Create a security policy rule.

   `rule` { *`rule-id`* | [*`rule-id`*] **`name`** *`rule-name`* }

5. (Optional.) Configure a description for the rule.

   `description` *`text`*

   By default, a security policy rule does not have a description.

Configuring filtering criteria for a security policy rule

Restrictions and guidelines

A rule matches all packets if no criteria are specified for the rule. If no action is set for the rule, the device drops the matched packets by default.

If a specified object group has no objects, the rule cannot match any packets.

Packets exchanged between the Management and Local security zones are allowed to pass by default and can only match local-to-management or management-to-local security policy rules. To discard packets between the Management and Local security zones, configure local-to-management and management-to-local rules and specify the rule actions as **drop**.

Security policy rules specified with an IP address object group that uses a user or user group cannot match packets. To filter packets by user or user group, configure security policy rules specified with user or user group criteria.

Procedure

1. Enter system view.

   `system-view`

2. Enter IPv6 security policy view.

   security-policy ipv6

3. Enter security policy rule view.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }

4. Configure source filtering criteria:
   - Specify a source security zone as a filtering criterion.

     source-zone *source-zone-name*

     By default, no source security zone is specified as a filtering criterion.
   - Specify a source IPv6 address object group as a filtering criterion.

     source-ip *object-group-name*

     By default, no source IPv6 address object group is specified as a filtering criterion.
   - Specify a source IPv6 host address as a filtering criterion.

     source-ip-host *ipv6-address*

     By default, no source IPv6 host address is specified as a filtering criterion.
   - Specify a source IPv6 subnet as a filtering criterion.

     source-ip-subnet *ipv6-address prefix-length*

     By default, no source IPv6 subnet is specified as a filtering criterion.
   - Specify a source IPv6 address range as a filtering criterion.

     source-ip-range *ipv6-address1 ipv6-address2*

     By default, no source IPv6 address range is specified as a filtering criterion.

5. Configure destination filtering criteria:
   - Specify a destination security zone as a filtering criterion.

     destination-zone *destination-zone-name*

     By default, no destination security zone is specified as a filtering criterion.
   - Specify a destination IPv6 address object group as a filtering criterion.

     destination-ip *object-group-name*

     By default, no destination IPv6 address object group is specified as a filtering criterion.
   - Specify a destination IPv6 host address as a filtering criterion.

     destination-ip-host *ipv6-address*

     By default, no destination IPv6 host address is specified as a filtering criterion.
   - Specify a destination IPv6 subnet as a filtering criterion.

     destination-ip-subnet *ipv6-address prefix-length*

     By default, no destination IPv6 subnet is specified as a filtering criterion.
   - Specify a destination IPv6 address range as a filtering criterion.

     destination-ip-range *ipv6-address1 ipv6-address2*

     By default, no destination IPv6 address range is specified as a filtering criterion.

6. Specify a service object group as a filtering criterion.

   service { *object-group-name* | **any** }

   By default, no service object group is specified as a filtering criterion.

7. Specify a service port as a filtering criterion.

   service-port *protocol* [{ **destination** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } | **source** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } } * | *icmpv6-type icmpv6-code*]

   By default, no service port is specified as a filtering criterion.

8. Configure application filtering criteria:
   - Specify an application as a filtering criterion.

     application *application-name*

     By default, no application is specified as a filtering criterion.

     For the application filtering criteria to be identified, you must permit the dependent applications to pass through.
   - Specify an application group as a filtering criterion.

     app-group *app-group-name*

     By default, no application group is specified as a filtering criterion.
9. Configure user filtering criterion:
   - Specify a user as a filtering criterion.

     user *username* [**domain** *domain-name*]

     By default, no user is specified as a filtering criterion.
   - Specify a user group as a filtering criterion.

     user-group *user-group-name* [**domain** *domain-name*]

     By default, no user group is specified as a filtering criterion.
10. Configure the rule to take effect on received packets of the specified VPN instance.

    vrf *vrf-name*

    By default, a security policy rule takes effect on received packets of the public network.

Specifying the action for a security policy rule

1. Enter system view.

   system-view
2. Enter IPv6 security policy view.

   security-policy ipv6
3. Enter security policy rule view.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }
4. Specify the action for the security policy rule.

   action { **drop** | **pass** }

   By default, the action for a security policy rule is **drop**.

Specifying a time range for a security policy rule

1. Enter system view.

   system-view
2. Enter IPv6 security policy view.

   security-policy ipv6
3. Enter security policy rule view.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }
4. Specify a time range during which the security policy rule is in effect.

   time-range *time-range-name*

   By default, a security policy rule is in effect at any time.

Applying a DPI application profile to a security policy rule

About this task

This feature enables the device to perform DPI on packets matching the specified rule. For more information about DPI, see *DPI Configuration Guide*.

Restrictions and guidelines

This feature takes effect only when the rule action is **pass**.

Procedure

1. Enter system view.

   `system-view`

2. Enter IPv6 security policy view.

   `security-policy ipv6`

3. Enter security policy rule view.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }

4. Specify the rule action as **pass**.

   action pass

   By default, the action for a security policy rule is **drop**.

5. Apply a DPI application profile to the rule.

   profile *app-profile-name*

   By default, no DPI application profile is applied to a rule.

Setting the session aging time for a security policy rule

About this task

Perform this task to specify the aging time for stable sessions and persistent sessions. The configuration takes effect only on sessions established afterwards.

The configured aging time for persistent sessions is effective only on TCP sessions in ESTABLISHED state.

The priorities of the session aging times configured by using the **session persistent aging-time**, **session aging-time**, and **session persistent acl** commands are in descending order.

Procedure

1. Enter system view.

   `system-view`

2. Enter IPv6 security policy view.

   `security-policy ipv6`

3. Enter security policy rule view.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }

4. Set the session aging time.

   session aging-time *time-value*

   By default, the session aging time is not configured.

5. Set the aging time for persistent sessions.

   session persistent aging-time *time-value*

By default, the aging time for persistent sessions is not configured.

CAUTION:

Setting too long an aging time might cause persistent sessions to increase rapidly and therefore cause the CPU usage to be high.

Associating a security policy rule with a track entry

About this task

Perform this task to enable the collaboration between the track module and a security policy rule. The collaboration operates as follows:

- If a rule is associated with the Negative state of a track entry, the device:
  - Sets the rule state to Active if the track entry is in Negative state.
  - Sets the rule state to Inactive if the track entry is in Positive state.
- If a rule is associated with the Positive state of a track entry, the device:
  - Sets the rule state to Active if the track entry is in Positive state.
  - Sets the rule state to Inactive if the track entry is in Negative state.

For more information about track entries, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter IPv6 security policy view.

   `security-policy ipv6`

3. Enter security policy rule view.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }

4. Associate the rule with a track entry.

   track { **negative** | **positive** } *track-entry-number*

   By default, no track entry is associated with a rule.

Enabling logging for matched packets

About this task

This feature enables the device to log matching packets and send the log to the information center for processing or fast output the log. The log destinations and output rules are determined by the information center or fast log output settings. For more information about the information center and fast log output, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enter IPv6 security policy view.

   `security-policy ipv6`

3. Enter security policy rule view.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }

4. Enable logging for matched packets.

logging enable

By default, logging for matched packets is disabled.

Enabling statistics collection for matched packets

About this task

Perform this task to enable the device to collect statistics about matched packets. The collected statistics can be viewed by executing the **display security-policy statistics** command.

If an enabling period is specified, the system disables the statistics collection feature and removes the configuration at period expiration. If no enabling period is specified, you must execute the **undo** command to disable the statistics collection feature.

Restrictions and guidelines

When inter-VLAN bridge forwarding is configured, this feature collects statistics only about packets discarded by security policies and DPI. Statistics about permitted packets are not collected. For more information about inter-VLAN bridge forwarding, see Layer 2 forwarding in *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter IPv6 security policy view.

   security-policy ipv6

3. Enter security policy rule view.

   rule { *rule-id* | [*rule-id*] **name** *rule-name* }

4. Enable statistics collection for matched packets.

   counting enable [**period** *value*]

   By default, the device does not collect statistics about matched packets.

Changing the rule match order

About this task

The device matches packets against security policy rules in the order the rules were created. You can change the rule match order by changing the position of a security policy rule in the rule list.

Procedure

1. Enter system view.

   system-view

2. Enter IPv4 or IPv6 security policy view.

   security-policy { **ip** | **ipv6** }

3. Move a security policy rule.

   - Move a security policy rule by rule ID.

     move rule *rule-id1* { { **after** | **before** } *rule-id2* | **bottom** | **down** | **top** | **up** }

   - Move a security policy rule by rule name.

     move rule name *rule-name1* { { **after** | **before** } **name** *rule-name2* | **bottom** | **down** | **top** | **up** }

Activating rule matching acceleration

About this task

Rule matching acceleration does not take effect on newly added, modified, and moved rules unless the feature is activated for the rules. By default, the system automatically activates rule matching acceleration for such rules at specific intervals. The interval is 2 seconds if 100 or fewer rules exist and 20 seconds if over 100 rules exist.

To activate rule matching acceleration immediately after a rule change, you can perform this task.

Restrictions and guidelines

If no rule change is detected, the system does not perform an activation operation.

Insufficient memory can cause rule matching acceleration failures. Unaccelerated rules do not take effect, and rules that have been accelerated are not affected.

Procedure

1. Enter system view.

   `system-view`

2. Enter IPv4 or IPv6 security policy view.

   `security-policy` { **`ip`** | **`ipv6`** }

3. Activate rule matching acceleration.

   `accelerate enhanced enable`

Disabling a security policy rule

1. Enter system view.

   `system-view`

2. Enter IPv4 or IPv6 security policy view.

   `security-policy` { **`ip`** | **`ipv6`** }

3. Enter security policy rule view.

   `rule` { *`rule-id`* | [*`rule-id`*] **name** *`rule-name`* }

4. Disable the security policy rule.

   `disable`

   By default, a security policy rule is enabled.

Renaming a security policy rule

1. Enter system view.

   `system-view`

2. Enter IPv4 or IPv6 security policy view.

   `security-policy` { **`ip`** | **`ipv6`** }

3. Rename a security policy rule.

   `rule` **rename** *`old-name new-name`*

Configuring security policy rule groups

Creating a security policy rule group

About this task

Perform this task to create a security policy rule group and add security policy rules to the group.

Restrictions and guidelines

To add a list of security policy rules, make sure the end rule is listed behind the start rule and the specified rules do not belong to any other security policy rule group.

A security policy rule group can contain only IPv4 rules or IPv6 rules.

Procedure

1. Enter system view.
   `system-view`
2. Enter IPv4 or IPv6 security policy view.
   `security-policy` { **`ip`** | **`ipv6`** }
3. Create a security policy rule group and add security policy rules to the group.
   `group name` *`group-name`* [**`from`** *`rule-name1`* **`to`** *`rule-name2`*] [**`description`** *`description-text`*] [**`disable`** | **`enable`**]

Specifying a security policy rule group for a security policy rule

1. Enter system view.
   `system-view`
2. Enter IPv4 or IPv6 security policy view.
   `security-policy` { **`ip`** | **`ipv6`** }
3. Enter security policy rule view.
   `rule` { *`rule-id`* | [*`rule-id`*] **`name`** *`rule-name`* }
4. Specify a security policy rule group for the security policy rule.
   `parent-group` *`group-name`*

Moving a security policy rule group

About this task

Perform this task to move a security policy rule group to change the match order of security policy rules.

Restrictions and guidelines

If you specify a target security policy rule that belongs to a security policy rule group, follow these restrictions and guidelines:

- If the target rule is neither the start nor end rule of the group, you cannot move a security policy rule group to the place before or after the rule.
- If the target rule is the start rule of the group, you can only move a security policy rule group to the place before the rule.

- If the target rule is the end rule of the group, you can only move a security policy rule group to the place after the rule.

You can move a security policy rule group before or after a security policy rule or group of the same type (IPv4 or IPv6).

Procedure

1. Enter system view.
   system-view
2. Enter IPv4 or IPv6 security policy view.
   security-policy { **ip** | **ipv6** }
3. Move a security policy rule group.
   group move *group-name1* { **after** | **before** } { **group** *group-name2* | **rule** *rule-name* }

Renaming a security policy rule group

1. Enter system view.
   system-view
2. Enter IPv4 or IPv6 security policy view.
   security-policy { **ip** | **ipv6** }
3. Rename a security policy rule group.
   group rename *old-name new-name*

Setting the time for fast output of security policy settings as logs

About this task

After the **customlog format security-policy sgcc** command is executed, the device fast outputs settings of enabled security policies as logs in SGCC format every day at the specified time. For more information about fast log output, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Set the time at which the device fast outputs security policy settings as logs every day.
   security-policy config-logging send-time *time*
   By default, the device fast outputs security policy settings as logs every day at 0 o'clock.

Display and maintenance commands for object policies

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display security policy configuration.	**display security-policy** { **ip** | **ipv6** }
Display security policy statistics.	**display security-policy statistics** { **ip** | **ipv6** } [**rule** *rule-name*]
Clear security policy statistics.	**reset security-policy statistics** [**ip** | **ipv6**] [**rule** *rule-name*]

Security policy configuration examples

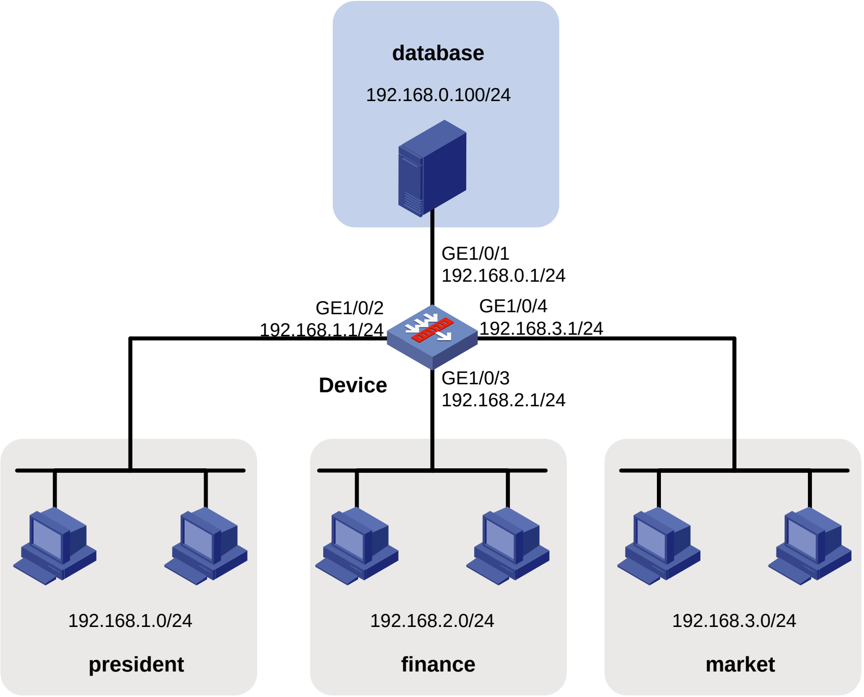
Example: Configuring an IPv4 security policy

Network configuration

Configure security policy to achieve the following goals:

- The president office can access the financial database server through HTTP at any time.
- The financial office can access the financial database server through HTTP from 8:00 to 18:00 on weekdays.
- The marketing office cannot access the financial database server through HTTP at any time.

Figure 6 Network diagram



Procedure

1. Assign IP addresses to interfaces.

   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.0.1 255.255.255.0
```

```
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name database
[Device-security-zone-database] import interface gigabitethernet 1/0/1
[Device-security-zone-database] quit
[Device] security-zone name president
[Device-security-zone-president] import interface gigabitethernet 1/0/2
[Device-security-zone-president] quit
[Device] security-zone name finance
[Device-security-zone-finance] import interface gigabitethernet 1/0/3
[Device-security-zone-finance] quit
[Device] security-zone name market
[Device-security-zone-market] import interface gigabitethernet 1/0/4
[Device-security-zone-market] quit
```

3. Create a time range named **work** to cover 8:00 to 18:00 on weekdays.

```
[Device] time-range work 08:00 to 18:00 working-day
```

4. Configure a security policy:

# Configure a rule named **president-database** to allow the president office to access the financial database server through HTTP at any time.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name president-database
[Device-security-policy-ip-0-president-database] source-zone president
[Device-security-policy-ip-0-president-database] destination-zone database
[Device-security-policy-ip-0-president-database] source-ip-subnet 192.168.1.0 24
[Device-security-policy-ip-0-president-database] destination-ip-subnet 192.168.0.0
24
[Device-security-policy-ip-0-president-database] service http
[Device-security-policy-ip-0-president-database] action pass
[Device-security-policy-ip-0-president-database] quit
```

# Configure a rule named **finance-database** to allow the financial office to access the financial database server through HTTP from 8:00 to 18:00 on weekdays.

```
[Device-security-policy-ip] rule name finance-database
[Device-security-policy-ip-1-finance-database] source-zone finance
[Device-security-policy-ip-1-finance-database] destination-zone database
[Device-security-policy-ip-1-finance-database] source-ip-subnet 192.168.2.0 24
[Device-security-policy-ip-1-finance-database] destination-ip-subnet 192.168.0.0
24
[Device-security-policy-ip-1-finance-database] service-port tcp destination eq 80
[Device-security-policy-ip-1-finance-database] action pass
[Device-security-policy-ip-1-finance-database] time-range work
[Device-security-policy-ip-1-finance-database] quit
```

# Configure a named **market-database** to prohibit the marketing office from accessing the financial database server through HTTP at any time.

```
[Device-security-policy-ip] rule name market-database
[Device-security-policy-ip-2-market-database] source-zone market
[Device-security-policy-ip-2-market-database] destination-zone database
[Device-security-policy-ip-2-market-database] source-ip-subnet 192.168.3.0 24
[Device-security-policy-ip-2-market-database] destination-ip-subnet 192.168.0.0 24
```

```
[Device-security-policy-ip-2-market-database] service http
[Device-security-policy-ip-2-market-database] action drop
[Device-security-policy-ip-2-market-database] quit
```

5. Activate rule matching acceleration.

```
[Device-security-policy-ip] accelerate enhanced enable
[Device-security-policy-ip] quit
```

Verifying the configuration

# Use a PC in each office to access the Web service of the financial database server through the browser. (Details not shown.)

Example: Configuring domain name-based security policy

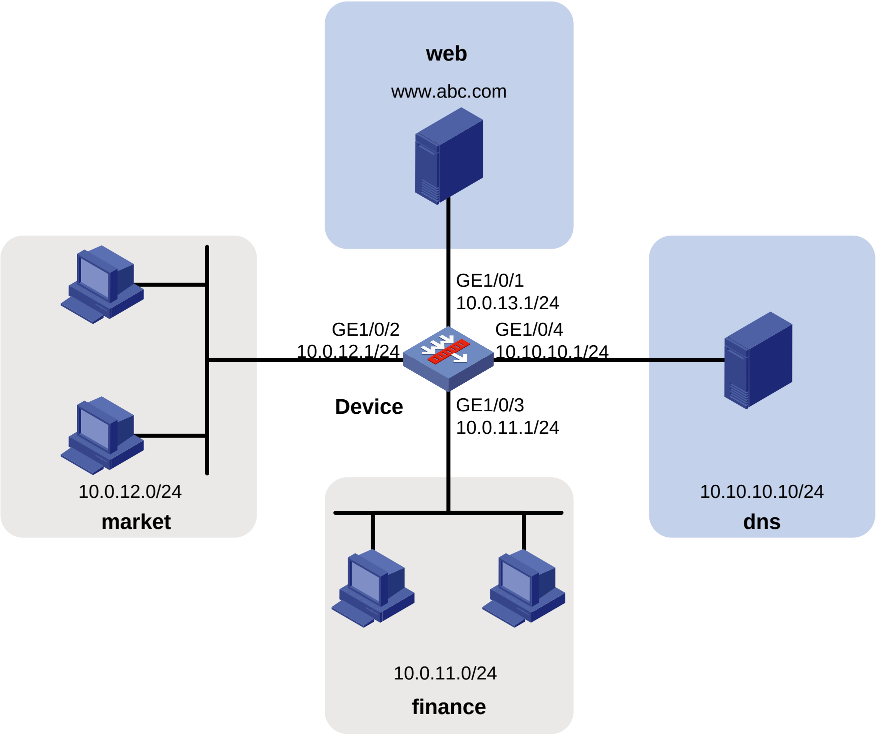
Network configuration

As shown in Figure 7, a Web server with domain name www.abc.com is deployed to process financial affairs. The domain name has been registered on the DNS server.

Configure security policy to achieve the following goals:

- The financial office can access the financial Web server through HTTP.
- The marketing office cannot access the financial Web server through HTTP at any time.

Figure 7 Network diagram



Procedure

1. Assign IP addresses to interfaces.

   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 10.0.13.1 255.255.255.0
```

```
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name web
[Device-security-zone-web] import interface gigabitethernet 1/0/1
[Device-security-zone-web] quit
[Device] security-zone name market
[Device-security-zone-market] import interface gigabitethernet 1/0/2
[Device-security-zone-market] quit
[Device] security-zone name finance
[Device-security-zone-finance] import interface gigabitethernet 1/0/3
[Device-security-zone-finance] quit
[Device] security-zone name dns
[Device-security-zone-dns] import interface gigabitethernet 1/0/4
[Device-security-zone-dns] quit
```

3. Create an IPv4 address object group named **web**. Configure an IPv4 address object with host name **www.abc.com** for the group.

```
[Device] object-group ip address web
[Device-obj-grp-ip-web] network host name www.abc.com
[Device-obj-grp-ip-web] quit
```

4. Specify the IP address of the DNS server as **10.10.10.10**.

```
[Device] dns server 10.10.10.10
```

5. Configure a security policy:

# Configure a rule named **dnslocalout** to allow the device to send packets to the DNS server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name dnslocalout
[Device-security-policy-ip-0-dnslocalout] source-zone local
[Device-security-policy-ip-0-dnslocalout] destination-zone dns
[Device-security-policy-ip-0-dnslocalout] destination-ip-host 10.10.10.10
[Device-security-policy-ip-0-dnslocalout] action pass
[Device-security-policy-ip-0-dnslocalout] quit
```

# Configure a rule named **host-dns** to allow the financial department and marketing department to access the DNS server.

```
[Device-security-policy-ip] rule name host-dns
[Device-security-policy-ip-1-host-dns] source-zone finance
[Device-security-policy-ip-1-host-dns] source-zone market
[Device-security-policy-ip-1-host-dns] destination-zone dns
[Device-security-policy-ip-1-host-dns] source-ip-subnet 10.0.11.0 24
[Device-security-policy-ip-1-host-dns] source-ip-subnet 10.0.12.0 24
[Device-security-policy-ip-1-host-dns] destination-ip-host 10.10.10.10
[Device-security-policy-ip-1-host-dns] service dns-udp
[Device-security-policy-ip-1-host-dns] action pass
[Device-security-policy-ip-1-host-dns] quit
```

# Configure a rule named **finance-web** to allow the financial department to access the financial Web server through HTTP.

```
[Device-security-policy-ip] rule name finance-web
[Device-security-policy-ip-2-finance-web] source-zone finance
[Device-security-policy-ip-2-finance-web] destination-zone web
```

```
[Device-security-policy-ip-2-finance-web] source-ip-subnet 10.0.11.0 24
[Device-security-policy-ip-2-finance-web] destination-ip web
[Device-security-policy-ip-2-finance-web] service http
[Device-security-policy-ip-2-finance-web] action pass
[Device-security-policy-ip-2-finance-web] quit
```

# Configure a rule named **market-web** to forbid the marketing department from accessing the financial Web server through HTTP.

```
[Device-security-policy-ip] rule name market-web
[Device-security-policy-ip-3-market-web] source-zone market
[Device-security-policy-ip-3-market-web] destination-zone web
[Device-security-policy-ip-3-market-web] source-ip-subnet 10.0.12.0 24
[Device-security-policy-ip-3-market-web] destination-ip web
[Device-security-policy-ip-3-market-web] service http
[Device-security-policy-ip-3-market-web] action drop
[Device-security-policy-ip-3-market-web] quit
```

6. Activate rule matching acceleration.

```
[Device-security-policy-ip] accelerate enhanced enable
[Device-security-policy-ip] quit
```

Verifying the configuration

# Use a PC in each office to access the Web service of the financial server. (Details not shown.)

Example: Configuring a security policy based on fuzzy domain name matching

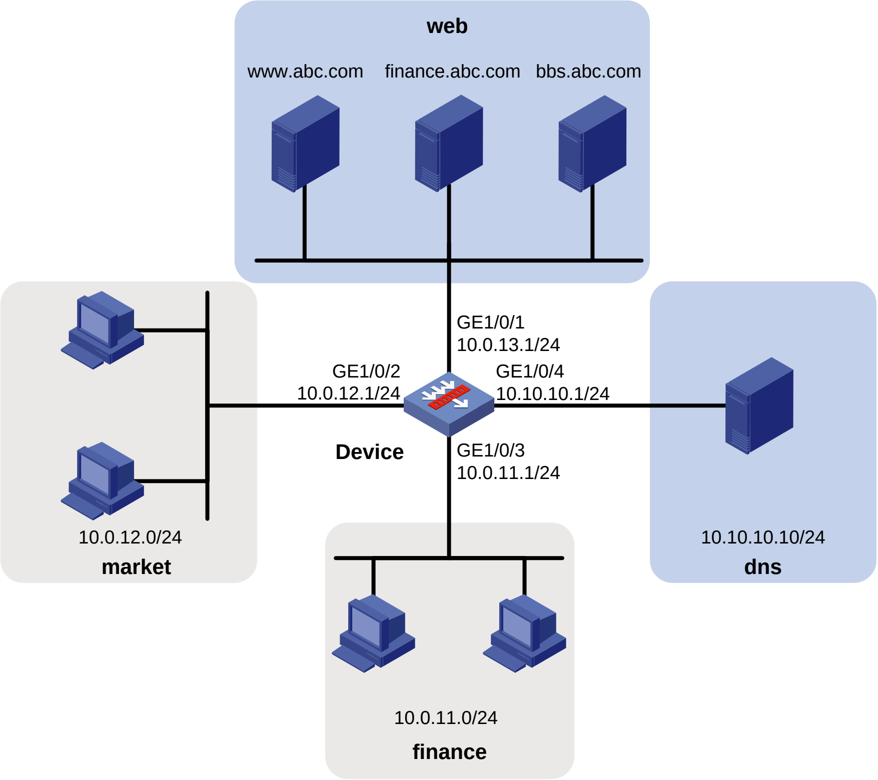
Network configuration

As shown in Figure 8, Web servers with domain names www.abc.com, finance.abc.com, and bbs.abc.com are deployed. The domain names have been registered on the DNS server.

Configure security policy to achieve the following goals:

- The financial office can access all Web servers through HTTP based on fuzzy domain name matching.
- The marketing office can access the bbs.abc.com server through HTTP based on exact domain matching.

Figure 8 Network diagram



Procedure

1. Specify the address of the DNS server for intranet hosts as the IP address of the device.
2. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 10.0.13.1 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)
3. Add interfaces to security zones.

   ```
   [Device] security-zone name web
   [Device-security-zone-web] import interface gigabitethernet 1/0/1
   [Device-security-zone-web] quit
   [Device] security-zone name market
   [Device-security-zone-market] import interface gigabitethernet 1/0/2
   [Device-security-zone-market] quit
   [Device] security-zone name finance
   [Device-security-zone-finance] import interface gigabitethernet 1/0/3
   [Device-security-zone-finance] quit
   [Device] security-zone name dns
   [Device-security-zone-dns] import interface gigabitethernet 1/0/4
   [Device-security-zone-dns] quit
   ```
4. Create object groups:

# Create an IPv4 address object group named **web**. Configure an IPv4 address object with host name ***.abc.com** for the group. The host name can match all domain names that contain the .abc.com string.

```
[Device] object-group ip address web
[Device-obj-grp-ip-web] network host name *.abc.com
[Device-obj-grp-ip-web] quit
```

# Create an IPv4 address object group named **bbs**. Configure an IPv4 address object with host name **bbs.abc.com** for the group.

```
[Device] object-group ip address bbs
[Device-obj-grp-ip-bbs] network host name bbs.abc.com
[Device-obj-grp-ip-bbs] quit
```

5. Configure DNS settings:

# Enable DNS proxy.

```
[Device] dns proxy enable
```

# Specify the IP address of the DNS server as **10.10.10.10**.

```
[Device] dns server 10.10.10.10
```

6. Configure security policies:

# Configure a rule named **local-dns** to allow the device to send packets to the DNS server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name local-dns
[Device-security-policy-ip-0-local-dns] source-zone local
[Device-security-policy-ip-0-local-dns] destination-zone dns
[Device-security-policy-ip-0-local-dns] destination-ip-host 10.10.10.10
[Device-security-policy-ip-0-local-dns] service dns-udp
[Device-security-policy-ip-0-local-dns] service dns-tcp
[Device-security-policy-ip-0-local-dns] action pass
[Device-security-policy-ip-0-local-dns] quit
```

# Configure a rule named **host-localdns** to allow the financial department and marketing department to access DNS proxy.

```
[Device-security-policy-ip] rule name host-localdns
[Device-security-policy-ip-1-host-localdns] source-zone finance
[Device-security-policy-ip-1-host-localdns] source-zone market
[Device-security-policy-ip-1-host-localdns] destination-zone local
[Device-security-policy-ip-1-host-localdns] source-ip-subnet 10.0.11.0 24
[Device-security-policy-ip-1-host-localdns] source-ip-subnet 10.0.12.0 24
[Device-security-policy-ip-1-host-localdns] service dns-udp
[Device-security-policy-ip-1-host-localdns] service dns-tcp
[Device-security-policy-ip-1-host-localdns] action pass
[Device-security-policy-ip-1-host-dns] quit
```

# Configure a rule named **finance-web** to allow the financial department to access all Web servers through HTTP.

```
[Device-security-policy-ip] rule name finance-web
[Device-security-policy-ip-2-finance-web] source-zone finance
[Device-security-policy-ip-2-finance-web] destination-zone web
[Device-security-policy-ip-2-finance-web] source-ip-subnet 10.0.11.0 24
[Device-security-policy-ip-2-finance-web] destination-ip web
[Device-security-policy-ip-2-finance-web] service http
[Device-security-policy-ip-2-finance-web] action pass
[Device-security-policy-ip-2-finance-web] quit
```

# Configure a rule named **market-web** to allow the marketing department to access the bbs.abc.com server through HTTP.

```
[Device-security-policy-ip] rule name market-web
[Device-security-policy-ip-3-market-web] source-zone market
[Device-security-policy-ip-3-market-web] destination-zone web
[Device-security-policy-ip-3-market-web] source-ip-subnet 10.0.12.0 24
[Device-security-policy-ip-3-market-web] destination-ip bbs
[Device-security-policy-ip-3-market-web] service http
[Device-security-policy-ip-3-market-web] action pass
[Device-security-policy-ip-3-market-web] quit
```

7. Activate rule matching acceleration.

```
[Device-security-policy-ip] accelerate enhanced enable
[Device-security-policy-ip] quit
```

Verifying the configuration

# Use a PC in the financial office to access all Web servers and a PC in the marketing office to access the bbs.abc.com server. (Details not shown.)

Example: Configuring user-based security policy

For more information about user-based security policy configuration examples, see "Configuring user identification."

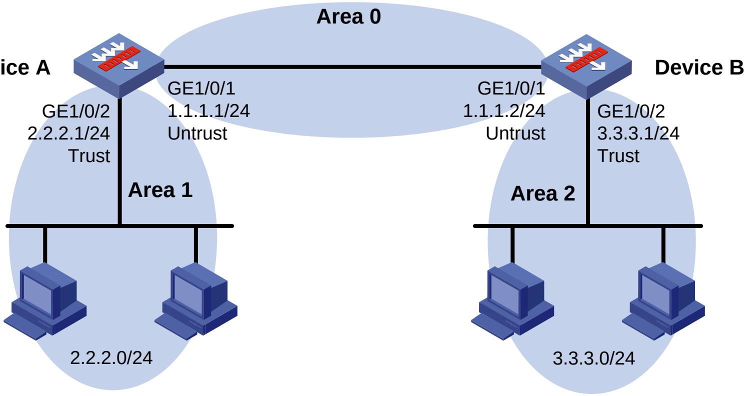
Example: Configuring a security policy for OSPF communication

Network configuration

As shown in Figure 9, OSPF is configured and the network is divided into three areas. Device A and Device B act as ABRs to exchange traffic between areas.

Configure the IPv4 security policy to make sure each router can learn the routes to all network segments in the AS.

Figure 9 Network diagram



Configuring Device A

1. Assign IP addresses to interfaces.

# Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 1.1.1.1 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[DeviceA] security-zone name untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] quit
[DeviceA] security-zone name trust
[DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceA-security-zone-Trust] quit
```

3. Configure a security policy:
   a. Configure rules to permit traffic between the **Untrust** and **Local** security zones, so the devices can establish OSPF neighbor relations:

   # Configure a rule named **ospflocalin** to permit the packets from security zone **Untrust** to security zone **Local**.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name ospflocalin
[DeviceA-security-policy-ip-0-ospflocalin] source-zone untrust
[DeviceA-security-policy-ip-0-ospflocalin] destination-zone local
[DeviceA-security-policy-ip-0-ospflocalin] service ospf
[DeviceA-security-policy-ip-0-ospflocalin] action pass
[DeviceA-security-policy-ip-0-ospflocalin] quit
```

   # Configure a rule named **ospflocalout** to permit the packets from security zone **Local** to security zone **Untrust**.

```
[DeviceA-security-policy-ip] rule name ospflocalout
[DeviceA-security-policy-ip-1-ospflocalout] source-zone local
[DeviceA-security-policy-ip-1-ospflocalout] destination-zone untrust
[DeviceA-security-policy-ip-1-ospflocalout] service ospf
[DeviceA-security-policy-ip-1-ospflocalout] action pass
[DeviceA-security-policy-ip-1-ospflocalout] quit
```

   b. Configure rules to permit traffic between the **Untrust** and **Trust** security zones, so devices in area 1 can communicate with devices in area 2.

   # Configure a rule named **trust-untrust** to permit the packets from security zone **Trust** to security zone **Untrust**.

```
[DeviceA-security-policy-ip] rule name trust-untrust
[DeviceA-security-policy-ip-2-trust-untrust] source-zone trust
[DeviceA-security-policy-ip-2-trust-untrust] destination-zone untrust
[DeviceA-security-policy-ip-2-trust-untrust] source-ip-subnet 2.2.2.0 24
[DeviceA-security-policy-ip-2-trust-untrust] destination-ip-subnet 3.3.3.0 24
[DeviceA-security-policy-ip-2-trust-untrust] action pass
[DeviceA-security-policy-ip-2-trust-untrust] quit
```

   # Configure a rule named **untrust-trust** to permit the packets from security zone **Untrust** to security zone **Trust**.

```
[DeviceA-security-policy-ip] rule name untrust-trust
[DeviceA-security-policy-ip-3-untrust-trust] source-zone untrust
[DeviceA-security-policy-ip-3-untrust-trust] destination-zone trust
[DeviceA-security-policy-ip-3-untrust-trust] source-ip-subnet 3.3.3.0 24
```

```
[DeviceA-security-policy-ip-3-untrust-trust] destination-ip-subnet 2.2.2.0 24
[DeviceA-security-policy-ip-3-untrust-trust] action pass
[DeviceA-security-policy-ip-3-untrust-trust] quit
[DeviceA-security-policy-ip] quit
```

4. Configure basic OSPF functions.

```
[DeviceA] router id 2.2.2.1
[DeviceA] ospf
[DeviceA-ospf-1] area 0
[DeviceA-ospf-1-area-0.0.0.0] network 1.1.1.0 0.0.0.255
[DeviceA-ospf-1-area-0.0.0.0] quit
[DeviceA-ospf-1] area 1
[DeviceA-ospf-1-area-0.0.0.1] network 2.2.2.0 0.0.0.255
[DeviceA-ospf-1-area-0.0.0.1] quit
[DeviceA-ospf-1] quit
```

Configuring Device B

1. Assign IP addresses to interfaces.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 1.1.1.2 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] ip address 3.3.3.1 255.255.255.0
[Device-GigabitEthernet1/0/2] quit
```

2. Add interfaces to security zones.

```
[DeviceB] security-zone name untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
[DeviceB] security-zone name trust
[DeviceB-security-zone-Trust] import interface gigabitethernet 1/0/2
[DeviceB-security-zone-Trust] quit
```

3. Configure a security policy:

   a. Configure rules to permit traffic between the **Untrust** and **Local** security zones, so **the device can establish OSPF neighbor relations:**

   # Configure a rule named **ospflocalin** to permit the packets from security zone **Untrust** to security zone **Local**.

```
[DeviceB] security-policy ip
[DeviceB-security-policy-ip] rule name ospflocalin
[DeviceB-security-policy-ip-0-ospflocalin] source-zone untrust
[DeviceB-security-policy-ip-0-ospflocalin] destination-zone local
[DeviceB-security-policy-ip-0-ospflocalin] service ospf
[DeviceB-security-policy-ip-0-ospflocalin] action pass
[DeviceB-security-policy-ip-0-ospflocalin] quit
```

   # Configure a rule named **ospflocalout** to permit the packets from security zone **Local** to security zone **Untrust**.

```
[DeviceB-security-policy-ip] rule name ospflocalout
[DeviceB-security-policy-ip-1-ospflocalout] source-zone local
[DeviceB-security-policy-ip-1-ospflocalout] destination-zone untrust
[DeviceB-security-policy-ip-1-ospflocalout] service ospf
```

```
[DeviceB-security-policy-ip-1-ospflocalout] action pass
[DeviceB-security-policy-ip-1-ospflocalout] quit
```

b. Configure rules to permit traffic between the **Trust** and **Untrust** security zones, so devices in area 1 can communicate with devices in area 2:

# Configure a rule named **trust-untrust** to permit the packets from security zone **Trust** to security zone **Untrust**.

```
[DeviceB-security-policy-ip] rule name trust-untrust
[DeviceB-security-policy-ip-2-trust-untrust] source-zone trust
[DeviceB-security-policy-ip-2-trust-untrust] destination-zone untrust
[DeviceB-security-policy-ip-2-trust-untrust] source-ip-subnet 3.3.3.0 24
[DeviceB-security-policy-ip-2-trust-untrust] destination-ip-subnet 2.2.2.0 24
[DeviceB-security-policy-ip-2-trust-untrust] action pass
[DeviceB-security-policy-ip-2-trust-untrust] quit
```

# Configure a rule named **untrust-trust** to permit the packets from security zone **Untrust** to security zone **Trust**.

```
[DeviceB-security-policy-ip] rule name untrust-trust
[DeviceB-security-policy-ip-3-untrust-trust] source-zone untrust
[DeviceB-security-policy-ip-3-untrust-trust] destination-zone trust
[DeviceB-security-policy-ip-3-untrust-trust] source-ip-subnet 2.2.2.0 24
[DeviceB-security-policy-ip-3-untrust-trust] destination-ip-subnet 3.3.3.0 24
[DeviceB-security-policy-ip-3-untrust-trust] action pass
[DeviceB-security-policy-ip-3-untrust-trust] quit
[DeviceB-security-policy-ip] quit
```

4. Configure basic OSPF functions.

```
[DeviceB] router id 3.3.3.1
[DeviceB] ospf
[DeviceB-ospf-1] area 0
[DeviceB-ospf-1-area-0.0.0.0] network 1.1.1.0 0.0.0.255
[DeviceB-ospf-1-area-0.0.0.0] quit
[DeviceB-ospf-1] area 2
[DeviceB-ospf-1-area-0.0.0.2] network 3.3.3.0 0.0.0.255
[DeviceB-ospf-1-area-0.0.0.2] quit
[DeviceB-ospf-1] quit
```

Verifying the configuration

# View detailed information about OSPF neighbors on Device A.

```
[DeviceA] display ospf peer verbose

Configuring ASPF

About ASPF

Advanced Stateful Packet Filter (ASPF) is proposed to address the issues that a packet-filter firewall cannot solve.

Main functions

An ASPF provides the following main functions:

- **Application layer protocol inspection**—ASPF checks the application layer information of packets, such as the protocol type and port number, and inspects the application layer protocol status for each connection. ASPF maintains the status information of each connection, and based on the status information, determines whether to permit a packet to pass through the firewall into the internal network. In this way, ASPF defends the internal network against attacks.
- **Transport layer protocol inspection**—ASPF checks the transportation layer information of packets. Transportation layer protocol includes TCP, UDP, UDP-Lite, SCTP, Raw IP, ICMP, ICMPv6, and DCCP. For example, ASPF checks a TCP/UDP packet's source and destination addresses and port numbers to determine whether to permit the packet to pass through the firewall into the internal network.
- **ICMP error message dropping**—ASPF inspects the connection information carried in an ICMP error message. If the information does not match the connection, ASPF drops the packet.
- **TCP SYN check**—ASPF checks the first packet of a TCP connection to determine if it is a SYN packet. If it is not a SYN packet, ASPF drops the packet. When a router attached to the network starts up, it can receive a non-SYN packet of an existing TCP connection for the first time. If you do not want to interrupt the existing TCP connection, you can disable the TCP SYN check. The router allows the first non-SYN packet that is used to establish a TCP connection to pass. After the network topology becomes steady, you can enable TCP SYN check again.

ASPF application

At the border of a network, ASPF can work with a packet-filter firewall to provide the network with a more comprehensive security policy that better meets the actual needs. The packet-filter firewall permits or denies packets according to ACL rules. The ASPF records information about the permitted packets to ensure that their return packets can pass through the packet-filter firewall.

Basic ASPF concepts

Single-channel protocol and multichannel protocol

- **Single-channel protocol**—A single-channel protocol establishes only one connection to exchange both control messages and data for a user. SMTP and HTTP are examples of single-channel protocols.
- **Multichannel protocol**—A multichannel protocol establishes more than one connection for a user and transfers control messages and user data through different connections. FTP is one example of multichannel protocols.

Zone pair

A zone pair specifies the source zone and destination zone of a traffic flow to be inspected:

- **Source zone**—A security zone from which the first packet of a traffic flow originates.
- **Destination zone**—A security zone for which the first packet of a traffic flow is destined.

For information about security zones, see "Configuring security zones."

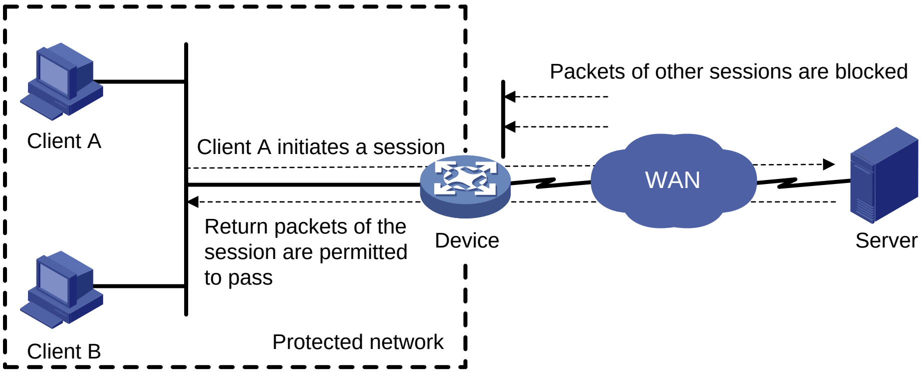
ASPF inspection principles

This section introduces the basic idea of ASPF inspection on application layer and transport layer protocols.

Application layer protocol inspection

As shown in Figure 1, ACLs on the edge device deny incoming packets to the internal network. The ASPF application layer protocol inspection allows return packets from the external network to the internal network.

Figure 1 Application layer protocol inspection



Client A
Client B
Client A initiates a session
Return packets of the session are permitted to pass
Protected network
Device
Packets of other sessions are blocked
WAN
Server

ASPF inspects all application layer sessions as follows:

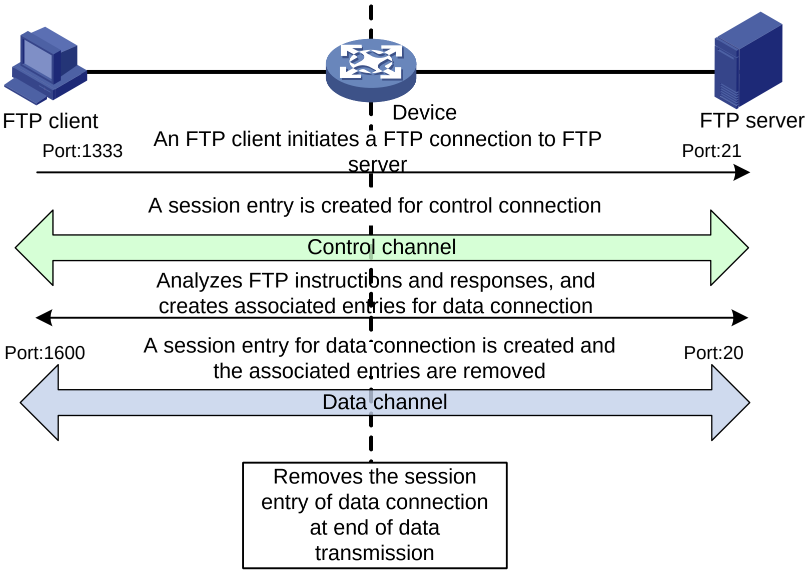
- For a single-channel protocol, such as HTTP, the inspection process is simple.

  ASPF creates a session entry immediately after it detects the session's first packet sent to the external network, and ASPF removes the entry when the connection is terminated.

  The session entry helps record outgoing packets and their return packets. It can maintain the session status and determine whether state transitions of the session are correct. All packets that match a session entry can pass through the packet-filter firewall.
- For a multichannel protocol, ASPF creates session entries, and one or more associated entries to associate the sessions initiated by the same application layer protocol. Associated entries are created during the protocol negotiation and are removed after the negotiation. ASPF uses the associated entries to match the first packets of the sessions. All packets of the sessions matching the associated entries can pass through the packet-filter firewall.

The following uses FTP to explain the process of multichannel application layer protocol inspection.

Figure 2 FTP inspection



FTP client
Device
FTP server
Port:1333
An FTP client initiates a FTP connection to FTP server
Port:21
A session entry is created for control connection
Control channel
Analyzes FTP instructions and responses, and creates associated entries for data connection
Port:1600
A session entry for data connection is created and the associated entries are removed
Port:20
Data channel
Removes the session entry of data connection at end of data transmission

As shown in Figure 2, FTP connections are established and removed as follows:

1. The FTP client initiates an FTP control connection from port 1333 to port 21 of the FTP server.
2. As a result of negotiation, the server initiates a data connection from port 20 to port 1600 of the client.
3. When data transmission times out or ends, the data connection is removed.

ASPF implements FTP inspection during the FTP connection lifetime as follows:

1. ASPF checks the IP packets the FTP client sends to the FTP server to identify TCP-based FTP packets. Based on the port number, ASPF identifies the control connection between the FTP client and server and creates a control connection session entry.
2. ASPF checks each FTP control connection packet, and examines their TCP status based on the control connection session entry. ASPF analyzes the FTP instructions in the control connection packet. If the packet contains a data channel setup instruction, ASPF creates an associated entry for the data connection.
3. For return FTP control connection packets, ASPF examines their TCP status based on the control connection session entry to make packet forwarding decisions.
4. When the FTP data passes through the device, ASPF is triggered to create a session entry for the data connection and remove the associated entry.
5. For returned FTP data packets, ASPF examines their TCP status based on the data connection session entry to make packet forwarding decisions.
6. When the data transmission ends, ASPF removes the data connection session entry. When the FTP connection is removed, ASPF removes the control connection session entry.

Transport layer protocol inspection

The transport layer protocol inspection creates session entries to record the transport layer information of the packets to dynamically filter packets. The transport layer information includes source and destination addresses and port numbers.

The transport layer protocol inspection requires that return packets must match the corresponding packets that are previously sent out of the external interface. The return packets must have the same source/destination addresses and source/destination port numbers as the outgoing packets (but reversed). Otherwise, the return packets are blocked. For multichannel application layer protocols like FTP, the deployment of TCP inspection without application layer inspection leads to failure of establishing a data connection.

Restrictions and guidelines: ASPF configuration

ASPF inspection is required to ensure successful data connections for multichannel protocols when either of the following conditions exists:

- The ALG feature is disabled in other service modules (such as NAT).
- Other service modules with the ALG feature (such as DPI) are not configured.

ASPF inspection is optional for multichannel protocols if ALG is enabled in other service modules or if other service modules with the ALG feature are configured.

Application protocols supported by the **detect** command (except HTTP, SMTP, and TFTP) are multichannel protocols.

ASPF inspection for transport layer protocols is always enabled and is not configurable.

ASPF also supports protocol status validity check for application layer protocols of DNS, FTP, H323, HTTP, SCCP, SIP, and SMTP. ASPF deals with packets with invalid protocol status, depending on the actions you have specified. For other application layer protocols, ASPF does not perform the protocol status validity check, and it only maintains connection status information.

ASPF tasks at a glance

To configure ASPF, perform the following tasks:

1. Configuring an ASPF policy
2. Applying an ASPF policy to a zone pair
3. (Optional.) Sending ICMP error message upon packet dropping by interzone policies applied to zone pairs

Configuring an ASPF policy

1. Enter system view.

   system-view

2. Create an ASPF policy and enter its view.

   aspf-policy *aspf-policy-number*

   After an ASPF policy is created, ASPF inspection for transport layer protocols is always enabled and is not configurable.

3. (Optional.) Configure ASPF inspection for application layer protocols.

   detect { **dns** [**action** { **drop** | **logging** } *] | { **ftp** | **h323** | **http** | **sccp** | **sip** | **smtp** } [**action drop**] | **gtp** | **ils** | **mgcp** | **nbt** | **pptp** | **rsh** | **rtsp** | **sqlnet** | **tftp** | **xdmcp** }

   By default, ASPF inspection for FTP is configured.

   The **action** keyword enables protocol status validity check for application protocols. ASPF takes the predefined actions on packets with invalid protocol status.

4. (Optional.) Enable ICMP error message dropping.

   icmp-error drop

   By default, ICMP error message dropping is disabled. ASPF does not drop faked ICMP error messages.

5. (Optional.) Enable TCP SYN check.

   tcp syn-check

By default, TCP SYN check is disabled. ASPF does not drop the non-SYN packet when it is the first packet to establish a TCP connection.

Applying an ASPF policy to a zone pair

About this task

You can apply an ASPF policy to a zone pair to inspect traffic from the source zone to the destination zone. ASPF compares all packets with session entries. If a packet that is permitted by packet filtering does not match any existing session entries, ASPF creates a new session entry.

ASPF for a zone pair takes effect only when it functions with a packet filter:

- The packet filter allows only solicited access from the source zone to the network that the destination zone connects.
- The ASPF policy compares the packets against session entries and allows matching packets from the source zone to the destination zone. The policy also allows return packets from the destination zone to the source zone.

Procedure

1. Enter system view.

   `system-view`

2. Enter zone pair view.

   `zone-pair security source` *`source-zone-name`* **`destination`** *`destination-zone-name`*

   For information about configuring a zone pair, see "Configuring security zones."

3. Apply an ASPF policy to the zone pair.

   `aspf apply policy` *`aspf-policy-number`*

   By default, the predefined ASPF policy is applied to the zone pair.

   With the predefined policy, ASPF inspects FTP packets and packets of all transport layer protocols, but it does not perform ICMP error message check or TCP SYN packet check.

Sending ICMP error message upon packet dropping by interzone policies applied to zone pairs

About this task

By default, the device drops packets that do not match interzone policies applied to zone pairs, and it does not send ICMP error messages for the dropping events. This mechanism reduces useless packets transmitted over the network and saves bandwidth.

Enable this feature when you use traceroute because ICMP error messages in this situation are required.

Procedure

1. Enter system view.

   `system-view`

2. Enable the device to send ICMP error messages upon packet dropping by interzone policies applied to zone pairs.

   `aspf icmp-error reply`

By default, the device does not send ICMP error messages when the device drops packets that do not match interzone policies applied to zone pairs.

Display and maintenance commands for ASPF

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the configuration of all ASPF policies and their applications to interfaces.	**display aspf all**
Display the configuration of an ASPF policy.	**display aspf policy** { *aspf-policy-number* | **default** }
Display ASPF sessions.	**display aspf session** [**ipv4** | **ipv6**] [**slot** *slot-number*] [**verbose**]
Clear ASPF session statistics.	**reset aspf session** [**ipv4** | **ipv6**] [**slot** *slot-number*]

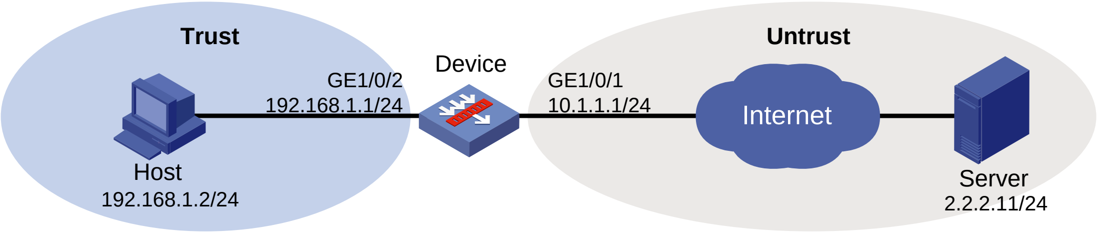
ASPF configuration examples

Example: Configuring ASPF FTP application inspection

Network configuration

Configure an ASPF policy on the device to inspect the FTP traffic flows passing through the device. Only return packets for FTP connections initiated by users on the internal network are permitted to pass through the device and get into the internal network. All other types of packets from the external network to the internal network are blocked.

Figure 3 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 10.1.1.1 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing.

   This example configures a static route, and the next hop in the route is 10.1.1.2.

```
[Device] ip route-static 2.2.2.0 24 10.1.1.2
```

3. Add interfaces to security zones.

```
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/2
[Device-security-zone-Trust] quit
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/1
[Device-security-zone-Untrust] quit
```

4. Configure ACL 3500 to permit the IP packets from the host to the Internet.

```
[Device] acl advanced 3500
[Device-acl-ipv4-adv-3500] rule permit ip source 192.168.1.0 0.0.0.255
[Device-acl-ipv4-adv-3500] quit
```

5. Create ASPF policy 1 for FTP inspection.

```
[Device] aspf policy 1
[Device-aspf-policy-1] detect ftp
[Device-aspf-policy-1] quit
```

6. Create a zone pair with the source security zone **Trust** and destination zone **Untrust**. Apply the ACL to the zone pair to permit the IP packets between the host and the Internet, and apply the ASPF policy to the zone pair.

```
[Device] zone-pair security source trust destination untrust
[Device-zone-pair-security-Trust-Untrust] packet-filter 3500
[Device-zone-pair-security-Trust-Untrust] aspf apply policy 1
[Device-zone-pair-security-Trust-Untrust] quit
```

Verifying the configuration

# Verify that an ASPF session has been established for the FTP connection between the host and the server.

```
<Device> display aspf session ipv4
Slot 0:
Initiator:
  Source      IP/port: 192.168.1.2/1877
  Destination IP/port: 2.2.2.11/21
  VPN instance/VLAN ID/Inline ID: -/-/-
  Protocol: TCP(6)
  Inbound interface: GigabitEthernet1/0/1
    Source security zone: Trust
Total sessions found: 1
```

# Verify that only return packets that match the entries can enter the internal network. (Details not shown.)

Contents

Managing sessions

About session management

Session management is a common module, providing basic services for NAT, ASPF, and attack detection and protection to implement their session-based services.

Session management defines packet exchanges at transport layer as sessions. It updates session states and ages out sessions according to data flows from the initiators or responders. Session management allows multiple features to process the same service packet.

Session management operation

Session management tracks the session status by inspecting the transport layer protocol information. It performs unified status maintenance and management of all connections based on session tables and relation tables.

When a connection request passes through the device from a client to a server, the device creates a session entry. The entry can contain the request and response information, such as:

- Source IP address and port number.
- Destination IP address and port number.
- Transport layer protocol.
- Application layer protocol.
- Protocol state of the session.

A multichannel protocol requires that the client and the server negotiate a new connection based on an existing connection to implement an application. Session management enables the device to create a relation entry for each connection during the negotiation phase. The entry is used to associate the connection with the application. Relation entries will be removed after the associated connections are established.

If the destination IP address of a packet is a multicast IP address, the packet will be forwarded out of multiple ports. When a multicast connection request is received on an inbound interface, the device performs the following operations:

- Creates a multicast session entry on the inbound interface.
- Creates a corresponding multicast session entry for each outbound interface.

Unless otherwise stated, "session entry" in this chapter refers to both unicast and multicast session entries.

Session types

When receiving the first packet of a data flow, the device processes the packet and creates a session entry based on the processing result. For subsequent packets of the data flow, the device performs fast forwarding based on the session entry. For more information about fast forwarding, see *Layer 3—IP Services Configuration Guide*.

Sessions are classified into the following types according to the action taken on the packets that match a session entry:

- **Permit session**—The device permits all packets of a permit session. The device generates a permit session entry for a data flow if it permits the first packet of the data flow.

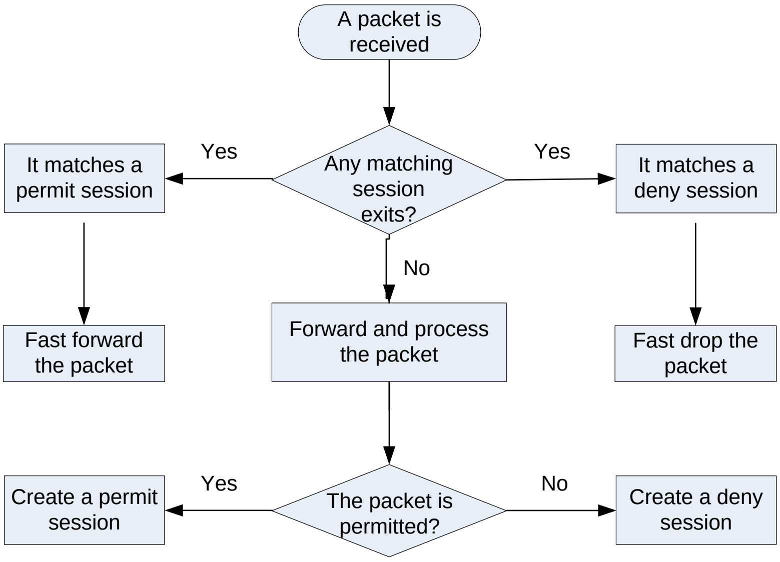
  A permit session can only track connection status. It cannot deny potential attack packets. To deny specific packets, you must use permit sessions together with security features.

- **Deny session**—The device drops all packets of a deny session. The device generates a deny session entry for a data flow if it drops the first packet of the data flow.

Unless otherwise stated, the sessions in this document refer to permit sessions.

Figure 1 shows the workflow of session-based traffic forwarding.

Figure 1 Session-based traffic forwarding



Session management functions

Session management enables the device to provide the following functions:

- Creates sessions for protocol packets, updates session states, and sets aging time for sessions in different protocol states.
- Supports port mapping for application layer protocols (see "Configuring APR"), enabling application layer protocols to use customized ports.
- Sets aging time for sessions based on application layer protocols.
- Supports ICMP/ICMPv6 error packet mapping, enabling the device to search for original sessions according to the payloads in the ICMP/ICMPv6 error packets.

  Because error packets are generated due to host errors, the mapping can help speed up the aging of the original sessions.
- Supports persistent sessions, which are kept alive for a long period of time.
- Supports session management for the control channels and dynamic data channels of application layer protocols, for example, FTP.
- Supports real-time synchronization for sessions and for dynamic entries of session-based services, such as NAT, ALG, and ASPF.

Restrictions and guidelines: Session management configuration

For a TCP session in ESTABLISHED state, the priority order of the associated aging time is as follows:

- Aging time for persistent sessions.

- Aging time for sessions of application layer protocols.
- Aging time for sessions in different protocol states.

If the device has excessive sessions, do not set the aging time shorter than the default for a certain protocol state or an application layer protocol. Short aging time settings can make the device slow in response.

Session management tasks at a glance

To configure session management, perform the following tasks:

- Configure session management timers
  - Setting the session aging time for different protocol states
  - Setting the session aging time for different application layer protocols or applications
  - Specifying persistent sessions
- Specifying the mode for session state machine
- Configuring session synchronization
  - Enabling session synchronization
  - Configuring session dual-active mode
- Configuring session logging
- Configuring session statistics collection
  - Enabling session statistics collection for software fast forwarding
  - Enabling top session statistics
- Configuring deny sessions
- Configuring alarms for abrupt session changes
- Enabling ALG to process fragments

Setting the session aging time for different protocol states

About this task

If a session in a certain protocol state has no packet hit before the aging time expires, the device automatically removes the session.

Procedure

1. Enter system view.

   system-view

2. Set the session aging time for different protocol states.

   session aging-time state { **fin** | **icmp-reply** | **icmp-request** | **icmpv6-reply** | **icmpv6-request** | **rawip-open** | **rawip-ready** | **syn** | **tcp-close** | **tcp-est** | **tcp-time-wait** | **udp-open** | **udp-ready** } *time-value*

   The default aging time for sessions in different protocol states is as follows:

   - FIN_WAIT: 30 seconds.
   - ICMP-REPLY: 30 seconds.
   - ICMP-REQUEST: 60 seconds.
   - ICMPv6-REPLY: 30 seconds.

- ICMPv6-REQUEST: 60 seconds.
- RAWIP-OPEN: 30 seconds.
- RAWIP-READY: 60 seconds.
- TCP SYN-SENT and SYN-RCV: 30 seconds.
- TCP-CLOSE: 2 seconds.
- TCP ESTABLISHED: 3600 seconds.
- TCP-TIME-WAIT: 2 seconds.
- UDP-OPEN: 30 seconds.
- UDP-READY: 60 seconds.

Setting the session aging time for different application layer protocols or applications

About this task

The aging time for sessions of different application layer protocols or applications are valid for TCP sessions in ESTABLISHED state or UDP sessions in READY state. For sessions used by other application layer protocols, the aging time for sessions in different protocol states applies.

Supported application layer protocols or applications specified in this command depend on the APR module. For information about APR, see "Configuring APR."

Procedure

1. Enter system view.

   system-view

2. Set the session aging time for different application layer protocols.

   session aging-time application *application-name time-value*

   By default, the aging time is 1200 seconds for sessions of application layer protocols or applications except for the following sessions:

   - BOOTPC sessions: 120 seconds.
   - BOOTPS sessions: 120 seconds.
   - DNS sessions: 30 seconds.
   - FTP sessions: 3600 seconds.
   - FTP-DATA sessions: 240 seconds.
   - GPRS-DATA sessions: 60 seconds.
   - GPRS-SIG sessions: 60 seconds.
   - GTP-CONTROL sessions: 60 seconds.
   - GTP-USER sessions: 60 seconds.
   - H.225 sessions: 3600 seconds.
   - H.245 sessions: 3600 seconds.
   - HTTPS sessions: 600 seconds.
   - ILS sessions: 3600 seconds.
   - L2TP sessions: 120 seconds.
   - MGCP-CALLAGENT sessions: 60 seconds.
   - MGCP-GATEWAY sessions: 60 seconds.
   - NETBIOS-DGM sessions: 3600 seconds.
   - NETBIOS-NS sessions: 3600 seconds.

- NETBIOS-SSN sessions: 3600 seconds.
- NTP sessions: 120 seconds.
- PPTP sessions: 3600 seconds.
- QQ sessions: 120 seconds.
- RAS sessions: 300 seconds.
- RIP sessions: 120 seconds.
- RSH sessions: 60 seconds.
- RTSP session: 3600 seconds.
- SCCP sessions: 3600 seconds.
- SIP sessions: 300 seconds.
- SNMP sessions: 120 seconds.
- SNMPTRAP sessions: 120 seconds.
- SQLNET sessions: 600 seconds.
- STUN sessions: 600 seconds.
- SYSLOG sessions: 120 seconds.
- TACACS-DS sessions: 120 seconds.
- TFTP sessions: 60 seconds.
- WHO sessions: 120 seconds.
- XDMCP sessions: 3600 seconds.

Specifying persistent sessions

About this task

This task is only for TCP sessions in ESTABLISHED state. You can specify TCP sessions that match the permit statements in the specified ACL as persistent sessions, and set longer lifetime or never-age-out persistent sessions.

A persistent session is not removed until one of the following events occurs:

- The session entry ages out.
- The device receives a connection close request from the initiator or responder.
- You manually clear the session entries.

Procedure

1. Enter system view.
   system-view
2. Specify persistent sessions.
   session persistent acl [**ipv6**] *acl-number* [**aging-time** *time-value*]

Specifying the mode for session state machine

About this task

When asymmetric-path traffic exists in a hot backup system operating in session active/standby mode, set the mode of session state machine to loose to avoid abnormal traffic loss.

When asymmetric-path traffic exists in a hot backup system operating in session dual-active mode, set the mode of session state machine to compact for disconnected sessions to age out timely.

As a best practice, change the mode of session state machine only when asymmetric-path traffic exists. This feature degrades performance of session-based security check. Make sure you are fully aware of its impact when you use it on a live network.

Procedure

1. Enter system view.

   system-view

2. Specify the mode for session state machine.

   session state-machine mode { **compact** | **loose** }

   By default, session state machine is in strict mode.

Enabling session synchronization

About this task

This feature enables devices to synchronize sessions and dynamic entries of session-based services. Typically, these devices back up each other and use a virtual IP address to communicate with a peer device. When the primary device fails, a backup device takes over to process and forward service traffic. The failover process is transparent to the peer device, and does not interrupt ongoing services.

This feature also provides automatic backup service for the device. The system automatically backs up session tables and relation tables that are generated by applications that use ALG. These applications include H.323, SIP, and ILS.

Enable session synchronization for DNS and HTTP in the following situations:

- Users are aware that the current HTTP or DNS sessions will last for a long time.
- HTTP or DNS session backup is required.

In a network that has asymmetric traffic, heavy service traffic might cause service delay or service unavailable because sessions cannot be backed up timely. For example, one device forwards the TCP SYN packets, and another device forwards its ACK packets. If the session tables of the two devices are not synchronized, the TCP packets will be dropped because of state error. To resolve this issue, enable session synchronization for asymmetric traffic.

Restrictions and guidelines

On an IRF fabric, the NAT configuration is dependent of session synchronization. If session synchronization is enabled, make sure NAT is configured on global interfaces such as aggregate interfaces and redundant interfaces. If you configure NAT on physical ports, disable session synchronization as a best practice.

This feature cannot be used together with RBM-based hot backup, which is enabled by using the **hot-backup enable** command. For information about RBM-based hot backup, see *High Availability Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Enable session synchronization.

   session synchronization enable [**asymmetric**]

   By default, session synchronization is disabled.

   After session synchronization is enabled, session synchronization is enabled for all application layer protocols except DNS and HTTP by default.

3. (Optional.) Enable session synchronization for DNS, HTTP, or both.

   session synchronization { **dns** | **http** } *

By default, session synchronization is disabled for DNS and HTTP.

Configuring session dual-active mode

About this task

In a hot backup system operating in session active/standby mode, only one device processes security services. Session dual-active mode increases load capacity of the system by enabling both devices to process security services.

To balance the service load on the devices, you can use one of the following session creation modes:

- **Hash-based session creation**—A session is created on the device to which its first packet is relayed according to the hash result. The device where a session is created might not be the device that receives the traffic. This mode applies if traffic is unevenly distributed among the devices.
- **Local-based session creation**—A session is created on the device where the first packet of the session arrives. This mode applies if traffic is evenly distributed among the devices.

In a hot backup system operating in session dual-active mode, a device cannot identify the direction of packets in a UDP traffic flow due to UDP mechanisms. By default, if the return packets of a session do not match any sessions, the device creates a new session. This results in the following issues:

- If the security control policy permits a UDP traffic flow in one direction, the return packets of the flow are dropped.
- If the security control policy permits a UDP traffic flow in both directions, two sessions are created for the flow. This affects traffic processing of security services.

To resolve these issues, you can enable transparent transmission for UDP packets. This feature allows a device to relay UDP packets that do not match any sessions to the other device in the hot back system. If the UDP packets also do not match any sessions on the other device, a new session is created locally.

In a hot backup system operating in session dual-active mode, a device can identify the direction of packets in a TCP traffic flow. If the device receives the packets of a new TCP traffic flow, it creates a session. If the return packets of an existing TCP traffic flow do not match any sessions, the device relays the packets to the other device.

Restrictions and guidelines

- As a best practice, enable transparent transmission for UDP packets only when asymmetric UDP traffic exists in the hot backup system and sessions cannot be synchronized timely. This feature degrades forwarding performance. Make sure you are fully aware of the impact of this feature when you use it on a live network.
- Transparent transmission for UDP packets takes effect only when local-based session creation is used. If hash-based session creation is used, the devices do not relay UDP packets.
- In dual-active mode, devices support only Layer 3 forwarding. Layer 2 forwarding is not supported.
- In dual-active mode, devices support only the flow-based policy for flow classification. For more information about flow classification policies, see multi-CPU packet distribution in *Layer 3—IP Services Configuration Guide*.
- AFT is not supported in dual-active mode.

Procedure

1. Enter system view.

```
system-view
```

2. Enable session dual-active mode.

session dual-active enable

By default, session dual-active mode is disabled. The device is operating in session active/standby mode.

3. Enable session synchronization.

   See "Enabling session synchronization."

4. Set the session creation mode.

   session dual-active create-mode { **hash** | **local** }

   By default, local-based session creation is used in session dual-active mode.

5. (Optional.) Enable transparent transmission for UDP packets.

   session dual-active transparent udp enable

   By default, transparent transmission for UDP packets is disabled in session dual-active mode.

6. (Optional.) Set the mode of session state machine to compact.

   See "Specifying the mode for session state machine."

Configuring session logging

About this task

Session logs provide information about user access, IP address translation, and network traffic for security auditing. These logs are sent to the log server or the information center.

The device supports time-based or traffic-based logging:

- **Time-based logging**—The device outputs session logs regularly.
- **Traffic-based logging**—The device outputs a session log when the traffic amount of a session reaches a threshold only when the session statistics collection for software fast forwarding feature is enabled. After outputting a session log, the device resets the traffic counter for the session. The traffic-based thresholds can be byte-based and packet-based. If you set both thresholds, the last configuration takes effect.

If you set both time-based and traffic-based logging, the device outputs a session log when whichever is reached. After outputting a session log, the device resets the traffic counter and restarts the interval for the session.

If you enable session logging but do not enable logging for session creation or deletion, the device does not output a session log when a session entry is created or removed.

Restrictions and guidelines

The session logging feature must work with the flow log or fast log output feature to generate session logs. Session logs can be output in flow log or fast log output format. By default, they are output in flow log format. For information about flow log and fast log output, see *Network Management and Monitoring*.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Set the threshold for time-based session logging.

   session log time-active *time-value*

   By default, no threshold is set for time-based session logging.

3. (Optional.) Set a threshold for traffic-based logging.

   session log { **bytes-active** *bytes-value* | **packets-active** *packets-value* }

   By default, no threshold is set for traffic-based logging.

4. (Optional.) Enable logging for session creation.

   session log flow-begin

   By default, logging for session creation is disabled.

5. (Optional.) Enable logging for session deletion.

   session log flow-end

   By default, logging for session deletion is disabled.

6. Enter interface view.

   interface *interface-type interface-number*

7. Enable session logging.

   session log enable { **ipv4** | **ipv6** } [**acl** *acl-number*] { **inbound** | **outbound** }

   By default, session logging is disabled.

Enabling session statistics collection for software fast forwarding

About this task

This feature enables the device to collect session-based outbound and inbound packets and bytes. You can display session statistics based on different criteria.

- To display statistics per unicast session, use the **display session table** command.
- To display statistics per unicast packet type, use the **display session statistics** command.
- To display statistics per multicast session, use the **display session table multicast** command.
- To display statistics per multicast packet type, use the **display session statistics multicast** command.

Procedure

1. Enter system view.

   system-view

2. Enable session statistics collection for software fast forwarding.

   session statistics enable

   The default setting varies by device model. For more information, see the command reference.

Enabling top session statistics

About this task

This feature collects the number of sessions for session-based services and ranks the sessions by source address and by destination address separately.

Procedure

1. Enter system view.

   system-view

2. Enable the top session statistics feature.

   session top-statistics enable

By default, the top session statistics feature is disabled.

3. (Optional.) Display top session statistics.

   display session top-statistics { **last-1-hour** | **last-24-hours** | **last-30-days** }

Configuring deny sessions

Enabling the deny session feature

About this task

By default, the device generates sessions only for permitted packets. If the device drops the first packet of a data flow, it will forward subsequent packets of the data flow according to the typical forwarding process. To improve forwarding performance, enable the deny session feature. This feature allows the device to generate a deny session for the dropped first packet of each data flow and perform fast packet dropping based on the deny sessions.

The system deletes deny sessions based on the deny session aging time. The deny session aging time is not refreshed when packets match deny sessions.

The maximum ratio of deny sessions to all sessions limits the number of deny sessions. When the ratio of deny session entries reaches this maximum ratio, the device stops generating deny sessions.

Restrictions and guidelines

The device generates deny sessions only for the packets dropped by the ASPF or connection limit module.

The device does not issue deny session entries to chips.

When session synchronization is enabled, the device synchronizes only permit session entries.

Procedure

1. Enter system view.

   system-view

2. Enable the deny session feature for modules.

   session fast-drop { **aspf** | **connection-limit** } * **enable**

   By default, the deny session feature is disabled.

3. Set the aging time for deny sessions.

   session fast-drop aging-time *time-value*

   By default, the aging time for deny sessions is 3 seconds.

4. Set the maximum ratio of deny sessions to all sessions.

   session fast-drop resource-ratio *ratio*

   By default, the maximum ratio of deny sessions to all sessions is 20‰.

Enabling top deny session statistics

About this task

This feature collects the number of deny sessions for session-based services and ranks the deny sessions by source address and by destination address.

To display the top deny session statistics, use the **display session fast-drop top-statistics** command.

Procedure

1. Enter system view.

   system-view

2. Enable the top deny session statistics feature.

   session fast-drop top-statistics enable

   By default, the top deny session statistics feature is disabled.

Configuring alarms for abrupt session changes

Configuring alarms for abrupt session table usage changes

About this task

Perform this task for the device to generate alarms for abrupt increase or drop in the session table usage. With this feature enabled, the system collects the session table usage at an interval of 10 seconds and checks whether the following indicators reach the corresponding alarm thresholds:

- **Session table usage change in percentage**—Obtained by dividing the difference between the session entry counts at the beginning and end of a collection interval by the session entry count at the beginning of the collection interval.
- **Base session table usage in percentage**—Obtained by dividing the session entry count at the beginning of a collection interval by the supported maximum number of session entries.

If both of the following conditions are met in a detection interval, the system generates an alarm for the abrupt change of the session table usage:

- The session table usage change threshold is reached.
- The base session table usage threshold is crossed.

Procedure

1. Enter system view.

   system-view

2. Enable alarms for abrupt session table usage changes.

   session alarm usage-abrupt enable

   By default, alarms are disabled for abrupt session table usage changes.

3. Set the alarm thresholds for abrupt session table usage changes.

   session alarm usage-abrupt threshold *threshold-value* [**base-threshold** *base-value*]

   By default, the session table usage change threshold is 20%, and the base session table usage threshold is 10%.

Configuring alarms for abrupt session creation rate changes

About this task

Perform this task for the device to generate alarms for abrupt increase or drop in the session creation rate. With this feature enabled, the system collects the session creation rate at an interval of 10 seconds and checks whether the following indicators reach the corresponding alarm thresholds:

- **Session creation rate change in percentage**—Obtained by dividing the difference between the session creation rates at the beginning and end of a collection interval by the session creation rate at the beginning of the collection interval.

- **Base session creation rate in percentage**—Obtained by dividing the session creation rate at the beginning of a collection interval by 100000.

If both of the following conditions are met in a detection interval, the system generates an alarm for the abrupt change of the session creation rate:

- The session creation rate change threshold is reached.
- The base session creation rate threshold is crossed.

Procedure

1. Enter system view.

   `system-view`

2. Enable alarms for abrupt session creation rate changes.

   `session alarm rate-abrupt enable`

   By default, alarms are disabled for abrupt session creation rate changes.

3. Set the alarm thresholds for abrupt session creation rate changes.

   session alarm rate-abrupt threshold *threshold-value* [**base-threshold** *base-value*]

   By default, the session creation rate change threshold is 20%, and the base session creation rate threshold is 10%.

Configuring alarms for abrupt session attempt rate changes

About this task

Perform this task for the device to generate alarms for abrupt increase or drop in the session creation attempt rate. With this feature enabled, the system collects the session creation attempt rate at an interval of 10 seconds and checks whether the following indicators reach the corresponding alarm thresholds:

- **Session attempt rate change in percentage**—Obtained by dividing the difference between the session creation attempt rates at the beginning and end of a collection interval by the session creation attempt rate at the beginning of the collection interval.
- **Base session attempt rate in percentage**—Obtained by dividing the session creation attempt rate at the beginning of a collection interval by 100000.

If both of the following conditions are met in a detection interval, the system generates an alarm for the abrupt change of the session creation attempt rate:

- The session attempt rate change threshold is reached.
- The base session attempt rate threshold is crossed.

Procedure

1. Enter system view.

   `system-view`

2. Enable alarms for abrupt session attempt rate changes.

   `session alarm try-rate-abrupt enable`

   By default, alarms are disabled for abrupt session attempt rate changes.

3. Set the alarm thresholds for abrupt session attempt rate changes.

   session alarm try-rate-abrupt threshold *threshold-value* [**base-threshold** *base-value*]

   By default, the session attempt rate change threshold is 20%, and the base session attempt rate threshold is 10%.

Enabling ALG to process fragments

About this task

This task enables ALG to process fragments of specified protocols. In the current software version, ALG can process only SIP fragments.

Procedure

1. Enter system view.

   system-view

2. Enable ALG to process fragments.

   session alg fragment sip

   By default, ALG does not process fragments.

Display and maintenance commands for session management

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the aging time for sessions of different application layer protocols.	**display session aging-time application**
Display the aging time for sessions in different protocol states.	**display session aging-time state**
Display unicast deny session statistics.	**display session fast-drop statistics** [**summary**] [**slot** *slot-number*]
Display IPv4 unicast deny session entries.	**display session fast-drop table ipv4** [**slot** *slot-number*] [**verbose**]
Display IPv6 unicast deny session entries.	**display session fast-drop table ipv6** [**slot** *slot-number*] [**verbose**]
Display top deny session statistics.	**display session fast-drop top-statistics { last-1-hour | last-24-hours | last-30-days }**
Display relation table entries.	**display session relation-table** { **ipv4** | **ipv6** } [**slot** *slot-number*]
Display unicast session statistics.	**display session statistics** [**history-max** | **summary**] [**slot** *slot-number*]
Display IPv4 unicast session statistics.	**display session statistics ipv4** [[**responder**] { **application** *application-name* | **destination-ip** *destination-ip* | **destination-port** *destination-port* | **destination-zone** *destination-zone-name* | **interface** *interface-type interface-number* | **protocol** { **dccp** | **dns** | **ftp** | **gtp** | **h323** | **http** | **icmp** | **ils** | **mgcp** | **nbt** | **pptp** | **raw-ip** | **rsh** | **rtsp** | **sccp** | **sctp** | **sip** | **smtp** | **sqlnet** | **ssh** | **tcp** |

Task	Command
	telnet | **tftp** | **udp** | **udp-lite** | **xdmcp** } | **security-policy-rule** *rule-name* | **source-ip** *source-ip* | **source-port** *source-port* | **source-zone** *source-zone-name* | **state** { **dccp-closereq** | **dccp-closing** | **dccp-open** | **dccp-partopen** | **dccp-request** | **dccp-respond** | **dccp-timewait** | **icmp-reply** | **icmp-request** | **rawip-open** | **rawip-ready** | **sctp-closed** | **sctp-cookie-echoed** | **sctp-cookie-wait** | **sctp-established** | **sctp-shutdown-ack-sent** | **sctp-shutdown-recd** | **sctp-shutdown-sent** | **tcp-close** | **tcp-close-wait** | **tcp-est** | **tcp-fin-wait** | **tcp-last-ack** | **tcp-syn-recv** | **tcp-syn-sent** | **tcp-syn-sent2** | **tcp-time-wait** | **udp-open** | **udp-ready** | **udplite-open** | **udplite-ready** } | **vpn-instance** *vpn-instance-name* } *] [**slot** *slot-number*]
Display IPv6 unicast session statistics.	**display session statistics ipv6** [[**responder**] { **application** *application-name* | **destination-ip** *destination-ip* | **destination-port** *destination-port* | **destination-zone** *destination-zone-name* | **interface** *interface-type interface-number* | **protocol** { **dccp** | **dns** | **ftp** | **gtp** | **h323** | **http** | **icmpv6** | **ils** | **mgcp** | **nbt** | **pptp** | **raw-ip** | **rsh** | **rtsp** | **sccp** | **sctp** | **sip** | **smtp** | **sqlnet** | **ssh** | **tcp** | **telnet** | **tftp** | **udp** | **udp-lite** | **xdmcp** } | **security-policy-rule** *rule-name* | **source-ip** *source-ip* | **source-port** *source-port* | **source-zone** *source-zone-name* | **state** { **dccp-closereq** | **dccp-closing** | **dccp-open** | **dccp-partopen** | **dccp-request** | **dccp-respond** | **dccp-timewait** | **icmpv6-reply** | **icmpv6-request** | **rawip-open** | **rawip-ready** | **sctp-closed** | **sctp-cookie-echoed** | **sctp-cookie-wait** | **sctp-established** | **sctp-shutdown-ack-sent** | **sctp-shutdown-recd** | **sctp-shutdown-sent** | **tcp-close** | **tcp-close-wait** | **tcp-est** | **tcp-fin-wait** | **tcp-last-ack** | **tcp-syn-recv** | **tcp-syn-sent** | **tcp-syn-sent2** | **tcp-time-wait** | **udp-open** | **udp-ready** | **udplite-open** | **udplite-ready** } | **vpn-instance** *vpn-instance-name* } *] [**slot** *slot-number*]
Display multicast session statistics.	**display session statistics multicast** [**slot** *slot-number*]
Display IPv4 unicast session table entries.	**display session table ipv4** [**slot** *slot-number*] [[**responder**] { **application** *application-name* | **destination-ip** *start-destination-ip* [*end-destination-ip*] | **destination-port** *destination-port* | **destination-zone** *destination-zone-name* | **interface** *interface-type interface-number* | **protocol** { **dccp** | **icmp** | **raw-ip** | **sctp** | **tcp** | **udp** |

Configuring object groups

About object groups

An object group is a group of objects that can be used by an ACL to identify packets. Object groups are divided into the following types:

- **MAC address object group**—A group of MAC address objects used to match the MAC address in a packet.
- **IPv4 address object group**—A group of IPv4 address objects used to match the IPv4 address in a packet or match the user from whom a packet comes.
- **IPv6 address object group**—A group of IPv6 address objects used to match the IPv6 address in a packet or match the user from whom a packet comes.
- **Service object group**—A group of service objects used to match the upper-layer service in a packet.

Restrictions and guidelines: Object group configuration

You cannot edit an object group if the group is used by a global static NAT rule.

Configuring a MAC address object group

1. Enter system view.

   `system-view`

2. Create a MAC address object group and enter its view.

   `object-group mac-address` *`object-group-name`*

   The system has one default IPv4 address object group named **any**.

3. (Optional.) Configure a description for the MAC address object group.

   `description` *`text`*

   By default, an object group does not have a description.

4. Configure a MAC address object.

   [*`object-id`*] **`mac`** { *`mac-address`* | **`group-object`** *`group-object-name`* }

5. Configure a description for the MAC address object.

   `object` *`object-id`* **`description`** *`text`*

   By default, a MAC address object does not have a description.

Configuring an IPv4 address object group

1. Enter system view.

   `system-view`

2. Create an IPv4 address object group and enter its view.

   `object-group ip address` *`object-group-name`*

   The system has one default IPv4 address object group named **any**.

3. (Optional.) Configure a description for the IPv4 address object group.

   description *text*

   By default, an object group does not have a description.

4. Configure an IPv4 address object.

   [*object-id*] **network** { **host** { **address** *ip-address* | **name** *host-name* [**vpn-instance** *vpn-instance-name*] } | **subnet** *ip-address* { *mask-length* | *mask* | **wildcard** *wildcard* } | **range** *ip-address1 ip-address2* | **group-object** *object-group-name* | **user** *user-name* [**domain** *domain-name*] | **user-group** *user-group-name* [**domain** *domain-name*] }

5. Configure a description for the IPv4 address object.

   object *object-id* **description** *text*

   By default, an IPv4 address object does not have a description.

6. Exclude an IPv4 address or a subnet from the IPv4 address object.

   object-id **network exclude** { *ip-address* | **subnet** *ip-address* { *mask-length* | *mask* } }

   By default, no IPv4 address in an IPv4 address object is excluded.

7. (Optional.) Specify a security zone for the IPv4 address object group.

   security-zone *security-zone-name*

   By default, no security zone is specified for an IPv4 address object group.

Configuring an IPv6 address object group

1. Enter system view.

   system-view

2. Create an IPv6 address object group and enter its view.

   object-group ipv6 address *object-group-name*

   The system has one default IPv6 address object group named **any**.

3. (Optional.) Configure a description for the IPv6 address object group.

   description *text*

   By default, an object group does not have a description.

4. Configure an IPv6 address object.

   [*object-id*] **network** { **host** { **address** *ipv6-address* | **name** *host-name* [**vpn-instance** *vpn-instance-name*] } | **subnet** *ipv6-address prefix-length* | **range** *ipv6-address1 ipv6-address2* | **group-object** *object-group-name* | **user** *user-name* [**domain** *domain-name*] | **user-group** *user-group-name* [**domain** *domain-name*] }

5. Configure a description for an IPv6 address object.

   object *object-id* **description** *text*

   By default, an IPv6 address object does not have a description.

6. Exclude an IPv6 address or a subnet from the IPv6 address object.

   object-id **network exclude** { *ip-address* | **subnet** *ipv6-address prefix-length* }

   By default, no IPv6 address in an IPv6 address object is excluded.

7. (Optional.) Specify a security zone for the IPv6 address object group.

   security-zone *security-zone-name*

   By default, no security zone is specified for an IPv6 address object group.

Configuring a service object group

1. Enter system view.

   system-view

2. Create a service object group and enter its view.

   object-group service *object-group-name*

   The system has multiple default service object groups.

3. (Optional.) Configure a description for the service object group.

   description *text*

   By default, an object group does not have a description.

4. Configure a service object.

   [*object-id*] **service** { *protocol* [{ **source** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } | **destination** { { **eq** | **lt** | **gt** } *port* | **range** *port1 port2* } } * | *icmp-type icmp-code* | *icmpv6-type icmpv6-code*] | **group-object** *object-group-name* }

5. Configure a description for the service object.

   object *object-id* **description** *text*

   By default, a service object does not have a description.

Renaming an object group

1. Enter system view.

   system-view

2. Rename an object group.

   object-group rename *old-object-group-name new-object-group-name*

   You can only rename non-default object groups.

Configuring aging of DNS-resolved IP addresses from host names

About this task

In load balancing scenarios where one host name maps to several IP addresses, DNS-resolved IP address for a host name changes between these mapping addresses. Upon every change, the object group module notifies relevant policies (such as security policy) of the change, which causes policies to submit changes frequently and consumes memory. To resolve this issue, you can enable aging of DNS-resolved IP addresses from host names.

With this feature enabled, the system maintains an IP address group for each host name. If a resolved IP address is not in the group, the system adds the address to the group and notifies relevant policies of the change. If a resolved IP address is in the group, the system does not notify relevant policies.

Hardware and feature compatibility

Models	Feature compatibility
NFNX5-HD6480, NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX3-HDB680, NFNX3-HDB1080	Yes

NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB1180, NFNX3-HDB1480	No

Restrictions and guidelines

As a best practice, set the aging time to be longer than the TTL of resolution records on the DNS server.

Procedure

1. Enter system view.

   system-view

2. Enable aging of DNS-resolved IP addresses from host names.

   object-group dns-aging [**time** *aging-time*]

   By default, aging of DNS-resolved IP addresses from host names is disabled.

Display and maintenance commands for object groups

Execute **display** commands in any view.

Task	Command
Display information about object groups.	**display object-group** [{ { **ip** | **ipv6** } **address** | **mac-address** | **service** } [**default**] [**name** *object-group-name*] | **name** *object-group-name*]
Display IPv4 or IPv6 addresses for host names.	**display object-group** { **ip** | **ipv6** } **host** { **object-group-name** *object-group-name* | **name** *host-name* [**vpn-instance** *vpn-instance-name*] } * [**slot** *slot-number* [**cpu** *cpu-number*]]

Configuring IP source guard

About IPSG

IP source guard (IPSG) prevents spoofing attacks by using an IPSG binding table to filter out illegitimate packets. This feature is typically configured on user-side interfaces.

IPSG operating mechanism

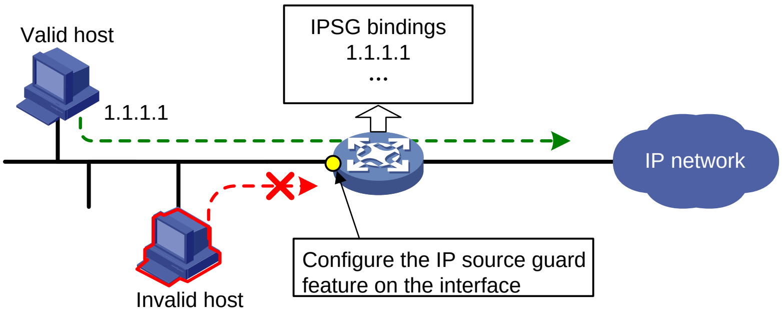
The IPSG binding table contains bindings that bind IP address, MAC address, VLAN, or any combinations. IPSG uses the bindings to match an incoming packet. If a match is found, the packet is forwarded. If no match is found, the packet is discarded.

IPSG is a per-interface packet filter. Configuring this feature on one interface does not affect packet forwarding on another interface.

IPSG bindings can be static or dynamic.

As shown in Figure 1, IPSG forwards only the packets that match an IPSG binding.

Figure 1 IPSG application



Static IPSG bindings

Static IPSG bindings are configured manually. They are suitable for scenarios where few hosts exist on a LAN and their IP addresses are manually configured. For example, you can configure a static IPSG binding on an interface that connects to a server. This binding allows the interface to receive packets only from the server.

Static IPSG bindings on an interface implement the following functions:

- Filter incoming IPv4 or IPv6 packets on the interface.
- Cooperate with ARP attack detection in IPv4 for user validity checking. For information about ARP attack detection, see "Configuring ARP attack protection."

Static IPSG bindings can be global or interface-specific.

- **Global static binding**—Binds the IP address and MAC address in system view. The binding takes effect on all interfaces to filter packets for user spoofing attack prevention.
- **Interface-specific static binding**—Binds the IP address, MAC address, VLAN, or any combination of the items in interface view. The binding takes effect only on the interface to check the validity of users who are attempting to access the interface.

Dynamic IPSG bindings

IPSG automatically obtains user information from other modules to generate dynamic bindings. A dynamic IPSG binding can contain MAC address, IPv4 or IPv6 address, VLAN tag, ingress interface, and binding type. The binding type identifies the source module for the binding, such as DHCP relay.

For example, DHCP-based IPSG bindings are suitable for scenarios where hosts on a LAN obtain IP addresses through DHCP. When a host obtains an IP address through DHCP, each of the following modules generates an entry:

- The DHCP server generates a DHCP binding.
- The DHCP relay agent generates a DHCP relay entry.

IPSG generates a dynamic IPSG binding based on each of the above entries. IPSG allows only packets from the DHCP clients to pass through.

Dynamic IPv4SG

Dynamic bindings generated based on different source modules are for different usages:

Interface types	Source modules	Binding usage
Layer 2 Ethernet interface	ARP snooping	For cooperation with modules (such as the ARP attack detection module) to provide security services.
Layer 3 Ethernet interface Layer 3 aggregate interface VLAN interface Reth interface Reth subinterface	DHCP relay agent	Packet filtering.
	DHCP server	For cooperation with modules (such as the authorized ARP module) to provide security services.

For information about DHCP relay and DHCP server, see *Layer 3—IP Services Configuration Guide*.

Dynamic IPv6SG

Dynamic IPv6SG bindings are generated based on different source modules.

IPSG tasks at a glance

To configure IPv4SG, perform the following tasks:

1. Enabling IPv4SG on an interface
2. (Optional.) Configuring a static IPv4SG binding

To configure IPv6SG, perform the following tasks:

1. Enabling IPv6SG on an interface
2. (Optional.) Configuring a static IPv6SG binding

Configuring the IPv4SG feature

Enabling IPv4SG on an interface

About this task

When you enable IPSG on an interface, the static and dynamic IPSG are both enabled.

- Static IPv4SG uses static bindings configured by using the **ip source binding** command. For more information, see "Configuring a static IPv4SG binding."
- Dynamic IPv4SG generates dynamic bindings from related source modules. IPv4SG uses the bindings to filter incoming IPv4 packets based on the matching criteria specified in the **ip verify source** command.

Restrictions and guidelines

> △ **CAUTION:**
>
> If you only enable IPv4SG on an interface but fail to configure static IPv4SG bindings or dynamic IPv4SG bindings, the interface discards all received packets.

To implement static IPv4SG, configure static IPv4SG bindings.

To implement dynamic IPv4SG, make sure ARP snooping, DHCP relay agent, or DHCP server operates correctly on the network.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   The following interface types are supported:
   - Layer 2 Ethernet interface.
   - Layer 3 Ethernet interface.
   - Layer 3 Ethernet subinterface.
   - Layer 3 aggregate interface.
   - Layer 3 aggregate subinterface.
   - VLAN interface.
   - Reth interface.
   - Reth subinterface.
3. Enable the IPv4SG feature.
   ip verify source { **ip-address** | **ip-address mac-address** | **mac-address** }
   By default, the IPv4SG feature is disabled on an interface.

Configuring a static IPv4SG binding

About this task

You can configure global static and interface-specific static IPv4SG bindings. Interface-specific static and dynamic bindings take priority over global static bindings. An interface first uses the static and dynamic bindings on the interface to match packets. If no match is found, the interface uses the global bindings.

Restrictions and guidelines

Global static bindings take effect on all interfaces on the device.

To configure a static IPv4SG binding for the ARP attack detection feature, make sure the following conditions are met:

- The **ip-address** *ip-address* option, the **mac-address** *mac-address* option, and the **vlan** *vlan-id* option must be specified.
- ARP attack detection must be enabled for the specified VLAN.

Configuring a global static IPv4SG binding

1. Enter system view.

   system-view

2. Configure a global static IPv4SG binding.

   ip source binding ip-address *ip-address* **mac-address** *mac-address*

Configuring a static IPv4SG binding on an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

   The following interface types are supported:

   - Layer 2 Ethernet interface.
   - Layer 3 Ethernet interface.
   - Layer 3 Ethernet subinterface.
   - Layer 3 aggregate interface.
   - Layer 3 aggregate subinterface.
   - VLAN interface.
   - Reth interface.
   - Reth subinterface.

3. Configure a static IPv4SG binding.

   ip source binding { **ip-address** *ip-address* | **ip-address** *ip-address* **mac-address** *mac-address* | **mac-address** *mac-address* } [**vlan** *vlan-id*]

   You can configure the same static IPv4SG binding on different interfaces.

Configuring the IPv6SG feature

Enabling IPv6SG on an interface

About this task

When you enable IPv6SG on an interface, the static and dynamic IPv6SG are both enabled.

- Static IPv6SG uses static bindings configured by using the **ipv6 source binding** command. For more information, see "Configuring a static IPv6SG binding."
- Dynamic IPv6SG generates dynamic bindings from related source modules. IPv6SG uses the bindings to filter incoming IPv6 packets based on the matching criteria specified in the **ipv6 verify source** command.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

   The following interface types are supported:

   - Layer 2 Ethernet interface.
   - Layer 3 Ethernet interface.

- Layer 3 Ethernet subinterface.
- Layer 3 aggregate interface.
- Layer 3 aggregate subinterface.
- VLAN interface.
- Reth interface.
- Reth subinterface.

3. Enable the IPv6SG feature.

```
ipv6 verify source { ip-address | ip-address mac-address |
mac-address }
```

By default, the IPv6SG feature is disabled on an interface.

Configuring a static IPv6SG binding

About this task

You can configure global static and interface-specific static IPv6SG bindings. Interface-specific static and dynamic bindings take priority over global static bindings. An interface first uses the static and dynamic bindings on the interface to match packets. If no match is found, the interface uses the global bindings.

Restrictions and guidelines

Global static bindings take effect on all interfaces on the device.

Configuring a global static IPv6SG binding

1. Enter system view.

```
system-view
```

2. Configure a global static IPv6SG binding.

```
ipv6 source binding ip-address ipv6-address mac-address mac-address
```

Configuring a static IPv6SG binding on an interface

1. Enter system view.

```
system-view
```

2. Enter interface view.

```
interface interface-type interface-number
```

The following interface types are supported:

- Layer 2 Ethernet interface.
- Layer 3 Ethernet interface.
- Layer 3 Ethernet subinterface.
- Layer 3 aggregate interface.
- Layer 3 aggregate subinterface.
- VLAN interface.
- Reth interface.
- Reth subinterface.

3. Configure a static IPv6SG binding.

```
ipv6 source binding { ip-address ipv6-address | ip-address ipv6-address
mac-address mac-address | mac-address mac-address } [ vlan vlan-id ]
```

You can configure the same static IPv6SG binding on different interfaces.

Display and maintenance commands for IPSG

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display IPv4SG bindings.	**display ip source binding** [**static** | [**vpn-instance** *vpn-instance-name*] [**dhcp-relay** | **dhcp-server** | **ip-mac-vlan** | **ip-mac-vpn**]] [**ip-address** *ip-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display IPv6SG bindings.	**display ipv6 source binding** [**static** | [**vpn-instance** *vpn-instance-name*] [**ipv6-mac-vlan** | **ipv6-mac-vpn**]] [**ip-address** *ipv6-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**slot** *slot-number*]

Contents

Configuring AAA

About AAA

AAA implementation

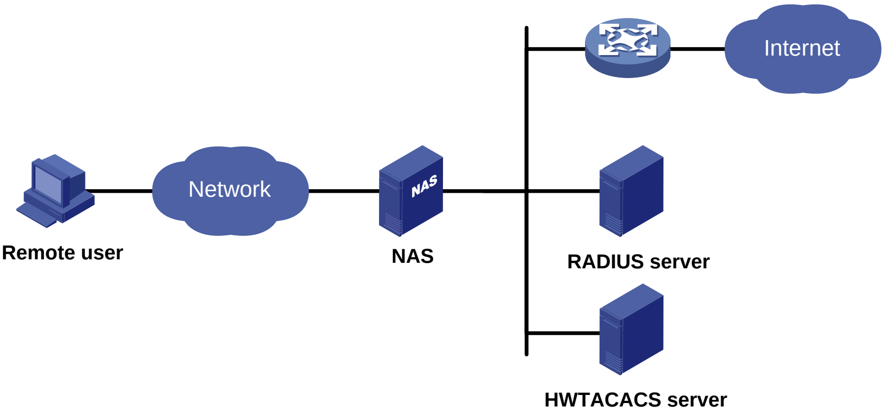
Authentication, Authorization, and Accounting (AAA) provides a uniform framework for implementing network access management. This feature specifies the following security functions:

- **Authentication**—Identifies users and verifies their validity.
- **Authorization**—Grants different users different rights, and controls the users' access to resources and services. For example, you can permit office users to read and print files and prevent guests from accessing files on the device.
- **Accounting**—Records network usage details of users, including the service type, start time, and traffic. This function enables time-based and traffic-based charging and user behavior auditing.

AAA network diagram

AAA uses a client/server model. The client runs on the access device, or the network access server (NAS), which authenticates user identities and controls user access. The server maintains user information centrally. See Figure 1.

Figure 1 AAA network diagram



To access networks or resources beyond the NAS, a user sends its identity information to the NAS. The NAS transparently passes the user information to AAA servers and waits for the authentication, authorization, and accounting result. Based on the result, the NAS determines whether to permit or deny the access request.

AAA has various implementations, including HWTACACS, LDAP, and RADIUS. RADIUS is most often used.

You can use different servers to implement different security functions. For example, you can use an HWTACACS server for authentication and authorization, and use a RADIUS server for accounting.

You can choose the security functions provided by AAA as needed. For example, if your company wants employees to be authenticated before they access specific resources, you would deploy an authentication server. If network usage information is needed, you would also configure an accounting server.

The device performs dynamic password authentication.

RADIUS

Remote Authentication Dial-In User Service (RADIUS) is a distributed information interaction protocol that uses a client/server model. The protocol can protect networks against unauthorized access and is often used in network environments that require both high security and remote user access.

The RADIUS authorization process is combined with the RADIUS authentication process, and user authorization information is piggybacked in authentication responses. RADIUS uses UDP port 1812 for authentication and UDP port 1813 for accounting.

RADIUS was originally designed for dial-in user access, and has been extended to support additional access methods, such as Ethernet and ADSL.

Client/server model

The RADIUS client runs on the NASs located throughout the network. It passes user information to RADIUS servers and acts on the responses to, for example, reject or accept user access requests.

The RADIUS server runs on the computer or workstation at the network center and maintains information related to user authentication and network service access.

The RADIUS server operates using the following process:

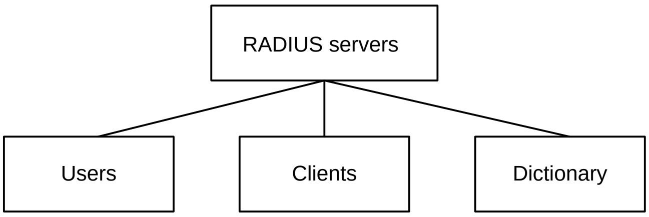
1. Receives authentication, authorization, and accounting requests from RADIUS clients.
2. Performs user authentication, authorization, or accounting.
3. Returns user access control information (for example, rejecting or accepting the user access request) to the clients.

The RADIUS server can also act as the client of another RADIUS server to provide authentication proxy services.

The RADIUS server maintains the following databases:

- **Users**—Stores user information, such as the usernames, passwords, applied protocols, and IP addresses.
- **Clients**—Stores information about RADIUS clients, such as shared keys and IP addresses.
- **Dictionary**—Stores RADIUS protocol attributes and their values.

Figure 2 RADIUS server databases



Information exchange security mechanism

The RADIUS client and server exchange information between them with the help of shared keys, which are preconfigured on the client and server. A RADIUS packet has a 16-byte field called Authenticator. This field includes a signature generated by using the MD5 algorithm, the shared key, and some other information. The receiver of the packet verifies the signature and accepts the packet only when the signature is correct. This mechanism ensures the security of information exchanged between the RADIUS client and server.

The shared keys are also used to encrypt user passwords that are included in RADIUS packets.

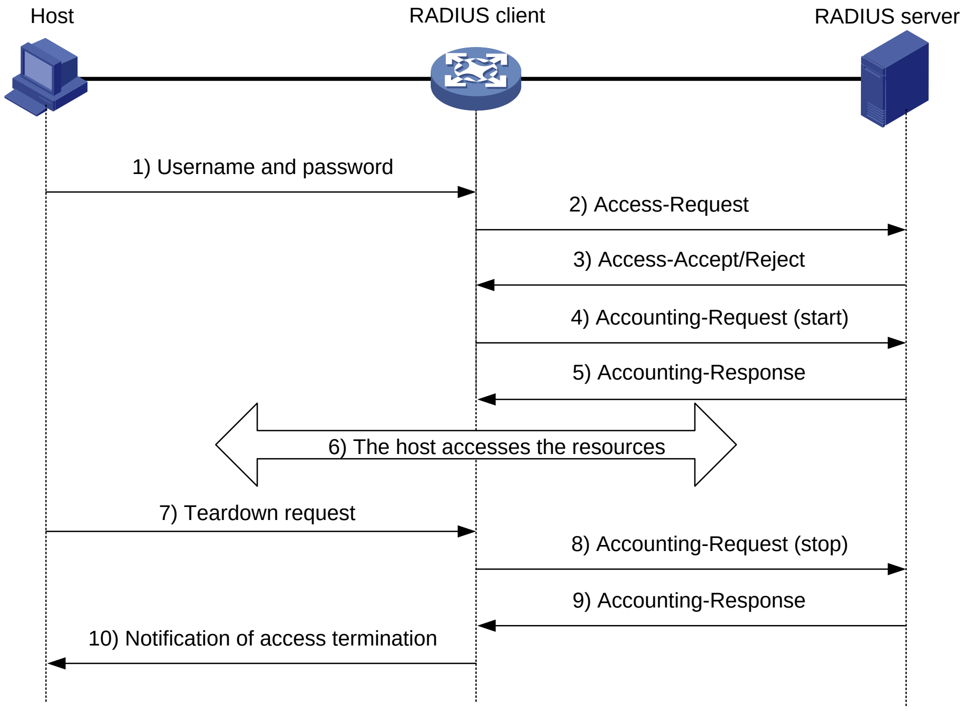
User authentication methods

The RADIUS server supports multiple user authentication methods, such as PAP, CHAP, and EAP.

Basic RADIUS packet exchange process

Figure 3 illustrates the interactions between a user host, the RADIUS client, and the RADIUS server.

Figure 3 Basic RADIUS packet exchange process



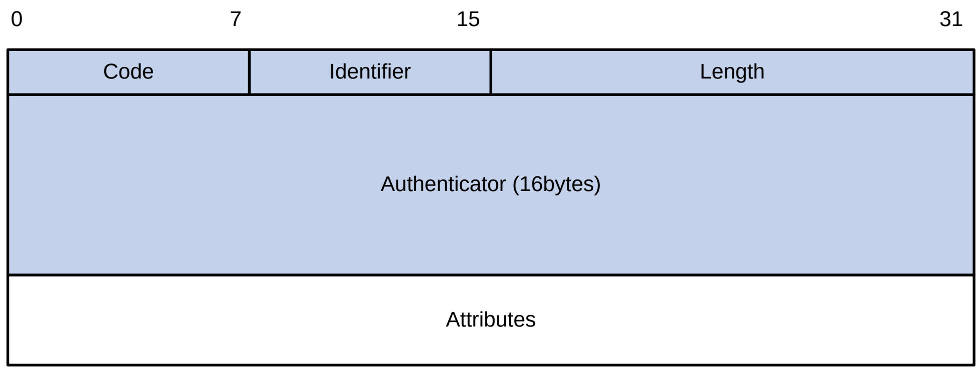
RADIUS uses in the following workflow:

1. The host sends a connection request that includes the user's username and password to the RADIUS client.
2. The RADIUS client sends an authentication request (Access-Request) to the RADIUS server. The request includes the user's password, which has been processed by the MD5 algorithm and shared key.
3. The RADIUS server authenticates the username and password. If the authentication succeeds, the server sends back an Access-Accept packet that contains the user's authorization information. If the authentication fails, the server returns an Access-Reject packet.
4. The RADIUS client permits or denies the user according to the authentication result. If the result permits the user, the RADIUS client sends a start-accounting request (Accounting-Request) packet to the RADIUS server.
5. The RADIUS server returns an acknowledgment (Accounting-Response) packet and starts accounting.
6. The user accesses the network resources.
7. The host requests the RADIUS client to tear down the connection.
8. The RADIUS client sends a stop-accounting request (Accounting-Request) packet to the RADIUS server.
9. The RADIUS server returns an acknowledgment (Accounting-Response) and stops accounting for the user.
10. The RADIUS client notifies the user of the termination.

RADIUS packet format

RADIUS uses UDP to transmit packets. The protocol also uses a series of mechanisms to ensure smooth packet exchange between the RADIUS server and the client. These mechanisms include the timer mechanism, the retransmission mechanism, and the backup server mechanism.

Figure 4 RADIUS packet format



Descriptions of the fields are as follows:

- The Code field (1 byte long) indicates the type of the RADIUS packet. Table 1 gives the main values and their meanings.

  Table 1 Main values of the Code field

Code	Packet type	Description
1	Access-Request	From the client to the server. A packet of this type includes user information for the server to authenticate the user. It must contain the User-Name attribute and can optionally contain the attributes of NAS-IP-Address, User-Password, and NAS-Port.
2	Access-Accept	From the server to the client. If all attribute values included in the Access-Request are acceptable, the authentication succeeds, and the server sends an Access-Accept response.
3	Access-Reject	From the server to the client. If any attribute value included in the Access-Request is unacceptable, the authentication fails, and the server sends an Access-Reject response.
4	Accounting-Request	From the client to the server. A packet of this type includes user information for the server to start or stop accounting for the user. The Acct-Status-Type attribute in the packet indicates whether to start or stop accounting.
5	Accounting-Response	From the server to the client. The server sends a packet of this type to notify the client that it has received the Accounting-Request and has successfully recorded the accounting information.

- The Identifier field (1 byte long) is used to match response packets with request packets and to detect duplicate request packets. The request and response packets of the same exchange process for the same purpose (such as authentication or accounting) have the same identifier.
- The Length field (2 bytes long) indicates the length of the entire packet (in bytes), including the Code, Identifier, Length, Authenticator, and Attributes fields. Bytes beyond this length are considered padding and are ignored by the receiver. If the length of a received packet is less than this length, the packet is dropped.
- The Authenticator field (16 bytes long) is used to authenticate responses from the RADIUS server and to encrypt user passwords. There are two types of authenticators: request authenticator and response authenticator.

- The Attributes field (variable in length) includes authentication, authorization, and accounting information. This field can contain multiple attributes, each with the following subfields:
    - **Type**—Type of the attribute.
    - **Length**—Length of the attribute in bytes, including the Type, Length, and Value subfields.
    - **Value**—Value of the attribute. Its format and content depend on the Type subfield.

Extended RADIUS attributes

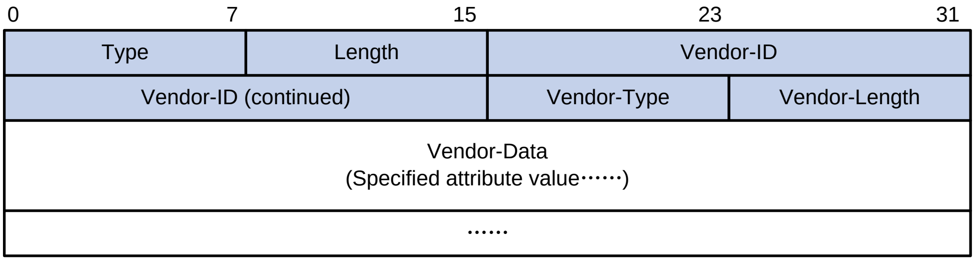
The RADIUS protocol features excellent extensibility. The Vendor-Specific attribute (attribute 26) allows a vendor to define extended attributes. The extended attributes can implement functions that the standard RADIUS protocol does not provide.

A vendor can encapsulate multiple subattributes in the TLV format in attribute 26 to provide extended functions. As shown in Figure 5, a subattribute encapsulated in attribute 26 consists of the following parts:

- **Vendor-ID**—ID of the vendor. The most significant byte is 0. The other three bytes contains a code compliant to RFC 1700.
- **Vendor-Type**—Type of the subattribute.
- **Vendor-Length**—Length of the subattribute.
- **Vendor-Data**—Contents of the subattribute.

The device supports private RADIUS subattributes with a vendor ID of 25506. For more information, see "Appendix C RADIUS subattributes (vendor ID 25506)."

Figure 5 Format of attribute 26



HWTACACS

HW Terminal Access Controller Access Control System (HWTACACS) is an enhanced security protocol based on TACACS (RFC 1492). HWTACACS is similar to RADIUS, and uses a client/server model for information exchange between the NAS and the HWTACACS server.

HWTACACS typically provides AAA services for VPDN, PPP, and terminal users. In a typical HWTACACS scenario, terminal users need to log in to the NAS. Working as the HWTACACS client, the NAS sends users' usernames and passwords to the HWTACACS server for authentication. After passing authentication and obtaining authorized rights, a user logs in to the device and performs operations. The HWTACACS server records the operations that each user performs.

Differences between HWTACACS and RADIUS

HWTACACS and RADIUS have many features in common, such as using a client/server model, using shared keys for data encryption, and providing flexibility and scalability. Table 2 lists the primary differences between HWTACACS and RADIUS.

Table 2 Primary differences between HWTACACS and RADIUS

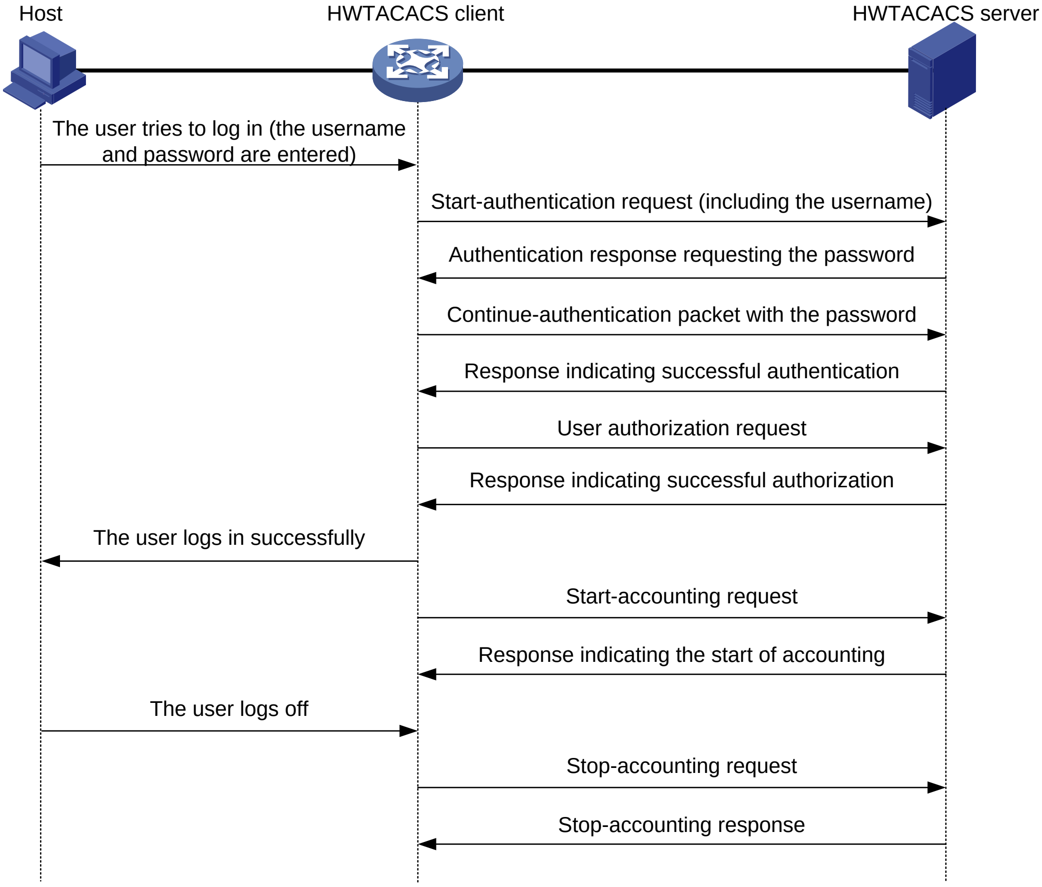
HWTACACS	RADIUS
Uses TCP, which provides reliable network	Uses UDP, which provides high transport efficiency.

HWTACACS	RADIUS
transmission.	
Encrypts the entire packet except for the HWTACACS header.	Encrypts only the user password field in an authentication packet.
Protocol packets are complicated and authorization is independent of authentication. Authentication and authorization can be deployed on different HWTACACS servers.	Protocol packets are simple and the authorization process is combined with the authentication process.
Supports authorization of configuration commands. Access to commands depends on both the user's roles and authorization. A user can use only commands that are permitted by the user roles and authorized by the HWTACACS server.	Does not support authorization of configuration commands. Access to commands solely depends on the user's roles. For more information about user roles, see *Fundamentals Configuration Guide*.

Basic HWTACACS packet exchange process

Figure 6 describes how HWTACACS performs user authentication, authorization, and accounting for a Telnet user.

Figure 6 Basic HWTACACS packet exchange process for a Telnet user



Host
HWTACACS client
HWTACACS server
The user tries to log in (the username and password are entered)
Start-authentication request (including the username)
Authentication response requesting the password
Continue-authentication packet with the password
Response indicating successful authentication
User authorization request
Response indicating successful authorization
The user logs in successfully
Start-accounting request
Response indicating the start of accounting
The user logs off
Stop-accounting request
Stop-accounting response

HWTACACS operates using in the following workflow:

1. A Telnet user requests to Telnet to the device (HWTACACS client) and provides the username and password as instructed by the system.
2. The HWTACACS client sends a start-authentication request that includes the username to the HWTACACS server when it receives the Telnet request.

3. The HWTACACS server sends back an authentication response to request the login password.
4. Upon receipt of the response, the HWTACACS client sends the HWTACACS server a continue-authentication packet that includes the login password.
5. If the authentication succeeds, the HWTACACS server sends back an authentication response to indicate that the user has passed authentication.
6. The HWTACACS client sends a user authorization request packet to the HWTACACS server.
7. If the authorization succeeds, the HWTACACS server sends back an authorization response, indicating that the user is now authorized.
8. Knowing that the user is now authorized, the HWTACACS client pushes its CLI to the user and permits the user to log in.
9. The HWTACACS client sends a start-accounting request to the HWTACACS server.
10. The HWTACACS server sends back an accounting response, indicating that it has received the start-accounting request.
11. The user logs off.
12. The HWTACACS client sends a stop-accounting request to the HWTACACS server.
13. The HWTACACS server sends back a stop-accounting response, indicating that the stop-accounting request has been received.

LDAP

The Lightweight Directory Access Protocol (LDAP) provides standard multiplatform directory service. LDAP was developed on the basis of the X.500 protocol. It improves the following functions of X.500:

- Read/write interactive access.
- Browse.
- Search.

LDAP is suitable for storing data that does not often change. The protocol is used to store user information. For example, LDAP server software Active Directory Server is used in Microsoft Windows operating systems. The software stores the user information and user group information for user login authentication and authorization.

LDAP directory service

LDAP uses directories to maintain the organization information, personnel information, and resource information. The directories are organized in a tree structure and include entries. An entry is a set of attributes with distinguished names (DNs). The attributes are used to store information such as usernames, passwords, emails, computer names, and phone numbers.

LDAP uses a client/server model, and all directory information is stored in the LDAP server. Commonly used LDAP server products include Microsoft Active Directory Server, IBM Tivoli Directory Server, and Sun ONE Directory Server.

LDAP authentication and authorization

AAA can use LDAP to provide authentication and authorization services for users. LDAP defines a set of operations to implement its functions. The main operations for authentication and authorization are the bind operation and search operation.

- The bind operation allows an LDAP client to perform the following operations:
    - Establish a connection with the LDAP server.
    - Obtain the access rights to the LDAP server.
    - Check the validity of user information.
- The search operation constructs search conditions and obtains the directory resource information of the LDAP server.

In LDAP authentication, the client completes the following tasks:

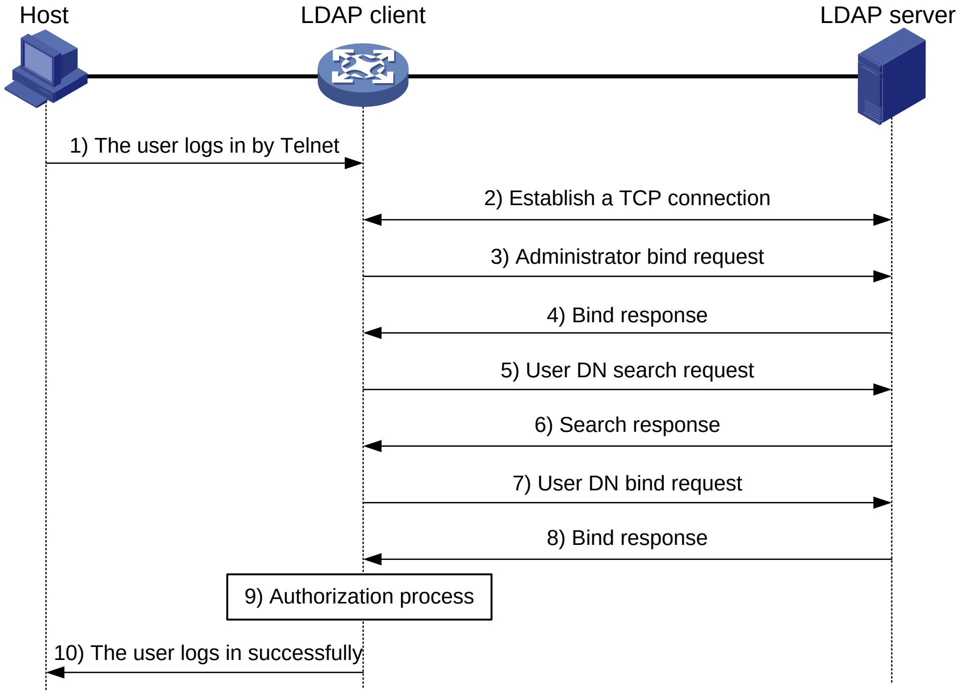
1. Uses the LDAP server administrator DN to bind with the LDAP server. After the binding is created, the client establishes a connection to the server and obtains the right to search.
2. Constructs search conditions by using the username in the authentication information of a user. The specified root directory of the server is searched and a user DN list is generated.
3. Binds with the LDAP server by using each user DN and password. If a binding is created, the user is considered legal.

In LDAP authorization, the client performs the same tasks as in LDAP authentication. When the client constructs search conditions, it obtains both authorization information and the user DN list.

Basic LDAP authentication process

The following example illustrates the basic LDAP authentication process for a Telnet user.

Figure 7 Basic LDAP authentication process for a Telnet user



Host
LDAP client
LDAP server
1) The user logs in by Telnet
2) Establish a TCP connection
3) Administrator bind request
4) Bind response
5) User DN search request
6) Search response
7) User DN bind request
8) Bind response
9) Authorization process
10) The user logs in successfully

The following shows the basic LDAP authentication process:

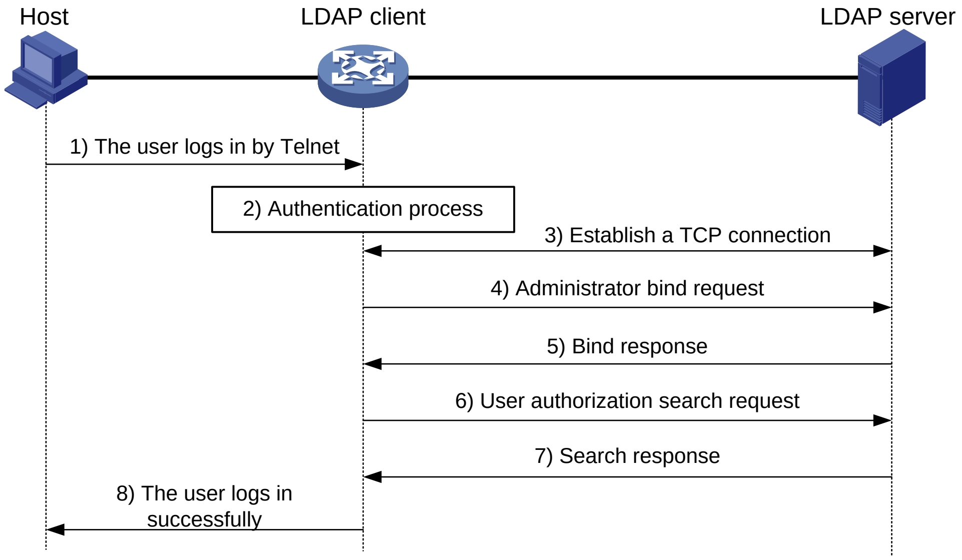
1. A Telnet user initiates a connection request and sends the username and password to the LDAP client.
2. After receiving the request, the LDAP client establishes a TCP connection with the LDAP server.
3. To obtain the right to search, the LDAP client uses the administrator DN and password to send an administrator bind request to the LDAP server.
4. The LDAP server processes the request. If the bind operation is successful, the LDAP server sends an acknowledgment to the LDAP client.
5. The LDAP client sends a user DN search request with the username of the Telnet user to the LDAP server.
6. After receiving the request, the LDAP server searches for the user DN by the base DN, search scope, and filtering conditions. If a match is found, the LDAP server sends a response to notify the LDAP client of the successful search. There might be one or more user DNs found.
7. The LDAP client uses the obtained user DN and the entered user password as parameters to send a user DN bind request to the LDAP server. The server will check whether the user password is correct.

8. The LDAP server processes the request, and sends a response to notify the LDAP client of the bind operation result. If the bind operation fails, the LDAP client uses another obtained user DN as the parameter to send a user DN bind request to the LDAP server. This process continues until a DN is bound successfully or all DNs fail to be bound. If all user DNs fail to be bound, the LDAP client notifies the user of the login failure and denies the user's access request.
9. The LDAP client saves the user DN that has been bound and exchanges authorization packets with the authorization server.
   - If LDAP authorization is used, see the authorization process shown in Figure 8.
   - If another method is expected for authorization, the authorization process of that method applies.
10. After successful authorization, the LDAP client notifies the user of the successful login.

Basic LDAP authorization process

The following example illustrates the basic LDAP authorization process for a Telnet user.

Figure 8 Basic LDAP authorization process for a Telnet user



Host
LDAP client
LDAP server
1) The user logs in by Telnet
2) Authentication process
3) Establish a TCP connection
4) Administrator bind request
5) Bind response
6) User authorization search request
7) Search response
8) The user logs in successfully

The following shows the basic LDAP authorization process:

1. A Telnet user initiates a connection request and sends the username and password to the device. The device will act as the LDAP client during authorization.
2. After receiving the request, the device exchanges authentication packets with the authentication server for the user:
   - If LDAP authentication is used, see the authentication process shown in Figure 7.
     - If the device (the LDAP client) uses the same LDAP server for authentication and authorization, skip to step 6.
     - If the device (the LDAP client) uses different LDAP servers for authentication and authorization, skip to step 4.
   - If another authentication method is used, the authentication process of that method applies. The device acts as the LDAP client. Skip to step 3.
3. The LDAP client establishes a TCP connection with the LDAP authorization server.
4. To obtain the right to search, the LDAP client uses the administrator DN and password to send an administrator bind request to the LDAP server.
5. The LDAP server processes the request. If the bind operation is successful, the LDAP server sends an acknowledgment to the LDAP client.

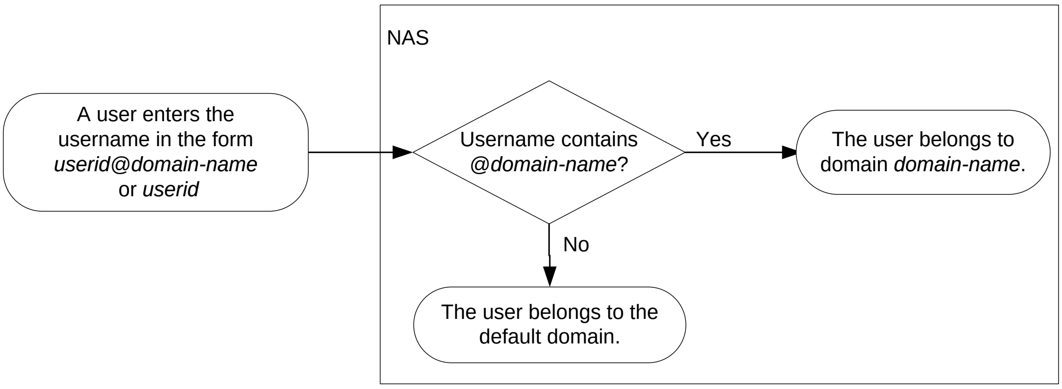
6. The LDAP client sends an authorization search request with the username of the Telnet user to the LDAP server. If the user uses the same LDAP server for authentication and authorization, the client sends the request with the saved user DN of the Telnet user to the LDAP server.
7. After receiving the request, the LDAP server searches for the user information by the base DN, search scope, filtering conditions, and LDAP attributes. If a match is found, the LDAP server sends a response to notify the LDAP client of the successful search.
8. After successful authorization, the LDAP client notifies the user of the successful login.

User management based on ISP domains and user access types

AAA manages users based on the users' ISP domains and access types.

On a NAS, each user belongs to one ISP domain. The NAS determines the ISP domain to which a user belongs based on the username entered by the user at login.

Figure 9 Determining the ISP domain for a user by username



NAS
A user enters the username in the form *userid@domain-name* or *userid*
Username contains *@domain-name*?
Yes
The user belongs to domain *domain-name*.
No
The user belongs to the default domain.

AAA manages users in the same ISP domain based on the users' access types. The device supports the following user access types:

- **LAN**—LAN users must pass MAC authentication to come online.
- **Login**—Login users include SSH, Telnet, FTP, and terminal users that log in to the device. Terminal users can access through a console port.
- ADVPN.
- **Portal**—Portal users must pass portal authentication to access the network.
- PPP.
- **IPoE**—IPoE users include Layer 2 and Layer 3 leased line users and Set Top Box (STB) users.
- **IKE**—IKE users must pass IKE extended authentication to access the network.
- **HTTP/HTTPS**—Users log in to the device through HTTP or HTTPS.
- SSL VPN.

Authentication, authorization, and accounting methods

AAA supports configuring different authentication, authorization, and accounting methods for different types of users in an ISP domain. The NAS determines the ISP domain and access type of a user. The NAS also uses the methods configured for the access type in the domain to control the user's access.

AAA also supports configuring a set of default methods for an ISP domain. These default methods are applied to users for whom no AAA methods are configured.

Authentication methods

The device supports the following authentication methods:

- **No authentication**—This method trusts all users and does not perform authentication. For security purposes, do not use this method.
- **Local authentication**—The NAS authenticates users by itself, based on the locally configured user information including the usernames, passwords, and attributes. Local authentication allows high speed and low cost, but the amount of information that can be stored is limited by the size of the storage space.
- **Remote authentication**—The NAS works with a remote server to authenticate users. The NAS communicates with the remote server through the RADIUS, LDAP, or HWTACACS protocol. The server manages user information in a centralized manner. Remote authentication provides high capacity, reliable, and centralized authentication services for multiple NASs. You can configure backup methods to be used when the remote server is not available.

Authorization methods

The device supports the following authorization methods:

- **No authorization**—The NAS performs no authorization exchange. The following default authorization information applies after users pass authentication:
  - Login users obtain the level-0 user role. For more information about the level-0 user role, see RBAC configuration in *Fundamentals Configuration Guide*.
  - The working directory for FTP, SFTP, and SCP login users is the root directory of the NAS. However, the users do not have permission to access the root directory.
  - Non-login users can access the network.
- **Local authorization**—The NAS performs authorization according to the user attributes locally configured for users.
- **Remote authorization**—The NAS works with a remote server to authorize users. RADIUS authorization is bound with RADIUS authentication. RADIUS authorization can work only after RADIUS authentication is successful, and the authorization information is included in the Access-Accept packet. HWTACACS or LDAP authorization is separate from authentication, and the authorization information is included in the authorization response after successful authentication. You can configure backup methods to be used when the remote server is not available.

Accounting methods

The device supports the following accounting methods:

- **No accounting**—The NAS does not perform accounting for the users.
- **Local accounting**—Local accounting is implemented on the NAS. It counts and controls the number of concurrent users that use the same local user account, but does not provide statistics for charging.
- **Remote accounting**—The NAS works with a RADIUS server or HWTACACS server for accounting. You can configure backup methods to be used when the remote server is not available.

AAA extended functions

The device provides the following login services to enhance device security:

- **Command authorization**—Enables the NAS to let the authorization server determine whether a command entered by a login user is permitted. Login users can execute only commands permitted by the authorization server. For more information about command authorization, see controlling user access to the device in *Fundamentals Configuration Guide*.
- **Command accounting**—When command authorization is disabled, command accounting enables the accounting server to record all valid commands executed on the device. When

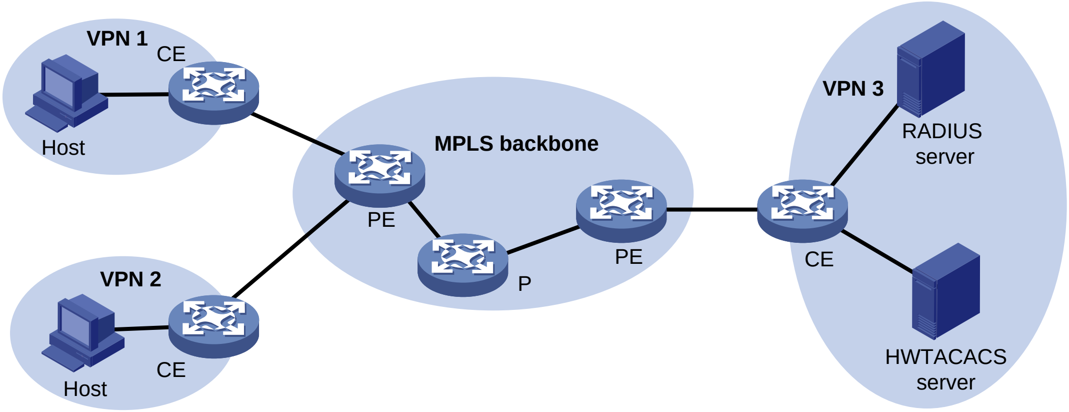
command authorization is enabled, command accounting enables the accounting server to record all authorized commands. For more information about command accounting, see controlling user access to the device in *Fundamentals Configuration Guide*.

- **User role authentication**—Authenticates each user that wants to obtain another user role without logging out or getting disconnected. For more information about user role authentication, see *Fundamentals Configuration Guide*.

AAA for VPNs

You can deploy AAA across VPNs to enable forwarding of authentication, authorization, and accounting packets across VPNs. For example, as shown in Figure 10, the PE at the left side of the MPLS backbone acts as a NAS. The NAS transparently delivers the AAA packets of private users in VPN 1 and VPN 2 to the AAA servers in VPN 3 for centralized authentication. Authentication packets of private users in different VPNs do not affect each other.

Figure 10 Network diagram



Protocols and standards

- RFC 2865, *Remote Authentication Dial In User Service (RADIUS)*
- RFC 2866, *RADIUS Accounting*
- RFC 2867, *RADIUS Accounting Modifications for Tunnel Protocol Support*
- RFC 2868, *RADIUS Attributes for Tunnel Protocol Support*
- RFC 2869, *RADIUS Extensions*
- RFC 3576, *Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)*
- RFC 4818, *RADIUS Delegated-IPv6-Prefix Attribute*

- RFC 1492, *An Access Control Protocol, Sometimes Called TACACS*
- RFC 1777, *Lightweight Directory Access Protocol*
- RFC 2251, *Lightweight Directory Access Protocol (v3)*

AAA tasks at a glance

To configure AAA, perform the following tasks:

1. Configuring AAA schemes

   If local authentication is used, configure local users and the related attributes. If remote authentication is used, configure the required RADIUS, LDAP, or HWTACACS schemes.

   - Configuring local users
   - Configuring RADIUS
   - Configuring HWTACACS
   - Configuring LDAP
2. Configuring an ISP domain
   a. Creating an ISP domain
   b. Configuring ISP domain attributes
3. Configuring AAA methods for an ISP domain

   Configure authentication, authorization, and accounting methods for an ISP domain as needed. These methods use existing AAA schemes.

   - Configuring authentication methods for an ISP domain
   - Configuring authorization methods for an ISP domain
   - Configuring accounting methods for an ISP domain
4. (Optional.) Configuring advanced AAA features
   - Configuring domain name delimiters
   - Setting the maximum number of concurrent login users
   - Configuring a NAS-ID
   - Enabling password change prompt logging
   - Configuring the device ID
   - Configuring the AAA test feature

Configuring local users

About local users

To implement local authentication, authorization, and accounting, create local users and configure user attributes on the device. The local users and attributes are stored in the local user database on the device. A local user is uniquely identified by the combination of a username and a user type.

Local users are classified into the following types:

- **Device management user**—User that logs in to the device for device management.
- **Network access user**—User that accesses network resources through the device.

  Network access users also include guests that access the network temporarily. Guests can use only LAN and portal services.

The following shows the configurable local user attributes:

- **Description**—Descriptive information of the user.
- **Service type**—Services that the user can use. Local authentication checks the service types of a local user. If none of the service types is available, the user cannot pass authentication.
- **User state**—Whether or not a local user can request network services. There are two user states: active and blocked. A user in active state can request network services, but a user in blocked state cannot.
- **Upper limit of concurrent logins using the same user name**—Maximum number of users that can concurrently access the device by using the same user name. When the number reaches the upper limit, no more local users can access the device by using the user name.

- **User group**—Each local user belongs to a local user group and has all attributes of the group. The attributes include the password control attributes and authorization attributes. For more information about local user group, see "Configuring user group attributes."
- **Identity group**—The user identification module controls the network access of a local user based on the identity group to which the user belongs. For more information about identity-based user identification, see "Configuring user identification."
- **Binding attributes**—Binding attributes control the scope of users, and are checked during local authentication of a user. If the attributes of a user do not match the binding attributes configured for the local user account, the user cannot pass authentication.
- **Authorization attributes**—Authorization attributes indicate the user's rights after it passes local authentication.

  Configure the authorization attributes based on the service type of local users. For example, you do not need to configure the FTP/SFTP/SCP working directory attribute for a PPP user.

  You can configure an authorization attribute in user group view or local user view. The setting of an authorization attribute in local user view takes precedence over the attribute setting in user group view.

The attribute configured in user group view takes effect on all local users in the user group.

The attribute configured in local user view takes effect only on the local user.

- **Password control attributes**—Password control attributes help control password security for local users. Password control attributes include password aging time, minimum password length, password composition checking, password complexity checking, and login attempt limit.

  You can configure a password control attribute in system view, user group view, or local user view. A password control attribute with a smaller effective range has a higher priority. For more information about password management and global password configuration, see "Configuring password control."
- **Validity period**—Time period in which a network access user is considered valid for authentication.

Local user configuration tasks at a glance

To configure local users, perform the following tasks:

1. Configuring local user attributes
   - Configuring attributes for device management users
   - Configuring attributes for network access users
   - Configuring local guest attributes
2. (Optional.) Configuring user group attributes
3. (Optional.) Configuring local users in batch
4. (Optional.) Managing network access users
5. (Optional.) Managing local guests

Configuring attributes for device management users

Restrictions and guidelines

The enabling status of global password control for device management users affects the way that the device stores the passwords of device management users.

- When password control is enabled globally for device management users, the device neither displays the passwords of the users nor retains the passwords in the running configuration.
- When you globally disable password control for device manangement users, the device automatically restores the passwords of the users to the running configuration.

To enable password control globally for device management users, use the **password-control enable** command. To display the running configuration, use the **display current-configuration** command.

You can configure authorization attributes and password control attributes in local user view or user group view. The setting in local user view takes precedence over the setting in user group view.

Procedure

1. Enter system view.

   system-view
2. Add a device management user and enter device management user view.

   local-user *user-name* [**class manage**]
3. Configure a password for the device management user.

   password [{ **hash** | **simple** } *string*]

   A non-password-protected user passes authentication if the user provides the correct username and passes attribute checks. To enhance security, configure a password for each device management user.
4. Assign services to the device management user.

   service-type { **ftp** | { **http** | **https** | **ssh** | **telnet** | **terminal** } * }

   By default, no services are authorized to a device management user.
5. (Optional.) Set the status of the device management user.

   state { **active** | **block** }

   By default, a device management user is in active state and can request network services.
6. (Optional.) Set the upper limit of concurrent logins using the device management username.

   access-limit *max-user-number*

   By default, the number of concurrent logins is not limited for a device management user.

   This command takes effect only when local accounting is configured for device management users. This command does not apply to FTP, SFTP, or SCP users that do not support accounting.
7. (Optional.) Configure authorization attributes for the device management user.

   authorization-attribute { **idle-cut** *minutes* | **user-role** *role-name* | **work-directory** *directory-name* } *

   The following default settings apply:
   - The working directory for FTP, SFTP, and SCP users is the root directory of the NAS. However, the users do not have permission to access the root directory.
   - The network-operator user role is assigned to local users that are created by a network-admin or level-15 user on the default context. The context-operator user role is assigned to local users that are created by a context-admin or level-15 user on a non-default context.
8. (Optional.) Configure password control attributes for the device management user. Choose the following tasks as needed:
   - Set the password aging time.

     password-control aging *aging-time*
   - Set the minimum password length.

     password-control length *length*
   - Configure the password composition policy.

     password-control composition type-number *type-number* [**type-length** *type-length*]

  - Configure the password complexity checking policy.

    password-control complexity { **same-character** | **user-name** } **check**
  - Configure the maximum login attempts and the action to take if there is a login failure.

    password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

   By default, a device management user uses password control attributes of the user group to which the user belongs.

9. (Optional.) Assign the device management user to a user group.

   group *group-name*

   By default, a device management user belongs to user group **system**.

Configuring attributes for network access users

Restrictions and guidelines

The enabling status of global password control for network access users affects the way that the device stores the passwords of device management users.

- When password control is enabled globally for network access users, the device neither displays the passwords of the users nor retains the passwords in the running configuration.
- When you globally disable password control for network access users, the device automatically restores the passwords of the users to the running configuration.

To enable password control globally for network access users, use the **password-control enable network-class** command. To display the running configuration, use the **display current-configuration** command.

You can configure authorization attributes and password control attributes in local user view or user group view. The setting in local user view takes precedence over the setting in user group view.

Configure the **location** binding attribute based on the service types of users.

- For portal users, specify the portal-enabled interfaces through which the users access the device. Specify the Layer 2 Ethernet interfaces if portal is enabled on VLAN interfaces and the **portal roaming enable** command is not used.

Procedure

1. Enter system view.

   system-view

2. Add a network access user and enter network access user view.

   local-user *user-name* **class network**

3. (Optional.) Configure a password for the network access user.

   password { **cipher** | **simple** } *string*

4. (Optional.) Configure a description for the network access user.

   description *text*

   By default, no description is configured for a local user.

5. Assign services to the network access user.

   service-type { **advpn** | **ike** | **ipoe** | **lan-access** | **portal** | **ppp** | **sslvpn** }

   By default, no services are authorized to a network access user.

6. (Optional.) Set the status of the network access user.

   state { **active** | **block** }

   By default, a network access user is in active state and can request network services.

7. (Optional.) Set the upper limit of concurrent logins using the network access username.

   access-limit *max-user-number*

   By default, the number of concurrent logins is not limited for a network access user.

8. (Optional.) Configure binding attributes for the network access user.

   bind-attribute { **call-number** *call-number* [**:** *subcall-number*] | **location interface** *interface-type interface-number* | **mac** *mac-address* | **vlan** *vlan-id* } *

   By default, no binding attributes are configured for a network access user.

9. (Optional.) Configure authorization attributes for the network access user.

   authorization-attribute { **acl** *acl-number* | **callback-number** *callback-number* | **idle-cut** *minutes* | **ip** *ipv4-address* | **ip-pool** *ipv4-pool-name* | **ipv6** *ipv6-address* | **ipv6-pool** *ipv6-pool-name* | **ipv6-prefix** *ipv6-prefix prefix-length* | { **primary-dns** | **secondary-dns** } { **ip** *ipv4-address* | **ipv6** *ipv6-address* } | **session-timeout** *minutes* | **sslvpn-policy-group** *group-name* | **url** *url-string* | **vlan** *vlan-id* | **vpn-instance** *vpn-instance-name* } *

   By default, a network access user does not have authorization attributes.

10. (Optional.) Configure password control attributes for the network access user. Choose the following tasks as needed:

    - Set the minimum password length.

      password-control length *length*

    - Configure the password composition policy.

      password-control composition type-number *type-number* [**type-length** *type-length*]

    - Configure the password complexity checking policy.

      password-control complexity { **same-character** | **user-name** } **check**

    By default, a network access user uses password control attributes of the user group to which the user belongs.

11. (Optional.) Assign the network access user to a user group.

    group *group-name*

    By default, a network access user belongs to user group **system**.

12. (Optional.) Assign the network access user to an identity group.

    identity-group *group-name*

    By default, a network access user does not belong to any identity groups.

    You can execute this command multiple times to add a network access user to multiple identity groups. After you add a network access user to an identity group, the system automatically synchronizes the configuration to the identity group. Then, the user is available in user group view of the identity group.

13. (Optional.) specify the validity period for the local user.

    validity-datetime { **from** *start-date start-time* **to** *expiration-date expiration-time* | **from** *start-date start-time* | **to** *expiration-date expiration-time* }

    By default, the validity period for a network access user does not expire.

Configuring local guest attributes

About this task

Create local guests and configure guest attributes to control temporary network access behavior. Guests can access the network after passing local authentication. You can configure the recipient addresses and email attribute information to the local guests and guest sponsors.

Procedure

1. Enter system view.

   system-view

2. Create a local guest and enter local guest view.

   local-user *user-name* **class network guest**

3. (Optional.) Configure a password for the local guest.

   password { **cipher** | **simple** } *string*

4. Configure basic information for the local guest. Choose the following tasks as needed:

   - Configure a description for the local guest.

     description *text*

     By default, no description is configured for a local guest.

   - Specify the name of the local guest.

     full-name *name-string*

     By default, no name is specified for a local guest.

   - Specify the company of the local guest.

     company *company-name*

     By default, no company is specified for a local guest.

   - Specify the phone number of the local guest.

     phone *phone-number*

     By default, no phone number is specified for a local guest.

   - Specify the email address of the local guest.

     email *email-string*

     By default, no email address is specified for a local guest.

   - Specify the sponsor name for the local guest.

     sponsor-full-name *name-string*

     By default, no sponsor name is specified for a local guest.

   - Specify the sponsor department for the local guest.

     sponsor-department *department-string*

     By default, no sponsor department is specified for a local guest.

   - Specify the sponsor email address for the local guest.

     sponsor-email *email-string*

     By default, no sponsor email address is specified for a local guest.

5. (Optional.) Configure the validity period for the local guest.

   validity-datetime from *start-date start-time* **to** *expiration-date expiration-time*

   By default, a local guest does not expire.

6. (Optional.) Assign the local guest to a user group.

   group *group-name*

By default, a local guest belongs to the system-defined user group **system**.

7. (Optional.) Configure the local guest status.

   state { **active** | **block** }

   By default, a local guest is in active state and is allowed to request network services.

Configuring user group attributes

About this task

User groups simplify local user configuration and management. A user group contains a group of local users and has a set of local user attributes. You can configure local user attributes for a user group to implement centralized user attributes management for the local users in the group. Local user attributes that are manageable include authorization attributes.

Procedure

1. Enter system view.

   system-view

2. Create a user group and enter user group view.

   user-group *group-name*

   By default, a system-defined user group exists. The group name is **system**.

3. Configure authorization attributes for the user group.

   authorization-attribute { **acl** *acl-number* | **callback-number** *callback-number* | **idle-cut** *minutes* | **ip-pool** *ipv4-pool-name* | **ipv6-pool** *ipv6-pool-name* | **ipv6-prefix** *ipv6-prefix prefix-length* | { **primary-dns** | **secondary-dns** } { **ip** *ipv4-address* | **ipv6** *ipv6-address* } | **session-timeout** *minutes* | **sslvpn-policy-group** *group-name* | **url** *url-string* | **vlan** *vlan-id* | **vpn-instance** *vpn-instance-name* | **work-directory** *directory-name* } *

   By default, no authorization attributes are configured for a user group.

4. (Optional.) Configure password control attributes for the user group. Choose the following tasks as needed:

   - Set the password aging time.

     password-control aging *aging-time*

   - Set the minimum password length.

     password-control length *length*

   - Configure the password composition policy.

     password-control composition type-number *type-number* [**type-length** *type-length*]

   - Configure the password complexity checking policy.

     password-control complexity { **same-character** | **user-name** } **check**

   - Configure the maximum login attempts and the action to take for login failures.

     password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

   By default, a user group uses the global password control settings. For more information, see "Configuring password control."

5. (Optional.) Assign identity members to the user group.

   identity-member { **group** *group-name* | **user** *user-name* }

   By default, no identity members exist in a user group.

   You cannot add a user group to a lower-level group that is an identity member of the group.

Configuring local users in batch

About this task

You can import or export local network access users in batch.

Importing local users in batch

1. Enter system view.

   system-view

2. Import user account information from a .csv file in the specified path to create network access users based on the imported information.

   local-user-import class network url *url-string* [**auto-create-group** | **override** | **start-line** *line-number*] *

   Make sure the .csv file contains at least the user name for each account. If other parameters are not specified for accounts in the file, the system automatically assigns them default values.

Exporting local users in batch

1. Enter system view.

   system-view

2. Export network access user account information to a .csv file in the specified path.

   local-user-export class network url *url-string* [**from** { **group** *group-name* | **user** *user-name* }]

   Before the import, you can edit the file as needed. For information about the editing restrictions, see *Security Command Reference*.

Managing network access users

About this task

You can configure the device to generate a random password for a network access user on the Web interface. The device supports sending the random password and other user account information to the user by email. The email and email server parameters can be configured from the Web interface or at the CLI.

Perform the tasks in this section to configure the email and email server parameters at the CLI.

Restrictions and guidelines

Make sure the device and the SMTP email server have routes to reach each other.

Make sure the user emails configured on the Web interface are valid and reachable.

The configurations on the Web interface and CLI for the same attribute will overwrite each other.

Procedure

1. Enter system view.

   system-view

2. Configure parameters for the email notifications sent to network access users.

   - Configure the email sender address.

     access-user email sender *email-address*

     By default, no email sender address is configured.

   - Configure the body and subject of the email notifications sent to network access users.

     access-user email format { **body** *body-string* | **subject** *sub-string* }

By default, the email subject is **Password reset notification**, and the email body is as follows:

```
A random password has been generated for your account.
Username: xxx
Password: yyy
Validity: YYYY/MM/DD hh:mm:ss to YYYY/MM/DD hh:mm:ss
```

3. Configure SMTP server parameters for the email notifications sent to network access users.
   - Specify an SMTP server to send email notifications to network access users.

     access-user email smtp-server *url-string*

     By default, no SMTP server is specified to send email notifications to network access users.
   - Configure the username and password of the SMTP server.

     access-user email authentication username *user-name* **password** { **cipher** | **simple** } *string*

     By default, no username or password is configured for logging in to an SMTP server.

     If the SMTP server requires a username and password for login, you must configure the username and password on the device for the server.

Managing local guests

About this task

The local guest management features are for registration, approval, maintenance, and access control of local guests.

The registration and approval processes are as follows:

1. The device pushes the portal user registration page to a user that wants to access the network as a local guest.
2. The user submits account information for registration, including the user name, password, and email address.
3. The device forwards the registration request to the guest manager in an email notification.
4. The guest manager adds supplementary information as needed and approves the registration information.

   The guest manager must process the registration request before the waiting-approval timeout timer expires. The device automatically deletes expired registration request information.
5. The device creates a local guest account and sends an email notification to the user and guest sponsor. The email contains local guest account, password, validity period, and other account information.

   The user can access the network as a local guest.

The device provides the following local guest management features:

- **Registration and approval**—The device creates local guests after the guest registration information is approved by a guest manager.
- **Email notification**—The device notifies the local guests, guest sponsors, or guest managers by email of the guest account information or guest registration requests.
- **Local guest creation in batch**—Create a batch of local guests.
- **Local guest import**—Import guest account information from a .csv file to create local guests on the device based on the imported information.
- **Local guest export**—Export local guest account information to a .csv file. You can import the account information to other devices as needed.
- **Guest auto-delete**—The device checks the validity status of each local guest and automatically deletes expired local guests.

Procedure

1. Enter system view

   system-view

2. Configure the email notification feature for local guests.

   a. Configure the subject and body of email notifications.

      local-guest email format to { **guest** | **manager** | **sponsor** } { **body** *body-string* | **subject** *sub-string* }

      By default, no subject or body is configured.

   b. Configure the email sender address in the email notifications sent by the device for local guests.

      local-guest email sender *email-address*

      By default, no email sender address is configured for the email notifications sent by the device.

   c. Specify an SMTP server for sending email notifications of local guests.

      local-guest email smtp-server *url-string*

      By default, no SMTP server is specified.

3. Configure the guest manager's email address.

   local-guest manager-email *email-address*

   By default, the guest manager's email address is not configured.

4. (Optional.) Set the waiting-approval timeout timer for guest registration requests.

   local-guest timer waiting-approval *time-value*

   By default, the waiting-approval timeout timer for guest registration requests is 24 hours.

5. (Optional.) Import guest account information from a .csv file in the specified path to create local guests based on the imported information.

   local-user-import class network guest url *url-string* **validity-datetime** *start-date start-time* **to** *expiration-date expiration-time* [**auto-create-group** | **override** | **start-line** *line-number*] *

6. (Optional.) Create local guests in batch.

   local-guest generate username-prefix *name-prefix* [**password-prefix** *password-prefix*] **suffix** *suffix-number* [**group** *group-name*] **count** *user-count* **validity-datetime** *start-date start-time* **to** *expiration-date expiration-time*

   Batch generated local guests share the same name prefix. You can also configure a password prefix to be shared by the guests.

7. (Optional.) Export local guest account information to a .csv file in the specified path.

   local-user-export class network guest url *url-string*

8. (Optional.) Enable the guest auto-delete feature.

   local-guest auto-delete enable

   By default, the guest auto-delete feature is disabled.

9. (Optional.) Send email notifications to the local guest or the guest sponsor.

   a. Return to user view.

      quit

   b. Send email notifications to the local guest or the guest sponsor. The email contents include the user name, password, and validity period of the guest account.

      local-guest send-email user-name *user-name* **to** { **guest** | **sponsor** }

Display and maintenance commands for local users and local user groups

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display pending registration requests for local guests.	**display local-guest waiting-approval** [**user-name** *user-name*]
Display the local user configuration and online user statistics.	**display local-user** [**class** { **manage** | **network** [**guest**] } | **idle-cut** { **disable** | **enable** } | **service-type** { **advpn** | **ftp** | **http** | **https** | **ike** | **ipoe** | **lan-access** | **portal** | **ppp** | **ssh** | **sslvpn** | **telnet** | **terminal** } | **state** { **active** | **block** } | **user-name** *user-name* **class** { **manage** | **network** [**guest**] } | **vlan** *vlan-id*]
Display user group configuration.	**display user-group** { **all** | **name** *group-name* } [**identity-member** { **all** | **group** | **user** }]
Clear pending registration requests for local guests.	**reset local-guest waiting-approval** [**user-name** *user-name*]

Configuring RADIUS

RADIUS tasks at a glance

To configure RADIUS, perform the following tasks:

1. Configuring a test profile for RADIUS server status detection

   To detect the status of a RADIUS server, you must configure a test profile and configure the RADIUS server to use the test profile in a RADIUS scheme.
2. Creating a RADIUS scheme
3. Specifying RADIUS authentication servers
4. Specifying the RADIUS accounting servers
5. Specifying the shared keys for secure RADIUS communication

   Perform this task if no shared keys are specified when configuring RADIUS authentication or accounting servers.
6. Specifying the MPLS L3VPN instance for a RADIUS scheme

   Perform this task if no MPLS L3VPN instances are specified when configuring RADIUS authentication or accounting servers.
7. (Optional.) Setting the status of RADIUS servers
8. (Optional.) Setting RADIUS timers
9. (Optional.) Configuring parameters for RADIUS packets
   - Specifying the source IP address for outgoing RADIUS packets
   - Setting the username format and traffic statistics units
   - Setting the maximum number of RADIUS request transmission attempts
   - Setting the maximum number of real-time accounting attempts
   - Setting the DSCP priority for RADIUS packets

10. (Optional.) Configuring parameters for RADIUS attributes
    - Configuring the Login-Service attribute check method for SSH, FTP, and terminal users
    - Enabling online user password change by using RADIUS attribute 17
    - Configuring parsing rules for the RDIUS Reply-Message attribute
    - Interpreting the RADIUS class attribute as CAR parameters
    - Configuring the MAC address format for the RADIUS Called-Station-Id attribute
    - Configuring the MAC address format for the RADIUS Calling-Station-Id attribute
    - Specifying a server version for interoperating with servers with a vendor ID of 2011
    - Setting the data measurement unit for the Remanent_Volume attribute
    - Interpreting the Microsegment-Id attribute to an authorization VLAN
    - Specifying the format for attribute Acct-Session-Id
    - Configuring the RADIUS attribute translation feature
11. (Optional.) Configuring extended RADIUS features
    - Configuring the RADIUS accounting-on feature
    - Configuring the RADIUS session-control feature
    - Configuring the RADIUS DAS feature
    - Enabling SNMP notifications for RADIUS

Configuring a test profile for RADIUS server status detection

About this task

To detect the reachability of a RADIUS authentication server, specify a test profile for the RADIUS server when you specify the server in a RADIUS scheme. With the test profile, the device refreshes the RADIUS server status at each detection interval according to the detection result. If the server is unreachable, the device sets the status of the server to blocked. If the server is reachable, the device sets the status of the server to active.

After you specify an existing test profile, the device starts detecting the status of a RADIUS server by simulating an authentication request with the username specified in the test profile. The authentication request is sent to the RADIUS server within each detection interval. The device determines that the RADIUS server is reachable if the device receives a response from the server within the interval.

Restrictions and guidelines

You can configure multiple test profiles in the system.

The device stops detecting the status of a RADIUS server when one of the following operations is performed:

- The RADIUS server is removed from the RADIUS scheme.
- The test profile configuration for the RADIUS server is removed in RADIUS scheme view.
- The test profile specified for the RADIUS server is deleted.
- The RADIUS server is manually set to the blocked state.
- The RADIUS scheme that contains the RADIUS server is deleted.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Configure a test profile for detecting the status of RADIUS authentication servers.

radius-server test-profile *profile-name* **username** *name* [**interval** *interval*]

Creating a RADIUS scheme

Restrictions and guidelines

You can configure a maximum of 16 RADIUS schemes. A RADIUS scheme can be used by multiple ISP domains.

Procedure

1. Enter system view.

   system-view

2. Create a RADIUS scheme and enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

Specifying RADIUS authentication servers

About this task

A RADIUS authentication server completes authentication and authorization together, because authorization information is piggybacked in authentication responses sent to RADIUS clients.

You can specify one primary authentication server and a maximum of 16 secondary authentication servers for a RADIUS scheme. Secondary servers provide AAA services when the primary server becomes unreachable. The device searches for an active server in the order the secondary servers are configured.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

A RADIUS authentication server can function as the primary authentication server for one scheme and a secondary authentication server for another scheme at the same time.

Two authentication servers in a scheme, primary or secondary, cannot have the same combination of IP address, VPN instance, and port number.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Specify the primary RADIUS authentication server.

   primary authentication { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **test-profile** *profile-name* | **vpn-instance** *vpn-instance-name*] *

   By default, no primary RADIUS authentication server is specified.

4. (Optional.) Specify a secondary RADIUS authentication server.

   secondary authentication { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **test-profile** *profile-name* | **vpn-instance** *vpn-instance-name*] *

   By default, no secondary RADIUS authentication servers are specified.

Specifying the RADIUS accounting servers

About this task

You can specify one primary accounting server and a maximum of 16 secondary accounting servers for a RADIUS scheme. Secondary servers provide AAA services when the primary server becomes unavailable. The device searches for an active server in the order the secondary servers are configured.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

A RADIUS accounting server can function as the primary accounting server for one scheme and a secondary accounting server for another scheme at the same time.

Two accounting servers in a scheme, primary or secondary, cannot have the same combination of IP address, VPN instance, and port number.

RADIUS does not support accounting for FTP, SFTP, and SCP users.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Specify the primary RADIUS accounting server.
   primary accounting { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **vpn-instance** *vpn-instance-name*] *
   By default, no primary RADIUS accounting server is specified.
4. (Optional.) Specify a secondary RADIUS accounting server.
   secondary accounting { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **vpn-instance** *vpn-instance-name*] *
   By default, no secondary RADIUS accounting servers are specified.

Specifying the shared keys for secure RADIUS communication

About this task

The RADIUS client and server use the MD5 algorithm and shared keys to generate the Authenticator value for packet authentication and user password encryption. The client and server must use the same key for each type of communication.

A key configured in this task is for all servers of the same type (accounting or authentication) in the scheme. The key has a lower priority than a key configured individually for a RADIUS server.

Restrictions and guidelines

The shared key configured on the device must be the same as the shared key configured on the RADIUS server.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.

radius scheme *radius-scheme-name*

3. Specify a shared key for secure RADIUS communication.

   key { **accounting** | **authentication** } { **cipher** | **simple** } *string*

   By default, no shared key is specified for secure RADIUS communication.

Specifying the MPLS L3VPN instance for a RADIUS scheme

About this task

The VPN instance specified for a RADIUS scheme applies to all authentication and accounting servers in that scheme. If a VPN instance is also configured for an individual RADIUS server, the VPN instance specified for the RADIUS scheme does not take effect on that server.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Specify a VPN instance for the RADIUS scheme.

   vpn-instance *vpn-instance-name*

   By default, a RADIUS scheme belongs to the public network.

Setting the status of RADIUS servers

About this task

To control the RADIUS servers with which the device communicates when the current servers are no longer available, set the status of RADIUS servers to blocked or active. You can specify one primary RADIUS server and multiple secondary RADIUS servers. The secondary servers function as the backup of the primary server. The device chooses servers based on the following rules:

- When the primary server is in active state, the device first tries to communicate with the primary server. If the primary server is unreachable, the device searches for an active secondary server in the order the servers are configured.
- When one or more servers are in active state, the device tries to communicate with these active servers only, even if the servers are unavailable.
- When all servers are in blocked state, the device tries to communicate with a server as follows:
  - If the primary server is placed in blocked state automatically, the device only tries to communicate with the primary server.
  - If the primary server is placed in blocked state manually, the device tries to communicate with secondary servers automatically placed in blocked state in the sequence they are configured.
- If a server is unreachable, the device performs the following operations:
  - Changes the server status to blocked.
  - Starts a quiet timer for the server.
  - Tries to communicate with the next secondary server in active state that has the highest priority.
- When the quiet timer of a server expires or you manually set the server to the active state, the status of the server changes back to active. The device does not check the server again during the authentication or accounting process.

- The search process continues until the device finds an available secondary server or has checked all secondary servers in active state. If no server is reachable, the device considers the authentication or accounting attempt a failure.
- When you remove a server in use, communication with the server times out. The device looks for a server in active state by first checking the primary server, and then checking secondary servers in the order they are configured.
- When a RADIUS server's status changes automatically, the device changes this server's status accordingly in all RADIUS schemes in which this server is specified.
- When a RADIUS server is manually set to blocked, server detection is disabled for the server, regardless of whether a test profile has been specified for the server. When the RADIUS server is set to active state, server detection is enabled for the server on which an existing test profile is specified.

By default, the device sets the status of all RADIUS servers to active. However, in some situations, you must change the status of a server. For example, if a server fails, you can change the status of the server to blocked to avoid communication attempts to the server.

Restrictions and guidelines

The configured server status cannot be saved to any configuration file, and can only be viewed by using the **display radius scheme** command.

After the device restarts, all servers are restored to the active state.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Set the RADIUS server status. Choose the following tasks as needed:
   - Set the status of the primary RADIUS authentication server.
     state primary authentication { **active** | **block** }
   - Set the status of the primary RADIUS accounting server.
     state primary accounting { **active** | **block** }
   - Set the status of a secondary RADIUS authentication server.
     state secondary authentication [{ *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **vpn-instance** *vpn-instance-name*] *] { **active** | **block** }
   - Set the status of a secondary RADIUS accounting server.
     state secondary accounting [{ *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **vpn-instance** *vpn-instance-name*] *] { **active** | **block** }

   By default, a RADIUS server is in active state.

Setting RADIUS timers

About this task

The device uses the following types of timers to control communication with a RADIUS server:

- **Server response timeout timer** (**response-timeout**)—Defines the RADIUS request retransmission interval. The timer starts immediately after a RADIUS request is sent. If the device does not receive a response from the RADIUS server before the timer expires, it resends the request.

- **Server quiet timer** (**quiet**)—Defines the duration to keep an unreachable server in blocked state. If one server is not reachable, the device changes the server status to blocked, starts this timer for the server, and tries to communicate with another server in active state. After the server quiet timer expires, the device changes the status of the server back to active.
- **Real-time accounting timer** (**realtime-accounting**)—Defines the interval at which the device sends real-time accounting packets to the RADIUS accounting server for online users.

Restrictions and guidelines

Consider the number of secondary servers when you configure the maximum number of RADIUS packet transmission attempts and the RADIUS server response timeout timer. If the RADIUS scheme includes many secondary servers, the retransmission process might be too long and the client connection in the access module, such as Telnet, can time out.

When the client connections have a short timeout period, a large number of secondary servers can cause the initial authentication or accounting attempt to fail. In this case, reconnect the client rather than adjusting the RADIUS packet transmission attempts and server response timeout timer. Typically, the next attempt will succeed, because the device has blocked the unreachable servers to shorten the time to find a reachable server.

Make sure the server quiet timer is set correctly. A timer that is too short might result in frequent authentication or accounting failures. This is because the device will continue to attempt to communicate with an unreachable server that is in active state. A timer that is too long might temporarily block a reachable server that has recovered from a failure. This is because the server will remain in blocked state until the timer expires.

A short real-time accounting interval helps improve accounting precision but requires many system resources. When there are 1000 or more users, set the interval to 15 minutes or longer.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enter RADIUS scheme view.
   ```
   radius scheme radius-scheme-name
   ```
3. Set RADIUS timers. Choose the following tasks as needed:
   - Set the RADIUS server response timeout timer.
     ```
     timer response-timeout seconds
     ```
     The default setting is 3 seconds.
   - Set the quiet timer for the servers.
     ```
     timer quiet minutes
     ```
     The default setting is 5 minutes.
   - Set the real-time accounting timer.
     ```
     timer realtime-accounting interval [ second ]
     ```
     The default setting is 12 minutes.

Specifying the source IP address for outgoing RADIUS packets

About this task

The source IP address of RADIUS packets that a NAS sends must match the IP address of the NAS configured on the RADIUS server. A RADIUS server identifies a NAS by its IP address. Upon receiving a RADIUS packet, the RADIUS server checks the source IP address of the packet.

- If it is the IP address of a managed NAS, the server processes the packet.

- If it is not the IP address of a managed NAS, the server drops the packet.

Before sending a RADIUS packet, the NAS selects a source IP address in the following order:

1. The source IP address specified for the RADIUS scheme.
2. The source IP address specified in system view for the VPN or public network, depending on where the RADIUS server resides.
3. The IP address of the outbound interface specified by the route.

Restrictions and guidelines for source IP address configuration

You can specify a source IP address for outgoing RADIUS packets in RADIUS scheme view or in system view.

- The IP address specified in RADIUS scheme view applies only to one RADIUS scheme.
- The IP address specified in system view applies to all RADIUS schemes.

The source IP address of RADIUS packets that a NAS sends must match the IP address of the NAS that is configured on the RADIUS server.

As a best practice, specify a loopback interface address as the source IP address for outgoing RADIUS packets to avoid RADIUS packet loss caused by physical port errors.

The source address of outgoing RADIUS packets is typically the IP address of an egress interface on the NAS to communicate with the RADIUS server.

Specifying a source IP address for all RADIUS schemes

1. Enter system view.

   system-view

2. Specify a source IP address for outgoing RADIUS packets.

   radius nas-ip { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

   By default, the source IP address of an outgoing RADIUS packet is the primary IPv4 address or the IPv6 address of the outbound interface.

Specifying a source IP address for a RADIUS scheme

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Specify a source IP address for outgoing RADIUS packets.

   nas-ip { *ipv4-address* | **ipv6** *ipv6-address* }

   By default, the source IP address of an outgoing RADIUS packet is that specified by using the **radius nas-ip** command in system view. If the **radius nas-ip** command is not used, the source IP address is the primary IP address of the outbound interface.

Setting the username format and traffic statistics units

About this task

A username is in the *userid@isp-name* format, where the *isp-name* part represents the user's ISP domain name. By default, the ISP domain name is included in a username. However, older RADIUS servers might not recognize usernames that contain the ISP domain names. In this case, you can configure the device to remove the domain name of each username to be sent.

The device reports online user traffic statistics in accounting packets. The traffic measurement units are configurable.

Restrictions and guidelines

If two or more ISP domains use the same RADIUS scheme, configure the RADIUS scheme to keep the ISP domain name in usernames for domain identification.

For accounting accuracy, make sure the traffic statistics units configured on the device and on the RADIUS accounting servers are the same.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Set the format for usernames sent to the RADIUS servers.

   user-name-format { **keep-original** | **with-domain** | **without-domain** }

   By default, the ISP domain name is included in a username.

4. Set the data flow and packet measurement units for traffic statistics.

   data-flow-format { **data** { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** } | **packet** { **giga-packet** | **kilo-packet** | **mega-packet** | **one-packet** } }*

   By default, traffic is counted in bytes and packets.

Setting the maximum number of RADIUS request transmission attempts

About this task

RADIUS uses UDP packets to transfer data. Because UDP communication is not reliable, RADIUS uses a retransmission mechanism to improve reliability. A RADIUS request is retransmitted if the NAS does not receive a server response for the request within the response timeout timer. For more information about the RADIUS server response timeout timer, see "Setting the status of RADIUS servers."

You can set the maximum number for the NAS to retransmit a RADIUS request to the same server. When the maximum number is reached, the NAS tries to communicate with other RADIUS servers in active state. If no other servers are in active state at the time, the NAS considers the authentication or accounting attempt a failure.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Set the maximum number of RADIUS request transmission attempts.

   retry *retries*

   By default, the maximum number is 3 for RADIUS request transmission attempts.

Setting the maximum number of real-time accounting attempts

About this task

If you set the maximum number of real-time accounting attempts, the device will disconnect users from whom no accounting responses are received within the permitted attempts.

Procedure

1. Enter system view.

   `system-view`

2. Enter RADIUS scheme view.

   `radius scheme` *`radius-scheme-name`*

3. Set the maximum number of real-time accounting attempts.

   `retry realtime-accounting` *`retries`*

   By default, the maximum number is 5 for real-time accounting attempts.

Setting the DSCP priority for RADIUS packets

About this task

The DSCP priority in the ToS field determines the transmission priority of RADIUS packets. A larger value represents a higher priority.

Procedure

1. Enter system view.

   `system-view`

2. Set the DSCP priority for RADIUS packets.

   `radius` [**`ipv6`**] **`dscp`** *`dscp-value`*

   By default, the DSCP priority is 0 for RADIUS packets.

Configuring the Login-Service attribute check method for SSH, FTP, and terminal users

About this task

The device supports the following check methods for the Login-Service attribute (RADIUS attribute 15) of SSH, FTP, and terminal users:

- **Strict**—Matches Login-Service attribute values 50, 51, and 52 for SSH, FTP, and terminal services, respectively.
- **Loose**—Matches the standard Login-Service attribute value 0 for SSH, FTP, and terminal services.

An Access-Accept packet received for a user must contain the matching attribute value. Otherwise, the user cannot log in to the device.

Restrictions and guidelines

Use the loose check method only when the server does not issue Login-Service attribute values 50, 51, and 52 for SSH, FTP, and terminal users.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Configure the Login-Service attribute check method for SSH, FTP, and terminal users.

   attribute 15 check-mode { **loose** | **strict** }

   The default check method is strict.

Enabling online user password change by using RADIUS attribute 17

About this task

This feature enables the device to cooperate with the RADIUS server to allow users to change their passwords online.

When this feature is enabled, the process of online password change is as follows for a user when the user passes authentication:

1. If the RADIUS authentication server sends an Access-Challenge packet that includes the Reply-Message attribute when a user passes authentication, the device prompts the user to change its password.
2. After receiving the password change request from the user, the device sends a RADIUS authentication request to the RADIUS authentication server.

   In the authentication request, the device uses attribute 2 to carry the new user password.
3. When the device receives a response from the RADIUS authentication server, the online user's password is changed successfully.

When this feature is enabled, the process of online password change is as follows for an online user:

1. After receiving the password change request from the user, the device sends a RADIUS authentication request to a reachable RADIUS server. In the authentication request, the device uses attribute 2 and attribute 17 to carry the new user password and old user password, respectively.

   The RADIUS server selection process for online password change is the same as the process used to select a RADIUS authentication server. Online password change might fail because the device selects a RADIUS server different from the RADIUS server that authenticated the user.
2. When the device receives a response from the selected RADIUS server, the online user's password is changed successfully.

Restrictions and guidelines

This feature is applicable only to SSL VPN users.

Do not enable this feature if the RADIUS server does not support online user password change.

In a RADIUS scheme with this feature enabled, do not configure parsing rules for the Reply-Message attribute by using the **attribute 18 match** command. A violation will cause this feature fail to take effect.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Enable online user password change by using RADIUS attribute 17.

   attribute 17 old-password

   By default, online user password change is disabled.

Configuring parsing rules for the RDIUS Reply-Message attribute

About this task

The RADIUS Reply-Message attribute (attribute 18) is intended for the RADIUS server to return a message to users. In the Access-Challenge packets, this attribute indicates the action that the RADIUS server expects users to take. For the access device to correctly parse this attribute, you can configure parsing rules for this attribute. For example, the device needs to parse the Reply-Message attribute containing the **new pin** string as to prompt users to change the passwords online.

Each parsing rule contains a match criterion and an action. The device uses the fuzzy match method to match the Reply-Message attribute value against the match criterion. If the attribute value partially matches the match criterion, the device prompts the users to take the action specified in the parsing rule. Supported actions include the following:

- **new-password**—Enters the new password.
- **next-token**—Enters the next authentication factor for double-factor authentication.

Restirctions and guidelines

This feature is applicable only to SSL VPN users.

Before you configure parsing rules, make sure you fully understand the implications of the Reply-Message attribute defined by the RADIUS server.

For a RADIUS scheme, you can configure a maximum of 18 parsing rules for the Reply-Message attribute. Make sure the match criterion in each parsing rule is not contained by the match criterion of another parsing rule.

When parsing rules for the Reply-Message attribute are configured, the online user password change feature configured by using the **attribute 17 old-password** command does not take effect. As a best practice, do not configure both parsing rules and online user password change in the same RADIUS scheme.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Configure a parsing rule for the RADIUS Reply-Message attribute.

   attribute 18 match *string* **action** { **new-password** | **next-token** }

   By default, no parsing rules for the RADIUS Reply-Message attribute are configured. The device parses the Reply-Message attribute as to prompt users to enter the next authentication factor for double-factor authentication.

Interpreting the RADIUS class attribute as CAR parameters

About this task

A RADIUS server may deliver CAR parameters for user-based traffic monitoring and control by using the RADIUS class attribute (attribute 25) in RADIUS packets. You can configure the device to interpret the class attribute to CAR parameters.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Interpret the RADIUS class attribute as CAR parameters.

   attribute 25 car

   By default, the RADIUS class attribute is not interpreted as CAR parameters.

Configuring the MAC address format for the RADIUS Called-Station-Id attribute

Restrictions and guidelines

RADIUS servers of different types might have different requirements for the MAC address format in the RADIUS Called-Station-Id attribute. Configure the MAC address format for this attribute to meet the requirements of the RADIUS servers.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Configure the MAC address format for the RADIUS Called-Station-Id attribute.

   attribute 30 mac-format section { **one** | { **six** | **three** } **separator** *separator-character* } { **lowercase** | **uppercase** }

   By default, the MAC address in the RADIUS Called-Station-Id attribute is in the format of HH-HH-HH-HH-HH-HH. The MAC address is separated by hyphen (-) into six sections with letters in upper case.

Configuring the MAC address format for the RADIUS Calling-Station-Id attribute

Restrictions and guidelines

RADIUS servers of different types might have different requirements for the MAC address format in the RADIUS Calling-Station-Id attribute (attribute 31). Configure the MAC address format for this attribute to meet the requirements of the RADIUS servers.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Configure the MAC address format for the RADIUS Calling-Station-Id attribute.

   attribute 31 mac-format section { **one** | { **six** | **three** } **separator** *separator-character* } { **lowercase** | **uppercase** }

By default, the MAC address in the RADIUS Calling-Station-Id attribute is in the format of HH-HH-HH-HH-HH-HH. The MAC address is separated by hyphen (-) into six sections with letters in upper case.

Specifying a server version for interoperating with servers with a vendor ID of 2011

About this task

For the device to correctly interpret RADIUS attributes from the servers with a vendor ID of 2011, specify a server version that is the same as the version of the RADIUS servers.

Procedure

1. Enter system view.

   `system-view`

2. Enter RADIUS scheme view.

   `radius scheme` *`radius-scheme-name`*

3. Specify a server version for interoperating with servers with a vendor ID of 2011.

   `attribute vendor-id 2011 version` { **`1.0`** | **`1.1`** }

   By default, version 1.0 is used.

Setting the data measurement unit for the Remanent_Volume attribute

About this task

The RADIUS server uses the Remanent_Volume attribute in authentication or real-time accounting responses to notify the device of the current amount of data available for online users.

Restrictions and guidelines

Make sure the configured measurement unit is the same as the user data measurement unit on the RADIUS server.

Procedure

1. Enter system view.

   `system-view`

2. Enter RADIUS scheme view.

   `radius scheme` *`radius-scheme-name`*

3. Set the data measurement unit for the Remanent_Volume attribute.

   `attribute remanent-volume unit` { **`byte`** | **`giga-byte`** | **`kilo-byte`** | **`mega-byte`** }

   By default, the data measurement unit is kilobyte.

Interpreting the Microsegment-Id attribute to an authorization VLAN

About this task

Use this feature only when the RADIUS server uses authorization microsegment IDs for granular user access control and the access device uses authorization VLANs to implement microsegment-based access control.

This feature enables the device to interpret the RADIUS Microsegment-Id attribute (attribute 182 with vendor ID 25506) assigned by the RADIUS server to an authorization VLAN.

- If the attribute value is an integer, the device interprets this attribute to a VLAN ID.
- If the attribute value is not an integer, the device interprets this attribute to a VLAN name.

Restrictions and guidelines

If the RADIUS server uses a RADIUS attribute other than the Microsegment-Id attribute to assign microsegment IDs, you must first convert the attribute to the Microsegment-Id attribute. To enable RADIUS attribute translation feature, use the **attribute translate** command.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Interpret the Microsegment-Id attribute to an authorization VLAN.

   attribute 182 vendor-id 25506 vlan

   By default, the Microsegment-Id attribute is not interpreted as an authorization VLAN.

Specifying the format for attribute Acct-Session-Id

About this task

RADIUS servers of different types might have different requirements for the format of attribute Acct-Session-Id. The following types are available:

- **Common format**—In this format, the Acct-Session-Id attribute is a string with a minimum length of 38 characters. This string contains the prefix (indicating the access type), date and time, sequence number, LIP address of the access node, device ID, and job ID of the access process.
- **Simplified format**—In this format, the Acct-Session-Id attribute is a string of 16 characters. This string contains the prefix (indicating the access type), month, sequence number, device ID, and LIP address of the access node.

Specify a format for attribute Acct-Session-Id to meet the requirements of the RADIUS servers.

Procedure

1. Enter system view.

   system-view

2. Specify the format for attribute Acct-Session-Id.

   aaa session-id mode { common | simplified }

   By default, the device uses the common format for attribute Acct-Session-Id.

Configuring the RADIUS attribute translation feature

About this task

The RADIUS attribute translation feature enables the device to work correctly with the RADIUS servers of different vendors that support RADIUS attributes incompatible with the device.

RADIUS attribute translation has the following implementations:

- **Attribute conversion**—Converts source RADIUS attributes into destination RADIUS attributes based on RADIUS attribute conversion rules.
- **Attribute rejection**—Rejects RADIUS attributes based on RADIUS attribute rejection rules.

When the RADIUS attribute translation feature is enabled, the device processes RADIUS packets as follows:

- For the sent RADIUS packets:
  - Deletes the rejected attributes from the packets.
  - Uses the destination RADIUS attributes to replace the attributes that match RADIUS attribute conversion rules in the packets.
- For the received RADIUS packets:
  - Ignores the rejected attributes in the packets.
  - Interprets the attributes that match RADIUS attribute conversion rules as the destination RADIUS attributes.

To identify proprietary RADIUS attributes, you can define the attributes as extended RADIUS attributes, and then convert the extended RADIUS attributes to device-supported attributes.

Restrictions and guidelines for RADIUS attribute translation configuration

Configure either conversion rules or rejection rules for a RADIUS attribute.

Configure either direction-based rules or packet type-based rules for a RADIUS attribute.

For direction-based translation of a RADIUS attribute, you can configure a rule for each direction (inbound or outbound). For packet type-based translation of a RADIUS attribute, you can configure a rule for each RADIUS packet type (RADIUS Access-Accept, RADIUS Access-Request, or RADIUS accounting).

Configuring the RADIUS attribute translation feature for a RADIUS scheme

1. Enter system view.

   system-view

2. (Optional.) Define an extended RADIUS attribute.

   radius attribute extended *attribute-name* [**vendor** *vendor-id*] **code** *attribute-code* **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** }

3. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

4. Enable the RADIUS attribute translation feature.

   attribute translate

   By default, this feature is disabled.

5. Configure a RADIUS attribute conversion rule or a RADIUS attribute reject rule. Choose the following tasks as needed:
   - Configure a RADIUS attribute conversion rule.

     attribute convert *src-attr-name* **to** *dest-attr-name* { { **access-accept** | **access-request** | **accounting** } * | { **received** | **sent** } * }

By default, no RADIUS attribute conversion rules are configured.

- Configure a RADIUS attribute rejection rule.

  attribute reject *attr-name* { { **access-accept** | **access-request** | **accounting** } * | { **received** | **sent** } * }

  By default, no RADIUS attribute rejection rules are configured.

Configuring the RADIUS attribute translation feature for a RADIUS DAS

1. Enter system view.

   system-view

2. (Optional.) Define an extended RADIUS attribute.

   radius attribute extended *attribute-name* [**vendor** *vendor-id*] **code** *attribute-code* **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** }

3. Enter RADIUS DAS view.

   radius dynamic-author server

4. Enable the RADIUS attribute translation feature.

   attribute translate

   By default, this feature is disabled.

5. Configure a RADIUS attribute conversion rule or a RADIUS attribute rejection rule. Choose the following tasks as needed:

   - Configure a RADIUS attribute conversion rule.

     attribute convert *src-attr-name* **to** *dest-attr-name* { { **coa-ack** | **coa-request** } * | { **received** | **sent** } * }

     By default, no RADIUS attribute conversion rules are configured.

   - Configure a RADIUS attribute rejection rule.

     attribute reject *attr-name* { { **coa-ack** | **coa-request** } * | { **received** | **sent** } * }

     By default, no RADIUS attribute rejection rules are configured.

Configuring the RADIUS accounting-on feature

About this task

The accounting-on feature in a RADIUS scheme enables the device to automatically perform the following operations after a reboot:

1. Monitor the status of all accounting servers in the RADIUS scheme.
2. Send accounting-on packets to the reachable servers to request the servers to stop accounting for all online users that use the RADIUS scheme and to log out the users.

You can configure the interval for which the device waits to resend an accounting-on packet and the maximum number of retries.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Enable accounting-on.

   accounting-on enable [**interval** *interval* | **send** *send-times*] *

By default, the accounting-on feature is disabled.

Configuring the RADIUS session-control feature

About this task

Enable this feature for the RADIUS server to dynamically change the user authorization information or forcibly disconnect users by using session-control packets. This task enables the device to receive RADIUS session-control packets on UDP port 1812.

To verify the session-control packets sent from a RADIUS server, specify the RADIUS server as a session-control client to the device.

Restrictions and guidelines

The RADIUS session-control feature can only work with RADIUS servers running on IMC. The session-control client configuration takes effect only when the session-control feature is enabled.

Procedure

1. Enter system view.

   `system-view`

2. Enable the session-control feature.

   `radius session-control enable`

   By default, the session-control feature is disabled.

3. Specify a session-control client.

   `radius session-control client` `{` **`ip`** *`ipv4-address`* `|` **`ipv6`** *`ipv6-address`* `}` `[` **`key`** `{` **`cipher`** `|` **`simple`** `}` *`string`* `|` **`vpn-instance`** *`vpn-instance-name`* `] *`

   By default, no session-control clients are specified.

Configuring the RADIUS DAS feature

About this task

Dynamic Authorization Extensions (DAE) to RADIUS, defined in RFC 5176, can log off online users and change online user authorization information.

In a RADIUS network, the RADIUS server typically acts as the DAE client (DAC) and the NAS acts as the DAE server (DAS).

DAE defines the following types of packets:

- **Disconnect Messages (DMs)**—The DAC sends DM requests to the DAS to log off specific online users.
- **Change of Authorization Messages (CoA Messages)**—The DAC sends CoA requests to the DAS to change the authorization information of specific online users.

When the RADIUS DAS feature is enabled, the NAS performs the following operations:

1. Listens to the default or specified UDP port to receive DAE requests.
2. Logs off online users that match the criteria in the requests and changes their authorization information.
3. Sends DAE responses to the DAC.

Procedure

1. Enter system view.

   `system-view`

2. Enable the RADIUS DAS feature and enter RADIUS DAS view.

```
radius dynamic-author server
```

By default, the RADIUS DAS feature is disabled.

3. Specify a RADIUS DAC.

```
client { ip ipv4-address | ipv6 ipv6-address } [ key { cipher | simple }
string | vendor-id 2011 version { 1.0 | 1.1 } | vpn-instance
vpn-instance-name ] *
```

By default, no RADIUS DACs are specified.

4. (Optional.) Specify the RADIUS DAS port.

```
port port-number
```

By default, the RADIUS DAS port is 3799.

Enabling SNMP notifications for RADIUS

About this task

When SNMP notifications are enabled for RADIUS, the SNMP agent supports the following notifications generated by RADIUS:

- **RADIUS server unreachable notification**—The RADIUS server cannot be reached. RADIUS generates this notification if it does not receive a response to an accounting or authentication request within the specified number of RADIUS request transmission attempts.
- **RADIUS server reachable notification**—The RADIUS server can be reached. RADIUS generates this notification for a previously blocked RADIUS server after the quiet timer expires.
- **Excessive authentication failures notification**—The number of authentication failures compared to the total number of authentication attempts exceeds the specified threshold.

For RADIUS SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

```
system-view
```

2. Enable SNMP notifications for RADIUS.

```
snmp-agent trap enable radius [ accounting-server-down |
accounting-server-up | authentication-error-threshold |
authentication-server-down | authentication-server-up ] *
```

By default, all SNMP notifications are disabled for RADIUS.

Display and maintenance commands for RADIUS

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the RADIUS scheme configuration.	**display radius scheme** [*radius-scheme-name*]
Display RADIUS packet statistics.	**display radius statistics**
Clear RADIUS statistics.	**reset radius statistics**

Configuring HWTACACS

HWTACACS tasks at a glance

To configure HWTACACS, perform the following tasks:

1. Creating an HWTACACS scheme
2. Specifying the HWTACACS authentication servers
3. Specifying the HWTACACS authorization servers
4. Specifying the HWTACACS accounting servers
5. Specifying the shared keys for secure HWTACACS communication

   Perform this task if no shared keys are specified when configuring HWTACACS servers.
6. Specifying an MPLS L3VPN instance for the scheme

   Perform this task if no MPLS L3VPN instances are specified when configuring HWTACACS servers.
7. (Optional.) Setting HWTACACS timers
8. (Optional.) Configuring parameters for HWTACACS packets
   - Specifying the source IP address for outgoing HWTACACS packets
   - Setting the username format and traffic statistics units
9. (Optional.) Associating an HWTACACS server with a track entry
10. (Optional.) Specifying the action to take for AAA requests if all HWTACACS servers are blocked

Creating an HWTACACS scheme

Restrictions and guidelines

You can configure a maximum of 16 HWTACACS schemes. An HWTACACS scheme can be used by multiple ISP domains.

Procedure

1. Enter system view.

   system-view
2. Create an HWTACACS scheme and enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

Specifying the HWTACACS authentication servers

About this task

You can specify one primary authentication server and a maximum of 16 secondary authentication servers for an HWTACACS scheme. When the primary server is unreachable, the device searches for the secondary servers in the order they are configured. The first secondary server in active state is used for communication.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

An HWTACACS server can function as the primary authentication server in one scheme and as the secondary authentication server in another scheme at the same time.

Two HWTACACS authentication servers in a scheme, primary or secondary, cannot have the same combination of IP address, VPN instance, and port number.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify the primary HWTACACS authentication server.

   primary authentication { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no primary HWTACACS authentication server is specified.

4. (Optional.) Specify a secondary HWTACACS authentication server.

   secondary authentication { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no secondary HWTACACS authentication servers are specified.

Specifying the HWTACACS authorization servers

About this task

You can specify one primary authorization server and a maximum of 16 secondary authorization servers for an HWTACACS scheme. When the primary server is not available, the device searches for the secondary servers in the order they are configured. The first secondary server in active state is used for communication.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

An HWTACACS server can function as the primary authorization server of one scheme and as the secondary authorization server of another scheme at the same time.

Two HWTACACS authorization servers in a scheme, primary or secondary, cannot have the same combination of IP address, VPN instance, and port number.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify the primary HWTACACS authorization server.

   primary authorization { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no primary HWTACACS authorization server is specified.

4. (Optional.) Specify a secondary HWTACACS authorization server.

   secondary authorization { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no secondary HWTACACS authorization servers are specified.

Specifying the HWTACACS accounting servers

About this task

You can specify one primary accounting server and a maximum of 16 secondary accounting servers for an HWTACACS scheme. When the primary server is not available, the device searches for the secondary servers in the order they are configured. The first secondary server in active state is used for communication.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

An HWTACACS server can function as the primary accounting server of one scheme and as the secondary accounting server of another scheme at the same time.

Two HWTACACS accounting servers in a scheme, primary or secondary, cannot have the same combination of IP address, VPN instance, and port number.

HWTACACS does not support accounting for FTP, SFTP, and SCP users.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify the primary HWTACACS accounting server.

   primary accounting { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no primary HWTACACS accounting server is specified.

4. (Optional.) Specify a secondary HWTACACS accounting server.

   secondary accounting { *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no secondary HWTACACS accounting servers are specified.

Specifying the shared keys for secure HWTACACS communication

About this task

The HWTACACS client and server use the MD5 algorithm and shared keys to generate the Authenticator value for packet authentication and user password encryption. The client and server must use the same key for each type of communication.

Perform this task to configure shared keys for servers in an HWTACACS scheme. The keys take effect on all servers for which a shared key is not individually configured.

Restrictions and guidelines

Make sure the shared key configured on the device is the same as the shared key configured on the HWTACACS server.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify a shared key for secure HWTACACS authentication, authorization, or accounting communication.

   key { **accounting** | **authentication** | **authorization** } { **cipher** | **simple** } *string*

   By default, no shared key is specified for secure HWTACACS communication.

Specifying an MPLS L3VPN instance for the scheme

About this task

The VPN instance specified for an HWTACACS scheme applies to all servers in that scheme. If a VPN instance is also configured for an individual HWTACACS server, the VPN instance specified for the HWTACACS scheme does not take effect on that server.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify a VPN instance for the HWTACACS scheme.

   vpn-instance *vpn-instance-name*

   By default, an HWTACACS scheme belongs to the public network.

Setting HWTACACS timers

About this task

The device uses the following timers to control communication with an HWTACACS server:

- **Server response timeout timer (response-timeout)**—Defines the HWTACACS server response timeout timer. The device starts this timer immediately after an HWTACACS authentication, authorization, or accounting request is sent. If the device does not receive a response from the server within the timer, it sets the server to blocked. Then, the device sends the request to another HWTACACS server.
- **Real-time accounting timer (realtime-accounting)**—Defines the interval at which the device sends real-time accounting packets to the HWTACACS accounting server for online users.
- **Server quiet timer (quiet)**—Defines the duration to keep an unreachable server in blocked state. If a server is not reachable, the device changes the server status to blocked, starts this timer for the server, and tries to communicate with another server in active state. After the server quiet timer expires, the device changes the status of the server back to active.

The server quiet timer setting affects the status of HWTACACS servers. If the scheme includes one primary HWTACACS server and multiple secondary HWTACACS servers, the device communicates with the HWTACACS servers based on the following rules:

- When the primary server is in active state, the device communicates with the primary server. When the primary server is unreachable, the device researches a secondary server in active status in the order they are configured.
- When one or more servers are in active state, the device tries to communicate with these servers only, even if they are unreachable.
- When all servers are in blocked state, the device only tries to communicate with the primary server.

- If the primary server is unreachable, the device changes the server status to blocked and starts a quiet timer for the server. When the quiet timer of the server expires, the status of the server changes back to active. The device does not check the server again during the authentication, authorization, or accounting process.
- The search process continues until the device finds an available secondary server or has checked all secondary servers in active state. If no server is available, the device considers the authentication, authorization, or accounting attempt a failure.
- When you remove a server in use, communication with the server times out. The device looks for a server in active state by first checking the primary server, and then checking secondary servers in the order they are configured.
- When an HWTACACS server's status changes automatically, the device changes this server's status accordingly in all HWTACACS schemes in which this server is specified.

Restrictions and guidelines

A short real-time accounting interval helps improve accounting precision but requires many system resources. When there are 1000 or more users, set a real-time accounting interval longer than 15 minutes.

Procedure

1. Enter system view.

   `system-view`

2. Enter HWTACACS scheme view.

   `hwtacacs scheme` *`hwtacacs-scheme-name`*

3. Set the HWTACACS timers. Choose the following tasks as needed:
   - Set the HWTACACS server response timeout timer.

     `timer response-timeout` *`seconds`*

     By default, the HWTACACS server response timeout timer is 5 seconds.
   - Set the real-time accounting interval.

     `timer realtime-accounting` *`minutes`*

     By default, the real-time accounting interval is 12 minutes.
   - Set the server quiet timer.

     `timer quiet` *`minutes`*

     By default, the server quiet timer is 5 minutes.

Specifying the source IP address for outgoing HWTACACS packets

About this task

The source IP address of HWTACACS packets that a NAS sends must match the IP address of the NAS configured on the HWTACACS server. An HWTACACS server identifies a NAS by IP address. When the HWTACACS server receives a packet, it checks the source IP address of the packet.

- If it is the IP address of a managed NAS, the server processes the packet.
- If it is not the IP address of a managed NAS, the server drops the packet.

Before sending an HWTACACS packet, the NAS selects a source IP address in the following order:

1. The source IP address specified for the HWTACACS scheme.
2. The source IP address specified in system view for the VPN or public network, depending on where the HWTACACS server resides.
3. The IP address of the outbound interface specified by the route.

Restrictions and guidelines for source IP address configuration

You can specify the source IP address for outgoing HWTACACS packets in HWTACACS scheme view or in system view.

- The IP address specified in HWTACACS scheme view applies to one HWTACACS scheme.
- The IP address specified in system view applies to all HWTACACS schemes.

The source IP address of HWTACACS packets that a NAS sends must match the IP address of the NAS that is configured on the HWTACACS server.

As a best practice, specify a loopback interface address as the source IP address for outgoing HWTACACS packets to avoid HWTACACS packet loss caused by physical port errors.

To communicate with the HWTACACS server, the source address of outgoing HWTACACS packets is typically the IP address of an egress interface on the NAS.

Specifying a source IP address for all HWTACACS schemes

1. Enter system view.

   system-view

2. Specify a source IP address for outgoing HWTACACS packets.

   hwtacacs nas-ip { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]

   By default, the source IP address of an HWTACACS packet sent to the server is the primary IPv4 address or the IPv6 address of the outbound interface.

Specifying a source IP address for an HWTACACS scheme

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify a source IP address for outgoing HWTACACS packets.

   nas-ip { *ipv4-address* | **ipv6** *ipv6-address* }

   By default, the source IP address of an outgoing HWTACACS packet is that configured by using the **hwtacacs nas-ip** command in system view. If the **hwtacacs nas-ip** command is not used, the source IP address is the primary IP address of the outbound interface.

Setting the username format and traffic statistics units

About this task

A username is typically in the *userid@isp-name* format, where the *isp-name* part represents the user's ISP domain name. By default, the ISP domain name is included in a username. If HWTACACS servers do not recognize usernames that contain ISP domain names, you can configure the device to send usernames without domain names to the servers.

The device reports online user traffic statistics in accounting packets.

Restrictions and guidelines

If two or more ISP domains use the same HWTACACS scheme, configure the HWTACACS scheme to keep the ISP domain name in usernames for domain identification.

For accounting accuracy, make sure the traffic measurement units configured on the device are the same as the traffic measurement units configured on the HWTACACS accounting servers.

Procedure

1. Enter system view.

system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Set the format of usernames sent to the HWTACACS servers.

   user-name-format { **keep-original** | **with-domain** | **without-domain** }

   By default, the ISP domain name is included in a username.

4. Set the data flow and packet measurement units for traffic statistics.

   data-flow-format { **data** { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** } | **packet** { **giga-packet** | **kilo-packet** | **mega-packet** | **one-packet** } }*

   By default, traffic is counted in bytes and packets.

Associating an HWTACACS server with a track entry

About this task

Perform this task on a network that has high real-time requirements for HWTACACS authentication, authorization, and accounting.

By default, the device does not actively detect the status of an HWTACACS server. It changes the state of an HWTACACS server to active or blocked based on the server response timeout timer and the server quiet timer. This timer-based state transition mechanism needs time to determine the server state, and it cannot ensure that the device obtains the actual server state in time. To resolve this issue, associate the server with a track entry and associate the track entry with a TCP-type NQA operation. This HWTACACS server-Track-NQA collaboration can actively detect the reachability of the server in real time.

By using HWTACACS server-Track-NQA collaboration, the device determines the status of an HWTACACS server only based on the detection result.

1. The NQA operation starts to detect the reachability of the server and obtains the result. NQA sends the detection result to the Track module for the Track module to set the state of the track entry.
   - If the server is reachable, the Track module sets the state of the track entry to Positive.
   - If the server is unreachable, the Track module sets the state of the track entry to Negative.
   - If the Track-NQA collaboration does not take effect, the Track module keeps the track entry in NotReady state or changes its state to NotReady.
2. AAA sets the status of the server based on the track entry state.
   - If the track entry is in Positive state, AAA sets the state of the server to active.
   - If the track entry is in Negative state, AAA sets the state of the server to blocked and disables the quiet timer for the server.
   - If the track entry stays in NotReady state or its state changes to NotReady, AAA sets the state of the server to active.

Prerequisites

Before you perform this task, you must complete the following tasks:

- Configure an NQA operation of the TCP type and start the NQA operation. For more information, see NQA configuration in *High Availability and Monitoring Configuration Guide*.
- Configure a track entry associated with the NQA operation. For more information, see Track configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Associate an HWTACACS server with a track entry to detect the server reachability.

   ```
   hwtacacs server-probe { ip ipv4-address | ipv6 ipv6-address }
   [ vpn-instance vpn-instance-name ] [ port port-number ] track
   track-entry-number
   ```

   By default, an HWTACACS server is not associated with a track entry.

Specifying the action to take for AAA requests if all HWTACACS servers are blocked

About this task

If all servers in an HWTACACS scheme are blocked, the device takes one of the following actions upon receiving AAA requests in the domain that uses the scheme:

- **attempt**—Attempts to connect to the server that has the highest priority in the scheme. (Typically, the highest-priority server is the primary server. If no primary server is specified, it is the firstly configured secondary server.) If the device fails to connect to the server, it turns to the backup method.
- **skip**—Skips all servers in the scheme and turns to the backup method.

The **attempt** action gives the device a chance to use the scheme in case the server with the highest priority in the scheme might be available. However, the attempt to communicate with an unavailable server increases the response time for AAA requests. As a best practice, specify the **skip** action in scenarios that require quick responses to AAA requests.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter HWTACACS scheme view.

   ```
   hwtacacs scheme hwtacacs-scheme-name
   ```

3. Specify the action to take for AAA requests if all servers in the scheme are blocked.

   ```
   server-block-action { attempt | skip }
   ```

   By default, the **attempt** action applies.

Display and maintenance commands for HWTACACS

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the configuration or server statistics of HWTACACS schemes.	**display hwtacacs scheme** [*hwtacacs-scheme-name* [**statistics**]]
Clear HWTACACS statistics.	**reset hwtacacs statistics** { **accounting** | **all** | **authentication** | **authorization** }

Configuring LDAP

LDAP tasks at a glance

To configure LDAP, perform the following tasks:

1. Configuring an LDAP server
    a. Creating an LDAP server
    b. Configuring the IP address of the LDAP server
    c. (Optional.) Specifying the LDAP version
    d. (Optional.) Specifying the source IP address of outgoing LDAP packets
    e. (Optional.) Setting the LDAP server timeout period
    f. Configuring administrator attributes
    g. Configuring LDAP user attributes
    h. Specifying the character encoding format
    i. (Optional.) Configuring a user group filter
2. Configuring an LDAP attribute map
3. Creating an LDAP scheme
4. Specifying the LDAP authentication server
5. (Optional.) Specifying the LDAP authorization server
6. (Optional.) Specifying an LDAP attribute map for LDAP authorization

Creating an LDAP server

1. Enter system view.
   `system-view`
2. Create an LDAP server and enter LDAP server view.
   `ldap server server-name`

Configuring the IP address of the LDAP server

Restrictions and guidelines

You can configure an IPv4 address or an IPv6 address for an LDAP server. If you configure the IP address for an LDAP server multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.
   `system-view`
2. Enter LDAP server view.
   `ldap server server-name`
3. Configure the IP address of the LDAP server.
   ```
   { ip ipv4-address | ipv6 ipv6-address } [ port port-number ]
   [ vpn-instance vpn-instance-name ]
   ```
   By default, an LDAP server does not have an IP address.

Specifying the LDAP version

Restrictions and guidelines

The device supports LDAPv2 and LDAPv3.

A Microsoft LDAP server supports only LDAPv3.

The LDAP version specified on the device must be consistent with the version specified on the LDAP server.

Procedure

1. Enter system view.

   system-view

2. Enter LDAP server view.

   ldap server *server-name*

3. Specify the LDAP version.

   protocol-version { **v2** | **v3** }

   By default, LDAPv3 is used.

Specifying the source IP address of outgoing LDAP packets

About this task

Perform this task to specify a source IP address for LDAP packets sent to an LDAP server.

Restrictions and guidelines

When you perform this task for an LDAP server, follow these restrictions and guidelines:

- You can specify only one source IPv4 address and one source IPv6 address for the LDAP packets sent to the server.
- You can specify only one source interface. Make sure the source interface can reach the server.
- To have the source interface configuration take effect, make sure the source interface is in the same VPN instance as the server.
- To have the source address configuration take effect, the IP version of the specified source address must be the same as that of the server IP address.
- The source interface configuration and the source IP address configuration overwrite each other.

Procedure

4. Enter system view.

   system-view

5. Enter LDAP server view.

   ldap server *server-name*

6. Specify a source IP address for LDAP packets sent to the LDAP server.

   source-ip { *ipv4-address* | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, no IP address is specified as the source IP address of LDAP packets sent to an LDAP server. The device uses the primary IPv4 address or the IPv6 address of the outbound interface that can reach the server as the source IP address of LDAP packets sent to the server.

Setting the LDAP server timeout period

About this task

If the device sends a bind or search request to an LDAP server without receiving the server's response within the server timeout period, the authentication or authorization request times out. Then, the device tries the backup authentication or authorization method. If no backup method is configured in the ISP domain, the device considers the authentication or authorization attempt a failure.

Procedure

1. Enter system view.

   system-view

2. Enter LDAP server view.

   ldap server *server-name*

3. Set the LDAP server timeout period.

   server-timeout *time-interval*

   By default, the LDAP server timeout period is 10 seconds.

Configuring administrator attributes

About this task

To configure the administrator DN and password for binding with the LDAP server during LDAP authentication:

Procedure

1. Enter system view.

   system-view

2. Enter LDAP server view.

   ldap server *server-name*

3. Specify the administrator DN.

   login-dn *dn-string*

   By default, no administrator DN is specified.

   The administrator DN specified on the device must be the same as the administrator DN configured on the LDAP server.

4. Configure the administrator password.

   login-password { **cipher** | **simple** } *string*

   By default, no administrator password is specified.

Configuring LDAP user attributes

About this task

To authenticate a user, an LDAP client must complete the following operations:

1. Establish a connection to the LDAP server.
2. Obtain the user DN from the LDAP server.
3. Use the user DN and the user's password to bind with the LDAP server.

LDAP provides a DN search mechanism for obtaining the user DN. According to the mechanism, an LDAP client sends search requests to the server based on the search policy determined by the LDAP user attributes of the LDAP client.

The LDAP user attributes include:

- Search base DN.
- Search scope.
- Username attribute.
- Username format.
- User object class.

Restrictions and guidelines

If the LDAP server contains many directory levels, a user DN search starting from the root directory can take a long time. To improve efficiency, you can change the start point by specifying the search base DN.

Procedure

1. Enter system view.

   `system-view`

2. Enter LDAP server view.

   `ldap server` *`server-name`*

3. Specify the user search base DN.

   `search-base-dn` *`base-dn`*

   By default, no user search base DN is specified.

4. (Optional.) Specify the user search scope.

   `search-scope` { **`all-level`** | **`single-level`** }

   By default, the user search scope is **`all-level`**.

5. (Optional.) Specify the username attribute.

   `user-parameters user-name-attribute` { *`name-attribute`* | **`cn`** | **`uid`** }

   By default, the username attribute is **cn**.

6. (Optional.) Specify the username format.

   `user-parameters user-name-format` { **`with-domain`** | **`without-domain`** }

   By default, the username format is **`without-domain`**.

7. (Optional.) Specify the user object class.

   `user-parameters user-object-class` *`object-class-name`*

   By default, no user object class is specified, and the default user object class on the LDAP server is used. The default user object class for this command varies by server model.

Specifying the character encoding format

About this task

By default, the device encodes the configuration made through the Web interface in GB18030 and that made through terminal software in the character encoding format used by the software. If the device and the LDAP server use different character encoding formats, some characters in the information exchanged between them might fail to be interpreted, causing further issues. For example, if user DNs on the LDPA server are Chinese and the user DNs on the device are English, user DN search will fail and then the users will fail to come online. To resolve this issue, use this feature to ensure that the device and the LDAP server use the same character encoding format during information exchange.

After you specify the character encoding format for an LDAP server, the device processes LDAP packets exchanged with the LDAP server as follows:

- For an LDAP packet sent to the LDAP server, the device first decodes the information in the packet by using GB18030. Then, the device uses the specified character encoding format to encode the information.
- For an LDAP packet received form the LDAP server, the device first uses the specified character encoding format to decode the information in the packet. Then, the device uses GB18030 to encode the information and saves the information.

Restriction and guidelines

As a best practice to avoid LDAP authentication failure caused by inconsistent character encoding format, change the character encoding format before using the LDAP server to perform authentication on users.

Procedure

1. Enter system view.

   system-view

2. Enter LDAP server view.

   ldap server *server-name*

3. Specify the character encoding format for the LDAP server.

   character-encoding { **gb18030** | **utf-8** }

   By default, no character encoding format is specified for an LDAP server. The device does not change the character encoding format for information exchanged with the LDAP server.

Configuring a user group filter

About this task

When the device requests to import user group information from an LDAP server, the LDAP server sends only user groups that match the user group filter to the device.

Procedure

1. Enter system view.

   system-view

2. Enter LDAP server view.

   ldap server *server-name*

3. Configure the user group filter.

   group-filter *group-filter*

   By default, the user group filter is **(objectclass=group)**.

Configuring an LDAP attribute map

About this task

Configure an LDAP attribute map to define a list of LDAP-AAA attribute mapping entries. To apply the LDAP attribute map, specify the name of the LDAP attribute map in the LDAP scheme used for authorization.

The LDAP attribute map feature enables the device to convert LDAP attributes obtained from an LDAP authorization server to device-recognizable AAA attributes based on the mapping entries. Because the device ignores unrecognized LDAP attributes, configure the mapping entries to include important LDAP attributes that should not be ignored.

An LDAP attribute can be mapped only to one AAA attribute. Different LDAP attributes can be mapped to the same AAA attribute.

Procedure

1. Enter system view.

   system-view

2. Create an LDAP attribute map and enter LDAP attribute map view.

   ldap attribute-map *map-name*

3. Configure a mapping entry.

   map ldap-attribute *ldap-attribute-name* [**prefix** *prefix-value* **delimiter** *delimiter-value*] **aaa-attribute user-group**

Creating an LDAP scheme

Restrictions and guidelines

You can configure a maximum of 16 LDAP schemes. An LDAP scheme can be used by multiple ISP domains.

Procedure

1. Enter system view.

   system-view

2. Create an LDAP scheme and enter LDAP scheme view.

   ldap scheme *ldap-scheme-name*

Specifying the LDAP authentication server

1. Enter system view.

   system-view

2. Enter LDAP scheme view.

   ldap scheme *ldap-scheme-name*

3. Specify the LDAP authentication server.

   authentication-server *server-name*

   By default, no LDAP authentication server is specified.

Specifying the LDAP authorization server

1. Enter system view.

   system-view

2. Enter LDAP scheme view.

   ldap scheme *ldap-scheme-name*

3. Specify the LDAP authorization server.

   authorization-server *server-name*

   By default, no LDAP authorization server is specified.

Specifying an LDAP attribute map for LDAP authorization

About this task

Specify an LDAP attribute map for LDAP authorization to convert LDAP attributes obtained from the LDAP authorization server to device-recognizable AAA attributes.

Restrictions and guidelines

You can specify only one LDAP attribute map in an LDAP scheme.

Procedure

1. Enter system view.

```
system-view
```

2. Enter LDAP scheme view.

```
ldap scheme ldap-scheme-name
```

3. Specify an LDAP attribute map.

```
attribute-map map-name
```

By default, no LDAP attribute map is specified.

Display and maintenance commands for LDAP

Execute **display** commands in any view.

Task	Command
Display the configuration of LDAP schemes.	**display ldap scheme** [*ldap-scheme-name*]

Creating an ISP domain

About ISP domains

In a networking scenario with multiple ISPs, the device can connect to users of different ISPs. These users can have different user attributes, such as different username and password structures, different service types, and different rights. To manage users of different ISPs, configure authentication, authorization, and accounting methods and domain attributes for each ISP domain as needed.

The device supports a maximum of 1024 ISP domains, including the system-defined ISP domain **system**. You can specify one of the ISP domains as the default domain.

On the device, each user belongs to an ISP domain. If a user does not provide an ISP domain name at login, the device considers the user belongs to the default ISP domain.

Each ISP domain has a set of system-defined AAA methods, which are local authentication, local authorization, and local accounting. If you do not configure any AAA methods for an ISP domain, the device uses the system-defined AAA methods for users in the domain.

The device chooses an authentication domain for each user in the following order:

1. The authentication domain specified for the access module.
2. The ISP domain in the username.
3. The default ISP domain of the device.

If the chosen domain does not exist on the device, the device searches for the ISP domain that accommodates users assigned to nonexistent domains. (Support for the authentication domain configuration depends on the access module.) If no such ISP domain is configured, user authentication fails.

Restrictions and guidelines for ISP domain configuration

An ISP domain cannot be deleted when it is the default ISP domain. Before you use the **undo domain** command, change the domain to a non-default ISP domain by using the **undo domain default enable** command.

You can modify the settings of the system-defined ISP domain **system**, but you cannot delete the domain.

To avoid RADIUS authentication, authorization, or accounting failures, use short domain names to ensure that usernames containing a domain name do not exceed 253 characters.

To avoid RADIUS accounting failures, make sure the domain name contained in usernames sent to the RADIUS server does not exceed 247 characters.

Creating an ISP domain

1. Enter system view.

   ```
   system-view
   ```

2. Create an ISP domain and enter ISP domain view.

   ```
   domain isp-name
   ```

   By default, a system-defined ISP domain exists. The domain name is **system**.

Specifying the default ISP domain

1. Enter system view.

   ```
   system-view
   ```

2. Specify the default ISP domain.

   ```
   domain default enable isp-name
   ```

   By default, the default ISP domain is the system-defined ISP domain **system**.

Specifying an ISP domain for users that are assigned to nonexistent domains

1. Enter system view.

   ```
   system-view
   ```

2. Specify the ISP domain to accommodate users that are assigned to nonexistent domains.

   ```
   domain if-unknown isp-name
   ```

   By default, no ISP domain is specified to accommodate users that are assigned to nonexistent domains.

Configuring ISP domain attributes

Setting ISP domain status

About this task

By placing the ISP domain in active or blocked state, you allow or deny network service requests from users in the domain.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter ISP domain view.

   ```
   domain isp-name
   ```

3. Set the status of the ISP domain.

   ```
   state { active | block }
   ```

By default, an ISP domain is in active state, and users in the domain can request network services.

Configuring authorization attributes for an ISP domain

About this task

The device supports the following authorization attributes:

- **ACL**—The device restricts authenticated users to access only the network resources permitted by the ACL.
- **CAR action**—The attribute controls the traffic flow of authenticated users.
- **Idle cut**—The device logs out a user if the user's total traffic in the idle timeout period at the specified direction is less than the specified minimum traffic.
- **Maximum number of multicast groups**—The attribute restricts the maximum number of multicast groups that an authenticated user can join concurrently.
- **IPv4 address pool**—The device assigns IPv4 addresses from the pool to authenticated users in the domain.
- **IPv6 address pool**—The device assigns IPv6 addresses from the pool to authenticated users in the domain.
- **IPv6 prefix**—The device authorizes the IPv6 prefix to authenticated users in the domain.
- **DNS server address**—The attribute specifies the DNS server that offers DNS services to authenticated users in the domain.
- **Session timeout time**—The device logs off a user when the user's session timeout timer expires.
- **Redirect URL**—The device redirects users in the domain to the URL after they pass authentication.
- **User group**—Authenticated users in the domain obtain all attributes of the user group.
- **VPN instance**—The device allows authenticated users in the domain to access network resources in the authorization VPN.

The device assigns the authorization attributes (excluding the idle cut attribute) in the ISP domain to the authenticated users that do not receive these attributes from the server.

If the idle cut attribute is configured in an ISP domain, the device assigns the attribute to the authenticated users in the domain. If no idle cut attribute is configured in the ISP domain, the device uses the idle cut attribute assigned by the server.

Procedure

1. Enter system view.

   system-view

2. Enter ISP domain view.

   domain *isp-name*

3. Configure authorization attributes for authenticated users in the ISP domain.

   authorization-attribute { **acl** *acl-number* | **car inbound cir** *committed-information-rate* [**pir** *peak-information-rate*] **outbound cir** *committed-information-rate* [**pir** *peak-information-rate*] | **idle-cut** *minutes* [*flow*] | **igmp max-access-number** *max-access-number* | **ip-pool** *ipv4-pool-name* | **ipv6-pool** *ipv6-pool-name* | **ipv6-prefix** *ipv6-prefix prefix-length* | { **primary-dns** | **secondary-dns** } { **ip** *ipv4-address* | **ipv6** *ipv6-address* } | **session-timeout** *minutes* | **url** *url-string* | **user-group** *user-group-name* | **vpn-instance** *vpn-instance-name* }

   The default settings are as follows:

- The idle cut feature is disabled.
- An IPv4 user can concurrently join a maximum of four IGMP multicast groups.
- No other authorization attributes exist.

Including the idle timeout period in the user online duration to be sent to the server

About this task

If a user goes offline due to connection failure or malfunction, the user's online duration sent to the server includes the idle timeout period assigned by the authorization server. The online duration generated on the server is longer than the actual online duration of the user.

For portal users, the device includes the idle timeout period set for the online portal user detection feature in the user online duration. For more information about online detection for portal users, see "Configuring portal authentication."

Procedure

1. Enter system view.

   `system-view`

2. Enter ISP domain view.

   `domain` *`isp-name`*

3. Configure the device to include the idle timeout period in the user online duration to be sent to the server.

   `session-time include-idle-time`

   By default, the user online duration sent to the server does not include the idle timeout period.

Specifying the user address type in an ISP domain

1. Enter system view.

   `system-view`

2. Enter ISP domain view.

   `domain` *`isp-name`*

3. Specify the user address type in the ISP domain.

   `user-address-type` { **`ds-lite`** | **`ipv6`** | **`nat64`** | **`private-ds`** | **`private-ipv4`** | **`public-ds`** | **`public-ipv4`** }

   By default, no user address type is specified.

Specifying the service type for users in an ISP domain

1. Enter system view.

   `system-view`

2. Enter ISP domain view.

   `domain` *`isp-name`*

3. Specify the service type for users in the ISP domain.

   `service-type` { **`hsi`** | **`stb`** | **`voip`** }

   By default, the service type is **hsi**.

Specifying the types of IP addresses that L2TP users must rely on to use the basic services

About this task

An L2TP user might request multiple services of different IP address types. By default, the device logs off the user if the user does not obtain an IP address. This feature enables the device to allow the user to come online if the user has obtained IP addresses of all the specified types for the basic services.

Restrictions and guidelines

This feature takes effect only when the device acts as an L2TP LNS and only on L2TP users.

Procedure

1. Enter system view.

   system-view

2. Enter ISP domain view.

   domain *isp-name*

3. Specify the types of IP addresses that L2TP users must rely on to use the basic services.

   basic-service-ip-type { **ipv4** | **ipv6** | **ipv6-pd** } *

   By default, L2TP users do not rely on any types of IP addresses to use the basic services.

Setting the IPv6 address wait timer for L2TP users

About this task

The IPv6 address wait timer defines the maximum amount of time that a user can wait before the device determines that the user fails to obtain an IPv6 address or PD prefix.

The device starts an IPv6 address wait timer for an L2TP user after it finishes IPv6CP negotiation with the user. If the user's basic service relies on an IPv6 address or PD prefix but it fails to obtain any IPv6 address or PD prefix when the timer expires, the user cannot come online.

Restrictions and guidelines

This feature takes effect only when the device acts as an L2TP LNS and only on L2TP users.

As a best practice, increase the IPv6 address wait timer in the following situations:

- The network communication is unstable.
- The device uses DHCPv6 to assign IPv6 addresses to users.
- The ISP domain serves a large number of users.

Procedure

1. Enter system view.

   system-view

2. Enter ISP domain view.

   domain *isp-name*

3. Set the IPv6 address wait timer for L2TP users.

   dhcpv6-follow-ipv6cp timeout *delay-time*

   By default, the IPv6 address wait timer for L2TP users is 60 seconds.

Configuring AAA methods for an ISP domain

Configuring authentication methods for an ISP domain

Restrictions and guidelines

When you configure authentication, follow these restrictions and guidelines:

- For high availability, you can specify one primary authentication method and multiple backup authentication methods. When the primary method is invalid, the device attempts to use the backup methods in sequence.

  For example, the **`radius-scheme`** *`radius-scheme-name`* **`local`** **none** parameters specify a primary RADIUS authentication method and two backup methods (local authentication and no authentication). The device performs RADIUS authentication by default and performs local authentication when the RADIUS server is invalid. The device does not perform authentication when both of the previous methods are invalid.

  The remote authentication method is invalid in the following situations:

  - The specified authentication scheme does not exist.
  - Authentication packet sending fails.
  - The device does not receive any authentication response packets from an authentication server.

  The local authentication method is invalid if the device fails to find the matching local user configuration.

- If the authentication method uses a RADIUS scheme and the authorization method does not use a RADIUS scheme, AAA accepts only the authentication result from the RADIUS server. The Access-Accept message from the RADIUS server also includes the authorization information, but the device ignores the information.
- If an HWTACACS scheme is specified, the device uses the entered username for role authentication.
- If a RADIUS scheme is specified, the device uses username **$enab*n*$** on the RADIUS server for role authentication.
  - To obtain a level-*n* user role, you must create a user account for the level-*n* user role in the **$enabn$** format on the RADIUS server. The variable *n* represents the target user role level.
  - To obtain a non-level-*n* user role, you must perform the following tasks:
    - Create a user account named **$enab0$** on the server.
    - Configure the cisco-av-pair attribute for the account in the form of **allowed-roles="***role***"**. The variable *role* represents the target user role.

  For more information about user role authentication, see *Fundamentals Configuration Guide*.

When the primary authentication method is local, the following rules apply to the authentication of a user:

- The device uses the backup authentication methods in sequence only if local authentication is invalid for one of the following reasons:
  - An exception occurs in the local authentication process.
  - The user account is not configured on the device or the user is not allowed to use the access service.
- The device does not turn to the backup authentication methods if local authentication is invalid because of any other reason. Authentication fails for the user.

If you specify multiple authentication methods for SSL VPN users in an ISP domain, the device does not support the online user password change feature for the SSL VPN users.

If you specify an LDAP scheme for SSL VPN users in an ISP domain, the device does not support the online user password change feature for the SSL VPN users.

Prerequisites

Before configuring authentication methods, complete the following tasks:

1. Determine the access type or service type to be configured. With AAA, you can configure an authentication method for each access type and service type.
2. Determine whether to configure the default authentication method for all access types or service types. The default authentication method applies to all access users. However, the method has a lower priority than the authentication method that is specified for an access type or service type.

Procedure

1. Enter system view.

   system-view

2. Enter ISP domain view.

   domain *isp-name*

3. (Optional.) Specify default authentication methods for all types of users.

   authentication default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

   By default, the default authentication method is **local**.

4. Specify authentication methods for a user type or a service.
   - Specify authentication methods for ADVPN users.

     authentication advpn { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default authentication methods are used for ADVPN users.
   - Specify authentication methods for IPoE users.

     authentication ipoe { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default authentication methods are used for IPoE users.
   - Specify extended authentication methods for IKE users.

     authentication ike { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default authentication methods are used for IKE extended authentication.
   - Specify authentication methods for login users.

     authentication login { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **local** [**ldap-scheme** *ldap-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

     By default, the default authentication methods are used for login users.
   - Specify authentication methods for portal users.

     authentication portal { **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**ldap-scheme** *ldap-scheme-name* | **radius-scheme**

```
radius-scheme-name ] [ none ] | none | radius-scheme
radius-scheme-name [ local ] [ none ] }
```

By default, the default authentication methods are used for portal users.

- Specify authentication methods for PPP users.

```
authentication ppp { hwtacacs-scheme hwtacacs-scheme-name
[ radius-scheme radius-scheme-name ] [ local ] [ none ] | ldap-scheme
ldap-scheme-name [ local ] [ none ] | local [ radius-scheme
radius-scheme-name | hwtacacs-scheme hwtacacs-scheme-name ] *
[ none ] local [ ldap-scheme ldap-scheme-name ] [ none ] | | none |
radius-scheme radius-scheme-name [ hwtacacs-scheme
hwtacacs-scheme-name ] [ local ] [ none ] }
```

By default, the default authentication methods are used for PPP users.

- Specify authentication methods for SSL VPN users.

```
authentication sslvpn { ldap-scheme ldap-scheme-name [ local ]
[ none ] | local [ ldap-scheme ldap-scheme-name | radius-scheme
radius-scheme-name ] [ none ] | none | radius-scheme
radius-scheme-name [ local ] [ none ] }
```

By default, the default authentication methods are used for SSL VPN users.

- Specify authentication methods for obtaining a temporary user role.

```
authentication super { hwtacacs-scheme hwtacacs-scheme-name |
radius-scheme radius-scheme-name } *
```

By default, the default authentication methods are used for obtaining a temporary user role.

Configuring authorization methods for an ISP domain

Restrictions and guidelines

For high availability, you can specify one primary authorization method and multiple backup authorization methods. When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **radius-scheme** *radius-scheme-name* **local none** parameters specify a primary RADIUS authorization method and two backup methods (local authorization and no authorization). The device performs RADIUS authorization by default and performs local authorization when the RADIUS server is invalid. The device does not perform authorization when both of the previous methods are invalid.

The remote authorization method is invalid in the following situations:

- The specified authorization scheme does not exist.
- Authorization packet sending fails.
- The device does not receive any authorization response packets from an authorization server.

The local authorization method is invalid if the device fails to find the matching local user configuration.

Only SSL VPN users support LDAP authorization in the current software version.

To use a RADIUS scheme as the authorization method, specify the name of the RADIUS scheme that is configured as the authentication method for the ISP domain. If an invalid RADIUS scheme is specified as the authorization method, RADIUS authentication and authorization fail.

When the primary authorization method is local, the following rules apply to the authorization of a user:

- The device uses the backup authorization methods in sequence only if local authorization is invalid for one of the following reasons:
    - An exception occurs in the local authorization process.

  - The user account is not configured on the device or the user is not allowed to use the access service.
- The device does not turn to the backup authorization methods if local authorization is invalid because of any other reason. Authorization fails for the user.

Prerequisites

Before configuring authorization methods, complete the following tasks:

1. Determine the access type or service type to be configured. With AAA, you can configure an authorization scheme for each access type and service type.
2. Determine whether to configure the default authorization method for all access types or service types. The default authorization method applies to all access users. However, the method has a lower priority than the authorization method that is specified for an access type or service type.

Procedure

1. Enter system view.

   system-view

2. Enter ISP domain view.

   domain *isp-name*

3. (Optional.) Specify default authorization methods for all types of users.

   authorization default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

   By default, the authorization method is **local**.

4. Specify authorization methods for a user type or a service.
   - Specify authorization methods for ADVPN users.

     authorization advpn { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default authorization methods are used for ADVPN users.
   - Specify command authorization methods.

     authorization command { **hwtacacs-scheme** *hwtacacs-scheme-name* [**local**] [**none**] | **local** [**none**] | **none** }

     By default, the default authorization methods are used for command authorization.
   - Specify authorization methods for IKE extended authentication.

     authorization ike { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default authorization methods are used for IKE extended authentication.
   - Specify authorization methods for IPoE users.

     authorization ipoe { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default authorization methods are used for IPoE users.
   - Specify authorization methods for login users.

     authorization login { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **none** | **radius-scheme**

radius-scheme-name [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

By default, the default authorization methods are used for login users.

- Specify authorization methods for portal users.

  authorization portal { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

  By default, the default authorization methods are used for portal users.

- Specify authorization methods for PPP users.

  authorization ppp { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] **local** [**ldap-scheme** *ldap-scheme-name*] [**none**] | | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

  By default, the default authorization methods are used for PPP users.

- Specify authorization methods for SSL VPN users.

  authorization sslvpn { **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**ldap-scheme** *ldap-scheme-name* | **radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

  By default, the default authorization methods are used for SSL VPN users.

Configuring accounting methods for an ISP domain

Restrictions and guidelines

For high availability, you can specify one primary accounting method and multiple backup accounting methods. When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **radius-scheme** *radius-scheme-name* **local none** parameters specify a primary RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

The remote accounting method is invalid in the following situations:

- The specified accounting scheme does not exist.
- Accounting packet sending fails.
- The device does not receive any accounting response packets from an accounting server.

The local accounting method is invalid if the device fails to find the matching local user configuration.

FTP, SFTP, and SCP users do not support accounting.

Local accounting does not provide statistics for charging. It only counts and controls the number of concurrent users that use the same local user account. The threshold is configured by using the **access-limit** command.

When the primary accounting method is local, the following rules apply to the accounting of a user:

- The device uses the backup accounting methods in sequence only if local accounting is invalid for one of the following reasons:
  - An exception occurs in the local accounting process.
  - The user account is not configured on the device or the user is not allowed to use the access service.

- The device does not turn to the backup accounting methods if local accounting is invalid because of any other reason. Accounting fails for the user.

Prerequisites

Before configuring accounting methods, complete the following tasks:

1. Determine the access type or service type to be configured. With AAA, you can configure an accounting method for each access type and service type.
2. Determine whether to configure the default accounting method for all access types or service types. The default accounting method applies to all access users. However, the method has a lower priority than the accounting method that is specified for an access type or service type.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter ISP domain view.

   ```
   domain isp-name
   ```

3. (Optional.) Specify default accounting methods for all types of users.

   ```
   accounting default { hwtacacs-scheme hwtacacs-scheme-name
   [ radius-scheme radius-scheme-name ] [ local ] [ none ] | local
   [ radius-scheme radius-scheme-name | hwtacacs-scheme
   hwtacacs-scheme-name ] * [ none ] | none | radius-scheme
   radius-scheme-name [ hwtacacs-scheme hwtacacs-scheme-name ] [ local ]
   [ none ] }
   ```

   By default, the accounting method is **local**.

4. Specify accounting methods for a user type.
   - Specify accounting methods for ADVPN users.

     ```
     accounting advpn { local [ radius-scheme radius-scheme-name ] [ none ]
     | none | radius-scheme radius-scheme-name [ local ] [ none ] }
     ```

     By default, the default accounting methods are used for ADVPN users.

   - Specify the command accounting method.

     ```
     accounting command hwtacacs-scheme hwtacacs-scheme-name
     ```

     By default, the default accounting methods are used for command accounting.

   - Specify accounting methods for IPoE users.

     ```
     accounting ipoe { broadcast radius-scheme radius-scheme-name1
     radius-scheme radius-scheme-name2 [ local ] [ none ] | local
     [ radius-scheme radius-scheme-name ] [ none ] | none | radius-scheme
     radius-scheme-name [ local ] [ none ] }
     ```

     By default, the default accounting methods are used for IPoE users.

   - Specify accounting methods for login users.

     ```
     accounting login { hwtacacs-scheme hwtacacs-scheme-name
     [ radius-scheme radius-scheme-name ] [ local ] [ none ] | local
     [ radius-scheme radius-scheme-name | hwtacacs-scheme
     hwtacacs-scheme-name ] * [ none ] | none | radius-scheme
     radius-scheme-name [ hwtacacs-scheme hwtacacs-scheme-name ]
     [ local ] [ none ] }
     ```

     By default, the default accounting methods are used for login users.

   - Specify accounting methods for portal users.

     ```
     accounting portal { broadcast radius-scheme radius-scheme-name1
     radius-scheme radius-scheme-name2 [ local ] [ none ] | local
     ```

[**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

By default, the default accounting methods are used for portal users.

- Specify accounting methods for PPP users.

  accounting ppp { **broadcast radius-scheme** *radius-scheme-name1* **radius-scheme** *radius-scheme-name2* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] | **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

  By default, the default accounting methods are used for PPP users.

- Specify accounting methods for SSL VPN users.

  accounting sslvpn { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

  By default, the default accounting methods are used for SSL VPN users.

5. (Optional.) Configure extended accounting policies.
   - Configure access control for users that encounter accounting-start failures.

     accounting start-fail { **offline** | **online** }

     By default, the device allows users that encounter accounting-start failures to stay online.

   - Configure access control for users that have failed all their accounting-update attempts.

     accounting update-fail { [**max-times** *max-times*] **offline** | **online** }

     By default, the device allows users that have failed all their accounting-update attempts to stay online.

   - Configure access control for users that have used up their data or time accounting quotas.

     accounting quota-out { **offline** | **online** }

     By default, the device logs off users that have used up their accounting quotas.

Display and maintenance commands for ISP domains

Execute **display** commands in any view.

Task	Command
Display configuration information about an ISP domain or all ISP domains.	**display domain** [*isp-name*]

Configuring domain name delimiters

About this task

A domain name delimiter separates the username part from the domain name part in a username. For the device to correctly extract the username and domain name parts in usernames, you can configure domain name delimiters. Table 3 shows the way that the device interprets a username based on different domain name delimiters.

Table 3 Domain name delimiters and username formats

Domain name delimiter	Username format
At sign (@)	*username@domain-name*
Backslash (\)	*domain-name\username*
Slash (/)	*username/domain-name*
Dot (.)	*username.domain-name*

If a username includes multiple domain name delimiters, the device selects the first delimiter in the search direction specified by using the **domain-delimiter search-from** command.

Restrictions and guidelines

The access module-specific domain name delimiters have higher priority than global domain name delimiters.

Modification of global domain name delimiters or search direction takes effect only on users that come online after the modification.

Procedure

1. Enter system view.

   system-view

2. Configure global domain name delimiters.

   domain-delimiter [**advpn** | **ike** | **ipoe** | **lanaccess** | **login** | **portal** | **ppp** | **sslvpn** | **super**] *string*

   By default, global domain name delimiters include at sign (@), slash (/), and backslash (\).

3. Specify the search direction for the domain name delimiter.

   domain-delimiter search-direction { **backward** | **forward** }

   By default, the search direction is right-to-left.

Setting the maximum number of concurrent login users

About this task

Perform this task to set the maximum number of concurrent users that can log on to the device through a specific protocol, regardless of their authentication methods. The authentication methods include no authentication, local authentication, and remote authentication.

Procedure

1. Enter system view.

   system-view

2. Set the maximum number of concurrent login users.

   aaa session-limit { **ftp** | **http** | **https** | **ssh** | **telnet** } *max-sessions*

   By default, the maximum number of concurrent login users is 32 for each user type.

Configuring a NAS-ID

About this task

During RADIUS authentication, the device uses a NAS-ID to set the NAS-Identifier attribute of RADIUS packets so that the RADIUS server can identify the access location of users.

The device selects the NAS-ID for the NAS-Identifier attribute in the following order:

3. NAS-ID bound with VLANs in a NAS-ID profile.
4. NAS-ID in an ISP domain.

If no NAS-ID is configured, the device uses the device name (set by using the **`sysname`** command) as the NAS-ID.

Configuring a NAS-ID profile

About this task

Configure a NAS-ID profile to maintain NAS-ID and VLAN bindings on the device so that the device can send different NAS-Identifier attribute strings in RADIUS requests from different VLANs.

Restrictions and guidelines

You can apply a NAS-ID profile to portal-enabled interfaces. For more information, see "Configuring portal authentication."

You can configure multiple NAS-ID and VLAN bindings in a NAS-ID profile.

A NAS-ID can be bound with more than one VLAN, but a VLAN can be bound with only one NAS-ID. If you configure multiple bindings for the same VLAN, the most recent configuration takes effect.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Create a NAS-ID profile and enter NAS-ID profile view.
   ```
   aaa nas-id profile profile-name
   ```
3. Configure a NAS-ID and VLAN binding in the profile.
   ```
   nas-id nas-identifier bind vlan vlan-id
   ```

Enabling password change prompt logging

About this task

Use this feature to enhance the protection of passwords for Telnet, SSH, HTTP, HTTPS, NETCONF over SSH, and NETCONF over SOAP users and improve the system security.

This feature enables the device to generate logs to prompt users to change their weak passwords at an interval of 24 hours and at the users' login.

A password is a weak password if it does not meet the following requirements:

- Password composition restriction configured by using the **`password-control composition`** command.
- Minimum password length restriction set by using the **`password-control length`** command.
- Password complexity checking policy configured by using the **`password-control complexity`** command.

For a NETCONF over SSH or NETCONF over SOAP user, the device also generates a password change prompt log if any of the following conditions exists:

- The current password of the user is the default password or has expired.
- The user logs in to the device for the first time or uses a new password to log in after global password control is enabled.

The device will no longer generate password change prompt logs for a user when one of the following conditions exists:

- The password change prompt logging feature is disabled.
- The user has changed the password and the new password meets the password control requirements.
- The enabling status of a related password control feature has changed so the current password of the user meets the password control requirements.
- The password composition policy or the minimum password length has changed.

Restrictions and guidelines

You can use the **`display password-control`** command to display password control configuration. For more information about password control commands, see password control commands in *Security Command Reference*.

Procedure

1. Enter system view.

   `system-view`

2. Enable password change prompt logging.

   `local-server log change-password-prompt`

   By default, password change prompt logging is enabled.

Setting the NAS-ID in an ISP domain

1. Enter system view.

   `system-view`

2. Enter ISP domain view.

   `domain` *`isp-name`*

3. Set the NAS-ID in the ISP domain.

   `nas-id` *`nas-identifier`*

   By default, no NAS-ID is set in an ISP domain.

Configuring the device ID

About this task

RADIUS uses the value of the Acct-Session-ID attribute as the accounting ID for a user. The device generates an Acct-Session-ID value that includes the device ID for each online user.

Procedure

1. Enter system view.

   `system-view`

2. Configure the device ID.

   `aaa device-id` *`device-id`*

   By default, the device ID is 0.

Configuring the AAA test feature

About this task

This feature enables the device to send authentication or accounting requests to the specified AAA servers to simulate an authentication or accounting process of a user. Use this feature to identify the reasons for the failure of the interaction between the device and the AAA servers. This feature is applicable only to RADIUS.

When performing an AAA test, the device ignores the status of the specified AAA servers and the RADIUS server load sharing feature. The process of an AAA test is as follows:

1. The device sends authentication requests that carry the specified username and password to the specified authentication server or to the authentication servers in the specified RADIUS scheme. The device tries to communicate with the authentication servers in the specified scheme in sequence.

   The process goes to the next step in the following situations:

   - The device receives an authentication response (no matter the authentication succeeds or fails).
   - The device does not receive any authentication response after making all authentication request attempts.

   This step is skipped if no correct authentication server is specified for the AAA test or no authentication servers are configured in the specified RADIUS scheme.

2. The device sends start-accounting requests to the specified accounting server or to the accounting servers in the specified RADIUS scheme. The device tries to communicate with the accounting servers in the specified scheme in sequence.

   The process goes to the next step in the following situations:

   - The device receives a start-accounting response (no matter the accounting succeeds or fails).
   - The device does not receive any start-accounting response after making all start-accounting request attempts.

   This step and the next step are skipped if no correct accounting server is specified for the AAA test or no accounting servers are configured in the specified RADIUS scheme.

3. The device sends stop-accounting requests to the accounting servers to which it has sent a start-accounting request.

   The process finishes in the following situations:

   - The device receives a stop-accounting response.
   - The device does not receive any stop-accounting response after making all stop-accounting request attempts.

To identify attributes that cause authentication or accounting failures, you can configure the device to carry specific attributes in RADIUS requests or define values for specific attributes in the requests. Table 4 shows the attributes that RADIUS requests carry by default.

Table 4 Attributes that RADIUS requests carry by default

Packet type	Attributes that the type of packets carry by default
RADIUS authentication request	User-Name CHAP-Password (or User-Password) CHAP-Challenge NAS-IP-Address (or NAS-IPv6-Address) Service-Type Framed-Protocol

Packet type	Attributes that the type of packets carry by default
	NAS-Identifier NAS-Port-Type Acct-Session-Id
RADIUS accounting request	User-Name Acct-Status-Type NAS-IP-Address (or NAS-IPv6-Address) NAS-Identifier Acct-Session-Id Acct-Delay-Time Acct-Terminate-Cause

Restrictions and guidelines

When you perform an AAA test, follow these restrictions and guidelines:

- The device might communicate with the AAA servers incorrectly during an AAA test. Make sure no users come online or go offline during an AAA text.
- If the configuration of the specified RADIUS scheme changes, the new configuration does not affect the current AAA test. The modification will take effect in the next test.
- The system can have only one AAA test at a time. Another AAA test can be performed only after the current test finishes.

When you configure attributes to be included in or excluded from RADIUS requests, follow these restrictions and guidelines:

- Before you include an attribute that is already configured to be excluded from RADIUS requests, you must cancel the exclusion configuration by using the **undo exclude** command.
- Before you exclude an attribute that is already configured to be included in RADIUS requests, you must cancel the inclusion configuration by using the **undo include** command.

Prerequisites

Before you perform an AAA test, you must configure a RADIUS scheme that contains the RADIUS servers to be tested.

Plan the RADIUS attributes to be included in RADIUS requests. Besides the attributes carried by default, the device adds the specified attributes to RADIUS packets in the order that they are specified by using the **include** command. Additional attributes cannot be added to a RADIUS request if the length of the RADIUS request will reach or exceed 4096 bytes.

Procedure

1. (Optional.) Configure a RADIUS attribute test group:
   a. Enter system view.
      system-view
   b. Create a RADIUS attribute test group and enter its view.
      radius attribute-test-group *attr-test-group-name*
      You can create multiple RADIUS attribute test groups.
   c. Include an attribute in RADIUS requests.
      include { **accounting** | **authentication** } { **name** *attribute-name* | [**vendor** *vendor-id*] **code** *attribute-code* } **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** } value *attribute-value*

For an attribute that RADIUS requests carry by default, use this command to change its attribute value.

d. Exclude an attribute from RADIUS requests.

```
exclude { accounting | authentication } name attribute-name
```

e. Return to system view.

```
quit
```

f. Return to user view.

```
quit
```

2. Perform an AAA test in user view.

```
test-aaa user user-name password password radius-scheme
radius-scheme-name [ radius-server { ipv4-address | ipv6
ipv6-address } port-number [ vpn-instance vpn-instance-name ] ] [ chap
| pap ] [ attribute-test-group attr-test-group-name ] [ trace ]
```

AAA configuration examples

Example: Configuring authentication and authorization for SSH users by a RADIUS server

Network configuration

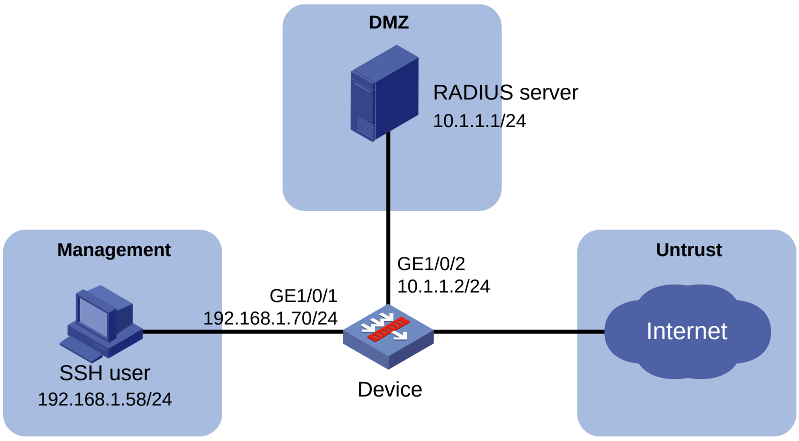
As shown in Figure 11, configure the device to meet the following requirements:

- Use the RADIUS server for SSH user authentication and authorization.
- Include domain names in the usernames sent to the RADIUS server.
- Assign the **network-admin** user role to SSH users after they pass authentication.

The RADIUS server runs IMC PLAT 7.3 (E0605) and IMC UAM 7.3 (E0512). Add an account named **hello@bbb** on the RADIUS server.

The RADIUS server and the device use **expert** as the shared key for secure RADIUS communication. The ports for authentication and accounting are **1812** and **1813**, respectively.

Figure 11 Network diagram



Configuring the RADIUS server

1. Add the device to the IMC Platform as an access device:

Log in to IMC, click the **User** tab, and select **User Access Policy** > **Access Device Management** > **Access Device** from the navigation tree. Then, click **Add** to configure an access device as follows:

a. Set the ports for authentication and accounting to 1812 and 1813, respectively.

b. Select **Device Management Service** from the **Service Type** list.

c. Select **(General)** from the **Access Device Type** list.

d. Set the shared key to **expert** for secure RADIUS communication.

e. Select an access device from the device list or manually add an access device. In this example, the device IP address is 10.1.1.2.

f. Use the default values for other parameters.

g. Click **OK**.

The IP address of the access device specified here must be the same as the source IP address of the RADIUS packets sent from the device. The source IP address is chosen in the following order on the device:

- IP address specified by using the **`nas-ip`** command.
- IP address specified by using the **`radius nas-ip`** command.
- IP address of the outbound interface (the default).

2. Add an account for device management:

Click the **User** tab, and select **Device User** > **Device User** from the navigation tree. Then, click **Add** to configure a device management account as follows:

a. Enter account name **hello@bbb** and set the password.

b. Select **SSH** from the **Login Type** list.

c. Enter **network-admin** in the **Role Name** field.

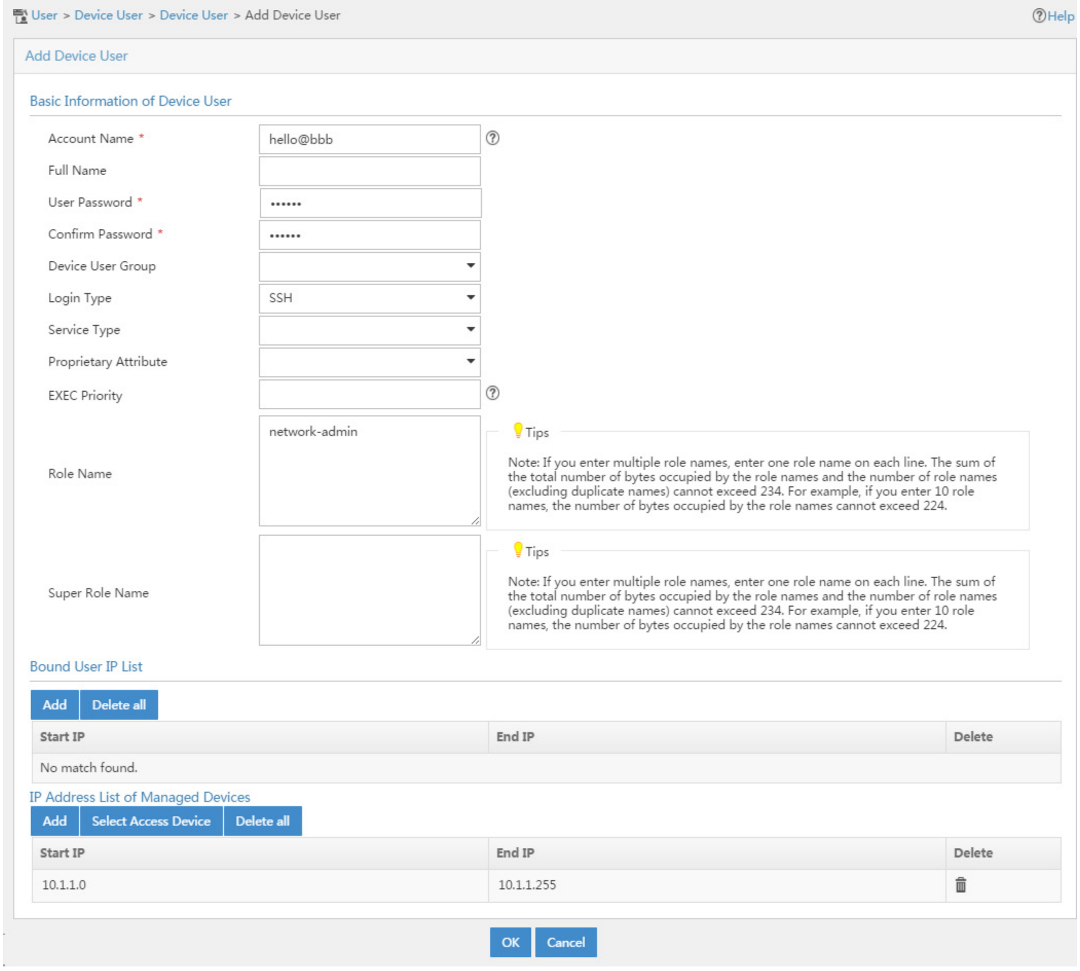
d. Specify 10.1.1.0 to 10.1.1.255 as the IP address range of hosts to be managed.

e. Click **OK**.

NOTE:

The IP address range must contain the IP address of the device.

Figure 12 Adding an account for device management



User > Device User > Device User > Add Device User

Add Device User

Basic Information of Device User

Account Name *	hello@bbb
Full Name	
User Password *	••••••
Confirm Password *	••••••
Device User Group	
Login Type	SSH
Service Type	
Proprietary Attribute	
EXEC Priority	
Role Name	network-admin
Super Role Name	

Tips

Note: If you enter multiple role names, enter one role name on each line. The sum of the total number of bytes occupied by the role names and the number of role names (excluding duplicate names) cannot exceed 234. For example, if you enter 10 role names, the number of bytes occupied by the role names cannot exceed 224.

Tips

Note: If you enter multiple role names, enter one role name on each line. The sum of the total number of bytes occupied by the role names and the number of role names (excluding duplicate names) cannot exceed 234. For example, if you enter 10 role names, the number of bytes occupied by the role names cannot exceed 224.

Bound User IP List

Start IP	End IP	Delete
No match found.		

IP Address List of Managed Devices

Start IP	End IP	Delete
10.1.1.0	10.1.1.255	🗑

Configuring the device

1. Assign IP addresses to interfaces:

   # Assign an IP address to GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.70 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing.

   In this example, the device is directly connected to the SSH user and the RADIUS server.

3. Add interfaces to security zones.

   ```
   [Device] security-zone name Management
   [Device-security-zone-Management] import interface gigabitethernet 1/0/1
   [Device-security-zone-Management] quit
   [Device] security-zone name DMZ
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/2
   [Device-security-zone-DMZ] quit
   ```

4. Configure a security policy to permit the request packets from the device to the RADIUS server.

   ```
   [Device] security-policy ip
   ```

```
[Device-security-policy-ip] rule name aaalocalout
[Device-security-policy-ip-1-aaalocalout] source-zone local
[Device-security-policy-ip-1-aaalocalout] source-ip-host 10.1.1.2
[Device-security-policy-ip-1-aaalocalout] destination-zone DMZ
[Device-security-policy-ip-1-aaalocalout] destination-ip-host 10.1.1.1
[Device-security-policy-ip-1-aaalocalout] action pass
[Device-security-policy-ip-1-aaalocalout] quit
[Device-security-policy-ip] quit
```

5. Configure key pairs:

   # Create local RSA key pairs, a local DSA key pair, and a local ECDSA key pair.

```
[Device] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.
Create the key pair successfully.
[Device] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..
Create the key pair successfully.
[Device] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

6. Configure SSH:

   # Enable the Stelnet server, and enable scheme authentication for user lines VTY 0 through VTY 63.

```
[Device] ssh server enable
[Device] line vty 0 63
[Device-line-vty0-63] authentication-mode scheme
[Device-line-vty0-63] quit
```

7. Configure a RADIUS scheme:

   # Create a RADIUS scheme, configure the authentication server parameters, and configure the device to include domain names in the usernames sent to the RADIUS server.

```
[Device] radius scheme rad
[Device-radius-rad] primary authentication 10.1.1.1 1812
[Device-radius-rad] key authentication simple expert
[Device-radius-rad] user-name-format with-domain
[Device-radius-rad] quit
```

8. Create an ISP domain named **bbb** and configure authentication, authorization, and accounting methods for login users. Because RADIUS user authorization information is piggybacked in authentication responses, the authentication and authorization methods must use the same RADIUS scheme.

```
[Device] domain bbb
[Device-isp-bbb] authentication login radius-scheme rad
[Device-isp-bbb] authorization login radius-scheme rad
[Device-isp-bbb] accounting login none
[Device-isp-bbb] quit
```

# Specify ISP domain **bbb** as the default ISP domain.

```
[Device] domain default enable bbb
```

Verifying the configuration

# Initiate an SSH connection to the device, and enter username **hello@bbb** and the correct password. The user logs in to the device. (Details not shown.)

# Verify that the user can use the commands permitted by the **network-admin** user role. (Details not shown.)

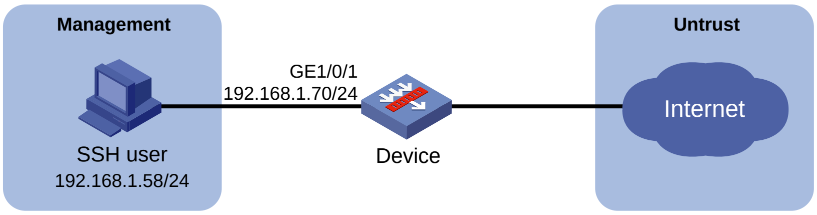
Example: Configuring local authentication and authorization for SSH users

Network configuration

As shown in Figure 13, configure the device to meet the following requirements:

- Perform local authentication and authorization for SSH users.
- Assign the **network-admin** user role to SSH users after they pass authentication.

Figure 13 Network diagram



Procedure

1. Assign an IP address to GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.1.70 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

2. Configure settings for routing.

   In this example, the device is directly connected to the SSH user.

3. Add interface GigabitEthernet 1/0/1 to security zone **Management**.

```
[Device] security-zone name Management
[Device-security-zone-Management] import interface gigabitethernet 1/0/1
[Device-security-zone-Management] quit
```

4. Configure key pairs:

   # Create local RSA key pairs, a local DSA key pair, and a local ECDSA key pair.

```
[Device] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
```

```
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.
Create the key pair successfully.
[Device] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..
Create the key pair successfully.
[Device] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

5. Configure SSH:

   # Enable the Stelnet server, and enable scheme authentication for user lines VTY 0 through VTY 63.

   ```
   [Device] ssh server enable
   [Device] line vty 0 63
   [Device-line-vty0-63] authentication-mode scheme
   [Device-line-vty0-63] quit
   ```

6. Configure a local SSH user:

   # Create a device management user, and configure the service type, password, and user role for the user.

   ```
   [Device] local-user ssh class manage
   [Device-luser-manage-ssh] service-type ssh
   [Device-luser-manage-ssh] password simple 123456TESTplat&!
   [Device-luser-manage-ssh] authorization-attribute user-role network-admin
   [Device-luser-manage-ssh] quit
   ```

7. Configure an ISP domain:

   # Create an ISP domain named **bbb** and configure the domain to use local authentication and authorization for login users.

   ```
   [Device] domain bbb
   [Device-isp-bbb] authentication login local
   [Device-isp-bbb] authorization login local
   [Device-isp-bbb] quit
   ```

   # Specify ISP domain **bbb** as the default ISP domain.

   ```
   [Device] domain default enable bbb
   ```

Verifying the configuration

# Initiate an SSH connection to the device, and enter username **ssh@bbb** and the correct password. The user logs in to the device. (Details not shown.)

# Verify that the user can use the commands permitted by the network-admin user role. (Details not shown.)

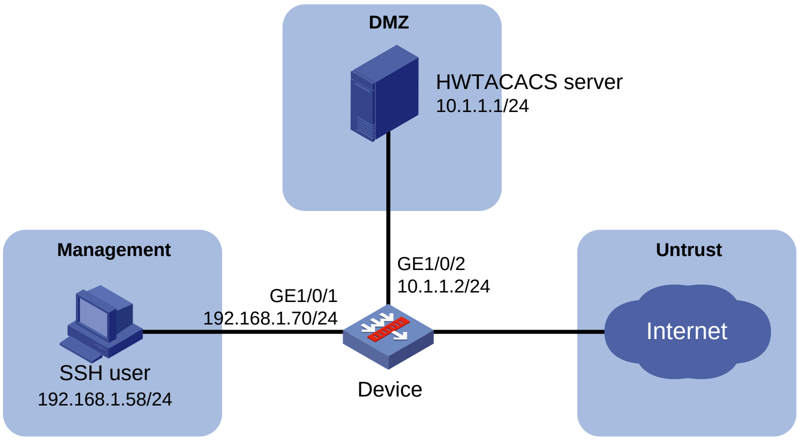
Example: Configuring AAA for SSH users by an HWTACACS server

Network configuration

As shown in Figure 14, configure the device to meet the following requirements:

- Use the HWTACACS server for SSH user authentication, authorization, and accounting.
- Assign the default user role **network-operator** to SSH users after they pass authentication.
- Exclude domain names from the usernames sent to the HWTACACS server.
- Use **expert** as the shared keys for secure HWTACACS communication.

Figure 14 Network diagram



Configuring the HWTACACS server

# Set the shared keys to **expert** for secure communication with the device, add an account for the SSH user, and specify the password. (Details not shown.)

Configuring the device

1. Assign IP addresses to interfaces:

   # Assign an IP address to GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.70 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing.

   In this example, the device is directly connected to the SSH user and the HWTACACS server.

3. Add interfaces to security zones.

   ```
   [Device] security-zone name Management
   [Device-security-zone-Management] import interface gigabitethernet 1/0/1
   [Device-security-zone-Management] quit
   [Device] security-zone name DMZ
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/2
   [Device-security-zone-DMZ] quit
   ```

4. Configure a security policy to permit the request packets from the device to the HWTACACS server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name aaalocalout
[Device-security-policy-ip-1-aaalocalout] source-zone local
[Device-security-policy-ip-1-aaalocalout] source-ip-host 10.1.1.2
[Device-security-policy-ip-1-aaalocalout] destination-zone DMZ
[Device-security-policy-ip-1-aaalocalout] destination-ip-host 10.1.1.1
[Device-security-policy-ip-1-aaalocalout] action pass
[Device-security-policy-ip-1-aaalocalout] quit
[Device-security-policy-ip] quit
```

5. Configure key pairs:

   # Create local RSA key pairs, a local DSA key pair, and a local ECDSA key pair.

```
[Device] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.
Create the key pair successfully.
[Device] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..
Create the key pair successfully.
[Device] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

6. Configure SSH:

   # Enable the Stelnet server, and enable scheme authentication for user lines VTY 0 through VTY 63.

```
[Device] ssh server enable
[Device] line vty 0 63
[Device-line-vty0-63] authentication-mode scheme
[Device-line-vty0-63] quit
```

   # Enable the default user role feature to assign authenticated SSH users the default user role **network-operator**.

```
[Device] role default-role enable
```

7. Configure an HWTACACS scheme:

   # Create an HWTACACS scheme, configure the HWTACACS server parameters, and configure the device to exclude domain names from the usernames sent to the HWTACACS server.

```
[Device] hwtacacs scheme hwtac
[Device-hwtacacs-hwtac] primary authentication 10.1.1.1 49
[Device-hwtacacs-hwtac] primary authorization 10.1.1.1 49
```

```
[Device-hwtacacs-hwtac] primary accounting 10.1.1.1 49
[Device-hwtacacs-hwtac] key authentication simple expert
[Device-hwtacacs-hwtac] key authorization simple expert
[Device-hwtacacs-hwtac] key accounting simple expert
[Device-hwtacacs-hwtac] user-name-format without-domain
[Device-hwtacacs-hwtac] quit
```

8. Configure an ISP domain:

   # Create an ISP domain named **bbb**, and configure the domain to use the HWTACACS scheme for login user authentication, authorization, and accounting.

   ```
   [Device] domain bbb
   [Device-isp-bbb] authentication login hwtacacs-scheme hwtac
   [Device-isp-bbb] authorization login hwtacacs-scheme hwtac
   [Device-isp-bbb] accounting login hwtacacs-scheme hwtac
   [Device-isp-bbb] quit
   ```

   # Specify ISP domain **bbb** as the default ISP domain.

   ```
   [Device] domain default enable bbb
   ```

Verifying the configuration

# Initiate an SSH connection to the device, and enter the correct username and password. The user logs in to the device. (Details not shown.)

# Verify that the user can use the commands permitted by the network-operator user role. (Details not shown.)

Example: Configuring authentication for SSH users by an LDAP server

Network configuration

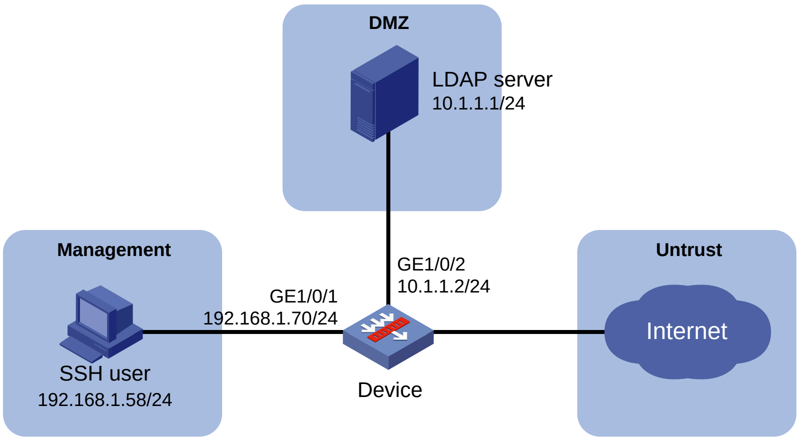
As shown in Figure 15, the LDAP server runs Microsoft Windows 2003 Server Active Directory and uses domain **ldap.com**.

Configure the device to meet the following requirements:

- Use the LDAP server to authenticate SSH users.
- Assign the level-0 user role to SSH users after they pass authentication.

On the LDAP server, set the administrator password to **admin!123456**, add a user named **aaa**, and set the user's password to **ldap!123456**.

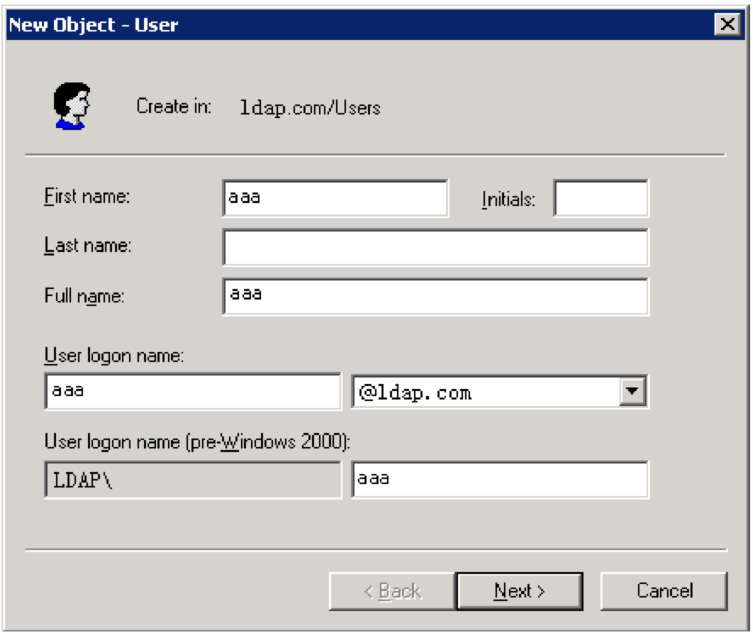
Figure 15 Network diagram



Configuring the LDAP server

1. Add a user named **aaa** and set the password to **ldap!123456**:
   a. On the LDAP server, select **Start** > **Control Panel** > **Administrative Tools**.
   b. Double-click **Active Directory Users and Computers**.
   The **Active Directory Users and Computers** window is displayed.
   c. From the navigation tree, click **Users** under the **ldap.com** node.
   d. Select **Action** > **New** > **User** from the menu to display the dialog box for adding a user.
   e. Enter logon name **aaa** and click **Next**.

Figure 16 Adding user aaa



Create in: ldap.com/Users

First name: aaa

Initials:

Last name:

Full name: aaa

User logon name:

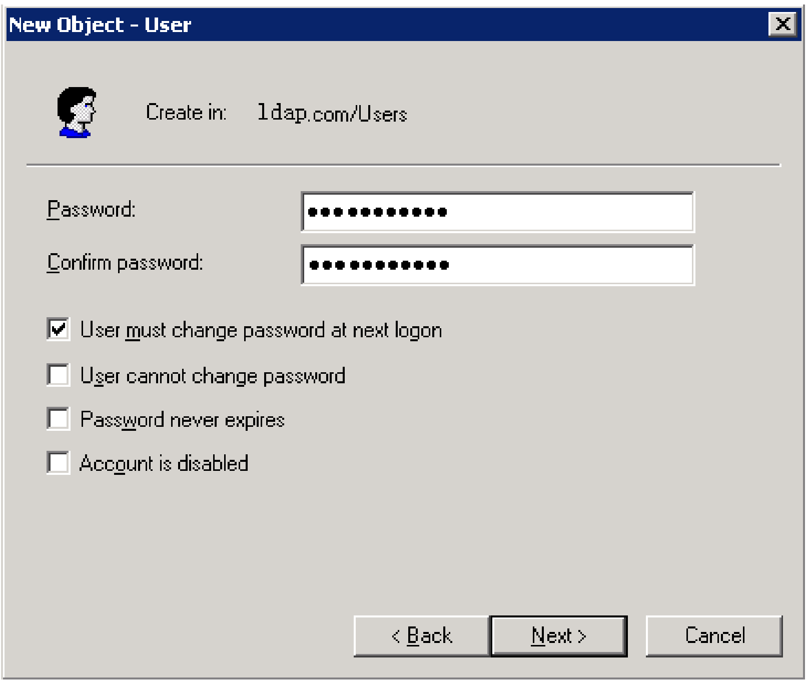
aaa @ldap.com

User logon name (pre-Windows 2000):

LDAP\ aaa

   f. In the dialog box, enter password **ldap!123456**, select options as needed, and click **Next**.

Figure 17 Setting the user's password



New Object - User

Create in: ldap.com/Users

Password: ●●●●●●●●●●●●

Confirm password: ●●●●●●●●●●●●

☑ User must change password at next logon

□ User cannot change password

□ Password never expires

□ Account is disabled

g. Click **OK**.

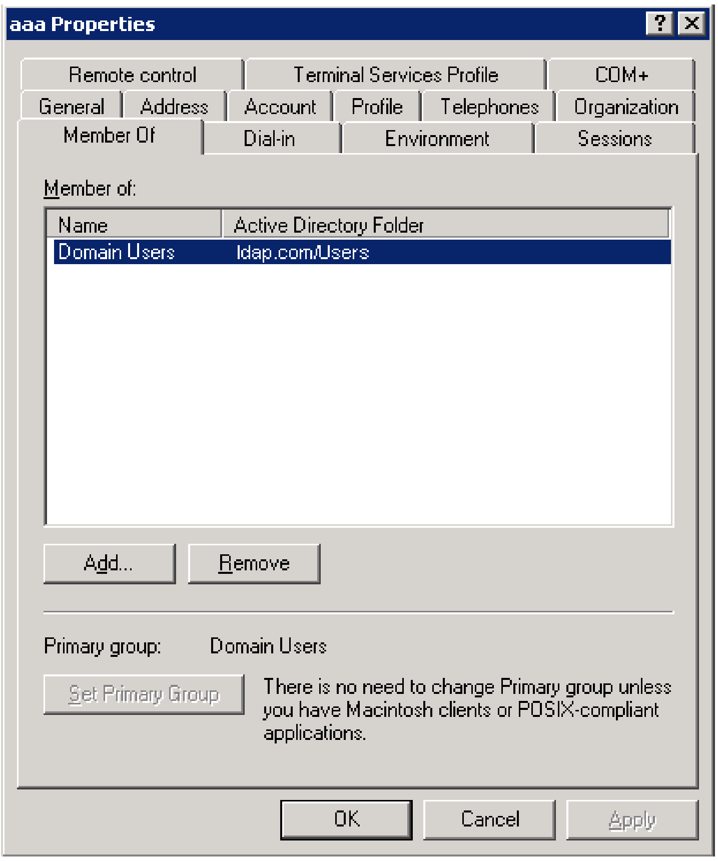
2. Add user **aaa** to group **Users**:

a. From the navigation tree, click **Users** under the **ldap.com** node.

b. In the right pane, right-click user **aaa** and select **Properties**.

c. In the dialog box, click the **Member Of** tab and click **Add**.

Figure 18 Modifying user properties



Member of:

Name	Active Directory Folder
Domain Users	ldap.com/Users

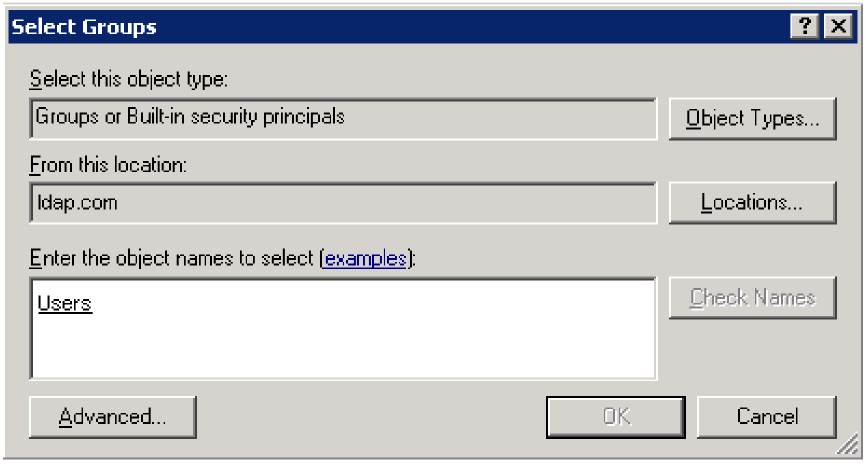
Primary group: Domain Users

There is no need to change Primary group unless you have Macintosh clients or POSIX-compliant applications.

d. In the **Select Groups** dialog box, enter **Users** in the **Enter the object names to select** field, and click **OK**.

User **aaa** is added to group **Users**.

Figure 19 Adding user aaa to group Users



Select this object type:
Groups or Built-in security principals

From this location:
ldap.com

Enter the object names to select (examples):
Users

3. Set the administrator password to **admin!123456**:

   a. In the right pane, right-click user **Administrator** and select **Set Password**.

   b. In the dialog box, enter the administrator password. (Details not shown.)

Configuring the device

1. Assign IP addresses to interfaces:

# Assign an IP address to GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.1.70 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing.

In this example, the device is directly connected to the SSH user and the LDAP server.

3. Add interfaces to security zones.

```
[Device] security-zone name Management
[Device-security-zone-Management] import interface gigabitethernet 1/0/1
[Device-security-zone-Management] quit
[Device] security-zone name DMZ
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/2
[Device-security-zone-DMZ] quit
```

4. Configure a security policy to permit the request packets from the device to the LDAP server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name laaalocalout
[Device-security-policy-ip-1-aaalocalout] source-zone local
[Device-security-policy-ip-1-aaalocalout] source-ip-host 10.1.1.2
[Device-security-policy-ip-1-aaalocalout] destination-zone DMZ
[Device-security-policy-ip-1-aaalocalout] destination-ip-host 10.1.1.1
[Device-security-policy-ip-1-aaalocalout] action pass
[Device-security-policy-ip-1-aaalocalout] quit
[Device-security-policy-ip] quit
```

5. Configure key pairs:

# Create local RSA key pairs, a local DSA key pair, and a local ECDSA key pair.

```
[Device] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.
Create the key pair successfully.
[Device] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..
Create the key pair successfully.
[Device] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

6. Configure SSH:

# Enable the Stelnet server, and enable scheme authentication for user lines VTY 0 through VTY 63.

```
[Device] ssh server enable
[Device] line vty 0 63
[Device-line-vty0-63] authentication-mode scheme
[Device-line-vty0-63] quit
```

7. Configure LDAP:

# Configure an LDAP server, specify the IP address of the LDAP server, the administrator DN, and the administrator password, and configure the base DN for user search.

```
[Device] ldap server ldap1
[Device-ldap-server-ldap1] ip 10.1.1.1
[Device-ldap-server-ldap1] login-dn cn=administrator,cn=users,dc=ldap,dc=com
[Device-ldap-server-ldap1] login-password simple admin!123456
[Device-ldap-server-ldap1] search-base-dn dc=ldap,dc=com
[Device-ldap-server-ldap1] quit
```

# Create an LDAP scheme, and specify the LDAP authentication server.

```
[Device] ldap scheme ldap1-shml
[Device-ldap-ldap-shml] authentication-server ldap1
[Device-ldap-ldap1-shml] quit
```

8. Configure an ISP domain:

# Create an ISP domain named **bbb** and configure the authentication, authorization, and accounting methods for login users.

```
[Device] domain bbb
[Device-isp-bbb] authentication login ldap-scheme ldap1-shml
[Device-isp-bbb] authorization login none
[Device-isp-bbb] accounting login none
[Device-isp-bbb] quit
```

# Specify ISP domain **bbb** as the default ISP domain.

```
[Device] domain default enable bbb
```

Verifying the configuration

# Initiate an SSH connection to the device, and enter username **aaa@bbb** and password **ldap!123456**. The user logs in to the device. (Details not shown.)

# Verify that the user can use the commands permitted by the level-0 user role. (Details not shown.)

Example: Configuring authentication and authorization for SSL VPN users by an LDAP server

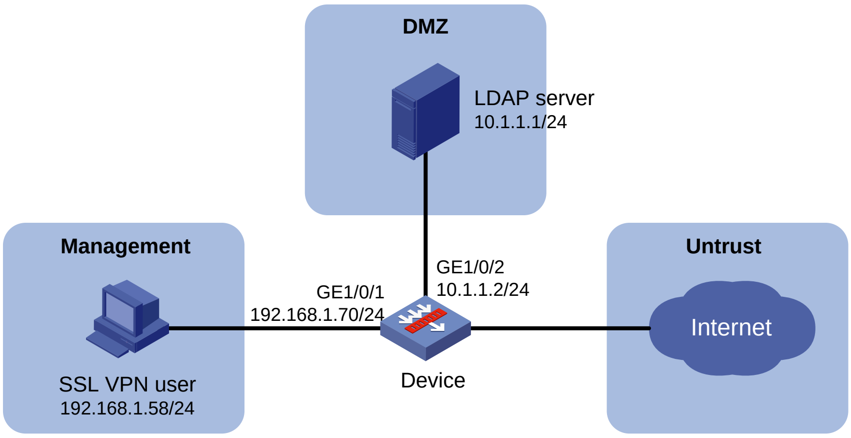
Network configuration

As shown in Figure 20, configure the device to meet the following requirements:

- Use the LDAP server to perform authentication and authorization for the SSL VPN user.
- Act as an SSL VPN gateway. The gateway IP address is 192.168.1.70 and the service port number is 8080.

The LDAP server runs Microsoft Windows 2003 Server Active Directory and uses domain **ldap.com**. The server assigns an SSL VPN policy group named **pg1** to the user after authentication. The policy group specifies the Web resources that the user can access.

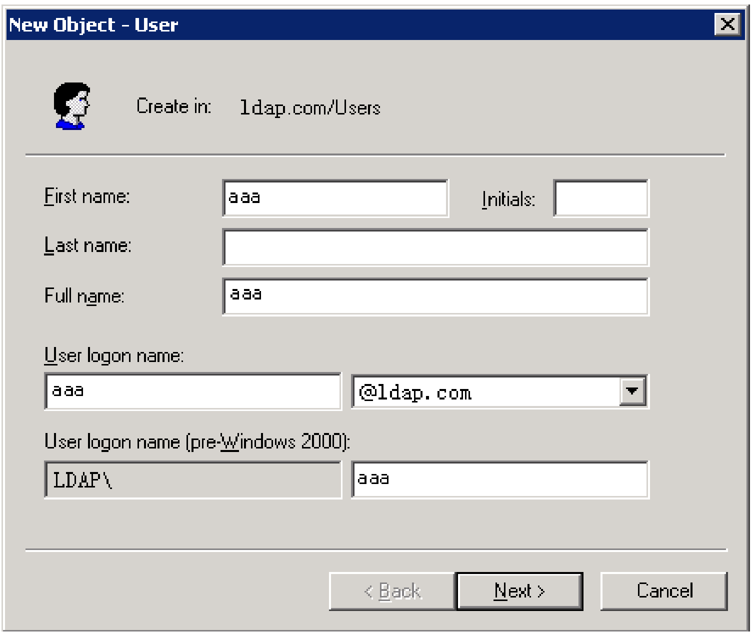
Figure 20 Network diagram



Configuring the LDAP server

1. Add a user named **aaa** and set the password to **ldap!123456**:
   a. On the LDAP server, select **Start** > **Control Panel** > **Administrative Tools**.
   b. Double-click **Active Directory Users and Computers**.
      The **Active Directory Users and Computers** window is displayed.
   c. From the navigation tree, click **Users** under the **ldap.com** node.
   d. Select **Action** > **New** > **User** from the menu to display the dialog box for adding a user.
   e. Enter logon name **aaa** and click **Next**.

      Figure 21 Adding user aaa



New Object - User

Create in: ldap.com/Users

First name: aaa

Initials:

Last name:

Full name: aaa

User logon name:

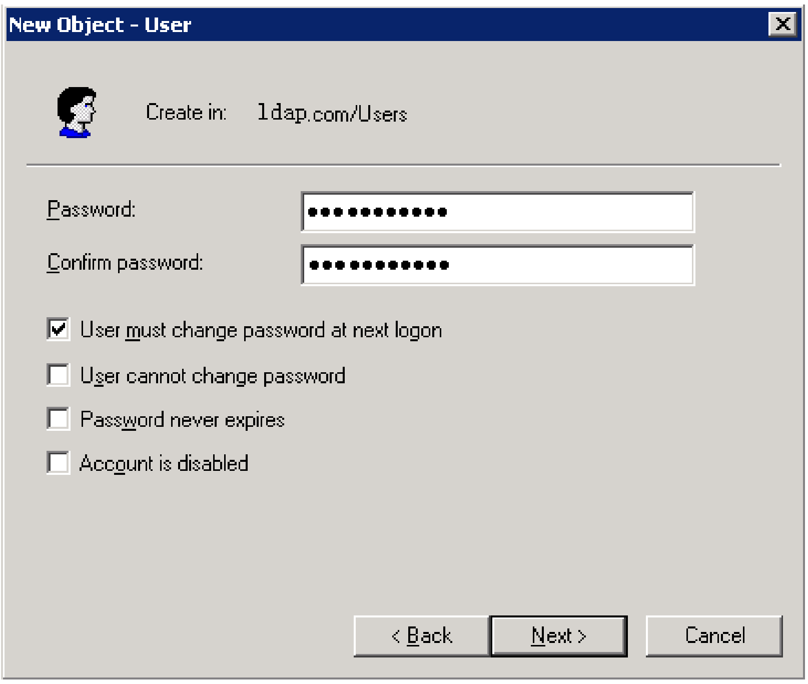
aaa @ldap.com

User logon name (pre-Windows 2000):

LDAP\ aaa

   f. In the dialog box, enter password **ldap!123456**, select options as needed, and click **Next**.

Figure 22 Setting the user's password



New Object - User

Create in: ldap.com/Users

Password: ●●●●●●●●●●●●

Confirm password: ●●●●●●●●●●●●

☑ User must change password at next logon

□ User cannot change password

□ Password never expires

□ Account is disabled

g. Click **OK**.

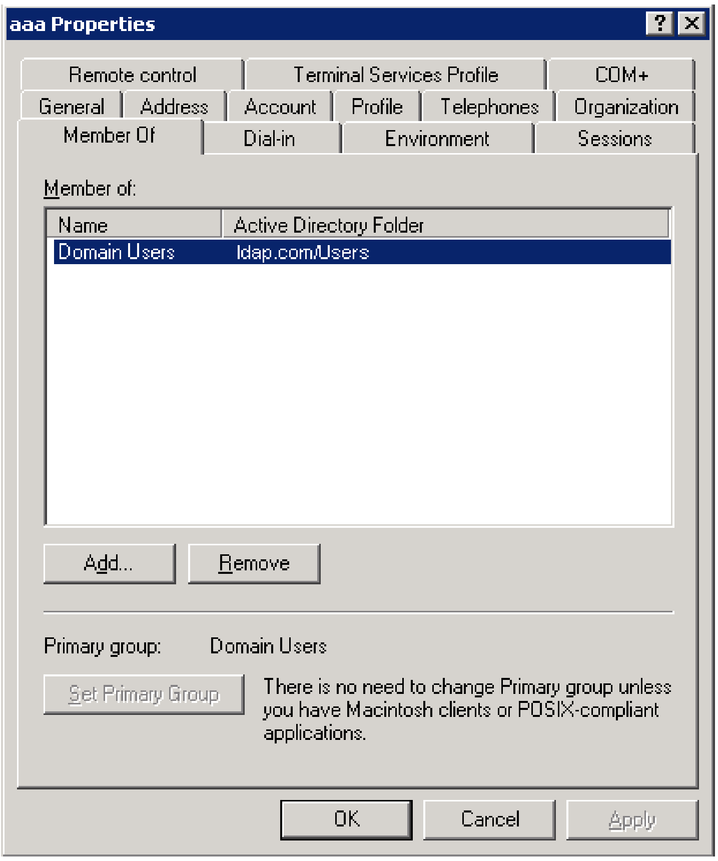
2. Add user **aaa** to group **Users**:

a. From the navigation tree, click **Users** under the **ldap.com** node.

b. In the right pane, right-click user **aaa** and select **Properties**.

c. In the dialog box, click the **Member Of** tab and click **Add**.

Figure 23 Modifying user properties



Member of:

Name	Active Directory Folder
Domain Users	ldap.com/Users

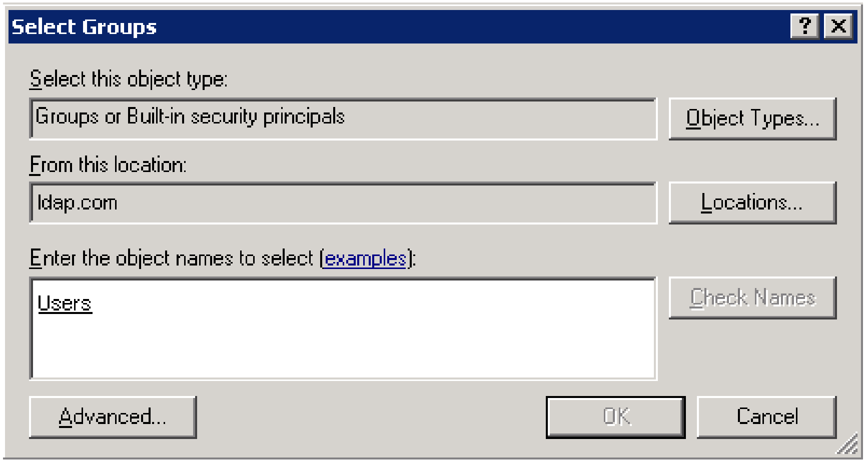
Primary group: Domain Users

There is no need to change Primary group unless you have Macintosh clients or POSIX-compliant applications.

d. In the **Select Groups** dialog box, enter **Users** in the **Enter the object names to select** field, and click **OK**.

User **aaa** is added to group **Users**.

Figure 24 Adding user aaa to group Users



Select this object type:
Groups or Built-in security principals

From this location:
ldap.com

Enter the object names to select (examples):
Users

3. Set the administrator password to **admin!123456**:

   a. In the right pane, right-click user **Administrator** and select **Set Password**.

   b. In the dialog box, enter the administrator password. (Details not shown.)

Configuring the device

1. Assign IP addresses to interfaces:

# Assign an IP address to GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.1.70 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing.

   In this example, the device is directly connected to the SSL VPN user and the LDAP server.

3. Add interfaces to security zones.

```
[Device] security-zone name Trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/1
[Device-security-zone-Trust] quit
[Device] security-zone name DMZ
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/2
[Device-security-zone-DMZ] quit
[Device] security-zone name Untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/3
[Device-security-zone-Untrust] quit
```

4. Configure a security policy:

   # Configure a rule to permit the traffic from the SSL VPN user to the device.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name sslvpnlocalin
[Device-security-policy-ip-1-sslvpnlocalin] source-zone Trust
[Device-security-policy-ip-1-sslvpnlocalin] destination-zone Local
[Device-security-policy-ip-1-sslvpnlocalin] action pass
[Device-security-policy-ip-1-sslvpnlocalin] quit
```

# Configure a rule to permit the traffic from the device to the SSL VPN user.

```
[Device-security-policy-ip] rule name sslvpnlocalout
[Device-security-policy-ip-2-sslvpnlocalout] source-zone Local
[Device-security-policy-ip-2-sslvpnlocalout] destination-zone Trust
[Device-security-policy-ip-2-sslvpnlocalout] action pass
[Device-security-policy-ip-2-sslvpnlocalout] quit
```

# Configure a rule to permit the traffic from the device to the LDAP server.

```
[Device-security-policy-ip] rule name ldaplocalout
[Device-security-policy-ip-3-ldaplocalout] source-zone local
[Device-security-policy-ip-3-ldaplocalout] source-ip-host 10.1.1.2
[Device-security-policy-ip-3-ldaplocalout] destination-zone DMZ
[Device-security-policy-ip-3-ldaplocalout] destination-ip-host 10.1.1.1
[Device-security-policy-ip-3-ldaplocalout] action pass
[Device-security-policy-ip-3-ldaplocalout] quit
```

# Configure a rule to permit the traffic from the device to the **Untrust** security zone.

```
[Device-security-policy-ip] rule name accesslocalout
[Device-security-policy-ip-4-accesslocalout] source-zone Local
[Device-security-policy-ip-4-accesslocalout]destination-zone Untrust
[Device-security-policy-ip-4-accesslocalout] action pass
[Device-security-policy-ip-4-accesslocalout] quit
```

# Configure a rule to permit the traffic from the **Untrust** security zone to the device.

```
[Device-security-policy-ip] rule name returnlocalin
[Device-security-policy-ip-5-returnlocalin] source-zone Untrust
[Device-security-policy-ip-5-returnlocalin] destination-zone Local
[Device-security-policy-ip-5-returnlocalin] action pass
[Device-security-policy-ip-5-returnlocalin] quit
[Device-security-policy-ip] quit
```

5. Create a PKI domain named **sslvpn** and obtain the CA and local certificates (see "Configuring PKI"). (Details not shown.)
6. Configure SSL:

   # Create an SSL server policy named **myssl**, and specify PKI domain **sslvpn** for the SSL server policy.

```
[Device] ssl server-policy myssl
[Device-server-policy-myssl] pki-domain sslvpn
[Device-server-policy-myssl] quit
```

7. Configure SSL VPN:

   # Create and configure SSL VPN gateway name **g1**.

```
[Device] sslvpn gateway g1
[Device-sslvpn-gateway-g1] ssl server-policy myssl
[Device-sslvpn-gateway-g1] ip address 192.168.1.70 port 8080
[Device-sslvpn-gateway-g1] service enable
[Device-sslvpn-gateway-g1] quit
```

   # Create an SSL VPN context named **aaa**, specify gateway **g1** for the SSL VPN context, and specify domain **bbb** for authentication, authorization, and accounting of SSL VPN users in the context.

```
[Device] sslvpn context aaa
[Device-sslvpn-context-aaa] gateway g1
[Device-sslvpn-context-aaa] aaa domain bbb
```

   # Create a URL item named **urlitem** and specify the resource URL in the URL item.

```
[Device-sslvpn-context-aaa] url-item urlitem
[Device-sslvpn-context-aaa-url-item-urlitem] url http://20.2.2.2
[Device-sslvpn-context-aaa-url-item-urlitem] quit
[Device-sslvpn-context-aaa] url-list urllist
[Device-sslvpn-context-aaa-url-list-urllist] heading web
[Device-sslvpn-context-aaa-url-list-urllist] resources url-item urlitem
[Device-sslvpn-context-aaa-url-list-urllist] quit
```

   # Create an SSL VPN policy group named **pg1** for SSL VPN context **aaa**, add URL list **urllist** to the policy group for Web access, and enable the SSL VPN context.

```
[Device-sslvpn-context-aaa] policy-group pg1
[Device-sslvpn-context-aaa-policy-group-pg1] resources url-list urllist
[Device-sslvpn-context-aaa-policy-group-pg1] quit
[Device-sslvpn-context-aaa] service enable
[Device-sslvpn-context-aaa] quit
```

8. Configure LDAP:

   # Configure LDAP server **ldap1**, specify the IP address of the server, the administrator DN, and the administrator password, and configure the base DN for user search.

```
[Device] ldap server ldap1
[Device-ldap-server-ldap1] ip 10.1.1.1
[Device-ldap-server-ldap1] login-dn cn=administrator,cn=users,dc=ldap,dc=com
```

```
[Device-ldap-server-ldap1] login-password simple admin!123456
[Device-ldap-server-ldap1] search-base-dn dc=ldap,dc=com
[Device-ldap-server-ldap1] quit
```

# Create an LDAP attribute map named **test.**, and map a partial value string of the LDAP attribute named **memberof** to AAA attribute named **user-group**.

```
[Device] ldap attribute-map test
[Device-ldap-attr-map-test] map ldap-attribute memberof prefix cn= delimiter,
aaa-attribute user-group
[Device-ldap-attr-map-test] quit
```

# Create an LDAP scheme, specify the LDAP authentication and authorization servers, and specify LDAP attribute map **test** in the LDAP scheme.

```
[Device] ldap scheme shml
[Device-ldap-shml] authentication-server ldap1
[Device-ldap-shml] authorization-server ldap1
[Device-ldap-shml] attribute-map test
[Device-ldap-shml] quit
```

9. Create an ISP domain named **bbb** and configure the authentication, authorization, and accounting methods for SSL VPN users.

```
[Device] domain bbb
[Device-isp-bbb] authentication sslvpn ldap-scheme shml
[Device-isp-bbb] authorization sslvpn ldap-scheme shml
[Device-isp-bbb] accounting sslvpn none
[Device-isp-bbb] quit
```

10. Create a user group named **users** and authorize SSL VPN policy group **pg1** to the group.

```
[Device] user-group users
[Device-ugroup-users] authorization-attribute sslvpn-policy-group pg1
[Device-ugroup-users] quit
```

Verifying the configuration

# In the Web browser, enter **https://192.168.1.70:8080** in the address bar.

# Enter username **aaa@bbb** and password **ldap!123456**. The user logs in to the website. (Details not shown.)

# Verify that the user can access the Web resources in SSL VPN policy group **pg1**.

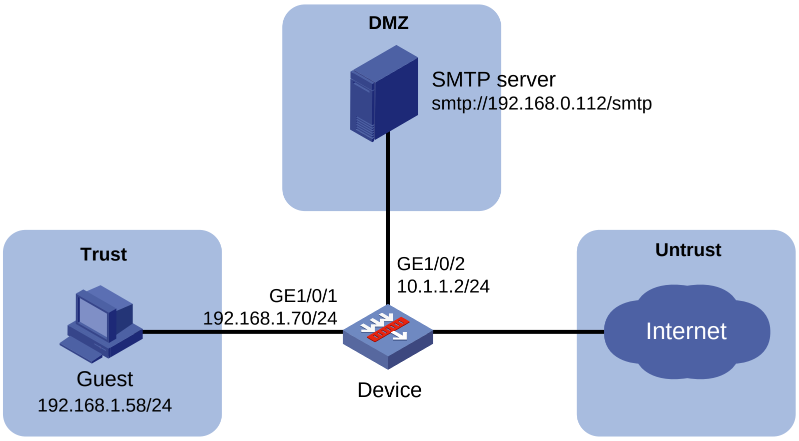
Example: Configuring and managing a local guest

Network configuration

As shown in Figure 25, create a local guest named **user1** for Jack. Configure local guest attributes and manage the local guest on the device as follows:

- Configure attributes for the local guest, including the password, user group, validity period, and sponsor information.
- Enable the guest auto-delete feature.
- Specify an SMTP server and email sender address for the device to send local guest email notifications.
- Configure email addresses for the local guest, guest sponsor, and guest manager.
- Configure the subject and body of the email notifications to be sent to the guest, guest sponsor, and guest manager.
- Send email notifications of the local guest account information to the guest and guest sponsor.

Figure 25 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   # Assign an IP address to GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.70 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing.

   In this example, the device is directly connected to the guest and the SMTP server.

3. Add interfaces to security zones.

   ```
   [Device] security-zone name Trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/1
   [Device-security-zone-Trust] quit
   [Device] security-zone name DMZ
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/2
   [Device-security-zone-DMZ] quit
   ```

4. Configure a security policy:

   # Configure a rule named **guestlocalin** to permit the traffic from the guest to the device.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name guestlocalin
   [Device-security-policy-ip-1-guestlocalin] source-zone Trust
   [Device-security-policy-ip-1-guestlocalin] destination-zone Local
   [Device-security-policy-ip-1-guestlocalin] action pass
   [Device-security-policy-ip-1-guestlocalin] quit
   ```

   # Configure a rule named **guestlocalout** to permit the traffic from the device to the guest.

   ```
   [Device-security-policy-ip] rule name guestlocalout
   [Device-security-policy-ip-2-guestlocalout] source-zone Local
   [Device-security-policy-ip-2-guestlocalout] destination-zone Trust
   [Device-security-policy-ip-2-guestlocalout] action pass
   [Device-security-policy-ip-2-guestlocalout] quit
   ```

   # Configure a rule named **smtplocalout**to permit the traffic from the device to the SMTP server.

   ```
   [Device-security-policy-ip] rule name smtplocalout
   ```

```
[Device-security-policy-ip-3-smtplocalout] source-zone local
[Device-security-policy-ip-3-smtplocalout] destination-zone DMZ
[Device-security-policy-ip-3-smtplocalout] action pass
[Device-security-policy-ip-3-smtplocalout] quit
```

# Configure a rule named **smtplocalin** to permit the traffic from the SMTP server to the device.

```
[Device-security-policy-ip] rule name smtplocalin
[Device-security-policy-ip-4-smtplocalin] source-zone DMZ
[Device-security-policy-ip-4-smtplocalin] destination-zone Local
[Device-security-policy-ip-4-smtplocalin] action pass
[Device-security-policy-ip-4-smtplocalin] quit
[Device-security-policy-ip] quit
```

5. Manage local guests:

# Enable the guest auto-delete feature for expired local guests.

```
[Device] local-guest auto-delete enable
```

# Specify an SMTP server to send local guest email notifications.

```
[Device] local-guest email smtp-server smtp://192.168.0.112/smtp
```

# Specify the email sender address as **bbb@ccc.com** in the email notifications sent by the device for local guests.

```
[Device] local-guest email sender bbb@ccc.com
```

# Specify the email address of the guest manager as **guest-manager@ccc.com**.

```
[Device] local-guest manager-email guest-manager@ccc.com
```

# Configure the subject and body of the email notifications to be sent to the local guest.

```
[Device] local-guest email format to guest subject Guest account information
[Device] local-guest email format to guest body A guest account has been created for
your use. The username, password, and valid dates for the account are given below.
```

# Configure the subject and body of the email notifications to be sent to the guest sponsor.

```
[Device] local-guest email format to sponsor subject Guest account information
[Device] local-guest email format to sponsor body A guest account has been created.
The username, password, and valid dates for the account are given below.
```

# Configure the subject and body of the email notifications to be sent to the guest manager.

```
[Device] local-guest email format to manager subject Guest registration information
[Device] local-guest email format to manager body A guest account has been registered.
The username for the account is given below. Please approve the register information.
```

6. Configure the local guest:

# Create a user group named **guest1**.

```
[Device] user-group guest1
[Device-ugroup-guest1] quit
```

# Create a local guest named **user1**, configure the password of the guest, and configure the user group, name, company, email address, phone number, description, and validity period.

```
[Device] local-user user1 class network guest
[Device-luser-network(guest)-user1] password simple 123456
[Device-luser-network(guest)-user1] group guest1
[Device-luser-network(guest)-user1] full-name Jack
[Device-luser-network(guest)-user1] company cc
[Device-luser-network(guest)-user1] email Jack@cc.com
[Device-luser-network(guest)-user1] phone 131129237
[Device-luser-network(guest)-user1] description A guest from company cc
```

```
[Device-luser-network(guest)-user1] validity-datetime from 2015/4/1 08:00:00 to
2015/4/3 18:00:00
```

# Configure the name, email address, and department of the guest sponsor.

```
[Device-luser-network(guest)-user1] sponsor-full-name Sam
[Device-luser-network(guest)-user1] sponsor-email Sam@aa.com
[Device-luser-network(guest)-user1] sponsor-department security
[Device-luser-network(guest)-user1] quit
[Device] quit
```

7. Configure the device to send guest email notifications:

   # Send an email notification to the guest sponsor.

```
<Device> local-guest send-email user-name user1 to sponsor
```

   # Send an email notification to the guest.

```
<Device> local-guest send-email user-name user1 to guest
```

Verifying the configuration

# Display local guest information.

```
<Device> display local-user user-name user1 class network guest
Total 1 local users matched.

Network access guest user user1:
  State:                     Active
  Service type:              LAN access/Portal
  User group:                guest1
  Full name:                 Jack
  Company:                   cc
  Email:                     Jack@cc.com
  Phone:                     131129237
  Description:               A guest from company cc
  Sponsor full name:         Sam
  Sponsor department:        security
  Sponsor email:             Sam@aa.com
  Period of validity:
    Start date and time:     2015/04/01-08:00:00
    Expiration date and time:2015/04/03-18:00:00
```

# Verify that Jack can use username **user1** and password **123456** to pass local authentication and come online during the validity period. (Details not shown.)

Troubleshooting AAA

RADIUS authentication failure

Symptom

User authentication always fails.

Analysis

Possible reasons include:

- A communication failure exists between the NAS and the RADIUS server.

- The username is not in the *userid@isp-name* format, or the ISP domain is not correctly configured on the NAS.
- The user is not configured on the RADIUS server.
- The password entered by the user is incorrect.
- The RADIUS server and the NAS are configured with different shared keys.

Solution

To resolve the problem:

1. Verify the following items:
   - The NAS and the RADIUS server can ping each other.
   - The username is in the *userid@isp-name* format and the ISP domain is correctly configured on the NAS.
   - The user is configured on the RADIUS server.
   - The correct password is entered.
   - The same shared key is configured on both the RADIUS server and the NAS.
2. If the problem persists, contact NSFOCUS Support.

RADIUS packet delivery failure

Symptom

RADIUS packets cannot reach the RADIUS server.

Analysis

Possible reasons include:

- A communication failure exists between the NAS and the RADIUS server.
- The NAS is not configured with the IP address of the RADIUS server.
- The authentication and accounting UDP ports configured on the NAS are incorrect.
- The RADIUS server's authentication and accounting port numbers are being used by other applications.

Solution

To resolve the problem:

1. Verify the following items:
   - The link between the NAS and the RADIUS server works well at both the physical and data link layers.
   - The IP address of the RADIUS server is correctly configured on the NAS.
   - The authentication and accounting UDP port numbers configured on the NAS are the same as those of the RADIUS server.
   - The RADIUS server's authentication and accounting port numbers are available.
2. If the problem persists, contact NSFOCUS Support.

RADIUS accounting error

Symptom

A user is authenticated and authorized, but accounting for the user is not normal.

Analysis

The accounting server configuration on the NAS is not correct. Possible reasons include:

- The accounting port number configured on the NAS is incorrect.
- The accounting server IP address configured on the NAS is incorrect. For example, the NAS is configured to use a single server to provide authentication, authorization, and accounting services, but in fact the services are provided by different servers.

Solution

To resolve the problem:

1. Verify the following items:
   - The accounting port number is correctly configured.
   - The accounting server IP address is correctly configured on the NAS.
2. If the problem persists, contact NSFOCUS Support.

Troubleshooting HWTACACS

Similar to RADIUS troubleshooting. See "RADIUS authentication failure", "RADIUS packet delivery failure", and "RADIUS accounting error."

LDAP authentication failure

Symptom

User authentication fails.

Analysis

Possible reasons include:

- A communication failure exists between the NAS and the LDAP server.
- The LDAP server IP address or port number configured on the NAS is not correct.
- The username is not in the *userid@isp-name* format, or the ISP domain is not correctly configured on the NAS.
- The user is not configured on the LDAP server.
- The password entered by the user is incorrect.
- The administrator DN or password is not configured.
- Some user attributes (for example, the username attribute) configured on the NAS are not consistent with those configured on the server.
- No user search base DN is specified for the LDAP scheme.

Solution

To resolve the problem:

1. Verify the following items:
   - The NAS and the LDAP server can ping each other.
   - The IP address and port number of the LDAP server configured on the NAS match those of the server.
   - The username is in the correct format and the ISP domain for the user authentication is correctly configured on the NAS.
   - The user is configured on the LDAP server.
   - The correct password is entered.
   - The administrator DN and the administrator password are correctly configured.
   - The user attributes (for example, the username attribute) configured on the NAS are consistent with those configured on the LDAP server.

- The user search base DN for authentication is specified.

2. If the problem persists, contact NSFOCUS Support.

Appendix A Commonly used RADIUS attributes

Commonly used RADIUS attributes are defined in RFC 2865, RFC 2866, RFC 2867, and RFC 2868.

Table 5 Commonly used RADIUS attributes

No.	Attribute	No.	Attribute
1	User-Name	45	Acct-Authentic
2	User-Password	46	Acct-Session-Time
3	CHAP-Password	47	Acct-Input-Packets
4	NAS-IP-Address	48	Acct-Output-Packets
5	NAS-Port	49	Acct-Terminate-Cause
6	Service-Type	50	Acct-Multi-Session-Id
7	Framed-Protocol	51	Acct-Link-Count
8	Framed-IP-Address	52	Acct-Input-Gigawords
9	Framed-IP-Netmask	53	Acct-Output-Gigawords
10	Framed-Routing	54	(unassigned)
11	Filter-ID	55	Event-Timestamp
12	Framed-MTU	56-59	(unassigned)
13	Framed-Compression	60	CHAP-Challenge
14	Login-IP-Host	61	NAS-Port-Type
15	Login-Service	62	Port-Limit
16	Login-TCP-Port	63	Login-LAT-Port
17	(unassigned)	64	Tunnel-Type
18	Reply-Message	65	Tunnel-Medium-Type
19	Callback-Number	66	Tunnel-Client-Endpoint
20	Callback-ID	67	Tunnel-Server-Endpoint
21	(unassigned)	68	Acct-Tunnel-Connection
22	Framed-Route	69	Tunnel-Password
23	Framed-IPX-Network	70	ARAP-Password
24	State	71	ARAP-Features
25	Class	72	ARAP-Zone-Access
26	Vendor-Specific	73	ARAP-Security
27	Session-Timeout	74	ARAP-Security-Data

41	Acct-Delay-Time	88	Framed-Pool
42	Acct-Input-Octets	89	(unassigned)
43	Acct-Output-Octets	90	Tunnel-Client-Auth-id
44	Acct-Session-Id	91	Tunnel-Server-Auth-id

Appendix B Descriptions for commonly used standard RADIUS attributes

No.	Attribute	Description
1	User-Name	Name of the user to be authenticated.
2	User-Password	User password for PAP authentication, only present in Access-Request packets when PAP authentication is used.
3	CHAP-Password	Digest of the user password for CHAP authentication, only present in Access-Request packets when CHAP authentication is used.
4	NAS-IP-Address	IP address for the server to use to identify the client. Typically, a client is identified by the IP address of its access interface. This attribute is only present in Access-Request packets.
5	NAS-Port	Physical port of the NAS that the user accesses.
6	Service-Type	Type of service that the user has requested or type of service to be provided.
7	Framed-Protocol	Encapsulation protocol for framed access.
8	Framed-IP-Address	IP address assigned to the user.
11	Filter-ID	Name of the filter list. This attribute is parsed as follows: • If the name is a string of all digits, it indicates an ACL number. • If the name is a string in the format of user-group=*name1*;*name2*;..;*namex*, it indicates a list of user group names. This type of filter list is applicable only to SSL VPN users.

No.	Attribute	Description
		- If the name is not a string of all digits and the name string does not contain an equal sign (=), the device parses this attribute as follows: - If the NSFOCUS-ACL-Version attribute is issued next to this attribute, the value for this attribute is an ACL name. - If the NSFOCUS-ACL-Version attribute is not issued next to this attribute, the value for this attribute is a user profile name.
12	Framed-MTU	MTU for the data link between the user and NAS.
14	Login-IP-Host	IP address of the NAS interface that the user accesses.
15	Login-Service	Type of service that the user uses for login.
18	Reply-Message	Text to be displayed to the user, which can be used by the server to communicate information, for example, the cause of the authentication failure.
26	Vendor-Specific	Vendor-specific proprietary attribute. A packet can contain one or more proprietary attributes, each of which can contain one or more subattributes.
27	Session-Timeout	Maximum service duration for the user before termination of the session.
28	Idle-Timeout	Maximum idle time permitted for the user before termination of the session.
31	Calling-Station-Id	User identification that the NAS sends to the server. For the LAN access service provided by an NSFOCUS device, this attribute includes the MAC address of the user.
32	NAS-Identifier	Identification that the NAS uses to identify itself to the RADIUS server.
40	Acct-Status-Type	Type of the Accounting-Request packet. Possible values include: - **1**—Start. - **2**—Stop. - **3**—Interim-Update. - **4**—Reset-Charge. - **7**—Accounting-On. (Defined in the 3rd Generation Partnership Project.) - **8**—Accounting-Off. (Defined in the 3rd Generation Partnership Project.) - **9 to 14**—Reserved for tunnel accounting. - **15**—Reserved for failed.
45	Acct-Authentic	Authentication method used by the user. Possible values include: - **1**—RADIUS. - **2**—Local. - **3**—Remote.
60	CHAP-Challenge	CHAP challenge generated by the NAS for MD5 calculation during CHAP authentication.
61	NAS-Port-Type	Type of the physical port of the NAS that is authenticating the user. Possible values include: - **15**—Ethernet. - **16**—Any type of ADSL. - **17**—Cable. (With cable for cable TV.) - **19**—WLAN-IEEE 802.11. - **201**—VLAN. - **202**—ATM.

No.	Attribute	Description
		If the port is an ATM or Ethernet one and VLANs are implemented on it, the value of this attribute is 201.
64	Tunnel-Type	Tunneling protocols used. The value **13** represents VLAN. If the value is 13, the device interprets the Tunnel-Type, Tunnel-Medium-Type, and Tunnel-Private-Group-ID attributes as attributes to assign VLANs.
65	Tunnel-Medium-Type	Transport medium type to use for creating a tunnel. For VLAN assignment, the value must be **6** to indicate the 802 media plus Ethernet.
79	EAP-Message	Used to encapsulate EAP packets to allow RADIUS to support EAP authentication.
80	Message-Authenticator	Used for authentication and verification of authentication packets to prevent spoofing Access-Requests. This attribute is present when EAP authentication is used.
81	Tunnel-Private-Group-ID	Group ID for a tunnel session. To assign VLANs, the NAS conveys VLAN IDs by using this attribute.
87	NAS-Port-Id	String for describing the port of the NAS that is authenticating the user.

Appendix C RADIUS subattributes (vendor ID 25506)

Table 6 lists all RADIUS subattributes with a vendor ID of 25506. Support for these subattributes depends on the device model.

Table 6 RADIUS subattributes (vendor ID 25506)

No.	Subattribute	Description
1	Input-Peak-Rate	Peak rate in the direction from the user to the NAS, in bps.
2	Input-Average-Rate	Average rate in the direction from the user to the NAS, in bps.
3	Input-Basic-Rate	Basic rate in the direction from the user to the NAS, in bps.
4	Output-Peak-Rate	Peak rate in the direction from the NAS to the user, in bps.
5	Output-Average-Rate	Average rate in the direction from the NAS to the user, in bps.
6	Output-Basic-Rate	Basic rate in the direction from the NAS to the user, in bps.
15	Remanent_Volume	Total amount of data available for the connection, in different units for different server types.
17	ISP-ID	ISP domain where the user obtains authorization information.
20	Command	Operation for the session, used for session control. Possible values include: • **1**—Trigger-Request. • **2**—Terminate-Request. • **3**—SetPolicy. • **4**—Result. • **5**—PortalClear.
21	ACL-Version	IP protocol version for an ACL. This attribute is used with the Filter-ID attribute to identify the IP protocol version of the ACL in the filter list. • **1**—IPv4.

No.	Subattribute	Description
		• **2**—IPv6.
24	Control_Identifier	Identifier for a packet that is resent by the server. For packets resent by the server during the same session, the value of this attribute is the same. For packets resent by the server during different sessions, the value of this attribute might be the same. Response packets from the corresponding client must carry this attribute with the value the same as the packet resent by the server. This attribute can be ignored in start-accounting, stop-accounting, and interim-update-accounting requests.
25	Result_Code	Result of the Trigger-Request or SetPolicy operation, zero for success and any other value for failure.
26	Connect_ID	Index of the user connection.
27	PortalURL	PADM redirect URL assigned to PPPoE users.
28	Ftp_Directory	FTP, SFTP, or SCP user working directory. When the RADIUS client acts as the FTP, SFTP, or SCP server, this attribute is used to set the working directory for an FTP, SFTP, or SCP user on the RADIUS client.
29	Exec_Privilege	EXEC user priority.
32	NAT-IP-Address	Public IP address assigned to the user when the source IP address and port are translated.
33	NAT-Start-Port	Start port number of the port range assigned to the user when the source IP address and port are translated.
34	NAT-End-Port	End port number of the port range assigned to the user when the source IP address and port are translated.
59	NAS_Startup_Timestamp	Startup time of the NAS in seconds, which is represented by the time elapsed after 00:00:00 on Jan. 1, 1970 (UTC).
60	Ip_Host_Addr	User IP address and MAC address included in authentication and accounting requests, in the format A.B.C.D hh:hh:hh:hh:hh:hh. A space is required between the IP address and the MAC address.
61	User_Notify	Information that must be sent from the server to the client transparently.
98	Multicast_Receive_Group	IP address of the multicast group that the user's host joins as a receiver. This subattribute can appear multiple times in a multicast packet to indicate that the user belongs to multiple multicast groups.
100	IP6_Multicast_Receive_Group	IPv6 address of the multicast group that the user's host joins as a receiver. This subattribute can appear multiple times in a multicast packet to indicate that the user belongs to multiple multicast groups.
101	MLD-Access-Limit	Maximum number of MLD multicast groups that the user can join concurrently.
102	local-name	L2TP local tunnel name.
103	IGMP-Access-Limit	Maximum number of IGMP multicast groups that the user can join concurrently.
104	VPN-Instance	MPLS L3VPN instance to which a user belongs.
105	ANCP-Profile	ANCP profile name.

No.	Subattribute	Description
111	Longitude-Latitude	Longitude and latitude information of the NAS.
135	Client-Primary-DNS	IP address of the primary DNS server.
136	Client-Secondary-DNS	IP address of the secondary DNS server.
140	User_Group	User groups assigned after the user passes authentication. Typically, a user can belong to only one user group. An SSL VPN user can belong to multiple user groups that are separated by semicolons.
141	Security_Level	Security level assigned after the SSL VPN user passes security authentication.
144	Acct_IPv6_Input_Octets	Bytes of IPv6 packets in the inbound direction. The measurement unit depends on the configuration on the device.
145	Acct_IPv6_Output_Octets	Bytes of IPv6 packets in the outbound direction. The measurement unit depends on the configuration on the device.
146	Acct_IPv6_Input_Packets	Number of IPv6 packets in the inbound direction. The measurement unit depends on the configuration on the device.
147	Acct_IPv6_Output_Packets	Number of IPv6 packets in the outbound direction. The measurement unit depends on the configuration on the device.
148	Acct_IPv6_Input_Gigawords	Bytes of IPv6 packets in the inbound direction. The measurement unit is 4G bytes.
149	Acct_IPv6_Output_Gigawords	Bytes of IPv6 packets in the outbound direction. The measurement unit is 4G bytes.
155	User-Roles	List of space-separated user roles.
182	Microsegment-Id	Microsegment ID.
210	Av-Pair	User-defined attribute pair. Available attribute pairs include: • Server-assigned voice VLAN in the format of device-traffic-class=voice. • Server-assigned user role in the format of shell:role=xxx. • Server-deployed command to reboot a port, in the format of subscriber:command=bounce-host-port. • Server-assigned port shutdown duration in the format of bounce:seconds=xxx. • Server-deployed command to shut down a port, in the format of subscriber:command=disable-host-port.
246	Auth_Detail_Result	Accounting details. The server sends Access-Accept packets with subattributes 246 and 250 in the following situations: • **1**—The subscriber charge is overdue. The subscriber is allowed to access network resources in the whitelist. If the subscriber accesses other network resources, the device redirects it to the URL specified by subattribute 250. • **2**—The broadband lease of the subscriber expires. The device redirects the subscriber to the URL specified by subattribute 250 when the subscriber requests to access webpages for the first time.
247	Input-Committed-Burst-Size	Committed burst size from the user to the NAS, in bits. The total length cannot exceed 4 bytes for this field. This subattribute must be assigned together with the Input-Average-Rate attribute.
248	Output-Committed-Burst-Size	Committed burst size from the NAS to the user, in bits. The total

No.	Subattribute	Description
		length cannot exceed 4 bytes for this field. This subattribute must be assigned together with the Output-Average-Rate attribute.
249	authentication-type	Authentication type. The value can be: • **1**—Intranet access authentication. • **2**—Internet access authentication. If the packet does not contain this subattribute, common authentication applies.
250	WEB-URL	Redirect URL for PPP users.
251	Subscriber-ID	Family plan ID.
252	Subscriber-Profile	QoS policy name for the family plan of the subscriber.
255	Product_ID	Product name.

Appendix D HWTACACS attributes

HWTACACS authorization and accounting packets include the HWTACACS attributes assigned by the server to a user and the HWTACACS attributes uploaded by a user to the server. Table 7 shows the HWTACACS attributes supported by the device. The device ignores an HWTACACS attribute if it does not support that attribute.

Table 7 Supported HWTACACS attributes

Attribute name	Description
acl	Number of the ACL assigned to the user.
idletime	Idle timeout period, in seconds.
priv-lvl	User privilege level in the range of level 0 to level 15.
ftp-directory	Initial working directory of the FTP user.
addr	IP address assigned to the user.
addr-pool	IP address pool assigned to the user.
tunnel-type	Type of the tunnel to be established. Only L2TP is supported.
ip-addresses	LNS IP addresses.
tunnel-id	Group ID of the L2TP tunnel.
gw-password	Authentication password of the L2TP tunnel.
roles	User roles assigned to the user.
allowed-roles	Roles for which the user is allowed to obtain temporary authorization.

Contents

802.1X overview

About the 802.1X protocol

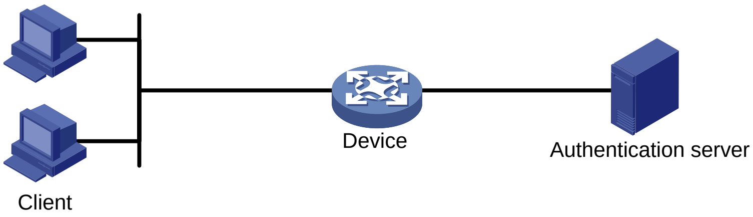
802.1X is a port-based network access control protocol widely used on Ethernet networks. The protocol controls network access by authenticating the devices connected to 802.1X-enabled LAN ports.

802.1X architecture

802.1X operates in the client/server model. As shown in Figure 1, 802.1X authentication includes the following entities:

- **Client (supplicant)**—A user terminal seeking access to the LAN. The terminal must have 802.1X software to authenticate to the access device.
- **Access device (authenticator)**—Authenticates the client to control access to the LAN. In a typical 802.1X environment, the access device uses an authentication server to perform authentication.
- **Authentication server**—Provides authentication services for the access device. The authentication server first authenticates 802.1X clients by using the data sent from the access device. Then, the server returns the authentication results to the access device to make access decisions. The authentication server is typically a RADIUS server. In a small LAN, you can use the access device as the authentication server.

Figure 1 802.1X architecture

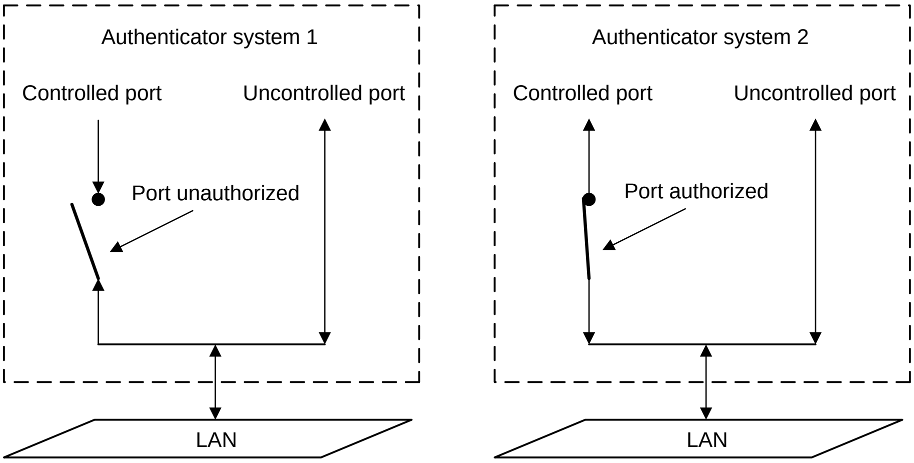


Controlled/uncontrolled port and port authorization status

802.1X defines two logical ports for the network access port: controlled port and uncontrolled port. Any packet arriving at the network access port is visible to both logical ports.

- **Uncontrolled port**—Is always open to receive and transmit authentication packets.
- **Controlled port**—Filters packets depending on the port state.
    - **Authorized state**—The controlled port is in authorized state when the client has passed authentication. The port allows traffic to pass through.
    - **Unauthorized state**—The port is in unauthorized state when the client has failed authentication. The port controls traffic by using one of the following methods:
        - Performs bidirectional traffic control to deny traffic to and from the client.
        - Performs unidirectional traffic control to deny traffic from the client. The device supports only unidirectional traffic control.

Figure 2 Authorization state of a controlled port



Packet exchange methods

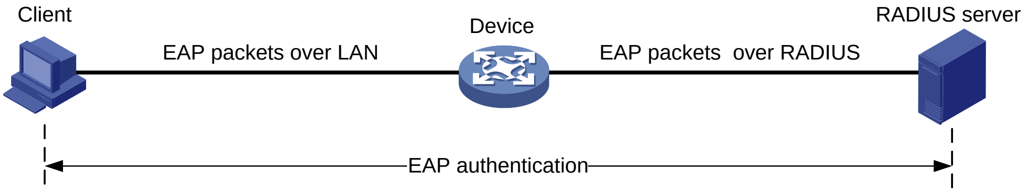
802.1X uses the Extensible Authentication Protocol (EAP) to transport authentication information for the client, the access device, and the authentication server. EAP is an authentication framework that uses the client/server model. The framework supports a variety of authentication methods, including MD5-Challenge, EAP-Transport Layer Security (EAP-TLS), and Protected EAP (PEAP).

802.1X defines EAP over LAN (EAPOL) for passing EAP packets between the client and the access device over a wired or wireless LAN. Between the access device and the authentication server, 802.1X delivers authentication information by either EAP relay or EAP termination.

EAP relay

EAP relay is defined in IEEE 802.1X. In this mode, the network device uses EAP over RADIUS (EAPOR) packets to send authentication information to the RADIUS server, as shown in Figure 3.

Figure 3 EAP relay



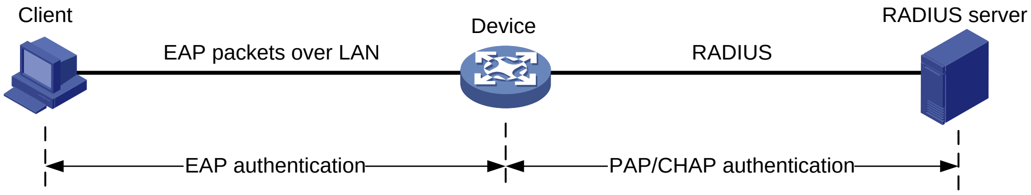
In EAP relay mode, the client must use the same authentication method as the RADIUS server. On the access device, you only need to use the **dot1x authentication-method eap** command to enable EAP relay.

EAP termination

As shown in Figure 4, the access device performs the following operations in EAP termination mode:

1. Terminates the EAP packets received from the client.
2. Encapsulates the client authentication information in standard RADIUS packets.
3. Uses PAP or CHAP to authenticate to the RADIUS server.

Figure 4 EAP termination



Comparing EAP relay and EAP termination

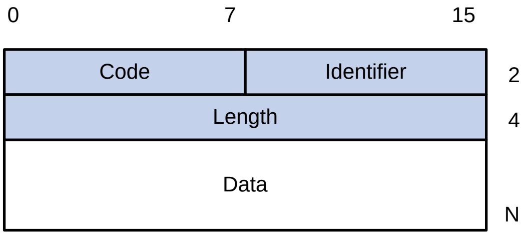
Packet exchange method	Benefits	Limitations
EAP relay	• Supports various EAP authentication methods. • The configuration and processing are simple on the access device.	The RADIUS server must support the EAP-Message and Message-Authenticator attributes, and the EAP authentication method used by the client.
EAP termination	Works with any RADIUS server that supports PAP or CHAP authentication.	• Supports only the following EAP authentication methods: ○ MD5-Challenge EAP authentication. ○ The username and password EAP authentication initiated by an iNode 802.1X client. • The processing is complex on the access device.

Packet formats

EAP packet format

Figure 5 shows the EAP packet format.

Figure 5 EAP packet format

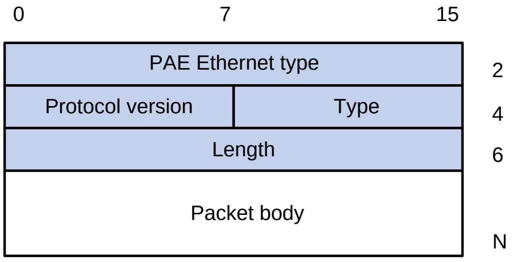


- **Code**—Type of the EAP packet. Options include Request (1), Response (2), Success (3), or Failure (4).
- **Identifier**—Used for matching Responses with Requests.
- **Length**—Length (in bytes) of the EAP packet. The EAP packet length is the sum of the Code, Identifier, Length, and Data fields.
- **Data**—Content of the EAP packet. This field appears only in a Request or Response EAP packet. The **Data** field contains the request type (or the response type) and the type data. Type 1 (Identity) and type 4 (MD5-Challenge) are two examples for the type field.

EAPOL packet format

Figure 6 shows the EAPOL packet format.

Figure 6 EAPOL packet format



- **PAE Ethernet type**—Protocol type. It takes the value 0x888E for EAPOL.
- **Protocol version**—The EAPOL protocol version used by the EAPOL packet sender.
- **Type**—Type of the EAPOL packet. Table 1 lists the types of EAPOL packets supported by the 802.1X implementation of the device.

  Table 1 Types of EAPOL packets

Value	Type	Description
0x00	EAP-Packet	The client and the access device uses EAP-Packets to transport authentication information.
0x01	EAPOL-Start	The client sends an EAPOL-Start message to initiate 802.1X authentication to the access device.
0x02	EAPOL-Logoff	The client sends an EAPOL-Logoff message to tell the access device that the client is logging off.

- **Length**—Data length in bytes, or length of the Packet body. If packet type is EAPOL-Start or EAPOL-Logoff, this field is set to 0, and no Packet body field follows.
- **Packet body**—Content of the packet. When the EAPOL packet type is EAP-Packet, the Packet body field contains an EAP packet.

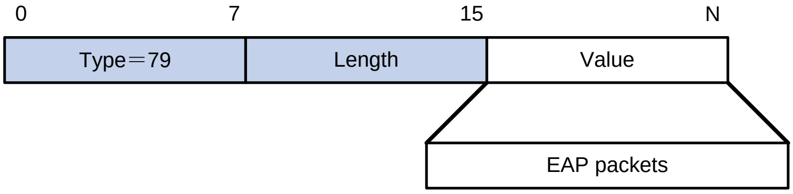
EAP over RADIUS

RADIUS adds two attributes, EAP-Message and Message-Authenticator, for supporting EAP authentication. For more information about the RADIUS packet format, see "Configuring AAA."

- EAP-Message.

  RADIUS encapsulates EAP packets in the EAP-Message attribute, as shown in Figure 7. The Type field takes 79, and the Value field can be up to 253 bytes. If an EAP packet is longer than 253 bytes, RADIUS encapsulates it in multiple EAP-Message attributes.

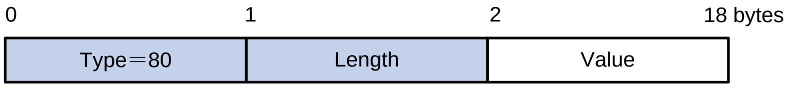
  Figure 7 EAP-Message attribute format



- Message-Authenticator.

  As shown in Figure 8, RADIUS includes the Message-Authenticator attribute in all packets that have an EAP-Message attribute to check their integrity. The packet receiver drops the packet if the calculated packet integrity checksum is different from the Message-Authenticator attribute value. The Message-Authenticator prevents EAP authentication packets from being tampered with during EAP authentication.

Figure 8 Message-Authenticator attribute format



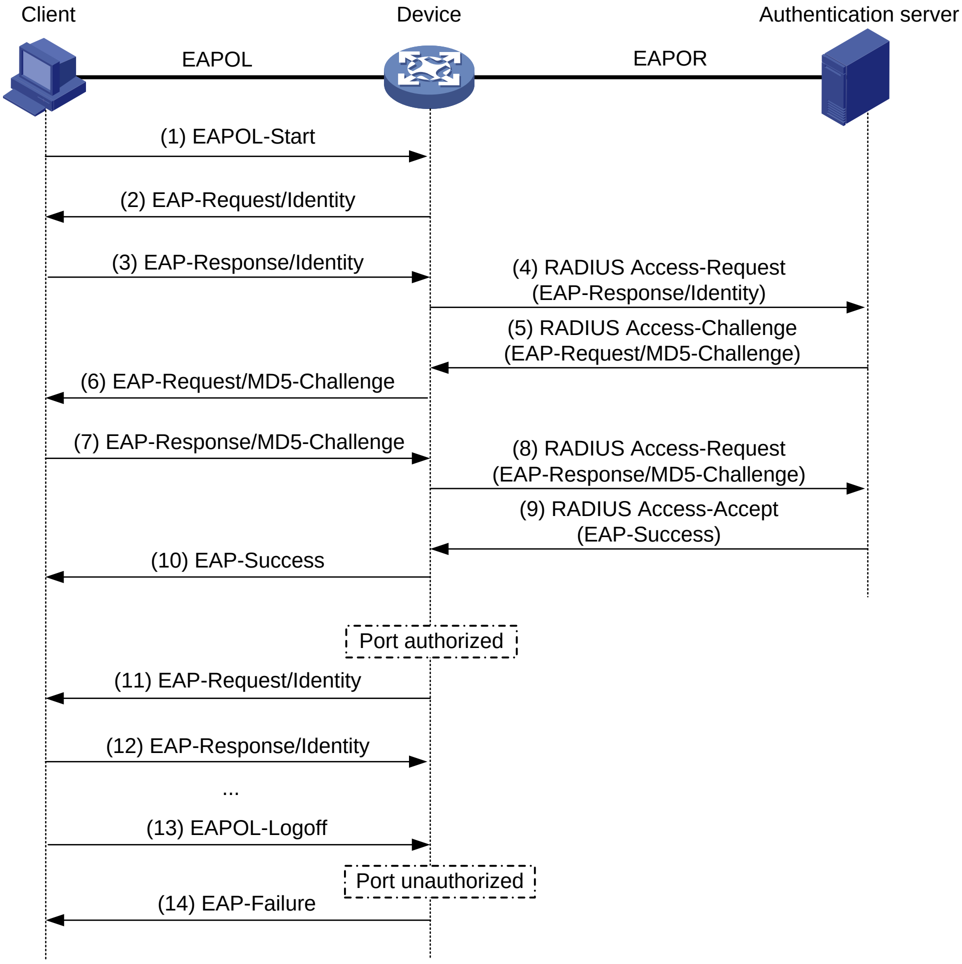
802.1X authentication procedures

802.1X authentication has two methods: EAP relay and EAP termination. You choose either mode depending on support of the RADIUS server for EAP packets and EAP authentication methods.

EAP relay

Figure 9 shows the basic 802.1X authentication procedure in EAP relay mode, assuming that MD5-Challenge EAP authentication is used.

Figure 9 802.1X authentication procedure in EAP relay mode



Client
Device
Authentication server
EAPOL
EAPOR
(1) EAPOL-Start
(2) EAP-Request/Identity
(3) EAP-Response/Identity
(4) RADIUS Access-Request (EAP-Response/Identity)
(5) RADIUS Access-Challenge (EAP-Request/MD5-Challenge)
(6) EAP-Request/MD5-Challenge
(7) EAP-Response/MD5-Challenge
(8) RADIUS Access-Request (EAP-Response/MD5-Challenge)
(9) RADIUS Access-Accept (EAP-Success)
(10) EAP-Success
Port authorized
(11) EAP-Request/Identity
(12) EAP-Response/Identity
...
(13) EAPOL-Logoff
Port unauthorized
(14) EAP-Failure

The following steps describe the 802.1X authentication procedure:

1. When a user launches the 802.1X client and enters a registered username and password, the 802.1X client sends an EAPOL-Start packet to the access device.
2. The access device responds with an EAP-Request/Identity packet to ask for the client username.
3. In response to the EAP-Request/Identity packet, the client sends the username in an EAP-Response/Identity packet to the access device.

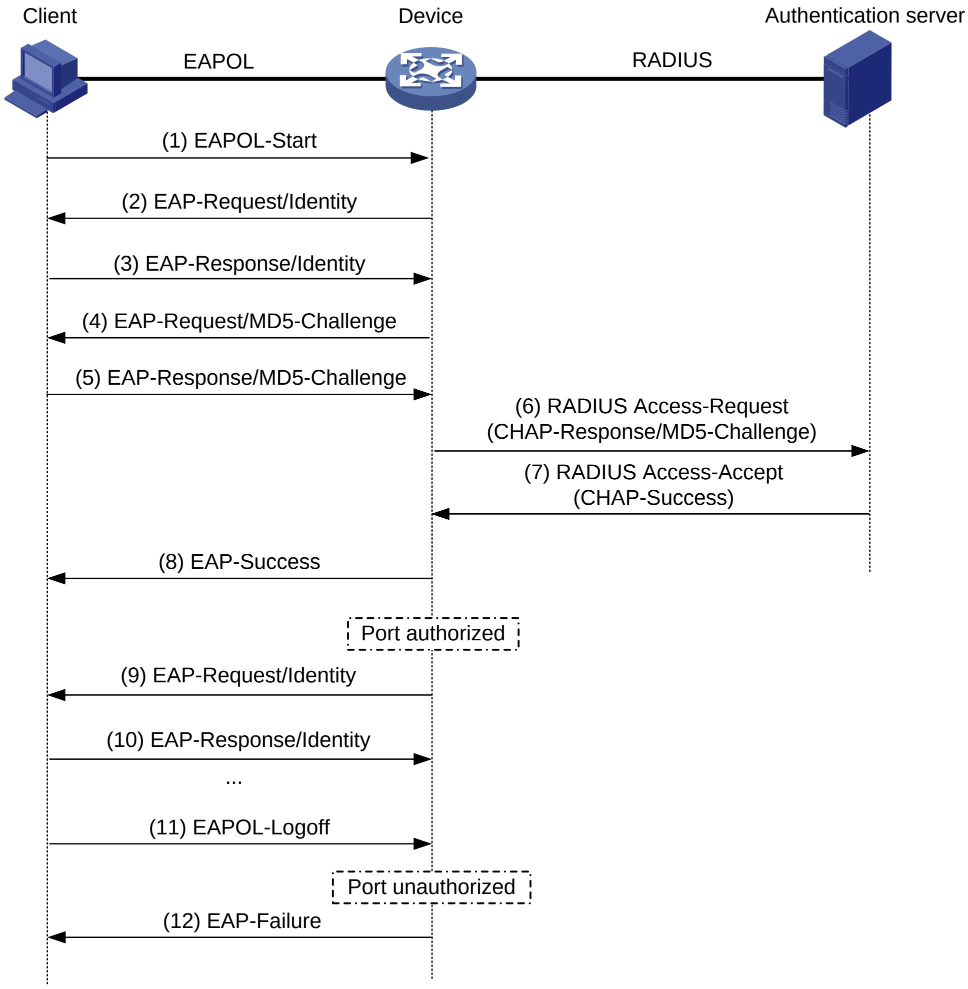
4. The access device relays the EAP-Response/Identity packet in a RADIUS Access-Request packet to the authentication server.
5. The authentication server uses the identity information in the RADIUS Access-Request to search its user database. If a matching entry is found, the server uses a randomly generated challenge (EAP-Request/MD5-Challenge) to encrypt the password in the entry. Then, the server sends the challenge in a RADIUS Access-Challenge packet to the access device.
6. The access device transmits the EAP-Request/MD5-Challenge packet to the client.
7. The client uses the received challenge to encrypt the password, and sends the encrypted password in an EAP-Response/MD5-Challenge packet to the access device.
8. The access device relays the EAP-Response/MD5-Challenge packet in a RADIUS Access-Request packet to the authentication server.
9. The authentication server compares the received encrypted password with the encrypted password it generated at step 5. If the two passwords are identical, the server considers the client valid and sends a RADIUS Access-Accept packet to the access device.
10. Upon receiving the RADIUS Access-Accept packet, the access device performs the following operations:
    a. Sends an EAP-Success packet to the client.
    b. Sets the controlled port in authorized state.

    The client can access the network.
11. After the client comes online, the access device periodically sends handshake requests to check whether the client is still online. By default, if two consecutive handshake attempts fail, the device logs off the client.
12. Upon receiving a handshake request, the client returns a response. If the client fails to return a response after a number of consecutive handshake attempts (two by default), the access device logs off the client. This handshake mechanism enables timely release of the network resources used by 802.1X users that have abnormally gone offline.
13. The client can also send an EAPOL-Logoff packet to ask the access device for a logoff.
14. In response to the EAPOL-Logoff packet, the access device changes the status of the controlled port from authorized to unauthorized. Then, the access device sends an EAP-Failure packet to the client.

EAP termination

Figure 10 shows the basic 802.1X authentication procedure in EAP termination mode, assuming that CHAP authentication is used.

Figure 10 802.1X authentication procedure in EAP termination mode



In EAP termination mode, the access device rather than the authentication server generates an MD5 challenge for password encryption. The access device then sends the MD5 challenge together with the username and encrypted password in a standard RADIUS packet to the RADIUS server.

802.1X authentication initiation

Both the 802.1X client and the access device can initiate 802.1X authentication.

802.1X client as the initiator

The client sends an EAPOL-Start packet to the access device to initiate 802.1X authentication. The destination MAC address of the packet is the IEEE 802.1X specified multicast address 01-80-C2-00-00-03 or the broadcast MAC address. If any intermediate device between the client and the authentication server does not support the multicast address, you must use an 802.1X client that can send broadcast EAPOL-Start packets. For example, you can use the iNode 802.1X client.

Access device as the initiator

If the client cannot send EAPOL-Start packets, configure the access device to initiate authentication.

The access device supports the following modes:

- **Multicast trigger mode**—The access device multicasts EAP-Request/Identity packets to initiate 802.1X authentication at the identity request interval.

- **Unicast trigger mode**—Upon receiving a frame from an unknown MAC address, the access device sends an EAP-Request/Identity packet out of the receiving port to the MAC address. The device retransmits the packet if no response has been received within the identity request timeout interval. This process continues until the maximum number of request attempts set by using the **`dot1x retry`** command is reached.

The username request timeout timer sets both the identity request interval for the multicast trigger and the identity request timeout interval for the unicast trigger.

Access control methods

NSFOCUS implements port-based access control as defined in the 802.1X protocol, and extends the protocol to support MAC-based access control.

- **Port-based access control**—Once an 802.1X user passes authentication on a port, any subsequent user can access the network through the port without authentication. When the authenticated user logs off, all other users are logged off.
- **MAC-based access control**—Each user is separately authenticated on a port. When a user logs off, no other online users are affected.

802.1X VLAN manipulation

Authorization VLAN

The authorization VLAN controls the access of an 802.1X user to authorized network resources. The device supports authorization VLANs assigned locally or by a remote server.

ⓘ **IMPORTANT:**

Only remote servers can assign tagged authorization VLANs.

Remote VLAN authorization

In remote VLAN authorization, you must configure an authorization VLAN for a user on the remote server. After the user authenticates to the server, the server assigns authorization VLAN information to the device. Then, the device assigns the user access port to the authorization VLAN as a tagged or untagged member.

The device supports assignment of the following authorization VLAN information by the remote server:

- VLAN ID.
- VLAN name, which must be the same as the VLAN description on the access device.
- A string of VLAN IDs and VLAN names.

  In the string, some VLANs are represented by their IDs, and some VLANs are represented by their names.
- VLAN group name.

  For more information about VLAN groups, see VLAN configuration in *Layer 2—LAN Switching Configuration Guide*.
- VLAN ID with a suffix of **t** or **u**.

  The **t** and **u** suffixes require the device to assign the access port to the VLAN as a tagged or untagged member, respectively. For example, **2u** indicates assigning the port to VLAN 2 as an untagged member.

If a VLAN name or VLAN group name is assigned, the device converts the information into a VLAN ID before VLAN assignment.

IMPORTANT:

For a VLAN represented by its VLAN name to be assigned successfully, you must make sure the VLAN has been created on the device.

To assign VLAN IDs with suffixes, make sure the user access port is a hybrid or trunk port that performs port-based access control.

To ensure a successful assignment, the authorization VLANs assigned by the remote server cannot be any of the following types:

- Dynamically learned VLANs.
- Reserved VLANs.

If the server assigns a group of VLANs, the access device selects a VLAN as described in Table 2.

Table 2 Authorization VLAN selection from a group of VLANs

VLAN information	Authorization VLAN selection
VLANs by IDs VLANs by names VLAN group name	If the 802.1X-enabled port performs port-based access control, the device selects the VLAN with the lowest ID from the VLAN group. All subsequent 802.1X users are assigned to that VLAN.
VLAN IDs with suffixes	**1.** The device selects the leftmost VLAN ID without a suffix, or the leftmost VLAN ID suffixed by **u** as an untagged VLAN, whichever is more leftmost. **2.** The device assigns the untagged VLAN to the port as the PVID, and it assigns the remaining as tagged VLANs. If no untagged VLAN is assigned, the PVID of the port does not change. The port permits traffic from these tagged and untagged VLANs to pass through. For example, the authentication server sends the string **1u 2t 3** to the access device for a user. The device assigns VLAN 1 as an untagged VLAN and all remaining VLANs (including VLAN 3) as tagged VLANs. VLAN 1 becomes the PVID.

Local VLAN authorization

To perform local VLAN authorization for a user, specify the VLAN ID in the authorization attribute list of the local user account for that user. For each local user, you can specify only one authorization VLAN ID. The user access port is assigned to the VLAN as an untagged member.

IMPORTANT:

Local VLAN authorization does not support assignment of tagged VLANs.

For more information about local user configuration, see "Configuring AAA."

Authorization VLAN manipulation on an 802.1X-enabled port

Table 3 describes how the access device handles VLANs (except for the VLANs specified with suffixes) on an 802.1X-enabled port.

Table 3 VLAN manipulation

Port access control method	VLAN manipulation
Port-based	The device assigns the port to the first authenticated user's authorization VLAN. All subsequent 802.1X users can access the VLAN without authentication.

Port access control method	VLAN manipulation
	If the authorization VLAN has the untagged attribute, the device assigns the port to the authorization VLAN as an untagged member and sets the VLAN as the PVID. If the authorization VLAN has the tagged attribute, the device assigns the port to the VLAN as a tagged member without changing the PVID. **NOTE:** The tagged attribute is supported only on trunk and hybrid ports.
MAC-based	On a hybrid port with MAC-based VLAN enabled, the device maps the MAC address of each user to its own authorization VLAN. The PVID of the port does not change. On an access, trunk or MAC-based VLAN disabled hybrid port: • The device assigns the port to the first authenticated user's authorization VLAN and sets the VLAN as the PVID if that authorization VLAN has the untagged attribute. • If the authorization VLAN has the tagged attribute, the device assigns the port to the authorization VLAN without changing its PVID.

IMPORTANT:

- If the users are attached to a port whose link type is access, make sure the authorization VLAN assigned by the server has the untagged attribute. VLAN assignment will fail if the server issues a VLAN that has the tagged attribute.
- When you assign VLANs to users attached to a trunk port or a MAC-based VLAN disabled hybrid port, make sure there is only one untagged VLAN. If a different untagged VLAN is assigned to a subsequent user, the user cannot pass authentication.
- As a best practice to enhance network security, do not use the **port hybrid vlan** command to assign a hybrid port to an authorization VLAN as a tagged member.

For an 802.1X authenticated user to access the network on a hybrid port when no authorization VLAN is configured for the user, perform one of the following tasks:

- If the port receives tagged authentication packets from the user in a VLAN, use the **port hybrid vlan** command to configure the port as a tagged member in the VLAN.
- If the port receives untagged authentication packets from the user in a VLAN, use the **port hybrid vlan** command to configure the port as an untagged member in the VLAN.

On a port with periodic online user reauthentication enabled, the MAC-based VLAN feature does not take effect on a user that has been online since before this feature was enabled. The access device creates a MAC-to-VLAN mapping for the user when the following requirements are met:

- The user passes reauthentication.
- The authorization VLAN for the user is changed.

For more information about VLAN configuration and MAC-based VLANs, see *Layer 2—LAN Switching Configuration Guide*.

Guest VLAN

The 802.1X guest VLAN on a port accommodates users that have not performed 802.1X authentication. Users in the guest VLAN can access a limited set of network resources, such as a software server, to download antivirus software and system patches. Once a user in the guest VLAN passes 802.1X authentication, it is removed from the guest VLAN and can access authorized network resources.

The access device handles VLANs on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

Authentication status	VLAN manipulation
A user accesses the 802.1X-enabled port when the port is in auto state.	The device assigns the port to the 802.1X guest VLAN. All 802.1X users on this port can access only resources in the guest VLAN. The guest VLAN assignment varies by port link mode. For more information, see Table 3 in "Authorization VLAN."
A user in the 802.1X guest VLAN fails 802.1X authentication.	If an 802.1X Auth-Fail VLAN is available, the device assigns the port to the Auth-Fail VLAN. All users on this port can access only resources in the Auth-Fail VLAN. If no Auth-Fail VLAN is configured, the port is still in the 802.1X guest VLAN. All users on the port are in the guest VLAN. For information about the 802.1X Auth-Fail VLAN, see "Auth-Fail VLAN."
A user in the 802.1X guest VLAN passes 802.1X authentication.	The device removes the port from the 802.1X guest VLAN and assigns the port to the authorization VLAN of the user. If the authentication server does not assign an authorization VLAN, the initial PVID of the port applies. The user and all subsequent 802.1X users are assigned to the initial port VLAN. After the user logs off, the port is assigned to the guest VLAN again. **NOTE:** The initial PVID of an 802.1X-enabled port refers to the PVID used by the port before the port is assigned to any 802.1X VLANs.

MAC-based access control

Authentication status	VLAN manipulation
A user accesses the 802.1X-enabled port and has not performed 802.1X authentication.	The device creates a mapping between the MAC address of the user and the 802.1X guest VLAN. The user can access only resources in the guest VLAN.
A user in the 802.1X guest VLAN fails 802.1X authentication.	If an 802.1X Auth-Fail VLAN is available, the device remaps the MAC address of the user to the Auth-Fail VLAN. The user can access only resources in the Auth-Fail VLAN. If no 802.1X Auth-Fail VLAN is configured, the user is removed from the guest VLAN and added to the initial PVID.
A user in the 802.1X guest VLAN passes 802.1X authentication.	The device remaps the MAC address of the user to the authorization VLAN. If the authentication server does not assign an authorization VLAN, the device remaps the MAC address of the user to the initial PVID on the port.

Auth-Fail VLAN

The 802.1X Auth-Fail VLAN on a port accommodates users that have failed 802.1X authentication because of the failure to comply with the organization security strategy. For example, the VLAN accommodates users that have entered a wrong password. Users in the Auth-Fail VLAN can access a limited set of network resources, such as a software server, to download antivirus software and system patches.

The access device handles VLANs on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

Authentication status	VLAN manipulation
A user accesses the port and fails 802.1X authentication.	The device assigns the port to the Auth-Fail VLAN. All 802.1X users on this port can access only resources in the Auth-Fail VLAN. The Auth-Fail VLAN assignment varies by port link mode. For more information, see Table 3 in "Authorization VLAN."
A user in the 802.1X Auth-Fail VLAN fails 802.1X authentication.	The port is still in the Auth-Fail VLAN, and all 802.1X users on this port are in this VLAN.
A user in the 802.1X Auth-Fail VLAN passes 802.1X authentication.	The device assigns the port to the authorization VLAN of the user, and it removes the port from the Auth-Fail VLAN. If the authentication server does not assign an authorization VLAN, the initial PVID of the port applies. The user and all subsequent 802.1X users are assigned to the initial PVID. After the user logs off, the port is assigned to the guest VLAN. If no guest VLAN is configured, the port is assigned to the initial PVID of the port.

MAC-based access control

Authentication status	VLAN manipulation
A user accesses the port and fails 802.1X authentication.	The device maps the MAC address of the user to the 802.1X Auth-Fail VLAN. The user can access only resources in the Auth-Fail VLAN.
A user in the 802.1X Auth-Fail VLAN fails 802.1X authentication.	The user is still in the Auth-Fail VLAN.
A user in the 802.1X Auth-Fail VLAN passes 802.1X authentication.	The device remaps the MAC address of the user to the authorization VLAN. If the authentication server does not assign an authorization VLAN, the device remaps the MAC address of the user to the initial PVID on the port.

Critical VLAN

The 802.1X critical VLAN on a port accommodates 802.1X users that have failed authentication because none of the RADIUS servers in their ISP domain are reachable. Users in the critical VLAN can access a limited set of network resources depending on the configuration.

The critical VLAN feature takes effect when 802.1X authentication is performed only through RADIUS servers. If an 802.1X user fails local authentication after RADIUS authentication, the user is not assigned to the critical VLAN. For more information about the authentication methods, see "Configuring AAA."

The access device handles VLANs on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

Authentication status	VLAN manipulation
A user accesses the port and fails 802.1X authentication because all the RADIUS servers are unreachable.	The device assigns the port to the critical VLAN. The 802.1X user and all subsequent 802.1X users on this port can access only resources in the 802.1X critical VLAN. The critical VLAN assignment varies by port link mode. For more information, see Table 3 in "Authorization VLAN."
A user in the 802.1X critical VLAN fails authentication because all the RADIUS servers are unreachable.	The port is still in the critical VLAN.
A user in the 802.1X critical VLAN fails authentication for any reason other than unreachable servers.	If an 802.1X Auth-Fail VLAN has been configured, the port is assigned to the Auth-Fail VLAN. If no 802.1X Auth-Fail VLAN is configured, the port is assigned to the initial PVID of the port.
A user in the 802.1X critical VLAN passes 802.1X authentication.	The device assigns the port to the authorization VLAN of the user, and it removes the port from the 802.1X critical VLAN. If the authentication server does not assign an authorization VLAN, the initial PVID of the port applies. The user and all subsequent 802.1X users are assigned to this port VLAN. After the user logs off, the port is assigned to the guest VLAN. If no 802.1X guest VLAN is configured, the initial PVID of the port is restored.
A user in the 802.1X guest VLAN fails authentication because all the RADIUS servers are unreachable.	The device assigns the port to the 802.1X critical VLAN, and all 802.1X users on this port are in this VLAN.
A user in the 802.1X Auth-Fail VLAN fails authentication because all the RADIUS servers are unreachable.	The port is still in the 802.1X Auth-Fail VLAN. All 802.1X users on this port can access only resources in the 802.1X Auth-Fail VLAN.
A user that has passed authentication fails reauthentication because all the RADIUS servers are unreachable, and the user is logged out of the device.	The device assigns the port to the 802.1X critical VLAN.

MAC-based access control

Authentication status	VLAN manipulation
A user accesses the port and fails 802.1X authentication because all the RADIUS servers are unreachable.	The device maps the MAC address of the user to the 802.1X critical VLAN. The user can access only resources in the 802.1X critical VLAN.
A user in the 802.1X critical VLAN fails authentication because all the RADIUS servers are unreachable.	The user is still in the critical VLAN.
A user in the 802.1X critical VLAN fails 802.1X authentication for any reason other than unreachable servers.	If an 802.1X Auth-Fail VLAN has been configured, the device remaps the MAC address of the user to the Auth-Fail VLAN ID. If no 802.1X Auth-Fail VLAN has been configured, the device remaps the MAC address of the user to the initial PVID.

Authentication status	VLAN manipulation
A user in the 802.1X critical VLAN passes 802.1X authentication.	The device remaps the MAC address of the user to the authorization VLAN. If the authentication server does not assign an authorization VLAN to the user, the device remaps the MAC address of the user to the initial PVID on the port.
A user in the 802.1X guest VLAN fails authentication because all the RADIUS servers are unreachable.	The device remaps the MAC address of the user to the 802.1X critical VLAN. The user can access only resources in the 802.1X critical VLAN.
A user in the 802.1X Auth-Fail VLAN fails authentication because all the RADIUS servers are unreachable.	The user remains in the 802.1X Auth-Fail VLAN.

ACL assignment

You can specify an ACL for an 802.1X user on the authentication server to control the user's access to network resources. After the user passes 802.1X authentication, the authentication server assigns the ACL to the user access port. Then, the port permits or drops the matching traffic from the user depending on the rules configured in the ACL.

The authentication server can be the local access device or a RADIUS server. In either case, the server only specifies the ACL number. You must configure the ACL and its rules on the access device.

To change the access control criteria for the user, you can use one of the following methods:

- Modify ACL rules on the access device.
- Specify another authorization ACL on the authentication server.

The supported authorization ACLs include the following types:

- Basic ACLs, which are numbered in the range of 2000 to 2999.
- Advanced ACLs, which are numbered in the range of 3000 to 3999.
- Layer 2 ACLs, which are numbered in the range of 4000 to 4999.

For an authorization ACL to take effect, make sure the ACL exists with rules and none of the rules contains the **counting**, **established**, **fragment**, **source-mac**, or **logging** keyword.

For more information about ACLs, see *ACL and QoS Command Reference*.

Periodic 802.1X reauthentication

Periodic 802.1X reauthentication tracks the connection status of online users and updates the authorization attributes (such as ACL and VLAN) assigned by the server.

The device reauthenticates online 802.1X users at the periodic reauthentication interval when the periodic online user reauthentication feature is enabled. The interval is controlled by a timer and the timer is user configurable. A change to the periodic reauthentication timer applies to online users only after the old timer expires and the users pass authentication.

The server-assigned session timeout timer (Session-Timeout attribute) and termination action (Termination-Action attribute) together can affect the periodic online user reauthentication feature. To display the server-assigned Session-Timeout and Termination-Action attributes, use the **display dot1x connection** command (see *Security Command Reference*).

- If the termination action is **Default** (logoff), periodic online user reauthentication on the device takes effect only when the periodic reauthentication timer is shorter than the session timeout timer.
- If the termination action is **Radius-request**, the periodic online user reauthentication settings on the device do not take effect. The device reauthenticates the online 802.1X users after the session timeout timer expires.

If no session timeout timer is assigned by the server, whether the device performs periodic 802.1X reauthentication depends on the periodic reauthentication configuration on the device. Support for the assignment of Session-Timeout and Termination-Action attributes depends on the server model.

By default, the device logs off online 802.1X users if no server is reachable for 802.1X reauthentication. The keep-online feature keeps authenticated 802.1X users online when no server is reachable for 802.1X reauthentication.

The VLANs assigned to an online user before and after reauthentication can be the same or different.

EAD assistant

Endpoint Admission Defense (EAD) is an NSFOCUS integrated endpoint access control solution to improve the threat defensive capability of a network. The solution enables the security client, security policy server, access device, and third-party server to operate together. If a terminal device seeks to access an EAD network, it must have an EAD client, which performs 802.1X authentication.

The EAD assistant feature enables the access device to redirect the HTTP requests of a user to a redirect URL for downloading and installing an EAD client. This feature eliminates the administrative task to deploy EAD clients.

EAD assistant is implemented by the following functionality:

- Free IP.

  A free IP is a freely accessible network segment, which has a limited set of network resources such as software and DHCP servers. To ensure security strategy compliance, an unauthenticated user can access only this segment to perform operations. For example, the user can download EAD client from a software server or obtain a dynamic IP address from a DHCP server.
- Redirect URL.

  If an unauthenticated 802.1X user is using a Web browser to access the network, EAD assistant redirects the network access requests of the user to a specific URL. For example, you can use this feature to redirect the user to the EAD client software download page.

The EAD assistant feature creates an ACL-based EAD rule automatically to open access to the redirect URL for each redirected user.

EAD rules are implemented by using ACL resources. When the EAD rule timer expires or the user passes authentication, the rule is removed. If users fail to download EAD client or fail to pass authentication before the timer expires, they must reconnect to the network to access the free IP.

SmartOn

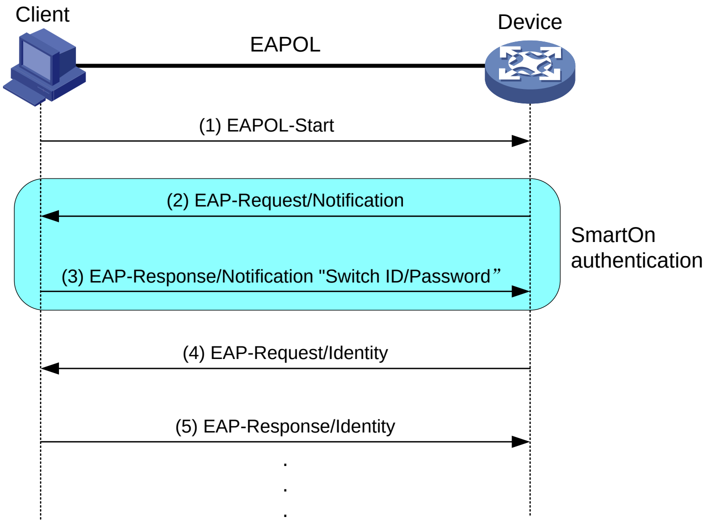
The SmartOn feature was developed to support the NEC 802.1X client.

As shown in Figure 11, the access device performs SmartOn authentication before 802.1X authentication. The following shows the authentication process:

1. When a SmartOn-enabled port receives an EAPOL-Start packet from an 802.1X client, it sends a unicast EAP-Request/Notification packet to the client for SmartOn authentication.

2. Upon receiving an EAP-Response/Notification from the client, the device compares the switch ID and password in the packet with the switch ID and password configured on the device.
   - If they are the same, 802.1X authentication can continue.
   - If they do not match, SmartOn authentication fails. The access device stops 802.1X authentication for the client.

Figure 11 802.1X authentication process with the SmartOn feature



Client
Device
EAPOL
(1) EAPOL-Start
(2) EAP-Request/Notification
(3) EAP-Response/Notification "Switch ID/Password"
SmartOn authentication
(4) EAP-Request/Identity
(5) EAP-Response/Identity

If the user attempts to use another 802.1X client for authentication, it will fail SmartOn authentication. The access device stops 802.1X authentication for the user.

NOTE:

After you install the SmartOn client software, add two values **QX_ID** and **QX_PASSWORD** to the Windows registry key [HKEY_LOCAL_MACHINE\SOFTWARE\Soliton Systems K.K.\SmartOn Client\Clients\1XGate]. Specify the switch ID and password for the QX_ID and QX_PASSWORD, respectively. The switch ID and password must be the same as the switch ID and password configured on the device.

Configuring 802.1X

Restrictions and guidelines: 802.1X configuration

Do not change the link type of a port when the 802.1X guest VLAN, Auth-Fail VLAN, or critical VLAN on the port has users.

802.1X tasks at a glance

To configure 802.1X authentication, perform the following tasks:

1. Enabling 802.1X
2. Configuring basic 802.1X features
   - Enabling EAP relay or EAP termination
   - Setting the port authorization state
   - Specifying an access control method
   - (Optional.) Specifying a mandatory authentication domain on a port
   - (Optional.) Setting the 802.1X authentication timeout timers
   - (Optional.) Configuring 802.1X reauthentication
   - (Optional.) Setting the quiet timer
3. (Optional.) Configuring 802.1X VLAN assignment
   - Configuring an 802.1X guest VLAN
   - Configuring an 802.1X Auth-Fail VLAN
   - Configuring an 802.1X critical VLAN
4. (Optional.) Configuring other 802.1X features
   - Configuring the authentication trigger feature

     Perform this task when 802.1X clients cannot initiate authentication.
   - Setting the maximum number of concurrent 802.1X users on a port
   - Setting the maximum number of authentication request attempts
   - Configuring online user handshake
   - Specifying supported domain name delimiters
   - Configuring the EAD assistant feature
   - Configuring 802.1X SmartOn

Prerequisites for 802.1X

Before you configure 802.1X, complete the following tasks:

- Configure an ISP domain and AAA scheme (local or RADIUS authentication) for 802.1X users.
- If RADIUS authentication is used, create user accounts on the RADIUS server.
- If local authentication is used, create local user accounts on the access device and set the service type to **lan-access**.

Enabling 802.1X

Restrictions and guidelines

For 802.1X to take effect on a port, you must enable it both globally and on the port.

Do not enable 802.1X on a port that is in a link aggregation group.

Procedure

1. Enter system view.

   `system-view`

2. Enable 802.1X globally.

   `dot1x`

   By default, 802.1X is disabled globally.

3. Enter interface view.

   `interface` *`interface-type interface-number`*

4. Enable 802.1X on a port.

   `dot1x`

   By default, 802.1X is disabled on a port.

Enabling EAP relay or EAP termination

About this task

Consider the following factors to select a proper EAP mode:

- Support of the RADIUS server for EAP packets.
- Authentication methods supported by the 802.1X client and the RADIUS server.

Restrictions and guidelines

- If EAP relay mode is used, the **`user-name-format`** command configured in RADIUS scheme view does not take effect. The access device sends the authentication data from the client to the server without any modification. For more information about the **`user-name-format`** command, see AAA commands in *Security Command Reference*.
- You can use both EAP termination and EAP relay in any of the following situations:
  - The client is using only MD5-Challenge EAP authentication. If EAP termination is used, you must enable CHAP authentication on the access device.
  - The client is an iNode 802.1X client and initiates only the username and password EAP authentication. If EAP termination is used, you can enable either PAP or CHAP authentication on the access device. However, for the purpose of security, you must use CHAP authentication on the access device.
- To use EAP-TLS, PEAP, or any other EAP authentication methods, you must use EAP relay. When you make your decision, see "Comparing EAP relay and EAP termination" for help.

Procedure

1. Enter system view.

   `system-view`

2. Configure EAP relay or EAP termination.

   `dot1x authentication-method` { **`chap`** | **`eap`** | **`pap`** }

   By default, the access device performs EAP termination and uses CHAP to communicate with the RADIUS server.

Setting the port authorization state

About this task

The port authorization state determines whether the client is granted access to the network. You can control the following authorization states of a port:

- **Authorized**—Places the port in the authorized state, enabling users on the port to access the network without authentication.
- **Unauthorized**—Places the port in the unauthorized state, denying any access requests from users on the port.
- **Auto**—Places the port initially in unauthorized state to allow only EAPOL packets to pass. After a user passes authentication, sets the port in the authorized state to allow access to the network. You can use this option in most scenarios.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the port authorization state.

   dot1x port-control { **authorized-force** | **auto** | **unauthorized-force** }

   By default, the **auto** state applies.

Specifying an access control method

About this task

The device supports port-based and MAC-based access control methods.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify an access control method.

   dot1x port-method { **macbased** | **portbased** }

   By default, MAC-based access control applies.

△ **CAUTION:**

If online 802.1X users are present on a port, changing its access control method will cause the online users to go offline.

Specifying a mandatory authentication domain on a port

About this task

You can place all 802.1X users in a mandatory authentication domain for authentication, authorization, and accounting on a port. No user can use an account in any other domain to access the network through the port. The implementation of a mandatory authentication domain enhances the flexibility of 802.1X access control deployment.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Specify a mandatory 802.1X authentication domain on the port.

   `dot1x mandatory-domain` *`domain-name`*

   By default, no mandatory 802.1X authentication domain is specified.

Setting the 802.1X authentication timeout timers

About this task

The network device uses the following 802.1X authentication timeout timers:

- **Client timeout timer**—Starts when the access device sends an EAP-Request/MD5-Challenge packet to a client. If no response is received when this timer expires, the access device retransmits the request to the client.
- **Server timeout timer**—Starts when the access device sends a RADIUS Access-Request packet to the authentication server. If no response is received when this timer expires, 802.1X authentication fails.

Restrictions and guidelines

In most cases, the default settings are sufficient. You can edit the timers, depending on the network conditions.

- In a low-speed network, increase the client timeout timer.
- In a network with authentication servers of different performance, adjust the server timeout timer.

Procedure

1. Enter system view.

   `system-view`

2. Set the client timeout timer.

   `dot1x timer supp-timeout` *`supp-timeout-value`*

   The default is 30 seconds.

3. Set the server timeout timer.

   `dot1x timer server-timeout` *`server-timeout-value`*

   The default is 100 seconds.

Configuring 802.1X reauthentication

Restrictions and guidelines

Any modification to the mandatory authentication domain or EAP message handling method setting does not affect the reauthentication of online 802.1X users. The modified setting takes effect only on 802.1X users that come online after the modification.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Set the periodic reauthentication timer.

   dot1x timer reauth-period *reauth-period-value*

   The default setting is 3600 seconds.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable periodic online user reauthentication.

   dot1x re-authenticate

   By default, the feature is disabled.

5. (Optional.) Enable the keep-online feature for 802.1X users.

   dot1x re-authenticate server-unreachable keep-online

   By default, this feature is disabled. The device logs off online 802.1X users if no authentication server is reachable for 802.1X reauthentication.

   Use the keep-online feature according to the actual network condition. In a fast-recovery network, you can use the keep-online feature to prevent 802.1X users from coming online and going offline frequently.

Setting the quiet timer

About this task

The quiet timer enables the access device to wait a period of time before it can process any authentication request from a client that has failed an 802.1X authentication.

Restrictions and guidelines

You can edit the quiet timer, depending on the network conditions.

- In a vulnerable network, set the quiet timer to a high value.
- In a high-performance network with quick authentication response, set the quiet timer to a low value.

Procedure

1. Enter system view.

   system-view

2. Enable the quiet timer.

   dot1x quiet-period

   By default, the timer is disabled.

3. (Optional.) Set the quiet timer.

   dot1x timer quiet-period *quiet-period-value*

   The default is 60 seconds.

Configuring an 802.1X guest VLAN

Restrictions and guidelines

- You can configure only one 802.1X guest VLAN on a port. The 802.1X guest VLANs on different ports can be different.
- Assign different IDs to the port VLAN, the voice VLAN, and the 802.1X guest VLAN on a port. The assignment makes sure the port can correctly process incoming VLAN-tagged traffic.
- On a hybrid port, the guest VLAN can only be an untagged VLAN.
- When you configure multiple security features on a port, follow the guidelines in Table 4.

Table 4 Relationships of the 802.1X guest VLAN and other security features

Feature	Relationship description	Reference
802.1X Auth-Fail VLAN on a port that performs MAC-based access control	The 802.1X Auth-Fail VLAN has a higher priority than the 802.1X guest VLAN.	See "802.1X VLAN manipulation."
Port intrusion protection actions on a port that performs MAC-based access control	The 802.1X guest VLAN feature has higher priority than the block MAC action. The 802.1X guest VLAN feature has lower priority than the shutdown port action of the port intrusion protection feature.	

Prerequisites

Before you configure an 802.1X guest VLAN, complete the following tasks:

- Create the VLAN to be specified as the 802.1X guest VLAN.
- If the 802.1X-enabled port performs MAC-based access control, perform the following operations for the port:
  - Configure the port as a hybrid port.
  - Enable MAC-based VLAN on the port. For more information about MAC-based VLANs, see *Layer 2—LAN Switching Configuration Guide*.
- If the port type is hybrid, verify that the VLAN to be specified as the guest VLAN is not in the tagged VLAN list on the port.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Configure the 802.1X guest VLAN on the port.

   `dot1x guest-vlan` *`guest-vlan-id`*

   By default, no 802.1X guest VLAN exists on a port.

Configuring an 802.1X Auth-Fail VLAN

Restrictions and guidelines

- Assign different IDs to the port VLAN, the voice VLAN, and the 802.1X Auth-Fail VLAN on a port. The assignment makes sure the port can correctly process VLAN-tagged incoming traffic.
- You can configure only one 802.1X Auth-Fail VLAN on a port. The 802.1X Auth-Fail VLANs on different ports can be different.
- On a hybrid port, the Auth-Fail VLAN can only be an untagged VLAN.
- When you configure multiple security features on a port, follow the guidelines in Table 5.

Table 5 Relationships of the 802.1X Auth-Fail VLAN with other features

Feature	Relationship description	Reference
MAC authentication guest VLAN on a port that performs MAC-based access control	The 802.1X Auth-Fail VLAN has a high priority.	See "Configuring MAC authentication."
Port intrusion protection actions on a port that performs MAC-based access control	The 802.1X Auth-Fail VLAN feature has higher priority than the block MAC action. The 802.1X Auth-Fail VLAN feature has lower priority than the shutdown port action of the port intrusion protection feature.	

Prerequisites

Before you configure an 802.1X Auth-Fail VLAN, complete the following tasks:

- Create the VLAN to be specified as the 802.1X Auth-Fail VLAN.
- If the 802.1X-enabled port performs MAC-based access control, perform the following operations for the port:
  - Configure the port as a hybrid port.
  - Enable MAC-based VLAN on the port. For more information about MAC-based VLANs, see *Layer 2—LAN Switching Configuration Guide*.
- If the port type is hybrid, verify that the VLAN to be specified as the Auth-Fail VLAN is not in the tagged VLAN list on the port.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter interface view.

   ```
   interface interface-type interface-number
   ```

3. Configure the 802.1X Auth-Fail VLAN on the port.

   ```
   dot1x auth-fail vlan authfail-vlan-id
   ```

   By default, no 802.1X Auth-Fail VLAN exists on a port.

Configuring an 802.1X critical VLAN

Restrictions and guidelines for 802.1X critical VLAN configuration

- Assign different IDs to the PVID, the voice VLAN, and the 802.1X critical VLAN on a port. The assignment makes sure the port can correctly process VLAN-tagged incoming traffic.
- You can configure only one 802.1X critical VLAN on a port. The 802.1X critical VLANs on different ports can be different.
- On a hybrid port, the critical VLAN can only be an untagged VLAN.

Prerequisites

Before you configure an 802.1X critical VLAN, complete the following tasks:

- Create the VLAN to be specified as a critical VLAN.
- If the 802.1X-enabled port performs MAC-based access control, perform the following operations for the port:
  - Configure the port as a hybrid port.
  - Enable MAC-based VLAN on the port. For more information about MAC-based VLANs, see *Layer 2—LAN Switching Configuration Guide*.
- If the port type is hybrid, verify that the VLAN to be specified as the critical VLAN is not in the tagged VLAN list on the port.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the 802.1X critical VLAN on the port.

   dot1x critical vlan *critical-vlan-id*

   By default, no 802.1X critical VLAN exists on a port.

Configuring the authentication trigger feature

About this task

The authentication trigger feature enables the access device to initiate 802.1X authentication when 802.1X clients cannot initiate authentication.

This feature provides the multicast trigger and unicast trigger (see 802.1X authentication initiation in "802.1X overview").

Restrictions and guidelines

- Enable the multicast trigger on a port when the clients attached to the port cannot send EAPOL-Start packets to initiate 802.1X authentication.
- Enable the unicast trigger on a port if only a few 802.1X clients are attached to the port and these clients cannot initiate authentication.
- To avoid duplicate authentication packets, do not enable both triggers on a port.
- As a best practice, do not use the unicast trigger on a port that performs port-based access control. If you do so, users on that port might fail to come online.

Procedure

1. Enter system view.

system-view

2. (Optional.) Set the username request timeout timer.

   dot1x timer tx-period *tx-period-value*

   The default is 30 seconds.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable an authentication trigger.

   dot1x { **multicast-trigger** | **unicast-trigger** }

   By default, the multicast trigger is enabled, and the unicast trigger is disabled.

Setting the maximum number of concurrent 802.1X users on a port

About this task

Perform this task to prevent the system resources from being overused.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the maximum number of concurrent 802.1X users on a port.

   dot1x max-user *max-number*

   The default is 4294967295.

Setting the maximum number of authentication request attempts

About this task

The access device retransmits an authentication request if it does not receive any responses to the request from the client within a period of time. To set the time, use the **dot1x timer tx-period** *tx-period-value* command or the **dot1x timer supp-timeout** *supp-timeout-value* command. The access device stops retransmitting the request if it has made the maximum number of request transmission attempts but still receives no response.

Procedure

1. Enter system view.

   system-view

2. Set the maximum number of attempts for sending an authentication request.

   dot1x retry *retries*

   The default setting is 2.

Configuring online user handshake

About this task

The online user handshake feature checks the connectivity status of online 802.1X users. The access device sends handshake requests (EAP-Request/Identity) to online users at the interval specified by the **dot1x timer handshake-period** command. If the device does not receive any EAP-Response/Identity packets from an online user after it has made the maximum handshake attempts, the device sets the user to offline state. To set the maximum handshake attempts, use the **dot1x retry** command.

Typically, the device does not reply to 802.1X clients' EAP-Response/Identity packets with EAP-Success packets. Some 802.1X clients will go offline if they do not receive the EAP-Success packets for handshake. To avoid this issue, enable the online user handshake reply feature.

If iNode clients are deployed, you can also enable the online user handshake security feature to check authentication information in the handshake packets from clients. This feature can prevent 802.1X users that use illegal client software from bypassing iNode security check, such as dual network interface cards (NICs) detection. If a user fails the handshake security checking, the device sets the user to the offline state.

Restrictions and guidelines

- If the network has 802.1X clients that cannot exchange handshake packets with the access device, disable the online user handshake feature. This operation prevents the 802.1X connections from being incorrectly torn down.
- The SmartOn feature and the online user handshake feature are mutually exclusive. Before you enable the online user handshake feature, make sure the SmartOn feature is disabled.
- To use the online user handshake security feature, make sure the online user handshake feature is enabled.
- The online user handshake security feature takes effect only on the network where the iNode client and IMC server are used.
- Enable the online user handshake reply feature only if 802.1X clients will go offline without receiving EAP-Success packets from the device.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Set the handshake timer.

   dot1x timer handshake-period *handshake-period-value*

   The default is 15 seconds.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable the online user handshake feature.

   dot1x handshake

   By default, the feature is enabled.

5. (Optional.) Enable the online user handshake security feature.

   dot1x handshake secure

   By default, the feature is disabled.

6. (Optional.) Enable the 802.1X online user handshake reply feature.

   dot1x handshake reply enable

By default, the device does not reply to 802.1X clients' EAP-Response/Identity packets during the online handshake process.

Specifying supported domain name delimiters

About this task

By default, the access device supports the at sign (@) as the delimiter. You can also configure the access device to accommodate 802.1X users that use other domain name delimiters. The configurable delimiters include the at sign (@), backslash (\), dot (.), and forward slash (/). Usernames that include domain names can use the format of *username@domain-name, domain-name\username*, *username.domain-name*, or *username/domain-name*.

If an 802.1X username string contains multiple configured delimiters, the rightmost delimiter is the domain name delimiter. For example, if you configure the backslash (\), dot (.), and forward slash (/) as delimiters, the domain name delimiter for the username string 121.123/22\@abc is the backslash (\). The username is **@abc** and the domain name is **121.123/22**.

Restrictions and guidelines

If a username string contains none of the delimiters, the access device authenticates the user in the mandatory or default ISP domain.

If you configure the access device to send usernames with domain names to the RADIUS server, make sure the domain delimiter can be recognized by the RADIUS server. For username format configuration, see the **`user-name-format`** command in *Security Command Reference*.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Specify a set of domain name delimiters for 802.1X users.

   ```
   dot1x domain-delimiter string
   ```

   By default, only the at sign (@) delimiter is supported.

Configuring the EAD assistant feature

Restrictions and guidelines

- To make the EAD assistant feature take effect on an 802.1X-enabled port, you must set the port authorization mode to **auto**.
- For the 802.1X guest VLAN feature to work correctly, do not enable EAD assistant together with the 802.1X guest VLAN feature.
- If you use free IP and Auth-Fail VLAN features together, make sure the resources in the Auth-Fail VLAN are on the free IP segments.
- To allow a user to obtain a dynamic IP address before it passes 802.1X authentication, make sure the DHCP server is on the free IP segment.
- The server that provides the redirect URL must be on the free IP accessible to unauthenticated users.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable the EAD assistant feature.

   ```
   dot1x ead-assistant enable
   ```

By default, this feature is disabled.

3. Configure a free IP.

   dot1x ead-assistant free-ip *ip-address* { *mask-length* | *mask-address* }

   By default, no free IPs exist.

   Repeat this command to configure multiple free IPs.

4. (Optional.) Configure the redirect URL if users will use Web browsers to access the network.

   dot1x ead-assistant url *url-string*

   By default, no redirect URL exists.

5. (Optional.) Set the EAD rule timer.

   dot1x timer ead-timeout *ead-timeout-value*

   The default setting is 30 minutes.

   To avoid using up ACL resources when a large number of EAD users exist, you can shorten the EAD rule timer.

Configuring 802.1X SmartOn

About this task

When the device sends a unicast EAP-Request/Notification packet to the client, it starts the SmartOn client timeout timer (set by using the **dot1x smarton timer supp-timeout** command).

- If the device does not receive any EAP-Response/Notification packets from the client within the timeout timer, it retransmits the EAP-Request/Notification packet to the client. After the device has made the maximum retransmission attempts but received no response, it stops the 802.1X authentication process for the client.
- If the device receives an EAP-Response/Notification packet within the timer or before the maximum retransmission attempts have been made, it starts the SmartOn authentication. If the SmartOn switch ID and the MD5 digest of the SmartOn password in the packet match those on the device, 802.1X authentication continues for the client. Otherwise, the device denies the client's 802.1X authentication request.

Restrictions and guidelines

The SmartOn feature is mutually exclusive with the 802.1X online user handshake feature.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the SmartOn feature on the port.

   dot1x smarton

   By default, this feature is disabled.

4. Return to system view.

   quit

5. Configure the SmartOn switch ID.

   dot1x smarton switchid *switch-string*

   By default, no SmartOn switch ID exists.

6. Set the SmartOn password.

   dot1x smarton password { **cipher** | **simple** } *string*

By default, no SmartOn password exists.

7. (Optional.) Set the SmartOn client timeout timer.

   dot1x smarton timer supp-timeout *supp-timeout-value*

   The default timer is 30 seconds.

8. (Optional.) Set the maximum attempts for retransmitting an EAP-Request/Notification packet to a client.

   dot1x smarton retry *retries*

   By default, the device allows a maximum of 3 attempts for retransmitting an EAP-Request/Notification packet to a client.

Display and maintenance commands for 802.1X

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display 802.1X session information, statistics, or configuration information of specified or all ports.	**display dot1x** [**sessions** | **statistics**] [**interface** *interface-type interface-number*]
Display online 802.1X user information.	**display dot1x connection** [**interface** *interface-type interface-number* | **slot** *slot-number* | **user-mac** *mac-address* | **user-name** *name-string*]
Remove users from the 802.1X guest VLAN on a port.	**reset dot1x guest-vlan interface** *interface-type interface-number* [**mac-address** *mac-address*]
Clear 802.1X statistics.	**reset dot1x statistics** [**interface** *interface-type interface-number*]

802.1X authentication configuration examples

Example: Configuring basic 802.1X authentication

Network configuration

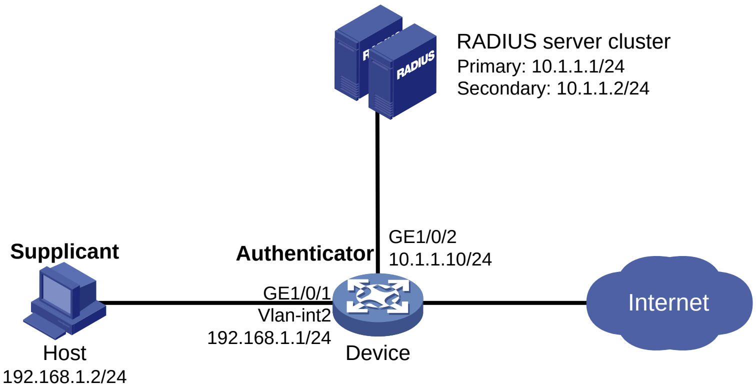
As shown in Figure 12, the access device performs 802.1X authentication for users that connect to GigabitEthernet 1/0/1. Implement MAC-based access control on the port, so the logoff of one user does not affect other online 802.1X users.

Use RADIUS servers to perform authentication, authorization, and accounting for the 802.1X users. If RADIUS authentication fails, perform local authentication on the access device.

Configure the RADIUS server at 10.1.1.1/24 as the primary authentication and accounting server, and the RADIUS server at 10.1.1.2/24 as the secondary authentication and accounting server. Assign all users to ISP domain **bbb**.

Set the shared key to **name** for packets between the access device and the authentication server. Set the shared key to **money** for packets between the access device and the accounting server.

Figure 12 Network diagram



Procedure

For information about the RADIUS commands used on the access device in this example, see *Security Command Reference*.

1. Configure the RADIUS servers and add user accounts for the 802.1X users. Make sure the RADIUS servers can provide authentication, authorization, and accounting services. (Details not shown.)
2. Configure IP addresses for interfaces, as shown in Figure 12. (Details not shown.)
3. Configure user accounts for the 802.1X users on the access device:

   # Add a local network access user with username **localuser** and password **123456TESTplat&!** in plaintext. (Make sure the username and password are the same as those configured on the RADIUS servers.)

   ```
   <Device> system-view
   [Device] local-user localuser class network
   [Device-luser-network-localuser] password simple 123456TESTplat&!
   ```

   # Set the service type to **lan-access**.

   ```
   [Device-luser-network-localuser] service-type lan-access
   [Device-luser-network-localuser] quit
   ```

4. Configure a RADIUS scheme on the access device:

   # Create a RADIUS scheme named **radius1** and enter RADIUS scheme view.

   ```
   [Device] radius scheme radius1
   ```

   # Specify the IP addresses of the primary authentication and accounting RADIUS servers.

   ```
   [Device-radius-radius1] primary authentication 10.1.1.1
   [Device-radius-radius1] primary accounting 10.1.1.1
   ```

   # Configure the IP addresses of the secondary authentication and accounting RADIUS servers.

   ```
   [Device-radius-radius1] secondary authentication 10.1.1.2
   [Device-radius-radius1] secondary accounting 10.1.1.2
   ```

   # Specify the shared key between the access device and the authentication server.

   ```
   [Device-radius-radius1] key authentication simple name
   ```

# Specify the shared key between the access device and the accounting server.

```
[Device-radius-radius1] key accounting simple money
```

# Exclude the ISP domain names from the usernames sent to the RADIUS servers.

```
[Device-radius-radius1] user-name-format without-domain
[Device-radius-radius1] quit
```

NOTE:

The access device must use the same username format as the RADIUS server. If the RADIUS server includes the ISP domain name in the username, so must the access device.

5. Configure the ISP domain on the access device:

   # Create an ISP domain named **bbb** and enter ISP domain view.

   ```
   [Device] domain bbb
   ```

   # Apply RADIUS scheme **radius1** to the ISP domain, and specify local authentication as the secondary authentication method.

   ```
   [Device-isp-bbb] authentication lan-access radius-scheme radius1 local
   [Device-isp-bbb] authorization lan-access radius-scheme radius1 local
   [Device-isp-bbb] accounting lan-access radius-scheme radius1 local
   [Device-isp-bbb] quit
   ```

6. Configure 802.1X on the access device:

   # Enable 802.1X on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] dot1x
   ```

   # Enable MAC-based access control on the port. By default, the port uses MAC-based access control.

   ```
   [Device-GigabitEthernet1/0/1] dot1x port-method macbased
   ```

   # Specify ISP domain **bbb** as the mandatory domain.

   ```
   [Device-GigabitEthernet1/0/1] dot1x mandatory-domain bbb
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Enable 802.1X globally.

   ```
   [Device] dot1x
   ```

7. Configure the 802.1X client. If an iNode client is used, do not select the **Carry version info** option in the client configuration. (Details not shown.)

Verifying the configuration

# Verify the 802.1X configuration on GigabitEthernet 1/0/1.

```
[Device] display dot1x interface gigabitethernet 1/0/1
```

# Display the user connection information after an 802.1X user passes authentication.

```
[Device] display dot1x connection
```

Example: Configuring 802.1X guest VLAN and authorization VLAN

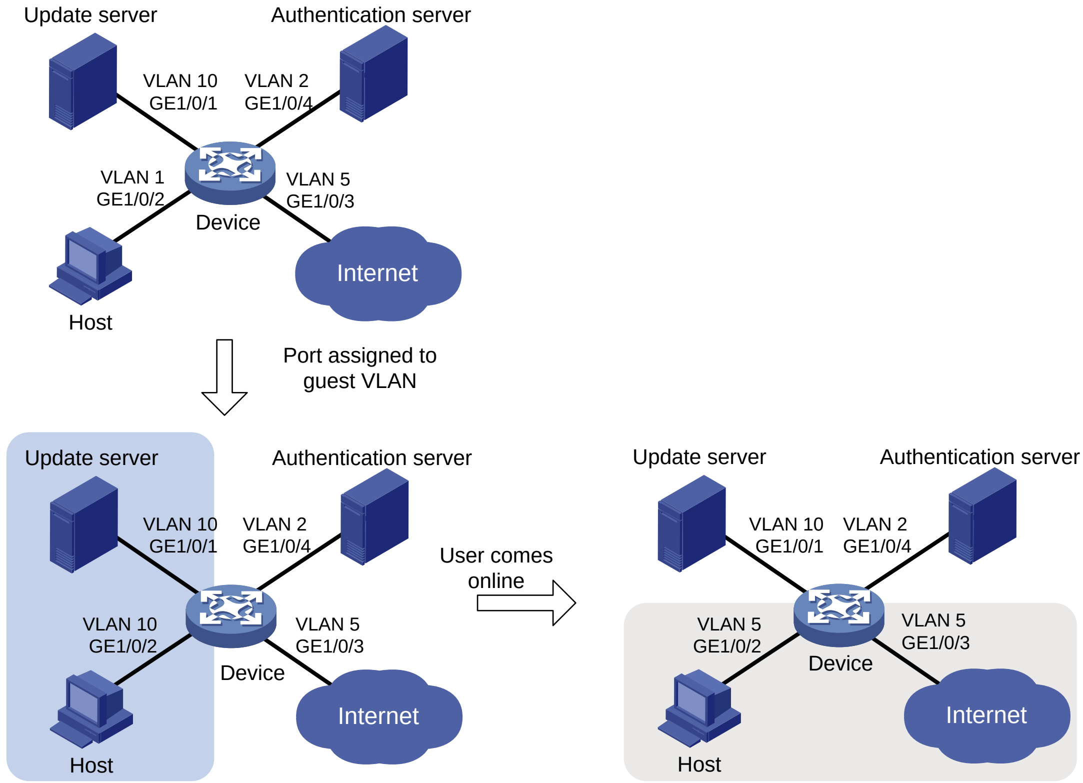
Network configuration

As shown in Figure 13:

- Use RADIUS servers to perform authentication, authorization, and accounting for 802.1X users that connect to GigabitEthernet 1/0/2. Implement port-based access control on the port.

- Configure VLAN 10 as the 802.1X guest VLAN on GigabitEthernet 1/0/2. The host and the update server are both in VLAN 10, and the host can access the update server and download the 802.1X client software.
- Configure a QoS policy to deny packets destined for the Internet (5.1.1.1) and apply the QoS policy to the outbound direction of VLAN 10. The configuration prevents users in the 802.1X guest VLAN from accessing the Internet before they pass 802.1X authentication.
- After the host passes 802.1X authentication, the access device assigns the host to VLAN 5 where GigabitEthernet 1/0/3 is. The host can access the Internet.

Figure 13 Network diagram



Procedure

For information about the RADIUS commands used on the access device in this example, see *Security Command Reference*.

1. Configure the RADIUS server to provide authentication, authorization, and accounting services. Configure user accounts and authorization VLAN (VLAN 5 in this example) for the users. (Details not shown.)
2. Create VLANs, and assign ports to the VLANs on the access device.

NOTE:

By default, VLAN 1 exists and all ports belong to the VLAN. You do not need to create the VLAN or assign GigabitEthernet 1/0/2 to the VLAN.

```
<Device> system-view
[Device] vlan 10
[Device-vlan10] port gigabitethernet 1/0/1
[Device-vlan10] quit
[Device] vlan 2
[Device-vlan2] port gigabitethernet 1/0/4
```

```
[Device-vlan2] quit
[Device] vlan 5
[Device-vlan5] port gigabitethernet 1/0/3
[Device-vlan5] quit
```

3. Configure a QoS policy:

   # Configure advanced ACL 3000 to match packets destined for 5.1.1.1.

   ```
   [Device] acl advanced 3000
   [Device-acl-ipv4-adv-3000] rule permit ip destination 5.1.1.1 0.0.0.255
   [Device-acl-ipv4-adv-3000] quit
   ```

   # Specify advanced ACL 3000 in traffic class **classifier_1** to match traffic.

   ```
   [Device] traffic classifier classifier_1
   [Device-classifier-classifier_1] if-match acl 3000
   [Device-classifier-classifier_1] quit
   ```

   # Configure traffic behavior **behavior_1** to deny matching packets.

   ```
   [Device] traffic behavior behavior_1
   [Device-behavior-behavior_1] filter deny
   [Device-behavior-behavior_1] quit
   ```

   # Configure QoS policy **policy_1** to associate traffic class **classifier_1** with traffic behavior **behavior_1**.

   ```
   [Device] qos policy policy_1
   [Device-qospolicy-policy_1] classifier classifier_1 behavior behavior_1
   [Device-qospolicy-policy_1] quit
   ```

   # Apply QoS policy **policy_1** to the outbound direction of VLAN 10.

   ```
   [Device] qos vlan-policy policy_1 vlan 10 outbound
   ```

4. Configure a RADIUS scheme on the access device:

   # Create RADIUS scheme **2000** and enter RADIUS scheme view.

   ```
   [Device] radius scheme 2000
   ```

   # Specify the server at 10.11.1.1 as the primary authentication server, and set the authentication port to 1812.

   ```
   [Device-radius-2000] primary authentication 10.11.1.1 1812
   ```

   # Specify the server at 10.11.1.1 as the primary accounting server, and set the accounting port to 1813.

   ```
   [Device-radius-2000] primary accounting 10.11.1.1 1813
   ```

   # Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

   ```
   [Device-radius-2000] key authentication simple abc
   ```

   # Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

   ```
   [Device-radius-2000] key accounting simple abc
   ```

   # Exclude the ISP domain names from the usernames sent to the RADIUS server.

   ```
   [Device-radius-2000] user-name-format without-domain
   [Device-radius-2000] quit
   ```

5. Configure an ISP domain on the access device:

   # Create ISP domain **bbb** and enter ISP domain view.

   ```
   [Device] domain bbb
   ```

   # Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

   ```
   [Device-isp-bbb] authentication lan-access radius-scheme 2000
   ```

```
[Device-isp-bbb] authorization lan-access radius-scheme 2000
[Device-isp-bbb] accounting lan-access radius-scheme 2000
[Device-isp-bbb] quit
```

6. Configure 802.1X on the access device:

   # Enable 802.1X on GigabitEthernet 1/0/2.

   ```
   [Device] interface gigabitethernet 1/0/2
   [Device-GigabitEthernet1/0/2] dot1x
   ```

   # Implement port-based access control on the port.

   ```
   [Device-GigabitEthernet1/0/2] dot1x port-method portbased
   ```

   # Set the port authorization mode to **auto**. By default, the port uses the auto mode.

   ```
   [Device-GigabitEthernet1/0/2] dot1x port-control auto
   ```

   # Specify VLAN 10 as the 802.1X guest VLAN on GigabitEthernet 1/0/2.

   ```
   [Device-GigabitEthernet1/0/2] dot1x guest-vlan 10
   [Device-GigabitEthernet1/0/2] quit
   ```

   # Enable 802.1X globally.

   ```
   [Device] dot1x
   ```

7. Configure the 802.1X client. Make sure the 802.1X client can update its IP address after the access port is assigned to the guest VLAN or an authorization VLAN. (Details not shown.)

Verifying the configuration

# Verify the 802.1X guest VLAN configuration on GigabitEthernet 1/0/2.

```
[Device] display dot1x interface gigabitethernet 1/0/2
```

# Verify that GigabitEthernet 1/0/2 is assigned to VLAN 10 before any user passes authentication on the port.

```
[Device] display vlan 10
```

# After a user passes authentication, display information on GigabitEthernet 1/0/2. Verify that GigabitEthernet 1/0/2 is assigned to VLAN 5.

```
[Device] display interface gigabitethernet 1/0/2
```

Example: Configuring 802.1X with ACL assignment

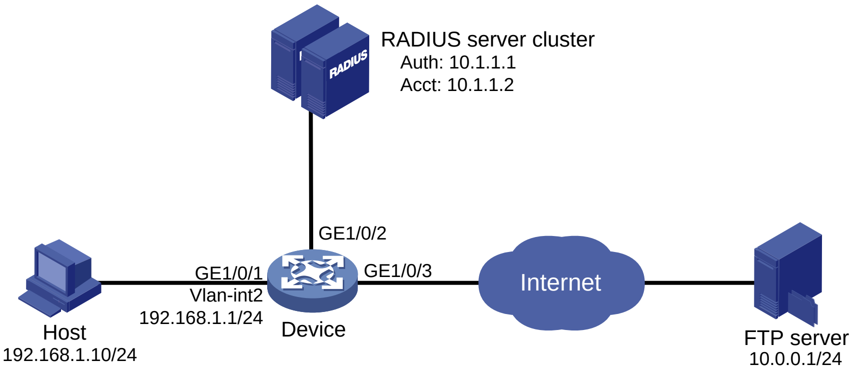
Network configuration

As shown in Figure 14, the host that connects to GigabitEthernet 1/0/1 must pass 802.1X authentication to access the Internet.

Perform 802.1X authentication on GigabitEthernet 1/0/1. Use the RADIUS server at 10.1.1.1 as the authentication and authorization server, and the RADIUS server at 10.1.1.2 as the accounting server.

Configure ACL assignment on GigabitEthernet 1/0/1 to deny access of 802.1X users to the FTP server from 8:00 to 18:00 on weekdays.

Figure 14 Network diagram



Procedure

For information about the RADIUS commands used on the access device in this example, see *Security Command Reference*.

1. Configure the RADIUS servers to provide authentication, authorization, and accounting services. Add user accounts and specify the ACL (ACL 3000 in this example) for the users. (Details not shown.)
2. Configure IP addresses for interfaces, as shown in Figure 14. (Details not shown.)
3. Configure a RADIUS scheme on the access device:

# Create RADIUS scheme **2000** and enter RADIUS scheme view.

```
<Device> system-view
[Device] radius scheme 2000
```

# Specify the server at 10.1.1.1 as the primary authentication server, and set the authentication port to 1812.

```
[Device-radius-2000] primary authentication 10.1.1.1 1812
```

# Specify the server at 10.1.1.2 as the primary accounting server, and set the accounting port to 1813.

```
[Device-radius-2000] primary accounting 10.1.1.2 1813
```

# Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

```
[Device-radius-2000] key authentication simple abc
```

# Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

```
[Device-radius-2000] key accounting simple abc
```

# Exclude the ISP domain names from the usernames sent to the RADIUS server.

```
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

4. Configure an ISP domain on the access device:

# Create ISP domain **bbb** and enter ISP domain view.

```
[Device] domain bbb
```

# Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

```
[Device-isp-bbb] authentication lan-access radius-scheme 2000
[Device-isp-bbb] authorization lan-access radius-scheme 2000
[Device-isp-bbb] accounting lan-access radius-scheme 2000
[Device-isp-bbb] quit
```

5. Configure a time range named **ftp** from 8:00 to 18:00 on weekdays on the access device.

   ```
   [Device] time-range ftp 8:00 to 18:00 working-day
   ```

6. Configure ACL 3000 to deny packets destined for the FTP server at 10.0.0.1 during the specified time range on the access device.

   ```
   [Device] acl advanced 3000
   [Device-acl-ipv4-adv-3000] rule 0 deny ip destination 10.0.0.1 0 time-range ftp
   [Device-acl-ipv4-adv-3000] quit
   ```

7. Configure 802.1X on the access device:

   # Enable 802.1X on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] dot1x
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Enable 802.1X globally.

   ```
   [Device] dot1x
   ```

8. Configure the 802.1X client. Make sure the client is able to update its IP address after the access port is assigned to the 802.1X guest VLAN or an authorization VLAN. (Details not shown.)

Verifying the configuration

# Use the user account to pass authentication. (Details not shown.)

# Verify that the user cannot ping the FTP server at any time from 8:00 to 18:00 on any weekday.

```
C:\>ping 10.0.0.1

Pinging 10.0.0.1 with 32 bytes of data:

Request timed out.
Request timed out.
Request timed out.
Request timed out.

Ping statistics for 10.0.0.1:
    Packets: Sent = 4, Received = 0, Lost = 4 (100% loss),
```

The output shows that ACL 3000 is active on the user, and the user cannot access the FTP server.

Example: Configuring 802.1X with EAD assistant (with DHCP relay agent)

Network configuration

As shown in Figure 15:

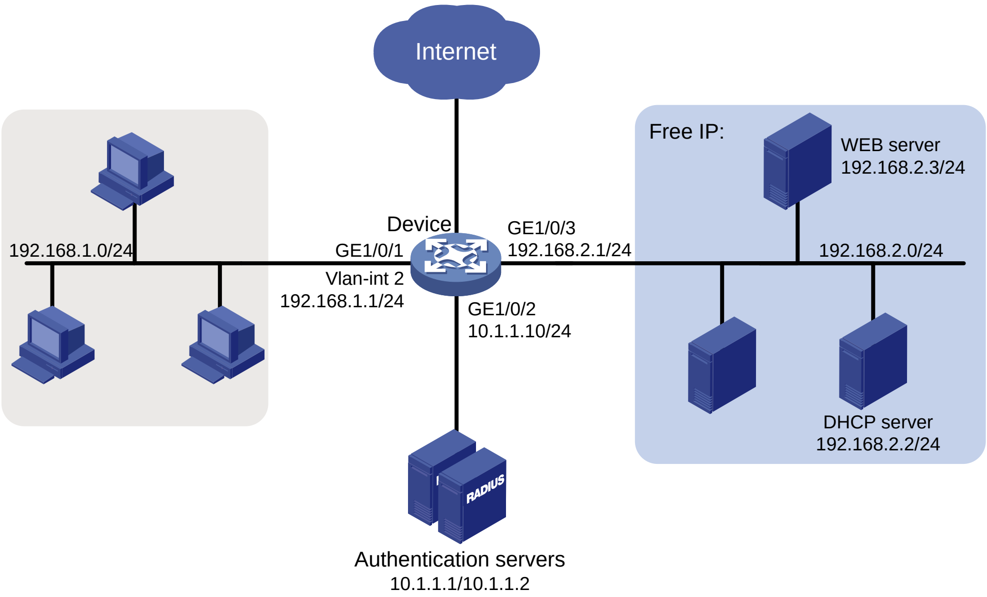
- The intranet 192.168.1.0/24 is attached to GigabitEthernet 1/0/1 of the access device.
- The hosts use DHCP to obtain IP addresses.
- A DHCP server and a Web server are deployed on the 192.168.2.0/24 subnet for users to obtain IP addresses and download client software.

Deploy an EAD solution for the intranet to meet the following requirements:

- Allow unauthenticated users and users that have failed 802.1X authentication to access 192.168.2.0/24. The users can obtain IP addresses and download software.

- If these users use a Web browser to access a network other than 192.168.2.0/24, redirect them to the Web server for 802.1X client downloading.
- Allow authenticated 802.1X users to access the network.

Figure 15 Network diagram



Procedure

1. Make sure the DHCP server, the Web server, and the authentication servers have been configured correctly. (Details not shown.)
2. Configure IP addresses for interfaces, as shown in Figure 15. (Details not shown.)
3. Configure DHCP relay:

   # Enable DHCP.

   ```
   <Device> system-view
   [Device] dhcp enable
   ```

   # Enable the DHCP relay agent on VLAN-interface 2.

   ```
   [Device] interface vlan-interface 2
   [Device-Vlan-interface2] dhcp select relay
   ```

   # Specify the DHCP server 192.168.2.2 on the relay agent interface VLAN-interface 2.

   ```
   [Device-Vlan-interface2] dhcp relay server-address 192.168.2.2
   [Device-Vlan-interface2] quit
   ```

4. Configure a RADIUS scheme:

   # Create RADIUS scheme **2000** and enter RADIUS scheme view.

   ```
   [Device] radius scheme 2000
   ```

   # Specify the server at 10.1.1.1 as the primary authentication server, and set the authentication port to 1812.

   ```
   [Device-radius-2000] primary authentication 10.1.1.1 1812
   ```

   # Specify the server at 10.1.1.2 as the primary accounting server, and set the accounting port to 1813.

   ```
   [Device-radius-2000] primary accounting 10.1.1.2 1813
   ```

   # Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

   ```
   [Device-radius-2000] key authentication simple abc
   ```

# Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

```
[Device-radius-2000] key accounting simple abc
```

# Exclude the ISP domain names from the usernames sent to the RADIUS server.

```
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

5. Configure an ISP domain:

   # Create ISP domain **bbb** and enter ISP domain view.

   ```
   [Device] domain bbb
   ```

   # Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

   ```
   [Device-isp-bbb] authentication lan-access radius-scheme 2000
   [Device-isp-bbb] authorization lan-access radius-scheme 2000
   [Device-isp-bbb] accounting lan-access radius-scheme 2000
   [Device-isp-bbb] quit
   ```

6. Configure 802.1X:

   # Configure the free IP.

   ```
   [Device] dot1x ead-assistant free-ip 192.168.2.0 24
   ```

   # Configure the redirect URL for client software download.

   ```
   [Device] dot1x ead-assistant url http://192.168.2.3
   ```

   # Enable the EAD assistant feature.

   ```
   [Device] dot1x ead-assistant enable
   ```

   # Enable 802.1X on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] dot1x
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Enable 802.1X globally.

   ```
   [Device] dot1x
   ```

Verifying the configuration

# Verify the 802.1X configuration.

```
[Device] display dot1x
```

# Verify that you can ping an IP address on the free IP subnet from a host. (Details not shown.)

# Verify that you are redirected to the Web server when you enter in your Web browser an IP address not on the free IP. (Details not shown.)

Example: Configuring 802.1X with EAD assistant (with DHCP server)

Network configuration

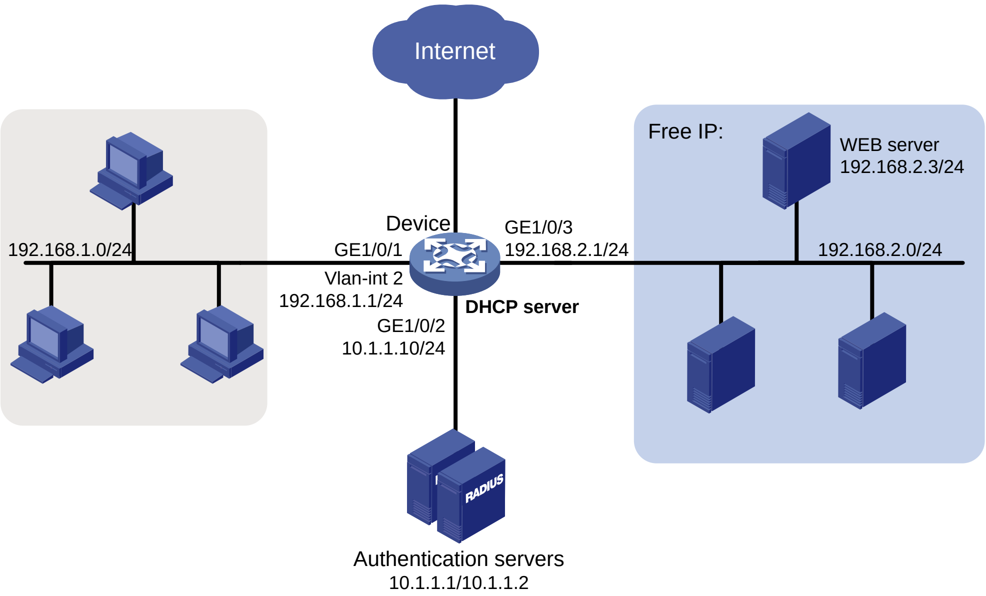
As shown in Figure 16:

- The intranet 192.168.1.0/24 is attached to GigabitEthernet 1/0/1 of the access device.
- The hosts use DHCP to obtain IP addresses.
- A Web server is deployed on the 192.168.2.0/24 subnet for users to download client software.

Deploy an EAD solution for the intranet to meet the following requirements:

- Allow unauthenticated users and users that have failed 802.1X authentication to access 192.168.2.0/24. The users can download software.
- If these users use a Web browser to access a network other than 192.168.2.0/24, redirect them to the Web server for 802.1X client downloading.
- Allow authenticated 802.1X users to access the network.

Figure 16 Network diagram



Procedure

1. Make sure the Web server and the authentication servers have been configured correctly. (Details not shown.)
2. Configure IP addresses for interfaces, as shown in Figure 16. (Details not shown.)
3. Configure the DHCP server:

   # Enable DHCP.

```
<Device> system-view
[Device] dhcp enable
```

   # Enable the DHCP server on VLAN-interface 2.

```
[Device] interface vlan-interface 2
[Device-Vlan-interface2] dhcp select server
[Device-Vlan-interface2] quit
```

   # Create DHCP address pool **0**.

```
[Device] dhcp server ip-pool 0
```

   # Specify subnet 192.168.1.0/24 in DHCP address pool 0.

```
[Device-dhcp-pool-0] network 192.168.1.0 mask 255.255.255.0
```

   # Specify the gateway address 192.168.1.1 in DHCP address pool 0.

```
[Device-dhcp-pool-0] gateway-list 192.168.1.1
[Device-dhcp-pool-0] quit
```

4. Configure a RADIUS scheme:

   # Create RADIUS scheme **2000** and enter RADIUS scheme view.

```
[Device] radius scheme 2000
```

# Specify the server at 10.1.1.1 as the primary authentication server, and set the authentication port to 1812.

```
[Device-radius-2000] primary authentication 10.1.1.1 1812
```

# Specify the server at 10.1.1.2 as the primary accounting server, and set the accounting port to 1813.

```
[Device-radius-2000] primary accounting 10.1.1.2 1813
```

# Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

```
[Device-radius-2000] key authentication simple abc
```

# Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

```
[Device-radius-2000] key accounting simple abc
```

# Exclude the ISP domain names from the usernames sent to the RADIUS server.

```
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

5. Configure an ISP domain:

# Create ISP domain **bbb** and enter ISP domain view.

```
[Device] domain bbb
```

# Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

```
[Device-isp-bbb] authentication lan-access radius-scheme 2000
[Device-isp-bbb] authorization lan-access radius-scheme 2000
[Device-isp-bbb] accounting lan-access radius-scheme 2000
[Device-isp-bbb] quit
```

6. Configure 802.1X:

# Configure the free IP.

```
[Device] dot1x ead-assistant free-ip 192.168.2.0 24
```

# Configure the redirect URL for client software download.

```
[Device] dot1x ead-assistant url http://192.168.2.3
```

# Enable the EAD assistant feature.

```
[Device] dot1x ead-assistant enable
```

# Enable 802.1X on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] dot1x
[Device-GigabitEthernet1/0/1] quit
```

# Enable 802.1X globally.

```
[Device] dot1x
```

Verifying the configuration

# Verify the 802.1X configuration.

```
[Device] display dot1x
```

# Verify that you can ping an IP address on the free IP subnet from a host. (Details not shown.)

# Verify that you are redirected to the Web server when you enter in your Web browser an IP address not on the free IP. (Details not shown.)

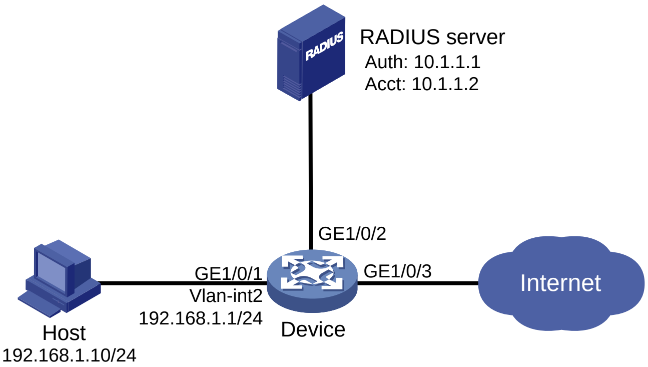
Example: Configuring 802.1X SmartOn

Network configuration

As shown in Figure 17, configure the SmartOn feature on GigabitEthernet 1/0/1 so that the host must pass SmartOn authentication before 802.1X authentication.

Set the SmartOn password to **1234** in plain text and switch ID to **XYZ**. Set the SmartOn client timeout timer to 40 seconds.

Figure 17 Network diagram



Procedure

1. Configure a RADIUS scheme:

   # Create RADIUS scheme **2000** and enter RADIUS scheme view.

   ```
   <Device> system-view
   [Device] radius scheme 2000
   ```

   # Specify the server at 10.1.1.1 as the primary authentication server, and set the authentication port to 1812.

   ```
   [Device-radius-2000] primary authentication 10.1.1.1 1812
   ```

   # Specify the server at 10.1.1.2 as the primary accounting server, and set the accounting port to 1813.

   ```
   [Device-radius-2000] primary accounting 10.1.1.2 1813
   ```

   # Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

   ```
   [Device-radius-2000] key authentication simple abc
   ```

   # Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

   ```
   [Device-radius-2000] key accounting simple abc
   ```

   # Exclude the ISP domain names from the usernames sent to the RADIUS server.

   ```
   [Device-radius-2000] user-name-format without-domain
   [Device-radius-2000] quit
   ```

2. Configure an ISP domain:

   # Create ISP domain **bbb** and enter ISP domain view.

   ```
   [Device] domain bbb
   ```

   # Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

   ```
   [Device-isp-bbb] authentication lan-access radius-scheme 2000
   [Device-isp-bbb] authorization lan-access radius-scheme 2000
   ```

```
[Device-isp-bbb] accounting lan-access radius-scheme 2000
[Device-isp-bbb] quit
```

3. Configure 802.1X and SmartOn:

   # Enable 802.1X on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] dot1x
   ```

   # Enable SmartOn on GigabitEthernet 1/0/1.

   ```
   [Device-GigabitEthernet1/0/1] dot1x smarton
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Set the SmartOn password to **1234** in plain text and the switch ID to **XYZ**.

   ```
   [Device] dot1x smarton password simple 1234
   [Device] dot1x smarton switchid XYZ
   ```

   # Set the SmartOn client timeout timer to 40 seconds.

   ```
   [Device] smarton timer supp-timeout 40
   ```

   # Enable 802.1X globally.

   ```
   [Device] dot1x
   ```

Troubleshooting 802.1X

EAD assistant URL redirection failure

Symptom

Unauthenticated users are not redirected to the specified redirect URL after they enter external website addresses in their Web browsers.

Analysis

Redirection will not happen for one of the following reasons:

- The address is in the string format. The operating system of the host regards the string as a website name and tries to resolve the string. If the resolution fails, the operating system sends an ARP request, but the target address is not in the dotted decimal notation. The redirection feature does redirect this kind of ARP request.
- The address is within a free IP segment. No redirection will take place, even if no host is present with the address.
- The redirect URL is not in a free IP segment.
- No server is using the redirect URL, or the server with the URL does not provide Web services.

Solution

To resolve the issue:

1. Enter a dotted decimal IP address that is not in any free IP segments.
2. Verify that the access device and the server are configured correctly.
3. If the issue persists, contact NSFOCUS Support.

Contents

Configuring user identification

About user identification

The user identification feature works with other security features such as blacklist and object policy to control users' network access based on the users' IP addresses or MAC addresses. This feature provides facilitation for network administrators to deploy policies for security features and to collect statistics and analysis for network attack behaviors and traffic flow on a per-user basis. It also enables the network administrators to implement policy control regardless of changes to the user IP or MAC addresses.

Identity-based user access control

The following shows the process for identity-based user access control:

1. Identity authentication. A network access user passes identity authentication and comes online.
2. User identification. The device obtains the username and IP or MAC address of the online user, and associates the information with the local identity user account and the local identity group. Then, the username-IP or username-MAC mapping for the network access user is created. The administrator can also add static username-IP or username-MAC mappings to permit network access without identity authentication.
3. Identity-based access control. The device identifies the source IP or MAC address of the traffic destined for the network, and resolves the IP or MAC address to the username and user group based on the mapping. The device performs network access control for the user or user group based on other security feature settings such as blacklist and object policy.

Identity user management

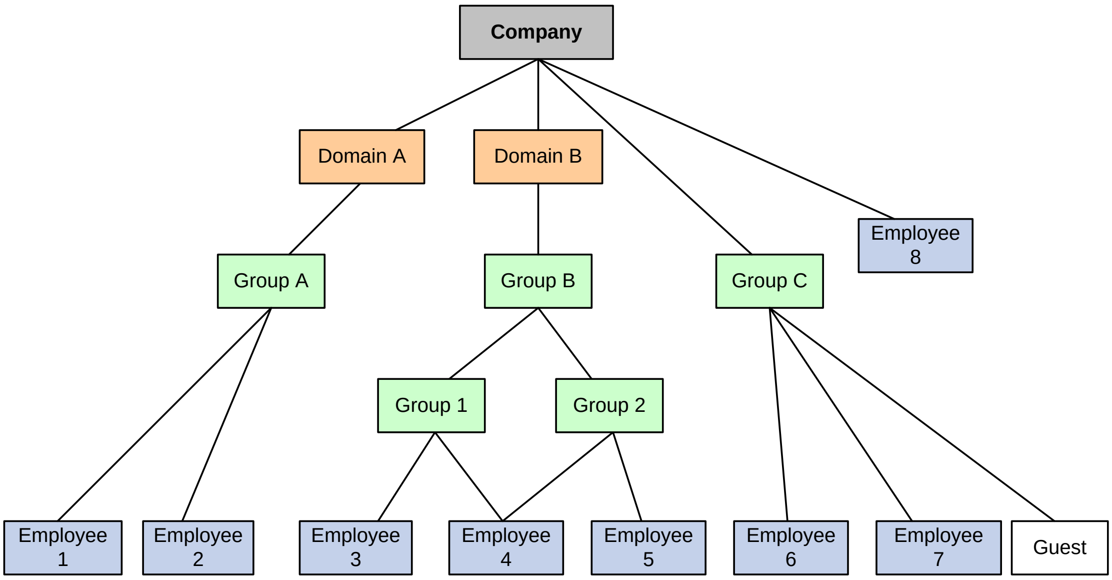
All identity users are organized in a tree structure. Identity user, identity group, and identity domain are management units, and their hierarchy levels are in ascending order.

- An identity user can belong to one or multiple identity groups.
- An identity group can belong to one or multiple higher-layer identity groups.
- An identity user or an identity group can belong to no or one identity domain.

The device uniquely identifies a managed object by the combination of identity domain and username or the combination of identity domain and identity group.

The tree structure facilitates user location and query. As shown in Figure 1, the network administrator creates identity groups and identity users for different departments and employees to implement identity-based network access control.

Figure 1 Identity user management architecture



Identity user accounts

Identity user accounts are used to record identification information of network access users from different sources. The identification information includes the username, user group name, and identity domain name of the users. The user identification module uniformly manages identity users from different sources.

The device supports the following methods to create identity user accounts:

- **Learning from the local user database**—The user identification module learns network access user information from the local user database and saves the user information as identity user accounts. For more information about network access users, see "Configuring AAA."
- **Importing from a .csv file**—The network administrator imports user information from a .csv file to the device and the device automatically creates identity user accounts based on the imported information.
- **Importing from remote servers**—The device initiates user information requests to remote servers, imports network access user information, and then creates identity user accounts based on the imported information. This method enables the network administrator to manage identity user accounts when user information is on the remote servers. Supported remote servers include LDAP servers and IMC RESTful servers.

Online identity users

Online identity users are online network access users that are managed by the user identification module. The device records the username, identity domain name, IP address, and MAC address of online identity users.

Online identity users include dynamic online identity users and static online identity users.

Dynamic online identity users

Dynamic online identity users have the following sources:

- **Online network access users that access the network through the device**—After a user passes local or remote authentication and comes online, the user identification module searches the user's username and domain name in local identity user accounts. If a matching entry is found, the device creates an online identity user entry for the user.

- **Online network access users obtained from remote servers**—After the device obtains information about an online user from a remote server, the user identification module searches the user's username and domain name in local identity user accounts. If a matching entry is found, the device creates an online identity user entry for the user. The device can obtain information about all online users of remote servers (including online users on the other devices) for unified management and monitoring.

  Supported remote servers include security management servers and IMC RESTful servers.

  - The device obtains online network access user information pushed by security management servers.
  - The device actively imports online network access user information from an IMC RESTful server.

Static online identity users

Static online identity users originate from static identity users configured by the network administrator. Each static identity user contains the mapping between the username and the IP or MAC addresses of the user. After a static identity user is created, the user identification module searches the user's username and domain name in local identity user accounts. If a matching entry is found, the device creates a static online identity user entry for the static identity user. Static online identity users can access the network without identity authentication but their access to the network is controlled by security features. The network administrator can configure static identity users when only few people need to temporarily access the network.

Application of online identity users

Application modules can impose policies of security features on online identity users. When online identity user entries are deleted, the user identification module will instruct the application modules to stop processing services for the users.

Identity groups

Identity users can be added to different groups for batch configuration and hierarchical user management. The groups are called identity groups. The user identification module uniformly manages identity groups from different sources.

Creation of identity groups

The device supports the following methods to create identity groups:

- **Learning from the local user database**—When a local user group is created, the device instructs the user identification module to create an identity group with the same group name. For more information about local user groups, see "Configuring AAA."
- **Importing from a .csv file**—The device imports identity user account information from a .csv file and then automatically creates identity groups based on the imported information.
- **Importing from remote servers**—The device can import identity user account information from an IMC RESTful server or LDAP servers and then create identity groups based on the group information in the accounts. The device can also directly obtain user group information from LDAP servers and then creates identity groups.

Application of identity groups

An identity group is activated when it is used by an application module, and all services based on the identity group will take effect. When the application module stops using the identity group, the identity group is inactive.

Restrictions and guidelines: User identification configuration

The user identity feature on the device can interact with the following remote servers to learn user information:

- **IMC RESTful server**—The device imports identity user accounts, identity groups, and online identity users from the IMC RESTful server.
- **LDAP servers**—The device imports identity user accounts and identity groups from LDAP servers.
- **Security management servers**—The device obtains online identity users from security management servers.

To use the IMC RESTful server, make sure the server runs IMC PLAT 7.3 (E0605P04) installed with the SSM E0503P04 component or IMC PLAT 7.3(E0605) installed with the EIA E0512 component.

User identification is not applicable to portal users that perform MAC-based quick portal authentication. For more information about MAC-based quick portal authentication, see "Configuring portal authentication."

User identification tasks at a glance

To configure user identification, perform the following tasks:

1. Enabling the user identification feature
2. Configuring remote servers and an identity user import policy

   Perform this task if the device needs to import user information from RESTful or LDAP servers.

   a. Configure remote server parameters

      Configuring a RESTful server

      Configuring an LDAP scheme

   b. Configuring an identity user import policy
3. Configuring a security management server set

   Perform this task if the device needs to obtain user information from security management servers.
4. (Optional.) Managing identity user accounts
   - Enabling automatic identity user account import
   - Manually importing identity user accounts from remote servers
   - Manually importing identity user accounts from a .csv file
   - Manually exporting identity user accounts
   - Deleting identity user accounts
5. (Optional.) Managing online identity users
   - Configuring static identity users
   - Specifying the username match mode for user identification
   - Importing online identity users from a remote server
   - Deleting online identity users
6. (Optional.) Deleting identity groups

Enabling the user identification feature

About this task

With the user identification feature, the device learns information about online usersfrom the user access modules. The device uses the obtained information for user identification and works with other security features for identity-based network access control.

Procedure

1. Enter system view.

   system-view

2. Enable the user identification feature.

   user-identity enable

   By default, the user identification feature is disabled.

Configuring remote servers and an identity user import policy

Configuring a RESTful server

About this task

The RESTful server view defines the related parameter settings for the device to communicate with the RESTful server. The parameters include the login account and the URIs of the RESTful server. After establishing a connection with the RESTful server, the device can import identity user accounts, identity groups, and online identity users from the server.

Restrictions and guidelines

The system can have only one RESTful server.

Procedure

1. Enter system view.

   system-view

2. Create a RESTful server and enter its view.

   user-identity restful-server *server-name*

3. Specify the username and password to log in to the RESTful server.

   login-name *user-name* **password** { **cipher** | **simple** } *string*

   By default, no username or password is specified for the device to log in to the RESTful server.

   The specified username and password must exist on the RESTful server. Otherwise, the device cannot establish a connection with the RESTful server.

4. Specify a URI for the RESTful server.

   uri { **get-online-user** | **get-user-database** | **get-user-group-database** | **put-offline-user** | **put-online-user** } *uri-string*

   By default, no URIs are specified for the RESTful server.

   The specified URIs must be the same as those on the RESTful server. Otherwise, user information interaction will fail.

   You can repeat this command to specify multiple URIs of the RESTful server.

5. Specify an MPLS L3VPN instance for the RESTful server.

vpn-instance *vpn-instance-name*

By default, the RESTful server belongs to the public network.

6. (Optional.) Configure RESTful server reachability detection:
   a. Enable RESTful server reachability detection.

      connection-detect enable

      By default, RESTful server reachability detection is disabled.
   b. Configure parameters for RESTful server reachability detection.

      connection-detect { **interval** *interval* | **maximum** *max-times* }

      By default, the reachability detection interval is 5 minutes and the maximum number of probes per detection is 3.

Configuring an LDAP scheme

About this task

An LDAP scheme includes the LDAP server that interacts with the device and the related parameter settings. After establishing a connection with the LDAP server, the device can import identity user accounts and identity groups from the server.

For more information about LDAP attribute maps, see "Configuring AAA."

Restrictions and guidelines

The device cannot import online identity users from the LDAP server.

When importing identity user accounts and identity groups from the LDAP server, the device does not carry parent groups to which the identity users or identity groups belong by default. To configure the device to carry the parent group information, you must configure an LDAP attribute map and specify the LDAP attribute map in the LDAP scheme.

Procedure

1. Enter system view.

   system-view
2. Configure an LDAP server.

   The LDAP server configuration includes the server IP address, the administrator DN and password for binding with the LDAP server, DN search policy, and user group filter. For more information, see "Configuring AAA."
3. Create an LDAP attribute map and enter LDAP attribute map view.

   ldap attribute-map *map-name*
4. Configure an LDAP attribute mapping entry for the user group attribute.

   map ldap-attribute *ldap-attribute-name* [**prefix** *prefix-value* **delimiter** *delimiter-value*] **aaa-attribute user-group**
5. Return to system view.

   quit
6. Create an LDAP scheme and enter LDAP scheme view.

   ldap scheme *ldap-scheme-name*
7. Specify the LDAP authentication server.

   authentication-server *server-name*

   By default, no LDAP authentication server is specified.
8. Specify the LDAP attribute map.

   attribute-map *map-name*

By default, no LDAP attribute map is specified.

After this command is executed, the device imports identity user accounts and identity groups with parent group information. However, the device does not create new identity groups based on the parent group information.

Configuring an identity user import policy

About this task

To import identity user accounts, online identity users, or identity groups from a RESTful server or LDAP servers, you must configure an identity user import policy. In this policy, you can set the parameters for the device to interact with the RESTful server or LDAP servers.

Restrictions and guidelines

The system can have only one identity user import policy. Before you configure a new identity user import policy, you must delete the existing one.

Procedure

1. Enter system view.

   `system-view`

2. Create an identity user import policy and enter its view.

   `user-identity user-import-policy` *`policy-name`*

3. Specify a RESTful server.

   `restful-server` *`server-name`*

   By default, no RESTful server is specified.

   You can specify only one RESTful server. Before you specify a new RESTful server, remove the currently specified one.

4. Specify an LDAP scheme.

   `ldap-scheme` *`ldap-scheme-name`*

   By default, no LDAP schemes are specified.

   You can specify a maximum of 16 LDAP schemes.

5. (Optional.) Set the interval for automatic identity user account import.

   `account-update-interval` *`interval`*

   By default, the interval for automatic identity user account import is 24 hours.

6. Specify the type of user information to be imported from LDAP servers.

   `import-type` `{` **`all`** `|` **`group`** `|` **`user`** `}`

   By default, the device imports both user information and user group information from LDAP servers.

Configuring a security management server set

About this task

The security management server set view defines the related parameters of the device to communicate with security management servers. The parameters include the IP addresses of the servers, the port number for listening to the servers, and the shared key to secure communication between the device and the servers.

When the device establishes connections with security management servers, it can receive user online and offline notifications that the servers push to the device.

- Based on user online notifications, the device obtains online user information and creates online identity user entries for users that match identity user accounts.
- Based on user offline notifications, the device obtains information about users that have gone offline and deletes the corresponding online identity user entries.

Restrictions and guidelines

The system can have only one security management server set.

Procedure

1. Enter system view.
   system-view
2. Create a security management server set and enter its view.
   user-identity security-manage-server *server-set-name*
3. Specify IP addresses of security management servers.
   ip *ip-address*&<1-10>

   By default, no IP addresses of security management servers are specified.
4. Configure the encryption algorithm and shared key for securing communication with security management servers.
   encryption algorithm { **3des** | **aes128** } **key** { **simple** | **cipher** } *string*

   By default, no encryption algorithm or shared key is configured for securing communication with security management servers.
5. Set the port number for listening to security management servers.
   listen-port *port-num*

   By default, the device listens to security management servers on port 8001.

Managing identity user accounts

Enabling automatic identity user account import

About this task

After this feature is enabled, the device first imports all identity user accounts and online identity user information from the servers specified in the identity user import policy. Then, the device periodically imports identity user accounts from the remote servers at the interval set by using the **account-update-interval** command.

Restrictions and guidelines

If automatic identity user account import is enabled but user identity is disabled, the device can import only identity user accounts from the remote servers specified in the policy.

If RESTful server reachability detection is enabled for the RESTful server in the specified policy, the device will automatically import online identity user information from that server when the state of that server changes from unreachable to reachable.

Procedure

1. Enter system view.
   system-view
2. Enable automatic identity user account import.
   user-identity user-account auto-import policy *policy-name*

   By default, automatic identity user account import is disabled.

Manually importing identity user accounts from remote servers

About this task

Perform this task to manually import identity user accounts from remote servers. The device initiates user information requests to the servers, imports network access user account information from the servers, and then creates corresponding identity user accounts. If the device fails to import an account, the device skips the account and continues to import the next account.

Prerequisites

Before you import identity user accounts from remote servers, make sure the following conditions are met:

- An identity user import policy is configured.
- The specified URIs of the RESTful server or the IP addresses of the LDAP servers in the policy must be valid.

Procedure

1. Enter system view.

   system-view

2. Import identity user accounts from remote servers.

   user-identity user-account import policy *policy-name*

Manually importing identity user accounts from a .csv file

About this task

Perform this task to manually import identity user accounts from a .csv file. If the device fails to import an account, it stops importing the remaining identity user accounts in the file.

Prerequisites

Before you import identity user accounts from a .csv file, make sure the .csv file is a standard .csv file. To see the format of a standard .csv file, use the **user-identity user-account export url** command to export a standard template.

Procedure

1. Enter system view.

   system-view

2. Import identity user accounts from a .csv file.

   user-identity user-account import url *url-string* [**vpn-instance** *vpn-instance-name*] [**auto-create-group** | **override** | **start-line** *line-number*] *

Manually exporting identity user accounts

About this task

Perform this task to export identity user accounts on the device to a .csv file. You can directly import identity user accounts in the exported file to other devices. Or, you can edit the exported file and then import identity user accounts in the file back to the device or to other devices.

If you specify the **template** keyword, the device exports a standard .csv file template. You can use this file template as a reference when you edit .csv files.

Procedure

1. Enter system view.

   system-view

2. Export identity user accounts to a .csv file.

   user-identity user-account export url *url-string* [{ **domain** *domain-name* | **null-domain** } [**user** *user-name*] | **template**] [**vpn-instance** *vpn-instance-name*]

Deleting identity user accounts

About this task

Identity user accounts can be deleted by using the following methods:

- **Manual deletion**—The administrator uses a command to delete identity user accounts imported from remote servers or .csv files.
- **Dynamic deletion**—Deletion of network access users in the local user database triggers the deletion of corresponding identity user accounts.

Manually deleting identity user accounts

To manually delete identity user accounts, execute the following command in user view:

reset user-identity user-account { **all** | { **domain** *domain-name* | **null-domain** } [**name** *user-name*] }

Managing online identity users

Configuring static identity users

Restrictions and guidelines

A username can be bound with multiple IP addresses, multiple MAC addresses, or multiple IP-MAC address combinations. However, an IP address, MAC address, or IP-MAC address combination cannot be bound with multiple usernames.

Procedure

1. Enter system view.

   system-view

2. Configure a static identity user.

user-identity static-user *user-name* [**domain** *domain-name*] **bind** { { **ipv4** *ipv4-address* | **ipv6** *ipv6-address* } | **mac** *mac-address* } *

Specifying the username match mode for user identification

About this task

Perform this task to specify the username match mode for user identification. The device creates online identity users only for online users whose usernames can match the usernames in the local identity user accounts.

Restrictions and guidelines

This feature takes effect only on online identity users that access the current device.

Procedure

1. Enter system view.

   `system-view`

2. Specify the username match mode for user identification.

   `user-identity online-user-name-match` { **`keep-original`** | **`with-domain`** | **`without-domain`** }

   By default, the username match mode for user identification is **`keep-original`**.

Importing online identity users from a remote server

About this task

Perform this task to import online identity user information from a remote server. The device initiates a real-time online user information request to the server and then imports all online user information.

Restrictions and guidelines

The device can import online identity users only from an IMC RESTful server.

For the device to successfully import online identity users from a remote server, make sure the user identification feature is enabled.

Prerequisites

Before you import online identity users from a remote server, make sure the following conditions are met:

- An identity user import policy is configured.
- The specified URIs of the RESTful server in the policy must be valid.

Procedure

1. Enter system view.

   `system-view`

2. Import online identity users.

   `user-identity online-user import policy` *`policy-name`*

Deleting online identity users

About this task

Online identity users can be deleted by using the following methods:

- **Manual deletion**—The administrator uses a command to delete dynamic online identity users imported from remote servers and static online identity users.
- **Dynamic deletion**—Multiple events trigger the deletion of identity users.
  - After a network access user goes offline, the access module instructs the user identification module to delete the associated online identity users.
  - After the device reboots, all dynamic online identity users are deleted.
  - After the user identification feature is disabled, all dynamic online identity users are deleted.
  - After a user on a remote server goes offline, the remote server instructs the device to delete the associated online identity user.

Manually deleting dynamic online identity users

To manually delete dynamic online identity users, execute the following command in user view:

reset user-identity dynamic-online-user { **all** | { **domain** *domain-name* | **null-domain** } [**name** *user-name*] | { { **ip** *ipv4-address* | **ipv6** *ipv6-address* } | **mac** *mac-address* } * }

Manually deleting static online identity users

1. Enter system view.

   system-view

2. Delete static online identity users.

   undo user-identity static-user *user-name* [**domain** *domain-name*] [**bind** { { **ipv4** *ipv4-address* | **ipv6** *ipv6-address* } | **mac** *mac-address* } *]

Deleting identity groups

About this task

Identity groups can be deleted by using the following methods:

- **Manual deletion**—The administrator uses a command to delete identity groups imported from remote servers or .csv files.
- **Dynamic deletion**—Deletion of user groups in the local user database triggers the deletion of corresponding identity groups.

Manually deleting identity groups

To manually delete identity groups, execute the following command in user view:

reset user-identity user-group { **all** | { **domain** *domain-name* | **null-domain** } [**name** *group-name*] }

Display and maintenance commands for user identification

Execute **display** commands in any view.

Task	Command
Display information about identity users or identity groups.	**display user-identity** { **domain** *domain-name* | **null-domain** } { **user** [*user-name* [**group**]] | **user-group** [*group-name* [**member** { **group** | **user** }]] }
Display information about active identity groups.	**display user-identity active-user-group** { **all** | **domain** *domain-name* | **null-domain** }
Display information about all identity users or identity groups.	**display user-identity all** { **user** | **user-group** }
Display information about online identity users.	**display user-identity online-user** { **domain** *domain-name* | **null-domain** } **name** *user-name*
Display RESTful server configuration.	**display user-identity restful-server** [*server-name*]
Display configuration information for security	**display user-identity**

Task	Command
management server sets.	**security-manage-server** [*server-set-name*]
Display identity user import policy information.	**display user-identity user-import-policy** [*policy-name*]

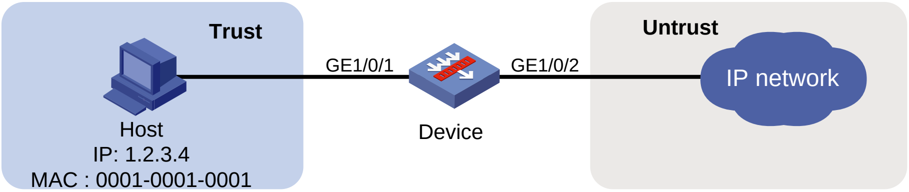
User identification configuration examples

Example: Configuring static user identification

Network configuration

As shown in Figure 2, the administrator permits user **usera** with IP address 1.2.3.4 and MAC address 0001-0001-0001 to access the network without identity authentication. Configure a security policy for access control, which permits the user to access the network only from 8:00 to 18:00 in working days.

Figure 2 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 1.2.3.5 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/1
   [Device-security-zone-Trust] quit
   [Device] security-zone name untrust
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Untrust] quit
   ```

3. Configure settings for routing. This example configures a static route, and the next hop in the route is 2.2.2.2.

   ```
   [Device] ip route-static 3.1.1.2 24 2.2.2.2
   ```

4. Configure user identification:

   # Create a network access user named **usera**.

   ```
   [Device] local-user usera class network
   [Device-luser-network-usera] quit
   ```

# Configure a static identity user named **usera** with IP address 1.2.3.4 and MAC address 0001-0001-0001.

```
[Device] user-identity static-user usera bind ipv4 1.2.3.4 mac 0001-0001-0001
```

# Enable the user identification feature.

```
[Device] user-identity enable
```

5. Configure time range and security policy settings:

   # Create a time range named **work** and specify the time range in working days.

   ```
   [Device] time-range work 08:00 to 18:00 working-day
   ```

   # Configure a rule named **ippolicy1** in the IPv4 security policy to permit user **usera** to access the IP network only from 8:00 to 18:00 in working days.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name ippolicy1
   [Device-security-policy-ip-1-ippolicy1] source-zone trust
   [Device-security-policy-ip-1-ippolicy1] destination-zone untrust
   [Device-security-policy-ip-1-ippolicy1] action pass
   [Device-security-policy-ip-1-ippolicy1] user usera
   [Device-security-policy-ip-1-ippolicy1] time-range work
   [Device-security-policy-ip-1-ippolicy1] quit
   [Device-security-policy-ip] quit
   ```

Verifying the configuration

# Display online identity user information for user **usera**.

```
[Device] display user-identity online-user null-domain name usera
User name: usera
  IP  : 1.2.3.4
  MAC : 0001-0001-0001
  Type: Static

Total 1 records matched
```

# Verify that the user can access the network only from 8:00 to 18:00 in working days. (Details not shown.)

Contents

Configuring password control

About password control

Password control allows you to implement the following features:

- Manage login and super password setup, expirations, and updates for device management users.
- Control user login status based on predefined policies.

For more information about local users, see "Configuring AAA." For information about super passwords, see RBAC in *Fundamentals Configuration Guide*.

Password setting

Minimum password length

You can define the minimum length of user passwords. The system rejects the setting of a password that is shorter than the configured minimum length.

Password composition policy

A password can be a combination of characters from the following types:

- Uppercase letters A to Z.
- Lowercase letters a to z.
- Digits 0 to 9.
- Special characters in Table 1.

Table 1 Special Characters

Character name	Symbol	Character name	Symbol
Ampersand sign	&	Apostrophe	'
Asterisk	*	At sign	@
Back quote	`	Back slash	\
Blank space	N/A	Caret	^
Colon	:	Comma	,
Dollar sign	$	Dot	.
Equal sign	=	Exclamation point	!
Left angle bracket	<	Left brace	{
Left bracket	[	Left parenthesis	(
Minus sign	-	Percent sign	%
Plus sign	+	Pound sign	#
Quotation marks	"	Right angle bracket	>
Right brace	}	Right bracket	]
Right parenthesis	)	Semi-colon	;

Character name	Symbol	Character name	Symbol
Slash	/	Tilde	~
Underscore	_	Vertical bar	|

Depending on the system's security requirements, you can set the minimum number of character types a password must contain and the minimum number of characters for each type, as shown in Table 2.

Table 2 Password composition policy

Password combination level	Minimum number of character types	Minimum number of characters for each type
Level 1	One	One
Level 2	Two	One
Level 3	Three	One
Level 4	Four	One

When a user sets or changes a password, the system checks if the password meets the combination requirement. If it does not, the operation fails.

Password complexity checking policy

A less complicated password is more likely to be cracked, such as a password containing the username or repeated characters. For higher security, you can configure a password complexity checking policy to ensure that all user passwords are relatively complicated. When a user configures a password, the system checks the complexity of the password. If the password is complexity-incompliant, the configuration will fail.

You can apply the following password complexity requirements:

- A password cannot contain the username or the reverse of the username. For example, if the username is **abc**, a password such as **abc982** or **2cba** is not complex enough.
- A minimum of three identical consecutive characters is not allowed. For example, password **a111** is not complex enough.

Password updating and expiration

Password updating

This feature allows you to set the minimum interval at which users can change their passwords. A user can only change the password once within the specified interval.

The minimum interval does not apply to the following situations:

- A user is prompted to change the password at the first login.
- The password aging time expires.

Password expiration

Password expiration imposes a lifecycle on a user password. After the password expires, the user needs to change the password.

The system displays an error message for a login attempt with an expired password. The user is asked to provide a new password. The new password must be valid, and the user must enter exactly the same password when confirming it.

Web users, Telnet users, SSH users, and console users can change their own passwords. FTP users must have their passwords changed by the administrator.

Early notice on pending password expiration

When a user logs in, the system checks whether the password will expire in a time equal to or less than the specified notification period. If so, the system notifies the user when the password will expire and provides a choice for the user to change the password.

- If the user sets a new valid password, the system records the new password and the setup time.
- If the user does not or fails to change the password, the system allows the user to log in by using the current password until the password expires.

Web users, Telnet users, SSH users, and console users can change their own passwords. FTP users must have their passwords changed by the administrator.

Login with an expired password

You can allow a user to log in a certain number of times within a period of time after the password expires. For example, if you set the maximum number of logins with an expired password to 3 and the time period to 15 days, a user can log in three times within 15 days after the password expires.

Password history

This feature allows the system to store passwords that a user has used.

When a network access user changes the password, the system compares the new password with the current password and those stored in the password history records. The new password must be different from the current one and those stored in the history records by a minimum of four different characters. Otherwise, the system will display an error message, and the new password is not successfully set.

The local passwords and super passwords for device management users are stored in hash form and cannot be converted to plain texts. When a device management user changes a local password or super password, follow these rules:

- If the new password is set by using the hash method, the system will not compare the new password with the current one and those stored in the history password records.
- If the new password is set in plain text, the system compares the new password with the current password and those stored in the password history records. A new password must be different from those stored in the history password records. If the current password is required, the new password must also be different from the current one by a minimum of four different characters. Otherwise, the system will display an error message, and the new password is not successfully set.

You can set the maximum number of history password records for the system to maintain for each user. When the number of history password records exceeds the setting, the most recent record overwrites the earliest one.

Current login passwords are not stored in the password history for device management users. Device management users have their passwords saved in cipher text, which cannot be recovered to plaintext passwords.

User login control

First login

By default, if the global password control feature is enabled, users must change the password at first login before they can access the system. In this situation, password changes are not subject to the minimum password update interval. If it is not necessary for users to change the password at first login, disable the password change at first login feature.

Password control blacklist

The password control blacklist prevents abnormal users from logging in by recording the login failures and maintaining the status of blacklisted user accounts.

The system adds the information of the following users that fail to log in to the password control blacklist:

- FTP, Web, or VTY users.
- Users logging in to the device through console ports.

The system does not add the user accounts of nonexistent users (users not configured on the device) to the password control blacklist if they fail to log in.

The device supports the following recording modes for adding the user information to the blacklist for users failing authentication:

- **Username only**—Adds only usernames to the blacklist. In this mode, a user account matches a blacklist entry as long as the username matches the entry.
- **Username and IP address**—Adds both usernames and IP addresses to the blacklist. In this mode, a user account matches a blacklist entry only when both the username and the login IP address match the entry.

The device will create a blacklist entry for each IP address for a user account when the following conditions are both met:

- Both usernames and IP addresses are added to the password control blacklist.
- A user uses the same user account to log in to the device from different IP addresses and fails the logins.

When the maximum number of blacklist entries for the user account is reached, a blacklist entry for a new IP address of the user account will overwrite the earliest blacklist entry for the user account.

Login attempt limit

Limiting the number of consecutive login failures can effectively prevent password guessing.

When the user fails the maximum number of consecutive attempts, login attempt limit limits the user and user account in any of the following ways:

- Locks the user account and the user's IP address permanently. No users can use this account to log in to the device from this IP address unless the account is manually removed from the password control blacklist.
- Allows the user to continue using the user account. The user's IP address and user account are removed from the password control blacklist when the user uses this account to successfully log in to the device.
- Locks the user account and the user's IP address for a period of time.

  The user can use the account to log in from the IP address when either of the following conditions exists:

  - The locking timer expires.
  - The account is manually removed from the password control blacklist before the locking timer expires.

NOTE:

This account is locked only for the user at the locked IP address. A user from an unlocked IP address can still use this account, and the user at the locked IP address can use other unlocked user accounts.

Maximum account idle time

You can set the maximum account idle time for user accounts. When an account is idle for this period of time since the last successful login, the account becomes invalid.

Login control with a weak password

The system checks for weak passwords for Telnet, SSH, HTTP, or HTTPS device management users. A password is weak if it does not meet the following requirements:

- Password composition restriction.
- Minimum password length restriction.
- Password complexity checking policy.

By default, the system displays a message about a weak password but does not force the user to change it. To improve the device security, you can enable the mandatory weak password change feature, which forces the users to change the identified weak passwords. The users can log in to the device only after their passwords meet the password requirements.

First login with a default username and password

The factory defaults contain a default username and password. If the device starts up with factory defaults, whether the system checks the default password depends on the device model.

Password not displayed in any form

For security purposes, nothing is displayed when a user enters a password.

Logging

The system generates a log each time a user changes its password successfully or is added to the password control blacklist because of login failures.

Restrictions and guidelines: Password control configuration

IMPORTANT:

To successfully enable the global password control feature and allow device management users to log in to the device, make sure the device have sufficient storage space.

The password control features can be configured in several different views, and different views support different features. The settings configured in different views or for different objects have the following application ranges:

- Settings for super passwords apply only to super passwords.
- Settings in local user view apply only to the password of the local user.
- Settings in user group view apply to the passwords of the local users in the user group if you do not configure password policies for these users in local user view.
- Global settings in system view apply to the passwords of the local users in all user groups if you do not configure password policies for these users in both local user view and user group view.

For local user passwords, the settings with a smaller application scope have higher priority.

Password control tasks at a glance

To configure password control, perform the following tasks:

1. Enabling password control
2. (Optional.) Setting global password control parameters
3. (Optional.) Setting user group password control parameters
4. (Optional.) Setting local user password control parameters
5. (Optional.) Setting super password control parameters

Enabling password control

About this task

The password composition policy, minimum password length, and username checking features are independent of the global password control feature. Other password control features (such as password expiration or password history management) can take effect only after the global password control feature is also enabled.

Restrictions and guidelines

After global password control is enabled, follow these restrictions and guidelines:

- You cannot display the password and super password configurations for device management users by using the corresponding **display** commands.
- You cannot display the password configuration for network access users by using the corresponding **display** command.
- The passwords configured for local users must contain a minimum of four different characters.
- To ensure correct function of password control, configure the device to use NTP to obtain the UTC time. After global password control is enabled, password control will record the UTC time when the password is set. The recorded UTC time might not be consistent with the actual UTC time due to power failure or device reboot. The inconsistency will cause the password expiration feature to malfunction. For information about NTP, see *Network Management and Monitoring Configuration Guide*.
- The device automatically generates a .dat file and saves the file to the storage media. The file is used to record authentication and login information of the local users. Do not manually delete or modify the file.

Procedure

1. Enter system view.

   system-view

2. Enable the global password control feature.

   password-control enable [**network-class**]

   By default, the global password control feature is disabled for device management and network access users.

3. (Optional.) Enable a specific password control feature.

   password-control { **aging** | **composition** | **history** | **length** } **enable**

   By default, all four password restriction features are enabled.

Setting global password control parameters

Restrictions and guidelines

The global password control parameters in system view apply to all device management and network access local users.

You can configure all password control features for device management users. The password aging time, minimum password length, password complexity policy, password composition policy, and user login attempt limit can be configured in system view, user group view, and local user view.

You can configure only the following password control features for network access users:

- Minimum password length.
- Password complexity policy.
- Password composition policy.

- Minimum password update interval.
- Maximum number of history password records for each user.

Where, the minimum password length, password complexity policy, and password composition policy can be configured in system view, user group view, and local user view.

The password settings with a smaller application scope have higher priority. For local users, password settings configured in local user view have the highest priority, and global settings in system view have the lowest priority.

The global password control feature enables the system to record history passwords. When the number of history password records of a user reaches the maximum number, the newest history record overwrites the earliest one. To delete the existing history password records, use one of the following methods:

- Use the **undo password-control enable** command to disable the password control feature globally.
- Use the **reset password-control history-record** command to clear the passwords manually.

The **password-control login-attempt** command takes effect immediately and can affect the users already in the password control blacklist. If the user information items to add to the password control blacklist change, the system will clear the password control blacklist and restart the recording. Other password control configurations do not take effect on users that have been logged in or passwords that have been configured.

Procedure

1. Enter system view.

   system-view

2. Configure password settings.
   - Set the minimum password length.

     password-control length *length*

     The default length is 10 characters.
   - Configure the password composition policy.

     password-control composition type-number *type-number* [**type-length** *type-length*]

     By default, a password must contain a minimum of two character types and a minimum of one character for each type.
   - Configure the password complexity checking policy.

     password-control complexity { **same-character** | **user-name** } **check**

     By default, the username checking is enabled but repeated character checking is disabled.
   - Set the maximum number of history password records for each user.

     password-control history *max-record-number*

     The default setting is 4.

3. Configure password updating and expiration.
   - Set the minimum password update interval.

     password-control update interval *interval*

     The default setting is 24 hours.
   - Set the password aging time.

     password-control aging *aging-time*

     The default setting is 90 days.
   - Set the number of days during which a user is notified of the pending password expiration.

password-control alert-before-expire *alert-time*

The default setting is 7 days.

- Set the maximum number of days and maximum number of times that a user can log in after the password expires.

  password-control expired-user-login delay *delay* **times** *times*

  By default, a user can log in three times within 30 days after the password expires.

4. Configure user login control.
   - Set the maximum number of blacklist entries for a user account.

     password-control per-user blacklist-limit *max-number*

     By default, the maximum number of blacklist entries for a user account is 32.
   - Configure the login attempt limit.

     password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

     By default, the maximum number of login attempts is 3 and a user failing to log in after the specified number of attempts must wait for 1 minute before trying again.
   - Add only usernames to the password control blacklist for users failing authentication.

     password-control blacklist user-info username-only

     By default, both usernames and IP addresses are added to the password control blacklist when the users fail authentication.
   - Set the maximum account idle time.

     password-control login idle-time *idle-time*

     The default setting is 90 days.

     If a user account is idle for this period of time, the account becomes invalid and can no longer be used to log in to the device. To disable the account idle time restriction, set the idle time value to 0.
   - Disable password change at first login.

     undo password-control change-password first-login enable

     By default, the password change at first login is enabled.
   - Enable mandatory weak password change.

     password-control change-password weak-password enable

     By default, the mandatory weak password change feature is disabled.

Setting user group password control parameters

1. Enter system view.

   system-view
2. Create a user group and enter its view.

   user-group *group-name*

   For information about how to configure a user group, see "Configuring AAA."
3. Configure the password aging time for the user group.

   password-control aging *aging-time*

   By default, the password aging time of the user group equals the global password aging time.
4. Configure the minimum password length for the user group.

   password-control length *length*

By default, the minimum password length of the user group equals the global minimum password length.

5. Configure the password composition policy for the user group.

   password-control composition type-number *type-number* [**type-length** *type-length*]

   By default, the password composition policy of the user group equals the global password composition policy.

6. Configure the password complexity checking policy for the user group.

   password-control complexity { **same-character** | **user-name** } **check**

   By default, the password complexity checking policy of the user group equals the global password complexity checking policy.

7. Configure the login attempt limit.

   password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

   By default, the login-attempt policy of the user group equals the global login-attempt policy.

Setting local user password control parameters

1. Enter system view.

   system-view

2. Create a device management or network access user and enter its view.
   - Create a device management user and enter its view.

     local-user *user-name* **class manage**
   - Create a network access user and enter its view.

     local-user *user-name* **class network**

   For information about how to configure a local user, see "Configuring AAA."

3. Configure the password aging time for the local user.

   password-control aging *aging-time*

   By default, the setting equals that for the user group to which the local user belongs. If no aging time is configured for the user group, the global setting applies to the local user.

   This command is available only for device management users.

4. Configure the minimum password length for the local user.

   password-control length *length*

   By default, the setting equals that for the user group to which the local user belongs. If no minimum password length is configured for the user group, the global setting applies to the local user.

5. Configure the password composition policy for the local user.

   password-control composition type-number *type-number* [**type-length** *type-length*]

   By default, the settings equal those for the user group to which the local user belongs. If no password composition policy is configured for the user group, the global settings apply to the local user.

6. Configure the password complexity checking policy for the local user.

   password-control complexity { **same-character** | **user-name** } **check**

   By default, the settings equal those for the user group to which the local user belongs. If no password complexity checking policy is configured for the user group, the global settings apply to the local user.

7. Configure the login attempt limit.

   password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

   By default, the settings equal those for the user group to which the local user belongs. If no login-attempt policy is configured for the user group, the global settings apply to the local user.

   This command is available only for device management users.

Setting super password control parameters

1. Enter system view.

   system-view

2. Set the password aging time for super passwords.

   password-control super aging *aging-time*

   The default setting is 90 days.

3. Configure the minimum length for super passwords.

   password-control super length *length*

   The default setting is 10 characters.

4. Configure the password composition policy for super passwords.

   password-control super composition type-number *type-number* [**type-length** *type-length*]

   By default, a super password must contain a minimum of two character types and a minimum of one character for each type.

Display and maintenance commands for password control

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display password control configuration.	**display password-control** [**super**]
Display information about users in the password control blacklist.	**display password-control blacklist** [**user-name** *user-name* | **ip** *ipv4-address* | **ipv6** *ipv6-address*]
Delete users from the password control blacklist.	**reset password-control blacklist** [**user-name** *user-name*]
Clear history password records.	**reset password-control history-record** [**user-name** *user-name* | **super** [**role** *role name*] | **network-class** [**user-name** *user-name*]]

Contents

Configuring portal authentication

About portal authentication

Portal authentication controls user access to networks. Portal authenticates a user by the username and password the user enters on a portal authentication page. Typically, portal authentication is deployed on the access layer and vital data entries.

In a portal-enabled network, users can actively initiate portal authentication by visiting the authentication website provided by the portal Web server. Or, they are redirected to the portal authentication page for authentication when they visit other websites.

The device supports Portal 1.0, Portal 2.0, and Portal 3.0.

Advantages of portal authentication

Portal authentication has the following advantages:

- Allows users to perform authentication through a Web browser without installing client software.
- Provides ISPs with diversified management choices and extended functions. For example, the ISPs can place advertisements, provide community services, and publish information on the authentication page.
- Supports multiple authentication modes. For example, re-DHCP authentication implements a flexible address assignment scheme and saves public IP addresses. Cross-subnet authentication can authenticate users who reside in a different subnet than the access device.

Extended portal functions

By forcing patching and anti-virus policies, extended portal functions help hosts to defend against viruses. Portal supports the following extended functions:

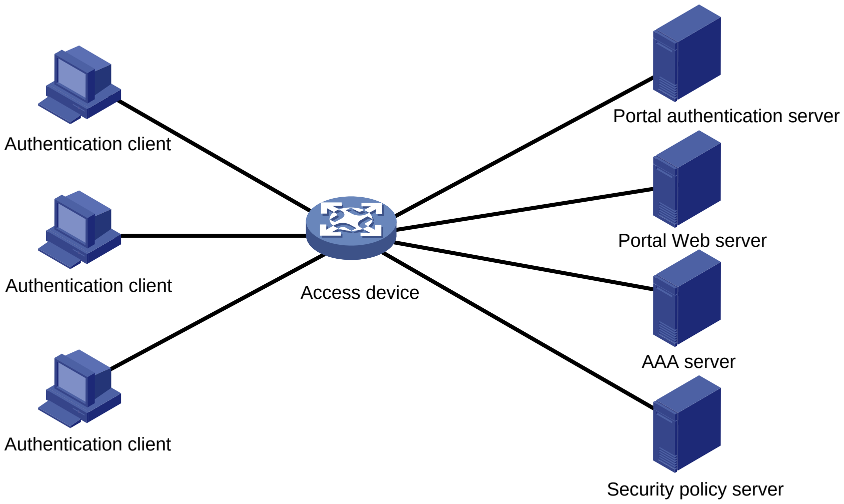
- **Security check**—Detects after authentication whether or not a user host installs anti-virus software, virus definition file, unauthorized software, and operating system patches.
- **Resource access restriction**—Allows an authenticated user to access certain network resources such as the virus server and the patch server. Users can access more network resources after passing security check.

Security check must cooperate with the IMC security policy server and the iNode client.

Portal system

A typical portal system consists of these basic components: authentication client, access device, portal authentication server, portal Web server, AAA server, and security policy server.

Figure 1 Portal system



Authentication client

An authentication client is a Web browser that runs HTTP/HTTPS or a user host that runs a portal client. Security check for the user host is implemented through the interaction between the portal client and the security policy server. Only the iNode client is supported.

Access device

An access device provides access services. It has the following functions:

- Redirects all HTTP or HTTPS requests of unauthenticated users to the portal Web server.
- Interacts with the portal authentication server and the AAA server to complete authentication, authorization, and accounting.
- Allows users that pass portal authentication to access authorized network resources.

Portal server

A portal server collectively refers to a portal authentication server and portal Web server.

The portal Web server pushes the Web authentication page to authentication clients and forwards user authentication information (username and password) to the portal authentication server. The portal authentication server receives authentication requests from authentication clients and interacts with the access device to authenticate users. The portal Web server is typically integrated with the portal authentication server and it can also be an independent server.

AAA server

The AAA server interacts with the access device to implement authentication, authorization, accounting for portal users. In a portal system, a RADIUS server can perform authentication, authorization, accounting for portal users, and an LDAP server can perform authentication for portal users.

Security policy server

The security policy server interacts with the portal client and the access device for security check and authorization for users. Only hosts that run portal clients can interact with the security policy server.

Portal authentication using a remote portal server

The components of a portal system interact as follows:

1. An unauthenticated user initiates authentication by accessing an Internet website through a Web browser. When receiving the HTTP or HTTPS request, the access device redirects it to the

Web authentication page provided by the portal Web server. The user can also visit the authentication website to log in. The user must log in through the iNode client for extended portal functions.

2. The user enters the authentication information on the authentication page/dialog box and submits the information. The portal Web server forwards the information to the portal authentication server. The portal authentication server processes the information and forwards it to the access device.
3. The access device interacts with the AAA server to implement authentication, authorization, accounting for the user.
4. If security policies are not imposed on the user, the access device allows the authenticated user to access networks.

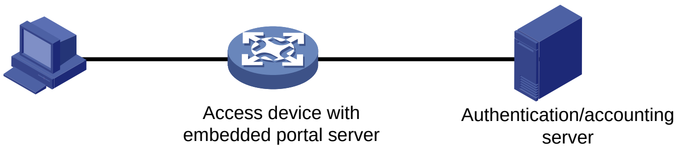
   If security policies are imposed on the user, the portal client, the access device, and the security policy server interact to check the user host. If the user passes the security check, the security policy server authorizes the user to access resources based on the check result.

Local portal service

System components

As shown in Figure 2, a local portal system consists of an authentication client, access device, and AAA server. The access device acts as both the portal Web server and the portal authentication server to provide the local portal Web service for the authentication client. The authentication client can only be a Web browser, and it cannot be a user host that runs a portal client. Therefore, extended portal functions are not supported and no security policy server is required.

Figure 2 System components



Portal page customization

To provide the local portal web service, you must customize a set of authentication pages that the device will push to users. You can customize multiple sets of authentication pages, compress each set of the pages to a .zip file, and upload the compressed files to the storage medium of the device. On the device, you must specify one of the files as the default authentication page file by using the **`default-logon-page`** command.

For more information about authentication page customization, see "Customizing authentication pages."

Portal authentication modes

Portal authentication has three modes: direct authentication, re-DHCP authentication, and cross-subnet authentication. In direct authentication and re-DHCP authentication, no Layer 3 forwarding devices exist between the authentication client and the access device. In cross-subnet authentication, Layer 3 forwarding devices can exist between the authentication client and the access device.

Direct authentication

A user manually configures a public IP address or obtains a public IP address through DHCP. Before authentication, the user can access only the portal Web server and predefined authentication-free websites. After passing authentication, the user can access other network resources. The process of direct authentication is simpler than that of re-DHCP authentication.

Re-DHCP authentication

Before a user passes authentication, DHCP allocates an IP address (a private IP address) to the user. The user can access only the portal Web server and predefined authentication-free websites. After the user passes authentication, DHCP reallocates an IP address (a public IP address) to the user. The user then can access other network resources. No public IP address is allocated to users who fail authentication. Re-DHCP authentication saves public IP addresses. For example, an ISP can allocate public IP addresses to broadband users only when they access networks beyond the residential community network.

Only the iNode client supports re-DHCP authentication. IPv6 portal authentication does not support the re-DHCP authentication mode.

Cross-subnet authentication

Cross-subnet authentication is similar to direct authentication, except it allows Layer 3 forwarding devices to exist between the authentication client and the access device.

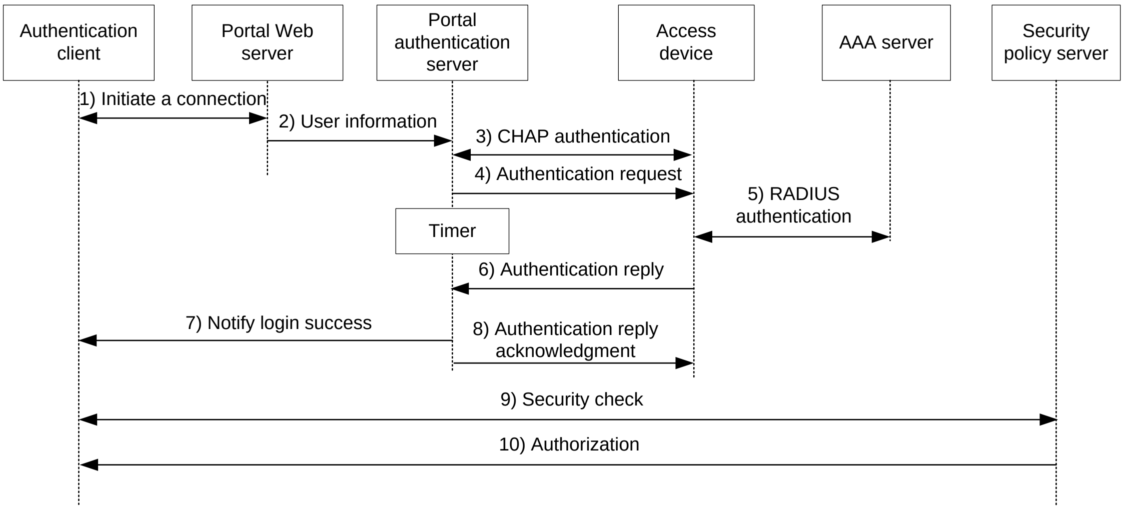
In direct authentication, re-DHCP authentication, and cross-subnet authentication, a user's IP address uniquely identifies the user. After a user passes authentication, the access device generates an ACL for the user based on the user's IP address to control forwarding of the packets from the user. Because no Layer 3 forwarding device exists between authentication clients and the access device in direct authentication and re-DHCP authentication, the access device can learn the user MAC addresses. The access device can enhance its capability of controlling packet forwarding by using the learned MAC addresses.

Portal authentication process

Direct authentication and cross-subnet authentication share the same authentication process. Re-DHCP authentication has a different process as it has two address allocation procedures.

Direct authentication/cross-subnet authentication process (with CHAP/PAP authentication)

Figure 3 Direct authentication/cross-subnet authentication process



The direct/cross-subnet authentication process is as follows:

1. A portal user access the Internet through HTTP or HTTPS, and the HTTP or HTTPS packet arrives at the access device.
   - If the packet matches a portal free rule, the access device allows the packet to pass.
   - If the packet does not match any portal-free rule, the access device redirects the packet to the portal Web server. The portal Web server pushes the Web authentication page to the user for him to enter his username and password.

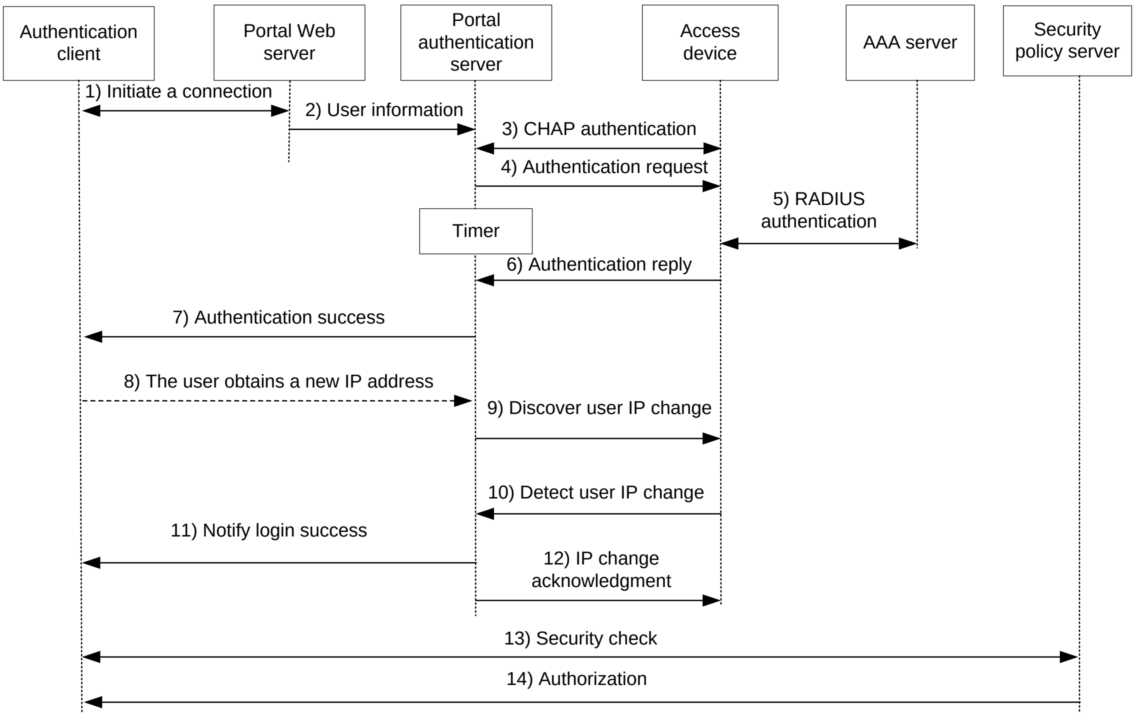
2. The portal Web server submits the user authentication information to the portal authentication server.
3. The portal authentication server and the access device exchange CHAP messages. This step is skipped for PAP authentication. The portal authentication server decides the method (CHAP or PAP) to use.
4. The portal authentication server adds the username and password into an authentication request packet and sends it to the access device. Meanwhile, the portal authentication server starts a timer to wait for an authentication reply packet.
5. The access device and the RADIUS server exchange RADIUS packets.
6. The access device sends an authentication reply packet to the portal authentication server to notify authentication success or failure.
7. The portal authentication server sends an authentication success or failure packet to the client.
8. If the authentication is successful, the portal authentication server sends an authentication reply acknowledgment packet to the access device.

If the client is an iNode client, the authentication process includes step 9 and step 10 for extended portal functions. Otherwise the authentication process is complete.

9. The client and the security policy server exchange security check information. The security policy server detects whether or not the user host installs anti-virus software, virus definition files, unauthorized software, and operating system patches.
10. The security policy server authorizes the user to access certain network resources based on the check result. The access device saves the authorization information and uses it to control access of the user.

Re-DHCP authentication process (with CHAP/PAP authentication)

Figure 4 Re-DHCP authentication process



The re-DHCP authentication process is as follows:

Step 1 through step 7 are the same as those in the direct authentication/cross-subnet authentication process.

8. After receiving the authentication success packet, the client obtains a public IP address through DHCP. The client then notifies the portal authentication server that it has a public IP address.
9. The portal authentication server notifies the access device that the client has obtained a public IP address.
10. The access device detects the IP change of the client through DHCP and then notifies the portal authentication server that it has detected an IP change of the client IP.
11. After receiving the IP change notification packets sent by the client and the access device, the portal authentication server notifies the client of login success.
12. The portal authentication server sends an IP change acknowledgment packet to the access device.

Step 13 and step 14 are for extended portal functions.

13. The client and the security policy server exchanges security check information. The security policy server detects whether or not the user host installs anti-virus software, virus definition files, unauthorized software, and operating system patches.
14. The security policy server authorizes the user to access certain network resources based on the check result. The access device saves the authorization information and uses it to control access of the user.

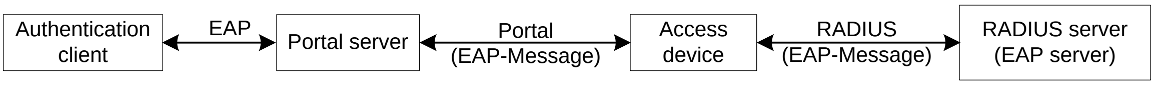
Portal support for EAP

To use portal authentication that supports EAP, the portal authentication server and client must be the IMC portal server and the iNode portal client. Local portal authentication does not support EAP authentication.

Compared with username and password based authentication, digital certificate-based authentication ensures higher security.

The Extensible Authentication Protocol (EAP) supports several digital certificate-based authentication methods, for example, EAP-TLS. Working together with EAP, portal authentication can implement digital certificate-based user authentication.

Figure 5 Portal support for EAP working flow diagram



As shown in Figure 5, the authentication client and the portal authentication server exchange EAP authentication packets. The portal authentication server and the access device exchange portal authentication packets that carry the EAP-Message attributes. The access device and the RADIUS server exchange RADIUS packets that carry the EAP-Message attributes. The RADIUS server that supports the EAP server function processes the EAP packets encapsulated in the EAP-Message attributes, and provides the EAP authentication result.

The access device does not process but only transports EAP-Message attributes between the portal authentication server and the RADIUS server. Therefore, the access device requires no additional configuration to support EAP authentication.

Portal filtering rules

The access device uses portal filtering rules to control user traffic forwarding.

Based on the configuration and authentication status of portal users, the device generates the following categories of portal filtering rules:

- **Category-1**—The rule permits user packets that are destined for the portal Web server and packets that match the portal-free rules to pass through.

- **Category-2**—For an authenticated user with no ACL authorized, the rule allows the user to access any destination network resources. For an authenticated user with an ACL authorized, the rule allows users to access resources permitted by the ACL. The device adds the rule when a user comes online and deletes the rule when the user goes offline.

  The device supports the following types of authorization ACLs:

  - Basic ACLs (ACL 2000 to ACL 2999).
  - Advanced ACLs (ACL 3000 to ACL 3999).

  For an authorization ACL to take effect, make sure the ACL exists and has ACL rules excluding rules configured with the **`counting`**, **`established`**, **`fragment`**, **`source-mac`**, or **`logging`** keyword. For more information about ACL rules, see ACL commands in *ACL and QoS Command Reference*.
- **Category-3**—The rule redirects all HTTP or HTTPS requests from unauthenticated users to the portal Web server.
- **Category-4**—For direct authentication and cross-subnet authentication, the rule forbids any user packets to pass through. For re-DHCP authentication, the device forbids user packets with private source addresses to pass.

After receiving a user packet, the device compares the packet against the filtering rules from category-1 to category-4. Once the packet matches a rule, the matching process completes.

MAC-based quick portal authentication

MAC-based quick portal authentication is applicable to scenarios where users access the network frequently. It allows users to pass authentication without entering a username and password. MAC-based quick portal authentication is also called MAC-trigger authentication or transparent portal authentication.

A MAC binding server is required for MAC-trigger authentication. The MAC binding server records the MAC-to-account bindings of portal users for authentication. The account contains the portal authentication information of the user, including username and password.

Only IPv4 direct authentication supports MAC-based quick portal authentication.

The authentication is implemented as follows:

1. When a user accesses the network for the first time, the access device generates a MAC-trigger entry that records the user's MAC address and access interface. The user can access the network without performing portal authentication if the user's network traffic is below the free-traffic threshold.
2. When the user's network traffic reaches the threshold, the access device sends a MAC binding query to the MAC binding server.
3. The MAC binding server checks whether the MAC address of the user is bound with a portal user account.
   - If a matching MAC-account binding exists, the MAC binding server sends the user authentication information to the access device to initiate portal authentication. The user is authenticated without entering the username and password.
     - If the user fails portal authentication, an authentication failure message is returned to the user. The MAC-trigger entry of the user on the access device is deleted when the entry ages out.
     - If the user passes portal authentication, the access device deletes the MAC-trigger entry of the user.
   - If no matching MAC-account binding exists, the MAC binding server notifies the access device to perform normal portal authentication for the user.
     - If the user fails portal authentication, an authentication failure message is returned to the user. The whole process is finished.

– If the user passes portal authentication, the access device sends the user's MAC address and authentication information to the MAC binding server for MAC-account binding. Additionally, the access device deletes the MAC-trigger entry of the user.

NOTE:

- For information about MAC binding server configuration, see the user manual of the server.

Portal support for NAT444

On a network where portal is used in conjunction with NAT444, portal and NAT444 cooperate as follows:

1. After a portal user passes AAA authentication and is assigned a private IP address, portal notifies NAT444 of the user login.
2. The NAT444 gateway assigns a public IP address and a port block to the portal user. Then, it sends the user private address, public address, and port block mapping to portal.

   On the NAT444 gateway, if no public IP address is available to allocate to the user, portal logs out the user.
3. Portal records the mapping, and reports the mapping to the AAA server. Then, the portal user can use the public IP address and port block to access the external network.

Through the portal and NAT444 cooperation, the AAA server can obtain and maintain NAT mapping information for all portal users, which facilitates user tracing.

To use portal in conjunction with NAT444, specify the user address type as private IPv4 address in the authentication ISP domain for portal users by using the **`user-address-type private-ipv4`** command. For more information about specifying the user address type in an ISP domain, see "Configuring AAA." For more information about NAT444, see NAT in *Layer 3—IP Services Configuration Guide*.

Restrictions and guidelines: Portal configuration

In portal authentication, the device can redirect users' HTTPS requests to the portal Web server. You can use one of the following local certificates for the HTTPS redirect service according to the security requirements and the configuration complexity:

- **Self-signed certificate**—Using this type of certificate is simple in configuration but has low security. You do not need to associate an SSL server policy with the HTTPS redirect service and the default SSL parameters are used. However, a self-signed certificate is not trusted by the browser. When the device redirects HTTPS requests to the portal Web server, a certificate security warning prompt might appear on the browser. If you accept the security risks stated in the prompt, you can ignore the prompt to browse the page.
- **CA-signed certificate**—Using this type of certificate is complex in configuration but has high security. You must obtain a CA certificate, request a local certificate from the CA, create an SSL server policy (with policy name of **https_redirect**), and associate the SSL server policy with the HTTPS redirect service.

For more information about digital certificates, see "Configuring PKI." For more information about the SSL server policy configuration, see "Configuring SSL."

Portal authentication through Web does not support security check for users. To implement security check, the client must be the iNode client.

Portal authentication supports NAT traversal whether it is initiated by a Web client or an iNode client. NAT traversal must be configured when the portal client is on a private network and the portal server is on a public network.

Portal authentication tasks at a glance

To configure portal authentication, perform the following tasks:

1. Configuring a remote portal service

   Perform this task if a remote portal server is used.

   - Configuring a remote portal authentication server
   - Configuring a portal Web server
2. Configuring a local portal service

   Perform this task if the access device acts as a portal authentication server and portal Web server.

   - Configuring the local portal service features
   - Configuring a portal Web server
3. Enabling portal authentication and specifying a portal Web server

   Choose the options to configure on an interface.

   - Enabling portal authentication on an interface
   - Specifying a portal Web server on an interface
4. (Optional.) Configure parameters for preauthentication portal users
   - Configuring a portal preauthentication domain
   - Specifying a preauthentication IP address pool
5. (Optional.) Specifying a portal authentication domain
6. (Optional.) Controlling portal user access
   - Configuring a portal-free rule
   - Configuring an authentication source subnet
   - Configuring an authentication destination subnet
   - Configuring a portal-forbidden rule
   - Specifying port numbers of Web proxy servers
   - Setting the maximum number of portal users
   - Enabling strict-checking on portal authorization information
   - Allowing only users with DHCP-assigned IP addresses to pass portal authentication
   - Blocking portal users that fail portal authentication
   - Configuring support of portal authentication for dual stack
   - Enabling intra-VLAN roaming for portal users
   - Enabling outgoing packets filtering
   - Configuring the portal fail-permit feature
7. (Optional.) Configuring portal detection features
   - Configuring online detection of portal users
   - Configuring portal authentication server detection
   - Configuring portal Web server detection
   - Enabling DHCP packet capture
   - Configuring portal user synchronization
8. (Optional.) Configuring attributes for portal packets and RADIUS packets
   - Configuring portal packet attributes

     You can configure the BAS-IP or BAS-IPv6 attribute for portal packets and specify the device ID.

   - Configuring attributes for RADIUS packets

     You can configure the NAS-Port-Id attribute and apply a NAS-ID profile to an interface.

9. (Optional.) Configuring MAC-based quick portal authentication
   a. Configuring a remote MAC binding server
   b. Configuring a local MAC binding server
   c. Specifying a MAC binding server on an interface
   d. Configure cloud MAC-trigger authentication
10. (Optional.) Configuring online and offline related features for portal users
    - Logging out online portal users
11. (Optional.) Configuring extended portal authentication features
    - Setting the user traffic backup threshold
    - Disabling the Rule ARP or ND entry feature for portal clients
    - Disabling traffic accounting for portal users
    - Configuring Web redirect
    - Configuring portal safe-redirect
    - Setting the maximum number of portal redirection sessions for a single user
    - Excluding an attribute from portal protocol packets
    - Configuring support of portal authentication for third-party authentication
    - Setting the user synchronization interval for portal authentication using OAuth
    - Configuring user synchronization for portal authentication using the WiFiDog protocol
    - Configuring portal authentication information report interval
    - Configuring portal advertisement push
12. (Optional.) Monitoring portal authentication
    - Enabling portal logging
    - Configuring the portal authentication monitoring feature

Prerequisites for portal authentication

The portal feature provides a solution for user identity authentication and security check. To complete user identity authentication, portal must cooperate with RADIUS.

Before you configure portal, you must complete the following tasks:

- The portal authentication server, portal Web server, and RADIUS server have been installed and configured correctly.
- To use the re-DHCP portal authentication mode, make sure the DHCP relay agent is enabled on the access device, and the DHCP server is installed and configured correctly.
- The portal client, access device, and servers can reach each other.
- To use the remote RADIUS server, configure usernames and passwords on the RADIUS server, and configure the RADIUS client on the access device. For information about RADIUS client configuration, see "Configuring AAA."
- To implement extended portal functions, install and configure IMC EAD. Make sure the ACLs configured on the access device correspond to the isolation ACL and the security ACL on the security policy server. For information about security policy server configuration on the access device, see "Configuring AAA." For installation and configuration about the security policy server, see *IMC EAD Security Policy Help*.

Configuring a remote portal authentication server

About this task

With portal authentication enabled, the device searches for a portal authentication server for a received portal request packet according to the source IP address and VPN instance information of the packet.

- If a matching portal authentication server is found, the device regards the packet valid and sends an authentication response packet to the portal authentication server. After a user logs in to the device, the user interacts with the portal authentication server as needed.
- If no matching portal authentication server is found, the device drops the packet.

Restrictions and guidelines

Do not delete a portal authentication server in use. Otherwise, users authenticated by that server cannot log out correctly.

Procedure

1. Enter system view.

   system-view

2. Create a portal authentication server and enter its view.

   portal server *server-name*

   You can create multiple portal authentication servers.

3. Specify the IP address of the portal authentication server.

   IPv4:

   ip *ipv4-address* [**vpn-instance** *vpn-instance-name*] [**key** { **cipher** | **simple** } *string*]

   IPv6:

   ipv6 *ipv6-address* [**vpn-instance** *vpn-instance-name*] [**key** { **cipher** | **simple** } *string*]

4. (Optional.) Set the destination UDP port number used by the device to send unsolicited portal packets to the portal authentication server.

   port *port-number*

   By default, the UDP port number is 50100.

   This port number must be the same as the listening port number specified on the portal authentication server.

5. (Optional.) Specify the portal authentication server type.

   server-type { **cmcc** | **imc** }

   By default, the portal authentication server type is IMC.

   The specified server type must be the same as the type of the portal authentication server actually used.

6. (Optional.) Set the maximum number of times and the interval for retransmitting a logout notification packet.

   logout-notify retry *retries* **interval** *interval*

   By default, the device does not retransmit a logout notification packet.

7. (Optional.) Configure the device to periodically register with the portal authentication server.

   server-register [**interval** *interval-value*]

   By default, the device does not register with a portal authentication server.

Configuring a portal Web server

Portal Web server tasks at a glance

To configure a portal Web server, perform the following tasks:

1. Configure basic parameters for a portal Web server
2. (Optional.) Enabling the captive-bypass feature
3. (Optional.) Configuring a match rule for URL redirection

Configure basic parameters for a portal Web server

1. Enter system view.

   `system-view`

2. Create a portal Web server and enter its view.

   `portal web-server` *`server-name`*

   You can create multiple portal Web servers.

3. Specify the VPN instance to which the portal Web server belongs.

   `vpn-instance` *`vpn-instance-name`*

   By default, the portal Web server belongs to the public network.

4. Specify the URL of the portal Web server.

   `url` *`url-string`*

   By default, no URL is specified for a portal Web server.

5. Configure the parameters to be carried in the URL when the device redirects it to users.

   `url-parameter` *`param-name`* { **`nas-id`** | **`nas-port-id`** | **`original-url`** | **`source-address`** | **`source-mac`** [**`format`** **`section`** { **`1`** | **`3`** | **`6`** } { **`lowercase`** | **`uppercase`** }] [**`encryption`** { **`aes`** | **`des`** } **`key`** { **`cipher`** | **`simple`** } *`string`*] | **`value`** *`expression`* | **`vlan`** }

   By default, no redirection URL parameters are configured.

6. (Optional.) Specify the portal Web server type.

   `server-type` { **`cmcc`** | **`imc`** | **`ise`** | **`oauth`** | **`wifidog`** }

   By default, the portal Web server type is IMC.

   This configuration is applicable to only to the remote portal service.

   The specified server type must be the same as the type of the portal Web server actually used.

Enabling the captive-bypass feature

About this task

Typically, when iOS mobile devices or some Android mobile devices are connected a portal-enabled network, the device pushes the authentication page to the mobile devices.

The captive-bypass feature enables the device to push the portal authentication page to the iOS and Android devices only when the users access the Internet by using a browser. If the users do not perform authentication but press the home button to return to the desktop, the Wi-Fi connection is terminated. To maintain the Wi-Fi connection in such cases, you can enable the optimized captive-bypass feature.

When optimized captive-bypass is enabled, the portal authentication page is automatically pushed to iOS mobile devices after they connects to the network. Users can perform authentication on the page or press the home button to return to the desktop without performing authentication, and the Wi-Fi connection is not terminated.

When an iOS client is connected to a network, it automatically sends a server reachability detection packet to determine whether the Apple server is reachable. If the server is reachable, the Wi-Fi connection displays connected. If the server is not reachable, the Wi-Fi connection is terminated.

When the network condition is poor, the device cannot detect a server reachability detection packet from an iOS mobile client within the captive-bypass detection timeout time. The client cannot receive a response for the server reachability detection packet, and therefore it determines the server to be unreachable and terminates the Wi-Fi connection. To avoid Wi-Fi disconnections caused by server reachability detection failure, set a longer captive-bypass detection timeout time when the network condition is poor.

Procedure

1. Enter system view.

   `system-view`

2. Enter portal Web server view.

   `portal web-server` *`server-name`*

3. Enable the captive-pass feature.

   `captive-bypass` [**`android`** | **`ios`** [**`optimize`**]] **`enable`**

   By default, the captive-bypass feature is disabled. The device automatically pushes the portal authentication page to iOS mobile devices and some Android mobile devices when they are connected to a portal-enabled network.

4. (Optional.) Set the captive-bypass detection timeout time.

   a. Return to system view.

      `quit`

   b. Set the captive-bypass detection timeout time.

      `portal captive-bypass optimize delay` *`seconds`*

      By default, the captive-bypass detection timeout time is 6 seconds.

Configuring a match rule for URL redirection

About this task

A URL redirection match rule matches HTTP or HTTPS requests by user-requested URL or User-Agent information, and redirects the matching HTTP or HTTPS requests to the specified redirection URL.

For a portal Web server, you can configure the **`url`** command and the **`if-match`** command for URL redirection. The **`url`** command redirects all HTTP or HTTPS requests from unauthenticated users to the portal Web server for authentication. The **`if-match`** command allows for flexible URL redirection by redirecting specific HTTP or HTTPS requests to specific redirection URLs.

Restrictions and guidelines

For a user to successfully access a redirection URL, configure a portal-free rule to allow HTTP or HTTPS requests destined for the redirection URL to pass. For information about configuring portal-free rules, see the **`portal free-rule`** command.

If both the **`url`** and **`if-match`** commands are executed, the **`if-match`** command takes priority to perform URL redirection.

If both portal safe-redirect and URL redirection match rules are configured, the device preferentially uses URL redirection match rules to perform URL redirection.

Procedure

1. Enter system view.

   `system-view`

2. Enter portal Web server view.

   `portal web-server` *`server-name`*

3. Configure a match rule for URL redirection.

   `if-match` { **`original-url`** *`url-string`* **`redirect-url`** *`url-string`* [**`url-param-encryption`** { **`aes`** | **`des`** } **`key`** { **`cipher`** | **`simple`** } *`string`*] | **`user-agent`** *`string`* **`redirect-url`** *`url-string`* }

Configuring the local portal service features

About the local portal service

After a local portal service is configured, the device acts as the portal Web server and portal authentication server to perform portal authentication on users. The portal authentication page file is saved in the root directory of the device.

Restrictions and guidelines for configuring local portal service features

For an interface to use the local portal service, the URL of the portal Web server specified for the interface must meet the following requirements:

- The IP address in the URL must be the IP address of a Layer 3 interface (except 127.0.0.1) on the device, and the IP address must be reachable to portal clients.
- The URL must be ended with **/portal/**. For example: **http://1.1.1.1/portal/**.

You must customize the authentication pages and upload them to the device.

Customizing authentication pages

About this task

Authentication pages are HTML files. Local portal authentication requires the following authentication pages:

- Logon page
- Logon success page
- Logon failure page
- Online page
- System busy page
- Logoff success page

You must customize the authentication pages, including the page elements that the authentication pages will use, for example, **back.jpg** for authentication page **Logon.htm**.

Follow the authentication page customization rules when you edit the authentication page files.

File name rules

The names of the main authentication page files are fixed (see Table 1). You can define the names of the files other than the main authentication page files. File names and directory names are case insensitive.

Table 1 Main authentication page file names

Main authentication page	File name
Logon page	logon.htm
Logon success page	logonSuccess.htm
Logon failure page	logonFail.htm
Online page Pushed after the user gets online for online notification	online.htm
System busy page Pushed when the system is busy or the user is in the logon process	busy.htm
Logoff success page	logoffSuccess.htm

Page request rules

A local portal Web service supports only Get and Post requests.

- **Get requests**—Used to get the static files in the authentication pages and allow no recursion. For example, if file **Logon.htm** includes contents that perform Get action on file **ca.htm**, file **ca.htm** cannot include any reference to file **Logon.htm**.
- **Post requests**—Used when users submit username and password pairs, log in, and log out.

Post request attribute rules

1. Observe the following requirements when editing a form of an authentication page:
   - An authentication page can have multiple forms, but there must be one and only one form whose action is **logon.cgi**. Otherwise, user information cannot be sent to the access device.
   - The username attribute is fixed as **PtUser**. The password attribute is fixed as **PtPwd**.
   - The value of the **PtButton** attribute is either **Logon** or **Logoff**, which indicates the action that the user requests.
   - A logon Post request must contain **PtUser**, **PtPwd**, and **PtButton** attributes.
   - A logoff Post request must contain the **PtButton** attribute.
2. Authentication pages **logon.htm** and **logonFail.htm** must contain the logon Post request.

   The following example shows part of the script in page **logon.htm**.

   ```
   <form action=logon.cgi method = post >
   <p>User name:<input type="text" name = "PtUser" style="width:160px;height:22px" maxlength=64>
   <p>Password :<input type="password" name = "PtPwd" style="width:160px;height:22px" maxlength=32>
   <p><input type=SUBMIT value="Logon" name = "PtButton" style="width:60px;" onclick="form.action=form.action+location.search;">
   </form>
   ```
3. Authentication pages **logonSuccess.htm** and **online.htm** must contain the logoff Post request.

   The following example shows part of the script in page **online.htm**.

   ```
   <form action=logon.cgi method = post >
   ```

```
<p><input type=SUBMIT value="Logoff" name="PtButton" style="width:60px;">
</form>
```

Page file compression and saving rules

You must compress the authentication pages and their page elements into a standard zip file.

- The name of a zip file can contain only letters, numbers, and underscores.
- The authentication pages must be placed in the root directory of the zip file.
- Zip files can be transferred to the device through FTP or TFTP and must be saved in the root directory of the device.

  Examples of zip files on the device:

  ```
  <Sysname> dir
  Directory of flash:
     1     -rw-      1405  Feb 28 2008 15:53:20   abc1.zip
     0     -rw-      1405  Feb 28 2008 15:53:31   abc2.zip
     2     -rw-      1405  Feb 28 2008 15:53:39   abc3.zip
     3     -rw-      1405  Feb 28 2008 15:53:44   abc4.zip
  2540 KB total (1319 KB free)
  ```

Redirecting authenticated users to a specific webpage

To make the device automatically redirect authenticated users to a specific webpage, do the following in logon.htm and logonSuccess.htm:

1. In logon.htm, set the target attribute of Form to **_blank**.

   See the contents in gray:

   ```
       <form method=post action=logon.cgi target="_blank">
   ```

2. Add the function for page loading pt_init() to LogonSuccess.htm.

   See the contents in gray:

   ```
       <html>
       <head>
       <title>LogonSuccess</title>
       <script type="text/javascript" language="javascript"
   src="pt_private.js"></script>
       </head>
       <body onload="pt_init();" onbeforeunload="return pt_unload();">
       ... ...
       </body>
   </html>
   ```

Configuring a local portal Web service

Prerequisites

Before you configure an HTTPS-based local portal Web service, you must complete the following tasks:

- Configure a PKI policy, obtain the CA certificate, and request a local certificate. For more information, see "Configuring PKI."
- Configure an SSL server policy, and specify the PKI domain configured in the PKI policy.

  During SSL connection establishment, the user browser might display a message that it cannot verify server identity by certificate. For users to perform portal authentication without checking such a message, configure an SSL server policy to request a client-trusted certificate on the device. The name of the policy must be **https_redirect**. For more information about SSL server policy configuration, see "Configuring SSL."

Procedure

1. Enter system view.

   system-view

2. Create an HTTP- or HTTPS-based local portal Web service and enter its view.

   portal local-web-server { **http** | **https** [**ssl-server-policy** *policy-name*] [**tcp-port** *port-number*] }

3. Specify the default authentication page file for the local portal Web service.

   default-logon-page *filename*

   The default setting varies by device model. For more information, see the command reference.

4. (Optional.) Configure the listening TCP port for the local portal Web service.

   tcp-port *port-number*

   By default, the HTTP service listening port number is 80 and the HTTPS service listening port number is the TCP port number set by the **portal local-web-server** command.

1. (Optional.) Bind an endpoint type to an authentication page file.

   logon-page bind { **device-type** { **computer** | **pad** | **phone** } | **device-name** *device-name* } * **file** *file-name*

   By default, no endpoint type is bound to an authentication page file.

2. (Optional.) Enable local portal user password modification.

   user-password modify enable

   By default, local portal user password modification is disabled.

   If global password control is enabled by using the **password-control enable network-class** command, the new password of a local portal user must meet the password control requirements. For more information about password control, see "Configuring password control."

3. Configure the redirect URL for authentication success.

   login success-url *url*-string

   By default, no redirection URL for authentication success is configured.

4. Configure the redirect URL for authentication failure.

   login failed-url *url*-string

   By default, no redirection URL for authentication failure is configured.

Configuring the User-Agent match string

About this task

When portal users use third-party software to perform portal authentication, the device checks the User-Agent string in portal authentication requests. If the User-Agent string does not include the match string specified on the device, users will fail portal authentication.

The User-Agent string includes hardware vendor, software operating system, browser, and search engine information. Perform this task to specify a string that can match the User-Agent information of the third-party software, so users can pass portal authentication by using that third-party software. For example, for users to pass portal authentication by following a WeChat official account, configure the User-Agent match string on the device as **MicroMessenger**.

Procedure

1. Enter system view.

system-view

2. Enter local portal Web service view.

   portal local-web-server { **http** | **https** [**ssl-server-policy** *policy-name*] [**tcp-port** *port-number*] }

3. Configure the User-Agent match string.

   user-agent *user-agent-string*

   By default, the User-Agent match string is **MicroMessenger**.

Enabling portal authentication on an interface

Restrictions and guidelines

When you enable portal authentication on an interface, follow these restrictions and guidelines:

- For portal authentication to take effect on an Ethernet interface, do not add the Ethernet interface to an aggregation group.
- Cross-subnet authentication mode (**layer3**) does not require Layer 3 forwarding devices between the access device and the portal authentication clients. However, if a Layer 3 forwarding device exists between the authentication client and the access device, you must use the cross-subnet portal authentication mode.
- You can enable both IPv4 portal authentication and IPv6 portal authentication on an interface.

When you configure re-DHCP portal authentication on an interface, follow these restrictions and guidelines:

- Make sure the interface has a valid IP address before you enable re-DHCP portal authentication on the interface.
- With re-DHCP portal authentication, configure authorized ARP on the interface as a best practice to make sure only valid users can access the network. With authorized ARP configured on the interface, the interface learns ARP entries only from the users who have obtained a public address from DHCP.
- For successful re-DHCP portal authentication, make sure the BAS-IP or BAS-IPv6 attribute value is the same as the device IP address specified on the portal authentication server. To configure the attribute, use the **portal** { **bas-ip** | **bas-ipv6** } command.
- An IPv6 portal server does not support re-DHCP portal authentication.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Enable portal authentication.

   IPv4:

   portal enable method { **direct** | **layer3** | **redhcp** }

   IPv6:

   portal ipv6 enable method { **direct** | **layer3** }

   By default, portal authentication is disabled.

Specifying a portal Web server on an interface

About this task

With a portal Web server specified on an interface, the device redirects the HTTP requests of portal users on the interface to the portal Web server.

You can specify both an IPv4 portal Web server and an IPv6 portal Web server on an interface.

Procedure

1. Enter system view.
   `system-view`
2. Enter Layer 3 interface view.
   `interface` *`interface-type interface-number`*
3. Specify a portal Web server on the interface.
   `portal` [**`ipv6`**] **`apply web-server`** *`server-name`* [**`secondary`**]
   By default, no portal Web servers are specified on an interface.

Configuring a portal preauthentication domain

About this task

A portal preauthentication domain defines user attributes assigned to preauthentication portal users on a portal-enabled interface after the users obtain IP addresses. Before the preauthentication users pass portal authentication, they have limited access to the network based on the assigned user attributes (such as ACL and CAR). After the users pass portal authentication, they are assigned new attributes by the AAA server. After the users go offline, they are re-assigned user attributes in the preauthentication domain.

Restrictions and guidelines

The portal preauthentication domain takes effect only on portal users with IP addresses obtained through DHCP or DHCPv6.

The portal preauthentication domain does not take effect on interfaces enabled with cross-subnet portal authentication.

Make sure you specify an existing ISP domain as a portal preauthentication domain. If the specified ISP domain does not exist, the device might operate incorrectly.

You must delete a preauthentication domain (by using the **`undo portal`** [**`ipv6`**] **`pre-auth domain`** command) and reconfigure it in the following situations:

- You create the ISP domain after specifying it as the preauthentication domain.
- You delete the specified ISP domain and then re-create it.

For the authorization ACL in the preauthentication domain, the following rules apply:

- If the traffic of preauthentication users matches a rule in the ACL, the device processes the traffic based on the permit or deny statement of the rule.
- If the ACL does not exist or the destination address permitted by a rule in the ACL is set to **`any`**, the device does not control user access. Users can access any network resources without passing portal authentication.
- If the ACL does not have any rules, the device allows users to access network resources only after the users pass authentication.

- If the traffic of preauthentication users does not match any rule in the ACL, the device pushes the authentication page to the users. The users can access the network resources after passing authentication.
- If the ACL contains rules that specify a source address, users might not be able to get online. Do not specify a source IPv4, IPv6, or MAC address when you configure a rule in the ACL.

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 3 interface view.

   `interface` *`interface-type interface-number`*

3. Specify a portal preauthentication domain.

   `portal` `[` **`ipv6`** `]` **`pre-auth domain`** *`domain-name`*

   By default, no portal preauthentication domain is specified.

Specifying a preauthentication IP address pool

About this task

You must specify a preauthentication IP address pool on a portal-enabled Layer 3 interface in the following situation:

- Portal users access the network through a subinterface of the portal-enabled Layer 3 interface.
- The subinterface does not have an IP address.
- Portal users need to obtain IP addresses through DHCP.

After a user connects to a portal-enabled interface, the user uses an IP address for portal authentication according to the following rules:

- If the interface is configured with a preauthentication IP address pool, the user uses the following IP address:
  - If the client is configured to obtain an IP address automatically through DHCP, the user obtains an address from the specified IP address pool.
  - If the client is configured with a static IP address, the user uses the static IP address. However, if the interface does not have an IP address, users using static IP addresses cannot pass authentication.
- If the interface has an IP address but no preauthentication IP pool specified, the user uses the static IP address or the IP address obtained from a DHCP server.
- If the interface has no IP address or preauthentication IP pool specified, the user cannot perform portal authentication.

After the user passes portal authentication, the AAA server authorizes an IP address pool for re-assigning an IP address to the user. If no authorized IP address pool is deployed, the user continues using the previous IP address.

Restrictions and guidelines

This configuration takes effect only when the direct IPv4 portal authentication is enabled on the interface.

Make sure the specified IP address pool exists and is complete. Otherwise, the user cannot obtain the IP address and cannot perform portal authentication.

If the portal user does not perform authentication or fails to pass authentication, the assigned IP address is still retained.

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 3 interface view.

   `interface` *`interface-type interface-number`*

3. Specify a preauthentication IP address pool on the interface.

   `portal` [**`ipv6`**] **`pre-auth ip-pool`** *`pool-name`*

   By default, no preauthentication IP address pool is specified on an interface.

Specifying a portal authentication domain

About portal authentication domains

An authentication domain defines a set of authentication, authorization, and accounting policies. Each portal user belongs to an authentication domain and is authenticated, authorized, and accounted in the domain.

With an authentication domain specified on an interface, the device uses the authentication domain for AAA of portal users. This allows for flexible portal access control.

Restrictions and guidelines for specifying a portal authentication domain

The device selects the authentication domain for a portal user in this order:

1. ISP domain specified for the interface.
2. ISP domain carried in the username.
3. System default ISP domain.

If the chosen domain does not exist on the device, the device searches for the ISP domain configured to accommodate users assigned to nonexistent domains. If no such ISP domain is configured, user authentication fails. For information about ISP domains, see "Configuring AAA."

If an authorization VPN instance is specified in the authentication domain, follow these restrictions and guidelines:

- Make sure the authorization VPN instance exists. If you specify a nonexistent VPN instance, users cannot come online.
- When users are online, do not delete the authorization VPN instance. Deleting the authorization VPN instance will log out the users.

For the authorization ACL in the authentication domain, the following rules apply:

- If the user traffic matches a rule in the ACL, the device processes the traffic based on the permit or deny statement of the rule.
- If the user traffic does not match any rule in the ACL, the device permits the traffic. To deny such traffic, configure the last rule in the ACL to deny all packets by using the **`rule deny ip`** command.
- If the ACL contains rules that specify a source address, users might not be able to get online. Do not specify a source IPv4, IPv6, or MAC address when you configure a rule in the ACL.

Specifying a portal authentication domain on an interface

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Specify an portal authentication domain on the interface.

   portal [**ipv6**] **domain** *domain-name*

   By default, no portal authentication domain is specified on an interface.

   You can specify both an IPv4 portal authentication domain and an IPv6 portal authentication domain on an interface.

Controlling portal user access

Configuring a portal-free rule

About this task

A portal-free rule allows specified users to access specified external websites without portal authentication.

The matching items for a portal-free rule include the host name, source/destination IP address, TCP/UDP port number, source MAC address, access interface, and VLAN. Packets matching a portal-free rule will not trigger portal authentication, so users sending the packets can directly access the specified external websites.

Restrictions and guidelines for configuring a portal-free rule

If you specify both a VLAN and an interface, the interface must belong to the VLAN. If the interface does not belong to the VLAN, the portal-free rule does not take effect.

You cannot configure two or more portal-free rules with the same filtering criteria. Otherwise, the system prompts that the rule already exists.

Regardless of whether portal authentication is enabled or not, you can only add or remove a portal-free rule. You cannot modify it.

The ACL used by a portal-free rule can contain only IP address object groups and IP quintuples (source and destination IP addresses, source and destination port numbers, and transport layer protocol).

Configuring an IP-based portal-free rule

1. Enter system view.

   system-view

2. Configure an IP-based portal-free rule.

   IPv4:

   portal free-rule *rule-number* { **destination ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-numbe*r | **udp** *udp-port-number*] | **source ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] } * [**interface** *interface-type interface-number*]

   IPv6:

   portal free-rule *rule-number* { **destination ipv6** { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-numbe*r | **udp** *udp-port-number*] |

source ipv6 { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] } * [**interface** *interface-type interface-number*]

By default, no IP-based portal-free rules are configured.

Configuring a source-based portal-free rule

1. Enter system view.

   system-view

2. Configure a source-based portal-free rule.

   portal free-rule *rule-number* **source** { **interface** *interface-type interface-number* | **mac** *mac-address* | **object-group** *object-group-name* | **vlan** *vlan-id* } * }

   By default, no source-based portal-free rules are configured.

   The **vlan** *vlan-id* option takes effect only on portal users that access the network through VLAN interfaces.

Configuring a destination-based portal-free rule

1. Enter system view.

   system-view

2. Configure a destination-based portal-free rule.

   portal free-rule *rule-number* **destination** *host-name*

   By default, no destination-based portal-free rules are configured.

   Before you configure destination-based portal-free rules, make sure a DNS server has been deployed in the network.

Configuring an ACL-based portal-free rule

1. Enter system view.

   system-view

2. Configure an ACL-based portal-free rule.

   IPv4:

   portal free-rule *rule-number* **acl** *acl-number*

   IPv6:

   portal free-rule *rule-number* **acl ipv6** *acl-number*

Configuring a description for a portal-free rule

1. Enter system view.

   system-view

2. Configure a description for a portal-free rule.

   portal free-rule *rule-number* **description** *text*

   By default, no description is configured for a portal-free rule.

Configuring an authentication source subnet

About this task

By configuring authentication source subnets, you specify that only HTTP or HTTPS packets from users on the authentication source subnets can trigger portal authentication. If an unauthenticated user is not on any authentication source subnet, the access device discards all the user's HTTP or HTTPS packets that do not match any portal-free rule.

Restrictions and guidelines

Authentication source subnets apply only to cross-subnet portal authentication.

In direct or re-DHCP portal authentication mode, a portal user and its access interface (portal-enabled) are on the same subnet. It is not necessary to specify the subnet as the authentication source subnet.

- In direct mode, the access device regards the authentication source subnet as any source IP address.
- In re-DHCP mode, the access device regards the authentication source subnet on an interface as the subnet to which the private IP address of the interface belongs.

If both authentication source subnets and destination subnets are configured on an interface, only the authentication destination subnets take effect.

You can configure multiple authentication source subnets. If the source subnets overlap, the subnet with the largest address scope (with the smallest mask or prefix) takes effect.

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 3 interface view.

   `interface` *`interface-type interface-number`*

3. Configure a portal authentication source subnet.

   IPv4:

   `portal layer3 source` *`ipv4-network-address`* { *`mask-length`* | *`mask`* }

   By default, users from any subnets must pass portal authentication.

   IPv6:

   `portal ipv6 layer3 source` *`ipv6-network-address prefix-length`*

   By default, users from any subnets must pass portal authentication.

Configuring an authentication destination subnet

About this task

By configuring authentication destination subnets, you specify that users trigger portal authentication only when they accessing the specified subnets (excluding the destination IP addresses and subnets specified in portal-free rules). Users can access other subnets without portal authentication.

Restrictions and guidelines

If both authentication source subnets and destination subnets are configured on an interface, only the authentication destination subnets take effect.

You can configure multiple authentication destination subnets. If the destination subnets overlap, the subnet with the largest address scope (with the smallest mask or prefix) takes effect.

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 3 interface view.

   `interface` *`interface-type interface-number`*

3. Configure a portal authentication destination subnet.

   IPv4:

portal free-all except destination *ipv4-network-address* { *mask-length* | *mask* }

IPv6:

portal ipv6 free-all except destination *ipv6-network-address prefix-length*

By default, users accessing any subnets must pass portal authentication.

Configuring a portal-forbidden rule

About this task

Portal-forbidden rules are used to filter user packets from the specified sources or destined for the specified destinations. The device drops HTTP or HTTPS packets that match the portal-forbidden rules.

Restrictions and guidelines

In a portal-forbidden rule, the source and destination IP addresses must be of the same IP type, and the source and destination ports must be of the same transport protocol type.

You can configure multiple portal-forbidden rules.

If the source or destination information in a portal-free rule and that in a portal-forbidden rule overlap, the portal-forbidden rule takes effect.

If you specify a destination host name in a portal-forbidden rule, the device drops users' DNS query packets for the specified host name. In addition, if a DNS server is correctly configured on the device, the device also drops user packets destined for the IP address resolved from the specified host name. If the DNS server is not correctly configured, the rule does not take effect on user packets destined for that IP address.

Procedure

1. Enter system view.

   system-view

2. Configure a portal-forbidden rule.

   IPv4:

portal forbidden-rule *rule-number* [**source** { **ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] | **ssid** *ssid-name* } *] **destination** { *host-name* | **ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] }

   IPv6:

   portal forbidden-rule *rule-number* [**source** { **ipv6** { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] | **ssid** *ssid-name* } *] **destination** { *host-name* | **ipv6** { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] }

   By default, portal-forbidden rules are configured.

Specifying port numbers of Web proxy servers

About this task

To allow HTTP or HTTPS requests proxied by Web proxy servers to trigger portal authentication, specify the port numbers of the Web proxy servers on the device. If a Web proxy server port is not specified on the device, HTTP or HTTPS requests proxied by the Web proxy server are dropped, and portal authentication cannot be triggered.

Restrictions and guidelines

Do not specify TCP port number 80 or 443 as the port numbers for Web proxy servers because 80 and 443 are port numbers reserved for portal.

You can specify a maximum of 64 Web proxy server ports for HTTP and HTTPS.

Do not specify the same Web proxy server port for HTTP and HTTPS.

If a user's browser uses the Web Proxy Auto-Discovery (WPAD) protocol to discover Web proxy servers, you must perform the following tasks on the device:

- Specify the port numbers of the Web proxy servers on the device.
- Configure portal-free rules to allow user packets destined for the IP address of the WPAD server to pass without authentication.

If portal users enable Web proxy in their browsers, the users must add the IP address of the portal authentication server as a proxy exception in their browsers. Then, HTTP or HTTPS packets that the users send to the portal authentication server will not be sent to Web proxy servers.

Procedure

1. Enter system view.

   system-view

2. Specify the port number of a Web proxy server.

   portal web-proxy { **http** | **https** } **port** *port-number*

   By default, no port numbers of Web proxy servers are specified. Proxied HTTP and HTTPS requests are dropped.

Setting the maximum number of portal users

About this task

Perform this task to control the total number of portal users in the system, and the maximum number of IPv4 or IPv6 portal users on an interface.

Restrictions and guidelines for setting the maximum number of portal users

Make sure the maximum combined number of IPv4 and IPv6 portal users specified on all interfaces does not exceed the system-allowed maximum number. Otherwise, the exceeding number of portal users will not be able to log in to the device.

Setting the global maximum number of portal users

1. Enter system view.

   system-view

2. Set the global maximum number of portal users.

   portal max-user *max-number*

   By default, no limit is placed on the number of portal users allowed in the system.

   If you set the global maximum number smaller than the number of current online portal users on the device, this configuration still takes effect. The online users are not affected but the system forbids new portal users to log in.

Setting the maximum number of portal users on an interface

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Set the maximum number of portal users.

portal { **ipv4-max-user** | **ipv6-max-user** } *max-number*

By default, no limit is placed on the number of portal users on an interface.

If you set the maximum number smaller than the current number of portal users on an interface, this configuration still takes effect. The online users are not affected but the system forbids new portal users to log in from the interface.

Enabling strict-checking on portal authorization information

About this task

The strict checking feature allows a portal user to stay online only when the authorization information for the user is successfully deployed.

Enabling strict checking on portal authentication information on an interface

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Enable strict checking on portal authorization information.

   portal authorization acl strict-checking

   By default, strict checking on portal authorization information is disabled on an interface. Portal users stay online even when the authorized ACL or user profile does not exist or the device fails to deploy the authorized ACL or user profile

△ **CAUTION:**

- The device logs out a portal user if the authorized ACL does not exist on the device or the device fails to deploy the authorized ACL.

Allowing only users with DHCP-assigned IP addresses to pass portal authentication

About this task

This feature allows only users with DHCP-assigned IP addresses to pass portal authentication. Use this feature to ensure that only users with valid IP addresses can access the network.

Restrictions and guidelines

This feature takes effect only when the device acts as both the access device and the DHCP server.

Configuration of this feature does not affect the online portal users.

Allowing only users with DHCP-assigned IP addresses to pass portal authentication on an interface

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Allow only users with DHCP-assigned IP addresses to pass portal authentication.

   portal [**ipv6**] **user-dhcp-only**

   By default, both users with IP addresses obtained through DHCP and users with static IP addresses can pass authentication to come online.

△ **CAUTION:**

- With this feature enabled, users with static IP addresses cannot pass portal authentication to come online.
- To ensure that IPv6 users can pass portal authentication when this feature is enabled, disable the temporary IPv6 address feature on terminal devices. Otherwise, IPv6 users will use temporary IPv6 addresses to access the IPv6 network and will fail portal authentication.

Blocking portal users that fail portal authentication

About this task

This feature prevents exhaustive password cracking. It blocks a portal user if the user consecutively fails authentication for the specified times within the failure detection period. All authentication requests from the user are dropped by the device till the blocking times out. The blocked portal user can perform portal authentication again when the blocking timeout time expires.

Restrictions and guidelines

This feature does not block preauthentication portal users.

Procedure

1. Enter system view.

   `system-view`

2. Configure the device to block portal users that fail portal authentication for the specified times within the specified period.

   `portal user-block failed-times` *`failed-times`* **`period`** *`period`* [**`method`** { **`ip`** | **`mac`** | **`username`** }]

   By default, the device does not block portal users that fail portal authentication.

3. Set the portal user blocking timeout time.

   `portal user-block reactive` *`period`*

   By default, the portal user blocking timeout time is 30 minutes.

   If you set the portal user blocking timeout time to 0 minutes, blocked portal users cannot perform portal authentication any more.

Configuring support of portal authentication for dual stack

About this task

Typically, IPv4 portal users can access only the IPv4 network after passing portal authentication, and IPv6 portal users can access only the IPv6 network after passing portal authentication. To allow portal users to access both IPv4 and IPv6 networks after passing one type (IPv4 or IPv6) of portal authentication, enable the portal dual-stack feature.

Configuring support of portal authentication for dual stack on an interface

1. Enter system view.

   `system-view`

2. Enable separate IPv4 and IPv6 traffic statistics in portal user offline logs.

   `portal user-log traffic-separate`

   By default, IPv4 and IPv6 traffic statistics of a portal user are collectively counted as IPv4 traffic statistics in portal user offline logs.

3. Enter Layer 3 interface view.

interface *interface-type interface-number*

4. Enable the portal dual-stack feature on the interface.

   portal dual-stack enable

   By default, the portal dual-stack feature is disabled on an interface.

5. Enable separate IPv4 and IPv6 traffic statistics for dual-stack portal users on the interface.

   portal dual-stack traffic-separate enable

   By default, separate IPv4 and IPv6 traffic statistics is disabled for dual-stack portal users on an interface. The device collects IPv4 and IPv6 traffic statistics collectively.

6. Enable the dual IP feature to carry both IPv4 and IPv6 addresses for single-stack users in remote portal authentication.

   portal dual-ip enable

   By default, the dual IP feature is disabled.

Enabling intra-VLAN roaming for portal users

About this task

If intra-VLAN roaming is enabled for portal users on a VLAN interface, an online portal user can access resources from any Layer 2 port in the VLAN without re-authentication.

If intra-VLAN roaming is disabled for portal users, to access external network resources from a Layer 2 port different from the current access port in the VLAN, the user must do the following:

1. Logs out from the current port.
2. Re-authenticates on the new Layer 2 port.

Restrictions and guidelines

Intra-VLAN roaming takes effect only on portal users logging in from VLAN interfaces. It does not take effect on portal users logging in from common Layer 3 interface.

You cannot enable intra-VLAN roaming when online portal users or preauthentication portal users exist on the device.

For intra-VLAN roaming to take effect, you must disable the Rule ARP or ND entry feature by using the **undo portal refresh** { **arp** | **nd** } **enable** command.

Procedure

1. Enter system view.

   system-view

2. Enable intra-VLAN roaming for portal users.

   portal roaming enable

   By default, intra-VLAN roaming is disabled for portal users.

Enabling outgoing packets filtering

About this task

When you enable this feature on a portal-enabled interface, the device permits the interface to send the following packets:

- Packets whose destination IP addresses are IP addresses of authenticated portal users.
- Packets that match portal-free rules.

Other outgoing packets on the interface are dropped.

Enabling outgoing packets filtering on an interface

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Enable outgoing packets filtering on the interface.

   portal [**ipv6**] **outbound-filter enable**

   By default, outgoing packets filtering is disabled on an interface. The interface can send any packets.

Configuring the portal fail-permit feature

About this task

You can configure the portal fail-permit feature on an interface. When the access device detects that the portal authentication server or portal Web server is unreachable, it allows users to have network access without portal authentication.

If you enable fail-permit for both the portal authentication server and the portal Web servers, the device does the following:

- Disables portal authentication when the portal authentication server is unreachable or all the portal Web servers are unreachable.
- Resumes portal authentication when both the portal authentication and Web servers are reachable.

After portal authentication resumes, unauthenticated users must pass portal authentication to access the network. Users who have passed portal authentication before the fail-permit event can continue accessing the network.

Configuring portal fail-permit on an interface

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Enable portal fail-permit for a portal authentication server on the interface.

   portal [**ipv6**] **fail-permit server** *server-name*

   By default, portal fail-permit is disabled for a portal authentication server on an interface.

4. Enable portal fail-permit for portal Web servers on the interface.

   portal [**ipv6**] **fail-permit web-server**

   By default, portal fail-permit is disabled for portal Web servers on an interface.

Configuring portal detection features

Configuring online detection of portal users

About this task

Use the online detection feature to quickly detect abnormal logouts of portal users. Configure ARP or ICMP detection for IPv4 portal users. Configure ND or ICMPv6 detection for IPv6 portal users.

If the device receives no packets from a portal user within the idle time, the device detects the user's online status as follows:

- **ICMP or ICMPv6 detection**—Sends ICMP or ICMPv6 requests to the user at configurable intervals to detect the user status.
  - If the device receives a reply within the maximum number of detection attempts, it considers that the user is online and stops sending detection packets. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the device receives no reply after the maximum number of detection attempts, the device logs out the user.
- **ARP or ND detection**—Sends ARP or ND requests to the user and detects the ARP or ND entry status of the user at configurable intervals.
  - If the ARP or ND entry of the user is refreshed within the maximum number of detection attempts, the device considers that the user is online and stops detection. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the ARP or ND entry of the user is not refreshed after the maximum number of detection attempts, the device logs out the user.

Restrictions and guidelines

ARP detection and ND detection apply only to direct and re-DHCP portal authentication. ICMP detection applies to all portal authentication modes.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Configure online detection of portal users.

   IPv4:

   portal user-detect type { **arp** | **icmp** } [**retry** *retries*] [**interval** *interval*] [**idle** *time*]

   IPv6:

   portal ipv6 user-detect type { **icmpv6** | **nd** } [**retry** *retries*] [**interval** *interval*] [**idle** *time*]

   By default, online detection is disabled for portal users on an interface.

Configuring portal authentication server detection

About this task

During portal authentication, if the communication between the access device and portal authentication server is broken, new portal users are not able to log in. Online portal users are not able to log out normally.

To address this problem, the access device needs to be able to detect the reachability changes of the portal server quickly and take corresponding actions to deal with the changes.

The portal authentication server detection feature enables the device to periodically detect portal packets sent by a portal authentication server to determine the reachability of the server. If the device receives a portal packet within a detection timeout (**timeout** *timeout*) and the portal packet is valid, the device considers the portal authentication server to be reachable. Otherwise, the device considers the portal authentication server to be unreachable.

Portal packets include user login packets, user logout packets, and heartbeat packets. Heartbeat packets are periodically sent by a server. By detecting heartbeat packets, the device can detect the server's actual status more quickly than by detecting other portal packets.

Restrictions and guidelines

The portal authentication server detection feature takes effect only when the device has a portal-enabled interface.

Only the IMC portal authentication server supports sending heartbeat packets. To test server reachability by detecting heartbeat packets, you must enable the server heartbeat feature on the IMC portal authentication server.

You can configure the device to take one or more of the following actions when the server reachability status changes:

- Sending a trap message to the NMS. The trap message contains the name and current state of the portal authentication server.
- Sending a log message, which contains the name, the current state, and the original state of the portal authentication server.
- Enabling portal fail-permit. When the portal authentication server is unreachable, the portal fail-permit feature on an interface allows users on the interface to have network access. When the server recovers, it resumes portal authentication on the interface. For more information, see "Configuring the portal fail-permit feature."

Make sure the detection timeout configured on the device is greater than the server heartbeat interval configured on the portal authentication server.

Procedure

1. Enter system view.

   system-view

2. Enter portal authentication server view.

   portal server *server-name*

3. Configure portal authentication server detection.

   server-detect [**timeout** *timeout*] { **log** | **trap** } *

   By default, portal authentication server detection is disabled.

Configuring portal Web server detection

About this task

A portal authentication process cannot complete if the communication between the access device and the portal Web server is broken. To address this problem, you can enable portal Web server detection on the access device.

With the portal Web server detection feature, the access device simulates a Web access process to initiate a TCP connection to the portal Web server. If the TCP connection can be established successfully, the access device considers the detection successful, and the portal Web server is reachable. Otherwise, it considers the detection to have failed.

You can configure the following detection parameters:

- **Detection interval**—Interval at which the device detects the server reachability.
- **Maximum number of consecutive failures**—If the number of consecutive detection failures reaches this value, the access device considers that the portal Web server is unreachable.

You can configure the device to take one or more of the following actions when the server reachability status changes:

- Sending a trap message to the NMS. The trap message contains the name and current state of the portal Web server.
- Sending a log message, which contains the name, the current state, and the original state of the portal Web server.
- Enabling portal fail-permit. When the portal Web server is unreachable, the portal fail-permit feature on an interface allows users on the interface to have network access. When the server recovers, it resumes portal authentication on the interface. For more information, see "Configuring the portal fail-permit feature."

Restrictions and guidelines

The portal Web server detection feature takes effect only when the URL of the portal Web server is specified and the device has a portal-enabled interface.

Procedure

1. Enter system view.

   system-view

2. Enter portal Web server view.

   portal web-server *server-name*

3. Configure portal Web server detection.

   server-detect [**interval** *interval*] [**retry** *retries*] { **log** | **trap** } *

   By default, portal Web server detection is disabled.

4. Configure the URL and the type for portal Web server detection.

   server-detect url *string* [**detect-type** { **http** | **tcp** }]

   By default, the URL for portal Web server detection is the URL of the portal Web server. The type of portal Web server detection is TCP detection.

Enabling DHCP packet capture

About this task

This feature enables the AC to detect the online status of portal users by capturing DHCP packets of the portal users.

When this feature is enabled, the AC captures DHCP packets between a portal user and the DHCP server and obtains the IP address lease information of the user. The AC then detects the online status of the portal user as follows:

- If the AC captures a DHCP lease renewal packet from the portal user before the lease expires, the AC determines that the portal user is online.
- If no DHCP lease renewal packet is captured before the lease expires, the AC forcibly logs out the portal user.

For more information about DHCP packets, see DHCP configuration in *Layer 3—IP Services Configuration Guide*.

The timeout time of the DHCP packet capture timer is the same as the IP address lease time in DHCP packets. This timer resets each time a DHCP packet is captured.

Procedure

1. Enter system view.

   system-view

2. Enable DHCP packet capture to detect online status of portal users.

   portal idle-cut dhcp-capture enable

   By default, DHCP packet capture is disabled.

Configuring portal user synchronization

About this task

Once the access device loses communication with a portal authentication server, the portal user information on the access device and that on the portal authentication server might be inconsistent after the communication resumes. To address this problem, the device provides the portal user synchronization feature. This feature is implemented by sending and detecting portal synchronization packets, as follows:

1. The portal authentication server sends the online user information to the access device in a synchronization packet at the user heartbeat interval.

   The user heartbeat interval is set on the portal authentication server.

2. Upon receiving the synchronization packet, the access device compares the users carried in the packet with its own user list and performs the following operations:
   - If a user contained in the packet does not exist on the access device, the access device informs the portal authentication server to delete the user. The access device starts the synchronization detection timer (**`timeout`** *`timeout`*) immediately when a user logs in.
   - If the user does not appear in any synchronization packet within a synchronization detection interval, the access device considers the user does not exist on the portal authentication server and logs the user out.

Restrictions and guidelines

Portal user synchronization requires a portal authentication server to support the portal user heartbeat function. Only the IMC portal authentication server supports the portal user heartbeat function. To implement the portal user synchronization feature, you also need to configure the user heartbeat function on the portal authentication server. Make sure the user heartbeat interval configured on the portal authentication server is not greater than the synchronization detection timeout configured on the access device.

Deleting a portal authentication server on the access device also deletes the user synchronization configuration for the portal authentication server.

Procedure

1. Enter system view.

   `system-view`

2. Enter portal authentication server view.

   `portal server` *`server-name`*

3. Configure portal user synchronization.

   `user-sync timeout` *`timeout`*

   By default, portal user synchronization is disabled.

Configuring portal packet attributes

Configuring the BAS-IP or BAS-IPv6 attribute

About this task

If the device runs Portal 2.0, the unsolicited packets sent to the portal authentication server must carry the BAS-IP attribute. If the device runs Portal 3.0, the unsolicited packets sent to the portal authentication server must carry the BAS-IP or BAS-IPv6 attribute.

After this attribute is configured, the source IP address for unsolicited notification portal packets the device sends to the portal authentication server is the configured BAS-IP or BAS-IPv6 address. If the attribute is not configured, the source IP address of the portal packets is the IP address of the packet output interface.

Restrictions and guidelines

During a re-DHCP portal authentication or mandatory user logout process, the device sends portal notification packets to the portal authentication server. For the authentication or logout process to complete, make sure the BAS-IP or BAS-IPv6 attribute is the same as the device IP address specified on the portal authentication server.

You must configure the BAS-IP or BAS-IPv6 attribute on a portal authentication-enabled interface if the following conditions are met:

- The portal authentication server is an IMC server.
- The portal device IP address specified on the portal authentication server is not the IP address of the portal packet output interface.

Configuring the BAS-IP or BAS-IPv6 attribute on an interface

1. Enter system view.
   `system-view`
2. Enter Layer 3 interface view.
   `interface` *`interface-type interface-number`*
3. Configure the BAS-IP or BAS-IPv6 attribute.
   IPv4:
   `portal bas-ip` *`ipv4-address`*
   By default, the BAS-IP attribute of an IPv4 portal reply packet is the source IPv4 address of the packet. The BAS-IP attribute of an IPv4 portal notification packet is the IPv4 address of the packet's output interface.
   IPv6:
   `portal bas-ipv6` *`ipv6-address`*
   By default, the BAS-IPv6 attribute of an IPv6 portal reply packet is the source IPv6 address of the packet. The BAS-IPv6 attribute of an IPv6 portal notification packet is the IPv6 address of the packet's output interface.

Specifying the device ID

About this task

The portal authentication server uses device IDs to identify the devices that send protocol packets to the portal server.

Restrictions and guidelines

Make sure the configured device ID is different than any other access devices communicating with the same portal authentication server.

Procedure

1. Enter system view.
   `system-view`
2. Specify the device ID.
   `portal device-id` *`device-id`*
   By default, a device is not configured with a device ID.

Configuring attributes for RADIUS packets

Specifying a format for the NAS-Port-Id attribute

About this task

RADIUS servers from different vendors might require different formats of the NAS-Port-Id attribute in the RADIUS packets. You can specify the NAS-Port-Id attribute format as required.

The device supports predefined formats (format 1, 2, 3, and 4). For more information about the formats, see portal commands in *Security Command Reference*.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Specify the format for the NAS-Port-Id attribute.

   ```
   portal nas-port-id format { 1 | 2 | 3 | 4 }
   ```

   By default, the format for the NAS-Port-Id attribute is format 2.

Applying a NAS-ID profile to an interface

About this task

By default, the device sends its device name in the NAS-Identifier attribute of all RADIUS requests.

A NAS-ID profile enables you to send different NAS-Identifier attribute strings in RADIUS requests from different VLANs. The strings can be organization names, service names, or any user categorization criteria, depending on the administrative requirements.

For example, map the NAS-ID **companyA** to all VLANs of company A. The device will send **companyA** in the NAS-Identifier attribute for the RADIUS server to identify requests from any Company A users.

Restrictions and guidelines

You can apply a NAS-ID profile to a portal-enabled interface. If no NAS-ID profile is specified on the interface or no matching NAS-ID is found in the specified profile, the device uses the device name as the interface NAS-ID.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Create a NAS-ID profile and enter NAS-ID profile view.

   ```
   aaa nas-id profile profile-name
   ```

   For more information about this command, see AAA commands in *Security Command Reference*.

3. Configure a NAS ID and VLAN binding in the profile.

   ```
   nas-id nas-identifier bind vlan vlan-id
   ```

   For more information about this command, see AAA commands in *Security Command Reference*.

4. Specify the NAS-ID profile on the interface.

   a. Return to system view.

      ```
      quit
      ```

b. Enter Layer 3 interface view.

   interface *interface-type interface-number*

c. Specify the NAS-ID profile on the interface.

   portal nas-id-profile *profile-name*

Configuring MAC-based quick portal authentication

Restrictions and guidelines for configuring MAC-based quick portal authentication

Only IPv4 direct authentication supports MAC-based quick portal authentication.

For MAC-based quick portal authentication to take effect on an interface configured with a portal preauthentication domain, set the free-traffic threshold to 0 bytes.

Configuring a remote MAC binding server

About this task

You can configure multiple MAC binding servers on the device. For each server, you can configure MAC binding server parameters, such as the server's IP address, VPN instance, port number, and the free-traffic threshold.

Procedure

1. Enter system view.

   system-view

2. Create a MAC binding server and enter its view.

   portal mac-trigger-server *server-name*

3. Configure a MAC binding server.

   - Specify the IP address of the MAC binding server.

     ip *ipv4-address* [**vpn-instance** *vpn-instance-name*] [**key** { **cipher** | **simple** } *string*]

     By default, no IP address is specified for a MAC binding server.

   - (Optional.) Set the UDP port number on which the MAC binding server listens for MAC binding query packets.

     port *port-number*

     By default, the MAC binding server listens for MAC binding query packets on UDP port 50100.

   - (Optional.) Set the maximum number of attempts and the interval for sending MAC binding queries to the MAC binding server.

     binding-retry { *retries* | **interval** *interval* } *

     By default, the maximum number of query attempts is 3 and the query interval is 1 second.

   - (Optional.) Specify the type of the MAC binding server.

     server-type { **cmcc** | **imc** }

     By default, the type of a MAC binding server is IMC.

4. (Optional.) Set the free-traffic threshold.

free-traffic threshold *value*

By default, the free-traffic threshold is 0 bytes.

5. (Optional.) Set the NAS-Port-Type value carried in RADIUS requests sent to the RADIUS server.

   nas-port-type *value*

   By default, the NAS-Port-Type value carried in RADIUS requests is 15.

6. (Optional.) Specify the version of the portal protocol.

   version *version-number*

   By default, the version of the portal protocol is 1.

7. (Optional.) Set the timeout the device waits for portal authentication to complete after receiving the MAC binding query response.

   authentication-timeout *minutes*

   By default, the portal authentication timeout time is 3 minutes.

8. (Optional.) Set the aging time for MAC-trigger entries.

   aging-time *seconds*

   By default, the aging time for MAC-trigger entries is 300 seconds.

9. (Optional.) Enable AAA failure unbinding.

   aaa-fail nobinding enable

   By default, AAA failure unbinding is disabled.

Configuring a local MAC binding server

About this task

To provide MAC-based quick portal authentication for local portal users, perform this task so that the access device acts as the local MAC binding server.

You can configure multiple MAC binding servers on the device. For each server, you can configure parameters related to MAC-based quick portal authentication.

Procedure

1. Enter system view.

   system-view

2. Create a MAC binding server and enter its view.

   portal mac-trigger-server *server-name*

3. Enable local MAC-based quick portal authentication.

   local-binding enable

   By default, local MAC-based quick portal authentication is disabled.

4. (Optional.) Set the free-traffic threshold.

   free-traffic threshold *value*

   By default, the free-traffic threshold is 0 bytes.

5. (Optional.) Set the aging time for local MAC-account binding entries.

   local-binding aging-time *minutes*

   By default, the aging time for local MAC-account binding entries is 720 minutes.

6. (Optional.) Set the aging time for MAC-trigger entries.

   aging-time *seconds*

   By default, the aging time for MAC-trigger entries is 300 seconds.

7. (Optional.) Enable AAA failure unbinding.

   `aaa-fail nobinding enable`

   By default, AAA failure unbinding is disabled.

Specifying a MAC binding server on an interface

About this task

After a MAC binding server is specified on an interface, the device can implement MAC-based quick portal authentication for portal users on the interface.

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 3 interface view.

   `interface` *`interface-type interface-number`*

3. Specify a MAC binding server on the interface.

   `portal apply mac-trigger-server` *`server-name`*

   By default, no MAC binding server is specified on an interface.

Configure cloud MAC-trigger authentication

About this task

This feature enables the cloud portal server to act as a MAC binding server to perform cloud MAC-trigger authentication on portal users.

Procedure

1. Enter system view.

   `system-view`

2. Create a MAC binding server and enter its view.

   `portal mac-trigger-server` *`server-name`*

3. Enable cloud MAC-trigger authentication.

   `cloud-binding enable`

   By default, cloud MAC-trigger authentication is disabled.

4. Specify the URL of the cloud portal authentication server.

   `cloud-server url` *`url-string`*

   By default, the cloud portal authentication server URL is not specified. The device uses the URL of the portal Web server as the URL of the cloud portal authentication server.

Logging out online portal users

About this task

This feature deletes users that have passed portal authentication and terminates ongoing portal authentications.

Restrictions and guidelines

If any device in a VSRP group executes the **`portal delete-user`** command to log out a user, all devices in this group log out the user.

When the number of online users exceeds 2000, executing the **portal delete-user** command takes a few minutes.

To ensure successful logout of online users, do not perform the following operations during the command execution:

- Master/backup device switchover.
- Breaking the data channel in the VSRP group.
- Active/standby MPU switchover.
- Disabling portal authentication on the interface.

Procedure

1. Enter system view.

   system-view

2. Log out online portal users.

   IPv4:

   portal delete-user { *ipv4-address* | **all** | **auth-type** { **cloud** | **email** | **facebook** | **local** | **normal** | **qq** | **wechat** } | **interface** *interface-type interface-number* | **mac** *mac-address* | **username** *username* }

   IPv6:

   portal delete-user { **all** | **auth-type** { **cloud** | **email** | **facebook** | **local** | **normal** | **qq** | **wechat** } | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* | **mac** *mac-address* | **username** *username* }

Setting the user traffic backup threshold

About this task

The device backs up traffic for a user when the user's traffic reaches the user traffic backup threshold. A smaller threshold provides more accurate backup for user traffic. However, when a large number of users exist, a small threshold results in frequent user traffic backups, affecting the user online, offline, and accounting processes. Set a proper threshold to balance between service performance and traffic backup accuracy.

Procedure

1. Enter system view.

   system-view

2. Set the user traffic backup threshold.

   portal traffic-backup threshold *value*

   By default, the user traffic backup threshold is 10 MB.

Disabling the Rule ARP or ND entry feature for portal clients

About this task

When the Rule ARP or ND entry feature is enabled for portal clients, ARP or ND entries for portal clients are Rule entries after the clients come online. The Rule entries will not age out and will be deleted immediately after the portal clients go offline. If a portal client goes offline and then tries to get online before the ARP or ND entry is relearned for the client, the client will fail the authentication. To avoid such authentication failure, disable this feature. Then, ARP or ND entries for portal clients are dynamic entries after the clients come online and are deleted only when they age out.

Restrictions and guidelines

Enabling or disabling of this feature does not affect existing Rule/dynamic ARP or ND entries.

Procedure

1. Enter system view.
   system-view
2. Disable the Rule ARP or ND entry feature for portal clients.
   undo portal refresh { **arp** | **nd** } **enable**
   By default, the Rule ARP or ND entry feature is disabled.

Disabling traffic accounting for portal users

About this task

The accounting server might perform time-based or traffic-based accounting, or it might not perform accounting.

If the accounting server does not perform traffic-based accounting, disable traffic accounting for portal users on the device. The device will provide quick accounting for portal users, and the traffic statistics will be imprecise.

If the accounting server performs traffic-based accounting, enable traffic accounting for portal users. The device will provide precise traffic statistics for portal users.

Procedure

1. Enter system view.
   system-view
2. Disable traffic accounting for portal users.
   portal traffic-accounting disable
   By default, traffic accounting is enabled for portal users.

Configuring Web redirect

About Web redirect

Web redirect is a simplified portal feature. With Web redirect, a user does not perform portal authentication but is directly redirected to the specified URL on the first Web access attempt in a browser. After the specified redirect interval, the user is redirected from the visiting website to the specified URL again.

Web redirect can provide ISPs with extended services. For example, the ISPs can place advertisements and publish information on the redirected webpage.

Configuring Web redirect on an interface

Restrictions and guidelines

The Web redirect feature takes effect only on HTTP packets that use the default port number 80.

To use the device URL as the Web redirect URL or allow users to successfully access the device URL, you must enable the HTTP service. To enable the HTTP service, use the **ip http enable** command.

When Web redirect and portal authentication are all enabled on an interface, the device redirects users on the interface as follows:

- The device redirects the first HTTP request of a user to the specified URL. Then, the device redirects the next HTTP request of the user to the portal authentication page. After the user logs out, the user is redirected to the specified URL again at the first Web access.
- After the specified redirect interval, a user is redirected to the specified URL regardless of whether the user is online or not. This process does not cause online users to be offline.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Configure Web redirect.

   web-redirect [**ipv6**] **url** *url-string* [**interval** *interval*]

   By default, Web redirect is disabled.

Configuring destination-based portal redirection rules

About this task

The device uses destination-based portal redirection rules to perform URL redirection. If the Web request of a portal user matches the specified destination in a redirection rule, the device redirects the user to the URL specified in the redirection rule.

Restrictions and guidelines

If the Web request of a portal user matches a destination-based portal redirection rule and a URL redirection match rule (configured by using the **if-match** command), the redirection rule takes effect.

If you specify a host name or IP address in a destination-based portal redirection rule, do not specify a URL that includes the host name or IP address as the redirection URL in another rule. A violation will cause redirect loops.

The system supports a maximum of 10 destination-based portal redirection rules. For the same host or IP address, only one destination-based portal redirection rule is supported.

Procedure

1. Enter system view.

   system-view

2. Configure a destination-based portal redirection rule.

   portal redirect-rule destination { **host** { *host-name* | *ip-address* } | **ipv6** *ipv6-address* } [**redirect-url** *url*]

   By default, no destination-based portal redirection rules are configured.

Configuring portal safe-redirect

About this task

Portal safe-redirect filters HTTP requests by HTTP request method, browser type (in HTTP User Agent), and destination URL, and redirects only the permitted HTTP requests. This reduces the risk that the portal Web server cannot respond to HTTP requests because of overload.

Table 2 Browser types supported by portal safe-redirect

Browser type	Description
Safari	Apple browser
Chrome	Google browser
Firefox	Firefox browser
UC	UC browser
QQBrowser	QQ browser
LBBROWSER	Cheetah browser
TaoBrowser	Taobao browser
Maxthon	Maxthon browser
BIDUBrowser	Baidu browser
MSIE 10.0	Microsoft IE 10.0 browser
MSIE 9.0	Microsoft IE 9.0 browser
MSIE 8.0	Microsoft IE 8.0 browser
MSIE 7.0	Microsoft IE 7.0 browser
MSIE 6.0	Microsoft IE 6.0 browser
MetaSr	Sogou browser

Procedure

1. Enter system view.

   `system-view`

2. Enable portal safe-redirect.

   `portal safe-redirect enable`

   By default, the portal safe-redirect feature is disabled.

3. (Optional.) Specify HTTP request methods permitted by portal safe-redirect.

   `portal safe-redirect method` { **`get`** | **`post`** }

   By default, the device can redirect only HTTP requests with GET method after portal safe-redirect is enabled.

4. (Optional.) Specify a browser type permitted by portal safe-redirect.

   `portal safe-redirect user-agent` *`user-agent-string`*

   By default, no browser types are specified. The device can redirect HTTP requests sent by all supported browsers (see Table 2) after portal safe-redirect is enabled.

5. (Optional.) Configure a URL forbidden by portal safe-redirect.

   `portal safe-redirect user-agent` *`user-agent-string`*

   By default, no forbidden URLs are configured. The device can redirect HTTP requests with any URLs.

6. (Optional.) Configure a filename extension forbidden by portal safe-redirect.

   `portal safe-redirect forbidden-url` *`user-url-string`*

   By default, no forbidden filename extensions are configured. The device redirects HTTP requests regardless of the file extension in the URL.

7. (Optional.) Configure a URL keyword forbidden by portal safe-redirect.

portal safe-redirect forbidden-keyword *keyword*

By default, no forbidden URL keywords are configured. The device redirects HTTP requests regardless of the keywords in the URL.

8. (Optional.) Configure the default action for portal safe-redirect.

   portal safe-redirect default-action { **forbidden** | **permit** }

   By default, no default action is configured for portal safe-redirect.

9. Configure a URL permitted by portal safe-redirect.

   portal safe-redirect permit-url *user-url-string*

   By default, the device can redirect Web requests that contain any URLs.

Setting the maximum number of portal redirection sessions for a single user

About this task

If a user client is attacked by malicious software or viruses, it might initiate a large number of portal redirect sessions. You can perform this task to limit the number of portal redirect sessions that can be established for that user.

The maximum number applies to the HTTP redirect sessions and HTTPS redirect sessions separately. For example, assume you set the maximum number to 50. Then, a portal user can establish a maximum of 50 HTTP redirect sessions and a maximum of 50 HTTPS redirect sessions.

Procedure

1. Enter system view.

   system-view

2. Set the maximum number of portal redirection sessions for a single user.

   portal redirect max-session per-user *number*

   By default, no limit is set on the number of portal redirect sessions for a single user.

Excluding an attribute from portal protocol packets

About this task

Support of the portal authentication server for portal protocol attributes varies by the server type. If the device sends the portal authentication server a packet that contains an attribute unsupported by the server, the device and the server cannot communicate.

To address this issue, you can configure portal protocol packets to not carry the attributes unsupported by the portal authentication server.

Excluding an attribute from portal protocol packets for a portal authentication server

1. Enter system view.

   system-view

2. Enter portal authentication server view.

   portal server *server-name*

3. Exclude an attribute from portal protocol packets.

   exclude-attribute *number* { **ack-auth** | **ntf-logout** | **ack-logout** }

   By default, no attributes are excluded from portal protocol packets.

Excluding an attribute from portal protocol packets for a MAC binding server

1. Enter system view.

   system-view
2. Enter MAC binding server view.

   portal mac-trigger-server *server-name*
3. Exclude an attribute from portal protocol packets.

   exclude-attribute *attribute-number*

   By default, no attributes are excluded from portal protocol packets.

Configuring support of portal authentication for third-party authentication

About third-party authentication

The device supports using a third-party authentication server, such as QQ, email, WeChat, or Facebook authentication server as the portal authentication server to complete portal authentication. No portal authentication servers are required to be deployed, and no local portal users are required to be created on the device. This reduces the management and maintenance cost.

You need to add a third-party authentication button on the portal authentication page. A user clicks the button and is redirected to the third-party authentication page. The user then uses the third-party authentication account to perform portal authentication.

Restrictions and guidelines for third-party authentication

Only direct portal authentication that uses a local portal Web service supports third-party authentication.

Editing buttons and pages for third-party authentication

Restrictions and guidelines

No authentication button or authentication page is required for WeChat authentication.

Editing a third-party authentication button

To provide QQ, email, or Facebook authentication for portal users, you must add a QQ, email, or Facebook authentication button to the portal logon page.

When you edit the QQ authentication button, you must call the **pt_getQQSubmitUrl()** function to get the URL of the QQ authentication page. The following example shows part of the script of the QQ authentication button.

```
    <html>
    <head>
    <title>Logon</title>
    <script type="text/javascript" language="javascript" src="pt_private.js"></script>
<script type="text/javascript">
      function setQQUrl(){
          document.getElementById("qqurl").href = pt_getQQSubmitUrl();
            }
</script>
```

```
    </head>
    <body>
    ... ...
<a href="javascript:void(null)" id="qqurl" onclick="setQQUrl()">QQ</a>
    ... ...
    </body>
</html>
```

No special requirements exist in the process of editing an email or Facebook authentication button.

Editing a third-party authentication page

You need to edit the email authentication page and the Facebook authentication page. The QQ authentication page is provided by Tencent.

When you edit the email authentication page, follow the rules in "Customizing authentication pages" and the following rules:

- Set the action attribute of the beginning form tag to **maillogin.html**. Otherwise, the device cannot send the user information
- Save the login page as **emailLogon.htm**.

The following example shows part of the script of the **emailLogon.htm** page.

```
<form action= maillogin.html method = post >
<p>User name:<input type="text" name = "PtUser" style="width:160px;height:22px"
maxlength=64>
<p>Password :<input type="password" name = "PtPwd" style="width:160px;height:22px"
maxlength=32>
<p><input type=SUBMIT value="Logon" name = "PtButton" style="width:60px;"
onclick="form.action=form.action+location.search;">
</form>
```

When you edit the Facebook authentication page, follow the rules in "Customizing authentication pages."

Configuring QQ authentication

About this task

After a portal user passes QQ authentication, the QQ authentication server sends the authorization code of the user to the portal Web server. After the portal Web server receives the authorization code, it sends the authorization code of the user, the app ID, and the app key to the QQ authentication server for verification. If the information is verified as correct, the device determines that the user passes QQ authentication.

Prerequisites

To provide QQ authentication for portal users, you must go to Tencent Open Platform (**http://connect.qq.com/intro/login**) to finish the following tasks:

1. Register as a developer by using a valid QQ account.
2. Apply the access to the platform for your website. The website is the webpage to which users are redirected after passing QQ authentication.

You will obtain the app ID and app key from the Tencent Open Platform after your application succeeds.

Procedure

1. Enter system view.

   `system-view`

2. Create a QQ authentication server and enter its view.

   portal extend-auth-server qq

3. (Optional.) Specify the URL of the QQ authentication server.

   auth-url *url-string*

   By default, the URL of a QQ authentication server is **https://graph.qq.com**.

4. (Optional.) Specify the URL to which portal users are redirected after they pass QQ authentication.

   redirect-url *url-string*

   By default, portal users are redirected to URL **http://oauthindev.nsfocus.com.cn/portal/qqlogin.html** after they pass QQ authentication.

5. (Optional.) Specify the app ID for QQ authentication.

   app-id *app-id*

   By default, an app ID for QQ authentication exists.

6. (Optional.) Specify the app key for QQ authentication.

   app-key *app-key*

   By default, an app key for QQ authentication exists.

Configuring email authentication

About this task

If a portal user chooses email authentication, the user can access the network after passing email authentication.

Procedure

1. Enter system view.

   system-view

2. Create an email authentication server and enter its view.

   portal extend-auth-server mail

3. Specify protocols for email authentication.

   mail-protocol { **imap** | **pop3** } *

   By default, no protocols are specified for email authentication.

4. Specify an email domain name for email authentication.

   mail-domain-name *string*

   By default, no email domain names are specified for email authentication.

Configuring WeChat authentication

About this task

During WeChat authentication, the device first sends the credentials (app ID, app key, and shop ID) for WeChat authentication to the WeChat Official Account Platform for verification. After the credentials are verified, the device continues the portal authentication and allows the user to use the WiFi network after the authentication.

The subscribe-required feature requires users to follow the WeChat official account during WeChat authentication. If the users do not follow the WeChat official account, they fail WeChat authentication.

When subscribe-required feature is configured, the device sends the app ID and app secret to the WeChat Official Account Admin Platform to obtain the access token. Upon receiving authentication requests from portal users, the device sends the access token and the open ID in the authentication requests to the WeChat server to obtain user information. Based on the returned user information, the device determines whether the portal users have followed the WeChat official account.

Prerequisites

Before you configure WeChat authentication, you must go to the WeChat Official Account Admin Platform (**https://mp.weixin.qq.com**) to finish the following tasks:

1. Apply a WeChat official account.
2. Use the account to log in to the platform and enable the WeChat WiFi hotspot feature.
3. Click the device management tab, add the device: select the shop where the device is deployed, select the **portal** device type, and enter the device settings.

   After the previous configurations, you will obtain the credentials (app ID, app key, and shop ID) for WeChat authentication.

To obtain the app secret for WeChat authentication, perform the following tasks:

1. Use the WeChat official account to log in to the WeChat Official Account Admin Platform.
2. From the navigation tree, select **Developer Centers**.

   In the **Configuration Items** area, you can see the app secret for the WeChat Official account.

Procedure

1. Enter system view.

   `system-view`
2. Create a WeChat authentication server and enter its view.

   `portal extend-auth-server wechat`
3. (Optional.) Specify the app ID for WeChat authentication.

   `app-id` *`app-id`*

   By default, no app ID is specified for WeChat authentication.
4. (Optional.) Specify the app key for WeChat authentication.

   `app-key` *`app-key`*

   By default, no app key is specified for WeChat authentication.
5. (Optional.) Specify the shop ID for WeChat authentication.

   `shop-id` *`shop-id`*

   By default, no app key is specified for WeChat authentication.
6. (Optional.) Configure the subscribe-required feature.
   a. Enable the subscribe-required feature:

      `subscribe-required enable`

      By default, the subscribe-required feature is disabled.

      This feature must be used with the portal temporary pass feature. As a best practice, set the temporary pass period to 600 seconds.

   b. Specify the app secret for WeChat authentication.

      `app-secret` { **`cipher`** | **`simple`** } *`string`*

      By default, no app secret is specified for WeChat authentication.

Configuring Facebook authentication

Prerequisites

To use Facebook authentication for portal users, you must register as a developer on the Facebook website to obtain an app ID and app key.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Create a Facebook authentication server and enter its view.

   ```
   portal extend-auth-server facebook
   ```

3. (Optional.) Specify the URL of the Facebook authentication server.

   ```
   auth-url url-string
   ```

   By default, the URL of Facebook authentication server is **https://graph.facebook.com**.

4. (Optional.) Specify the URL to which portal users are redirected after they pass Facebook authentication.

   ```
   redirect-url url-string
   ```

   By default, portal users are redirected to URL **http://oauthindev.nsfocus.com.cn/portal/fblogin.html** after they pass Facebook authentication.

5. (Optional.) Specify the app ID for Facebook authentication.

   ```
   app-id app-id
   ```

   By default, no app ID is specified for Facebook authentication.

6. (Optional.) Specify the app key for Facebook authentication.

   ```
   app-key app-key
   ```

   By default, no app key is specified for Facebook authentication.

Specifying an authentication domain for third-party authentication

About this task

Specify an authentication domain for third-party authentication on an interface to apply the authentication, authorization, and accounting methods in the domain to portal users.

Restrictions and guidelines

Make sure the authentication, authorization, and accounting methods in the specified authentication domain are **none**.

Specifying an authentication domain for third-party authentication on an interface

1. Enter system view.

   ```
   system-view
   ```

2. Enter Layer 3 interface view.

   ```
   interface interface-type interface-number
   ```

3. Specify an authentication domain for third-party authentication on the interface.

   ```
   portal extend-auth domain domain-name
   ```

   By default, no authentication domain is specified for third-party authentication on an interface.

Configuring portal temporary pass

About this task

Typically, a portal user cannot access the Internet before passing portal authentication. This feature allows a user to access the Internet temporarily if the user uses a WeChat account to perform portal authentication. During the temporary pass period, the user can provide WeChat authentication information to the WeChat server for the server to interact with the access device to finish portal authentication.

Restrictions and guidelines

This feature is available only for direct portal authentication mode.

If both portal safe-redirect and portal temporary pass match rules are configured, portal temporary pass match rules take precedence.

Configuring portal temporary pass on an interface

1. Enter system view.
   `system-view`
2. Enter Layer 3 interface view.
   `interface` *`interface-type`* *`interface-number`*
3. Enable portal temporary pass and set the temporary pass period on the interface.
   `portal temp-pass` [**`period`** *`period-value`*] **`enable`**
   By default, portal temporary pass is disabled on an interface.
4. Configure a match rule for portal temporary pass:
   a. Return to system view.
      `quit`
   b. Enter portal Web server view.
      `portal web-server` *`server-name`*
   c. Configure a match rule for portal temporary pass.
      `if-match` { **`original-url`** *`url-string`* | **`user-agent`** *`user-agent`* } * **`temp-pass`** [**`redirect-url`** *`url-string`* | **`original`**]
      By default, no match rules for portal temporary pass are configured.

Setting the user synchronization interval for portal authentication using OAuth

About this task

If portal authentication uses OAuth, the device periodically reports user information to the portal authentication server for user synchronization on the server. To disable user synchronization from the device to the portal authentication server, set the user synchronization interval to 0 seconds on the device.

Procedure

1. Enter system view.
   `system-view`
2. Set the user synchronization interval for portal authentication using OAuth.
   `portal oauth user-sync interval` *`interval`*
   By default, the user synchronization interval is 60 seconds.

Configuring user synchronization for portal authentication using the WiFiDog protocol

About this task

Use this feature when users perform portal authentication using the WiFiDog protocol. This feature enables the device to periodically synchronize user information with the portal server to ensure user information consistency between the device and the portal server.

Restrictions and guidelines

For this feature to take effect, make sure the type of the portal Web server is WiFiDog before you perform this task. To specify the type of the portal Web server, use the **server-type** command.

Procedure

1. Enter system view.

   system-view

2. Enable user information synchronization and set the synchronization interval for portal authentication using WiFiDog.

   portal wifidog user-sync interval *interval*

   By default, user information synchronization is disabled for portal authentication using WiFiDog.

Configuring portal authentication information report interval

About this task

After you configure this feature, the device reports portal authentication failure and error information to the cloud server. The first report is sent to the cloud server 30 seconds after the device is connected to the server. The subsequent reports are sent at regularly intervals as configured by this feature.

If you modify the report interval, the modified interval takes effect on the next report.

Procedure

1. Enter system view.

   system-view

2. Configure the time interval at which portal authentication information is reported to the cloud server.

   portal cloud report interval *minutes*

   By default, the portal authentication information is reported to the cloud server at intervals of 5 minutes.

Enabling portal logging

About this task

To help with security audits, you can enable portal logging to record portal authentication information.

For portal log messages to be sent correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable logging for portal user logins and logouts.

   portal user log enable

   By default, portal user login and logout logging is disabled.

3. Enable logging for portal protocol packets.

   portal packet log enable

   By default, portal protocol packet logging is disabled.

4. Enable logging for portal redirect.

   portal redirect log enable

   By default, portal redirect logging is disabled.

Configuring the portal authentication monitoring feature

About this task

The portal authentication monitoring feature records portal user offlines, authentication failures, and authentication errors. These records help the administrator quickly identify causes of authentication faults.

Procedure

1. Enter system view.

   system-view

2. Enable portal user offline recording.

   portal logout-record enable

   By default, portal user offline recording is disabled.

3. Set the maximum number of portal user offline records.

   portal logout-record max *number*

   The default setting varies by device model. For more information, see the command reference.

4. Export portal user offline records to a path.

   portal logout-record export url *url-string* [**start-time** *start-date start-time* **end-time** *end-date end-time*]

5. Enable portal authentication failure recording.

   portal auth-fail-record enable

   By default, portal authentication failure recording is enabled.

6. Set the maximum number of portal authentication failure records.

   portal auth-fail-record max *number*

   The default setting varies by device model. For more information, see the command reference.

7. Export portal authentication failure records to a path.

   portal auth-fail-record export url *url-string* [**start-time** *start-date start-time* **end-time** *end-date end-time*]

8. Enable portal authentication error recording.

   portal auth-error-record enable

   By default, portal authentication error recording is enabled.

9. Set the maximum number of portal authentication error records.

   portal auth-error-record max *number*

   The default setting varies by device model. For more information, see the command reference.

10. Export portal authentication error records to a path.

    portal auth-error-record export url *url-string* [**start-time** *start-date start-time* **end-time** *end-date end-time*]

Configuring portal advertisement push

About this task

This feature enables the device to push advertisements to portal users after they pass portal authentication.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Enable portal advertisement push.

   portal ad-push enable

   By default, portal advertisement push is disabled.

4. Configure the advertisement URL or advertisement group to be pushed to portal users.

   portal [**ipv6**] **ad-push** { **url** *url-string* [**interval** *interval* | **time-range** *time-range-name* | **traffic-threshold** *traffic-threshold*] | **url-group** *group-name* }

   By default, no advertisement URL or advertisement group is configured.

5. (Optional.) Return to system view.

   quit

6. (Optional.) Configure a portal advertisement whitelist.

   portal ad-push whitelist { **ip** *ipv4-address* | **ipv6** *ipv6-address* | **mac-address** *mac-address* }

   By default, no portal advertisement whitelist is configured.

7. (Optional.) Create an advertisement group and enter its view.

   portal ad-url-group *group-name* [**method** { **interval** | **time-range** | **traffic** }]

8. (Optional.) Configure an advertisement URL in the advertisement group.

   ad-url *url-string* [**time-range** *time-range-name*]

   By default, no advertisement URLs are configured in an advertisement group.

9. (Optional.) Set the time interval or traffic threshold for portal advertisement push in the advertisement group.

   ad-url-group { **interval** *interval* | **traffic-threshold** *traffic-threshold* }

By default, the interval is 360 minutes and the traffic threshold is 100 MB for portal advertisement push in an advertisement group.

Display and maintenance commands for portal

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display portal configuration and portal running state.	**display portal interface** *interface-type interface-number*
Display statistics about portal advertisement push.	**display portal ad-push statistics** { **ad-url-group** | **url** }
Display portal authentication error records.	**display portal auth-error-record** { **all** | **ipv4** *ipv4-address* | **ipv6** *ipv6-address* | **start-time** *start-date start-time* **end-time** *end-date end-time* }
Display portal authentication failure records.	**display portal auth-fail-record** { **all** | **ipv4** *ipv4-address* | **ipv6** *ipv6-address* | **start-time** *start-date start-time* **end-time** *end-date end-time* | **username** *username* }
Display packet statistics for portal captive-bypass.	**display portal captive-bypass statistics** [**slot** *slot-number*]
Display IP addresses corresponding to host names in destination-based portal-free rules.	**display portal dns free-rule-host** [*host-name*]
Display IP addresses resolved by host names in destination-based portal redirection rules.	**display portal dns redirect-rule-host** [*host-name*]
Display information about third-party authentication servers.	**display portal extend-auth-server** { **all** | **facebook** | **mail** | **qq** | **wechat** }
Display information about local MAC-account binding entries.	**display portal local-binding mac-address** { **all** | *mac-address* }
Display portal user offline records.	**display portal logout-record** { **all** | **ipv4** *ipv4-address* | **ipv6** *ipv6-address* | **start-time** *start-date start-time* **end-time** *end-date end-time* | **username** *username* }

Portal configuration examples

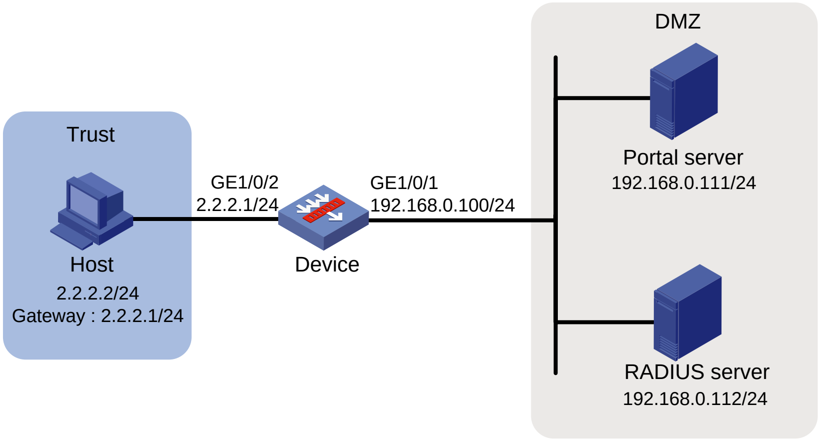
Example: Configuring direct portal authentication

Network configuration

As shown in Figure 6, the host is directly connected to the device (the access device). The host is assigned a public IP address either manually or through DHCP. An IMC server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server. In this example, the IMC server runs IMC 7.1 (E0303) and IMC UAM 7.1 (E0304).

Configure direct portal authentication, so the host can access only the portal server before passing the authentication and access other network resources after passing the authentication.

Figure 6 Network diagram



Configuring the RADIUS server

# Configure the RADIUS server correctly to provide authentication and accounting functions. (Details not shown.)

Configuring the portal server

1. Configure the portal authentication server:
   a. Log in to IMC and click the **User** tab.
   b. Select **User Access Policy** > **Portal Service** > **Server** from the navigation tree to open the portal server configuration page, as shown in Figure 7.
   c. Configure the portal server parameters as needed.

      This example uses the default settings.
   d. Click **OK**.

2. Configure the IP address group:
   a. Select **User Access Policy** > **Portal Service** > **IP Group** from the navigation tree to open the portal IP address group configuration page.

b. Click **Add** to open the page as shown in Figure 8.

c. Enter the IP group name.

d. Enter the start IP address and end IP address of the IP group.

   Make sure the host IP address is in the IP group.

e. Select a service group.

   This example uses the default group **Ungrouped**.

f. Select **Normal** from the **Action** list.

g. Click **OK**.

3. Add a portal device:

   a. Select **User Access Policy** > **Portal Service** > **Device** from the navigation tree to open the portal device configuration page.

   b. Click **Add** to open the page as shown in Figure 9.

   c. Enter device name **NAS**.

   d. Enter the IP address of the device's interface connected to the host.

   e. Select whether to support server heartbeat and user heartbeat functions.

      In this example, select **No** for both **Support Server Heartbeat** and **Support User Heartbeat**.

   f. Enter the key, which must be the same as that configured on the device.

   g. Select **Directly Connected** from the **Access Method** list.

   h. Use the default settings for other parameters.

   i. Click **OK**.

4. Associate the portal device with the IP address group:

   a. As shown in Figure 10, click the **Port Group Information Management** icon for device **NAS** to open the port group configuration page.

   b. Click **Add** to open the page as shown in Figure 11.

   c. Enter the port group name.

   d. Select the configured IP address group.

      The IP address used by the user to access the network must be within this IP address group.

   e. Use the default settings for other parameters.

   f. Click **OK**.

Configuring the device

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.0.100 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name dmz
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/1
[Device-security-zone-DMZ] quit
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/2
[Device-security-zone-Trust] quit
```

3. Configure a security policy:

   # Configure a rule named **trust-dmz** to allow the host to access the portal server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name trust-dmz
[Device-security-policy-ip-1-trust-dmz] source-zone trust
[Device-security-policy-ip-1-trust-dmz] destination-zone dmz
[Device-security-policy-ip-1-trust-dmz] source-ip-host 2.2.2.2
[Device-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.111
[Device-security-policy-ip-1-trust-dmz] action pass
[Device-security-policy-ip-1-trust-dmz] quit
```

   # Configure a rule named **portallocalout** to allow the device to send packets to the RADIUS server and portal server.

```
[Device-security-policy-ip] rule name portallocalout
[Device-security-policy-ip-2-portallocalout] source-zone local
[Device-security-policy-ip-2-portallocalout] destination-zone dmz
```

```
[Device-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.111
[Device-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.112
[Device-security-policy-ip-2-portallocalout] action pass
[Device-security-policy-ip-2-portallocalout] quit
```

# Configure a rule named **portallocalin** to allow the device to receive and process packets from the RADIUS server and portal server.

```
[Device-security-policy-ip] rule name portallocalin
[Device-security-policy-ip-3-portallocalin] source-zone dmz
[Device-security-policy-ip-3-portallocalin] destination-zone local
[Device-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.111
[Device-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.112
[Device-security-policy-ip-3-portallocalin] action pass
[Device-security-policy-ip-3-portallocalin] quit
[Device-security-policy-ip] quit
```

4. Configure a RADIUS scheme:

# Create a RADIUS scheme named **rs1**, configure the device to exclude the ISP domain name from the username sent to the RADIUS server, and enable RADIUS session control.

```
<Device> system-view
[Device] radius scheme rs1
[Device-radius-rs1] primary authentication 192.168.0.112
[Device-radius-rs1] primary accounting 192.168.0.112
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
[Device] radius session-control enable
```

5. Configure an authentication domain:

# Create an ISP domain named **dm1**, configure AAA methods for the ISP domain, and specify domain **dm1** as the default ISP domain.

```
[Device] domain dm1
[Device-isp-dm1] authentication portal radius-scheme rs1
[Device-isp-dm1] authorization portal radius-scheme rs1
[Device-isp-dm1] accounting portal radius-scheme rs1
[Device-isp-dm1] quit
[Device] domain default enable dm1
```

6. Configure portal authentication:

# Configure a portal authentication server and a portal Web server. On GigabitEthernet 1/0/2, enable direct portal authentication, specify the portal Web server, and configure the BAS-IP as 2.2.2.1.

```
[Device] portal server newpt
[Device-portal-server-newpt] ip 192.168.0.111 key simple portal
[Device-portal-server-newpt] port 50100
[Device-portal-server-newpt] quit
[Device] portal web-server newpt
[Device-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Device-portal-websvr-newpt] quit
[Device] interface gigabitethernet 1/0/2
[Device–GigabitEthernet1/0/2] portal enable method direct
[Device–GigabitEthernet1/0/2] portal apply web-server newpt
```

```
[Device–GigabitEthernet1/0/2] portal bas-ip 2.2.2.1
[Device–GigabitEthernet1/0/2] quit
```

Verifying the configuration

# Verify that the portal configuration has taken effect.

```
[Device] display portal interface gigabitethernet 1/0/2
 Portal information of GigabitEthernet1/0/2

    Advertisement push: Not configured
```

A user can perform portal authentication by using the iNode client or a Web browser. Before passing the authentication, the user can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page. After passing the authentication, the user can access other network resources.

# After the user passes authentication, display information about the portal user.

```
[Device] display portal user interface gigabitethernet 1/0/2
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC                IP                 VLAN   Interface
  0015-e9a6-7cfe     2.2.2.2            --     GigabitEthernet1/0/2
  Authorization information:
    DHCP IP pool: N/A
    ACL number/name: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
```

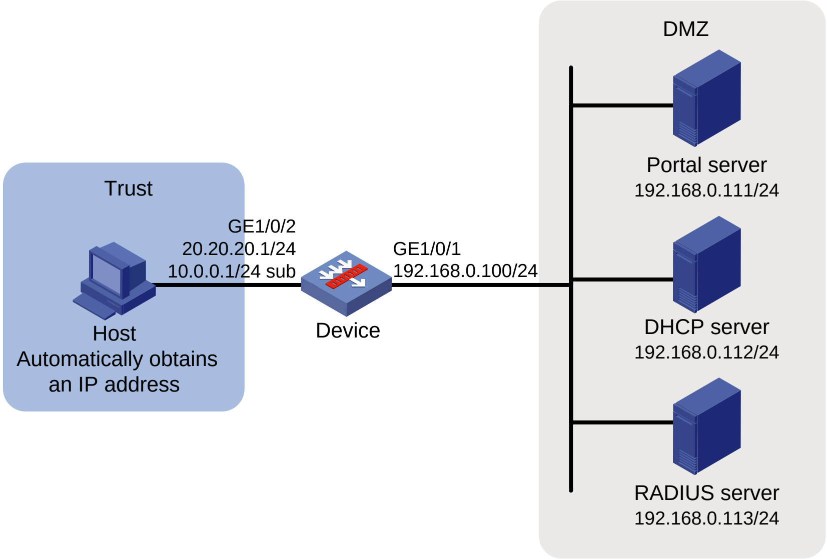
Example: Configuring re-DHCP portal authentication

Network configuration

As shown in Figure 12, the host is directly connected to the device (the access device). The host obtains an IP address through the DHCP server. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure re-DHCP portal authentication. Before passing the authentication, the host is assigned a private IP address. After passing the authentication, the host gets a public IP address and can access network resources.

Figure 12 Network diagram



Prerequisites and guidelines

- For re-DHCP portal authentication, configure a public address pool (20.20.20.0/24) and a private address pool (10.0.0.0/24) on the DHCP server. (Details not shown.)
- For re-DHCP portal authentication:
  - The device must be configured as a DHCP relay agent.
  - The portal-enabled interface must be configured with a primary IP address (a public IP address) and a secondary IP address (a private IP address).

  For information about DHCP relay agent configuration, see *Layer 3—IP Services Configuration Guide*.
- Make sure the IP address of the portal device added on the portal server is the public IP address (20.20.20.1) of the device's interface connecting the host. The private IP address range for the IP address group associated with the portal device is the private subnet 10.0.0.0/24 where the host resides. The public IP address range for the IP address group is the public subnet 20.20.20.0/24.

Procedure

1. Configure the RADIUS server correctly to provide authentication and accounting functions. (Details not shown.)
2. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.0.100 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)
3. Add interfaces to security zones.

   ```
   [Device] security-zone name dmz
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/1
   [Device-security-zone-DMZ] quit
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/2
   ```

```
[Device-security-zone-Trust] quit
```

4. Configure a security policy:

# Configure a rule named **trust-dmz** to allow the host to access the portal server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name trust-dmz
[Device-security-policy-ip-1-trust-dmz] source-zone trust
[Device-security-policy-ip-1-trust-dmz] destination-zone dmz
[Device-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.111
[Device-security-policy-ip-1-trust-dmz] action pass
[Device-security-policy-ip-1-trust-dmz] quit
```

# Configure a rule named **portallocalout1** to allow the device to send packets to the RADIUS server, portal server, and DHCP server.

```
[Device-security-policy-ip] rule name portallocalout1
[Device-security-policy-ip-2-portallocalout1] source-zone local
[Device-security-policy-ip-2-portallocalout1] destination-zone dmz
[Device-security-policy-ip-2-portallocalout1] destination-ip-host 192.168.0.111
[Device-security-policy-ip-2-portallocalout1] destination-ip-host 192.168.0.112
[Device-security-policy-ip-2-portallocalout1] destination-ip-host 192.168.0.113
[Device-security-policy-ip-2-portallocalout1] action pass
[Device-security-policy-ip-2-portallocalout1] quit
```

# Configure a rule named **portallocalin1** to allow the device to receive and process the packets from the RADIUS server, portal server, and DHCP server.

```
[Device-security-policy-ip] rule name portallocalin1
[Device-security-policy-ip-3-portallocalin1] source-zone dmz
[Device-security-policy-ip-3-portallocalin1] destination-zone local
[Device-security-policy-ip-3-portallocalin1] source-ip-host 192.168.0.111
[Device-security-policy-ip-3-portallocalin1] source-ip-host 192.168.0.112
[Device-security-policy-ip-3-portallocalin1] source-ip-host 192.168.0.113
[Device-security-policy-ip-3-portallocalin1] action pass
[Device-security-policy-ip-3-portallocalin1] quit
```

# Configure a rule named **portallocalin2** to allow the host to send DHCP requests to the DHCP server.

```
[Device-security-policy-ip] rule 4 name portallocalin2
[Device-security-policy-ip-4-portallocalin2] source-zone trust
[Device-security-policy-ip-4-portallocalin2] service dhcp-relay
[Device-security-policy-ip-4-portallocalin2] destination-zone local
[Device-security-policy-ip-4-portallocalin2] action pass
[Device-security-policy-ip-4-portallocalin2] quit
```

# Configure a rule named **portallocalout2** to allow the host to obtain the IP address allocated by the DHCP server.

```
[Device-security-policy-ip] rule 5 name portallocalout2
[Device-security-policy-ip-5-portallocalout2] source-zone local
[Device-security-policy-ip-5-portallocalout2] service dhcp-client
[Device-security-policy-ip-5-portallocalout2] destination-zone trust
[Device-security-policy-ip-5-portallocalout2] action pass
[Device-security-policy-ip-5-portallocalout2] quit
[Device-security-policy-ip] quit
```

5. Configure a RADIUS scheme:

# Create a RADIUS scheme named **rs1**, configure the device to exclude the ISP domain name from the username sent to the RADIUS server, and enable RADIUS session control.

```
<Device> system-view
[Device] radius scheme rs1
[Device-radius-rs1] primary authentication 192.168.0.113
[Device-radius-rs1] primary accounting 192.168.0.113
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
[Device] radius session-control enable
```

6. Configure an authentication domain:

# Create an ISP domain named **dm1**, configure AAA methods for the ISP domain, and specify domain **dm1** as the default ISP domain.

```
[Device] domain dm1
[Device-isp-dm1] authentication portal radius-scheme rs1
[Device-isp-dm1] authorization portal radius-scheme rs1
[Device-isp-dm1] accounting portal radius-scheme rs1
[Device-isp-dm1] quit
[Device] domain default enable dm1
```

7. Configure DHCP relay and authorized ARP to allow the host to obtain an IP address from the DHCP server:

```
[Device] dhcp enable
[Device] dhcp relay client-information record
[Device] interface gigabitethernet 1/0/2
[Device–GigabitEthernet1/0/2] ip address 20.20.20.1 255.255.255.0
[Device–GigabitEthernet1/0/2] ip address 10.0.0.1 255.255.255.0 sub
[Device-GigabitEthernet1/0/2] dhcp select relay
[Device-GigabitEthernet1/0/2] dhcp relay server-address 192.168.0.112
[Device-GigabitEthernet1/0/2] arp authorized enable
[Device-GigabitEthernet1/0/2] quit
```

8. Configure portal authentication:

# Configure a portal authentication server and a portal Web server. On GigabitEthernet 1/0/2, enable re-DHCP portal authentication, specify the portal Web server, and configure the BAS-IP as 20.20.20.1.

```
[Device] portal server newpt
[Device-portal-server-newpt] ip 192.168.0.111 key simple portal
[Device-portal-server-newpt] port 50100
[Device-portal-server-newpt] quit
[Device] portal web-server newpt
[Device-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Device-portal-websvr-newpt] quit
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] portal enable method redhcp
[Device–GigabitEthernet1/0/2] portal apply web-server newpt
[Device–GigabitEthernet1/0/2] portal bas-ip 20.20.20.1
[Device–GigabitEthernet1/0/2] quit
```

Verifying the configuration

# Verify that the portal configuration has taken effect.

```
[Device] display portal interface gigabitethernet 1/0/2

        Server type    Server name                        Action
        --             --                                 --
    Layer3 source network:
        IP address                                        Prefix length

    Destination authenticate subnet:
        IP address                                        Prefix length
    Advertisement push: Not configured
```

Before passing the authentication, a user that uses the iNode client can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page. After passing the authentication, the user can access other network resources.

# After the user passes authentication, display information about the portal user.

```
[Device] display portal user interface gigabitethernet 1/0/2
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC                IP                 VLAN   Interface
  0015-e9a6-7cfe     20.20.20.2         --     GigabitEthernet1/0/2
  Authorization information:
    DHCP IP pool: N/A
    ACL number/name: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
```

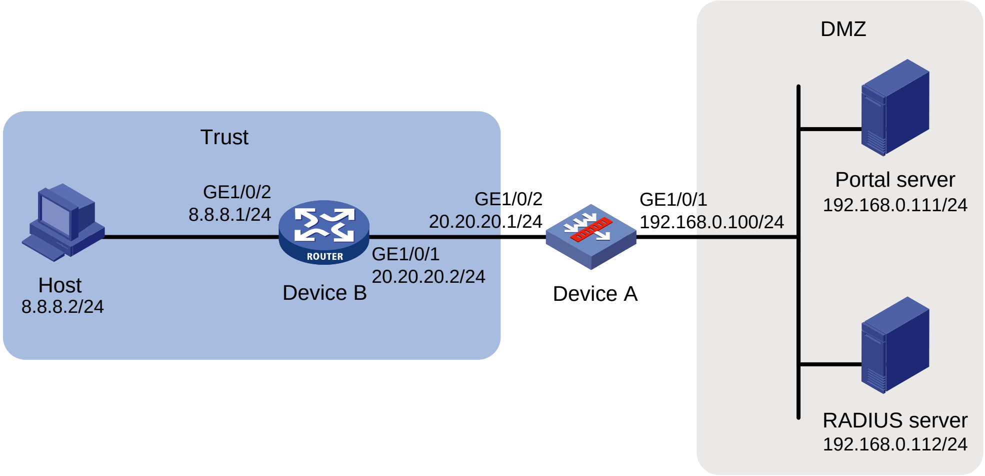
Example: Configuring cross-subnet portal authentication

Network configuration

As shown in Figure 13, Device A supports portal authentication. The host accesses Device A through Device B. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure Device A for cross-subnet portal authentication. Before passing the authentication, the host can access only the portal server. After passing the authentication, the user can access other network resources.

Figure 13 Network diagram



Prerequisites and guidelines

Make sure the IP address of the portal device added on the portal authentication server is the IP address (20.20.20.1) of the device's interface connecting the host. The IP address group associated with the portal device is the subnet of the host (8.8.8.0/24).

Procedure

1. Configure the RADIUS server and the portal server correctly to provide authentication and accounting functions. (Details not shown.)
2. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 192.168.0.100 255.255.255.0
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)
3. Add interfaces to security zones.

   ```
   [DeviceA] security-zone name dmz
   [DeviceA-security-zone-DMZ] import interface gigabitethernet 1/0/1
   [DeviceA-security-zone-DMZ] quit
   [DeviceA] security-zone name trust
   [DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
   [DeviceA-security-zone-Trust] quit
   ```
4. Configure settings for routing:

   This example configures a static route, and the next hop in the route is 20.20.20.2.

   ```
   [DeviceA] ip route-static 8.8.8.0 24 20.20.20.2
   ```
5. Configure a security policy:

   # Configure a rule named **trust-dmz** to allow the host to access the portal server.

   ```
   [DeviceA] security-policy ip
   [DeviceA-security-policy-ip] rule name trust-dmz
   [DeviceA-security-policy-ip-1-trust-dmz] source-zone trust
   [DeviceA-security-policy-ip-1-trust-dmz] destination-zone dmz
   [DeviceA-security-policy-ip-1-trust-dmz] source-ip-host 8.8.8.2
   [DeviceA-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.111
   ```

```
[DeviceA-security-policy-ip-1-trust-dmz] action pass
[DeviceA-security-policy-ip-1-trust-dmz] quit
```

# Configure a rule named **portallocalout** to allow Device A to send packets to the RADIUS server and portal server.

```
[DeviceA-security-policy-ip] rule name portallocalout
[DeviceA-security-policy-ip-2-portallocalout] source-zone local
[DeviceA-security-policy-ip-2-portallocalout] destination-zone dmz
[DeviceA-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.111
[DeviceA-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.112
[DeviceA-security-policy-ip-2-portallocalout] action pass
[DeviceA-security-policy-ip-2-portallocalout] quit
```

# Configure a rule named **portallocalin** to allow Device A to receive and process the packets from the RADIUS server and portal server.

```
[DeviceA-security-policy-ip] rule name portallocalin
[DeviceA-security-policy-ip-3-portallocalin] source-zone dmz
[DeviceA-security-policy-ip-3-portallocalin] destination-zone local
[DeviceA-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.111
[DeviceA-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.112
[DeviceA-security-policy-ip-3-portallocalin] action pass
[DeviceA-security-policy-ip-3-portallocalin] quit
[DeviceA-security-policy-ip] quit
```

6. Configure a RADIUS scheme:

# Create a RADIUS scheme named **rs1**, configure Device A to exclude the ISP domain name from the username sent to the RADIUS server, and enable RADIUS session control.

```
<DeviceA> system-view
[DeviceA] radius scheme rs1
[DeviceA-radius-rs1] primary authentication 192.168.0.112
[DeviceA-radius-rs1] primary accounting 192.168.0.112
[DeviceA-radius-rs1] key authentication simple radius
[DeviceA-radius-rs1] key accounting simple radius
[DeviceA-radius-rs1] user-name-format without-domain
[DeviceA-radius-rs1] quit
[DeviceA] radius session-control enable
```

7. Configure an authentication domain:

# Create an ISP domain named **dm1**, configure AAA methods for the ISP domain, and specify domain **dm1** as the default ISP domain.

```
[DeviceA] domain dm1
[DeviceA-isp-dm1] authentication portal radius-scheme rs1
[DeviceA-isp-dm1] authorization portal radius-scheme rs1
[DeviceA-isp-dm1] accounting portal radius-scheme rs1
[DeviceA-isp-dm1] quit
[DeviceA] domain default enable dm1
```

8. Configure portal authentication:

# Configure a portal authentication server and a portal Web server. On GigabitEthernet 1/0/2, enable cross-subnet portal authentication, specify the portal Web server, and configure the BAS-IP as 20.20.20.1.

```
[DeviceA] portal server newpt
[DeviceA-portal-server-newpt] ip 192.168.0.111 key simple portal
[DeviceA-portal-server-newpt] port 50100
```

```
[DeviceA-portal-server-newpt] quit
[DeviceA] portal web-server newpt
[DeviceA-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[DeviceA-portal-websvr-newpt] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA–GigabitEthernet1/0/2] portal enable method layer3
[DeviceA–GigabitEthernet1/0/2] portal apply web-server newpt
[DeviceA–GigabitEthernet1/0/2] portal bas-ip 20.20.20.1
[DeviceA–GigabitEthernet1/0/2] quit
```

Verifying the configuration

# Verify that the portal configuration has taken effect.

```
[DeviceA] display portal interface gigabitethernet 1/0/2
 Portal information of GigabitEthernet1/0/2

  Authorization information:
    DHCP IP pool: N/A
    ACL number/name: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
```

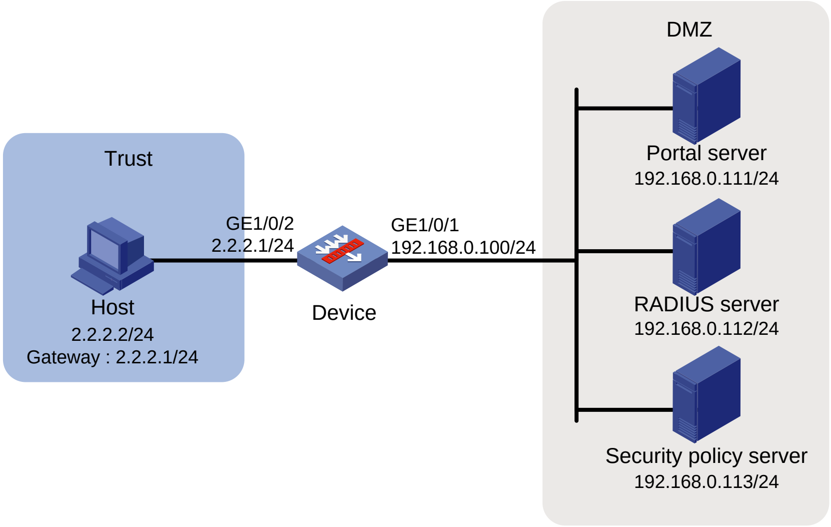
Example: Configuring extended direct portal authentication

Network configuration

As shown in Figure 14, the host is directly connected to the device (the access device). The host is assigned a public IP address either manually or through DHCP. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure extended direct portal authentication. If the host fails security check after passing identity authentication, it can access only subnet 192.168.0.0/24. After passing security check, the host can access other network resources.

Figure 14 Network diagram



Procedure

1. Configure the RADIUS server and the portal server correctly to provide authentication and accounting functions. (Details not shown.)
2. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.0.100 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)
3. Add interfaces to security zones.

   ```
   [Device] security-zone name dmz
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/1
   [Device-security-zone-DMZ] quit
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Trust] quit
   ```
4. Configure a security policy:

   # Configure a rule named **trust-dmz** to allow the host to access the portal server.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name trust-dmz
   [Device-security-policy-ip-1-trust-dmz] source-zone trust
   [Device-security-policy-ip-1-trust-dmz] destination-zone dmz
   [Device-security-policy-ip-1-trust-dmz] source-ip-host 2.2.2.2
   [Device-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.111
   [Device-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.113
   [Device-security-policy-ip-1-trust-dmz] action pass
   [Device-security-policy-ip-1-trust-dmz] quit
   ```

# Configure a rule named **portallocalout** to allow the device to send packets to the RADIUS server, portal server, and security policy server.

```
[Device-security-policy-ip] rule name portallocalout
[Device-security-policy-ip-2-portallocalout] source-zone local
[Device-security-policy-ip-2-portallocalout] destination-zone dmz
[Device-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.111
[Device-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.112
[Device-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.113
[Device-security-policy-ip-2-portallocalout] action pass
[Device-security-policy-ip-2-portallocalout] quit
```

# Configure a rule named **portallocalin** to allow the device to receive and process the packets from the RADIUS server, portal server, and security policy server.

```
[Device-security-policy-ip] rule name portallocalin
[Device-security-policy-ip-3-portallocalin] source-zone dmz
[Device-security-policy-ip-3-portallocalin] destination-zone local
[Device-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.111
[Device-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.112
[Device-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.113
[Device-security-policy-ip-3-portallocalin] action pass
[Device-security-policy-ip-3-portallocalin] quit
[Device-security-policy-ip] quit
```

5. Configure a RADIUS scheme:

# Create a RADIUS scheme named **rs1**. and configure the device to exclude the ISP domain name from the username sent to the RADIUS server.

```
<Device> system-view
[Device] radius scheme rs1
[Device-radius-rs1] primary authentication 192.168.0.112
[Device-radius-rs1] primary accounting 192.168.0.112
[Device-radius-rs1] key accounting simple radius
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] user-name-format without-domain
```

6. Enable RADIUS session control, and specify a session-control client and shared key.

```
[Device] radius session-control enable
[Device] radius session-control client ip 192.168.0.112 key simple 12345
```

7. Configure an authentication domain:

# Create an ISP domain named **dm1**, configure AAA methods for the ISP domain, and specify domain **dm1** as the default ISP domain.

```
[Device] domain dm1
[Device-isp-dm1] authentication portal radius-scheme rs1
[Device-isp-dm1] authorization portal radius-scheme rs1
[Device-isp-dm1] accounting portal radius-scheme rs1
[Device-isp-dm1] quit
[Device] domain default enable dm1
```

8. Configure ACL 3000 as the isolation ACL and ACL 3001 as the security ACL.

```
[Device] acl advanced 3000
[Device-acl-ipv4-adv-3000] rule permit ip destination 192.168.0.0 0.0.0.255
[Device-acl-ipv4-adv-3000] rule deny ip
[Device-acl-ipv4-adv-3000] quit
```

```
[Device] acl advanced 3001
[Device-acl-ipv4-adv-3001] rule permit ip
[Device-acl-ipv4-adv-3001] quit
```

NOTE:

Make sure you specify ACL 3000 as the isolation ACL and ACL 3001 as the security ACL on the security policy server.

9. Configure portal authentication:

   # Configure a portal authentication server and a portal Web server. On GigabitEthernet 1/0/2, enable direct portal authentication, specify the portal Web server, and configure the BAS-IP as 2.2.2.1.

```
[Device] portal server newpt
[Device-portal-server-newpt] ip 192.168.0.111 key simple portal
[Device-portal-server-newpt] port 50100
[Device-portal-server-newpt] quit
[Device] portal web-server newpt
[Device-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Device-portal-websvr-newpt] quit
[Device] interface gigabitethernet 1/0/2
[Device–GigabitEthernet1/0/2] portal enable method direct
[Device–GigabitEthernet1/0/2] portal apply web-server newpt
[Device–GigabitEthernet1/0/2] portal bas-ip 2.2.2.1
[Device–GigabitEthernet1/0/2] quit
```

Verifying the configuration

# Verify that the portal configuration has taken effect.

```
[Device] display portal interface gigabitethernet 1/0/2

  Outbound CAR: N/A
```

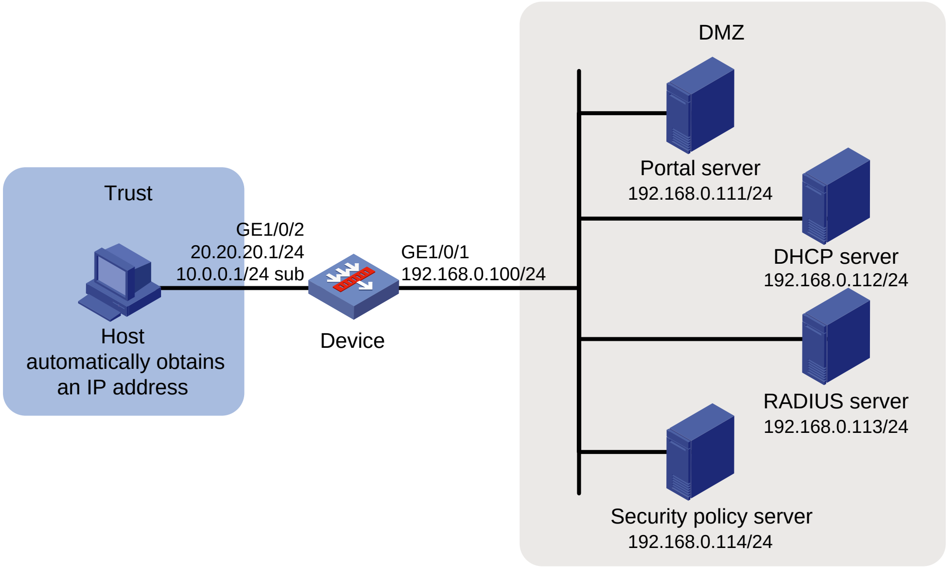
Example: Configuring extended re-DHCP portal authentication

Network configuration

As shown in Figure 15, the host is directly connected to the device (the access device). The host obtains an IP address through the DHCP server. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure extended re-DHCP portal authentication. Before passing portal authentication, the host is assigned a private IP address. After passing portal identity authentication, the host obtains a public IP address and accepts security check. If the host fails the security check, it can access only subnet 192.168.0.0/24. After passing the security check, the host can access other network resources.

Figure 15 Network diagram



Prerequisites and guidelines

- For re-DHCP portal authentication, configure a public address pool (20.20.20.0/24) and a private address pool (10.0.0.0/24) on the DHCP server. (Details not shown.)
- For re-DHCP portal authentication:
  - The device must be configured as a DHCP relay agent.
  - The portal-enabled interface must be configured with a primary IP address (a public IP address) and a secondary IP address (a private IP address).

  For information about DHCP relay agent configuration, see *Layer 3—IP Services Configuration Guide*.

- Make sure the IP address of the portal device added on the portal server is the public IP address (20.20.20.1) of the device's interface connecting the host. The private IP address range for the IP address group associated with the portal device is the private subnet 10.0.0.0/24 where the host resides. The public IP address range for the IP address group is the public subnet 20.20.20.0/24.

Procedure

1. Configure the RADIUS server and the portal server correctly to provide authentication and accounting functions. (Details not shown.)
2. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.0.100 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)
3. Add interfaces to security zones.

   ```
   [Device] security-zone name dmz
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/1
   [Device-security-zone-DMZ] quit
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Trust] quit
   ```
4. Configure a security policy:

   # Configure a rule named **trust-dmz** to allow the host to access the DHCP server, portal server, and security policy server.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name trust-dmz
   [Device-security-policy-ip-1-trust-dmz] source-zone trust
   [Device-security-policy-ip-1-trust-dmz] destination-zone dmz
   [Device-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.111
   [Device-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.112
   [Device-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.114
   [Device-security-policy-ip-1-trust-dmz] action pass
   [Device-security-policy-ip-1-trust-dmz] quit
   ```

   # Configure a rule named **portallocalout1** to allow the device to send packets to the RADIUS server, portal server, DHCP server, and security policy server.

   ```
   [Device-security-policy-ip] rule name portallocalout1
   [Device-security-policy-ip-2-portallocalout1] source-zone local
   [Device-security-policy-ip-2-portallocalout1] destination-zone dmz
   [Device-security-policy-ip-2-portallocalout1] destination-ip-host 192.168.0.111
   [Device-security-policy-ip-2-portallocalout1] destination-ip-host 192.168.0.112
   [Device-security-policy-ip-2-portallocalout1] destination-ip-host 192.168.0.113
   [Device-security-policy-ip-2-portallocalout1] destination-ip-host 192.168.0.114
   [Device-security-policy-ip-2-portallocalout1] action pass
   [Device-security-policy-ip-2-portallocalout1] quit
   ```

   # Configure a rule named **portallocalin1** to allow the device to receive and process the packets from the RADIUS server, portal server, DHCP server, and security policy server.

   ```
   [Device-security-policy-ip] rule name portallocalin1
   ```

```
[Device-security-policy-ip-3-portallocalin1] source-zone dmz
[Device-security-policy-ip-3-portallocalin1] destination-zone local
[Device-security-policy-ip-3-portallocalin1] source-ip-host 192.168.0.111
[Device-security-policy-ip-3-portallocalin1] source-ip-host 192.168.0.112
[Device-security-policy-ip-3-portallocalin1] source-ip-host 192.168.0.113
[Device-security-policy-ip-3-portallocalin1] source-ip-host 192.168.0.114
[Device-security-policy-ip-3-portallocalin1] action pass
[Device-security-policy-ip-3-portallocalin1] quit
```

# Configure a rule named **portallocalin2** to allow the host to send DHCP requests to the device.

```
[Device-security-policy-ip] rule name portallocalin2
[Device-security-policy-ip-4-portallocalin2] source-zone trust
[Device-security-policy-ip-4-portallocalin2] service dhcp-relay
[Device-security-policy-ip-4-portallocalin2] destination-zone local
[Device-security-policy-ip-4-portallocalin2] action pass
[Device-security-policy-ip-4-portallocalin2] quit
```

# Configure a rule named **portallocalout2** to allow the host to obtain the IP address allocated by the DHCP server.

```
[Device-security-policy-ip] rule name portallocalout2
[Device-security-policy-ip-5-portallocalout2] source-zone local
[Device-security-policy-ip-4-portallocalout2] service dhcp-client
[Device-security-policy-ip-5-portallocalout2] destination-zone trust
[Device-security-policy-ip-5-portallocalout2] action pass
[Device-security-policy-ip-5-portallocalout2] quit
[Device-security-policy-ip] quit
```

5. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1**, and configure the device to exclude the ISP domain name from the username sent to the RADIUS server.

```
<Device> system-view
[Device] radius scheme rs1
[Device-radius-rs1] primary authentication 192.168.0.113
[Device-radius-rs1] primary accounting 192.168.0.113
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
[Device-radius-rs1] user-name-format without-domain
```

6. Enable RADIUS session control, and specify a session-control client and shared key.

```
[Device] radius session-control enable
[Device] radius session-control client ip 192.168.0.113 key simple 12345
```

7. Configure an authentication domain:

   # Create an ISP domain named **dm1**, configure AAA methods for the ISP domain, and specify domain **dm1** as the default ISP domain.

```
[Device] domain dm1
[Device-isp-dm1] authentication portal radius-scheme rs1
[Device-isp-dm1] authorization portal radius-scheme rs1
[Device-isp-dm1] accounting portal radius-scheme rs1
[Device-isp-dm1] quit
[Device] domain default enable dm1
```

8. Configure ACL 3000 as the isolation ACL and ACL 3001 as the security ACL.

```
[Device] acl advanced 3000
[Device-acl-ipv4-adv-3000] rule permit ip destination 192.168.0.0 0.0.0.255
[Device-acl-ipv4-adv-3000] rule deny ip
[Device-acl-ipv4-adv-3000] quit
[Device] acl advanced 3001
[Device-acl-ipv4-adv-3001] rule permit ip
[Device-acl-ipv4-adv-3001] quit
```

NOTE:

Make sure you specify ACL 3000 as the isolation ACL and ACL 3001 as the security ACL on the security policy server.

9. Configure DHCP relay and authorized ARP:

```
[Device] dhcp enable
[Device] dhcp relay client-information record
[Device] interface gigabitethernet 1/0/2
[Device–GigabitEthernet1/0/2] ip address 20.20.20.1 255.255.255.0
[Device–GigabitEthernet1/0/2] ip address 10.0.0.1 255.255.255.0 sub
[Device-GigabitEthernet1/0/2] dhcp select relay
[Device-GigabitEthernet1/0/2] dhcp relay server-address 192.168.0.112
[Device-GigabitEthernet1/0/2] arp authorized enable
[Device-GigabitEthernet1/0/2] quit
```

10. Configure portal authentication:

# Configure a portal authentication server and a portal Web server. On GigabitEthernet 1/0/2, enable re-DHCP portal authentication, specify the portal Web server, and configure the BAS-IP as 20.20.20.1.

```
[Device] portal server newpt
[Device-portal-server-newpt] ip 192.168.0.111 key simple portal
[Device-portal-server-newpt] port 50100
[Device-portal-server-newpt] quit
[Device] portal web-server newpt
[Device-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Device-portal-websvr-newpt] quit
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] portal enable method redhcp
[Device–GigabitEthernet1/0/2] portal apply web-server newpt
[Device–GigabitEthernet1/0/2] portal bas-ip 20.20.20.1
[Device–GigabitEthernet1/0/2] quit
```

Verifying the configuration

# Verify that the portal configuration has taken effect.

```
[Device] display portal interface gigabitethernet 1/0/2
 Portal information of GigabitEthernet1/0/2
     NAS-ID profile: Not configured
     Authorization : Strict checking
     ACL           : Disabled
     User profile  : Disabled

    Destination authenticate subnet:
        IP address                                          Prefix length
    Advertisement push: Not configured
```

Before passing portal authentication, a user that uses the iNode client can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page.

- The user can access the resources permitted by ACL 3000 after passing only identity authentication.
- The user can access network resources permitted by ACL 3001 after passing both identity authentication and security check.

# After the user passes identity authentication and security check, display information about the portal user.

```
[Device] display portal user interface gigabitethernet 1/0/2
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC                IP                 VLAN   Interface
  0015-e9a6-7cfe     20.20.20.2         --     GigabitEthernet1/0/2
  Authorization information:
    DHCP IP pool: N/A
    ACL number/name: 3001
    Inbound CAR: N/A
    Outbound CAR: N/A
```

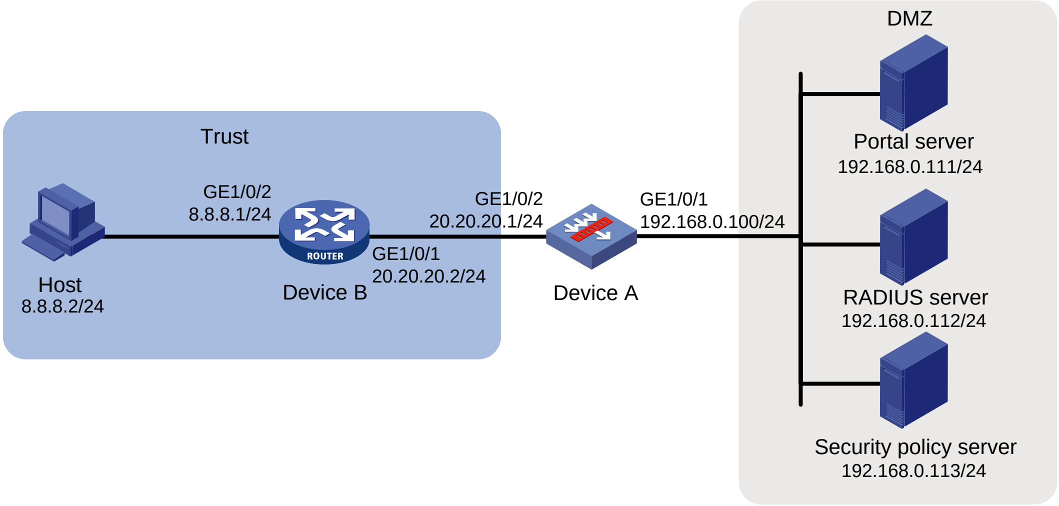
Example: Configuring extended cross-subnet portal authentication

Network configuration

As shown in Figure 16, Device A supports portal authentication. The host accesses Device A through Device B. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure Device A for extended cross-subnet portal authentication. Before passing portal authentication, the host can access only the portal server. After passing portal identity authentication, the host accepts security check. If the host fails the security check it can access only the subnet 192.168.0.0/24. After passing the security check, the host can access other network resources.

Figure 16 Network diagram



Prerequisites and guidelines

Make sure the IP address of the portal device added on the portal server is the IP address (20.20.20.1) of the device's interface connecting the host. The IP address group associated with the portal device is the subnet of the host (8.8.8.0/24).

Procedure

1. Configure the RADIUS server and the portal server correctly to provide authentication and accounting functions. (Details not shown.)
2. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 192.168.0.100 255.255.255.0
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)
3. Add interfaces to security zones.

   ```
   [DeviceA] security-zone name dmz
   [DeviceA-security-zone-DMZ] import interface gigabitethernet 1/0/1
   [DeviceA-security-zone-DMZ] quit
   [DeviceA] security-zone name trust
   [DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/2
   [DeviceA-security-zone-Trust] quit
   ```
4. Configure settings for routing:

   This example configures a static route, and the next hop in the route is 20.20.20.2.

   ```
   [DeviceA] ip route-static 8.8.8.0 24 20.20.20.2
   ```
5. Configure a security policy:

   # Configure a rule named **trust-dmz** to allow the host to access the RADIUS server, portal server, and security policy server.

   ```
   [DeviceA] security-policy ip
   [DeviceA-security-policy-ip] rule name trust-dmz
   [DeviceA-security-policy-ip-1-trust-dmz] source-zone trust
   [DeviceA-security-policy-ip-1-trust-dmz] destination-zone dmz
   ```

```
[DeviceA-security-policy-ip-1-trust-dmz] source-ip-host 8.8.8.2
[DeviceA-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.111
[DeviceA-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.112
[DeviceA-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.113
[DeviceA-security-policy-ip-1-trust-dmz] action pass
[DeviceA-security-policy-ip-1-trust-dmz] quit
```

# Configure a rule named **portallocalout** to allow Device A to send packets to the RADIUS server, portal server, and security policy server.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name portallocalout
[DeviceA-security-policy-ip-2-portallocalout] source-zone local
[DeviceA-security-policy-ip-2-portallocalout] destination-zone dmz
[DeviceA-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.111
[DeviceA-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.112
[DeviceA-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.113
[DeviceA-security-policy-ip-2-portallocalout] action pass
[DeviceA-security-policy-ip-2-portallocalout] quit
```

# Configure a rule named **portallocalin** to allow Device A to receive and process the packets from the RADIUS server, portal server, and security policy server.

```
[DeviceA-security-policy-ip] rule name portallocalin
[DeviceA-security-policy-ip-3-portallocalin] source-zone dmz
[DeviceA-security-policy-ip-3-portallocalin] destination-zone local
[DeviceA-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.111
[DeviceA-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.112
[DeviceA-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.113
[DeviceA-security-policy-ip-3-portallocalin] action pass
[DeviceA-security-policy-ip-3-portallocalin] quit
[Device-security-policy-ip] quit
```

6. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1**, and configure Device A to exclude the ISP domain name from the username sent to the RADIUS server.

```
<DeviceA> system-view
[DeviceA] radius scheme rs1
[DeviceA-radius-rs1] primary authentication 192.168.0.112
[DeviceA-radius-rs1] primary accounting 192.168.0.112
[DeviceA-radius-rs1] key authentication simple radius
[DeviceA-radius-rs1] key accounting simple radius
[DeviceA-radius-rs1] user-name-format without-domain
```

7. Enable RADIUS session control, and specify a session-control client and shared key.

```
[DeviceA] radius session-control enable
[DeviceA] radius session-control client ip 192.168.0.112 key simple 12345
```

8. Configure an authentication domain:

   # Create an ISP domain named **dm1**, configure AAA methods for the ISP domain, and specify domain **dm1** as the default ISP domain.

```
[DeviceA] domain dm1
[DeviceA-isp-dm1] authentication portal radius-scheme rs1
[DeviceA-isp-dm1] authorization portal radius-scheme rs1
[DeviceA-isp-dm1] accounting portal radius-scheme rs1
```

```
[DeviceA-isp-dm1] quit
[DeviceA] domain default enable dm1
```

9. Configure ACL 3000 as the isolation ACL and ACL 3001 as the security ACL.

```
[DeviceA] acl advanced 3000
[DeviceA-acl-ipv4-adv-3000] rule permit ip destination 192.168.0.0 0.0.0.255
[DeviceA-acl-ipv4-adv-3000] rule deny ip
[DeviceA-acl-ipv4-adv-3000] quit
[DeviceA] acl advanced 3001
[DeviceA-acl-ipv4-adv-3001] rule permit ip
[DeviceA-acl-ipv4-adv-3001] quit
```

NOTE:

Make sure you specify ACL 3000 as the isolation ACL and ACL 3001 as the security ACL on the security policy server.

10. Configure portal authentication:

# Configure a portal authentication server and a portal Web server. On GigabitEthernet 1/0/2, enable cross-subnet portal authentication, specify the portal Web server newpt, and configure the BAS-IP as 20.20.20.1.

```
[DeviceA] portal server newpt
[DeviceA-portal-server-newpt] ip 192.168.0.111 key simple portal
[DeviceA-portal-server-newpt] port 50100
[DeviceA-portal-server-newpt] quit
[Device] portal web-server newpt
[DeviceA-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[DeviceA-portal-websvr-newpt] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA–GigabitEthernet1/0/2] portal enable method layer3
[DeviceA–GigabitEthernet1/0/2] portal apply web-server newpt
[DeviceA–GigabitEthernet1/0/2] portal bas-ip 20.20.20.1
[DeviceA–GigabitEthernet1/0/2] quit
```

Verifying the configuration

# Verify that the portal configuration has taken effect.

```
[DeviceA] display portal interface gigabitethernet 1/0/2
 Portal information of GigabitEthernet1/0/2
     NAS-ID profile: Not configured
     Authorization : Strict checking
     ACL           : Disabled
     User profile  : Disabled
     Dual stack    : Disabled
     Dual IP       : Disabled
     Advertisement-push     : Disabled
     Embedded advertisement : Disabled

     Destination authenticate subnet:
         IP address                                        Prefix length
     Advertisement push: Not configured
```

Before passing portal authentication, a user that uses the iNode client can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user are redirected to the authentication page.

- The user can access the resources permitted by ACL 3000 after passing only identity authentication.

- The user can access network resources permitted by ACL 3001 after passing both identity authentication and security check.

# After the user passes identity authentication and security check, display information about the portal user.

```
[DeviceA] display portal user interface gigabitethernet 1/0/2
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC                IP                 VLAN   Interface
  0015-e9a6-7cfe     8.8.8.2            --     GigabitEthernet1/0/2
  Authorization information:
    DHCP IP pool: N/A
    ACL number/name: 3001
    Inbound CAR: N/A
    Outbound CAR: N/A
```

Example: Configuring portal server detection and portal user synchronization

Network configuration

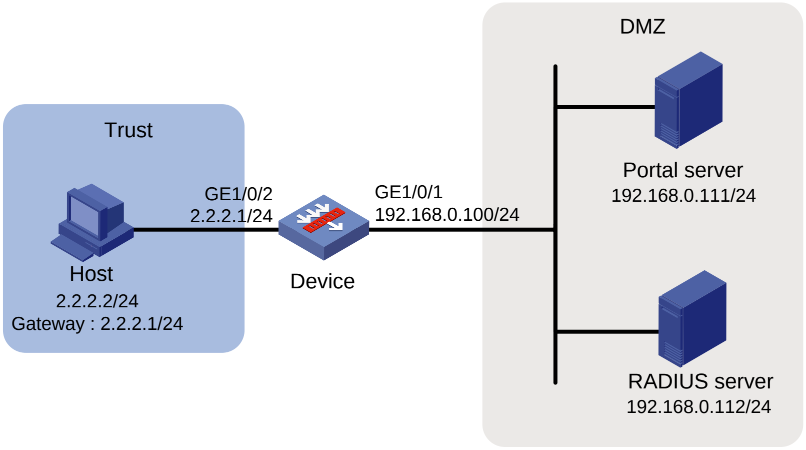
As shown in Figure 17, the host is directly connected to the device (the access device). The host is assigned a public IP address either manually or through DHCP. An IMC server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server. In this example, the IMC server runs IMC 7.1 (E0303) and IMC UAM 7.1 (E0304).

Configure direct portal authentication on the device, so the host can access only the portal server before passing the authentication and access other network resources after passing the authentication.

Configure the device to do the following:

- Detect the reachability state of the portal authentication server.
- Send log messages upon state changes.
- Disable portal authentication when the authentication server is unreachable.
- Synchronize portal user information with the portal server periodically.

Figure 17 Network diagram



Prerequisites and guidelines

- Configure the portal authentication server. Be sure to enable the server heartbeat function and the user heartbeat function.
- Configure the device (access device) as follows:
  - Configure direct portal authentication on GigabitEthernet 1/0/2, the interface to which the host is connected.
  - Configure portal authentication server detection, so that the device can detect the reachability of the portal authentication server by cooperating with the portal server heartbeat function.
  - Configure portal user synchronization, so that the device can synchronize portal user information with the portal authentication server by cooperating with the portal user heartbeat function.

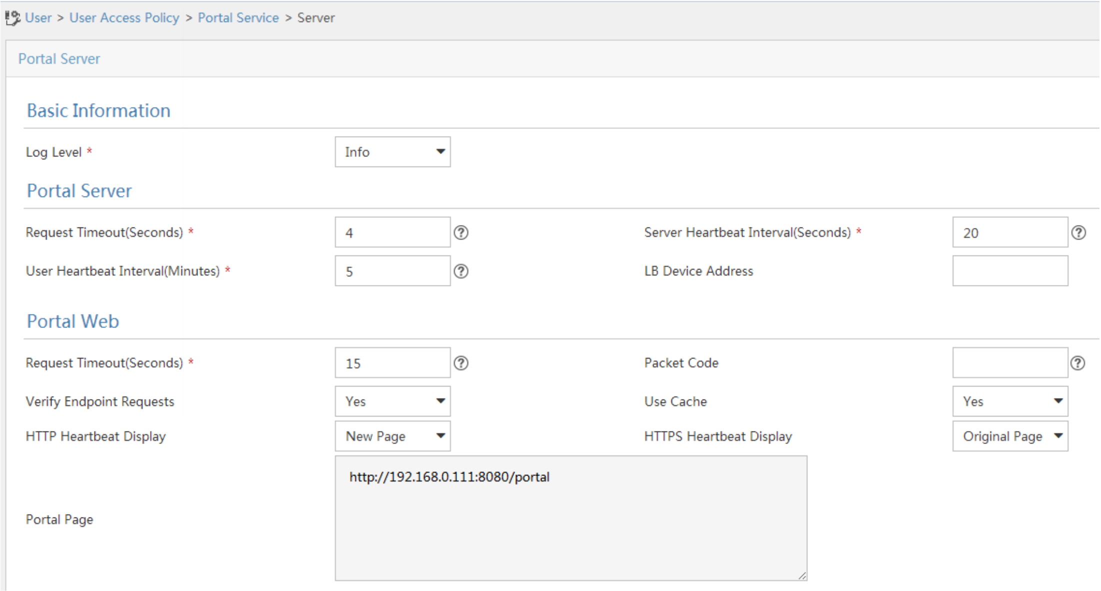
Configuring the RADIUS server

# Configure the RADIUS server correctly to provide authentication and accounting functions. (Details not shown.)

Configuring the portal server

1. Configure the portal server:
   a. Log in to IMC and click the **Service** tab.
   b. Select **User Access Policy** > **Portal Service** > **Server** from the navigation tree to open the portal server configuration page as shown in Figure 18.
   c. Configure the portal server parameter as needed.
      This example uses the default settings.
   d. Click **OK**.

Figure 18 Portal authentication server configuration



User > User Access Policy > Portal Service > Server

Portal Server

Basic Information

Log Level *	Info

Portal Server

Request Timeout(Seconds) *	4	Server Heartbeat Interval(Seconds) *	20
User Heartbeat Interval(Minutes) *	5	LB Device Address	

Portal Web

Request Timeout(Seconds) *	15	Packet Code	
Verify Endpoint Requests	Yes	Use Cache	Yes
HTTP Heartbeat Display	New Page	HTTPS Heartbeat Display	Original Page
Portal Page	http://192.168.0.111:8080/portal		

2. Configure the IP address group:

   a. Select **User Access Policy** > **Portal Service** > **IP Group** from the navigation tree to open the portal IP address group configuration page.

   b. Click **Add** to open the page as shown in Figure 19.

   c. Enter the IP group name.

   d. Enter the start IP address and end IP address of the IP group.

      Make sure the host IP address is in the IP group.

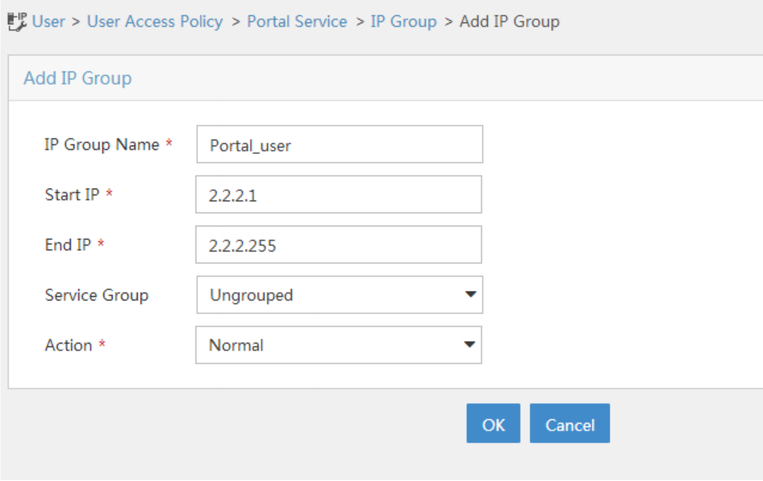
   e. Select a service group.

      This example uses the default group **Ungrouped**.

   f. Select **Normal** from the **Action** list.

   g. Click **OK**.

Figure 19 Adding an IP address group



User > User Access Policy > Portal Service > IP Group > Add IP Group

Add IP Group

IP Group Name *	Portal_user
Start IP *	2.2.2.1
End IP *	2.2.2.255
Service Group	Ungrouped
Action *	Normal

3. Add a portal device:

   a. Select **User Access Policy** > **Portal Service** > **Device** from the navigation tree to open the portal device configuration page.

b. Click **Add** to open the page as shown in Figure 20.

c. Enter device name **NAS**.

d. Enter the IP address of the device's interface connected to the host.

e. Select whether to support sever heartbeat and user heartbeat functions.

   In this example, select **Yes** for both **Support Server Heartbeat** and **Support User Heartbeat**.

f. Enter the key, which must be the same as that configured on the device.

g. Select **Directly Connected** from the **Access Method** list.

h. Use the default settings for other parameters.

i. Click **OK**.

Device Description			

4. Associate the portal device with the IP address group:

   a. As shown in Figure 21, click the **Port Group Information Management** icon for device **NAS** to open the port group configuration page.

   b. Click **Add** to open the page as shown in Figure 22.

   c. Enter the port group name.

   d. Select the configured IP address group.

      The IP address used by the user to access the network must be within this IP address group.

   e. Use the default settings for other parameters.

   f. Click **OK**.

Configuring the device

1. Assign IP addresses to interfaces:

# Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.0.100 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name dmz
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/1
[Device-security-zone-DMZ] quit
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/2
[Device-security-zone-Trust] quit
```

3. Configure a security policy:

# Configure a rule named **trust-dmz** to allow the host to access the portal server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name trust-dmz
[Device-security-policy-ip-1-trust-dmz] source-zone trust
[Device-security-policy-ip-1-trust-dmz] destination-zone dmz
[Device-security-policy-ip-1-trust-dmz] source-ip-host 2.2.2.2
[Device-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.111
[Device-security-policy-ip-1-trust-dmz] action pass
[Device-security-policy-ip-1-trust-dmz] quit
```

# Configure a rule named **portallocalout** to allow the device to send packets to the RADIUS server and portal server

```
[Device-security-policy-ip] rule name portallocalout
[Device-security-policy-ip-2-portallocalout] source-zone local
```

```
[Device-security-policy-ip-2-portallocalout] destination-zone dmz
[Device-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.111
[Device-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.112
[Device-security-policy-ip-2-portallocalout] action pass
[Device-security-policy-ip-2-portallocalout] quit
```

# Configure a rule named **portallocalin** to allow the device to receive and process the packets from the RADIUS server and portal server.

```
[Device-security-policy-ip] rule name portallocalin
[Device-security-policy-ip-3-portallocalin] source-zone dmz
[Device-security-policy-ip-3-portallocalin] destination-zone local
[Device-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.111
[Device-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.112
[Device-security-policy-ip-3-portallocalin] action pass
[Device-security-policy-ip-3-portallocalin] quit
[Device-security-policy-ip] quit
```

4. Configure a RADIUS scheme:

# Create a RADIUS scheme named **rs1**, configure the device to exclude the ISP domain name from the username sent to the RADIUS server, and enable RADIUS session control.

```
<Device> system-view
[Device] radius scheme rs1
[Device-radius-rs1] primary authentication 192.168.0.112
[Device-radius-rs1] primary accounting 192.168.0.112
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
[Device] radius session-control enable
```

5. Configure an authentication domain:

# Create an ISP domain named **dm1**, configure AAA methods for the ISP domain, and specify domain **dm1** as the default ISP domain.

```
[Device] domain dm1
[Device-isp-dm1] authentication portal radius-scheme rs1
[Device-isp-dm1] authorization portal radius-scheme rs1
[Device-isp-dm1] accounting portal radius-scheme rs1
[Device-isp-dm1] quit
[Device] domain default enable dm1
```

6. Configure portal authentication:

# Configure a portal authentication server, and configure reachability detection of the portal authentication server: set the server detection interval and specify the action upon reachability status changes.

```
[Device] portal server newpt
[Device-portal-server-newpt] ip 192.168.0.111 key simple portal
[Device-portal-server-newpt] port 50100
[Device-portal-server-newpt] server-detect timeout 40 log
```

NOTE:

The value of **timeout** must be greater than or equal to the portal server heartbeat interval.

# Configure portal user synchronization with the portal authentication server, and set the synchronization detection interval to 600 seconds.

```
[Device-portal-server-newpt] user-sync timeout 600
[Device-portal-server-newpt] quit
```

NOTE:

The value of **timeout** must be greater than or equal to the portal user heartbeat interval.

# Configure a portal Web server. On GigabitEthernet 1/0/2, enable direct portal authentication, enable portal fail-permit for the portal authentication server, specify the portal Web server, and configure the BAS-IP as 2.2.2.1.

```
[Device] portal web-server newpt
[Device-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Device-portal-websvr-newpt] quit
[Device] interface gigabitethernet 1/0/2
[Device–GigabitEthernet1/0/2] portal enable method direct
[Device–GigabitEthernet1/0/2] portal fail-permit server newpt
[Device–GigabitEthernet1/0/2] portal apply web-server newpt
[Device–GigabitEthernet1/0/2] portal bas-ip 2.2.2.1
[Device–GigabitEthernet1/0/2] quit
```

Verifying the configuration

# Display information about the portal authentication server.

```
[Device] display portal server newpt
Portal server: newpt
  Type                     : IMC
  IP                       : 192.168.0.111
  VPN instance             : Not configured
  Port                     : 50100
  Server Detection         : Timeout 40s  Action: log
  User synchronization     : Timeout 600s
  Status                   : Up
  Exclude-attribute        : Not configured
  Logout notification      : Not configured
```

The **Up** status of the portal authentication server indicates that the portal authentication server is reachable. If the access device detects that the portal authentication server is unreachable, the **Status** field in the command output displays **Down**. The access device generates a server unreachable log "Portal server newpt turns down from up." and disables portal authentication on the access interface, so the host can access the external network without authentication.

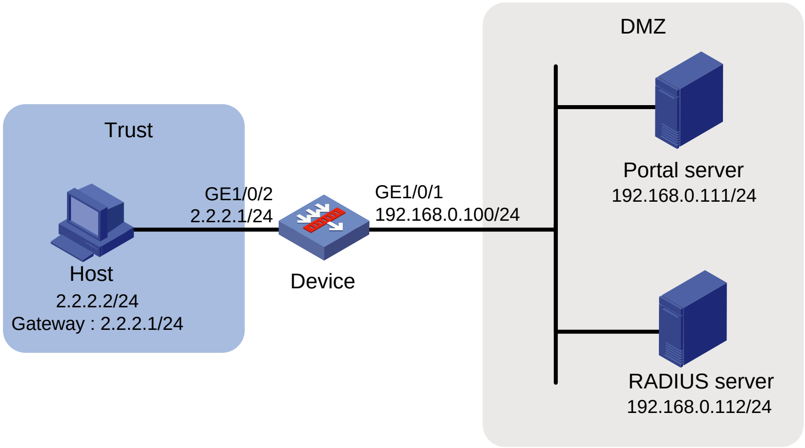
Example: Configuring direct portal authentication with a preauthentication domain

Network configuration

As shown in Figure 23, the host is directly connected to the device (the access device). The host is assigned a public IP address through DHCP. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure direct portal authentication, so the host can access only subnet 192.168.0.0/24 before passing the authentication and access other network resources after passing the authentication.

Figure 23 Network diagram



Procedure

1. Configure the RADIUS server and the portal server correctly to provide authentication and accounting functions. (Details not shown.)
2. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.0.100 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)
3. Add interfaces to security zones.

   ```
   [Device] security-zone name dmz
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/1
   [Device-security-zone-DMZ] quit
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Trust] quit
   ```
4. Configure a security policy:

   # Configure a rule named **portallocalin1** to allow the host to send DHCP requests to the device.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name portallocalin1
   [Device-security-policy-ip-1-portallocalin1] source-zone trust
   [Device-security-policy-ip-1-portallocalin1] service dhcp-server
   [Device-security-policy-ip-1-portallocalin1] destination-zone local
   [Device-security-policy-ip-1-portallocalin1] action pass
   [Device-security-policy-ip-1-portallocalin1] quit
   ```

   # Configure a rule named **portallocalout1** to allow the device to send DHCP response packets to the host.

   ```
   [Device-security-policy-ip] rule name portallocalout1
   [Device-security-policy-ip-2-portallocalout1] source-zone local
   [Device-security-policy-ip-2-portallocalout1] service dhcp-client
   [Device-security-policy-ip-2-portallocalout1] destination-zone trust
   ```

```
[Device-security-policy-ip-2-portallocalout1] action pass
[Device-security-policy-ip-2-portallocalout1] quit
```

# Configure a rule named **trust-dmz** to allow the host to access the portal server.

```
[Device-security-policy-ip] rule name trust-dmz
[Device-security-policy-ip-3-trust-dmz] source-zone trust
[Device-security-policy-ip-3-trust-dmz] destination-zone dmz
[Device-security-policy-ip-3-trust-dmz] source-ip-subnet 2.2.2.0 24
[Device-security-policy-ip-3-trust-dmz] destination-ip-host 192.168.0.111
[Device-security-policy-ip-3-trust-dmz] action pass
[Device-security-policy-ip-3-trust-dmz] quit
```

# Configure a rule named **portallocalout2** to allow the device to send packets to the RADIUS server and portal server.

```
[Device-security-policy-ip] rule name portallocalout2
[Device-security-policy-ip-4-portallocalout2] source-zone local
[Device-security-policy-ip-4-portallocalout2] destination-zone dmz
[Device-security-policy-ip-4-portallocalout2] destination-ip-host 192.168.0.111
[Device-security-policy-ip-4-portallocalout2] destination-ip-host 192.168.0.112
[Device-security-policy-ip-4-portallocalout2] action pass
[Device-security-policy-ip-4-portallocalout2] quit
```

# Configure a rule named **portallocalin2** to allow the device to receive and process packets from the RADIUS server and portal server.

```
[Device-security-policy-ip] rule name portallocalin2
[Device-security-policy-ip-5-portallocalin2] source-zone dmz
[Device-security-policy-ip-5-portallocalin2] destination-zone local
[Device-security-policy-ip-5-portallocalin2] source-ip-host 192.168.0.111
[Device-security-policy-ip-5-portallocalin2] source-ip-host 192.168.0.112
[Device-security-policy-ip-5-portallocalin2] action pass
[Device-security-policy-ip-5-portallocalin2] quit
[Device-security-policy-ip] quit
```

5. Configure a preauthentication IP address pool, and enable the DHCP server on GigabitEthernet 1/0/2.

```
<Device> system-view
[Device] dhcp server ip-pool pre
[Device-dhcp-pool-pre] gateway-list 2.2.2.1
[Device-dhcp-pool-pre] network 2.2.2.0 24
[Device-dhcp-pool-pre] quit
[Device] interface gigabitethernet 1/0/2
[Device–GigabitEthernet1/0/2] dhcp select server
[Device–GigabitEthernet1/0/2] quit
```

6. Configure a preauthentication domain:

# Create an ISP domain named **abc**, and specify authorization ACL 3010 in the domain. In ACL 3010, configure a rule to permit the traffic to the subnet 192.168.0.0/24. On GigabitEthernet 1/0/2, configure preauthentication domain as ISP domain **abc**.

```
[Device] domain abc
[Device-isp-abc] authorization-attribute acl 3010
[Device-isp-abc] quit
[Device] acl advanced 3010
[Device-acl-ipv4-adv-3010] rule 1 permit ip destination 192.168.0.0 0.0.0.255
[Device-acl-ipv4-adv-3010] quit
```

```
[Device] interface gigabitethernet 1/0/2
[Device–GigabitEthernet1/0/2] portal pre-auth domain abc
[Device–GigabitEthernet1/0/2] quit
```

7. Configure portal authentication:

   # Configure a portal authentication server and a portal Web server. On GigabitEthernet 1/0/2, enable direct portal authentication, specify the portal Web server, and configure the BAS-IP as 2.2.2.1.

```
[Device] portal server newpt
[Device-portal-server-newpt] ip 192.168.0.111 key simple portal
[Device-portal-server-newpt] port 50100
[Device-portal-server-newpt] quit
[Device] portal web-server newpt
[Device-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Device-portal-websvr-newpt] quit
[Device] interface gigabitethernet 1/0/2
[Device–GigabitEthernet1/0/2] portal enable method direct
[Device–GigabitEthernet1/0/2] portal apply web-server newpt
[Device–GigabitEthernet1/0/2] portal bas-ip 2.2.2.1
[Device–GigabitEthernet1/0/2] quit
```

Verifying the configuration

# Verify the portal configuration by executing the **display portal interface** command. (Details not shown.)

# Display information about preauthentication portal users.

```
[Device] display portal user pre-auth interface gigabitethernet 1/0/2
Total portal pre-auth users: 1
MAC               IP                VLAN   Interface
0015-e9a6-7cfe    2.2.2.4           --     GigabitEthernet1/0/2
  State: Online
  VPN instance: --
  Authorization information:
    DHCP IP pool: N/A
    ACL number/name: 3010
    Inbound CAR: N/A
    Outbound CAR: N/A
```

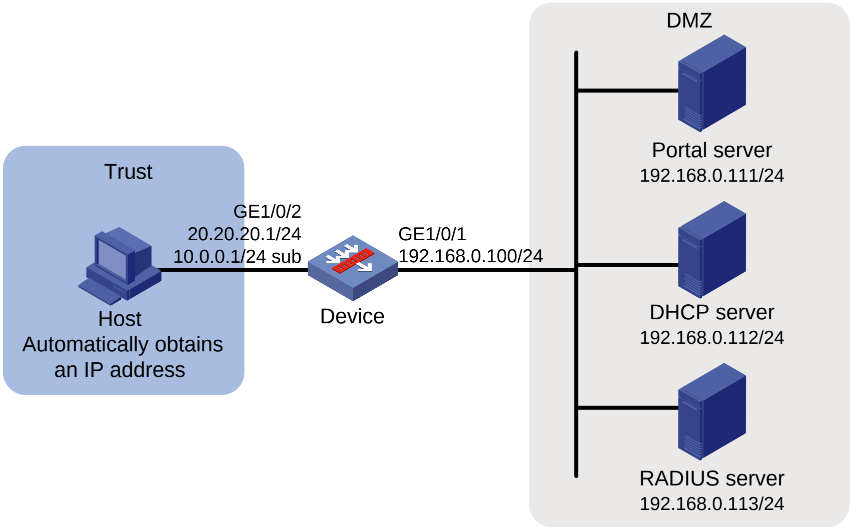
Example: Configuring re-DHCP portal authentication with a preauthentication domain

Network configuration

As shown in Figure 24, the host is directly connected to the device (the access device). The host obtains an IP address through the DHCP server. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure re-DHCP portal authentication. Before passing the authentication, the host is assigned a private IP address and can access only the subnet 192.168.0.0/24. After passing the authentication, the host gets a public IP address and can access other network resources.

Figure 24 Network diagram



Prerequisites and guidelines

- For re-DHCP portal authentication, configure a public address pool (20.20.20.0/24) and a private address pool (10.0.0.0/24) on the DHCP server. (Details not shown.)
- For re-DHCP portal authentication:
  - The device must be configured as a DHCP relay agent.
  - The portal-enabled interface must be configured with a primary IP address (a public IP address) and a secondary IP address (a private IP address).

  For information about DHCP relay agent configuration, see *Layer 3—IP Services Configuration Guide*.
- Make sure the IP address of the portal device added on the portal server is the public IP address (20.20.20.1) of the device's interface connecting the host. The private IP address range for the IP address group associated with the portal device is the private subnet 10.0.0.0/24 where the host resides. The public IP address range for the IP address group is the public subnet 20.20.20.0/24.
- If you have configured a preauthentication IP address pool on portal-enabled interfaces, configure a DHCP relay address pool with the same name on the device. For the DHCP relay address pool, specify the subnet address where the unauthenticated users reside (with the **export-router** keyword specified) and the DHCP server address.

Procedure

1. Configure the RADIUS server and the portal server correctly to provide authentication and accounting functions. (Details not shown.)
2. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.0.100 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)
3. Add interfaces to security zones.

   ```
   [Device] security-zone name dmz
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/1
   ```

```
[Device-security-zone-DMZ] quit
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/2
[Device-security-zone-Trust] quit
```

4. Configure a security policy:

   # Configure a rule named **portallocalin1** to allow the host to send DHCP requests to the device.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name portallocalin1
[Device-security-policy-ip-1-portallocalin1] source-zone trust
[Device-security-policy-ip-1-portallocalin1] service dhcp-relay
[Device-security-policy-ip-1-portallocalin1] destination-zone local
[Device-security-policy-ip-1-trust-local] action pass
[Device-security-policy-ip-1-trust-local] quit
```

   # Configure a rule named **portallocalout1** to allow the device to send DHCP response packets to the host.

```
[Device-security-policy-ip] rule name portallocalout1
[Device-security-policy-ip-2-portallocalout1] source-zone local
[Device-security-policy-ip-2-portallocalout1] service dhcp-client
[Device-security-policy-ip-2-portallocalout1] destination-zone trust
[Device-security-policy-ip-2-portallocalout1] action pass
[Device-security-policy-ip-2-portallocalout1] quit
```

   # Configure a rule named **portallocalout2** to allow the device to send packets to the RADIUS server, portal server, and DHCP server.

```
[Device-security-policy-ip] rule name portallocalout2
[Device-security-policy-ip-3-portallocalout2] source-zone local
[Device-security-policy-ip-3-portallocalout2] destination-zone dmz
[Device-security-policy-ip-3-portallocalout2] destination-ip-host 192.168.0.111
[Device-security-policy-ip-3-portallocalout2] destination-ip-host 192.168.0.112
[Device-security-policy-ip-3-portallocalout2] destination-ip-host 192.168.0.113
[Device-security-policy-ip-3-portallocalout2] action pass
[Device-security-policy-ip-3-portallocalout2] quit
```

   # Configure a rule named **portallocalin2** to allow the device to receive and process the packets from the RADIUS server, portal server, and DHCP server.

```
[Device-security-policy-ip] rule name portallocalin2
[Device-security-policy-ip-4-portallocalin2] source-zone dmz
[Device-security-policy-ip-4-portallocalin2] destination-zone local
[Device-security-policy-ip-4-portallocalin2] source-ip-host 192.168.0.111
[Device-security-policy-ip-4-portallocalin2] source-ip-host 192.168.0.112
[Device-security-policy-ip-4-portallocalin2] source-ip-host 192.168.0.113
[Device-security-policy-ip-4-portallocalin2] action pass
[Device-security-policy-ip-4-portallocalin2] quit
```

   # Configure a rule named **trust-dmz** to allow the host to access the portal server.

```
[Device-security-policy-ip] rule name trust-dmz
[Device-security-policy-ip-5-trust-dmz] source-zone trust
[Device-security-policy-ip-5-trust-dmz] destination-zone dmz
[Device-security-policy-ip-5-trust-dmz] destination-ip-host 192.168.0.111
[Device-security-policy-ip-5-trust-dmz] action pass
[Device-security-policy-ip-5-trust-dmz] quit
```

```
[Device-security-policy-ip] quit
```

5. Configure a preauthentication domain:

   # Create an ISP domain named **abc**, and specify authorization ACL 3010 in the domain. In ACL 3010, configure a rule to permit the traffic to the subnet 192.168.0.0/24. On GigabitEthernet 1/0/2, configure the preauthentication domain as ISP domain **abc**.

```
<Device> system-view
[Device] domain abc
[Device-isp-abc] authorization-attribute acl 3010
[Device-isp-abc] quit
[Device] acl advanced 3010
[Device-acl-ipv4-adv-3010] rule 1 permit ip destination 192.168.0.0 0.0.0.255
[Device-acl-ipv4-adv-3010] quit
[Device] interface gigabitethernet 1/0/2
[Device–GigabitEthernet1/0/2] portal pre-auth domain abc
[Device–GigabitEthernet1/0/2] quit
```

6. Configure DHCP relay and authorized ARP to allow the host to obtain an IP address from the DHCP:

```
[Device] dhcp enable
[Device] dhcp relay client-information record
[Device] interface gigabitethernet 1/0/2
[Device–GigabitEthernet1/0/2] ip address 20.20.20.1 255.255.255.0
[Device–GigabitEthernet1/0/2] ip address 10.0.0.1 255.255.255.0 sub
[Device-GigabitEthernet1/0/2] dhcp select relay
[Device-GigabitEthernet1/0/2] dhcp relay server-address 192.168.0.112
[Device-GigabitEthernet1/0/2] arp authorized enable
[Device-GigabitEthernet1/0/2] quit
```

7. Configure portal authentication:

   # Configure a portal authentication server and a portal Web server. On GigabitEthernet 1/0/2, enable re-DHCP portal authentication, specify the portal Web server, and configure the BAS-IP as 20.20.20.1.

```
[Device] portal server newpt
[Device-portal-server-newpt] ip 192.168.0.111 key simple portal
[Device-portal-server-newpt] port 50100
[Device-portal-server-newpt] quit
[Device] portal web-server newpt
[Device-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Device-portal-websvr-newpt] quit
[Device] interface gigabitethernet 1/0/2
[Device–GigabitEthernet1/0/2] portal enable method redhcp
[Device–GigabitEthernet1/0/2] portal apply web-server newpt
[Device–GigabitEthernet1/0/2] portal bas-ip 20.20.20.1
[Device–GigabitEthernet1/0/2] quit
```

Verifying the configuration

# Verify the portal configuration by executing the **display portal interface** command. (Details not shown.)

# Display information about preauthentication portal users.

```
[Device] display portal user pre-auth interface gigabitethernet 1/0/2
Total portal pre-auth users: 1
```

```
MAC                 IP                  VLAN    Interface
0015-e9a6-7cfe      10.10.10.4          --      GigabitEthernet1/0/2
  State: Online
  VPN instance: --
    DHCP IP pool: N/A
    ACL number/name: 3010
    Inbound CAR: N/A
    Outbound CAR: N/A
```

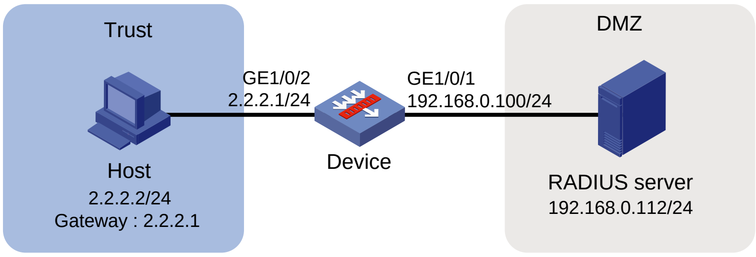
Example: Configuring direct portal authentication using a local portal Web service

Network configuration

As shown in Figure 25, the host is directly connected to the device (the access device). The host is assigned a public IP address either manually or through DHCP. The device acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure direct portal authentication on the device. Before a user passes portal authentication, the user can access only the portal Web server. After passing portal authentication, the user can access other network resources.

Figure 25 Network diagram



Prerequisites

Customize the authentication pages, compress them to a file, and upload the file to the root directory of the storage medium of the device.

Procedure

1. Configure the RADIUS server correctly to provide authentication and accounting functions. (Details not shown.)
2. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.0.100 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)
3. Add interfaces to security zones.

   ```
   [Device] security-zone name dmz
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/1
   [Device-security-zone-DMZ] quit
   [Device] security-zone name trust
   ```

```
[Device-security-zone-Trust] import interface gigabitethernet 1/0/2
[Device-security-zone-Trust] quit
```

4. Configure a security policy:

   # Configure a rule named **portallocalout** to allow the device to send packets to the RADIUS server.

   ```
   [Device-security-policy-ip] rule name portallocalout
   [Device-security-policy-ip-2-portallocalout] source-zone local
   [Device-security-policy-ip-2-portallocalout] destination-zone dmz
   [Device-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.112
   [Device-security-policy-ip-2-portallocalout] action pass
   [Device-security-policy-ip-2-portallocalout] quit
   ```

   # Configure a rule named **portallocalin1** to allow the device to receive and process the packets from the RADIUS server.

   ```
   [Device-security-policy-ip] rule name portallocalin1
   [Device-security-policy-ip-3-portallocalin1] source-zone dmz
   [Device-security-policy-ip-3-portallocalin1] destination-zone local
   [Device-security-policy-ip-3-portallocalin1] source-ip-host 192.168.0.112
   [Device-security-policy-ip-3-portallocalin1] action pass
   [Device-security-policy-ip-3-portallocalin1] quit
   ```

   # Configure a rule named **portallocalin2** to allow the host to send packets to the portal server.

   ```
   [Device-security-policy-ip] rule name portallocalin2
   [Device-security-policy-ip-4-portallocalin2] source-zone trust
   [Device-security-policy-ip-4-portallocalin2] source-ip-host 2.2.2.2
   [Device-security-policy-ip-4-portallocalin2] destination-zone local
   [Device-security-policy-ip-4-portallocalin2] action pass
   [Device-security-policy-ip-4-portallocalin2] quit
   [Device-security-policy-ip] quit
   ```

5. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1**, and configure the device to exclude the ISP domain name from the username sent to the RADIUS server, and enable RADIUS session control.

   ```
   <Device> system-view
   [Device] radius scheme rs1
   [Device-radius-rs1] primary authentication 192.168.0.112
   [Device-radius-rs1] primary accounting 192.168.0.112
   [Device-radius-rs1] key authentication simple radius
   [Device-radius-rs1] key accounting simple radius
   [Device-radius-rs1] user-name-format without-domain
   [Device-radius-rs1] quit
   [Device] radius session-control enable
   ```

6. Configure an authentication domain:

   # Create an ISP domain named **dm1**, configure AAA methods for the ISP domain, and specify domain **dm1** as the default ISP domain.

   ```
   [Device] domain dm1
   [Device-isp-dm1] authentication portal radius-scheme rs1
   [Device-isp-dm1] authorization portal radius-scheme rs1
   [Device-isp-dm1] accounting portal radius-scheme rs1
   [Device-isp-dm1] quit
   [Device] domain default enable dm1
   ```

7. Configure portal authentication:

   # Configure a portal Web server named **newpt**, and configure the URL of the portal Web server. On GigabitEthernet 1/0/2, enable direct portal authentication, and specify the portal Web server.

   ```
   [Device] portal web-server newpt
   [Device-portal-websvr-newpt] url http://2.2.2.1:2331/portal
   [Device-portal-websvr-newpt] quit
   [Device] interface gigabitethernet 1/0/2
   [Device–GigabitEthernet1/0/2] portal enable method direct
   [Device–GigabitEthernet1/0/2] portal apply web-server newpt
   [Device–GigabitEthernet1/0/2] quit
   ```

   # Create an HTTP-based local portal Web service. Specify file **abc.zip** as the default authentication page file for the local portal Web service (Make sure the file exist under the root directory of the device). Then, set the HTTP listening port number to 2331 for the local portal Web service.

   ```
   [Device] portal local-web-server http
   [Device–portal-local-websvr-http] default-logon-page abc.zip
   [Device–portal-local-websvr-http] tcp-port 2331
   [Device–portal-local-websvr-http] quit
   ```

Verifying the configuration

# Verify that the portal configuration has taken effect.

```

    Outbound CAR: N/A
```

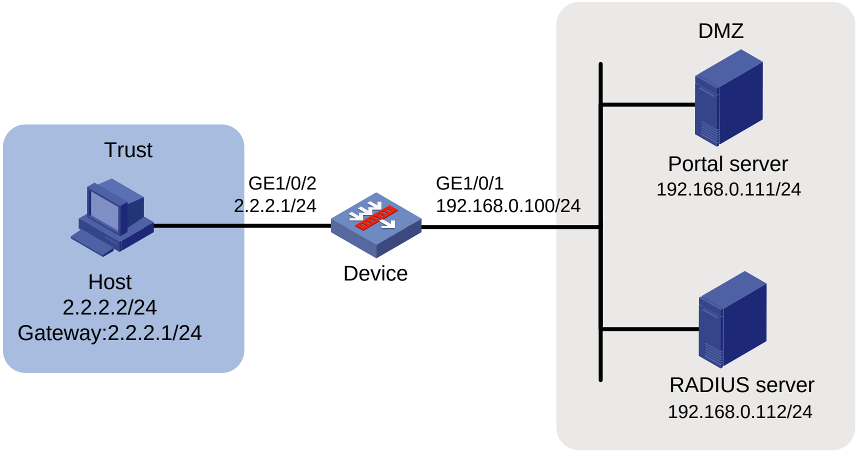
Example: Configuring MAC-based quick portal authentication

Network configuration

As shown in Figure 26, the host accesses the network through a device. The host is assigned a public IP address either manually or through DHCP. An IMC server acts as a portal authentication server, a portal Web server, and a MAC binding server. A RADIUS server acts as the authentication and accounting server. In this example, the IMC server runs IMC 7.1 (E0303) and IMC UAM 7.1 (E0303).

Configure direct portal authentication, so the host can access only the portal Web server before passing the authentication and can access other network resources after passing the authentication.

Figure 26 Network diagram



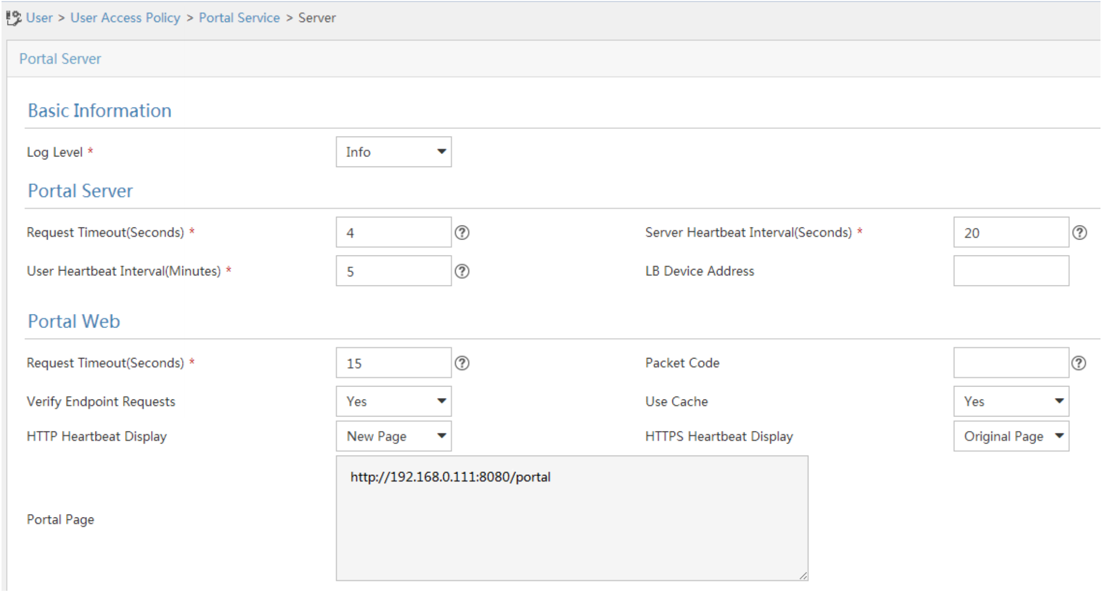
Configuring the RADIUS server

# Configure the RADIUS server correctly to provide authentication and accounting functions. (Details not shown.)

Configuring the portal server

1. Configure the portal authentication server:
   a. Log in to IMC and click the **User** tab.
   b. Select **User Access Policy** > **Portal Service** > **Server** from the navigation tree to open the portal server configuration page, as shown in Figure 27.
   c. Configure the portal server parameters as needed.
      This example uses the default settings.
   d. Click **OK**.

Figure 27 Portal server configuration



User > User Access Policy > Portal Service > Server

Portal Server

Basic Information

Log Level *	Info		

Portal Server

Request Timeout(Seconds) *	4	Server Heartbeat Interval(Seconds) *	20
User Heartbeat Interval(Minutes) *	5	LB Device Address

Verify Endpoint Requests	Yes	Use Cache	Yes
HTTP Heartbeat Display	New Page	HTTPS Heartbeat Display	Original Page
Portal Page	http://192.168.0.111:8080/portal		

2. Configure the IP address group:

   a. Select **User Access Policy** > **Portal Service** > **IP Group** from the navigation tree to open the portal IP address group configuration page.

   b. Click **Add** to open the page as shown in Figure 28.

   c. Enter the IP group name.

   d. Enter the start IP address and end IP address of the IP group.

      Make sure the client IP address (2.2.2.2) is in the IP group.

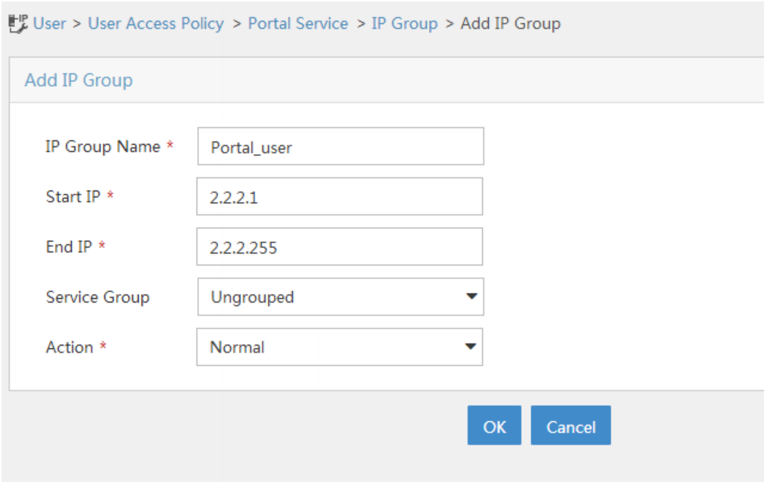
   e. Select a service group.

      This example uses the default group **Ungrouped**.

   f. Select **Normal** from the **Action** list.

   g. Click **OK**.

Figure 28 Adding an IP address group



User > User Access Policy > Portal Service > IP Group > Add IP Group

Add IP Group

IP Group Name *	Portal_user
Start IP *	2.2.2.1

3. Add a portal device:

   a. Select **User Access Policy** > **Portal Service** > **Device** from the navigation tree to open the portal device configuration page.

b. Click **Add** to open the page as shown in Figure 29.

c. Enter the device name.

d. Enter the IP address of the device's interface connected to the host.

e. Set whether to support the portal server heartbeat and user heartbeat functions.

   In this example, select **No** for both **Support Server Heartbeat** and **Support User Heartbeat**.

f. Enter the key, which must be the same as that configured on the device.

g. Select **Directly Connected** from the **Access Method** list.

h. Use the default settings for other parameters.

i. Click **OK**.

4. Associate the portal device with the IP address group:

a. As shown in Figure 30, click the **Port Group Information Management** icon for device **NAS** to open the port group configuration page.

b. Click **Add** to open the page as shown in Figure 31.

c. Enter the port group name.

d. Select the configured IP address group.

   The IP address used by the user to access the network must be within this IP address group.

e. Select **Supported** for **Transparent Authentication**.

f. Use the default settings for other parameters.

g. Click **OK**.

4. Configure system parameters:
   a. Select **User Access Policy** > **Service Parameters** > **System Settings** from the navigation tree to open the system settings page.
   b. Click the **Configure** icon ⚙ for **User Endpoint Settings** to open the page as shown in Figure 35.
   c. Select whether to enable transparent portal authentication on non-smart devices.
      In this example, select **Enable** for **Non-Terminal Authentication**.
   d. Click **OK**.
   e. Click the **Configure** icon ⚙ for **Endpoint Aging Time** to open the page as shown in Figure 36.
   f. Set the endpoint aging time as needed.
      This example uses the default value.

Configuring the device

1. Assign IP addresses to interfaces:

# Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.0.100 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name dmz
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/1
[Device-security-zone-DMZ] quit
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/2
[Device-security-zone-Trust] quit
```

3. Configure a security policy:

# Configure a rule named **trust-dmz** to allow the host to access the portal server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule 1 name trust-dmz
[Device-security-policy-ip-1-trust-dmz] source-zone trust
[Device-security-policy-ip-1-trust-dmz] destination-zone dmz
[Device-security-policy-ip-1-trust-dmz] source-ip-host 2.2.2.2
[Device-security-policy-ip-1-trust-dmz] destination-ip-host 192.168.0.111
[Device-security-policy-ip-1-trust-dmz] action pass
[Device-security-policy-ip-1-trust-dmz] quit
```

# Configure a rule named **portallocalout** to allow the device to send packets to the RADIUS server and portal server.

```
[Device-security-policy-ip] rule 2 name portallocalout
[Device-security-policy-ip-2-portallocalout] source-zone local
[Device-security-policy-ip-2-portallocalout] destination-zone dmz
[Device-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.111
[Device-security-policy-ip-2-portallocalout] destination-ip-host 192.168.0.112
[Device-security-policy-ip-2-portallocalout] action pass
[Device-security-policy-ip-2-portallocalout] quit
```

# Configure a rule named **portallocalin** to allow the device to receive and process the packets from the RADIUS server, portal server, and MAC-trigger server.

```
[Device-security-policy-ip] rule 3 name portallocalin
[Device-security-policy-ip-3-portallocalin] source-zone dmz
[Device-security-policy-ip-3-portallocalin] destination-zone local
[Device-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.111
[Device-security-policy-ip-3-portallocalin] source-ip-host 192.168.0.112
[Device-security-policy-ip-3-portallocalin] action pass
[Device-security-policy-ip-3-portallocalin] quit
[Device-security-policy-ip] quit
```

4. Configure a RADIUS scheme:

# Create a RADIUS scheme named **rs1**, and configure the device to exclude the ISP domain name from the username sent to the RADIUS server, and enable RADIUS session control.

```
<Device> system-view
[Device] radius scheme rs1
[Device-radius-rs1] primary authentication 192.168.0.112
```

```
[Device-radius-rs1] primary accounting 192.168.0.112
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
[Device] radius session-control enable
```

5. Configure an authentication domain:

   # Create an ISP domain named **dm1**, configure AAA methods for the ISP domain, and specify domain **dm1** as the default ISP domain.

   ```
   [Device] domain dm1
   [Device-isp-dm1] authentication portal radius-scheme rs1
   [Device-isp-dm1] authorization portal radius-scheme rs1
   [Device-isp-dm1] accounting portal radius-scheme rs1
   [Device-isp-dm1] quit
   [Device] domain default enable dm1
   ```

6. Configure portal authentication:

   # Configure a portal authentication server and a portal Web server. On GigabitEthernet 1/0/2, enable direct authentication, specify the portal Web server, and configure the BAS-IP as 2.2.2.1.

   ```
   [Device] portal server newpt
   [Device-portal-server-newpt] ip 192.168.0.111 key simple portal
   [Device-portal-server-newpt] port 50100
   [Device-portal-server-newpt] quit
   [Device] portal web-server newpt
   [Device-portal-websvr-newpt] url http://192.168.0.111:8080/portal
   [Device-portal-websvr-newpt] quit
   [Device] interface gigabitethernet 1/0/2
   [Device-GigabitEthernet1/0/2] portal enable method direct
   [Device-GigabitEthernet1/0/2] portal apply web-server newpt
   [Device-GigabitEthernet1/0/2] portal bas-ip 2.2.2.1
   [Device-GigabitEthernet1/0/2] quit
   ```

7. Configure MAC-based quick portal authentication:

   # Create the MAC binding server **mts**., set the free-traffic threshold, and specify the IP address of the MAC binding server. Specify the MAC binding server on GigabitEthernet 1/0/2.

   ```
   [Device] portal mac-trigger-server mts
   [Device-portal-mac-trigger-server-mts] free-traffic threshold 1024000
   [Device-portal-mac-trigger-server-mts] ip 192.168.0.111
   [Device-portal-mac-trigger-server-mts] quit
   [Device] interface gigabitethernet 1/0/2
   [Device-GigabitEthernet1/0/2] portal apply mac-trigger-server mts
   [Device-GigabitEthernet1/0/2] quit
   ```

Verifying the configuration

# Display information about the MAC binding server.

```
[Device] display portal mac-trigger-server name mts
Portal mac-trigger server name: mts
  Version                    : 1.0

```

A user can perform portal authentication by using the iNode client or a Web browser. Before passing the authentication, the user can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page. After passing the authentication, the user can access other network resources.

For the first portal authentication, the user is required to enter the username and password. When the user goes offline and then accesses the network again, the user does not need to enter the authentication username and password.

# Display portal user information.

```
[Device] display portal user interface gigabitethernet 1/0/2
Total portal users: 1
Username: Client1
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC                IP                 VLAN   Interface
  0015-e9a6-7cfe     2.2.2.2            --     GigabitEthernet1/0/2
  Authorization information:
    DHCP IP pool: N/A
    ACL number/name: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
```

Troubleshooting portal

No portal authentication page is pushed for users

Symptom

When a user is redirected to the IMC portal authentication server, no portal authentication page or error message is prompted for the user. The login page is blank.

Analysis

The key configured on the portal access device and that configured on the portal authentication server are inconsistent. As a result, packet verification fails, and the portal authentication server refuses to push the authentication page.

Solution

Use the **`display this`** command in portal authentication server view on the access device to check whether a key is configured for the portal authentication server.

- If no key is configured, configure the right key.
- If a key is configured, use the **`ip`** or **`ipv6`** command in the portal authentication server view to correct the key, or correct the key configured for the access device on the portal authentication server.

Cannot log out portal users on the access device

Symptom

You cannot use the **`portal delete-user`** command on the access device to log out a portal user, but the portal user can log out by clicking the **`Disconnect`** button on the portal authentication client.

Analysis

When you execute the **`portal delete-user`** command on the access device to log out a user, the access device sends an unsolicited logout notification message to the portal authentication server. The destination port number in the logout notification is the listening port number of the portal authentication server configured on the access device. If this listening port number is not the actual listening port number configured on the server, the server cannot receive the notification. As a result, the server does not log out the user.

When a user uses the **`Disconnect`** button on the authentication client to log out, the portal authentication server sends an unsolicited logout request message to the access device. The access device uses the source port in the logout request as the destination port in the logout ACK message. As a result, the portal authentication server can definitely receive the logout ACK message and log out the user.

Solution

1. Use the **`display portal server`** command to display the listening port of the portal authentication server configured on the access device.
2. Use the **`portal server`** command in system view to change the listening port number to the actual listening port of the portal authentication server.

Cannot log out portal users on the RADIUS server

Symptom

The access device uses the IMC server as the RADIUS server to perform identity authentication for portal users. You cannot log out the portal users on the RADIUS server.

Analysis

The IMC server uses session control packets to send disconnection requests to the access device. On the access device, the listening UDP port for session control packets is disabled by default. Therefore, the access device cannot receive the portal user logout requests from the RADIUS server.

Solution

On the access device, execute the **`radius session-control enable`** command in system view to enable the RADIUS session control function.

Users logged out by the access device still exist on the portal authentication server

Symptom

After you log out a portal user on the access device, the user still exists on the portal authentication server.

Analysis

When you execute the **`portal delete-user`** command on the access device to log out a user, the access device sends an unsolicited logout notification to the portal authentication server. If the BAS-IP or BAS-IPv6 address carried in the logout notification is different from the portal device IP address specified on the portal authentication server, the portal authentication server discards the logout notification. When sending of the logout notifications times out, the access device logs out the user. However, the portal authentication server does not receive the logout notification successfully, and therefore it regards the user is still online.

Solution

Configure the BAS-IP or BAS-IPv6 attribute on the interface enabled with portal authentication. Make sure the attribute value is the same as the portal device IP address specified on the portal authentication server.

Re-DHCP portal authenticated users cannot log in successfully

Symptom

The device performs re-DHCP portal authentication for users. A user enters the correct username and password, and the client successfully obtains the private and public IP addresses. However, the authentication result for the user is failure.

Analysis

When the access device detects that the client IP address is changed, it sends an unsolicited portal packet to notify of the IP change to the portal authentication server. The portal authentication server notifies of the authentication success only after it receives the IP change notification from both the access device and the client.

If the BAS-IP or BAS-IPv6 address carried in the portal notification packet is different from the portal device IP address specified on the portal authentication server, the portal authentication server discards the portal notification packet. As a result, the portal authentication server considers that the user has failed the authentication.

Solution

Configure the BAS-IP or BAS-IPv6 attribute on the interface enabled with portal authentication. Make sure the attribute value is the same as the portal device IP address specified on the portal authentication server.

Contents

Configuring MAC authentication

About MAC authentication

MAC authentication controls network access by authenticating source MAC addresses on a port. The feature does not require client software, and users do not have to enter a username and password for network access. The device initiates a MAC authentication process when it detects an unknown source MAC address on a MAC authentication-enabled port. If the MAC address passes authentication, the user can access authorized network resources. If the authentication fails, the device marks the MAC address as a silent MAC address, drops the packet, and starts a quiet timer. The device drops all subsequent packets from the MAC address within the quiet time. The quiet mechanism avoids repeated authentication during a short time.

User account policies

MAC authentication supports the following user account policies:

- One MAC-based user account for each user. As shown in Figure 1, the access device uses the source MAC addresses in packets as the usernames and passwords of users for MAC authentication. This policy is suitable for an insecure environment.
- One shared user account for all users. You specify one username and password, which are not necessarily a MAC address, for all MAC authentication users on the access device. This policy is suitable for a secure environment. See Figure 2.

Figure 1 MAC-based user account policy

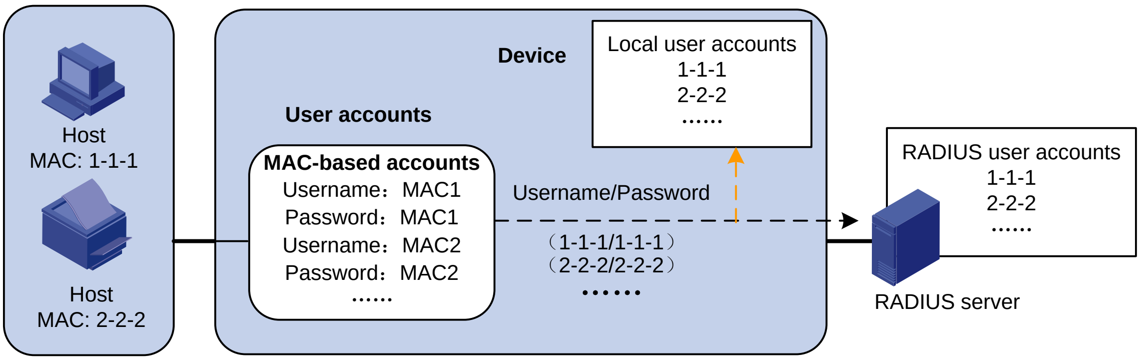

Figure 2 Shared user account policy

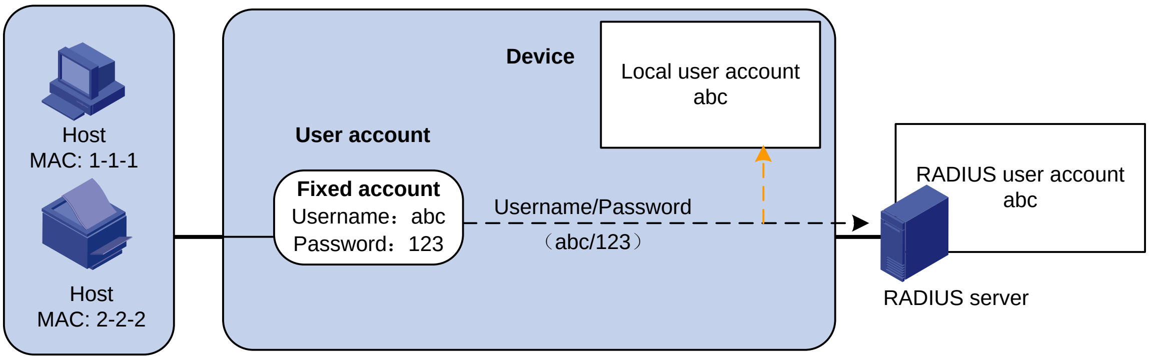


Authentication methods

You can perform MAC authentication on the access device (local authentication) or through a RADIUS server.

For more information about configuring local authentication and RADIUS authentication, see "Configuring AAA."

RADIUS authentication

If MAC-based accounts are used, the access device sends the source MAC address of the packet as the username and password to the RADIUS server for authentication.

If a shared account is used, the access device sends the shared account username and password to the RADIUS server for authentication.

Local authentication

If MAC-based accounts are used, the access device uses the source MAC address of the packet as the username and password to search the local account database for a match.

If a shared account is used, the access device uses the shared account username and password to search the local account database for a match.

VLAN assignment

Authorization VLAN

The authorization VLAN controls the access of a MAC authentication user to authorized network resources. The device supports authorization VLANs assigned locally or by a remote server.

IMPORTANT:

Only remote servers can assign tagged authorization VLANs.

Remote VLAN authorization

In remote VLAN authorization, you must configure an authorization VLAN for a user on the remote server. After the user authenticates to the server, the server assigns authorization VLAN information to the device. Then, the device assigns the user access port to the authorization VLAN as a tagged or untagged member.

The device supports assignment of the following authorization VLAN information by the remote server:

- VLAN ID.
- VLAN name, which must be the same as the VLAN description on the access device.
- A string of VLAN IDs and VLAN names.

  In the string, some VLANs are represented by their IDs, and some VLANs are represented by their names.
- VLAN group name.

  For more information about VLAN groups, see VLAN configuration in *Layer 2—LAN Switching Configuration Guide*.
- VLAN ID with a suffix of **t** or **u**.

  The **t** and **u** suffixes require the device to assign the access port to the VLAN as a tagged or untagged member, respectively. For example, **2u** indicates assigning the port to VLAN 2 as an untagged member.

If a VLAN name or VLAN group name is assigned, the device converts the information into a VLAN ID before VLAN assignment.

IMPORTANT:

For a VLAN represented by its VLAN name to be assigned successfully, you must make sure the VLAN has been created on the device.

To assign VLAN IDs with suffixes, make sure the user access port is a hybrid or trunk port.

To ensure a successful assignment, the authorization VLANs assigned by the remote server cannot be any of the following types:

- Dynamically learned VLANs.
- Reserved VLANs.

If the server assigns a group of VLANs, the access device selects a VLAN as described in Table 1.

Table 1 Authorization VLAN selection from a group of VLANs

VLAN information	Authorization VLAN selection
VLANs by IDs VLANs by names VLAN group name	On an access, trunk or hybrid port, the device selects an authorization VLAN from the VLAN group for a user according to the following rules: • If the port does not have online users, the device selects the VLAN with the lowest ID. • If the port has online users, the device examines whether the VLAN that has online users is in the VLAN group. If the VLAN is found in the group, the VLAN is assigned to the user as the authorization VLAN. If the VLAN is not found in the group, the VLAN authorization fails.
VLAN IDs with suffixes	**1.** The device selects the leftmost VLAN ID without a suffix, or the leftmost VLAN ID suffixed by **u** as an untagged VLAN, whichever is more leftmost. **2.** The device assigns the untagged VLAN to the port as the PVID, and it assigns the remaining as tagged VLANs. If no untagged VLAN is assigned, the PVID of the port does not change. The port permits traffic from these tagged and untagged VLANs to pass through. For example, the authentication server sends the string **1u 2t 3** to the access device for a user. The device assigns VLAN 1 as an untagged VLAN and all remaining VLANs (including VLAN 3) as tagged VLANs. VLAN 1 becomes the PVID.

Local VLAN authorization

To perform local VLAN authorization for a user, specify the VLAN ID in the authorization attribute list of the local user account for that user. For each local user, you can specify only one authorization VLAN ID. The user access port is assigned to the VLAN as an untagged member.

IMPORTANT:

Local VLAN authorization does not support assignment of tagged VLANs.

For more information about local user configuration, see "Configuring AAA."

Authorization VLAN manipulation on a MAC authentication-enabled port

Table 2 describes the way the network access device handles authorization VLANs (except for the VLANs specified with suffixes) for MAC authenticated users.

Table 2 VLAN manipulation

Port type	VLAN manipulation
• Access port • Trunk port	• The device assigns the port to the first authenticated user's authorization VLAN and sets the VLAN as the PVID if that authorization VLAN has the untagged attribute.

Port type	VLAN manipulation
• Hybrid port	• If the authorization VLAN has the tagged attribute, the device assigns the port to the authorization VLAN without changing its PVID. **NOTE:** The tagged attribute is supported only on trunk and hybrid ports.

IMPORTANT:

- If the users are attached to a port whose link type is access, make sure the authorization VLAN assigned by the server has the untagged attribute. VLAN assignment will fail if the server issues a VLAN that has the tagged attribute.
- As a best practice to enhance network security, do not use the **`port hybrid vlan`** command to assign a hybrid port to an authorization VLAN as a tagged member.

For a MAC authenticated user to access the network on a hybrid port when no authorization VLAN is configured for the user, perform one of the following tasks:

- If the port receives tagged authentication packets from the user in a VLAN, use the **`port hybrid vlan`** command to configure the port as a tagged member in the VLAN.
- If the port receives untagged authentication packets from the user in a VLAN, use the **`port hybrid vlan`** command to configure the port as an untagged member in the VLAN.

Guest VLAN

The MAC authentication guest VLAN on a port accommodates users that have failed MAC authentication for any reason other than server unreachable. For example, the VLAN accommodates users for which invalid passwords are entered.

You can deploy a limited set of network resources in the MAC authentication guest VLAN. For example, a software server for downloading software and system patches.

A hybrid port is always assigned to a MAC authentication guest VLAN as an untagged member. After the assignment, do not reconfigure the port as a tagged member in the VLAN.

The device reauthenticates users in the MAC authentication guest VLAN at a specific interval. Table 3 shows the way that the network access device handles guest VLANs for MAC authentication users.

Table 3 VLAN manipulation

Authentication status	VLAN manipulation
A user in the MAC authentication guest VLAN fails MAC authentication.	The user is still in the MAC authentication guest VLAN.
A user in the MAC authentication guest VLAN passes MAC authentication.	The device remaps the MAC address of the user to the authorization VLAN assigned by the authentication server. If no authorization VLAN is configured for the user on the authentication server, the device remaps the MAC address of the user to the PVID of the port.

Critical VLAN

The MAC authentication critical VLAN on a port accommodates users that have failed MAC authentication because no RADIUS authentication servers are reachable. Users in a MAC authentication critical VLAN can access only network resources in the critical VLAN.

The critical VLAN feature takes effect when MAC authentication is performed only through RADIUS servers. If a MAC authentication user fails local authentication after RADIUS authentication, the user is not assigned to the critical VLAN. For more information about the authentication methods, see "Configuring AAA."

Table 4 shows the way that the network access device handles critical VLANs for MAC authentication users.

Table 4 VLAN manipulation

Authentication status	VLAN manipulation
A user fails MAC authentication because all the RADIUS servers are unreachable.	The device maps the MAC address of the user to the MAC authentication critical VLAN. The user is still in the MAC authentication critical VLAN if the user fails MAC reauthentication because all the RADIUS servers are unreachable. If no MAC authentication critical VLAN is configured, the device maps the MAC address of the user to the PVID of the port.
A user in the MAC authentication critical VLAN fails MAC authentication for any reason other than server unreachable.	If a guest VLAN has been configured, the device maps the MAC address of the user to the guest VLAN. If no guest VLAN is configured, the device maps the MAC address of the user to the PVID of the port.
A user in the MAC authentication critical VLAN passes MAC authentication.	The device remaps the MAC address of the user to the authorization VLAN assigned by the authentication server. If no authorization VLAN is configured for the user on the authentication server, the device remaps the MAC address of the user to the PVID of the access port.

User profile assignment

You can specify a user profile in the user account for a MAC authentication user on the authentication server to control the user's access to network resources. After the user passes MAC authentication, the authentication server assigns the user profile to the user to filter traffic for this user.

The authentication server can be the local access device or a RADIUS server. In either case, the server only specifies the user profile name. You must configure the user profile on the access device.

To change the user's access permissions, you can use one of the following methods:

- Modify the user profile configuration on the access device.
- Specify another user profile for the user on the authentication server.

For more information about user profiles, see "Configuring user profiles."

Restrictions and guidelines: MAC authentication configuration

Do not change the link type of a port when the MAC authentication guest VLAN or critical VLAN on the port has users.

If the MAC address that has failed authentication is a static MAC address or a MAC address that has passed any security authentication, the device does not mark the MAC address as a silent address.

MAC authentication tasks at a glance

To configure MAC authentication, perform the following tasks:

1. Enabling MAC authentication
2. Configure basic MAC authentication features
   - Specifying a MAC authentication domain
   - Configuring the user account format
   - (Optional.) Configuring MAC authentication timers
3. (Optional.) Configuring MAC authentication VLAN assignment
   - Configuring a MAC authentication guest VLAN
   - Configuring a MAC authentication critical VLAN
4. (Optional.) Configuring other MAC authentication features
   - Setting the maximum number of concurrent MAC authentication users on a port
   - Enabling MAC authentication multi-VLAN mode on a port

     Perform this task to not reauthenticate online users when VLAN changes occur on a port.
   - Configuring the keep-online feature
   - Logging off MAC authentication users
   - Enabling MAC authentication user logging

Prerequisites for MAC authentication

Before you configure MAC authentication, complete the following tasks:

1. Configure an ISP domain and specify an AAA method. For more information, see "Configuring AAA."
   - For local authentication, you must also create local user accounts (including usernames and passwords) and specify the **lan-access** service for local users.
   - For RADIUS authentication, make sure the device and the RADIUS server can reach each other and create user accounts on the RADIUS server. If you are using MAC-based accounts, make sure the username and password for each account are the same as the MAC address of each MAC authentication user.

Enabling MAC authentication

Restrictions and guidelines

For MAC authentication to take effect on a port, you must enable this feature globally and on the port.

You cannot enable MAC authentication on a port that is in a link aggregation group.

Procedure

1. Enter system view.

   `system-view`
2. Enable MAC authentication globally.

   `mac-authentication`

   By default, MAC authentication is disabled globally.
3. Enter Layer 2 Ethernet interface view.

   `interface` *`interface-type interface-number`*

4. Enable MAC authentication on the port.

   mac-authentication

   By default, MAC authentication is disabled on a port.

Specifying a MAC authentication domain

About this task

By default, MAC authentication users are in the system default authentication domain. To implement different access policies for users, you can use one of the following methods to specify authentication domains for MAC authentication users:

- Specify a global authentication domain in system view. This domain setting applies to all ports enabled with MAC authentication.
- Specify an authentication domain for an individual port in Layer 2 Ethernet interface view.

MAC authentication chooses an authentication domain for users on a port in this order: the port-specific domain, the global domain, and the default domain. For more information about authentication domains, see "Configuring AAA."

Procedure

1. Enter system view.

   system-view

2. Specify an authentication domain for MAC authentication users.

   - In system view:

     mac-authentication domain *domain-name*

   - In Layer 2 Ethernet interface view:

     interface *interface-type interface-number*

     mac-authentication domain *domain-name*

   By default, the system default authentication domain is used for MAC authentication users.

Configuring the user account format

1. Enter system view.

   system-view

2. Configure the MAC authentication user account format.

   - Use one MAC-based user account for each user.

     mac-authentication user-name-format mac-address [{ **with-hyphen** [**six-section** | **three-section**] | **without-hyphen** } [**lowercase** | **uppercase**]]

   - Use one shared user account for all users.

     mac-authentication user-name-format fixed [**account** *name*] [**password** { **cipher** | **simple** } *string*]

   By default, the device uses the MAC address of a user as the username and password for MAC authentication. The MAC address is in hexadecimal notation without hyphens, and letters are in lower case.

Configuring MAC authentication timers

About this task

MAC authentication uses the following timers:

- **Offline detect timer**—Sets the interval that the device waits for traffic from a user before the device determines that the user is idle. If the device has not received traffic from a user before the timer expires, the device logs off that user and requests the accounting server to stop accounting for the user.
- **Quiet timer**—Sets the interval that the device must wait before the device can perform MAC authentication for a user that has failed MAC authentication. All packets from the MAC address are dropped during the quiet time. This quiet mechanism prevents repeated authentication from affecting system performance.
- **Server timeout timer**—Sets the interval that the device waits for a response from a RADIUS server before the device determines that the RADIUS server is unavailable. If the timer expires during MAC authentication, the user cannot access the network.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Configure MAC authentication timers.

   ```
   mac-authentication timer { offline-detect offline-detect-value |
   quiet quiet-value | server-timeout server-timeout-value }
   ```

   By default, the offline detect timer is 300 seconds, the quiet timer is 60 seconds, and the server timeout timer is 100 seconds.

Configuring a MAC authentication guest VLAN

Restrictions and guidelines

When you configure the MAC authentication guest VLAN on a port, follow the guidelines in Table 5.

Table 5 Relationships of the MAC authentication guest VLAN with other security features

Feature	Relationship description	Reference
Quiet feature of MAC authentication	The MAC authentication guest VLAN feature has higher priority. When a user fails MAC authentication, the user can access the resources in the guest VLAN. The user's MAC address is not marked as a silent MAC address.	See "Configuring MAC authentication timers."

Prerequisites

Before you configure the MAC authentication guest VLAN on a port, complete the following tasks:

- Create the VLAN to be specified as the MAC authentication guest VLAN.
- Configure the port as a hybrid port, and configure the VLAN as an untagged member on the port.

For information about VLAN configuration, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter Layer 2 Ethernet interface view.

   ```
   interface interface-type interface-number
   ```

3. Specify the MAC authentication guest VLAN on the port.

   ```
   mac-authentication guest-vlan guest-vlan-id
   ```

   By default, no MAC authentication guest VLAN is specified on a port.

   You can configure only one MAC authentication guest VLAN on a port. The MAC authentication guest VLANs on different ports can be different.

4. Set the authentication interval for users in the MAC authentication guest VLAN.

   ```
   mac-authentication guest-vlan auth-period period-value
   ```

   The default setting is 30 seconds.

Configuring a MAC authentication critical VLAN

Restrictions and guidelines

When you configure the MAC authentication critical VLAN on a port, follow the guidelines in Table 6.

Table 6 Relationships of the MAC authentication critical VLAN with other security features

Feature	Relationship description	Reference
Quiet feature of MAC authentication	The MAC authentication critical VLAN feature has higher priority. When a user fails MAC authentication because no RADIUS authentication server is reachable, the user can access the resources in the critical VLAN. The user's MAC address is not marked as a silent MAC address.	See "Configuring MAC authentication timers."

Prerequisites

Before you configure the MAC authentication critical VLAN on a port, complete the following tasks:

- Create the VLAN to be specified as the MAC authentication critical VLAN.
- Configure the port as a hybrid port, and configure the VLAN as an untagged member on the port.

For information about VLAN configuration, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter Layer 2 Ethernet interface view.

   ```
   interface interface-type interface-number
   ```

3. Specify the MAC authentication critical VLAN on the port.

   ```
   mac-authentication critical vlan critical-vlan-id
   ```

   By default, no MAC authentication critical VLAN is specified on a port.

   You can configure only one MAC authentication critical VLAN on a port. The MAC authentication critical VLANs on different ports can be different.

Setting the maximum number of concurrent MAC authentication users on a port

About this task

Perform this task to prevent the system resources from being overused.

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 2 Ethernet interface view.

   `interface` *`interface-type interface-number`*

3. Set the maximum number of concurrent MAC authentication users on the port.

   `mac-authentication max-user` *`max-number`*

   The default setting is 4294967295.

Enabling MAC authentication multi-VLAN mode on a port

About this task

The MAC authentication multi-VLAN mode prevents an authenticated online user from service interruption caused by VLAN changes on a port. When the port receives a packet sourced from the user in a VLAN not matching the existing MAC-VLAN mapping, the device neither logs off the user nor reauthenticates the user. The device creates a new MAC-VLAN mapping for the user, and traffic transmission is not interrupted. The original MAC-VLAN mapping for the user remains on the device until it dynamically ages out. As a best practice, configure this feature on hybrid or trunk ports.

Procedure

1. Enter system view.

   `system-view`

2. Enter Layer 2 Ethernet interface view.

   `interface` *`interface-type interface-number`*

3. Enable MAC authentication multi-VLAN mode.

   `mac-authentication host-mode multi-vlan`

   By default, this feature is disabled on a port. When the port receives a packet sourced from an authenticated user in a VLAN not matching the existing MAC-VLAN mapping, the device logs off and reauthenticates the user.

Configuring the keep-online feature

About this task

Periodic MAC reauthentication tracks the connection status of online users, and updates the authorization attributes assigned by the RADIUS server. The attributes include VLAN.

The device reauthenticates an online MAC authentication user periodically only after it receives the termination action **Radius-request** from the authentication server for this user. The Session-Timeout attribute (session timeout period) assigned by the server is the reauthentication interval. To display the server-assigned Session-Timeout and Termination-Action attributes, use the

display mac-authentication connection command. Support for the server configuration and assignment of Session-Timeout and Termination-Action attributes depends on the server model.

The keep-online feature enables the device to keep the MAC authentication users online when no server is reachable for MAC reauthentication.

Restrictions and guidelines

In a fast-recovery network, you can use the keep-online feature to prevent MAC authentication users from coming online and going offline frequently.

Any modification to the MAC authentication domain or user account format setting does not affect the reauthentication of online MAC authentication users. The modified setting takes effect only on MAC authentication users that come online after the modification.

Procedure

1. Enter system view.

   system-view
2. Enter Layer 2 Ethernet interface view.

   interface *interface-type interface-number*
3. Enable the keep-online feature for authenticated MAC authentication users on the port.

   mac-authentication re-authenticate server-unreachable keep-online

   By default, the keep-online feature is disabled. The device logs off online MAC authentication users if no server is reachable for MAC reauthentication.

Logging off MAC authentication users

About this task

Perform this task to log off specified MAC authentication users and clear information about these users from the device. These users must perform MAC authentication to come online again.

Restrictions and guidelines

With an interface specified, the **reset mac-authentication access-user** command logs off all MAC authentication users on the specified interface.

With a MAC address specified, the **reset mac-authentication access-user** command logs off the MAC authentication user with the specified MAC address.

With a VLAN specified, the **reset mac-authentication access-user** command logs off all MAC authentication users in the specified VLAN, including:

- Users that are performing MAC authentication in the specified VLAN.
- Users that have passed MAC authentication and have been assigned the specified VLAN as their authorization VLAN by the server.
- Users that stay in the specified VLAN after they have passed MAC authentication, because they have not been assigned an authorization VLAN yet.

To identify the VLAN in which a user is staying, use the **display mac-address** command.

With a VSI specified, the **reset mac-authentication access-user** command logs off all MAC authentication users in the specified VSI.

Procedure

To log off MAC authentication users, execute the following command in user view:

reset mac-authentication access-user [**interface** *interface-type interface-number* | **mac** *mac-address* | **username** *username* | **vlan** *vlan-id* | **vsi** *vsi-name*]

Enabling MAC authentication user logging

About this task

This feature enables the device to generate logs about MAC authentication users and send the logs to the information center. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

To prevent excessive MAC authentication user log entries, use this feature only if you need to analyze abnormal MAC authentication user logins or logouts.

Procedure

1. Enter system view.

   system-view

2. Enable MAC authentication user logging.

   mac-authentication access-user log enable [**failed-login** | **logoff** | **successful-login**] *

   By default, MAC authentication user logging is disabled.

   If you do not specify any parameters, this command enables all types of MAC authentication user logs.

Display and maintenance commands for MAC authentication

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display MAC authentication information.	**display mac-authentication** [**interface** *interface-type interface-number*]

Display MAC authentication connections.	**display mac-authentication connection** [**interface** *interface-type interface-number* | **slot** *slot-number* | **user-mac** *mac-address* | **user-name** *user-name*]
Clear MAC authentication statistics.	**reset mac-authentication statistics** [**interface** *interface-type interface-number*]
Remove users from the MAC authentication critical VLAN on a port.	**reset mac-authentication critical-vlan interface** *interface-type interface-number* [**mac-address** *mac-address*]
Remove users from the MAC authentication guest VLAN on a port.	**reset mac-authentication guest-vlan interface** *interface-type interface-number* [**mac-address** *mac-address*]

MAC authentication configuration examples

Example: Configuring local MAC authentication

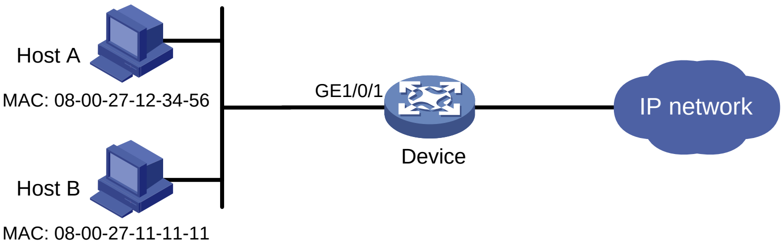
Network configuration

As shown in Figure 3, the device performs local MAC authentication on GigabitEthernet 1/0/1 to control Internet access of users.

Configure the device to meet the following requirements:

- Detect whether a user has gone offline every 180 seconds.
- Deny a user for 180 seconds if the user fails MAC authentication.
- Authenticate all users in ISP domain **bbb**.
- Use the MAC address of each user as the username and password for authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in lower case.

Figure 3 Network diagram



Procedure

# Add a network access local user. In this example, configure both the username and password as Host A's MAC address 08-00-27-12-34-56.

```
<Device> system-view
[Device] local-user 08-00-27-12-34-56 class network
[Device-luser-network-08-00-27-12-34-56] password simple 08-00-27-12-34-56
```

# Specify the LAN access service for the user.

```
[Device-luser-network-08-00-27-12-34-56] service-type lan-access

# Configure MAC authentication to use MAC-based accounts. Each MAC address is in hexadecimal notation with hyphens, and letters are in lower case.

```
[Device] mac-authentication user-name-format mac-address with-hyphen lowercase
```

# Enable MAC authentication globally.

```
[Device] mac-authentication
```

Verifying the configuration

# Display MAC authentication settings and statistics to verify your configuration.

```
<Device> display mac-authentication
Global MAC authentication parameters:
   MAC authentication     : Enabled
   User name format       : MAC address in lowercase(xx-xx-xx-xx-xx-xx)
           Username       : mac
           Password       : Not configured
   Offline detect period  : 180 s
   Quiet period           : 180 s
```

```
  Server timeout         : 100 s
  Authentication domain  : bbb
Online MAC-auth wired users    : 1

Silent MAC users:
         MAC address       VLAN ID  From port               Port index
         0800-2711-1111    8        Gigabitethernet1/0/1    1

Gigabitethernet1/0/1 is link-up
  MAC authentication         : Enabled
  Carry User-IP              : Disabled
  Authentication domain      : Not configured
  Auth-delay timer           : Disabled
  Re-auth server-unreachable : Logoff
  Guest VLAN                 : Not configured
  Guest VLAN auth-period     : 30 s
  Critical VLAN              : Not configured
  Critical voice VLAN        : Disabled
  Host mode                  : Single VLAN
  Max online users           : 4294967295
  Authentication attempts    : successful 1, failed 0
  Current online users       : 1
         MAC address       Auth state
         0800-2712-3456    Authenticated
```

The output shows that Host A has passed MAC authentication and has come online. Host B failed MAC authentication and its MAC address is marked as a silent MAC address.

Example: Configuring RADIUS-based MAC authentication

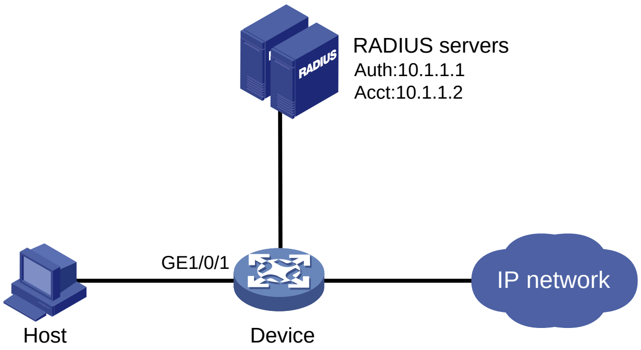
Network configuration

As shown in Figure 4, the device uses RADIUS servers to perform authentication, authorization, and accounting for users.

To control user access to the Internet by MAC authentication, perform the following tasks:

- Enable MAC authentication globally and on GigabitEthernet 1/0/1.
- Configure the device to detect whether a user has gone offline every 180 seconds.
- Configure the device to deny a user for 180 seconds if the user fails MAC authentication.
- Configure all users to belong to ISP domain **bbb**.
- Use a shared user account for all users, with username **aaa** and password **123456TESTplat&!TESTplat&!**.

Figure 4 Network diagram



Procedure

Make sure the RADIUS server and the access device can reach each other.

1. Configure the RADIUS servers to provide authentication, authorization, and accounting services. Create a shared account with username **aaa** and password **123456TESTplat&!TESTplat&!** for MAC authentication users. (Details not shown.)
2. Configure RADIUS-based MAC authentication on the device:

   # Configure a RADIUS scheme.

   ```
   <Device> system-view
   [Device] radius scheme 2000
   [Device-radius-2000] primary authentication 10.1.1.1 1812
   [Device-radius-2000] primary accounting 10.1.1.2 1813
   [Device-radius-2000] key authentication simple abc
   [Device-radius-2000] key accounting simple abc
   [Device-radius-2000] user-name-format without-domain
   [Device-radius-2000] quit
   ```

   # Apply the RADIUS scheme to ISP domain **bbb** for authentication, authorization, and accounting.

   ```
   [Device] domain bbb
   [Device-isp-bbb] authentication default radius-scheme 2000
   [Device-isp-bbb] authorization default radius-scheme 2000
   [Device-isp-bbb] accounting default radius-scheme 2000
   [Device-isp-bbb] quit
   ```

   # Enable MAC authentication on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] mac-authentication
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Specify the MAC authentication domain as ISP domain **bbb**.

   ```
   [Device] mac-authentication domain bbb
   ```

   # Set MAC authentication timers.

   ```
   [Device] mac-authentication timer offline-detect 180
   [Device] mac-authentication timer quiet 180
   ```

   # Specify username **aaa** and password **123456TESTplat&!TESTplat&!** in plain text for the account shared by MAC authentication users.

   ```
   [Device] mac-authentication user-name-format fixed account aaa password simple
   123456TESTplat&!TESTplat&!
   ```

   # Enable MAC authentication globally.

```
[Device] mac-authentication
```

Verifying the configuration

# Verify the MAC authentication configuration.

```
<Device> display mac-authentication
Global MAC authentication parameters:
   MAC authentication     : Enabled
   Username format        : Fixed account
           Username       : aaa

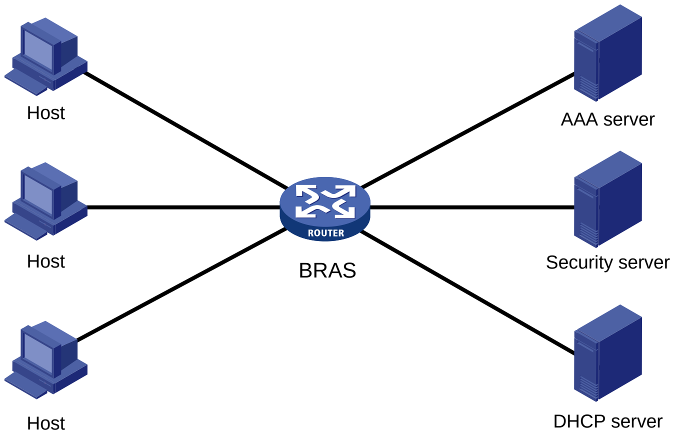
Configuring IPoE

About IPoE

IP over Ethernet (IPoE) enables a BRAS to connect and authenticate users over IPoE connections.

As shown in Figure 1, a BRAS connects hosts over IPoE connections, and provides AAA, security, and DHCP services for the hosts. This solution does not require the hosts to install any client software.

Figure 1 IPoE network diagram



IPoE access modes

IPoE supports Layer 2 and Layer 3 access modes.

- Layer 2 access mode

  Hosts directly access the BRAS. The hosts connect to the BRAS directly or through Layer 2 devices. The BRAS uses MAC addresses to identify the hosts.

- Layer 3 access mode

  Hosts use routing to access the BRAS. The hosts connect to the BRAS directly or through Layer 3 devices. When a Layer 3 device resides between the hosts and the BRAS, the source MAC address of packets received by the BRAS is the MAC address of the Layer 3 device. Therefore, the BRAS uses IP addresses or VLAN IDs to identify hosts.

IPoE users

IPoE users include individual users and leased users.

Individual users

Individual users use independent IPoE services. The BRAS authenticates, authorizes, and bills individual users based on user location and packet information. Individual users include dynamic and static individual users.

- Dynamic individual users

  IPoE defines the following dynamic individual users:

  - **DHCP user**—Sends DHCP packets to trigger IPoE session establishment.
  - **IPv6-ND-RS user**—Sends IPv6 ND RS packets to trigger IPoE session establishment.

  - **Unclassified-IP user**—Sends packets other than DHCP and IPv6 ND RS packets to trigger IPoE session establishment.
- Static individual users

  Static individual users trigger IPoE session establishment by sending IP packets. If an IP packet matches a manually configured IPoE session, the BRAS authenticates the user and establishes an IPoE session.

Leased users

Leased users include the following types:

- **Interface-leased user**—Represents hosts that rent the same interface.
- **Subnet-leased user**—Represents hosts that rent a subnet of an interface.

The BRAS automatically uses the credentials configured for a leased user to perform authentication. Users are not required to send IP packets to trigger authentication.

IPoE session

IPoE sessions include dynamic and static sessions.

Dynamic IPoE session

IPoE sessions established for dynamic individual users are dynamic IPoE sessions.

The BRAS disconnects a dynamic IPoE session in one of the following cases:

- The AAA-authorized service expires.
- The AAA server logs out the user.
- The user traffic is less than the authorized traffic during the idle-timeout time.
- The BRAS cannot detect the user after the number of detection attempts reaches the maximum.
- The IP address lease expires.
- The IPoE session is restarted.
- The access interface goes down.

Static IPoE session

IPoE sessions established for static individual users, interface-leased users, and subnet-leased users are static IPoE sessions.

The BRAS creates a static IPoE session based on configured information after you enable IPoE on an interface. The BRAS initiates user authentication based on the configured username and password upon receiving IP packets from static individual users. Static IPoE sessions can only be deleted manually at the CLI.

For static individual users, the BRAS creates a static IPoE session based on configured information after you enable IPoE on an interface. The BRAS initiates user authentication based on the configured username and password upon receiving IP packets from static individual users.

For interface-leased users and subnet-leased users, the BRAS creates a static IPoE session based on configured information after you enable IPoE on an interface. The BRAS initiates user authentication based on the configured username and password.

IPoE addressing

IPoE addressing varies with user types.

- DHCP users obtain IP addresses in the following sequence:
  - Obtain IP addresses from the AAA-authorized IP address pool.

    - Obtain IP addresses from the IP address pool configured in the ISP domain if the AAA server does not authorize any IP address pools.
    - Obtain IP addresses in the same network segment as the interface IP address if no IP address pool is configured in the ISP domain.
- IPv6-ND-RS users obtain the AAA-authorized IPv6 prefix from IPoE, and generate an IPv6 address based on the prefix. If no AAA-authorized IPv6 prefix exists, the user adopts the first 64-bit IPv6 prefix of the interface to generate an IPv6 address.
- Other users adopt static IP addresses or obtain IP addresses from the DHCP server without using IPoE.

IPoE access procedure

IPoE access includes the following steps:

1. The BRAS initiates authentication.

   The BRAS obtains information from user packets or IPoE sessions statically configured, and sends authentication requests.
2. The AAA server authenticates users.

   The AAA server completes user authentication and sends the result to the BRAS. The security server, if configured, completes security authorization and sends the result to the BRAS.
3. (Optional.) DHCP allocates IP addresses.

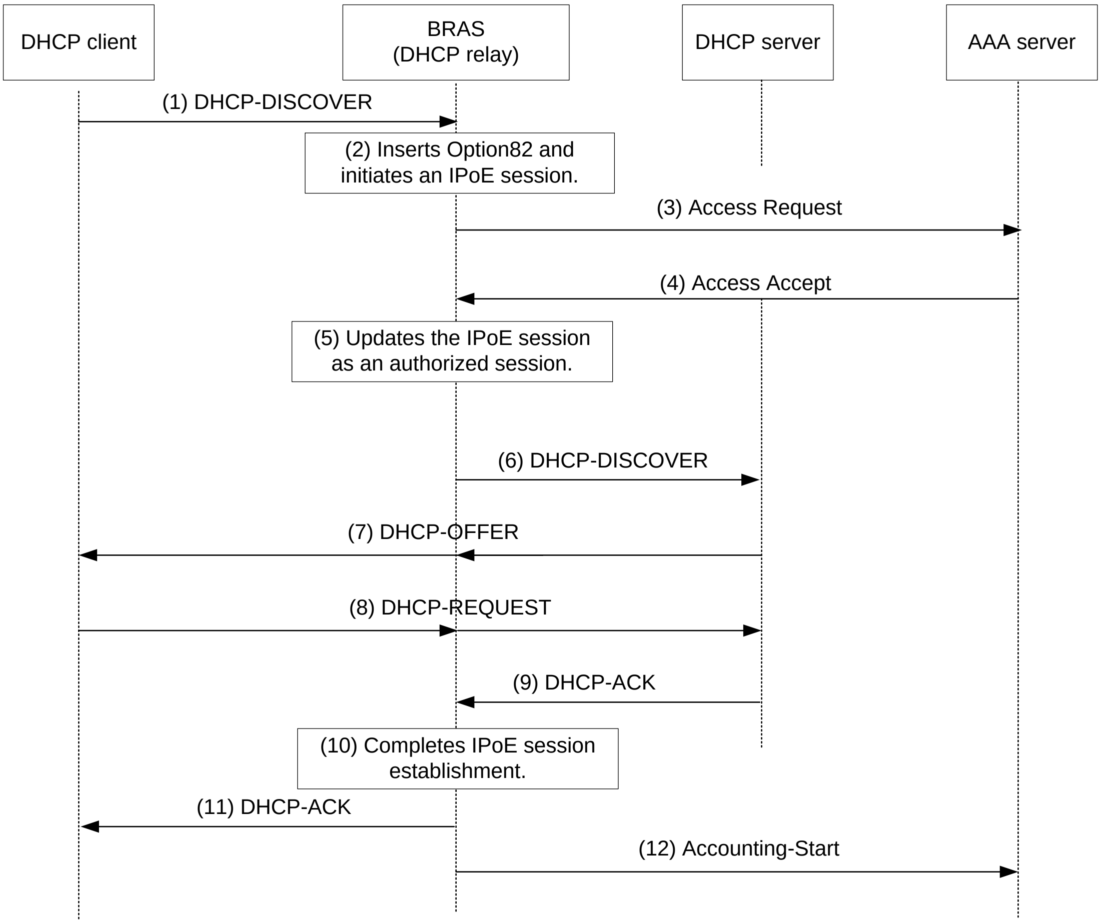
   The DHCP server assigns an IP address to a DHCP user and IPoE assigns an IPv6 prefix to an IPv6-ND-RS user.
4. The BRAS performs access control.

   The BRAS permits the user to get online and performs access control and billing based on the authorized result.

Access procedure for DHCP users

This section uses a DHCPv4 user as an example to illustrate the access procedure for DHCP users. The BRAS operates as a DHCP relay.

Figure 2 Access procedure for a DHCPv4 user



1. The DHCP client sends a DHCP-DISCOVER message to the BRAS.
2. The BRAS inserts Option 82 in the DHCP-DISCOVER message, and creates an IPoE session.
3. The BRAS sends the AAA server an access request that includes user information, such as the client ID and source MAC address.
4. The AAA server returns an access accept that contains authorization information to the BRAS if the authentication succeeds. If the authentication fails, the AAA server returns a reject message.
5. The BRAS marks the IPoE session state as success and forwards the DHCP-DISCOVER message to the DHCP server if the authentication succeeds. If the authentication fails, the BRAS marks the session as failure and discards the DHCP-DISCOVER message.
6. The DHCP server sends a DHCP-OFFER message to the BRAS.
7. The BRAS forwards the DHCP-OFFER message to the DHCP client.
8. The DHCP client sends a DHCP-REQUEST message to the BRAS.
9. The BRAS forwards the DHCP-REQUEST message to the specified DHCP sever.
10. The DHCP server sends a DHCP-ACK message containing the assigned IP address to the BRAS.
11. The BRAS performs the following:
    a. Obtains address information from the DHCP-ACK message.
    b. Assigns a user profile.
    c. Updates the IPoE session information.
    d. Forwards the DHCP-ACK message to the client.

   e. Marks the session state as online.

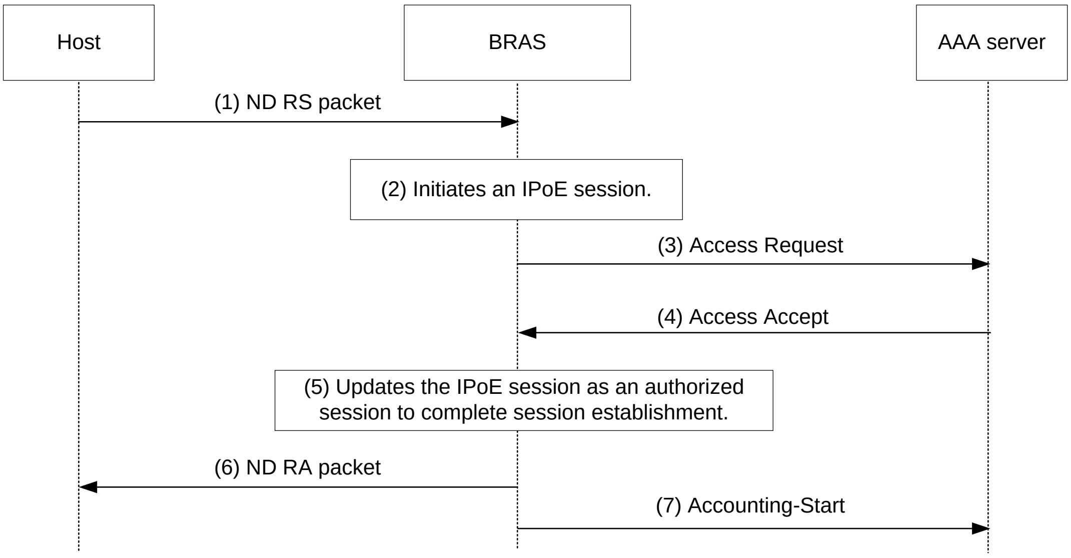
   If the authentication fails, the BRAS marks the session as failure and discards the DHCP-DISCOVER message.

12. The DHCP client obtains configuration information from the DHCP-ACK message.
13. The BRAS sends the AAA server a message to start accounting.

Access procedure for IPv6-ND-RS users

This example uses a Layer 2 device as the BRAS.

Figure 3 Access procedure for IPv6-ND-RS users



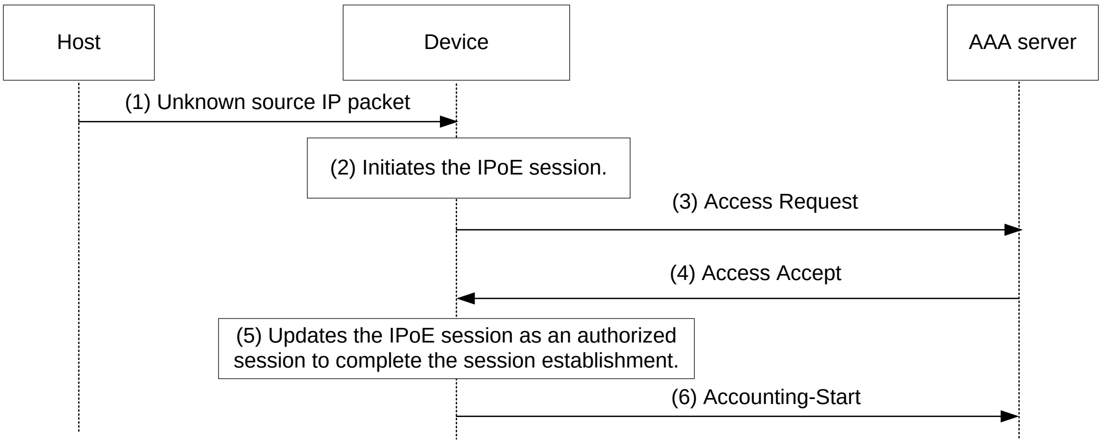
Host
BRAS
AAA server
(1) ND RS packet
(2) Initiates an IPoE session.
(3) Access Request
(4) Access Accept
(5) Updates the IPoE session as an authorized session to complete session establishment.
(6) ND RA packet
(7) Accounting-Start

1. The host sends an IPv6 ND RS packet to the BRAS.
2. The BRAS initiates an IPoE session and sends the AAA server an access request that contains user information, such as the source MAC address.
3. The AAA server returns an access accept that contains authorization information to the BRAS if the authentication succeeds. If the authentication fails, the AAA server returns a reject message.
4. The BRAS performs the following:
   a. Generates an IPv6 address based on the host's MAC address and the IPv6 prefix.
   b. Updates the IPoE session information.
   c. Marks the session as success.

   If the authentication fails, the BRAS marks the session as failure and discards the IPv6 ND RS packet.
5. The BRAS assigns a user profile and sends the host an IPv6 ND RA packet containing the IPv6 prefix.
6. The host generates an IPv6 address based on the received IPv6 prefix.
7. The BRAS sends the AAA server a message to start the service accounting.

Access procedure for unclassified-IP users

Figure 4 Access procedure for unclassified-IP users



Host
Device
AAA server
(1) Unknown source IP packet
(2) Initiates the IPoE session.
(3) Access Request
(4) Access Accept
(5) Updates the IPoE session as an authorized session to complete the session establishment.
(6) Accounting-Start

1. The host sends an IP packet to the BRAS.
2. The BRAS obtains user information from the IP packet, and matches the user information against existing IPoE sessions.
   - If no match is found, the BRAS initiates an IPoE session for the user. (This section uses this case as an example.)
   - If the information matches an authenticated session, the BRAS forwards the IP packet.
   - If the information matches an unauthenticated session, the BRAS discards the IP packet.
3. The BRAS sends the AAA server an access request containing the obtained information, such as the source IP address or source MAC address.
4. The AAA server returns an access accept that contains authorization information if the authentication succeeds. If the authentication fails, the AAA server returns a reject message.
5. The BRAS assigns a user profile and marks the IPoE session state as online.
6. The BRAS sends the AAA server a message to start the service accounting.

Access procedure for static and leased users

The access procedure for static users is as follows:

1. The user statically configures an IPoE session at the CLI on the BRAS.
2. The user sends an IP packet to the BRAS.
3. The BRAS obtains user information from the IP packet, and sends the AAA server an access request containing configured IPoE session information.
4. The AAA server returns an access accept that contains authorization information if the authentication succeeds. If the authentication fails, the AAA server returns a reject message.
5. The BRAS assigns the user profile and marks the IPoE session state as online.
6. The host receives the user profile.
7. The BRAS sends the AAA server a message to start the service accounting.

The access procedure for leased users is as follows:

1. The user statically configures an IPoE session at the CLI on the BRAS.
2. The BRAS automatically obtains configured IPoE session information and sends the AAA server an access request.
3. The AAA server returns an access accept that contains authorization information if the authentication succeeds. If the authentication fails, the AAA server returns a reject message.
4. The BRAS assigns the user profile and marks the IPoE session state as online.

5. The host receives the user profile.
6. The BRAS sends the AAA server a message to start the service accounting.

Support for MPLS L3VPN

IPoE supports MPLS L3VPN. It uses AAA to authorize VPNs for users. Before you bind a VPN instance to an interface, you must delete existing IPoE sessions on the interface for the users to communicate in their authorized VPNs.

NOTE:

Leased users do not support AAA-authorized VPNs through ISP domains or AAA servers. For more information about VPN authorization through ISP domains, see *Security Configuration Guide*.

Support for ITA

ITA provides accounting and bandwidth solutions for users based on the destination addresses they access.

For more information about configuring ITA, see *Security Configuration Guide*.

Restrictions and guidelines: IPoE configuration

IPoE supports the following interfaces:

- Layer 3 aggregate interfaces.
- Layer 3 aggregate subinterfaces
- Layer 3 Ethernet interfaces.
- Layer 3 Ethernet subinterfaces.

IPoE tasks at a glance

To configure IPoE, perform the following tasks:

1. Enabling IPoE and setting the IPoE access mode
2. Configure user types
   - Configuring dynamic individual users
   - Configuring static individual users
   - Configuring leased users

   Individual users and leased users cannot be configured on the same interface. Dynamic and static individual users can be configured on the same interface.
3. (Optional.) Configuring service-specific ISP domains
4. (Optional.) Configuring the quiet timer for users
5. (Optional.) Configuring online detection for IPoE users
6. (Optional.) Configuring NAS-Port-Type for an interface
7. (Optional.) Enabling IPoE user logging
8. (Optional.) Configuring NAS-Port-ID formats

Prerequisites for IPoE

Complete the following configuration as required:

- Configure the DHCP server.
- Enable the DHCP relay agent on the BRAS.
- Configure the RADIUS server and client. For more information about how to configure a RADIUS client, see AAA configuration in *Security Configuration Guide*.
- Configure security policies on the iMC security server and configure the security server's IP address on the BRAS. For more information about how to configure a security server, see AAA configuration in *Security Configuration Guide*.
- Configure local user accounts on the BRAS if local authentication is used. For more information about how to configure a local user account, see AAA configuration in *Security Configuration Guide*.
- Make sure the hosts, BRAS, and servers can reach each other.

Enabling IPoE and setting the IPoE access mode

Restrictions and guidelines

To change the IPoE access mode, disable IPoE, and then set the new IPoE mode when you enable IPoE.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable IPoE and set the IPoE access mode on an IPv4 interface
   ip subscriber { **l2-connected** | **routed** } **enable**
   By default, IPv4 IPoE is disabled.
4. Enable IPoE and set the IPoE access mode on an IPv6 interface
   ipv6 subscriber { **l2-connected** | **routed** } **enable**
   By default, IPv6 IPoE is disabled.

Configuring dynamic individual users

Dynamic individual user tasks at a glance

To configure dynamic individual users, perform the following tasks:

1. Enabling dynamic individual users
2. (Optional.) Configuring authentication user naming conventions for dynamic individual users
3. (Optional.) Configuring passwords for dynamic individual users
4. (Optional.) Configuring ISP domains for dynamic individual users
5. (Optional.) Configuring the maximum number of dynamic IPoE sessions
6. (Optional.) Configuring trusted DHCP options for DHCP users

Enabling dynamic individual users

About this task

Dynamic individual users include the unclassified-IP user, IPv6-ND-RS user, and DHCP user. After IPoE is enabled on an interface, the BRAS discards packets from users by default. You must enable dynamic individual users on the interface to trigger IPoE session establishment. You can enable multiple dynamic individual users on an interface.

Restrictions and guidelines

It requires the BRAS to send IPv6 ND RA packets. The interval for sending IPv6 ND RA packets should be no less than 6 minutes.

The IPv6-ND-RS user supports only hosts that use layer-2 access mode.

As a best practice, configure both the unclassified-IP user and IPv6-ND-RS user for an IPv6 interface. PCs running Windows generate IPv6 addresses randomly or using the EUI-64 method. The unclassified-IP user supports packets with randomly-generated IPv6 addresses. The IPv6-ND-RS user supports packets with EUI-64-generated IPv6 addresses.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the IPv4 dynamic individual user.

   ip subscriber initiator { **dhcp** | **unclassified-ip** } **enable**

   By default, no IPv4 dynamic individual users are enabled.

4. Enable the IPv6 dynamic individual user:

   ipv6 subscriber initiator { **dhcp** | **ndrs** | **unclassified-ip** } **enable**

   By default, no IPv6 dynamic individual users are enabled.

Configuring authentication user naming conventions for dynamic individual users

About this task

Usernames configured for dynamic individual users must be the same as those configured on the AAA server.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure authentication user naming conventions for IPv4 dynamic individual users.

   - Configure an authentication user naming convention for DHCPv4 users.

     ip subscriber dhcp username include { **circuit-id** [**separator** *separator*] | **client-id** [**separator** *separator*] | **nas-port-id** [**separator** *separator*] | **port** [**separator** *separator*] | **remote-id** [**separator** *separator*] | **second-vlan** [**separator** *separator*] | **slot** [**separator** *separator*] | **source-mac** [**address-separator** *address-separator*]

```
[separator separator ]|subslot [separator separator ]|sysname
[separator separator]|vendor-class [separator separator ] |
vendor-specific [separator separator ] | vlan [separator separator ]}
*
```

By default, usernames for DHCPv4 users are source MAC addresses.

- Configure an authentication user naming convention for unclassified-IP users.

```
ip subscriber unclassified-ip username include { nas-port-id
[separator separator ] | port [separator separator ]|second-vlan
[separator separator ]| slot [separator separator ]|source-ip
[ address-separator address-separator ] [separator separator ]|
source-mac [address-separator address-separator ] [separator
separator ]|subslot [separator separator]|sysname [separator
separator ]| vlan [separator separator ] }*
```

By default, usernames for unclassified-IP users are source IP addresses.

4. Configure authentication user naming conventions for IPv6 dynamic individual users.

- Configure an authentication user naming convention for DHCPv6 users.

```
ipv6 subscriber dhcp username include{ circuit-id [separator
separator ] | client-id [separator separator ]|nas-port-id
[separator separator ] | port [separator separator ]| remote-id
[separator separator ] | second-vlan [separator separator]| slot
[separator separator]| source-mac [ address-separator
address-separator ] [separator separator ] |subslot [separator
separator ]|sysname [separator separator ]|vendor-class [separator
separator ] | vendor-specific [separator separator ] | vlan [separator
separator ]}*
```

By default, usernames for DHCPv6 are source MAC addresses.

- Configure an authentication user naming convention for IPv6-ND-RS users.

```
ipv6 subscriber ndrs username include { nas-port-id [separator
separator ] | port [separator separator ]| second-vlan [separator
separator ]| slot [separator separator ] | source-mac
[ address-separator address-separator ] [separator separator ] |
subslot [separator separator ]|sysname [separator separator ]| vlan
[separator separator ]}*
```

By default, usernames for IPv6-ND-RS users are source MAC addresses.

- Configure an authentication user naming convention for unclassified-IP users.

```
ipv6 subscriber unclassified-ip username include{ nas-port-id
[ separator separator ] | port [separator separator ] |second-vlan
[separator separator ]|slot [separator separator ]|source-ip
[ address-separator address-separator ] [separator separator ] |
source-mac [ address-separator address-separator ] [separator
separator ] |subslot [separator separator]|sysname [separator
separator ]| vlan [separator separator]}*
```

By default, usernames for unclassified-IP users are source IP addresses.

Configuring passwords for dynamic individual users

About this task

Passwords configured for dynamic individual users must be the same as those configured on the AAA server.

If you configure multiple passwords for an DHCP user, the passwords are used in the following order:

1. Password specified in trusted Option 60 or Option 16.
2. Password specified the **ip subscriber password** or **ipv6 subscriber password** command.
3. Default system password.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure a password for IPv4 IPoE users.
   - Configure a password for IPv4 dynamic individual users.

     ip subscriber password { **ciphertext** | **plaintext** } *string*

     The default password for dynamic individual users is **vlan**.

   - Specify a string from the Option 60 as the password for IPv4 DHCP users.

     ip subscriber dhcp password option60 [**offset** *offset*] [**length** *length*]

     By default, the BRAS does not use the password specified in Option 60 for DHCP users.

     Configure Option 60 as the trusted DHCP option for the password specified by this command to take effect. For more information about Option 60, see "Configuring trusted DHCP options for DHCP users."

4. Configure a password for IPv6 IPoE users.
   - Configure a password for IPv6 dynamic individual users.

     ipv6 subscriber password { **ciphertext** | **plaintext** } *string*

     The default password for dynamic individual users is **vlan**.

   - Specify a string from the Option 16 as the password for IPv6 dynamic individual users:

     ipv6 subscriber dhcp password option16 [**offset** *offset*] [**length** *length*]

     By default, the BRAS does not use the password specified in Option 16 for DHCP users.

     Configure DHCPv6 Option 16 as the trusted DHCP option for the password specified by this command to take effect. For more information about Option 16, see "Configuring trusted DHCP options for DHCP users."

Configuring ISP domains for dynamic individual users

About this task

The following table shows how the BRAS selects ISP domains for dynamic individual users.

Dynamic individual users	Order in selecting an ISP domain
DHCP user	• ISP domain automatically selected from DHCPv4 Option 60 or DHCPv6 Option 16 if the option is trusted • Interface-specific ISP domain • Default system ISP domain
IPv6-ND-RS user	• Interface-specific ISP domain • Default system ISP domain

Dynamic individual users	Order in selecting an ISP domain
Unclassified-IP user	• Service-specific ISP domain • Interface-specific ISP domain • Default system ISP domain

For more information about how to configure service-specific ISP domains, see "Configuring service-specific ISP domains."

For more information about how to configure the default system ISP domain, see AAA configuration in *Security Configuration Guide*.

Restrictions and guidelines

Configure trusted DHCP options before you configure ISP domains automatically selected from DHCPv4 Option 60 or DHCPv6 Option 16. For more information about how to configure trusted DHCP options, see "Configuring trusted DHCP options for DHCP users."

The specified ISP domain must exist on the BRAS.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure an ISP domain for IPv4 dynamic individual users.
   ip subscriber { **dhcp** | **unclassified-ip** } **domain** *domain-name*
   By default, IPv4 dynamic individual users use the default system ISP domains.
4. Configure an ISP domain for IPv6 dynamic individual users.
   ipv6 subscriber { **dhcp** | **ndrs** | **unclassified-ip** } **domain** *domain-name*
   By default, IPv6 dynamic individual users use the default system ISP domains.

Configuring the maximum number of dynamic IPoE sessions

About this task

This feature limits the total number of dynamic IPoE sessions on an interface.

Restrictions and guidelines

You can set a smaller value than the number of existing dynamic IPoE sessions on an interface. In this scenario, the existing dynamic IPoE sessions are not affected.

Make sure the total maximum number of dynamic IPoE sessions for all interfaces on the device is less than the upper limit of the device. The maximum number of dynamic IPoE sessions supported by a device varies by license and device model. If the number of dynamic IPoE sessions reaches the upper limit on an interface or reaches the upper limit supported by the device, you cannot establish any additional IPoE sessions on the interface or on the device.

You can install a license that supports less dynamic IPoE sessions than the existing dynamic IPoE sessions. In this scenario, the existing dynamic IPoE sessions are not affected.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.

interface *interface-type interface-number*

3. Configure the maximum number of IPv4 dynamic IPoE sessions.

   ip subscriber { **dhcp** | **unclassified-ip** } **max-session** *max-number*

   By default, the maximum number of dynamic IPv4 IPoE sessions is not configured.

4. Configure the maximum number of IPv6 dynamic IPoE sessions.

   ipv6 subscriber { **dhcp** | **ndrs** | **unclassified-ip** } **max-session** *max-number*

   By default, the maximum number of dynamic IPv6 IPoE sessions is not configured.

Configuring trusted DHCP options for DHCP users

About this task

This feature enables a BRAS to obtain user access information from trusted DHCP options when the BRAS acts as a DHCP relay. The BRAS includes the obtained user access information in the RADIUS attributes sent to the RADIUS server based on the following matrix.

Table 1 Associated DHCP options for RADIUS attributes

RADIUS attributes	Associated DHCP options
NAS-PORT-ID	• DHCPv4 Option 82 Suboption Circuit-ID • DHCPv6 Option 18
DSL_AGENT_CIRCUIT_ID	• DHCPv4 Option 82 Suboption Circuit-ID • DHCPv6 Option 18
DSL_AGENT_REMOTE_ID	• DHCPv4 Option 82 Suboption Remote-ID • DHCPv6 Option 37

If the BRAS trusts DHCPv4 Option 60 and DHCPv6 Option 16, IPoE can use the ISP domains specified in the options when certain conditions exist. For more information about selecting ISP domains, see "Configuring ISP domains for dynamic individual users."

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure trusted DHCP options for DHCPv4 users.

   ip subscriber trust { **option60** | **option82** }

   By default, the BRAS does not trust DHCPv4 options.

4. Configure trusted DHCP options for DHCPv6 users.

   ipv6 subscriber trust { **option16** | **option18** | **option37** }

   By default, the BRAS does not trust DHCPv6 options.

Configuring static individual users

Static individual user tasks at a glance

To configure static individual users, perform the following tasks:

1. Enabling static individual users

2. Configuring static IPoE sessions
3. (Optional.) Configuring authentication user naming conventions for static individual users
4. (Optional.) Configuring passwords for static individual users
5. (Optional.) Configuring ISP domains for static individual users
6. (Optional.) Configuring the static IPoE whitelist feature

Enabling static individual users

About this task

This feature enables configured static IPoE sessions information to match IP packets.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable IPv4 static individual users.

   ip subscriber initiator unclassified-ip enable

   By default, no IPv4 static individual users are enabled.

4. Enable IPv6 static individual users.

   ipv6 subscriber initiator unclassified-ip enable

   By default, no static individual users are enabled.

Configuring static IPoE sessions

About this task

Static individual users trigger IPoE session establishment by sending IP packets. If an IP packet matches a manually configured IPoE session, the BRAS authenticates the user and establishes an IPoE session.

Restrictions and guidelines

On one interface, a maximum of one static IPoE session can be configured for one IP address.

Configuration procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure a static IPv4 IPoE session.

   ip subscriber session static ip *ip-address* [**vlan** *vlan-id* [**second-vlan** *vlan-id*]] [**mac** *mac-address*] [**domain** *domain-name*] [**description** *string*]

   By default, no static IPv4 IPoE session is configured.

   Only subinterfaces support parameters **vlan** and **second-vlan**.

4. Configure a static IPv6 IPoE session.

   ipv6 subscriber session static ipv6 *ipv6-address* [**vlan** *vlan-id* [**second-vlan** *vlan-id*]] [**mac** *mac-address*] [**domain** *domain-name*] [**description** *string*]

By default, no static IPv6 IPoE session is configured.

Only subinterfaces support parameters **vlan** and **second-vlan**.

Configuring authentication user naming conventions for static individual users

About this task

Usernames configured for static individual users must be the same as those configured on the AAA server.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure an authentication user naming convention for IPv4 static individual users.

   ip subscriber unclassified-ip username include { **nas-port-id** [**separator** *separator*] | **port** [**separator** *separator*] | **second-vlan** [**separator** *separator*] | **slot** [**separator** *separator*] | **source-ip** [**address-separator** *address-separator*] [**separator** *separator*] | **source-mac** [**address-separator** *address-separator*] [**separator** *separator*] | **subslot** [**separator** *separator*] | **sysname** [**separator** *separator*] | **vlan** [**separator** *separator*] } *

   The default username is the source IPv4 address of packets sent by users.

4. Configure an authentication user naming convention for IPv6 static individual users.

   ipv6 subscriber unclassified-ip username include { **nas-port-id** [**separator** *separator*] | **port** [**separator** *separator*] | **second-vlan** [**separator** *separator*] | **slot** [**separator** *separator*] | **source-ip** [**address-separator** *address-separator*] [**separator** *separator*] | **source-mac** [**address-separator** *address-separator*] [**separator** *separator*] | **subslot** [**separator** *separator*] | **sysname** [**separator** *separator*] | **vlan** [**separator** *separator*] } *

   The default username is the source IPv6 address of packets sent by users.

Configuring passwords for static individual users

About this task

Passwords configured for static individual users must be the same as those configured on the AAA server.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure a password for IPv4 static individual users.

   ip subscriber password { **ciphertext** | **plaintext** } *string*

   The default password for an IPv4 static individual user is **vlan**.

4. Configure a password for IPv6 static individual users.

   ipv6 subscriber password { **ciphertext** | **plaintext** } *string*

   The default password for an IPv6 static individual user is **vlan**.

Configuring ISP domains for static individual users

About this task

The BRAS selects ISP domains for static individual users in the following order:

- Domain configured in the static IPoE session
- Service-specific domain
- Interface-specific domain
- Default system domain

For more information about how to configure service-specific ISP domains, see "Configuring service-specific ISP domains." For more information about how to configure the default system domain, see *Security Configuration Guide*.

Restrictions and guidelines

The specified ISP domain must exist on the BRAS.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure an ISP domain for static IPv4 individual users.

   ip subscriber unclassified-ip domain *domain-name*

   By default, static IPv4 individual users use the default system domain.

4. Configure an ISP domain for static IPv6 individual users.

   ipv6 subscriber unclassified-ip domain *domain-name*

   By default, static IPv6 individual users use the default system domain.

Configuring the static IPoE whitelist feature

About this task

With this feature enabled, only IPv4 or IPv6 traffic matching static IPv4 or IPv6 IPoE sessions can initiate IPoE authentication, and IPoE directly permits the other traffic without any processing.

In some scenarios, an interface might need to have both IPoE and portal authentication enabled. For example, both dumb terminals and broadband dial-up users exist on an interface. Dumb terminals (for example, monitoring cameras) need to come online through IPoE without portal authentication, and broadband dial-up users need to come online through portal Web authentication. In this case, you can enable the IPv4 or IPv6 IPoE whitelist feature on the interface.

When both the IPv4 or IPv6 IPoE whitelist feature and portal authentication are enabled on an interface, the following rules apply:

- If the IPv4 or IPv6 traffic of a user matches a static IPv4 or IPv6 IPoE session, the user is processed by the static IPv4 or IPv6 IPoE authentication flow. For an IPoE user to bypass authentication, specify the authentication and authorization modes as **none** in the ISP domain of the IPoE user.

- If the IPv4 or IPv6 traffic of a user does not match any IPv4 or IPv6 IPoE session, the user is processed by portal authentication.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the IPv4 IPoE whitelist feature.

   ip subscriber whitelist enable

   By default, the IPv4 IPoE whitelist is disabled.

4. Enable the IPv6 IPoE whitelist feature.

   ipv6 subscriber whitelist enable

   By default, the IPv6 IPoE whitelist is disabled.

Configuring leased users

Leased user tasks at a glance

To configure leased users, perform the following tasks:

1. Configuring leased users
   - Configuring interface-leased users
   - Configuring subnet-leased users

   Interface-leased users and subnet-leased users cannot be configured on the same interface.

2. Configuring ISP domains for leased users

Configuring interface-leased users

About this task

An interface-leased user represents hosts that rent the same interface.

Restrictions and guidelines

You can configure up to one IPv4 interface-leased user and one IPv6 interface-leased user on an interface.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure an IPv4 interface-leased user.

   ip subscriber interface-leased username *name* **password** { **ciphertext** | **plaintext** } *string* [**domain** *domain-name*]

   By default, no IPv4 interface-leased user is configured.

4. Configure an IPv6 interface-leased user.

   ipv6 subscriber interface-leased username *name* **password** { **ciphertext** | **plaintext** } *string* [**domain** *domain-name*]

By default, no IPv6 interface-leased user is configured.

Configuring subnet-leased users

About this task

A subnet-leased user represents hosts that rent a subnet of an interface.

Restrictions and guidelines

You can configure multiple subnet-leased users on an interface. Different subnets must have the same mask length. Each subnet can be bound to only one subnet-leased user.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure an IPv4 subnet-leased user.

   ip subscriber subnet-leased ip *ip-address* { *mask* | *mask-length* } **username** *name* **password** { **ciphertext** | **plaintext** } *string* [**domain** *domain-name*]

   By default, no IPv4 subnet-leased user is configured.

4. Configure an IPv6 subnet-leased user.

   ipv6 subscriber subnet-leased ipv6 *ipv6-address prefix-length* **username** *name* **password** { **ciphertext** | **plaintext** } *string* [**domain** *domain-name*]

   By default, no IPv6 subnet-leased user is configured.

Configuring ISP domains for leased users

About this task

The BRAS selects ISP domains for leased users in the following order:

- Domains configured for each interface-leased user and each subnet-leased user
- Service-specific domain
- Domain configured for leased users
- Default system domain

For more information about how to configure the service-specific ISP domains, see "Configuring service-specific ISP domains."

For more information about how to configure the default system domain, see AAA configuration in *Security Configuration Guide*.

Restrictions and guidelines

The specified ISP domain must exist on the BRAS.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure a domain collectively for IPv4 leased users.

ip subscriber unclassified-ip domain *domain-name*

By default, IPv4 leased users use the default system ISP domain.

4. Configure a domain collectively for IPv6 leased users.

   ipv6 subscriber unclassified-ip domain *domain-name*

   By default, IPv6 leased users use the default system ISP domain.

Configuring service-specific ISP domains

About configuring service-specific ISP domains

This task enables you to assign ISP domains to users based on services. You can classify services by VLAN ID, 802.1P, and DSCP carried in packets from users.

Restrictions and guidelines

For DHCPv4 users, the trusted Option 60 configuration takes precedence over the global service identifier configuration.

For DHCPv6 users, the trusted Option 16 configuration takes precedence over the global service identifier configuration.

You must specify an identifier for a service before you bind an ISP domain to the service. Otherwise, the binding does not take effect.

Configuring service-specific ISP domains for IPv4 users

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure a service identifier for IPv4 users.

   ip subscriber service-identify { **8021p** { **second-vlan** | **vlan** } | **dscp** | **second-vlan** | **vlan** }

   By default, no service identifier is configured for IPv4 users.

4. Configure service-specific ISP domains for IPv4 users.

   - Bind an ISP domain to a VLAN list.

     ip subscriber vlan *vlan-list* **domain** *domain-name*

   - Bind an ISP domain to an 802.1p list.

     ip subscriber 8021p *8021p-list* **domain** *domain-name*

   - Bind an ISP domain to a DSCP list.

     ip subscriber dscp *dscp-value-list* **domain** *domain-name*

   By default, no service-specific ISP domains are configured for IPv6 users.

Configuring service-specific ISP domains for IPv6 users

1. Enter system view.

   system-view

2. Enter interface view.

interface *interface-type interface-number*

3. Configure a service identifier for IPv6 users.

   ipv6 subscriber service-identify { **8021p** { **second-vlan** | **vlan** } | **dscp** | **second-vlan** | **vlan** }

   By default, no service identifier is configured for IPv6 users.

4. Configure service-specific ISP domains for IPv6 users.
   - Bind an ISP domain to a VLAN list.

     ipv6 subscriber vlan *vlan-list* **domain** *domain-name*
   - Bind an ISP domain to an 802.1p list.

     ipv6 subscriber 8021p *8021p-list* **domain** *domain-name*
   - Bind an ISP domain to a DSCP list.

     ipv6 subscriber dscp *dscp-value-list* **domain** *domain-name*

   By default, no service-specific ISP domains are configured for IPv6 users.

Configuring the quiet timer for users

About this task

If this feature is enabled, the quiet timer starts when number of consecutive authentication failures of a user reaches the limit in the specified period. During the quiet timer period, packets from the user are dropped. After the quiet timer expires, the BRAS performs authentication upon receiving a packet from the user.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the quiet timer for IPv4 IPoE users.

   ip subscriber timer quiet *time*

   By default, the quite timer is disabled for IPv4 IPoE users.

4. Configure the quiet timer for IPv6 IPoE users.

   ipv6 subscriber timer quiet *time*

   By default, the quite timer is disabled for IPv6 IPoE users.

Configuring online detection for IPoE users

About this task

Online detection enables the BRAS to periodically detect the status of a user. It uses ARP or ICMP requests to detect IPv4 users, and uses NS packets of the ND protocol or ICMPv6 requests to detect IPv6 users.

After you configure online detection, the BRAS starts a detection timer to detect online users. If the BRAS does not receive user packets from a user when the detection timer expires, it sends a detection packet to the user and performs the following operations:

- If the BRAS receives user packets within the maximum number of detection attempts, the BRAS assumes that the user is online. It resets the detection timer, and starts the next detection attempt.

- If the BRAS does not receive user packets within the maximum number of detection attempts, the BRAS assumes that the user is offline and deletes the user session.

Restrictions and guidelines

This feature supports only individual users.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure online detection for IPv4 IPoE users.

   ip subscriber user-detect { **arp** | **icmp** } **retry** *retries* **interval** *interval*

   By default, online detection is disabled for IPv4 IPoE users.

4. Configure online detection for IPv6 IPoE users.

   ipv6 subscriber user-detect { **icmpv6** | **nd** } **retry** *retries* **interval** *interval*

   By default, online detection is disabled for IPv6 IPoE users.

Configuring NAS-Port-Type for an interface

About this task

The NAS-Port-Type attribute carries information about the access interface. The BRAS includes the configured NAS-Port-Type in RADIUS requests sent to the RADIUS server.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the IPv4 NAS-Port-Type.

   ip subscriber nas-port-type { **802.11** | **adsl-cap** | **adsl-dmt** | **async** | **cable** | **ethernet** | **g.3-fax** | **hdlc** | **idsl** | **isdn-async-v110** | **isdn-async-v120** | **isdn-sync** | **piafs** | **sdsl** | **sync** | **virtual** | **wireless-other** | **x.25** | **x.75** | **xdsl** }

   The default IPv4 NAS-Port-Type is **Ethernet**.

4. Configure the IPv6 NAS-Port-Type.

   ipv6 subscriber nas-port-type { **802.11** | **adsl-cap** | **adsl-dmt** | **async** | **cable** | **ethernet** | **g.3-fax** | **hdlc** | **idsl** | **isdn-async-v110** | **isdn-async-v120** | **isdn-sync** | **piafs** | **sdsl** | **sync** | **virtual** | **wireless-other** | **x.25** | **x.75** | **xdsl** }

   The default IPv6 NAS-Port-Type is **Ethernet**.

Enabling IPoE user logging

About this task

The IPoE user logging feature enables the device to generate IPoE logs and send them to the information center. Logs are generated after a user comes online successfully, fails to come online, normally goes offline, or abnormally goes offline. A log entry contains information such as the username, IP address, interface name, inner VLAN, outer VLAN, MAC address, and failure causes. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

Typically, disable this feature to prevent excessive IPoE log output.

Procedure

1. Enter system view.

   system-view

2. Enable IPv4 IPoE user logging.

   ip subscriber access-user log enable [**successful-login** | **failed-login** | **logout** [**normal**] [**abnormal**]] *

   By default, IPv4 IPoE user logging is disabled.

3. Enable IPv6 IPoE user logging.

   ipv6 subscriber access-user log enable [**successful-login** | **failed-login** | **logout** [**normal**] [**abnormal**]] *

   By default, IPv6 IPoE user logging is disabled.

Configuring NAS-Port-ID formats

About configuring NAS-Port-ID formats

The NAS-Port-ID RADIUS attribute specifies access location of a user. The BRAS supports the following formats for NAS-Port-ID:

- **version 1.0**—Format for China Telecom.
- **version 2.0**—Format specified in *YDT 2275-2011 Subscriber Access Loop (Port) Identification in Broadband Access Networks*.

You can configure the following settings if version 2.0 is used when the BRAS acts as a DHCP relay:

- Configure DHCPv4 Option 82 or DHCPv6 Option 18 as a trusted DHCP option and obtain information from the trusted option.
- Include the NAS information and obtained option information in NAS-Port-ID.

Configuring the NAS-Port-ID format for IPv4 users

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the NAS-Port-ID format for IPv4 users.

   ip subscriber nas-port-id format cn-telecom { **version1.0** | **version2.0** }

   The default format is **version1.0**.

4. (Optional.) Configure the trusted DHCPv4 option 82 for IPv4 users.

   ip subscriber trust option82

   By default, the BRAS does not trust Option 82.

5. (Optional.) Include the NAS information and DHCPv4 option 82 information in NAS-Port-ID for IPv4 users.

ip subscriber nas-port-id nasinfo-insert

By default, the BRAS includes only information obtained from the trusted DHCPv4 option 82 in NAS-Port-ID.

Configuring the NAS-Port-ID format for IPv6 users

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the NAS-Port-ID format for IPv6 users.
   ipv6 subscriber nas-port-id format cn-telecom { **version1.0** | **version2.0** }
   The default format is **version1.0**.
4. (Optional.) Configure the trusted DHCPv6 option 18 for IPv6 users.
   ipv6 subscriber trust option18
   By default, the BRAS does not trust Option 18.
5. (Optional.) Include the NAS information and DHCPv6 option 18 information in NAS-Port-ID for IPv6 users.
   ipv6 subscriber nas-port-id nasinfo-insert
   By default, the BRAS includes only information obtained from the trusted DHCPv6 option 18 in NAS-Port-ID.

Display and maintenance commands for IPoE

Display and maintenance commands for IPv4 IPoE

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display IPoE session information for individual users.	**display ip subscriber session** [**interface** *interface-type interface-number*] [**domain** *domain-name* | **ip** *ip-address* [**vpn-instance** *vpn-instance-name*] | **mac** *mac-address* | **static** | **username** *name*] [**slot** *slot-number*] [**verbose**]
Display information about IPoE interface-leased users.	**display ip subscriber interface-leased** [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display information about IPoE subnet-leased users.	**display ip subscriber subnet-leased** [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display IPoE session statistics for individual users.	**display ip subscriber session statistics** [**session-type** { **dhcp** | **static** | **unclassified-ip** }] [**interface** *interface-type interface-number*] [**slot** *slot-number*]

Task	Command
Display IPoE session statistics for interface-leased users.	**display ip subscriber interface-leased statistics** [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display IPoE session statistics for subnet-leased users.	**display ip subscriber subnet-leased statistics** [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display offline statistics for users.	**display ip subscriber offline statistics** [**interface** *interface-type interface-number*]
Delete dynamic IPoE sessions and log out the users.	**reset ip subscriber session** [**interface** *interface-type interface-number*] [**domain** *domain-name* | **ip** *ip-address* [**vpn-instance** *vpn-instance-name*] | **mac** *mac-address* | **username** *name*]
Delete offline statistics for users.	**reset ip subscriber offline statistics** [**interface** *interface-type interface-number*]

Display and maintenance commands for IPv6 IPoE

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display IPoE session information for individual users.	**display ipv6 subscriber session** [**interface** *interface-type interface-number*] [**domain** *domain-name* | **ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] | **mac** *mac-address* | **static** | **username** *name*] [**slot** *slot-number*] [**verbose**]
Display information about IPoE interface-leased users.	**display ipv6 subscriber interface-leased** [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display information about IPoE subnet-leased users.	**display ipv6 subscriber subnet-leased** [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display IPoE session statistics for individual users.	**display ipv6 subscriber session statistics** [**session-type** { **dhcp** | **ndrs** | **static** | **unclassified-ip** }] [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display IPoE session statistics for interface-leased users.	**display ipv6 subscriber interface-leased statistics** [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display IPoE session statistics for subnet-leased users.	**display ipv6 subscriber subnet-leased statistics** [**interface** *interface-type interface-number*] [**slot** *slot-number*]

Task	Command
Display offline statistics for users.	**display ipv6 subscriber offline statistics** [**interface** *interface-type interface-number*]
Delete dynamic IPoE sessions and log out the users.	**reset ipv6 subscriber session** [**interface** *interface-type interface-number*] [**domain** *domain-name* | **ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] | **mac** *mac-address* | **username** *name*]
Delete offline statistics for users.	**reset ipv6 subscriber offline statistics** [**interface** *interface-type interface-number*]

Troubleshooting IPoE

DHCP clients failed to come online

Symptom

DHCP clients cannot come online, although network connections and interface IPoE configurations are correct.

Solution

To solve the problem:

1. Use debug commands or a packet analyzer to check DHCP packets from the DHCP client.

   By default, DHCPv4 and DHCPv6 clients use ISP domains specified in Option 60 and Option 16, respectively.
2. If the DHCPv4 packet carries Option 60 or the DHCPv6 packet carries Option 16, verify that the ISP domain in the option exists on the BRAS.
3. If the DHCP packet does not carry Option 60 or Option 16, verify that the ISP domain specified on the interface exists on the BRAS.
4. If the problem persists, contact NSFOCUS Support.

Contents

Managing public keys

About public key management

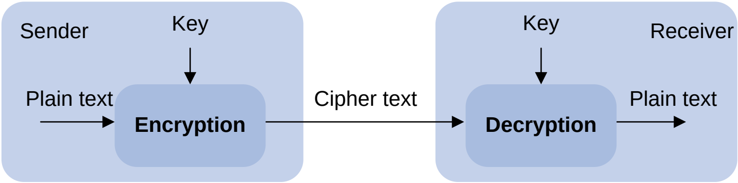
This chapter describes public key management for the following asymmetric key algorithms:

- Revest-Shamir-Adleman Algorithm (RSA).
- Digital Signature Algorithm (DSA).
- Elliptic Curve Digital Signature Algorithm (ECDSA).
- SM2.

Asymmetric key algorithm overview

Asymmetric key algorithms are used by security applications to secure communications between two parties, as shown in Figure 1. Asymmetric key algorithms use two separate keys (one public and one private) for encryption and decryption. Symmetric key algorithms use only one key.

Figure 1 Encryption and decryption



A key owner can distribute the public key in plain text on the network but must keep the private key in privacy. It is mathematically infeasible to calculate the private key even if an attacker knows the algorithm and the public key.

Usage of asymmetric key algorithms

Security applications (such as SSH, SSL, and PKI) use the asymmetric key algorithms for the following purposes:

- **Encryption and decryption**—Any public key receiver can use the public key to encrypt information, but only the private key owner can decrypt the information.
- **Digital signature**—The key owner uses the private key to digitally sign information to be sent. The receiver decrypts the information with the sender's public key to verify information authenticity.

RSA, DSA, ECDSA, and SM2 can all perform digital signature, but only RSA can perform encryption and decryption.

Public key management tasks at a glance

To manage public keys, perform the following tasks:

1. Creating a local key pair
2. Importing a local key pair
3. Distributing a local host public key

   Choose one of the following tasks:

   - Exporting a host public key
   - Displaying a host public key

   To enable the peer device to authenticate the local device, you must distribute the local device's public key to the peer device.

4. Configuring a peer host public key

   Choose one of the following tasks:

   - Importing a peer host public key from a public key file
   - Entering a peer host public key

   To encrypt information sent to a peer device or authenticate the digital signature of the peer device, you must configure the peer device's public key on the local device.

5. (Optional.) Destroying a local key pair

Creating a local key pair

Restrictions and guidelines

When you create a local key pair, follow these guidelines:

- The key algorithm must be the same as required by the security application.
- When you create an RSA or DSA key pair, enter an appropriate key modulus length at the prompt. The longer the key modulus length, the higher the security, and the longer the key generation time.

  When you create an ECDSA key pair, choose the appropriate elliptic curve. The elliptic curve determines the ECDSA key length. The longer the key length, the higher the security, and the longer the key generation time.

  When you create an SM2 key pair, you do not need to specify the key length. Only a 256-bit SM2 key pair can be created.

  See Table 1 for more information about key modulus lengths and key lengths.
- If you do not assign the key pair a name, the system assigns the default name to the key pair and marks the key pair as **default**. You can also assign the default name to another key pair, but the system does not mark the key pair as **default**. The key pair name must be unique among all manually named key pairs that use the same key algorithm. If a name conflict occurs, the system asks whether you want to overwrite the existing key pair.
- The key pairs are automatically saved and can survive system reboots.

Table 1 A comparison of different types of asymmetric key algorithms

Type	Generated key pairs	Modulus/key length
RSA	• One host key pair, if you specify a key pair name. • One server key pair and one host key pair, if you do not specify a key pair name. Both key pairs use their default names. **NOTE:** Only SSH 1.5 uses the RSA server key pair.	Key modulus length: 512 to 2048 bits. Default: 1024 bits. To ensure security, use a minimum of 768 bits.
DSA	One host key pair.	Key modulus length: 512 to 2048 bits. Default: 1024 bits. To ensure security, use a minimum of 768 bits.
ECDSA	One host key pair.	Key length: 192, 256, 384, or 521 bits.

Type	Generated key pairs	Modulus/key length
SM2	One host key pair.	Key length: 256 bits.

Procedure

1. Enter system view.

   system-view

2. Create a local key pair.

   public-key local create { **dsa** | **ecdsa** [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**] | **rsa** } [**name** *key-name*]

   public-key local create sm2 [**name** *key-name*] [**on** *device-name*]

Importing a local key pair

About this task

This task imports a key pair from a key pair file to the device. The imported key pairs are automatically saved and can survive system reboots.

Perform this task when the key pair to be imported is saved in a different file than the certificate. If the key pair and the certificate are saved in the same file, the device can obtain the key pair by importing the certificate.

Restrictions and guidelines

The device supports importing the RSA host key pair but not the RSA server key pair.

If you do not assign the key pair a name, the system assigns the default name to the key pair and marks the key pair as **default**. You can also assign the default name to another key pair, but the system does not mark the key pair as **default**. The name of a key pair must be unique among all manually named key pairs that use the same key algorithm. If a name conflict occurs, the system asks whether you want to overwrite the existing key pair.

To import the encrypted key pair into the device successfully, provide the decryption password.

See Table 2 for information about supported key modulus lengths and key lengths.

Table 2 Length of key pair

Type	Modulus/key length
RSA	Key modulus length: 512 to 2048 bits.
ECDSA	Key length: 192, 256, 384, or 521 bits.

Prerequisites

Before performing this task, save the key pair file to the local storage directory of the device through FTP or other methods.

Procedure

1. Enter system view.

   system-view

2. Import a local key pair.

   public-key local import { **ecdsa** | **rsa** } [*key-name*] **filename** *filename*

Distributing a local host public key

About distribution of local host public keys

You must distribute a local host public key to a peer device so the peer device can perform the following operations:

- Use the public key to encrypt information sent to the local device.
- Authenticate the digital signature signed by the local device.

To distribute a local host public key, you must first export or display the key.

- Export a host public key:
  - Export a host public key to a file.
  - Export a host public key to the monitor screen, and then save it to a file.

  After the key is exported to a file, transfer the file to the peer device. On the peer device, import the key from the file.
- Display a host public key.

  After the key is displayed, record the key, for example, copy it to an unformatted file. On the peer device, you must literally enter the key.

Exporting a host public key

Restrictions and guidelines

When you export a host public key, follow these restrictions and guidelines:

- If you specify a file name in the command, the command exports the key to the specified file.
- If you do not specify a file name, the command exports the key to the monitor screen. You must manually save the exported key to a file.

Procedure

1. Enter system view.

   system-view
2. Export a local host public key.
   - Export an RSA host public key:

     public-key local export rsa [**name** *key-name*] { **openssh** | **ssh1** | **ssh2** } [*filename*]
   - Export an ECDSA host public key.

     public-key local export ecdsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]
   - Export a DSA host public key.

     public-key local export dsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]
   - Export an SM2 host public key.

     public-key local export sm2 [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]

Displaying a host public key

Perform the following tasks in any view:

- Display local RSA public keys.

  display public-key local rsa public [**name** *key-name*]

  Do not distribute the RSA server public key **serverkey (default)** to a peer device.
- Display local ECDSA public keys.

  display public-key local ecdsa public [**name** *key-name*]
- Display local DSA public keys.

  display public-key local dsa public [**name** *key-name*]
- Display local SM2 public keys.

  display public-key local sm2 public [**name** *key-name*]

Configuring a peer host public key

About peer host public key configuration

To encrypt information sent to a peer device or authenticate the digital signature of the peer device, you must configure the peer device's public key on the local device.

You can configure the peer host public key by using the following methods:

- Import the peer host public key from a public key file (recommended).
- Manually enter (type or copy) the peer host public key.

For information about how to obtain the host public key of a device, see "Distributing a local host public key."

Restrictions and guidelines for peer host public key configuration

When you configure a peer host public key, follow these restrictions and guidelines:

- When you manually enter the peer host public key, make sure the entered key is in the correct format. To obtain the peer host public key in the correct format, use the **display public-key local public** command to display the public key on the peer device and record the key. The format of the public key displayed in any other way might be incorrect. If the key is not in the correct format, the system discards the key and displays an error message.
- Always import rather than enter the peer host public key if you are not sure whether the device supports the format of the recorded peer host public key.

Importing a peer host public key from a public key file

About this task

Before you perform this task, make sure you have exported the host public key to a file on the peer device and obtained the file from the peer device. For information about exporting a host public key, see "Exporting a host public key."

After you import the key, the system automatically converts the imported public key to a string in the Public Key Cryptography Standards (PKCS) format.

Procedure

1. Enter system view.

   system-view

2. Import a peer host public key from a public key file.

   public-key peer *keyname* **import sshkey** *filename*

   By default, no peer host public keys exist.

Entering a peer host public key

About this task

Before you perform this task, make sure you have displayed the key on the peer device and recorded the key. For information about displaying a host public key, see "Displaying a host public key."

Procedure

1. Enter system view.

   system-view

2. Specify a name for the peer host public key and enter public key view.

   public-key peer *keyname*

3. Type or copy the key.

   You can use spaces and carriage returns, but the system does not save them.

4. Exit public key view.

   peer-public-key end

   When you exit public key view, the system automatically saves the peer host public key.

Destroying a local key pair

About this task

To ensure security, destroy the local key pair and generate a new key pair in any of the following situations:

- The local key has leaked. An intrusion event might occur.
- The storage media of the device is replaced.
- The local certificate has expired. For more information about local certificates, see "Configuring PKI."

Procedure

1. Enter system view.

   system-view

2. Destroy a local key pair.

   public-key local destroy { **dsa** | **ecdsa** | **rsa** | **sm2** } [**name** *key-name*]

Display and maintenance commands for public keys

Execute **display** commands in any view.

Task	Command
Display local public keys.	**display public-key local** { **dsa** | **ecdsa** | **rsa** | **sm2** } **public** [**name** *key-name*]

Task	Command
Display peer host public keys.	**display public-key peer** [**brief** | **name** *publickey-name*]

Examples of public key management

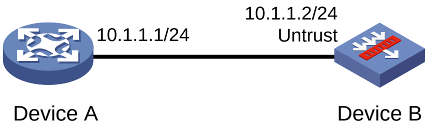
Example: Entering a peer host public key

Network configuration

As shown in Figure 2, to prevent illegal access, Device B authenticates Device A through a digital signature. Before configuring authentication parameters on Device B, use the following procedure to configure the public key of Device A on Device B:

- Create RSA key pairs on Device A and export the RSA host public key to a file.
- Manually specify the RSA host public key of Device A on Device B.

Figure 2 Network diagram



Procedure

1. Configure Device A:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 10.1.1.1 255.255.255.0
[DeviceA-GigabitEthernet1/0/1] quit
```

   # Create local RSA key pairs with default names on Device A, and use the default modulus length 1024 bits.

```
[DeviceA] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.
Create the key pair successfully.
```

   # Display all local RSA public keys.

```
[DeviceA] display public-key local rsa public

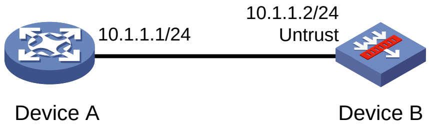
Example: Importing a public key from a public key file

Network configuration

As shown in Figure 3, Device B authenticates Device A through a digital signature. Before configuring authentication parameters on Device B, use the following procedure to configure the public key of Device A on Device B:

- Create RSA key pairs on Device A and export the RSA host public key to a file.
- Import the RSA host public key of Device A from the public key file to Device B.

Figure 3 Network diagram



Procedure

1. Configure Device A:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 10.1.1.1 255.255.255.0
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

2. Configure Device B:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 10.1.1.2 255.255.255.0
[DeviceB-GigabitEthernet1/0/1] quit
```

# Add the interface to the security zone.

```
[DeviceB] security-zone name Untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
```

# Configure a rule named **pkeylocalin** to permit the packets from Device A to Device B.

```
[DeviceB-security-policy-ip] rule name pkeylocalin
[DeviceB-security-policy-ip-1-pkeylocalin] source-zone untrust
[DeviceB-security-policy-ip-1-pkeylocalin] destination-zone local
[DeviceB-security-policy-ip-1-pkeylocalin] source-ip-host 10.1.1.1
[DeviceB-security-policy-ip-1-pkeylocalin] destination-ip-host 10.2.2.2
[DeviceB-security-policy-ip-1-pkeylocalin] action pass
[DeviceB-security-policy-ip-1-pkeylocalin] quit
[DeviceB-security-policy-ip] quit
```

3. Configure Device A:

# Create local RSA key pairs with default names on Device A, and use the default modulus length (1024 bits).

```
<DeviceA> system-view
[DeviceA] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.
Create the key pair successfully.
```

# Display all local RSA public keys.

```
[DeviceA] display public-key local rsa public

Configuring PKI

About PKI

Public Key Infrastructure (PKI) is an asymmetric key infrastructure to encrypt and decrypt data for securing network services.

PKI uses digital certificates to distribute and employ public keys, and provides network communication and e-commerce with security services such as user authentication, data confidentiality, and data integrity. For more information about public keys, see "Managing public keys."

PKI terminology

Digital certificate

A digital certificate is an electronic document signed by a CA that binds a public key with the identity of its owner.

A digital certificate includes the following information:

- Issuer name (name of the CA that issued the certificate).
- Subject name (name of the individual or group to which the certificate is issued).
- Identity information of the subject.
- Subject's public key.
- Signature of the CA.
- Validity period.

A digital certificate must comply with the international standards of ITU-T X.509, of which X.509 v3 is the most commonly used.

This chapter covers the following types of certificates:

- **CA certificate**—Certificate of a CA. Multiple CAs in a PKI system form a CA tree, with the root CA at the top. The root CA generates a self-signed certificate, and each lower level CA holds a CA certificate issued by the CA immediately above it. The chain of these certificates forms a chain of trust.
- **Registration authority (RA) certificate**—Certificate issued by a CA to an RA. RAs act as proxies for CAs to process enrollment requests in a PKI system.
- **Local certificate**—Certificate of a local PKI entity, which contains the entity's public key. Local certificates include the following types:
  - **CA-signed certificate**—Digital certificate signed and issued by a CA to the local PKI entity.
  - **Self-signed certificate**—Digital certificate signed and issued by the local PKI entity (the device) itself. When the device cannot request a local certificate from the CA, it can sign and issue a local certificate for communication with the peer to provide services. Using this type of certificate is simple in configuration but has low security. You can use self-signed certificates in scenarios with low security requirements.
- **Peer certificate**—CA-signed digital certificate of a peer, which contains the peer's public key.

Fingerprint of root CA certificate

Each root CA certificate has a unique fingerprint, which is the hash value of the certificate content. The fingerprint of a root CA certificate can be used to authenticate the validity of the root CA.

Certificate revocation list

A certificate revocation list (CRL) is a list of serial numbers for certificates that have been revoked. A CRL is created and signed by the CA that originally issued the certificates.

The CA publishes CRLs periodically to revoke certificates. Entities that are associated with the revoked certificates should not be trusted.

The CA must revoke a certificate when any of the following conditions occurs:

- The certificate subject name is changed.
- The private key is compromised.
- The association between the subject and CA is changed. For example, when an employee terminates employment with an organization.

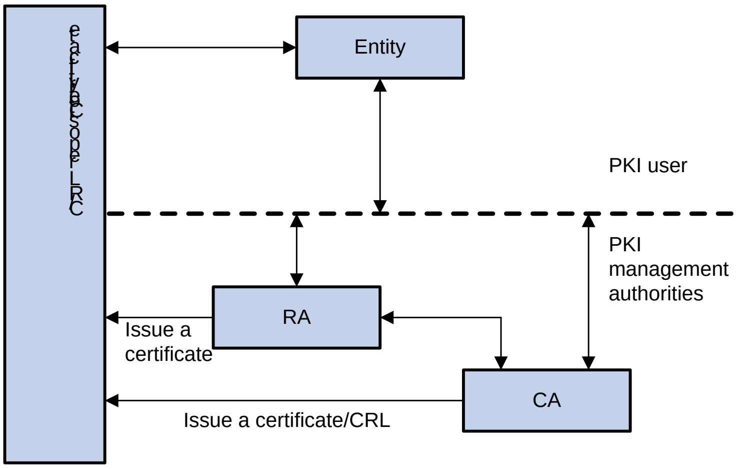
CA policy

A CA policy is a set of criteria that a CA follows to process certificate requests, to issue and revoke certificates, and to publish CRLs. Typically, a CA advertises its policy in a certification practice statement (CPS). You can obtain a CA policy through out-of-band means such as phone, disk, and email. Make sure you understand the CA policy before you select a trusted CA for certificate request because different CAs might use different policies.

PKI architecture

A PKI system consists of PKI entities, CAs, RAs and a certificate/CRL repository, as shown in Figure 1.

Figure 1 PKI architecture



PKI entity

A PKI entity is an end user using PKI certificates. A PKI entity can be an operator, an organization, a device like a router or a switch, or a process running on a computer. PKI entities use SCEP to communicate with the CA or RA.

CA

A certification authority (CA) grants and manages certificates. It issues certificates, defines the certificate validity periods, and revokes certificates by publishing CRLs.

RA

A registration authority (RA) offloads the CA by processing certificate enrollment requests. The RA accepts certificate requests, verifies user identity, and determines whether to ask the CA to issue certificates.

The RA is optional in a PKI system. In cases when there is security concern over exposing the CA to direct network access, it is advisable to delegate some of the tasks to an RA. Then, the CA can concentrate on its primary tasks of signing certificates and CRLs.

Certificate/CRL repository

A certificate/CRL repository is a certificate distribution point that stores certificates and CRLs, and distributes these certificates and CRLs to PKI entities. It also provides the query function. A PKI repository can be a directory server using the LDAP or HTTP protocol, of which LDAP is commonly used.

Retrieval, usage, and maintenance of a digital certificate

The following workflow describes the retrieval, usage, and maintenance of a digital certificate. This example uses a CA which has an RA to process certificate enrollment requests.

1. A PKI entity generates an asymmetric key pair and submits a certificate request to the RA.

   The certificate request contains the public key and its identity information.
2. The RA verifies the identity of the entity and sends a digital signature containing the identity information and the public key to the CA.
3. The CA verifies the digital signature, approves the request, and issues a certificate.
4. After receiving the certificate from the CA, the RA sends the certificate to the certificate repository and notifies the PKI entity that the certificate has been issued.
5. The PKI entity obtains the certificate from the certificate repository.
6. To establish a secure connection for communication, two PKI entities exchange local certificates to authenticate each other. The connection can be established only if both entities verify that the peer's certificate is valid.
7. You can remove the local certificate of a PKI entity and request a new one when any of the following conditions occur:
   - The local certificate is about to expire.
   - The certificate's private key is compromised.

PKI applications

The PKI technology can meet security requirements of online transactions. As an infrastructure, PKI has a wide range of applications. The PKI system of NSFOCUS can provide certificate management for IPsec and SSL.

The following are some application examples.

VPN

A VPN is a private data communication network built on the public communication infrastructure. A VPN can use network layer security protocols (for example, IPsec) in conjunction with PKI-based encryption and digital signature technologies for confidentiality.

Secure emails

PKI can address the email requirements for confidentiality, integrity, authentication, and non-repudiation. A common secure email protocol is Secure/Multipurpose Internet Mail Extensions (S/MIME), which is based on PKI and allows for transfer of encrypted mails with signature.

Web security

PKI can be used in the SSL handshake phase to verify the identities of the communicating parties by digital certificates.

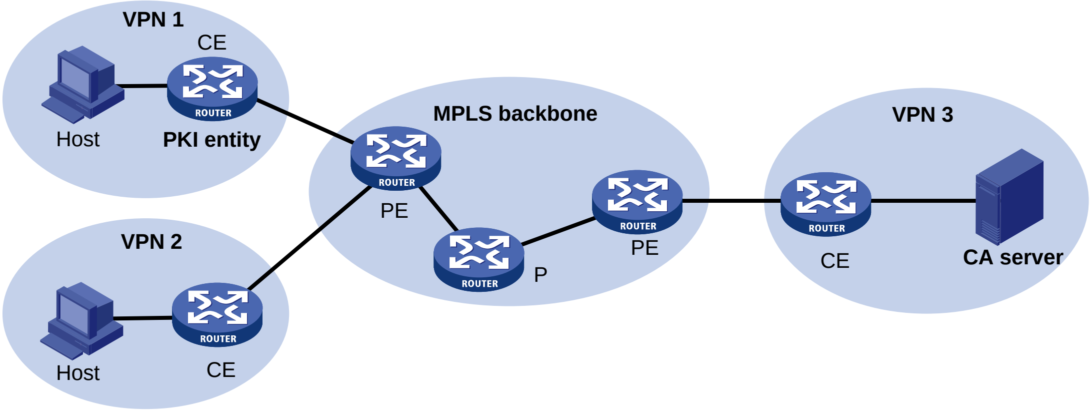
Support for VPN

An enterprise might have multiple branches in different VPNs. PKI support for VPN is required if users in different VPNs request certificates from the CA server in the headquarters VPN.

As shown in Figure 2, the PKI entity in VPN 1 requests a certificate from the CA server in VPN 3 in the following workflow:

1. The PKI entity submits a certificate request to the CA server.
2. The PE device connected to the PKI entity transmits the request to the CA server through the VPN instances.
3. The CA server verifies the request and issues the certificate.
4. The PE device connected to the CA server transmits the certificate to the PKI entity through the VPN instances.

Figure 2 PKI support for VPN



PKI tasks at a glance

To configure PKI, perform the following tasks:

1. Configuring a PKI entity
2. Configuring a PKI domain
3. (Optional.) Specifying the storage path for certificates and CRLs
4. Requesting a certificate

   Choose one of the following tasks:
   - Enabling the automatic online certificate request mode
   - Manually submitting an online certificate request
   - Manually submitting a certificate request in offline mode
5. (Optional.) Aborting a certificate request
6. (Optional.) Obtaining certificates

   You can obtain the CA certificate, local certificates, and peer certificates related to a PKI domain from a CA and save them locally for higher lookup efficiency.
7. (Optional.) Verifying PKI certificates
8. (Optional.) Exporting certificates
9. (Optional.) Removing a certificate
10. (Optional.) Configuring a certificate-based access control policy

Certificate-based access control policies allow you to authorize access to a device (for example, an HTTPS server) based on the attributes of an authenticated client's certificate.

11. (Optional.) Enabling local certificate expiration notification
12. (Optional.) Obtaining the CRL

Configuring a PKI entity

About PKI entities

A certificate applicant uses an entity to provide its identity information to a CA. A valid PKI entity must include one or more of following identity categories:

- Distinguished name (DN) of the entity, which further includes the common name, country code, locality, organization, unit in the organization, and state. If you configure the DN for an entity, a common name is required.
- FQDN of the entity.
- IP address of the entity.

Restrictions and guidelines for PKI entity configuration

Follow these restrictions and guidelines when you configure a PKI entity:

- Whether the identity categories are required or optional depends on the CA policy. Follow the CA policy to configure the entity settings. For example, if the CA policy requires the entity DN, but you configure only the IP address, the CA rejects the certificate request from the entity.
- The SCEP add-on on the Windows 2000 CA server has restrictions on the data length of a certificate request. If a request from a PKI entity exceeds the data length limit, the CA server does not respond to the certificate request. In this case, you can use an out-of-band means to submit the request. Other types of CA servers, such as RSA servers and OpenCA servers, do not have such restrictions.

PKI entity tasks at a glance

To configure a PKI entity, perform the following tasks:

1. Configuring the DN for the PKI entity
2. Configuring the FQDN for the PKI entity
3. Configuring the IP address for the PKI entity

Configuring the DN for the PKI entity

Restrictions and guidelines for configuring the DN for the PKI entity

You can configure the individual attributes used to construct the DN string for the PKI entity, or directly configure the full DN string by using the **subject-dn** command.

If the **subject-dn** command is configured, the individual DN attributes configured by using the **common-name**, **country**, **locality**, **organization, organization-unit**, and **state** commands do not take effect.

Configuring the individual DN attributes

1. Enter system view.

   ```
   system-view
   ```

2. Create a PKI entity and enter its view.

   pki entity *entity-name*

3. Set a common name for the entity.

   common-name *common-name-sting*

   By default, the common name is not set.

4. Set the country code of the entity.

   country *country-code-string*

   By default, the country code is not set.

5. Set the locality of the entity.

   locality *locality-name*

   By default, the locality is not set.

6. Set the organization of the entity.

   organization *org-name*

   By default, the organization is not set.

7. Set the unit of the entity in the organization.

   organization-unit *org-unit-name*

   By default, the unit is not set.

8. Set the state where the entity resides.

   state *state-name*

   By default, the state is not set.

Configuring the full DN string

1. Enter system view.

   system-view

2. Create a PKI entity and enter its view.

   pki entity *entity-name*

3. Configure the full subject DN string.

   subject-dn *dn-string*

   By default, the PKI entity DN is not configured.

Configuring the FQDN for the PKI entity

1. Enter system view.

   system-view

2. Create a PKI entity and enter its view.

   pki entity *entity-name*

3. Configure the FQDN for the PKI entity.

   fqdn *fqdn-name-string*

   By default, the FQDN is not configured.

Configuring the IP address for the PKI entity

1. Enter system view.

   system-view

2. Create a PKI entity and enter its view.

   pki entity *entity-name*

3. Configure the IP address for the PKI entity.

ip { *ip-address* | **interface** *interface-type interface-number* }

By default, the IP address is not configured.

Configuring a PKI domain

About PKI domains

A PKI domain contains enrollment information for a PKI entity. It is locally significant and is intended only for use by other applications like IKE and SSL.

PKI domain tasks at a glance

To configure a PKI domain, perform the following tasks:

1. Creating a PKI domain
2. Specifying the trusted CA
3. Specifying the PKI entity name
4. Specifying the certificate request reception authority
5. Specifying the certificate request URL
6. (Optional.) Specifying the VPN instance where the certificate request reception authority and the CRL repository belong
7. (Optional.) Setting the SCEP polling interval and maximum polling attempts
8. Specifying the LDAP server

   This task is required when either of the following conditions is met:

   - The device must obtain certificates from the CA by using the LDAP protocol.
   - An LDAP URL which does not contain the host name of the LDAP server is specified as the CRL repository URL.
9. Specifying the fingerprint for root CA certificate verification

   This step is required if the auto certificate request mode is configured in the PKI domain.

   If the manual certificate request mode is configured, you can skip this step and manually verify the fingerprint displayed during verification of the root CA certificate.
10. Specifying the key pair for certificate request
11. (Optional.) Specifying the intended purpose for the certificate
12. (Optional.) Specifying the source IP address for PKI protocol packets
13. (Optional.) Specifying the encryption algorithm for certificate files in PKCS#7 format

Creating a PKI domain

1. Enter system view.

   system-view
2. Create a PKI domain and enter its view.

   pki domain *domain-name*

Specifying the trusted CA

About this task

The PKI domain must have a CA certificate before you can request a local certificate. To obtain a CA certificate, the trusted CA name must be specified. The trusted CA name uniquely identifies the CA to be used if multiple CAs exist on the CA server.

Procedure

1. Enter system view.

   `system-view`
2. Enter PKI domain view.

   `pki domain` *`domain-name`*
3. Specify the trusted CA name.

   `ca identifier` *`name`*

   By default, no trusted CA name is specified.

Specifying the PKI entity name

1. Enter system view.

   `system-view`
2. Enter PKI domain view.

   `pki domain` *`domain-name`*
3. Specify the PKI entity name.

   `certificate request entity` *`entity-name`*

   By default, no PKI entity name is specified.

Specifying the certificate request reception authority

1. Enter system view.

   `system-view`
2. Enter PKI domain view.

   `pki domain` *`domain-name`*
3. Specify the certificate request reception authority.

   `certificate request from` { **`ca`** | **`ra`** }

   By default, no certificate request reception authority is specified.

Specifying the certificate request URL

1. Enter system view.

   `system-view`
2. Enter PKI domain view.

   `pki domain` *`domain-name`*
3. Specify the URL of the certificate request reception authority to which the device sends certificate requests.

   `certificate request url` *`url-string`*

   By default, the certificate request URL is not specified.

Specifying the VPN instance where the certificate request reception authority and the CRL repository belong

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Specify the VPN instance where the certificate request reception authority and the CRL repository belong.

   vpn-instance *vpn-instance-name*

   By default, the certificate request reception authority and the CRL repository belong to the public network.

Setting the SCEP polling interval and maximum polling attempts

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Set the SCEP polling interval and maximum number of polling attempts.

   certificate request polling { **count** *count* | **interval** *interval* }

   By default, the device polls the CA server for the certificate request status every 20 minutes. The maximum number of polling attempts is 50.

Specifying the LDAP server

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Specify the LDAP server.

   ldap-server host *hostname* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]

   By default, no LDAP server is specified.

Specifying the fingerprint for root CA certificate verification

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Configure the fingerprint for verifying the root CA certificate.

   root-certificate fingerprint { **md5** | **sha1** } *string*

   By default, no fingerprint is configured.

Specifying the key pair for certificate request

About this task

You can specify any of the following types of key pairs for certificate request in a PKI domain:

- DSA.
- ECDSA.
- RSA.
- SM2.

The private key of the key pair is kept secret. The public key of the key pair will be sent together with other information in a certificate request to the CA, which signs the request data and issues the certificate.

For more information about DSA, ECDSA, RSA, and SM2 key pairs, see "Managing public keys."

Restrictions and guidelines

You can specify a nonexistent key pair for certificate request. The PKI entity automatically creates the key pair before submitting a certificate request.

Procedure

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Specify the key pair for certificate request.
   - Specify an RSA key pair.
     public-key rsa { { **encryption name** *encryption-key-name* [**length** *key-length*] | **signature name** *signature-key-name* [**length** *key-length*] } * | **general name** *key-name* [**length** *key-length*] }
   - Specify an ECDSA key pair.
     public-key ecdsa name *key-name* [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**]
   - Specify a DSA key pair.
     public-key dsa name *key-name* [**length** *key-length*]
   - Specify an SM2 key pair.
     public-key sm2 { { **encryption name** *encryption-key-name* | **signature name** *signature-key-name* } * | **general name** *key-name* }

   By default, no key pair is specified.

Specifying the intended purpose for the certificate

About this task

An issued certificate contains the extensions which restrict the usage of the certificate to specific purposes. You can specify the intended purposes for a certificate, which will be included in the certificate request sent to the CA. However, the actual extensions contained in an issued certificate depend on the CA policy, and they might be different from those specified in the PKI domain. Whether an application (such as IKE and SSL) will use the certificate during authentication depends on the application's policy.

Supported certificate extensions include:

- **ike**—Certificates carrying this extension can be used by IKE peers.
- **ssl-client**—Certificates carrying this extension can be used by SSL clients.
- **ssl-server**—Certificates carrying this extension can be used by SSL servers.

Procedure

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Specify the intended use for the certificate.

   usage { **ike** | **ssl-client** | **ssl-server** } *

   By default, the certificate can be used by all supported applications, including IKE, SSL client, and SSL server.

Specifying the source IP address for PKI protocol packets

About this task

This task is required if the CA policy requires that the CA server accept certificate requests from a specific IP address or subnet.

Procedure

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Specify a source IP address for the PKI protocol packets.

   IPv4:

   source ip { *ip-address* | **interface** *interface-type interface-number* }

   IPv6:

   source ipv6 { *ipv6-address* | **interface** *interface-type interface-number* }

   By default, the source IP address of PKI protocol packets is the IP address of their outgoing interface.

Specifying the encryption algorithm for certificate files in PKCS#7 format

About this task

During online certificate request, the device uses the specified encryption algorithm to encrypt the certificate signing request in PKCS#7 format before sending the request to the CA. After obtaining the certificate issued by the CA, the device uses the encryption algorithm to decrypt the certificate file in PKCS#7 format. Make sure the specified encryption algorithm is supported on the CA server.

Procedure

1. Enter system view.

   system-view

2. Enter PKI domain view.

pki domain *domain-name*

3. Specify the encryption algorithm for certificate files in PKCS#7 format.

   pkcs7-encryption-algorithm { **3des-cbc** | **aes-cbc-128** | **des-cbc** | **sm4-cbc** }

   By default, the DES-CBC encryption algorithm is used.

Specifying the storage path for certificates and CRLs

About this task

The device has a default storage path for certificates and CRLs. You can change the storage path and specify different paths for the certificates and CRLs.

After you change the storage path for certificates or CRLs, the certificate files and CRL files in the original path are moved to the new path. Certificate files use the .cer or .p12 file extension and CRL files use the .crl file extension.

Restrictions and guidelines

If you change the storage path, save the configuration before you reboot or shut down the device to avoid loss of certificates or CRLs.

Procedure

1. Enter system view.

   system-view

2. Specify the storage path for certificates and CRLs.

   pki storage { **certificates** | **crls** } *dir-path*

   By default, the device stores certificates and CRLs in the PKI directory on the storage media of the device.

Requesting a certificate

About certificate request configuration

To request a certificate, a PKI entity must provide its identity information and public key to a CA.

A certificate request can be submitted to a CA in offline or online mode.

- **Offline mode**—A certificate request is submitted by using an out-of-band method, such as phone, disk, or email.
- **Online mode**—A certificate request can be automatically or manually submitted to a CA through the Simple Certificate Enrollment Protocol (SCEP).

Restrictions and guidelines for certificate request configuration

When you request a local certificate in a PKI domain, follow these restrictions and guidelines:

- To prevent an existing local certificate from becoming invalid, do not perform the following tasks:
  - Create a key pair with the same name as the key pair contained in the certificate.

To create a key pair, use the **`public-key local create`** command.

  - Destroy the key pair contained in the certificate.

    To destroy a key pair, use the **`public-key local destroy`** command.

  For more information about the **`public-key local create`** and **`public-key local destroy`** commands, see public key management commands in *Security Command Reference*.

- To manually request a new certificate in a PKI domain that already has a local certificate, use the following procedure:
  - **a.** Use the **`pki delete-certificate`** command to delete the existing local certificate.
  - **b.** Use the **`public-key local create`** command to generate a new key pair.
  - **c.** Manually submit a certificate request.
- A PKI domain can have local certificates using only one type of cryptographic algorithms (DSA, ECDSA, RSA, or SM2). If DSA or ECDSA is used, a PKI domain can have only one local certificate. If RSA or SM2 is used, a PKI domain can have one local certificate for signature, and one local certificate for encryption.

Prerequisites for certificate request configuration

Make sure the device is time synchronized with the CA server. If the device is not time synchronized with the CA server, the certificate request might fail because the certificate might be considered to be outside of the validity period. For information about configuring the system time, see device management in *Fundamentals Configuration Guide*.

Enabling the automatic online certificate request mode

About this task

In auto request mode, a PKI entity with no local certificates automatically submits a certificate request to the CA when an application works with the PKI entity. For example, when IKE negotiation uses a digital signature for identity authentication, but no local certificate is available, the entity automatically submits a certificate request. It saves the certificate locally after obtaining the certificate from the CA.

A CA certificate must be present before you request a local certificate. If no CA certificate exists in the PKI domain, the PKI entity automatically obtains a CA certificate before sending a certificate request.

Certificate auto-renewal enables the system to automatically request a new certificate the specified number of days before the old certificate expires. The old certificate is replaced immediately when the new certificate is received.

Restrictions and guidelines

In auto request mode, the device does not automatically request a new certificate if the current certificate is about to expire or has expired, which might cause service interruptions.

To avoid service interruptions caused by certificate expiration, specify the **`renew-before-expire`** *days* option to enable certificate auto-renewal in auto certificate request mode.

Some CAs require a new PKI entity common name for certificate auto-renewal to work. Specify the **`automatic-append common-name`** keyword to ensure successful certificate auto-renewal.

Procedure

1. Enter system view.

```
system-view
```

2. Enter PKI domain view.

   pki domain *domain-name*

3. Enable the automatic online certificate request mode.

   certificate request mode auto [**password** { **cipher** | **simple** } *string* | **renew-before-expire** *days* [**reuse-public-key**] [**automatic-append common-name**]] *

   By default, the manual request mode applies.

   If the CA policy requires a password for certificate revocation, specify the password in this command.

Manually submitting an online certificate request

About this task

In manual request mode, you must execute the **pki request-certificate domain** command to request a local certificate in a PKI domain. The certificate will be saved in the domain after it is obtained from the CA.

Procedure

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Set the certificate request mode to manual.

   certificate request mode manual

   By default, the manual request mode applies.

4. Return to system view.

   quit

5. Obtain a CA certificate.

   See "Obtaining certificates."

   This step is required if the PKI domain does not have a CA certificate. The CA certificate is used to verify the authenticity and validity of the obtained local certificate.

6. Manually submit an SCEP certificate request.

   pki request-certificate domain *domain-name* [**password** *password*]

   This command is not saved in the configuration file.

   If the CA policy requires a password for certificate revocation, specify the password in this command.

Manually submitting a certificate request in offline mode

About this task

Use this method if the CA does not support SCEP or if a network connection between the device and CA is not possible.

Procedure

1. Enter system view.

   system-view

2. Enter PKI domain view.

pki domain *domain-name*

3. Set the certificate request mode to manual.

   certificate request mode manual

   By default, the manual request mode applies.

4. Return to system view.

   quit

5. Obtain the CA certificate.

   See "Obtaining certificates."

   This step is required if the PKI domain does not have a CA certificate. The CA certificate is used to verify the authenticity and validity of the obtained local certificate.

6. Print the certificate request in PKCS10 format on the terminal or save the certificate request to a PKCS10 file.

   pki request-certificate domain *domain-name* **pkcs10** [**filename** *filename*]

   This command is not saved in the configuration file.

7. Transfer certificate request information to the CA by using an out-of-band method.

8. Transfer the issued local certificate from the CA to the local device by using an out-of-band method.

9. Import the local certificate to the PKI domain.

   pki import domain *domain-name* { **der local filename** *filename* | **p12 local filename** *filename* | **pem local** [**filename** *filename*] }

Aborting a certificate request

About this task

Before the CA issues a certificate, you can abort a certificate request and change its parameters, such as the common name, country code, or FQDN. You can use the **display pki certificate request-status** command to display the status of a certificate request.

Alternatively, you also can remove a PKI domain to abort the associated certificate request.

Procedure

1. Enter system view.

   system-view

2. Abort a certificate request.

   pki abort-certificate-request domain *domain-name*

   This command is not saved in the configuration file.

Obtaining certificates

About this task

You can obtain the CA certificate, local certificates, and peer certificates related to a PKI domain from a CA and save them locally for higher lookup efficiency. To do so, use either the offline mode or the online mode:

- In offline mode, obtain the certificates by an out-of-band means like FTP, disk, or email, and then import them locally. Use this mode when the CRL repository is not specified, the CA server does not support SCEP, or the CA server generates the key pair for the certificates.

- In online mode, you can obtain the CA certificate through SCEP and obtain local certificates or peer certificates through LDAP.

Restrictions and guidelines

Follow these restrictions and guidelines when obtain certificates from a CA

- If a CA certificate already exists locally, you cannot obtain it again in online mode. If you want to obtain a new CA certificate, use the **`pki delete-certificate`** command to delete the existing CA certificate and local certificates first.
- If local or peer certificates already exist, you can obtain new local or peer certificates to overwrite the existing ones. If RSA is used, a PKI domain can have two local certificates, one for signature and the other for encryption.
- If CRL checking is enabled, obtaining a certificate triggers CRL checking. If the certificate to be obtained has been revoked, the certificate cannot be obtained.
- The device compares the validity period of a certificate with the local system time to determine whether the certificate is valid. Make sure the system time of the device is synchronized with the CA server.

Prerequisites

- Before you obtain local or peer certificates in online mode, make sure an LDAP server is correctly configured in the PKI domain.
- Before you import certificates in offline mode, complete the following tasks:
  - Use FTP or TFTP to upload the certificate files to the storage media of the device.

    If FTP or TFTP is not available, display and copy the contents of a certificate to a file on the device. Make sure the certificate is in PEM format because only certificates in PEM format can be imported.
  - Before you import a local certificate or peer certificate, obtain the CA certificate chain that signs the certificate.

    This step is required only if the CA certificate chain is neither available in the PKI domain nor contained in the certificate to be imported.
  - Before you import a local certificate that contains an encrypted key pair, contact the CA administrator to obtain the password required for importing the certificate.

Procedure

1. Enter system view.

   `system-view`
2. Obtain certificates.
   - Import certificates in offline mode.

     `pki import domain` *`domain-name`* { **`der`** { **`ca`** | **`local`** | **`peer`** } **`filename`** *`filename`* | **`p12 local filename`** *`filename`* | **`pem`** { **`ca`** | **`local`** | **`peer`** } [**`filename`** *`filename`*] }
   - Obtain certificates in online mode.

     `pki retrieve-certificate domain` *`domain-name`* { **`ca`** | **`local`** | **`peer`** *`entity-name`* }

     This command is not saved in the configuration file.

Verifying PKI certificates

About certification verification

A certificate is automatically verified when it is requested, obtained, or used by an application. If the certificate expires, if it is not issued by a trusted CA, or if it is revoked, the certificate cannot be used You can also manually verify a certificate.

You can enable or disable CRL checking in a PKI domain. CRL checking checks whether a certificate is in the CRL. If it is, the certificate has been revoked and its home entity is not trusted.

To use CRL checking, a CRL must be obtained from a CRL repository. The device selects a CRL repository in the following order:

1. CRL repository specified in the PKI domain by using the **`crl url`** command.
2. CRL repository in the certificate that is being verified.
3. CRL repository in the CA certificate or CRL repository in the upper-level CA certificate if the certificate being verified is a CA certificate

If no CRL repository is found after the selection process, the device obtains the CRL through SCEP. In this scenario, the CA certificate and the local certificates must have been obtained.

A certificate fails CRL checking in the following situations:

- A CRL cannot be obtained during CRL checking of the certificate.
- CRL checking verifies that the certificate has been revoked.

Restrictions and guidelines for certificate verification

When verifying the CA certificate of a PKI domain, the system needs to verify all the certificates in the CA certificate chain. To ensure a successful certificate verification process, the device must have all the PKI domains to which the CA certificates in the certificate chain belong.

The system verifies the CA certificates in the CA certificate chain as follows:

1. Identifies the parent certificate of the lowest-level certificate.

   Each CA certificate contains an issuer field that identifies the parent CA that issued the certificate.
2. Locates the PKI domain to which the parent certificate belongs.
3. Performs CRL checking in the PKI domain to check whether the parent certificate has been revoked. If it has been revoked, the certificate cannot be used.

   This step will not be performed when CRL checking is disabled in the PKI domain.
4. Repeats the previous steps for upper-level certificates in the CA certificate chain until the root CA certificate is reached.
5. Verifies that each CA certificate in the certificate chain is issued by the named parent CA, starting from the root CA.

Specifying the certificate revocation checking methods

About this task

You can specify the following certificate revocation checking methods in a PKI domain:

- **CRL**—Uses the CRL for certificate revocation checking.
- **None**—Performs no revocation checking and treats all certificates as not revoked.

The method specified first will be used first. If you specify **CRL** as method 1 and **none** as method 2, the device will first check the CRL to identify whether the certificate has been revoked during certificate verification. If the device cannot obtain a CRL, it will treat the certificate as not revoked.

If you specify **none** as method 1, you cannot specify method 2 because no revocation checking is required.

Restrictions and guidelines

The CRL method takes effect only if CRL checking is enabled in the PKI domain (by using the **`crl check enable`** command). If CRL checking is disabled in the PKI domain, no CRL checking will be performed and all certificates will be treated as not revoked.

Procedure

1. Enter system view.

   `system-view`

2. Enter PKI domain view.

   `pki domain` *`domain-name`*

3. Specify the certificate revocation checking methods.
   - Specify both the **CRL** and **none** certificate revocation checking methods.

     `revocation-check method crl` [**`none`**]
   - Specify the **none** certificate revocation checking method.

     `revocation-check method none`

   By default, the CRL is used for certificate revocation checking.

Verifying certificates with CRL checking

Restrictions and guidelines

CRL checking does not take effect if the **`revocation-check method none`** command is configured in the PKI domain.

Procedure

1. Enter system view.

   `system-view`

2. Enter PKI domain view.

   `pki domain` *`domain-name`*

3. (Optional.) Specify the URL of the CRL repository.

   `crl url` *`url-string`*

   By default, the URL of the CRL repository is not specified.

4. (Optional.) Specify the VPN instance where the certificate request reception authority and the CRL repository belong.

   `vpn-instance` *`vpn-instance-name`*

   By default, the certificate request reception authority and the CRL repository belong to the public network.

5. Enable CRL checking.

   `crl check enable`

   By default, CRL checking is enabled.

6. Return to system view.

   `quit`

7. Obtain the CA certificate.

   See "Obtaining certificates."

   The PKI domain must have a CA certificate before you can verify certificates in it.

8. (Optional.) Obtain the CRL and save it locally.

   See "Obtaining the CRL."

   To verify a non-root CA certificate and local certificates, the device automatically retrieves the CRL if the PKI domain has no CRL.

   The newly obtained CRL overwrites the old one, if any.

   The obtained CRL is issued by a CA in the CA certificate chain stored in the PKI domain.

9. Manually verify the validity of the certificates.

   pki validate-certificate domain *domain-name* { **ca** | **local** }

Verifying certificates without CRL checking

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Disable CRL checking.

   undo crl check enable

   By default, CRL checking is enabled.

4. Return to system view.

   quit

5. Obtain a CA certificate for the PKI domain.

   See "Obtaining certificates."

   The PKI domain must have a CA certificate before you can verify certificates in it.

6. Manually verify the certificate validity.

   pki validate-certificate domain *domain-name* { **ca** | **local** }

   This command is not saved in the configuration file.

Exporting certificates

About this task

You can export the CA certificate and the local certificates in a PKI domain to certificate files. The exported certificate files can then be imported back to the device or other PKI applications.

Restrictions and guidelines

To export all certificates in PKCS12 format, the PKI domain must have a minimum of one local certificate. If the PKI domain does not have any local certificates, the certificates in the PKI domain cannot be exported.

If you do not specify a file name when you export a certificate in PEM format, this command displays the certificate content on the terminal.

When you export a local certificate with RSA key pairs to a file, the certificate file name might be different from the file name specified in the command. The actual certificate file name depends on the purpose of the key pair contained in the certificate. For more information about the file naming rule, see the **pki export** command in *Security Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Export certificates.

   - Export certificates in DER format.

     pki export domain *domain-name* **der** { **all** | **ca** | **local** } **filename** *filename*

   - Export certificates in PKCS12 format.

     pki export domain *domain-name* **p12** { **all** | **local** } **passphrase** *p12-key* **filename** *filename*

   - Export certificates in PEM format.

     pki export domain *domain-name* **pem** { { **all** | **local** } [{ **3des-cbc** | **aes-128-cbc** | **aes-192-cbc** | **aes-256-cbc** | **des-cbc** } *pem-key*] | **ca** } [**filename** *filename*]

Removing a certificate

About this task

You can remove certificates from a PKI domain in the following situations:

- Remove a CA certificate, local certificate, or peer certificate if the certificate has expired or is about to expire.
- Remove a local certificate if the certificate's private key is compromised, or if you want to request a new local certificate to replace the existing one.

Restrictions and guidelines

After you remove the CA certificate, the system automatically removes the local certificates, peer certificates, and CRLs from the domain.

To remove a local certificate and request a new certificate, perform the following tasks:

1. Remove the local certificate.
2. Use the **public-key local destroy** command to destroy the existing local key pair.
3. Use the **public-key local create** command to generate a new key pair.
4. Request a new certificate.

For more information about the **public-key local destroy** and **public-key local create** commands, see *Security Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Remove a certificate.

   pki delete-certificate domain *domain-name* { **ca** | **local** | **peer** [**serial** *serial-num*] }

   If you use the **peer** keyword without specifying a serial number, this command removes all peer certificates.

Configuring a certificate-based access control policy

About certificate-based access control policies

Certificate-based access control policies allow you to authorize access to a device (for example, an HTTPS server) based on the attributes of an authenticated client's certificate.

Access control rules and certificate attribute groups

A certificate-based access control policy is a set of access control rules (permit or deny statements), each associated with a certificate attribute group. A certificate attribute group contains multiple attribute rules, each defining a matching criterion for an attribute in the certificate issuer name, subject name, or alternative subject name field.

Certificate matching mechanism

If a certificate matches all attribute rules in a certificate attribute group associated with an access control rule, the system determines that the certificate matches the access control rule. In this scenario, the match process stops, and the system performs the access control action defined in the access control rule.

The following conditions describe how a certificate-based access control policy verifies the validity of a certificate:

- If a certificate matches a permit statement, the certificate passes the verification.
- If a certificate matches a deny statement or does not match any statements in the policy, the certificate is regarded invalid.
- If a statement is associated with a non-existing attribute group, or the attribute group does not have attribute rules, the certificate matches the statement.
- If the certificate-based access control policy specified for a security application (for example, HTTPS) does not exist, all certificates in the application pass the verification.

Procedure

1. Enter system view.

   system-view

2. Create a certificate attribute group and enter its view.

   pki certificate attribute-group *group-name*

3. Configure an attribute rule for issuer name, subject name, or alternative subject name.

   attribute *id* { **alt-subject-name** { **fqdn** | **ip** } | { **issuer-name** | **subject-name** } { **dn** | **fqdn** | **ip** } } { **ctn** | **equ** | **nctn** | **nequ**} *attribute-value*

   By default, not attribute rules are configured.

4. Return to system view.

   quit

5. Create a certificate-based access control policy and enter its view.

   pki certificate access-control-policy *policy-name*

   By default, no certificate-based access control policies exist.

6. Create a certificate access control rule.

   rule [*id*] { **deny** | **permit** } *group-name*

By default, no certificate access control rules are configured, and all certificates can pass the verification.

You can create multiple certificate access control rules for a certificate-based access control policy.

Enabling local certificate expiration notification

About this task

After this feature is enabled, the system checks the validity date for local certificates every other hour. When a local certificate is about to expire in 30 days (included) or has expired, the system sends a notification log message for the certificate every other day.

Procedure

1. Enter system view.

   system-view

2. Enable local certificate expiration notification.

   pki certificate logging { **local-will-expire** | **local-has-expired** } **enable**

   By default, local certificate expiration notification is disabled.

Obtaining the CRL

About the task

The device uses HTTP, LDAP, or SCEP to obtain the latest CRL from the CRL repository to update the local CRL, if any.

The CRL can be obtained manually or automatically.

- **Manually obtain the CRL**—Execute the **pki retrieve-crl** command on the device to immediately obtain the latest CRL from the CRL repository.
- **Automatically obtain the CRL**—Execute the **crl update-period** command to enable automatic CRL update and specify the update interval. The device automatically connects to the CRL repository to obtain the CRL at the specified update intervals. This method is applicable to scenarios that require strict certificate verification, such as bank systems.

Restrictions and guidelines

The obtained CRL must be issued by a CA in the CA certificate chain stored in the PKI domain.

Using automatic CRL update, the device might not be able to update the CRL immediately when the CRL expires. This is because the device must wait for the specified interval of time to perform a next update. Set the CRL update interval to a proper value to ensure the timeliness of CRL update.

Prerequisites

Before obtaining the CRL, complete the following tasks:

- Specify the trusted CA by using the **ca identifier** command.
- Make sure the PKI domain contains the CA certificate. To obtain a CA certificate, use the **pki retrieve-certificate domain** command.
- Synchronize the system time of the device with that of the CA server. Time inconsistency might result in failure of obtaining the CRL. To set the system time, see device management in *Fundamentals Configuration Guide*.

Obtaining the CRL manually

1. Enter system view.

   `system-view`

2. (Optional.) Execute the following commands in sequence to specify the URL of the CRL repository.

   a. Enter PKI domain view.

      `pki domain` *`domain-name`*

   b. Specify the URL of the CRL repository.

      `crl url` *`url-string`*

   c. Return to the system view.

      `quit`

   If you do not specify the URL of the CRL repository, make sure the CA certificate or the local certificates contain CRL repository information.

3. Obtain the CRL manually.

   `pki retrieve-crl domain` *`domain-name`*

Obtaining the CRL automatically

1. Enter system view.

   `system-view`

2. Enter PKI domain view.

   `pki domain` *`domain-name`*

3. (Optional.) Specify the URL of the CRL repository.

   `crl url` *`url-string`*

   If you do not specify the URL of the CRL repository, make sure the CA certificate or the local certificates contain CRL repository information.

4. Enable automatic CRL update and set the update interval.

   `crl update-period` *`hours`*

   By default, the device does not automatically update the CRL.

Display and maintenance commands for PKI

Execute **display** commands in any view.

Task	Command
Display certificate-based access control policy information.	**display pki certificate access-control-policy** [*policy-name*]
Display certificate attribute group information.	**display pki certificate attribute-group** [*group-name*]
Display the contents of a certificate.	**display pki certificate domain** *domain-name* { **ca** | **local** | **peer** [**serial** *serial-num*] }
Display the certificate renewal status.	**display pki certificate renew-status** [**domain** *domain-name*]
Display certificate request status.	**display pki certificate request-status** [**domain** *domain-name*]

Task	**Command**
Display locally stored CRLs in a PKI domain.	**display pki crl domain** *domain-name*

PKI configuration examples

General restrictions and guidelines

You can use different software applications, such as Windows server, RSA Keon, and OpenCA, to act as the CA server.

If you use Windows server or OpenCA, you must install the SCEP add-on for Windows server or enable SCEP for OpenCA. In either case, when you configure a PKI domain, you must use the **certificate request from ra** command to specify the RA to accept certificate requests.

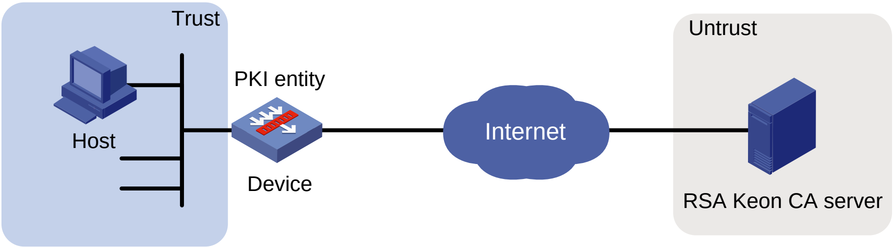
If you use RSA Keon, the SCEP add-on is not required. When you configure a PKI domain, you must use the **certificate request from ca** command to specify the CA to accept certificate requests.

Example: Requesting a certificate from an RSA Keon CA server

Network configuration

Configure the PKI entity (the device) to request a local certificate from the RSA Keon CA server.

Figure 3 Network diagram



Configuring the RSA Keon CA server

1. Create a CA server named **myca**:

   In this example, you must configure these basic attributes on the CA server:

   - **Nickname**—Name of the trusted CA.
   - **Subject DN**—DN attributes of the CA, including the common name (CN), organization unit (OU), organization (O), and country (C).

   You can use the default values for other attributes.

2. Configure extended attributes:

   Configure parameters in the **Jurisdiction Configuration** section on the management page of the CA server:

   - Select the correct extension profiles.
   - Enable the SCEP autovetting function to enable the CA server to automatically approve certificate requests without manual intervention.
   - Specify the IP address list for SCEP autovetting.

Configuring the device

1. Synchronize the system time of the device with the CA server for the device to correctly request certificates or obtain CRLs. (Details not shown.)
2. Assign IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 2.2.2.1 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

3. Configure settings for routing. This example configures a static route, and the next hop in the route is 2.2.2.2.

```
[Device] ip route-static 3.3.3.1 24 2.2.2.2
```

4. Add interface GigabitEthernet 1/0/1 to security zone **Untrust**.

```
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/1
[Device-security-zone-Untrust] quit
```

5. Configure a security policy to permit traffic between the **Untrust** and **Local** security zones:

# Configure a rule named **pkilocalout** to allow the device to send packets to the RSA Keon CA server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name pkilocalout
[Device-security-policy-ip-1-pkilocalout] source-zone local
[Device-security-policy-ip-1-pkilocalout] destination-zone untrust
[Device-security-policy-ip-1-pkilocalout] source-ip-host 2.2.2.1
[Device-security-policy-ip-1-pkilocalout] destination-ip-host 3.3.3.1
[Device-security-policy-ip-1-pkilocalout] action pass
[Device-security-policy-ip-1-pkilocalout] quit
```

# Configure a rule named **pkilocalin** to allow the device to receive the packets sent from the RSA Keon CA server.

```
[Device-security-policy-ip] rule name pkilocalin
[Device-security-policy-ip-2-pkilocalin] source-zone untrust
[Device-security-policy-ip-2-pkilocalin] destination-zone local
[Device-security-policy-ip-2-pkilocalin] source-ip-host 3.3.3.1
[Device-security-policy-ip-2-pkilocalin] destination-ip-host 2.2.2.1
[Device-security-policy-ip-2-pkilocalin] action pass
[Device-security-policy-ip-2-pkilocalin] quit
```

6. Create an entity named **aaa** and set the common name to **Device**.

```
[Device] pki entity aaa
[Device-pki-entity-aaa] common-name Device
[Device-pki-entity-aaa] quit
```

7. Configure a PKI domain and configure parameters for PKI certificate request.

# Create a PKI domain named **torsa** and enter its view.

```
[Device] pki domain torsa
```

# Specify the name of the trusted CA. The setting must be the same as CA name configured on the CA server. This example uses **myca**.

```
[Device-pki-domain-torsa] ca identifier myca
```

# Configure the URL of the CA server. The URL format is **http://***host:port***/***Issuing Jurisdiction ID*, where *Issuing Jurisdiction ID* is a hexadecimal string generated on the CA server.

```
[Device-pki-domain-torsa] certificate request url
http://1.1.2.22:446/80f6214aa8865301d07929ae481c7ceed99f95bd
```

# Configure the device to send certificate requests to **ca**.

```
[Device-pki-domain-torsa] certificate request from ca
```

# Set the PKI entity name to **aaa**.

```
[Device-pki-domain-torsa] certificate request entity aaa
```

# Specify the URL of the CRL repository.

```
[Device-pki-domain-torsa] crl url ldap://1.1.2.22:389/CN=myca
```

# Configure a general-purpose RSA key pair named **abc** with a length of 1024 bits.

```
[Device-pki-domain-torsa] public-key rsa general name abc length 1024
[Device-pki-domain-torsa] quit
```

8. Generate the RSA key pair.

```
[Device] public-key local create rsa name abc
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
....................................++++++
Create the key pair successfully.
```

9. Request a local certificate:

# Obtain the CA certificate and save it locally.

```
[Device] pki retrieve-certificate domain torsa ca
The trusted CA's finger print is:
    MD5  fingerprint:EDE9 0394 A273 B61A F1B3 0072 A0B1 F9AB
    SHA1 fingerprint: 77F9 A077 2FB8 088C 550B A33C 2410 D354 23B2 73A8
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

# Submit a certificate request manually and set the certificate revocation password to **1111**. The certificate revocation password is required when an RSA Keon CA server is used.

```
[Device] pki request-certificate domain torsa password 1111
Start to request certificate ...
……
Request certificate of domain torsa successfully
```

Verifying the configuration

# Display information about the local certificate in PKI domain **torsa**.

```
[Device] display pki certificate domain torsa local
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number:

```

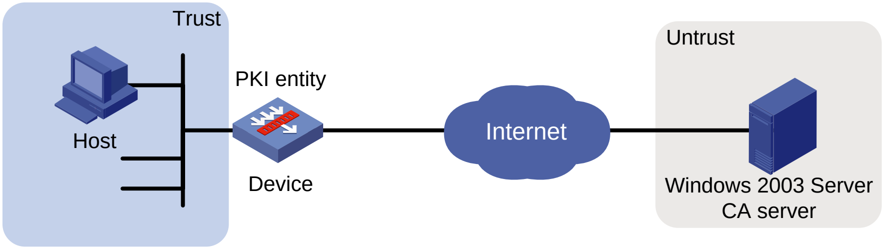
To display detailed information about the CA certificate, use the **display pki certificate domain** command.

Example: Requesting a certificate from a Windows Server 2003 CA server

Network configuration

Configure the PKI entity (the device) to request a local certificate from a Windows Server 2003 CA server.

Figure 4 Network diagram



Configuring the Windows Server 2003 CA server

1. Install the certificate service component:
   a. Select **Control Panel** > **Add or Remove Programs** from the start menu.
   b. Select **Add/Remove Windows Components** > **Certificate Services**.
   c. Click **Next** to begin the installation.
   d. Set the CA name. In this example, set the CA name to **myca**.
2. Install the SCEP add-on:

   By default, Windows Server 2003 does not support SCEP. You must install the SCEP add-on on the server for a PKI entity to register and obtain a certificate from the server. After the SCEP add-on installation is complete, you will see a URL. Specify this URL as the certificate request URL on the device.
3. Modify the certificate service attributes:
   a. Select **Control Panel** > **Administrative Tools** > **Certificate Authority** from the start menu.

      If the certificate service component and SCEP add-on have been installed successfully, there should be two certificates issued by the CA to the RA.
   b. Right-click the CA server in the navigation tree and select **Properties** > **Policy Module**.
   c. Click **Properties**, and then select **Follow the settings in the certificate template, if applicable. Otherwise, automatically issue the certificate**.
4. Modify the Internet information services attributes:
   a. Select **Control Panel** > **Administrative Tools** > **Internet Information Services (IIS) Manager** from the start menu.
   b. Select **Web Sites** from the navigation tree.
   c. Right-click **Default Web Site** and select **Properties** > **Home Directory**.
   d. Specify the path for certificate service in the **Local path** box.
   e. Specify a unique TCP port number for the default website to avoid conflict with existing services. In this example, port 8080 is used.

Configuring the device

1. Synchronize the system time of the device with the CA server for the device to correctly request certificates or obtain CRLs. (Details not shown.)
2. Assign IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 2.2.2.1 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

3. Configure settings for routing. This example configures a static route, and the next hop in the route is 2.2.2.2.

```
[Device] ip route-static 3.3.3.1 24 2.2.2.2
```

4. Add interface GigabitEthernet 1/0/1 to security zone **Untrust**.

```
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/1
[Device-security-zone-Untrust] quit
```

5. Configure a security policy to permit traffic between the **Untrust** and **Local** security zones:

   # Configure a rule named **pkilocalout** to allow the device to send packets to the Windows Server 2003 CA server.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name pkilocalout
   [Device-security-policy-ip-1-pkilocalout] source-zone local
   [Device-security-policy-ip-1-pkilocalout] destination-zone untrust
   [Device-security-policy-ip-1-pkilocalout] source-ip-host 2.2.2.1
   [Device-security-policy-ip-1-pkilocalout] destination-ip-host 3.3.3.1
   [Device-security-policy-ip-1-pkilocalout] action pass
   [Device-security-policy-ip-1-pkilocalout] quit
   ```

   # Configure a rule named **pkilocalin** to allow the device to receive the packets sent from the Windows Server 2003 CA server.

   ```
   [Device-security-policy-ip] rule name pkilocalin
   [Device-security-policy-ip-2-pkilocalin] source-zone untrust
   [Device-security-policy-ip-2-pkilocalin] destination-zone local
   [Device-security-policy-ip-2-pkilocalin] source-ip-host 3.3.3.1
   [Device-security-policy-ip-2-pkilocalin] destination-ip-host 2.2.2.1
   [Device-security-policy-ip-2-pkilocalin] action pass
   [Device-security-policy-ip-2-pkilocalin] quit
   ```

6. Create an entity named **aaa** and set the common name to **test**.

   ```
   [Device] pki entity aaa
   [Device-pki-entity-aaa] common-name test
   [Device-pki-entity-aaa] country CN
   [Device-pki-entity-aaa] locality pukras
   [Device-pki-entity-aaa] organization abc
   [Device-pki-entity-aaa] quit
   ```

7. Configure a PKI domain and configure parameters for PKI certificate request.

   # Create a PKI domain named **winserver** and enter its view.

   ```
   [Device] pki domain winserver
   ```

   # Set the name of the trusted CA to **myca**.

   ```
   [Device-pki-domain-winserver] ca identifier myca
   ```

   # Configure the certificate request URL. The URL format is **http://***host:port***/certsrv/mscep/mscep.dll**, where *host:port* is the IP address and port number of the CA server.

   ```
   [Device-pki-domain-winserver] certificate request url
   http://4.4.4.1:8080/certsrv/mscep/mscep.dll
   ```

   # Configure the device to send certificate requests to **ra**.

   ```
   [Device-pki-domain-winserver] certificate request from ra
   ```

   # Set the PKI entity name to **aaa**.

   ```
   [Device-pki-domain-winserver] certificate request entity aaa
   ```

   # Configure a general-purpose RSA key pair named **abc** with a length of 1024 bits.

   ```
   [Device-pki-domain-winserver] public-key rsa general name abc length 1024
   [Device-pki-domain-winserver] quit
   ```

8. Generate the RSA local key pair.

```
[Device] public-key local create rsa name abc
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

9. Request a local certificate:

# Obtain the CA certificate and save it locally.

```
[Device] pki retrieve-certificate domain winserver ca
The trusted CA's finger print is:
    MD5  fingerprint:766C D2C8 9E46 845B 4DCE 439C 1C1F 83AB
    SHA1 fingerprint:97E5 DDED AB39 3141 75FB DB5C E7F8 D7D7 7C9B 97B4
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

# Submit a certificate request manually.

```
[Device] pki request-certificate domain winserver
Start to request certificate ...
...
Request certificate of domain winserver successfully
```

Verifying the configuration

# Display information about the local certificate in PKI domain **winserver**.

```
[Device] display pki certificate domain winserver local

```

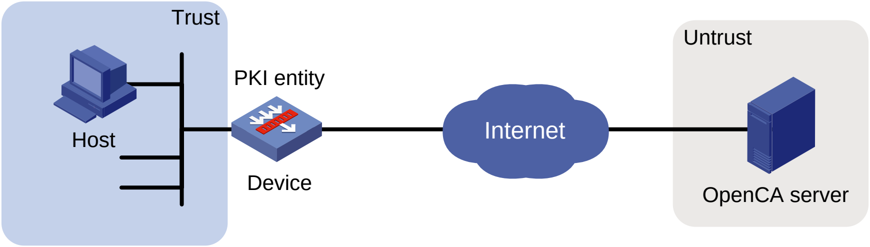
To display detailed information about the CA certificate, use the **display pki certificate domain** command.

Example: Requesting a certificate from an OpenCA server

Network configuration

Configure the PKI entity (the device) to request a local certificate from the OpenCA server.

Figure 5 Network diagram



Configuring the OpenCA server

Configure the OpenCA server as instructed in related manuals. (Details not shown.)

Make sure the version of the OpenCA server is later than version 0.9.2 because earlier versions do not support SCEP.

Configuring the device

1. Synchronize the system time of the device with the CA server for the device to correctly request certificates or obtain CRLs. (Details not shown.)
2. Assign IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 2.2.2.1 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

3. Configure settings for routing. This example configures a static route, and the next hop in the route is 2.2.2.2.

```
[Device] ip route-static 3.3.3.1 24 2.2.2.2
```

4. Add interface GigabitEthernet 1/0/1 to security zone **Untrust**.

```
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/1
[Device-security-zone-Untrust] quit
```

5. Configure a security policy to permit traffic between the **Untrust** and **Local** security zones:

   # Configure a rule named **pkilocalout** to allow the device to send packets to the OpenCA server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name pkilocalout
[Device-security-policy-ip-1-pkilocalout] source-zone local
[Device-security-policy-ip-1-pkilocalout] destination-zone untrust
[Device-security-policy-ip-1-pkilocalout] source-ip-host 2.2.2.1
[Device-security-policy-ip-1-pkilocalout] destination-ip-host 3.3.3.1
[Device-security-policy-ip-1-pkilocalout] action pass
[Device-security-policy-ip-1-pkilocalout] quit
```

# Configure a rule named **pkilocalin** to allow the device to receive the packets sent from the OpenCA server.

```
[Device-security-policy-ip] rule name pkilocalin
[Device-security-policy-ip-2-pkilocalin] source-zone untrust
[Device-security-policy-ip-2-pkilocalin] destination-zone local
[Device-security-policy-ip-2-pkilocalin] source-ip-host 3.3.3.1
[Device-security-policy-ip-2-pkilocalin] destination-ip-host 2.2.2.1
[Device-security-policy-ip-2-pkilocalin] action pass
[Device-security-policy-ip-2-pkilocalin] quit
```

6. Create a PKI entity named **aaa** and configure the common name, country code, organization name, and OU for the entity.

```
[Device] pki entity aaa
[Device-pki-entity-aaa] common-name rnd
[Device-pki-entity-aaa] country CN
[Device-pki-entity-aaa] organization test
[Device-pki-entity-aaa] organization-unit software
[Device-pki-entity-aaa] quit
```

7. Configure a PKI domain and configure parameters for PKI certificate request.

# Create a PKI domain named **openca** and enter its view.

```
[Device] pki domain openca
```

# Specify the name of the trusted CA as **myca**.

```
[Device-pki-domain-openca] ca identifier myca
```

# Configure the certificate request URL. The URL is in the format **http://*host*/cgi-bin/pki/scep**, where *host* is the IP address of the OpenCA server.

```
[Device-pki-domain-openca] certificate request url
http://192.168.222.218/cgi-bin/pki/scep
```

# Configure the device to send certificate requests to the RA.

```
[Device-pki-domain-openca] certificate request from ra
```

# Specify PKI entity **aaa** for certificate request.

```
[Device-pki-domain-openca] certificate request entity aaa
```

# Configure a general-purpose RSA key pair named **abc** with a length of 1024 bits.

```
[Device-pki-domain-openca] public-key rsa general name abc length 1024
[Device-pki-domain-openca] quit
```

8. Generate the RSA key pair.

```
[Device] public-key local create rsa name abc
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..........................++++++
.....................................++++++
Create the key pair successfully.
```

9. Request a local certificate:

# Obtain the CA certificate and save it locally.

```
[Device] pki retrieve-certificate domain openca ca
The trusted CA's finger print is:
    MD5  fingerprint:5AA3 DEFD 7B23 2A25 16A3 14F4 C81C C0FA
    SHA1 fingerprint:9668 4E63 D742 4B09 90E0 4C78 E213 F15F DC8E 9122
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

# Submit a certificate request manually.

```
[Device] pki request-certificate domain openca
Start to request certificate ...
...
Request certificate of domain openca successfully
```

Verifying the configuration

# Display information about the local certificate in PKI domain **openca**.

```
[Device] display pki certificate domain openca local

```

To display detailed information about the CA certificate, use the **display pki certificate domain** command.

Example: Configuring IKE negotiation with RSA digital signature from a Windows Server 2003 CA server

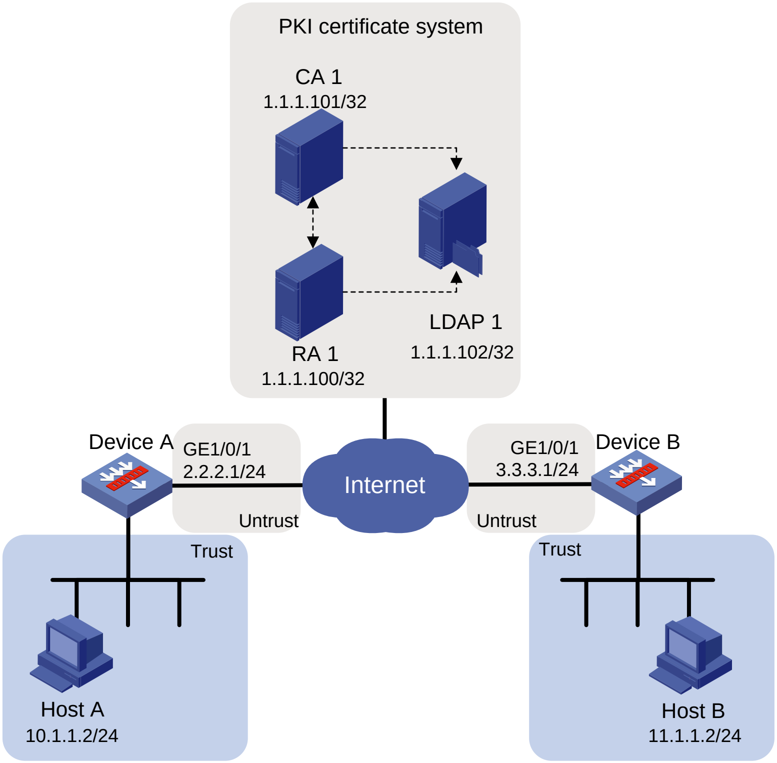
Network configuration

As shown in Figure 6, an IPsec tunnel is established between Device A and Device B to protect the traffic between Host A on subnet 10.1.1.0/24 and Host B on subnet 1.1.1.0/24.

Device A and Device use IKE to set up SAs, and the IKE proposal uses RSA digital signature for identity authentication.

Device A and Device B use the same CA server (Windows Server 2003 CA server).

Figure 6 Network diagram



Configuring the Windows Server 2003 CA server

See "Example: Requesting a certificate from a Windows Server 2003 CA server."

Configuring Device A

# Assign IP address to interface GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 2.2.2.1 255.255.255.0
[DeviceA-GigabitEthernet1/0/1] quit
```

# Configure settings for routing. This example configures static routes, and the next hop in the routes is 2.2.2.2.

```
[DeviceA] ip route-static 11.1.1.0 24 2.2.2.2
[DeviceA] ip route-static 3.3.3.1 24 2.2.2.2
```

# Add interface GigabitEthernet 1/0/1 to security zone **Untrust**.

```
[DeviceA] security-zone name untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] quit
```

# Configure a security policy rule named **pkilocalout** to allow Device A to send IPsec tunnel negotiation packets to Device B.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name pkilocalout
[DeviceA-security-policy-ip-1-pkilocalout] source-zone local
[DeviceA-security-policy-ip-1-pkilocalout] destination-zone untrust
[DeviceA-security-policy-ip-1-pkilocalout] source-ip-host 2.2.2.1
[DeviceA-security-policy-ip-1-pkilocalout] destination-ip-host 3.3.3.1
```

```
[DeviceA-security-policy-ip-1-pkilocalout] action pass
[DeviceA-security-policy-ip-1-pkilocalout] quit
```

# Configure a security policy rule named **pkilocalin** to allow Device A to receive the IPsec tunnel negotiation packets sent from Device B.

```
[DeviceA-security-policy-ip] rule name pkilocalin

[DeviceB-ike-proposal-1] quit
```

# Reference the PKI domain used in IKE negotiation for IKE profile **peer**.

```
[DeviceB] ike profile peer
[DeviceB-ike-profile-peer] certificate domain 1
[DeviceB-ike-profile-peer] quit
```

The configurations are for IKE negotiation with RSA digital signature. For information about how to configure IPsec SAs to be set up, see IPsec configuration in *VPN Configuration Guide*.

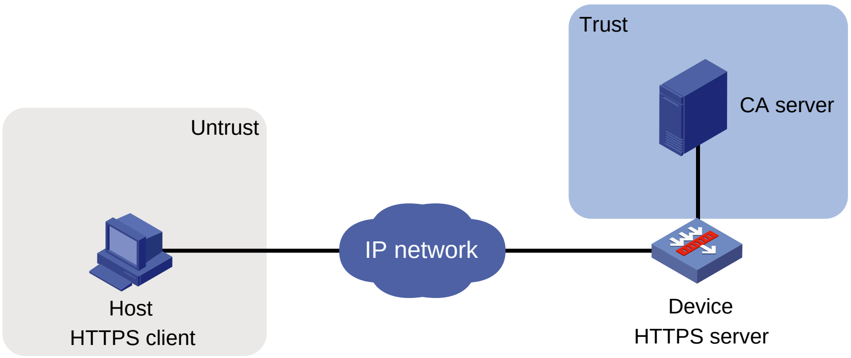
Example: Configuring a certificate-based access control policy

Network configuration

As shown in Figure 7, the host accesses the device through HTTPS.

Configure a certificate-based access control policy on the device to authenticate the host and verify the validity of the host's certificate.

Figure 7 Network diagram



Procedure

1. Create PKI domain **domain1** to be used by SSL. (Details not shown.)
2. Request an SSL server certificate for the device from the CA server. (Details not shown.)
3. Configure the HTTPS server:

# Assign IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 3.3.3.1 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

# Add interface GigabitEthernet 1/0/1 to security zone **Untrust**.

```
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/1
[Device-security-zone-Untrust] quit
```

# Configure settings for routing. This example configures a static route, and the next hop in the route is 3.3.3.2.

```
[Device] ip route-static 2.2.2.1 24 3.3.3.2
```

# Configure a security policy rule named **pkilocalin** to permit traffic from security zone **Untrust** to security zone **Local**, so that the host can send packets to the device.

```
[Device-security-policy-ip] rule name pkilocalin
[Device-security-policy-ip-1-pkilocalin] source-zone untrust
[Device-security-policy-ip-1-pkilocalin] destination-zone local
[Device-security-policy-ip-1-pkilocalin] source-ip-host 2.2.2.1
[Device-security-policy-ip-1-pkilocalin] destination-ip-host 3.3.3.1
[Device-security-policy-ip-1-pkilocalin] action pass
[Device-security-policy-ip-1-pkilocalin] quit
```

# Configure a security policy rule named **pkilocalout** to permit traffic from security zone **Local** to security zone **Untrust**, so that the device can send packets to the host.

```
[Device-security-policy-ip] rule name pkilocalout
[Device-security-policy-ip-2-pkilocalout] source-zone local
[Device-security-policy-ip-2-pkilocalout] destination-zone untrust
[Device-security-policy-ip-2-pkilocalout] source-ip-host 3.3.3.1
[Device-security-policy-ip-2-pkilocalout] destination-ip-host 2.2.2.1
[Device-security-policy-ip-2-pkilocalout] action pass
[Device-security-policy-ip-2-pkilocalout] quit
```

# Configure an SSL server policy for the HTTPS service.

```
[Device] ssl server-policy abc
```

```
[Device-ssl-server-policy-abc] pki-domain domain1
[Device-ssl-server-policy-abc] client-verify enable
[Device-ssl-server-policy-abc] quit
```

# Apply the SSL server policy to the HTTPS service.

```
[Device] ip https ssl-server-policy abc
```

# Enable the HTTPS service.

```
[Device] ip https enable
```

4. Configure certificate attribute groups:

# Create a certificate attribute group named **mygroup1** and add two attribute rules. The first rule defines that the DN in the subject DN contains the string of **aabbcc**. The second rule defines that the IP address of the certificate issuer is **10.0.0.1**.

```
[Device] pki certificate attribute-group mygroup1
[Device-pki-cert-attribute-group-mygroup1] attribute 1 subject-name dn ctn aabbcc
[Device-pki-cert-attribute-group-mygroup1] attribute 2 issuer-name ip equ 10.0.0.1
[Device-pki-cert-attribute-group-mygroup1] quit
```

# Create a certificate attribute group named **mygroup2** and add two attribute rules. The first rule defines that the FQDN in the alternative subject name does not contain the string of **apple**. The second rule defines that the DN of the certificate issuer name contains the string of **aabbcc**.

```
[Device] pki certificate attribute-group mygroup2
[Device-pki-cert-attribute-group-mygroup2] attribute 1 alt-subject-name fqdn nctn
apple
[Device-pki-cert-attribute-group-mygroup2] attribute 2 issuer-name dn ctn aabbcc
[Device-pki-cert-attribute-group-mygroup2] quit
```

5. Configure a certificate-based access control policy:

# Create a certificate-based access control policy named **myacp**.

```
[Device] pki certificate access-control-policy myacp
```

# Define a statement to deny the certificates that match the attribute rules in the certificate attribute group **mygroup1**.

```
[Device-pki-cert-acp-myacp] rule 1 deny mygroup1
```

# Define a statement to permit the certificates that match the attribute rules in the certificate attribute group **mygroup2**.

```
[Device-pki-cert-acp-myacp] rule 2 permit mygroup2
[Device-pki-cert-acp-myacp] quit
```

# Apply certificate-based access control policy **myacp** to the HTTPS service.

```
[Device] ip https certificate access-control-policy myacp
```

Verifying the configuration

# On the host, access the HTTPS server through a Web browser.

The server first verifies the validity of the host's certificate according to the configured certificate-based access control policy. In the host's certificate, the subject DN is **aabbcc**, the IP address of the certificate issuer is **1.1.1.1**, and the FQDN of the alternative subject name is **banaba**.

The host's certificate does not match the certificate attribute group **mygroup1** specified in **rule 1** of the certificate-based access control policy. The certificate continues to match against rule 2.

The host's certificate matches the certificate attribute group **mygroup2** specified in **rule 2**. Because **rule 2** is a permit statement, the certificate passes the verification and the host can access the HTTPS server.

Example: Importing and exporting certificates

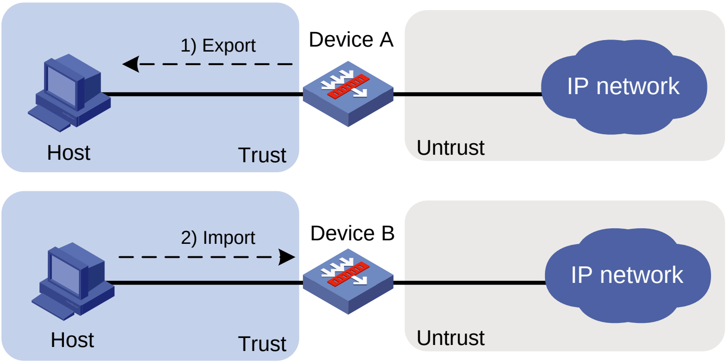
Network configuration

As shown in Figure 8, Device B will replace Device A in the network. The PKI domain **exportdomain** on Device A has two local certificates containing the private key and one CA certificate. To make sure the certificates are still valid after Device B replaces Device A, copy the certificates on Device A to Device B as follows:

1. Export the certificates in PKI domain **exportdomain** on Device A to .pem certificate files.

   During the export, encrypt the private key in the local certificates using 3DES_CBC with the password 11111.
2. Transfer the certificate files from Device A to Device B through FTP.
3. Import the certificate files to PKI domain **importdomain** on Device B.

Figure 8 Network diagram



Procedure

1. Export the certificates on Device A:

   # Assign IP address to interface GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 192.168.0.1 255.255.255.0
[DeviceA-GigabitEthernet1/0/1] quit
```

   # Add interface GigabitEthernet 1/0/1 to security zone **Trust**.

```
[DeviceA] security-zone name trust
[DeviceA-security-zone-Trust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Trust] quit
```

   # Configure a security policy rule named **pkilocalin** to permit traffic from security zone **Trust** to security zone **Local**, so that the host can send packets to Device A.

```
[DeviceA-security-policy-ip] rule name pkilocalin
[DeviceA-security-policy-ip-1-pkilocalin] source-zone trust
[DeviceA-security-policy-ip-1-pkilocalin] destination-zone local
[DeviceA-security-policy-ip-1-pkilocalin] source-ip-host 192.168.0.2
[DeviceA-security-policy-ip-1-pkilocalin] destination-ip-host 192.168.0.1
[DeviceA-security-policy-ip-1-pkilocalin] action pass
[DeviceA-security-policy-ip-1-pkilocalin] quit
```

   # Configure a security policy rule named **pkilocalout** to permit traffic from security zone **Local** to security zone **Trust**, so that Device A can send packets to the host.

```
[DeviceA-security-policy-ip] rule name pkilocalout
```

```
[DeviceA-security-policy-ip-2-pkilocalout] source-zone local
[DeviceA-security-policy-ip-2-pkilocalout] destination-zone trust
[DeviceA-security-policy-ip-2-pkilocalout] source-ip-host 192.168.0.1
[DeviceA-security-policy-ip-2-pkilocalout] destination-ip-host 192.168.0.2
[DeviceA-security-policy-ip-2-pkilocalout] action pass
[DeviceA-security-policy-ip-2-pkilocalout] quit
```

# Export the CA certificate to a .pem file.

```
[DeviceA] pki export domain exportdomain pem ca filename pkicachain.pem
```

# Export the local certificates to .pem files. Specify the file name as **pkilocal.pem** and use 3DES_CBC to encrypt the private keys with the password **111111**.

```
[DeviceA] pki export domain exportdomain pem local 3des-cbc 111111 filename
pkilocal.pem
```

Now, Device A has three certificate files in PEM format:

- A CA certificate file named **pkicachain.pem**.
- A local certificate file named **pkilocal.pem-signature**, which contains the private key for signature.
- A local certificate file named **pkilocal.pem-encryption**, which contains the private key for encryption.

# Display local certificate file **pkilocal.pem-signature**.

```
[DeviceA] quit
<DeviceA> more pkilocal.pem-signature

```

To display detailed information about the CA certificate, use the **`display pki certificate domain`** command.

Troubleshooting PKI configuration

This section provides troubleshooting information for common problems with PKI.

Failed to obtain the CA certificate

Symptom

The CA certificate cannot be obtained.

Analysis

- The network connection is down, for example, because the network cable is damaged or the connectors have bad contact.
- No trusted CA is specified.
- The certificate request URL is incorrect or not specified.
- The system time of the device is not synchronized with the CA server.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.
- The fingerprint of the root CA certificate is illegal.

Solution

1. Fix the network connection problems, if any.
2. Configure the trusted CA and all other required parameters in the PKI domain.
3. Use the **`ping`** command to verify that the CA server is reachable.
4. Synchronize the system time of the device with the CA server.
5. Specify the correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
6. Verify the fingerprint of the CA certificate on the CA server.
7. If the problem persists, contact NSFOCUS Support.

Failed to obtain local certificates

Symptom

The local certificates can be obtained.

Analysis

- The network connection is down.
- The PKI domain does not have a CA certificate before you submit the local certificate request.
- The LDAP server is not configured or is incorrectly configured.
- No key pair is specified for certificate request in the PKI domain, or the specified key pair does not match the one contained in the local certificates to the obtained.
- No PKI entity is configured in the PKI domain, or the PKI entity configuration is incorrect.
- CRL checking is enabled, but the PKI domain does not have a CRL and cannot obtain one.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.
- The system time of the device is not synchronized with the CA server.

Solution

1. Fix the network connection problems, if any..
2. Obtain or import the CA certificate.
3. Configure the correct LDAP server parameters.
4. Specify the key pair for certificate request, or remove the existing key pair, specify a new key pair, and submit a local certificate request again.
5. Check the registration policy on the CA or RA, and make sure the attributes of the PKI entity meet the policy requirements.
6. Obtain the CRL from the CRL repository.
7. Specify the correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
8. Synchronize the system time of the device with the CA server.
9. If the problem persists, contact NSFOCUS Support.

Failed to request local certificates

Symptom

Local certificate requests cannot be submitted.

Analysis

- The network connection is down, for example, because the network cable is damaged or the connectors have bad contact.
- The PKI domain does not have a CA certificate before the local certificate request is submitted.
- The certificate request URL is incorrect or is not specified.
- The certificate request reception authority is incorrect or is not specified.
- Required PKI entity parameters are not configured or are incorrectly configured.
- No key pair is specified in the PKI domain for certificate request, or the key pair is changed during a certificate request process.
- Exclusive certificate request applications are running in the PKI domain.

- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.
- The system time of the device is not synchronized with the CA server.

Solution

1. Fix the network connection problems, if any.
2. Obtain or import the CA certificate.
3. Use the **`ping`** command to verify that the registration server is reachable.
4. Use the **`certificate request from`** command to specify the correct certificate request reception authority.
5. Configure the PKI entity parameters as required by the registration policy on the CA or RA.
6. Specify the key pair for certificate request, or remove the existing key pair, specify a new key pair, and submit a local certificate request again.
7. Use the **`pki abort-certificate-request domain`** command to abort the certificate request.
8. Specify the correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
9. Synchronize the system time of the device with the CA server.
10. If the problem persists, contact NSFOCUS Support.

Failed to obtain CRLs

Symptom

CRLs cannot be obtained.

Analysis

- The network connection is down, for example, because the network cable is damaged or the connectors have bad contact.
- The PKI domain does not have a CA certificate before you try to obtain CRLs.
- The URL of the CRL repository is not configured and cannot be obtained from the CA certificate or local certificates in the PKI domain.
- The specified URL of the CRL repository is incorrect.
- The device tries to obtain CRLs through SCEP, but it experiences the following problems:
  - The PKI domain does not have local certificates.
  - The key pairs in the certificates have been changed.
  - The PKI domain has incorrect URL for certificate request.
- The CRL repository uses LDAP for CRL distribution. However, the IP address or host name of the LDAP server is neither contained in the CRL repository URL nor configured in the PKI domain.
- The CA does not issue CRLs.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.

Solution

1. Fix the network connection problems, if any.
2. Obtain or import the CA certificate.
3. If the URL of the CRL repository cannot be obtained, verify that the following conditions exist:
   - The URL for certificate request is valid.

- A local certificate has been successfully obtained.
- The local certificate contains a public key that matches the locally stored key pair.

4. Make sure the LDAP server address is contained in the CRL repository URL, or is configured in the PKI domain.
5. Make sure the CA server support publishing CRLs.
6. Specify a correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
7. If the problem persists, contact NSFOCUS Support.

Failed to import the CA certificate

Symptom

The CA certificate cannot be imported.

Analysis

- CRL checking is enabled, but the device does not have a CRL in the PKI domain and cannot obtain one.
- The specified format in which the CA certificate file is to be imported does not match actual certificate file format.

Solution

1. Use the **`undo crl check enable`** command to disable CRL checking in the PKI domain.
2. Make sure the format of the imported file is correct.
3. If the problem persists, contact NSFOCUS Support.

Failed to import the local certificate

Symptom

The local certificate cannot be imported.

Analysis

- The PKI domain does not have a CA certificate, and the local certificate file to be imported does not contain the CA certificate chain.
- CRL checking is enabled, but the device does not have a CRL in the PKI domain and cannot obtain one.
- The specified format in which the local certificate file is to be imported does not match actual certificate file format.
- The device and the certificate do not have the local key pair.
- The certificate has been revoked.
- The certificate is out of the validity period.
- The system time is incorrect.

Solution

1. Obtain or import the CA certificate.
2. Use the **`undo crl check enable`** command to disable CRL checking, or obtain the correct CRL before you import certificates.
3. Make sure the format of the file to be imported is correct.
4. Make sure the certificate file contains the private key.

5. Make sure the certificate is not revoked.
6. Make sure the certificate is valid.
7. Configure the correct system time for the device.
8. If the problem persists, contact NSFOCUS Support.

Failed to export certificates

Symptom

Certificates cannot be exported.

Analysis

- The PKI domain does not have local certificates when you export all certificates in PKCS12 format.
- The specified export path does not exist.
- The specified export path is illegal.
- The public key of the local certificate to be exported does not match the public key of the key pair configured in the PKI domain.
- The storage space of the device is full.

Solution

1. Obtain or request local certificates first.
2. Use the **`mkdir`** command to create the required path.
3. Specify a correct export path.
4. Configure the correct key pair in the PKI domain.
5. Clear up the storage space of the device.
6. If the problem persists, contact NSFOCUS Support.

Failed to set the storage path

Symptom

The storage path for certificates or CRLs cannot be set.

Analysis

- The specified storage path does not exist.
- The specified storage path is illegal.
- The storage space of the device is full.

Solution

1. Use the **`mkdir`** command to create the path.
2. Specify a valid storage path for certificates or CRLs.
3. Clear up the storage space of the device.
4. If the problem persists, contact NSFOCUS Support.

Contents

Configuring SSH

About SSH

Secure Shell (SSH) is a network security protocol. Using encryption and authentication, SSH can implement secure remote access and file transfer over an insecure network.

SSH uses the typical client-server model to establish a channel for secure data transfer based on TCP.

SSH includes two versions: SSH1.x and SSH2.0 (hereinafter referred to as SSH1 and SSH2), which are not compatible. SSH2 is better than SSH1 in performance and security.

SSH applications

The device supports the following SSH applications:

- **Secure Telnet**—Stelnet provides secure and reliable network terminal access services. Through Stelnet, a user can securely log in to a remote server. Stelnet can protect devices against attacks, such as IP spoofing and plain text password interception. The device can act as an Stelnet server or an Stelnet client.
- **Secure File Transfer Protocol**—Based on SSH2, SFTP uses SSH connections to provide secure file transfer. The device can act as an SFTP server, allowing a remote user to log in to the SFTP server for secure file management and transfer. The device can also act as an SFTP client, enabling a user to log in from the device to a remote device for secure file transfer.
- **Secure Copy**—Based on SSH2, SCP offers a secure method to copy files. The device can act as an SCP server, allowing a user to log in to the device for file upload and download. The device can also act as an SCP client, enabling a user to log in from the device to a remote device for secure file transfer.
- **NETCONF over SSH**—Based on SSH2, it enables users to securely log in to the device through SSH and perform NETCONF operations on the device through the NETCONF-over-SSH connections. The device can act only as a NETCONF-over-SSH server. For more information about NETCONF, see *Network Management and Monitoring Configuration Guide*.

When acting as an SSH server or client, the device supports the following SSH versions:

- When acting as an Stelnet, SFTP, or SCP server, the device supports both SSH2 and SSH1.
- When acting as an SSH client, the device supports only SSH2.
- When acting as a NETCONF-over-SSH server, the device supports only SSH2.

How SSH works

This section uses SSH2 as an example to describe the stages to establish an SSH session.

Table 1 Stages to establish an SSH session

Stages	Description
Connection establishment	The SSH server listens to connection requests on port 22. After a client initiates a connection request, the server and the client establish a TCP connection.
Version negotiation	The two parties determine a version to use.
Algorithm negotiation	SSH supports multiple algorithms. Based on the local algorithms, the

Stages	Description
	two parties negotiate the following algorithms: • Key exchange algorithm for generating session keys. • Encryption algorithm for encrypting data. • Public key algorithm for the digital signature and authentication. • HMAC algorithm for protecting data integrity.
Key exchange	The two parties use the DH exchange algorithm to dynamically generate the session keys and session ID. • The session keys are used for protecting data transfer. • The session ID is used for identifying the SSH connection. In this stage, the client also authenticates the server.
Authentication	The SSH server authenticates the client in response to the client's authentication request.
Session request	After passing the authentication, the client sends a session request to the server to request the establishment of a session (or request the Stelnet, SFTP, SCP, or NETCONF service).
Interaction	After the server grants the request, the client and the server start to communicate with each other in the session. In this stage, you can paste commands in text format and execute them at the CLI. The text pasted at one time must be no more than 2000 bytes. As a best practice to ensure the correct execution of commands, paste commands that are in the same view. To execute commands of more than 2000 bytes, save the commands in a configuration file, upload the file to the server through SFTP, and use it to restart the server.

SSH authentication methods

This section describes authentication methods that are supported by the device when it acts as an SSH server.

Password authentication

The SSH server authenticates a client through the AAA mechanism. The password authentication process is as follows:

1. The client sends the server an authentication request that includes the encrypted username and password.
2. The server performs the following operations:
   a. Decrypts the request to get the username and password in plain text.
   b. Verifies the username and password locally or through remote AAA authentication.
   c. Informs the client of the authentication result.

If the remote AAA server requires the user to enter a password for secondary authentication, it send the SSH server an authentication response carrying a prompt. The prompt is transparently transmitted to the client to notify the user to enter a specific password. When the user enters the correct password, the AAA sever examines the password validity. If the password is valid, the SSH server returns an authentication success message to the client.

SSH1 clients do not support secondary password authentication initiated by the AAA server.

For more information about AAA, see "Configuring AAA."

Publickey authentication

The server authenticates a client by verifying the digital signature of the client. The publickey authentication process is as follows:

1. The client sends the server a publickey authentication request that includes the username, public key, and public key algorithm name.

   If the digital certificate of the client is required in authentication, the client also encapsulates the digital certificate in the authentication request. The digital certificate carries the public key information of the client.

2. The server verifies the client's public key.
   - If the public key is invalid, the server informs the client of the authentication failure.
   - If the public key is valid, the server requests the digital signature of the client. After receiving the signature, the server uses the public key to verify the signature and informs the client of the authentication result.

When acting as an SSH server, the device supports using the public key algorithms DSA, ECDSA, and RSA to verify digital signatures.

When acting as an SSH client, the device supports using the public key algorithms DSA, ECDSA, and RSA to generate digital signatures.

For more information about public key configuration, see "Managing public keys."

Password-publickey authentication

The server requires SSH2 clients to pass both password authentication and publickey authentication. However, an SSH1 client only needs to pass either authentication.

Any authentication

The server requires clients to pass password authentication or publickey authentication.

SSH support for Suite B

Suite B contains a set of encryption and authentication algorithms that meet high security requirements. Table 2 lists all algorithms in Suite B.

The SSH server and client support using the X.509v3 certificate for identity authentication in compliance with the algorithm, negotiation, and authentication specifications defined in RFC 6239.

Table 2 Suite B algorithms

Security level	Key exchange algorithm	Encryption algorithm and HMAC algorithm	Public key algorithm
128-bit	ecdh-sha2-nistp256	AES128-GCM	x509v3-ecdsa-sha2-nistp256
192-bit	ecdh-sha2-nistp384	AES256-GCM	x509v3-ecdsa-sha2-nistp384
Both	ecdh-sha2-nistp256 ecdh-sha2-nistp384	AES128-GCM AES256-GCM	x509v3-ecdsa-sha2-nistp256 x509v3-ecdsa-sha2-nistp384

Configuring the device as an SSH server

SSH server tasks at a glance

To configure an SSH server, perform the following tasks:

1. Generating local key pairs

2. (Optional.) Specifying the SSH service port
3. Enabling the SSH server
   - Enabling the Stelnet server
   - Enabling the SFTP server
   - Enabling the SCP server
   - Enabling NETCONF over SSH
4. Configuring the user lines for SSH login

   Required only for Stelnet and NETCONF-over-SSH servers.
5. Configuring a client's host public key

   Required for authentication method **publickey**, **password-publickey,** or **any**.
6. Configuring an SSH user
   - Required for authentication method **publickey**, **password-publickey,** or **any**.
   - Optional for the **password** authentication method.
7. (Optional.) Configuring the SSH management parameters

   SSH management settings, such as authentication and connection control settings, help improve security of SSH connections.
8. (Optional.) Specifying a PKI domain for the SSH server

Generating local key pairs

About this task

The DSA, ECDSA, or RSA key pairs on the SSH server are required for generating the session keys and session ID in the key exchange stage. They can also be used by a client to authenticate the server. When a client authenticates the server, it compares the public key received from the server with the server's public key that the client saved locally. If the keys are consistent, the client uses the locally saved server's public key to decrypt the digital signature received from the server. If the decryption succeeds, the server passes the authentication.

To support SSH clients that use different types of key pairs, generate DSA, ECDSA, and RSA key pairs on the SSH server.

- **RSA key pairs**—The SSH server generates a server key pair and a host key pair for RSA. The RSA server key pair is only used in SSH1 to encrypt the session key for secure transmission of the session key. It is not used in SSH2, because no session key transmission is required in SSH2.
- **DSA key pair**—The SSH server generates only one DSA host key pair. SSH1 does not support the DSA algorithm.
- **ECDSA key pair**—The SSH server generates only one ECDSA host key pair.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs. For more information about creating local key pairs, see public key management commands in *Security Command Reference*.

If the device does not have RSA key pairs with default names, it automatically generates one RSA server key pair and one RSA host key pair when SSH starts. Both key pairs use their default names. The SSH application starts when you execute an SSH server command on the device.

The key modulus length must be less than 2048 bits when you generate the DSA key pair on the SSH server.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

Procedure

1. Enter system view.

   system-view

2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the SSH service port

About this task

The default port of the SSH service is 22. You can specify another port for the SSH service to improve security of SSH connections.

Procedure

1. Enter system view.

   system-view

2. Specify the SSH service port.

   ssh server port *port-number*

   △ **CAUTION:**

   - If you modify the SSH port number when the SSH server is enabled, the SSH service is restarted and all SSH connections are terminated after the modification. SSH users must reconnect to the SSH server to access the server.
   - If you set the SSH port to a well-known port number, the service that uses the well-known port number might fail to start. Well-known port numbers are in the range of 1 to 1024.

   By default, the SSH service port is 22.

Enabling the Stelnet server

About this task

After you enable the Stelnet server on the device, a client can log in to the device through Stelnet.

Procedure

1. Enter system view.

   system-view

2. Enable the Stelnet server.

   ssh server enable

   By default, the Stelnet server is disabled.

Enabling the SFTP server

About this task

After you enable the SFTP server on the device, a client can log in to the device through SFTP.

Restrictions and guidelines

When acting as an SFTP server, the device does not support SFTP connections initiated by SSH1 clients.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable the SFTP server.

   ```
   sftp server enable
   ```

   By default, the SFTP server is disabled.

Enabling the SCP server

About this task

After you enable the SCP server on the device, a client can log in to the device through SCP.

Restrictions and guidelines

When acting as an SCP server, the device does not support SCP connections initiated by SSH1 clients.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable the SCP server.

   ```
   scp server enable
   ```

   By default, the SCP server is disabled.

Enabling NETCONF over SSH

About this task

After you enable NETCONF over SSH on the device, a client can perform NETCONF operations on the device through a NETCONF-over-SSH connection.

Restrictions and guidelines

When acting as a server in the NETCONF-over-SSH connection, the device does not support connection requests initiated by SSH1 clients.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable NETCONF over SSH.

   ```
   netconf ssh server enable
   ```

   By default, NETCONF over SSH is disabled.

   For more information about NETCONF over SSH commands, see *Network Management and Monitoring Command Reference*.

Configuring the user lines for SSH login

About this task

Depending on the SSH application, an SSH client can be an Stelnet client, SFTP client, SCP client, or NETCONF-over-SSH client.

Only Stelnet and NETCONF-over-SSH clients require the user line configuration. The user line configuration takes effect on the clients at the next login.

Procedure

1. Enter system view.

   `system-view`

2. Enter VTY user line view.

   `line vty` *`number`* [*`ending-number`*]

3. Set the login authentication mode to scheme.

   `authentication-mode scheme`

   By default, the authentication mode is **password**.

   For more information about this command, see *Fundamentals Command Reference*.

Configuring a client's host public key

About this task

In publickey authentication, the server compares the SSH username and the client's host public key received from the client with the locally saved SSH username and the client's host public key. If they are the same, the server checks the digital signature that the client sends. The client generates the digital signature by using the private key that is paired with the client's host public key.

For publickey authentication, password-publickey authentication, or any authentication, you must perform the following tasks:

1. Configure the client's DSA, ECDSA, or RSA host public key on the server.
2. Specify the associated host private key on the client to generate the digital signature.

   If the device acts as an SSH client, specify the public key algorithm on the client. The algorithm determines the associated host private key for generating the digital signature.

Client public key configuration methods

You can configure the client host public key by using the following methods:

- Manually enter the content of a client's host public key on the server.
  - **a.** Display the host public key on the client and record the key.
  - **b.** Type the client's host public key character by character on the server, or use the copy and paste method.

  The manually entered key must be in DER format without being converted. For the displayed key to meet the requirement when the client is an NSFOCUS device, use the **`display public-key local public`** command. The format of the public key displayed in any other way (for example, by using the **`public-key local export`** command) might be incorrect. If the key is not in correct format, the system discards the key.

- Import the client host public key from a public key file.
  - **a.** Save the client public key file to the server. For example, transfer the client public key file to the server in binary mode through FTP or TFTP.
  - **b.** Import the client public key from the locally saved public key file.

    During the import process, the server automatically converts the host public key to a string in PKCS format.

Restrictions and guidelines

As a best practice, configure no more than 20 SSH client's host public keys on an SSH server.

Import the client's host public key as a best practice.

Entering a client's host public key

1. Enter system view.

   `system-view`

2. Enter public key view.

   `public-key peer` *`keyname`*

3. Configure a client's host public key.

   Enter the content of the client's host public key character by character, or use the copy and paste method.

   When you enter the content of a client's host public key, you can use spaces and carriage returns between characters but the system does not save them. For more information, see "Managing public keys."

4. Exit public key view and save the key.

   `peer-public-key` **end**

Importing a client's host public key from the public key file

1. Enter system view.

   `system-view`

2. Import a client's public key from the public key file.

   `public-key peer` *`keyname`* **`import sshkey`** *`filename`*

Configuring an SSH user

About this task

Configure an SSH user and a local user depending on the authentication method.

- If the authentication method is **publickey**, you must create an SSH user and a local user on the SSH server. The two users must have the same username, so that the SSH user can be assigned the correct working directory and user role.
- If the authentication method is **password**, you must perform one of the following tasks:
  - For local authentication, configure a local user on the SSH server.
  - For remote authentication, configure an SSH user on a remote authentication server, for example, a RADIUS server.

  You do not need to create an SSH user by using the **`ssh user`** command. However, if you want to display all SSH users, including the password-only SSH users, for centralized management, you can use this command to create them. If such an SSH user has been created, make sure you have specified the correct service type and authentication method.
- If the authentication method is **password-publickey** or **any**, you must create an SSH user on the SSH server and perform one of the following tasks:
  - For local authentication, configure a local user on the SSH server.
  - For remote authentication, configure an SSH user on a remote authentication server, for example, a RADIUS server.

  In either case, the local user or the SSH user configured on the remote authentication server must have the same username as the SSH user.

Restrictions and guidelines

If you change the authentication parameters for a logged-in SSH user, the change takes effect on the user at the next login.

For an SFTP or SCP user, the working directory depends on the authentication method.

- If the authentication method is **password**, the working directory is authorized by AAA.

- If the authentication method is **publickey** or **password-publickey**, the working folder is specified by the **`authorization-attribute`** command in the associated local user view.

For an SSH user, the user role also depends on the authentication method.

- If the authentication method is **password**, the user role is authorized by AAA.
- If the authentication method is **publickey** or **password-publickey**, the user role is specified by the **`authorization-attribute`** command in the associated local user view.

For all authentication methods except password authentication, you must specify a client's host public key or digital certificate.

- For a client that sends the user's public key information directly to the server, specify the client's host public key on the server. The specified public key must already exist. For more information about public keys, see "Configuring a client's host public key."
- For a client that sends the user's public key information to the server through a digital certificate, specify the PKI domain on the server. This PKI domain verifies the client's digital certificate. For successful verification, the specified PKI domain must have the correct CA certificate. To specify the PKI domain, use the **`ssh user`** or **`ssh server pki-domain`** command. For more information about configuring a PKI domain, see "Configuring PKI."

For information about configuring local users and remote authentication, see "Configuring AAA."

Procedure

1. Enter system view.

   `system-view`

2. Create an SSH user, and specify the service type and authentication method.

   `ssh user` *`username`* **`service-type`** { **`all`** | **`netconf`** | **`scp`** | **`sftp`** | **`stelnet`** } **`authentication-type`** { **`password`** | { **`any`** | **`password-publickey`** | **`publickey`** } [**`assign`** { **`pki-domain`** *`domain-name`* | **`publickey`** *`keyname`* }] }

   An SSH server supports up to 1024 SSH users.

Configuring the SSH management parameters

Enabling the SSH server to support SSH1 clients

1. Enter system view.

   `system-view`

2. Enable the SSH server to support SSH1 clients.

   `ssh server compatible-ssh1x enable`

   By default, the SSH server does not support SSH1 clients.

Setting the minimum interval for updating the RSA server key pair

1. Enter system view.

   `system-view`

2. Set the minimum interval for updating the RSA server key pair.

   `ssh server rekey-interval` *`interval`*

   By default, the device does not update the RSA server key pair.

   This configuration takes effect only on SSH1 clients.

Setting the SSH user authentication timeout timer

1. Enter system view.

   `system-view`

2. Set the SSH user authentication timeout timer.

ssh server authentication-timeout *time-out-value*

The default setting is 60 seconds.

Perform this task to prevent malicious occupation of TCP connections. If a user does not finish the authentication when the timeout timer expires, the connection cannot be established.

Setting the maximum number of SSH authentication attempts

1. Enter system view.

   system-view

2. Set the maximum number of SSH authentication attempts.

   ssh server authentication-retries *retries*

   The default setting is 3.

   Perform this task to prevent malicious hacking of usernames and passwords. If the authentication method is **any**, the total number of publickey authentication attempts and password authentication attempts cannot exceed the upper limit.

Specifying an SSH login control ACL

1. Enter system view.

   system-view

2. Specify an SSH login control ACL.

   IPv4:

   ssh server acl { *advanced-acl-number* | *basic-acl-number* | **mac** *mac-acl-number* }

   IPv6:

   ssh server ipv6 acl { **ipv6** { *advanced-acl-number* | *basic-acl-number* } | **mac** *mac-acl-number* }

   This feature uses an ACL to filter SSH clients that initiate SSH connections to the server. By default, no ACLs are specified and all SSH users can initiate SSH connections to the server.

Enabling logging for SSH login attempts that are denied by the SSH login control ACL

1. Enter system view.

   system-view

2. Enable logging for SSH login attempts that are denied by the SSH login control ACL.

   ssh server acl-deny-log enable

   By default, logging is disabled for login attempts that are denied by the SSH login control ACL.

   This command enables SSH to generate log messages for SSH login attempts that are denied by the SSH login control ACL and send the messages to the information center.

Setting the DSCP value in the packets that the SSH server sends to SSH clients

1. Enter system view.

   system-view

2. Set the DSCP value in the packets that the SSH server sends to the SSH clients.

   IPv4:

   ssh server dscp *dscp-value*

   IPv6:

   ssh server ipv6 dscp *dscp-value*

   By default, the DSCP value of SSH packets is 48.

   The DSCP value of a packet defines the priority of the packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Setting the SFTP connection idle timeout timer

1. Enter system view.

   `system-view`

2. Set the SFTP connection idle timeout timer.

   `sftp server idle-timeout` *`time-out-value`*

   By default, the SFTP connection idle timeout is 10 minutes.

   When the SFTP connection idle timeout timer expires, the system automatically tears the connection down and releases the connection resources.

Setting the maximum number of online SSH users

1. Enter system view.

   `system-view`

2. Set the maximum number of online SSH users.

   `aaa session-limit ssh` *`max-sessions`*

   The default setting is 32.

   When the number of online SSH users reaches the upper limit, the system denies new SSH connection requests. Changing the upper limit does not affect online SSH users.

   For more information about this command, see AAA commands in *Security Command Reference*.

Specifying a PKI domain for the SSH server

About this task

The PKI domain specified for the SSH server has the following functions:

- The SSH server uses the PKI domain to send its certificate to the client in the key exchange stage.
- The SSH server uses the PKI domain to authenticate the client's certificate if no PKI domain is specified for the client authentication by using the **`ssh user`** command.

Procedure

1. Enter system view.

   `system-view`

2. Specify a PKI domain for the SSH server.

   `ssh server pki-domain` *`domain-name`*

   By default, no PKI domain is specified for the SSH server.

Configuring the device as an Stelnet client

Stelnet client tasks at a glance

To configure an Stelnet client, perform the following tasks:

1. Generating local key pairs

   Only required for authentication method **publickey**, **password-publickey**, or **any**.

2. (Optional.) Specifying the source IP address for outgoing SSH packets
3. Establishing a connection to an Stelnet server
4. (Optional.) Establishing a connection to an Stelnet server based on Suite B

Generating local key pairs

About this task

You must generate local key pairs on Stelnet clients when the Stelnet server uses the **publickey**, **password-publickey**, or **any** authentication method.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs. For more information about creating local key pairs, see public key management commands in *Security Command Reference*.

The key modulus length must be less than 2048 bits when you generate a DSA key pair.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

Procedure

1. Enter system view.

   `system-view`

2. Generate local key pairs.

   `public-key local create` { **`dsa`** | **`ecdsa`** { **`secp256r1`** | **`secp384r1`** } | **`rsa`** }

Specifying the source IP address for outgoing SSH packets

About this task

After you specify the source IP address for outgoing SSH packets on an Stelnet client, the client uses the specified IP address to communicate with the Stelnet server.

Restrictions and guidelines

As a best practice, specify a loopback interface as the source interface or specify the IP address of a loopback or dialer interface as the source address of outgoing SSH packets for the following purposes:

- Ensuring the communication between the Stelnet client and the Stelnet server.
- Improving the manageability of Stelnet clients in authentication service.

Procedure

1. Enter system view.

   `system-view`

2. Specify the source address for outgoing SSH packets.

   IPv4:

   `ssh client source` { **`interface`** *`interface-type interface-number`* | **`ip`** *`ip-address`* }

   By default, an IPv4 Stelnet client uses the primary IPv4 address of the output interface in the matching route as the source address of the outgoing SSH packets.

   IPv6:

   `ssh client ipv6 source` { **`interface`** *`interface-type interface-number`* | **`ipv6`** *`ipv6-address`* }

   By default, an IPv6 Stelnet client automatically selects a source IPv6 address for outgoing SSH packets in compliance with RFC 3484.

Establishing a connection to an Stelnet server

About this task

Perform this task to enable the Stelnet client feature on the device and establish a connection to the Stelnet server. You can specify the public key algorithm and the preferred encryption, HMAC, and key exchange algorithms to be used during the connection.

To access the server, a client must use the server's host public key to authenticate the server. As a best practice, configure the server's host public key on the device in an insecure network. If the server's host public key is not configured on the client, the client will notify you to confirm whether to continue with the access.

- If you choose to continue, the client accesses the server and downloads the server's host public key. The downloaded public key will be used to authenticate the server in subsequent accesses.
- If you choose to not continue, the connection cannot be established.

Restrictions and guidelines for establishing a connection to an Stelnet server

An Stelnet client cannot establish connections to both IPv4 and IPv6 Stelnet servers.

Establishing a connection to an IPv4 Stelnet server

Execute the following command in user view to establish a connection with an IPv4 Stelnet server:

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

Establishing a connection to an IPv6 Stelnet server

Execute the following command in user view to establish a connection to an IPv6 Stelnet server:

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Establishing a connection to an Stelnet server based on Suite B

Execute the following command in user view to establish a connection to an Stelnet server based on Suite B:

IPv4:

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

IPv6:

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Configuring the device as an SFTP client

SFTP client tasks at a glance

To configure an SFTP client, perform the following tasks:

1. Generating local key pairs

   Only required for authentication method **publickey**, **password-publickey**, or **any**.
2. (Optional.) Specifying the source IP address for outgoing SFTP packets
3. Establishing a connection to an SFTP server
4. (Optional.) Establishing a connection to an SFTP server based on Suite B
5. (Optional.) Working with SFTP directories
6. (Optional.) Working with SFTP files
7. (Optional.) Displaying help information
8. (Optional.) Terminating the connection with the SFTP server

Generating local key pairs

About this task

You must generate local key pairs on SFTP clients when the SFTP server uses the **publickey**, **password-publickey**, or **any** authentication method.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs. For more information about creating local key pairs, see public key management commands in *Security Command Reference*.

The key modulus length must be less than 2048 bits when you generate a DSA key pair.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

Procedure

1. Enter system view.

   system-view

2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the source IP address for outgoing SFTP packets

About this task

After you specify the source IP address for outgoing SFTP packets on an SFTP client, the client uses the specified IP address to communicate with the SFTP server.

Restrictions and guidelines

As a best practice, specify a loopback interface as the source interface or specify the IP address of a loopback or dialer interface as the source address of outgoing SFTP packets for the following purposes:

- Ensuring the communication between the SFTP client and the SFTP server.
- Improving the manageability of SFTP clients in authentication service.

Procedure

1. Enter system view.

   system-view

2. Specify the source address for outgoing SFTP packets.

   IPv4:

   sftp client source { **ip** *ip-address* | **interface** *interface-type interface-number* }

   By default, an SFTP client uses the primary IPv4 address of the output interface in the matching route as the source address of the outgoing SFTP packets.

   IPv6:

   sftp client ipv6 source { **ipv6** *ipv6-address* | **interface** *interface-type interface-number* }

   By default, an IPv6 SFTP client automatically selects a source IPv6 address for the outgoing SFTP packets in compliance with RFC 3484.

Establishing a connection to an SFTP server

About this task

Perform this task to enable the SFTP client feature on the device and establish a connection to the SFTP server. You can specify the public key algorithm and the preferred encryption, HMAC, and key exchange algorithms to be used during the connection.

To access the server, a client must use the server's host public key to authenticate the server. As a best practice, configure the server's host public key on the device in an insecure network. If the server's host public key is not configured on the client, the client will notify you to confirm whether to continue with the access.

- If you choose to continue, the client accesses the server and downloads the server's host public key. The downloaded public key will be used to authenticate the server in subsequent accesses.
- If you choose to not continue, the connection cannot be established.

Restrictions and guidelines for establishing a connection to an SFTP server

An SFTP client cannot establish connections to both IPv4 and IPv6 SFTP servers.

Establishing a connection to an IPv4 SFTP server

Execute the following command in user view to establish a connection to an IPv4 SFTP server:

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

Establishing a connection to an IPv6 SFTP server

Execute the following command in user view to establish a connection to an IPv6 SFTP server:

sftp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Establishing a connection to an SFTP server based on Suite B

Execute the following command in user view to establish a connection to an SFTP server based on Suite B:

IPv4:

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

IPv6:

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**]

[**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Working with SFTP directories

About this task

After you establish a connection to an SFTP server, you can operate directories of the SFTP server.

Changing the working directory on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Change the working directory on the SFTP server.

   cd [*remote-path*]
3. (Optional.) Return to the upper-level directory.

   cdup

Displaying the current working directory on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Display the current working directory on the SFTP server.

   pwd

Displaying files under a directory

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Display files under a directory.
   - **dir** [**-a** | **-l**] [*remote-path*]
   - **ls** [**-a** | **-l**] [*remote-path*]

   The **dir** command has the same function as the **ls** command.

Changing the name of a directory on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Change the name of a directory on the SFTP server.

   rename *oldname newname*

Creating a new directory on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Create a new directory on the SFTP server.

   mkdir *remote-path*

Deleting directories on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Delete one or more directories from the SFTP server.

   rmdir *remote-path*

Working with SFTP files

About this task

After you establish a connection to an SFTP server, you can operate files on the SFTP server.

Changing the name of a file on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Change the name of a file on the SFTP server.

   `rename` *`old-name new-name`*

Downloading a file from the SFTP server and save it locally

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Download a file from the SFTP server and save it locally.

   `get` *`remote-file`* [*`local-file`*]

Uploading a local file to the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Upload a local file to the SFTP server.

   `put` *`local-file`* [*`remote-file`*]

Display files under a directory

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Display files under a directory.
   - **`dir`** [**`-a`** | **`-l`**] [*`remote-path`*]
   - **`ls`** [**`-a`** | **`-l`**] [*`remote-path`*]

   The **`dir`** command has the same function as the **`ls`** command.

Deleting a file from the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Delete a file from the SFTP server.
   - **`delete`** *`remote-file`*
   - **`remove`** *`remote-file`*

   The **`delete`** command has the same function as the **`remove`** command.

Displaying help information

About this task

After you establish a connection to the SFTP server, you can display the help information of SFTP client commands, including the command syntax and parameter configuration.

Procedure

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."

2. Display SFTP client command help information.
   - **help**
   - **?**

   The **help** command has the same function as the **?** command.

Terminating the connection with the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Terminate the connection with the SFTP server and return to user view.
   - **bye**
   - **exit**
   - **quit**

   The three commands have the same function.

Configuring the device as an SCP client

SCP client tasks at a glance

To configure an SCP client, perform the following tasks:

1. Generating local key pairs

   Only required for the **publickey**, **password-publickey**, or **any** authentication method.
2. Establishing a connection to an SCP server
3. (Optional.) Establishing a connection to an SCP server based on Suite B

Generating local key pairs

About this task

You must generate local key pairs on SCP clients when the SCP server uses the **publickey**, **password-publickey**, or **any** authentication method.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs. For more information about creating local key pairs, see public key management commands in *Security Command Reference*.

The key modulus length must be less than 2048 bits when you generate a DSA key pair.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

Procedure

1. Enter system view.

   system-view
2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Establishing a connection to an SCP server

About this task

Perform this task to enable the SCP client feature on the device, establish a connection to the SCP server, and transfer files with the server. You can specify the public key algorithm and the preferred encryption, HMAC, and key exchange algorithms to be used during the connection.

To access the server, a client must use the server's host public key to authenticate the server. As a best practice, configure the server's host public key on the device in an insecure network. If the server's host public key is not configured on the client, the client will notify you to confirm whether to continue with the access.

- If you choose to continue, the client accesses the server and downloads the server's host public key. The downloaded public key will be used to authenticate the server in subsequent accesses.
- If you choose to not continue, the connection cannot be established.

Restrictions and guidelines for establishing a connection to an SCP server

An SCP client cannot establish connections to both IPv4 and IPv6 SCP servers.

Establishing a connection to an IPv4 SCP server

Execute the following command in user view to connect to an IPv4 SCP server, and transfer files with the server:

```
scp server [ port-number ] [ vpn-instance vpn-instance-name ] { get | put }
source-file-name [ destination-file-name ] [ identity-key { dsa |
ecdsa-sha2-nistp256 | ecdsa-sha2-nistp384 | rsa |
{ x509v3-ecdsa-sha2-nistp256 | x509v3-ecdsa-sha2-nistp384 } pki-domain
domain-name } | prefer-compress zlib | prefer-ctos-cipher { 3des-cbc |
aes128-cbc | aes128-ctr | aes128-gcm | aes192-ctr | aes256-cbc | aes256-ctr
| aes256-gcm | des-cbc } | prefer-ctos-hmac { md5 | md5-96 | sha1 | sha1-96 |
sha2-256 | sha2-512 } | prefer-kex { dh-group-exchange-sha1 |
dh-group1-sha1 | dh-group14-sha1 | ecdh-sha2-nistp256 |
ecdh-sha2-nistp384 } | prefer-stoc-cipher { 3des-cbc | aes128-cbc |
aes128-ctr | aes128-gcm | aes192-ctr | aes256-cbc | aes256-ctr | aes256-gcm
| des-cbc } | prefer-stoc-hmac { md5 | md5-96 | sha1 | sha1-96 | sha2-256 |
sha2-512 } ] * [ { public-key keyname | server-pki-domain domain-name } |
source { interface interface-type interface-number | ip ip-address } ] *
```

Establishing a connection to an IPv6 SCP server

Execute the following command in user view to connect to an IPv6 SCP server, and transfer files with the server.

```
scp ipv6 server [ port-number ] [ vpn-instance vpn-instance-name ] [ -i
interface-type interface-number ] { get | put } source-file-name
[ destination-file-name ] [ identity-key { dsa | ecdsa-sha2-nistp256 |
ecdsa-sha2-nistp384 | rsa | { x509v3-ecdsa-sha2-nistp256 |
x509v3-ecdsa-sha2-nistp384 } pki-domain domain-name } | prefer-compress
zlib | prefer-ctos-cipher { 3des-cbc | aes128-cbc | aes128-ctr | aes128-gcm
| aes192-ctr | aes256-cbc | aes256-ctr | aes256-gcm | des-cbc } |
prefer-ctos-hmac { md5 | md5-96 | sha1 | sha1-96 | sha2-256 | sha2-512 } |
prefer-kex { dh-group-exchange-sha1 | dh-group1-sha1 | dh-group14-sha1 |
ecdh-sha2-nistp256 | ecdh-sha2-nistp384 } | prefer-stoc-cipher { 3des-cbc
| aes128-cbc | aes128-ctr | aes128-gcm | aes192-ctr | aes256-cbc |
aes256-ctr | aes256-gcm | des-cbc } | prefer-stoc-hmac { md5 | md5-96 | sha1
| sha1-96 | sha2-256 | sha2-512 } ] * [ { public-key keyname |
server-pki-domain domain-name } | source { interface interface-type
interface-number | ipv6 ipv6-address } ] *
```

Establishing a connection to an SCP server based on Suite B

Execute the following command in user view to establish a connection to an SCP server based on Suite B:

IPv4:

scp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] { **get** | **put** } *source-file-name* [*destination-file-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

IPv6:

scp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] { **get** | **put** } *source-file-name* [*destination-file-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Specifying algorithms for SSH2

About algorithms for SSH2

The SSH2 client and server use the following types of algorithms for algorithm negotiation during the Stelnet, SFTP, or SCP session establishment:

- Key exchange algorithms.
- Public key algorithms.
- Encryption algorithms.
- MAC algorithms.

If you specify algorithms, SSH2 uses only the specified algorithms for algorithm negotiation. The client uses the specified algorithms to initiate the negotiation, and the server uses the matching algorithms to negotiate with the client. If multiple algorithms of the same type are specified, the algorithm specified earlier has a higher priority during negotiation.

Specifying key exchange algorithms for SSH2

1. Enter system view.

   system-view

2. Specify key exchange algorithms for SSH2.

   ssh2 algorithm key-exchange { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } *

   By default, SSH2 uses the **ecdh-sha2-nistp256**, **ecdh-sha2-nistp384**, **dh-group-exchange-sha1**, **dh-group14-sha1**, and **dh-group1-sha1** key exchange algorithms in descending order of priority for algorithm negotiation.

Specifying public key algorithms for SSH2

1. Enter system view.

```
system-view
```

2. Specify public key algorithms for SSH2.

:

```
ssh2 algorithm public-key { dsa | ecdsa-sha2-nistp256 |
ecdsa-sha2-nistp384 | rsa | x509v3-ecdsa-sha2-nistp256 |
x509v3-ecdsa-sha2-nistp384 } *
```

By default, SSH2 uses the **x509v3-ecdsa-sha2-nistp256**, **x509v3-ecdsa-sha2-nistp384**, **ecdsa-sha2-nistp256**, **ecdsa-sha2-nistp384**, **rsa**, and **dsa** public key algorithms in descending order of priority for algorithm negotiation.

Specifying encryption algorithms for SSH2

1. Enter system view.

```
system-view
```

2. Specify encryption algorithms for SSH2.

```
ssh2 algorithm cipher { 3des-cbc | aes128-cbc | aes128-ctr | aes128-gcm
| aes192-ctr | aes256-cbc | aes256-ctr | aes256-gcm | des-cbc } *
```

By default, SSH2 uses the **aes128-ctr**, **aes192-ctr**, **aes256-ctr**, **aes128-gcm**, **aes256-gcm**, **aes128-cbc**, **3des-cbc**, **aes256-cbc**, and **des-cbc** encryption algorithms in descending order of priority for algorithm negotiation.

Specifying MAC algorithms for SSH2

1. Enter system view.

```
system-view
```

2. Specify MAC algorithms for SSH2.

```
ssh2 algorithm mac { md5 | md5-96 | sha1 | sha1-96 | sha2-256 | sha2-512 }
*
```

By default, SSH2 uses the **sha2-256**, **sha2-512, sha1**, **md5**, **sha1-96**, and **md5-96** MAC algorithms in descending order of priority for algorithm negotiation.

Display and maintenance commands for SSH

Execute **display** commands in any view.

Task	Command
Display the public keys of the local key pairs.	**display public-key local** { **dsa** | **ecdsa** | **rsa** | **sm2** } **public** [**name** *publickey-name*]
Display information about peer public keys.	**display public-key peer** [**brief** | **name** *publickey-name*]
Display the source IP address configuration of the SFTP client.	**display sftp client source**
Display the source IP address configuration of the Stelnet client.	**display ssh client source**
Display SSH server status or sessions.	**display ssh server** { **session** [**slot** *slot-number*] | **status** }

Task	Command
Display SSH user information on the SSH server.	**display ssh user-information** [*username*]
Display algorithms used by SSH2 in the algorithm negotiation stage.	**display ssh2 algorithm**

For more information about the **display public-key local** and **display public-key peer** commands, see public key management commands in *Security Command Reference*.

Stelnet configuration examples

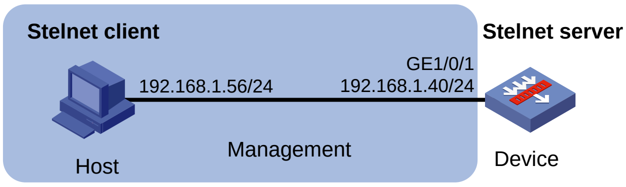
Example: Configuring the device as an Stelnet server (password authentication)

Network configuration

As shown in Figure 1:

- The device acts as the Stelnet server and uses password authentication to authenticate the Stelnet client. The username and password of the client are saved on the device.
- The host acts as the Stelnet client, using Stelnet client software (SSH2). After the user on the host logs in to the device through Stelnet, the user can configure and manage the device as a network administrator.

Figure 1 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.40 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [Device] security-zone name management
   [Device-security-zone-Management] import interface gigabitethernet 1/0/1
   [Device-security-zone-Management] quit
   ```

3. Configure the Stelnet server:

   # Generate RSA key pairs.

   ```
   <Device> system-view
   [Device] public-key local create rsa
   The range of public key modulus is (512 ~ 2048).
   ```

```
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..................
Create the key pair successfully.
```

# Generate a DSA key pair.

```
[Device] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..................
Create the key pair successfully.
```

# Generate an ECDSA key pair.

```
[Device] public-key local create ecdsa secp256r1

```

# Authorize local user **client001** to use the **SSH** service.

```
[Device-luser-manage-client001] service-type ssh
```

# Assign the **network-admin** user role to local user **client001**.

```
[Device-luser-manage-client001] authorization-attribute user-role network-admin
[Device-luser-manage-client001] quit
```

# Create an SSH user named **client001**. Specify the service type as **stelnet** and the authentication method as **password** for the user.

```
[Device] ssh user client001 service-type stelnet authentication-type password
```

4. Establish a connection to the Stelnet server:

There are different types of Stelnet client software, such as PuTTY and OpenSSH. This example uses an Stelnet client that runs PuTTY version 0.58.

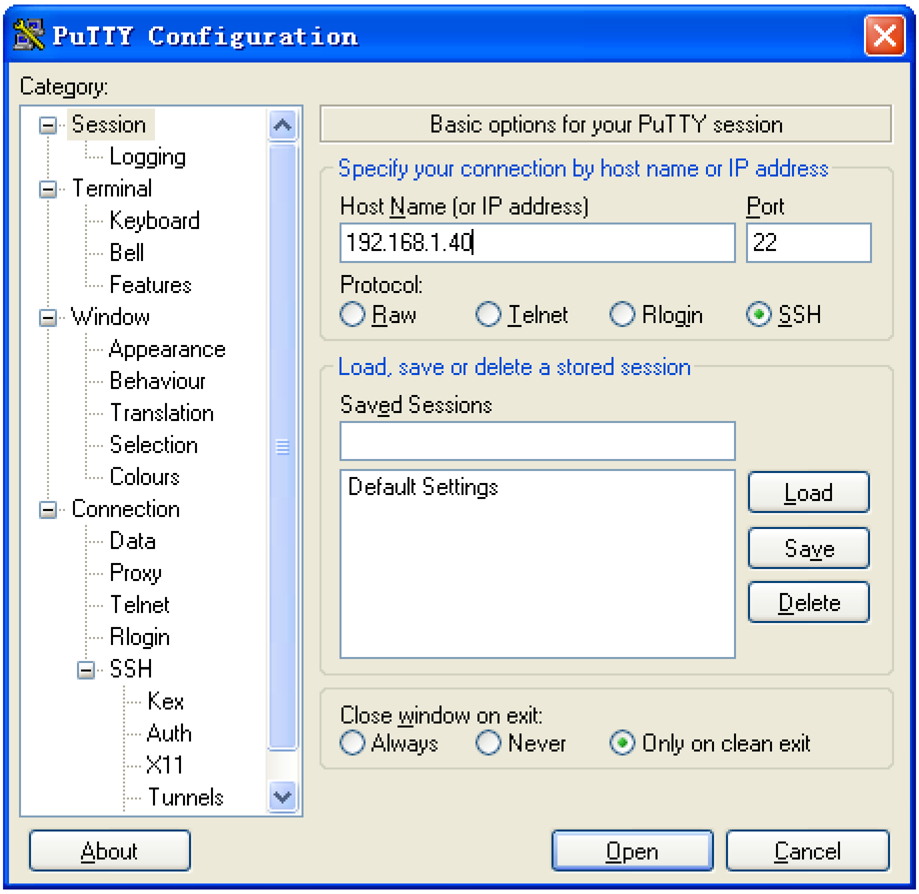
To establish a connection to the Stelnet server:

a. Launch PuTTY.exe to enter the interface shown in Figure 2.

b. In the **Host Name (or IP address)** field, enter the IP address **192.168.1.40** of the Stelnet server.

c. Click **Open**.

Figure 2 Specifying the host name (or IP address)



Host Name (or IP address): 192.168.1.40

Port: 22

Protocol: ○ Raw ○ Telnet ○ Rlogin ● SSH

Close window on exit: ○ Always ○ Never ● Only on clean exit

d. Enter username **client001** and password **aabbcc** to log in to the Stelnet server.

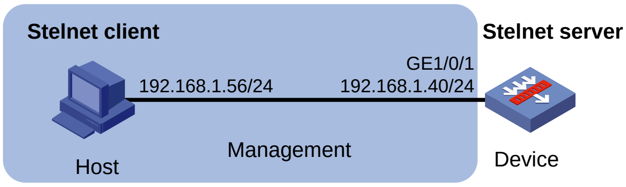
Example: Configuring the device as an Stelnet server (publickey authentication)

Network configuration

As shown in Figure 3:

- The device acts as the Stelnet server, and it uses publickey authentication and the RSA public key algorithm.
- The host acts as the Stelnet client, using Stelnet client software (SSH2). After the user on the host logs in to the device through Stelnet, the user can configure and manage the device as a network administrator.

Figure 3 Network diagram



Procedure

In the server configuration, the client's host public key is required. Use the client software to generate RSA key pairs on the client before configuring the Stelnet server.

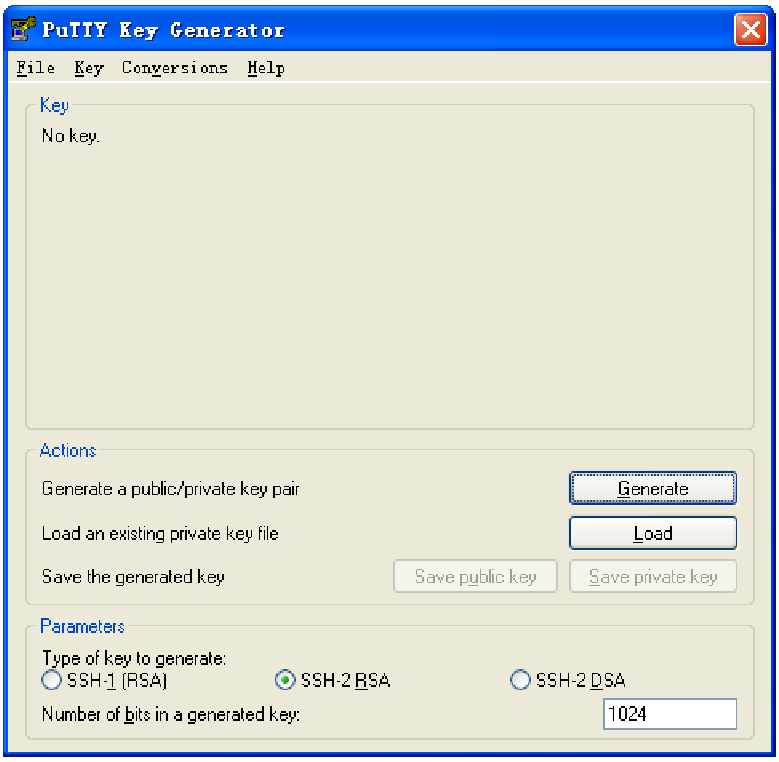
There are different types of Stelnet client software, such as PuTTY and OpenSSH. This example uses an Stelnet client that runs PuTTY version 0.58.

The configuration procedure is as follows:

1. Assign an IP address to GigabitEthernet 1/0/1 on the device. (Details not shown.)
2. Generate RSA key pairs on the Stelnet client:

   a. Run PuTTYGen.exe, select **SSH-2 RSA**, and click **Generate**.

   Figure 4 Generating a key pair on the client



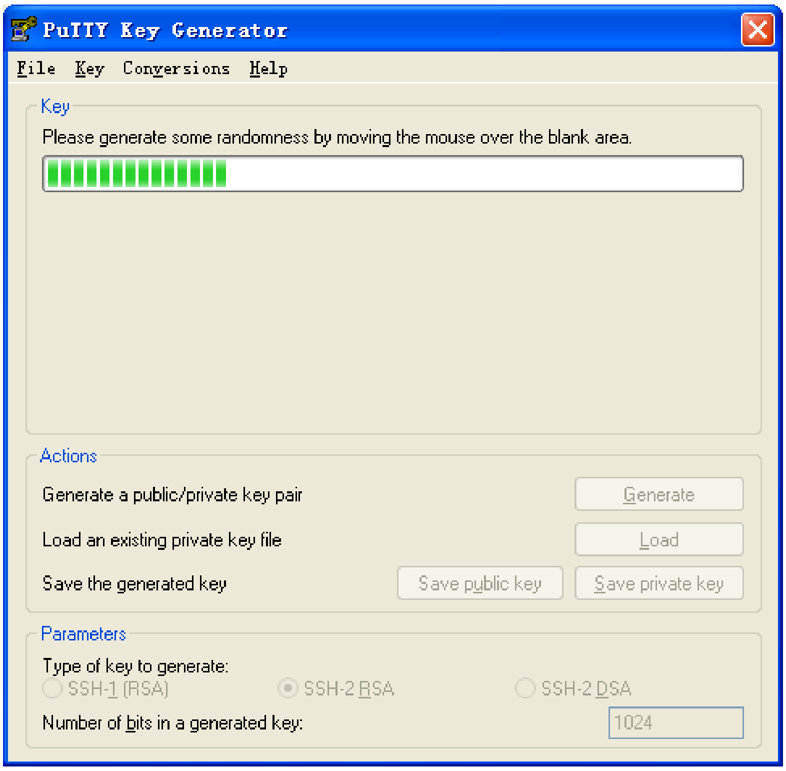
Key
No key.

Type of key to generate:
○ SSH-1 (RSA) ● SSH-2 RSA ○ SSH-2 DSA

Number of bits in a generated key: 1024

   b. Continue moving the mouse during the key generating process, but do not place the mouse over the green progress bar shown in Figure 5. Otherwise, the progress bar stops moving and the key pair generating process stops.

Figure 5 Generating process



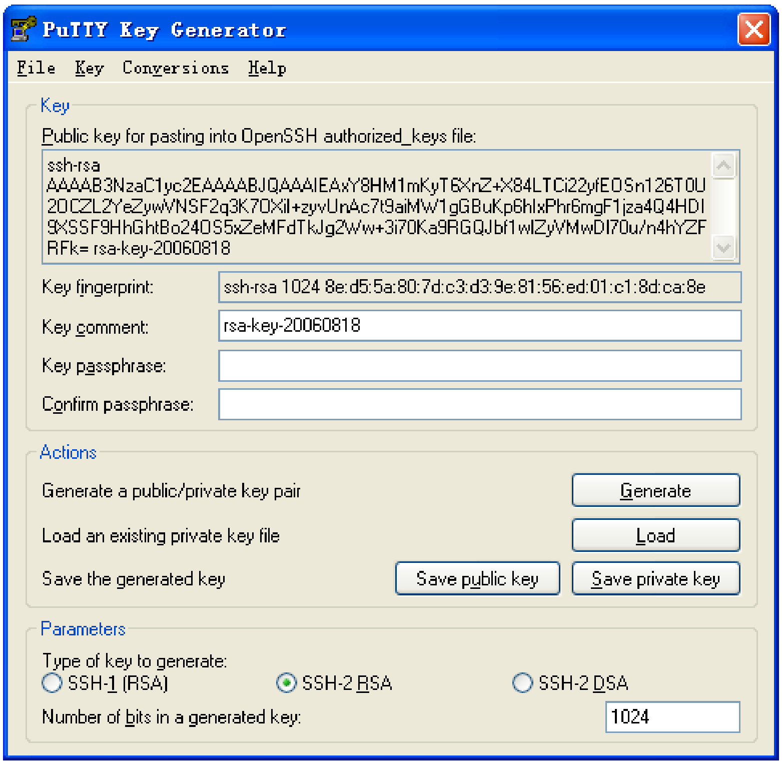
Please generate some randomness by moving the mouse over the blank area.

Type of key to generate:
○ SSH-1 (RSA) ● SSH-2 RSA ○ SSH-2 DSA

Number of bits in a generated key: 1024

c. After the key pair is generated, click **Save public key** to save the public key. A file saving window appears.

Figure 6 Saving a key pair on the client



Public key for pasting into OpenSSH authorized_keys file:

```
ssh-rsa
AAAAB3NzaC1yc2EAAAABJQAAAIEAxY8HM1mKyT6XnZ+X84LTCi22yfEOSn126T0U

RFk= rsa-key-20060818
```

Key fingerprint: ssh-rsa 1024 8e:d5:5a:80:7d:c3:d3:9e:81:56:ed:01:c1:8d:ca:8e

Key comment: rsa-key-20060818

Key passphrase:

Confirm passphrase:

Type of key to generate:
○ SSH-1 (RSA) ● SSH-2 RSA ○ SSH-2 DSA

Number of bits in a generated key: 1024

a. Enter a file name (**key.pub** in this example), and click **Save**.

b. On the page as shown in Figure 6, click **Save private key** to save the private key.

   A confirmation dialog box appears.

c. Click **Yes**.

   A file saving window appears.

d. Enter a file name (**private.ppk** in this example), and click **Save**.

e. Transmit the public key file to the server through FTP or TFTP. (Details not shown.)

3. Assign IP addresses to interfaces:

# Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.1.40 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

4. Add interfaces to security zones.

```
[Device] security-zone name management
[Device-security-zone-Management] import interface gigabitethernet 1/0/1
[Device-security-zone-Management] quit
```

5. Configure the Stelnet server:

# Generate RSA key pairs.

```
<Device> system-view
[Device] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..................
Create the key pair successfully.
```

# Generate a DSA key pair.

```
[Device] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..................
Create the key pair successfully.
```

# Generate an ECDSA key pair.

```
[Device] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

# Enable the Stelnet server.

```
[Device] ssh server enable
```

# Set the authentication mode to AAA for user lines.

```
[Device] line vty 0 63
[Device-line-vty0-63] authentication-mode scheme
```

```
[Device-line-vty0-63] quit
```

# Import the peer public key from the public key file **key.pub** and name it **clientkey**.

```
[Device] public-key peer clientkey import sshkey key.pub
```

# Create an SSH user named **client002**. Specify the authentication method as **publickey** for the user, and assign the public key **clientkey** to the user.

```
[Device] ssh user client002 service-type stelnet authentication-type publickey assign publickey clientkey
```

# Create a local device management user named **client002**.

```
[Device] local-user client002 class manage
```

# Authorize local user **client002** to use the **SSH** service.

```
[Device-luser-manage-client002] service-type ssh
```

# Assign the **network-admin** user role to local user **client002**.

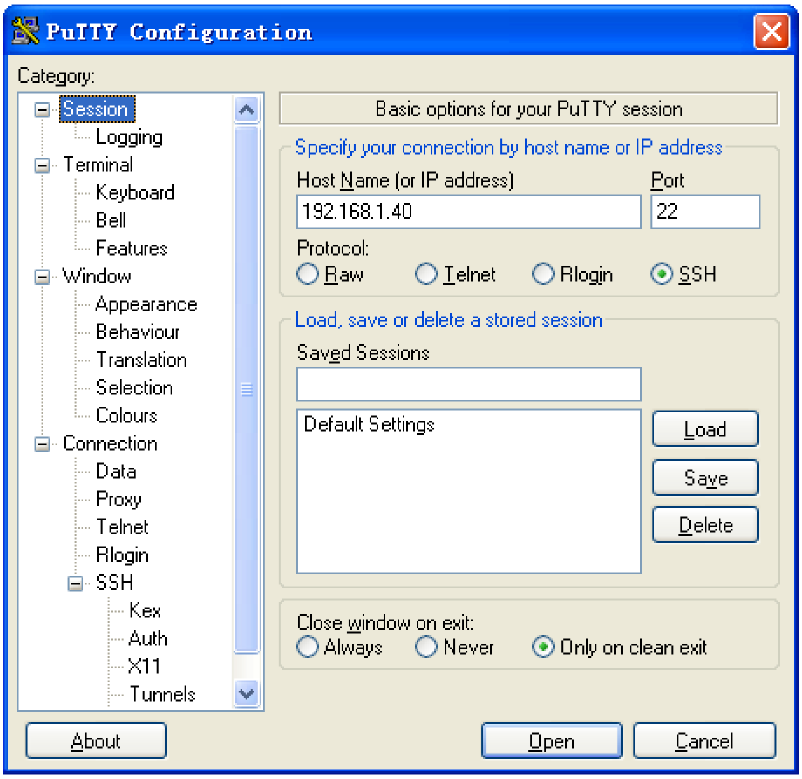
```
[Device-luser-manage-client002] authorization-attribute user-role network-admin
[Device-luser-manage-client002] quit
```

6. Specify the private key file and establish a connection to the Stelnet server:

a. Launch PuTTY.exe on the Stelnet client to enter the interface shown in Figure 7.

b. In the **Host Name (or IP address)** field, enter IP address **192.168.1.40** of the Stelnet server.

Figure 7 Specifying the host name (or IP address)



Host Name (or IP address): 192.168.1.40

Port: 22

Protocol: ○ Raw ○ Telnet ○ Rlogin ● SSH

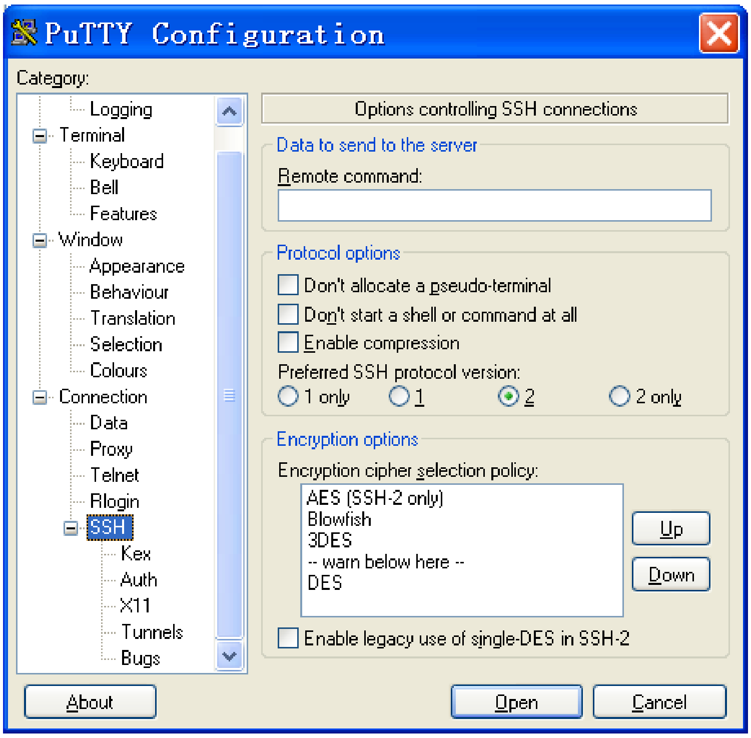
Close window on exit: ○ Always ○ Never ● Only on clean exit

c. From the navigation tree, select **Connection** > **SSH**.

The window shown in Figure 8 appears.

d. Set **Preferred SSH protocol version** to **2**.

Figure 8 Setting the preferred SSH version



Options controlling SSH connections

Data to send to the server

Remote command:

Protocol options

□ Don't allocate a pseudo-terminal

□ Don't start a shell or command at all

□ Enable compression

Preferred SSH protocol version:

○ 1 only ○ 1 ● 2 ○ 2 only

Encryption options

Encryption cipher selection policy:

AES (SSH-2 only)
Blowfish
3DES
-- warn below here --
DES

□ Enable legacy use of single-DES in SSH-2

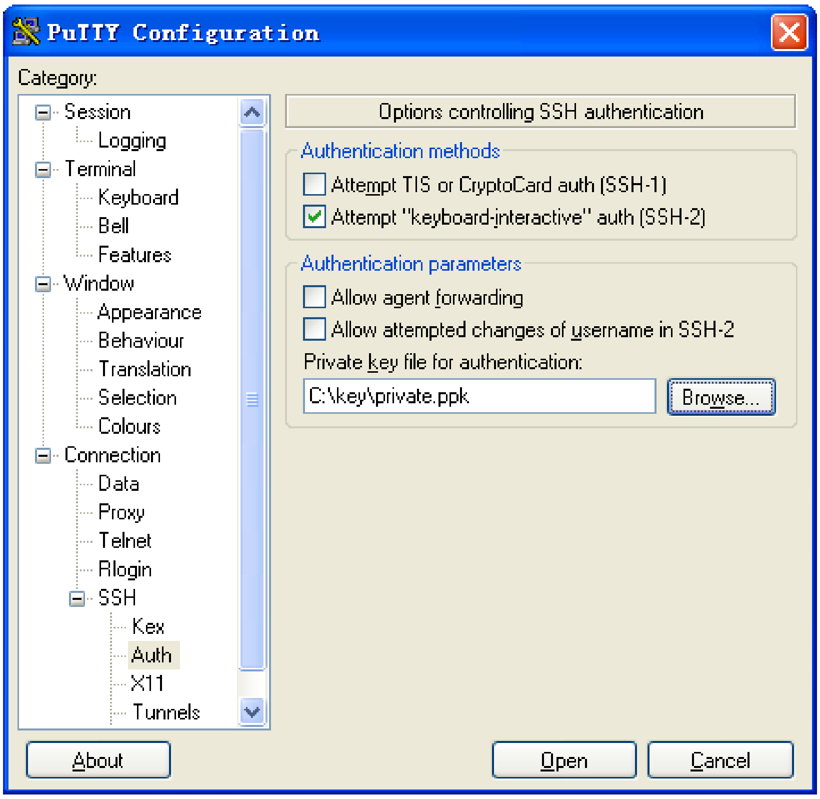
e. From the navigation tree, select **Connection** > **SSH** > **Auth**.

The window shown in Figure 9 appears.

f. Click **Browse…** and select the private key file (**private.ppk** in this example).

g. Click **Open**.

Figure 9 Specifying the private key file



Options controlling SSH authentication

Authentication methods

☐ Attempt TIS or CryptoCard auth (SSH-1)

☑ Attempt "keyboard-interactive" auth (SSH-2)

Authentication parameters

☐ Allow agent forwarding

☐ Allow attempted changes of username in SSH-2

Private key file for authentication:

C:\key\private.ppk Browse...

a. Enter username **client002** to log in to the Stelnet server.

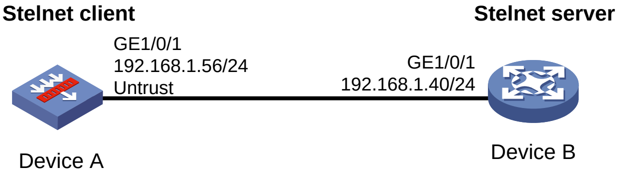
Example: Configuring the device as an Stelnet client (password authentication)

Network configuration

As shown in Figure 10:

- Device B acts as the Stelnet server and uses password authentication to authenticate the Stelnet client. The username and password of the client are saved on Device B.
- Device A acts as the Stelnet client. After the user on Device A logs in to Device B through Stelnet, the user can configure and manage Device B as a network administrator.

Figure 10 Network diagram



Procedure

1. Configure Device A:

   a. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceA> system-view
```

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 192.168.1.56 255.255.255.0
[DeviceA-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

b. Add interfaces to security zones.

```
[DeviceA] security-zone name Untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] quit
```

c. In the IPv4 security policy, configure a rule to permit traffic between the **Untrust** and **Local** security zones, so Device A can send packets to Device B.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name sshlocalin
[DeviceA-security-policy-ip-1-sshlocalin] source-zone untrust
[DeviceA-security-policy-ip-1-sshlocalin] destination-zone local
[DeviceA-security-policy-ip-1-sshlocalin] source-ip-host 192.168.1.40
[DeviceA-security-policy-ip-1-sshlocalin] destination-ip-host 192.168.1.56
[DeviceA-security-policy-ip-1-sshlocalin] action pass
[DeviceA-security-policy-ip-1-sshlocalin] quit
[DeviceA-security-policy-ip-1] quit
```

2. Configure Device B:

# Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 192.168.1.40 255.255.255.0
[DeviceB-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

3. Configure the Stelnet server:

# Generate RSA key pairs.

```
[DeviceB] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..................
Create the key pair successfully.
```

# Generate a DSA key pair.

```
[DeviceB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..................
Create the key pair successfully.
```

# Generate an ECDSA key pair.

```
[DeviceB] public-key local create ecdsa secp256r1
Generating Keys...
```

```
.
Create the key pair successfully.
```

# Enable the Stelnet server.

```
[DeviceB] ssh server enable
```

# Set the authentication mode to AAA for user lines.

```
[DeviceB] line vty 0 63
[DeviceB-line-vty0-63] authentication-mode scheme
[DeviceB-line-vty0-63] quit
```

# Create a local device management user named **client001**.

```
[DeviceB] local-user client001 class manage
```

# Set the password to **aabbcc** in plain text for local user **client001**.

```
[DeviceB-luser-manage-client001] password simple aabbcc
```

# Authorize local user **client001** to use the **SSH** service.

```
[DeviceB-luser-manage-client001] service-type ssh
```

# Assign the **network-admin** user role to local user **client001**.

```
[DeviceB-luser-manage-client001] authorization-attribute user-role network-admin
[DeviceB-luser-manage-client001] quit
```

# Create an SSH user named **client001**. Specify the service type as **stelnet** and the authentication method as **password** for the user.

```
[DeviceB] ssh user client001 service-type stelnet authentication-type password
```

# Specify public key algorithm **dsa** for SSH2.

```
[DeviceB] ssh2 algorithm public-key dsa
```

4. Establish a connection to the Stelnet server:

- If the client does not have the server's host public key and is connected to the server for the first time:

  # Establish an SSH connection to server 192.168.1.40. Enter username **client001**, and then enter **y** to continue accessing the server without authenticating the server, and enter **y** to download and save the server's host public key.

  ```
  <DeviceA> ssh2 192.168.1.40
  Username: client001
  Press CTRL+C to abort.
  Connecting to 192.168.1.40 port 22.
  The server is not authenticated. Continue? [Y/N]:y
  Do you want to save the server public key? [Y/N]:y
  client001@192.168.1.40's password:
  Enter a character ~ and a dot to abort.

******************************************************************************

<DeviceB>
```

After you enter the correct username and password, you can access Device B successfully.

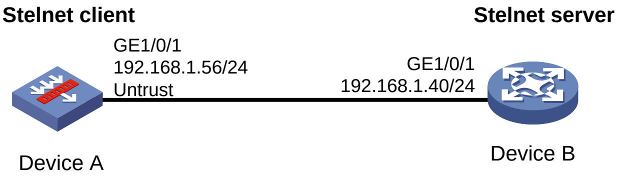
Example: Configuring the device as an Stelnet client (publickey authentication)

Network configuration

As shown in Figure 11:

- Device B acts as the Stelnet server, and it uses publickey authentication and the DSA public key algorithm.
- Device A acts as the Stelnet client. After the user on Device A logs in to Device B through Stelnet, the user can configure and manage Device B as a network administrator.

Figure 11 Network diagram



Procedure

In the server configuration, the client's host public key is required. Generate a DSA key pair on the client before configuring the Stelnet server.

1. Configure Device A:

   a. Assign IP addresses to interfaces:

      # Assign an IP address to interface GigabitEthernet 1/0/1.

      ```
      <DeviceA> system-view
      [DeviceA] interface gigabitethernet 1/0/1
      [DeviceA-GigabitEthernet1/0/1] ip address 192.168.1.56 255.255.255.0
      [DeviceA-GigabitEthernet1/0/1] quit
      ```

      # Assign IP addresses to other interfaces in the same way. (Details not shown.)

   b. Add interfaces to security zones.

      ```
      [DeviceA] security-zone name Untrust
      [DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
      [DeviceA-security-zone-Untrust] quit
      ```

   c. In the IPv4 security policy, configure a rule to permit traffic between the **Untrust** and **Local** security zones, so Device A can send packets to Device B.

      ```
      [DeviceA] security-policy ip
      [DeviceA-security-policy-ip] rule name sshlocalin
      [DeviceA-security-policy-ip-1-sshlocalin] source-zone untrust
      [DeviceA-security-policy-ip-1-sshlocalin] destination-zone local
      [DeviceA-security-policy-ip-1-sshlocalin] source-ip-host 192.168.1.40
      [DeviceA-security-policy-ip-1-sshlocalin] destination-ip-host 192.168.1.56
      [DeviceA-security-policy-ip-1-sshlocalin] action pass
      [DeviceA-security-policy-ip-1-sshlocalin] quit
      [DeviceA-security-policy-ip] quit
      ```

2. Configure Device B:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceB> system-view
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] ip address 192.168.1.40 255.255.255.0
   [DeviceB-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

3. Configure the Stelnet client:

   # Generate a DSA key pair.

   ```
   <DeviceA> system-view
   [DeviceA] public-key local create dsa
   The range of public key modulus is (512 ~ 2048).
   If the key modulus is greater than 512, it will take a few minutes.
   Press CTRL+C to abort.
   Input the modulus length [default = 1024]:
   Generating Keys...
   ..................
   Create the key pair successfully.
   ```

   # Export the DSA host public key to a public key file named **key.pub**.

   ```
   [DeviceA] public-key local export dsa ssh2 key.pub
   [DeviceA] quit
   ```

# Transmit the public key file **key.pub** to the server through FTP or TFTP. (Details not shown.)

4. Configure the Stelnet server:

# Generate RSA key pairs.

```
<DeviceB> system-view
[DeviceB] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.................
Create the key pair successfully.
```

# Generate a DSA key pair.

```
[DeviceB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.................
Create the key pair successfully.
```

# Generate an ECDSA key pair.

```
[DeviceB] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

# Enable the Stelnet server.

```
[DeviceB] ssh server enable
```

# Set the authentication mode to AAA for user lines.

```
[DeviceB] line vty 0 63
[DeviceB-line-vty0-63] authentication-mode scheme
[DeviceB-line-vty0-63] quit
```

# Import the peer public key from the public key file **key.pub**, and name it **clientkey**.

```
[DeviceB] public-key peer clientkey import sshkey key.pub
```

# Create an SSH user named **client002**. Specify the authentication method as **publickey** for the user, and assign the public key **clientkey** to the user.

```
[DeviceB] ssh user client002 service-type stelnet authentication-type publickey
assign publickey clientkey
```

# Create a local device management user named **client002**.

```
[DeviceB] local-user client002 class manage
```

# Authorize local user **client002** to use the **SSH** service.

```
[DeviceB-luser-manage-client002] service-type ssh
```

# Assign the **network-admin** user role to local user **client002**.

```
[DeviceB-luser-manage-client002] authorization-attribute user-role network-admin
[DeviceB-luser-manage-client002] quit
```

5. Establish an SSH connection to the Stelnet server.

```
<DeviceA> ssh2 192.168.1.40 identity-key dsa
Username: client002
```

```
Press CTRL+C to abort.
Connecting to 192.168.1.40 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
Enter a character ~ and a dot to abort.

******************************************************************************
* Copyright (c) 2004-2017 NSFOCUS. All rights reserved.                      *
* Without the owner's prior written consent,                                 *
* no decompiling or reverse-engineering shall be allowed.                    *
******************************************************************************

<DeviceB>
```

After you enter username **client002** and then enter **y** to continue accessing the server, you can log in to the server successfully.

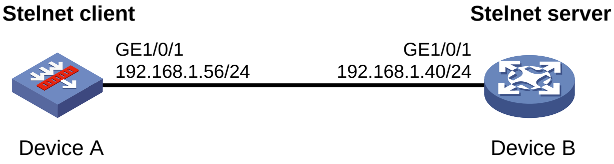
Example: Configuring Stelnet based on 128-bit Suite B algorithms

Network configuration

As shown in Figure 12:

- Device B acts as the Stelnet Suite B server (SSH2), and it uses publickey authentication to authenticate the client.
- Device A acts as an Stelnet Suite B client (SSH2). After the user on Device A logs in to Device B through the Stelnet Suite B client software, the user can configure and manage Device B as an administrator.

Figure 12 Network diagram



Procedure

1. Generate the client's certificate and the server's certificate. (Details not shown.)

   You must first configure the certificates of the server and the client because they are required for identity authentication between the two parties.

   In this example, the server's certificate file is **ssh-server-ecdsa256.p12** and the client's certificate file is **ssh-client-ecdsa256.p12**.

2. Configure Device A:

   a. Assign IP addresses to interfaces:

      # Assign an IP address to interface GigabitEthernet 1/0/1.

      ```
      <DeviceA> system-view
      [DeviceA] interface gigabitethernet 1/0/1
      [DeviceA-GigabitEthernet1/0/1] ip address 192.168.1.56 255.255.255.0
      [DeviceA-GigabitEthernet1/0/1] quit
      ```

      # Assign IP addresses to other interfaces in the same way. (Details not shown.)

b. Add interfaces to security zones.

```
[DeviceA] security-zone name Untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] quit
```

c. In the IPv4 security policy, configure a rule to permit traffic between the **Untrust** and **Local** security zones, so Device A can send packets to Device B.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name sshlocalin
[DeviceA-security-policy-ip-1-sshlocalin] source-zone untrust
[DeviceA-security-policy-ip-1-sshlocalin] destination-zone local
[DeviceA-security-policy-ip-1-sshlocalin] source-ip-host 192.168.1.40
[DeviceA-security-policy-ip-1-sshlocalin] destination-ip-host 192.168.1.56
[DeviceA-security-policy-ip-1-sshlocalin] action pass
[DeviceA-security-policy-ip-1-sshlocalin] quit
[DeviceA-security-policy-ip] quit
```

3. Configure Device B:

# Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 192.168.1.40 255.255.255.0
[DeviceB-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

4. Configure the Stelnet client:

You can modify the pkix version of the client software OpenSSH to support Suite B. This example uses an NSFOCUS device as an Stelnet client.

# Upload the server's certificate file **ssh-server-ecdsa256.p12** and the client's certificate file **ssh-client-ecdsa256.p12** to the Stelnet client through FTP or TFTP. (Details not shown.)

# Create a PKI domain named **server256** for verifying the server's certificate and enter its view.

```
<DeviceA> system-view
[DeviceA] pki domain server256
```

# Disable CRL checking.

```
[DeviceA-pki-domain-server256] undo crl check enable
[DeviceA-pki-domain-server256] quit
```

# Import local certificate file **ssh-server-ecdsa256.p12** to PKI domain **server256**.

```
[DeviceA] pki import domain server256 p12 local filename ssh-server-ecdsa256.p12
The system is going to save the key pair. You must specify a key pair name, which is
a case-insensitive string of 1 to 64 characters. Valid characters include a to z, A
to Z, 0 to 9, and hyphens (-).
Please enter the key pair name[default name: server256]:
```

# Display information about local certificates in PKI domain **server256**.

```
[DeviceA] display pki certificate domain server256 local
Certificate:
    Data:

<DeviceB>
```

SFTP configuration examples

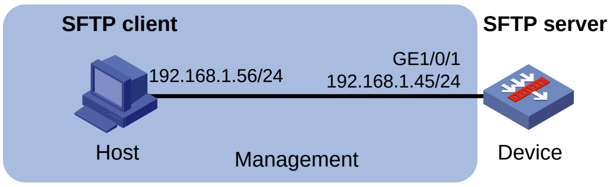
Example: Configuring the device as an SFTP server (password authentication)

Network configuration

As shown in Figure 13:

- The device acts as the SFTP server and uses password authentication to authenticate the SFTP client. The username and password of the client are saved on the device.
- The host acts as the SFTP client. After the user on the client logs in to the device through SFTP, the user can perform file management and transfer operations on the device as a network administrator.

Figure 13 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.45 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [Device] security-zone name management
   [Device-security-zone-Management] import interface gigabitethernet 1/0/1
   [Device-security-zone-Management] quit
   ```

3. Configure the SFTP server:

   # Generate RSA key pairs.

   ```
   <Device> system-view
   [Device] public-key local create rsa
   The range of public key modulus is (512 ~ 2048).
   If the key modulus is greater than 512, it will take a few minutes.
   Press CTRL+C to abort.
   Input the modulus length [default = 1024]:
   Generating Keys...
   ..................
   Create the key pair successfully.
   ```

   # Generate a DSA key pair.

   ```
   [Device] public-key local create dsa
   The range of public key modulus is (512 ~ 2048).
   If the key modulus is greater than 512, it will take a few minutes.
   Press CTRL+C to abort.
   Input the modulus length [default = 1024]:
   Generating Keys...
   ..................
   Create the key pair successfully.
   ```

   # Generate an ECDSA key pair.

   ```
   [Device] public-key local create ecdsa secp256r1
   Generating Keys...
   .
   Create the key pair successfully.
   ```

   # Enable the SFTP server.

   ```
   [Device] sftp server enable
   ```

   # Create a local device management user named **client002**.

```
[Device] local-user client002 class manage
```

# Set the password to **aabbcc** in plain text for local user **client002**.

```
[Device-luser-manage-client002] password simple aabbcc
```

# Authorize local user **client002** to use the **SSH** service.

```
[Device-luser-manage-client002] service-type ssh
```

# Assign the **network-admin** user role and working directory **flash:/** to local user **client002**.

```
[Device-luser-manage-client002] authorization-attribute user-role network-admin
work-directory flash:/
[Device-luser-manage-client002] quit
```

# Create an SSH user named **client002**. Specify the authentication method as **password** and service type as **sftp** for the user.

```
[Device] ssh user client002 service-type sftp authentication-type password
```

4. Establish a connection to the SFTP server:

   This example uses an SFTP client that runs PSFTP of PuTTY version 0.58. PSFTP supports only password authentication.

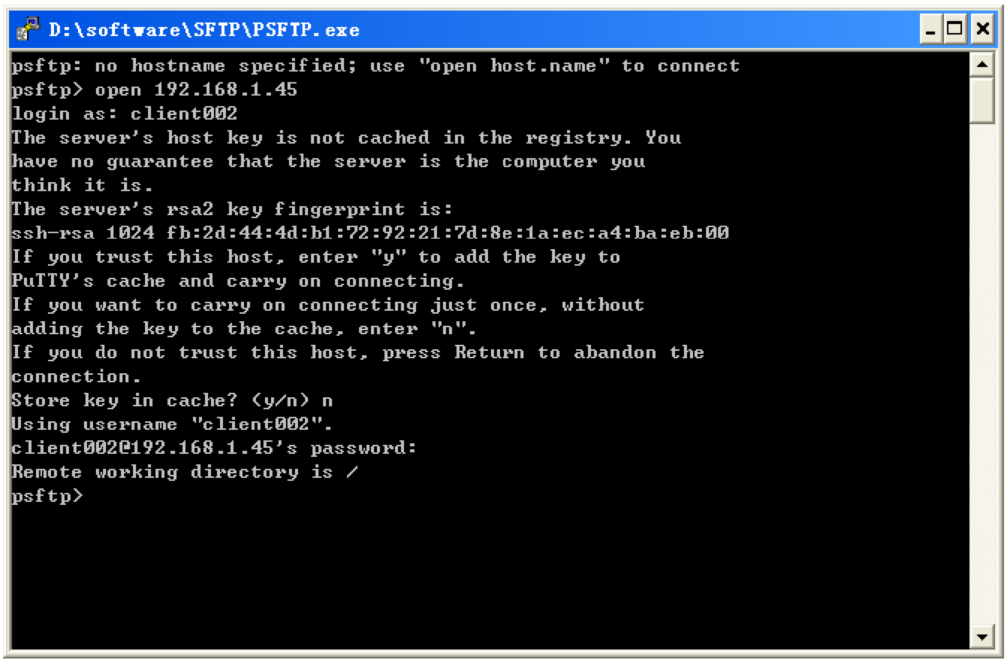
   To establish a connection to the SFTP server:

   a. Run the **psftp.exe** to launch the client interface shown in Figure 14, and enter the following command:

   ```
   open 192.168.1.45
   ```

   b. Enter username **client002** and password **aabbcc** to log in to the SFTP server.

Figure 14 SFTP client interface



```
psftp: no hostname specified; use "open host.name" to connect
psftp> open 192.168.1.45
login as: client002
The server's host key is not cached in the registry. You
have no guarantee that the server is the computer you
think it is.
The server's rsa2 key fingerprint is:
ssh-rsa 1024 fb:2d:44:4d:b1:72:92:21:7d:8e:1a:ec:a4:ba:eb:00
If you trust this host, enter "y" to add the key to
PuTTY's cache and carry on connecting.
If you want to carry on connecting just once, without
adding the key to the cache, enter "n".
If you do not trust this host, press Return to abandon the
connection.
Store key in cache? (y/n) n
Using username "client002".
client002@192.168.1.45's password:
Remote working directory is /
psftp>
```

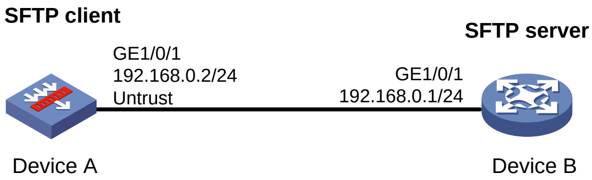
Example: Configuring the device as an SFTP client (publickey authentication)

Network configuration

As shown in Figure 15:

- Device B acts as the SFTP server, and it uses publickey authentication and the RSA public key algorithm.
- Device A acts as the SFTP client. After the user on Device A logs in to Device B through SFTP, the user can perform file management and transfer operations on Device B as a network administrator.

Figure 15 Network diagram



Procedure

In the server configuration, the client's host public key is required. Generate RSA key pairs on the client before configuring the SFTP server.

1. Configure Device A:
   a. Assign IP addresses to interfaces:
   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 192.168.0.2 255.255.255.0
[DeviceA-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

   b. Add interfaces to security zones.

```
[DeviceA] security-zone name Untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] quit
```

   c. In the IPv4 security policy, configure a rule to permit traffic between the **Untrust** and **Local** security zones, so Device A can send pacekts to Device B.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip] rule name sshlocalin
[DeviceA-security-policy-ip-1-sshlocalin] source-zone untrust
[DeviceA-security-policy-ip-1-sshlocalin] destination-zone local
[DeviceA-security-policy-ip-1-sshlocalin] source-ip-host 192.168.0.1
[DeviceA-security-policy-ip-1-sshlocalin] destination-ip-host 192.168.0.2
[DeviceA-security-policy-ip-1-sshlocalin] action pass
[DeviceA-security-policy-ip-1-sshlocalin] quit
[DeviceA-security-policy-ip] quit
```

2. Configure Device B:
   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 192.168.0.1 255.255.255.0
[DeviceB-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

3. Configure the SFTP client:
   # Generate RSA key pairs.

```
[DeviceA] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.................
Create the key pair successfully.
```

# Export the host public key to a public key file named **pubkey**.

```
[DeviceA] public-key local export rsa ssh2 pubkey
[DeviceA] quit
```

# Transmit the public key file **pubkey** to the server through FTP or TFTP. (Details not shown.)

4. Configure the SFTP server:

# Generate RSA key pairs.

```
<DeviceB> system-view
[DeviceB] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.................
Create the key pair successfully.
```

# Generate a DSA key pair.

```
[DeviceB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.................
Create the key pair successfully.
```

# Generate an ECDSA key pair.

```
[DeviceB] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

# Enable the SFTP server.

```
[DeviceB] sftp server enable
```

# Import the peer public key from the public key file **pubkey**, and name it **devicekey**.

```
[DeviceB] public-key peer devicekey import sshkey pubkey
```

# Create an SSH user named **client001**. Specify the service type as **sftp** and the authentication method as **publickey** for the user. Assign the public key **devicekey** to the user.

```
[DeviceB] ssh user client001 service-type sftp authentication-type publickey assign
publickey devicekey
```

# Create a local device management user named **client001**.

```
[DeviceB] local-user client001 class manage
```

# Authorize local user **client001** to use the **SSH** service.

```
[DeviceB-luser-manage-client001] service-type ssh
```

# Assign the **network-admin** user role and working directory **flash:/** to local user **client001**.

```
[DeviceB-luser-manage-client001] authorization-attribute user-role network-admin
work-directory flash:/
[DeviceB-luser-manage-client001] quit
```

5. Establish a connection between the SFTP client and the SFTP server:

# Establish a connection to the SFTP server and enter SFTP client view.

```
<DeviceA> sftp 192.168.0.1 identity-key rsa
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.0.1 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n

<DeviceA>
```

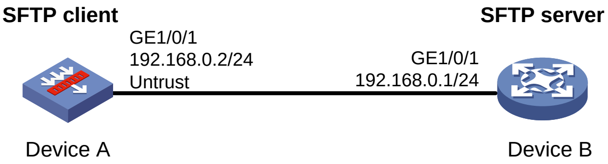
Example: Configuring SFTP based on 192-bit Suite B algorithms

Network configuration

As shown in Figure 16:

- Device B acts as the SFTP Suite B server (SSH2), and it uses publickey authentication to authenticate the SFTP client.
- Device A acts as an SFTP Suite B client (SSH2). After the user on Device A logs in to Device B based on the SFTP Suite B client software, the user can manage and transfer files on Device B as an administrator.

Figure 16 Network diagram



Procedure

1. Generate the client's certificate and the server's certificate. (Details not shown.)

   You must first configure the certificates of the server and the client because they are required for identity authentication between the two parties.

   In this example, the server's certificate file is **ssh-server-ecdsa384.p12** and the client's certificate file is **ssh-client-ecdsa384.p12**.

2. Configure Device A:

   a. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceA> system-view
   ```

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 192.168.0.2 255.255.255.0
[DeviceA-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

b. Add interfaces to security zones.

```
[DeviceA] security-zone name Untrust
[DeviceA-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceA-security-zone-Untrust] quit
```

c. In the IPv4 security policy, configure a rule to permit traffic between the **Untrust** and **Local** security zones, so Device A can send pacekts to Device B.

```
[DeviceA] security-policy ip
[DeviceA-security-policy-ip-1-sshlocalin] source-zone untrust
[DeviceA-security-policy-ip-1-sshlocalin] destination-zone local
[DeviceA-security-policy-ip-1-sshlocalin] source-ip-host 192.168.0.1
[DeviceA-security-policy-ip-1-sshlocalin] destination-ip-host 192.168.0.2
[DeviceA-security-policy-ip-1-sshlocalin] action pass
[DeviceA-security-policy-ip-1-sshlocalin] quit
[DeviceA-security-policy-ip-1-sshlocalin] quit
[DeviceA-security-policy-ip] quit
```

3. Configure Device B:

# Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 192.168.0.1 255.255.255.0
[DeviceB-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

4. Configure the SFTP client:

You can modify the pkix version of the client software OpenSSH to support Suite B. This example uses an NSFOCUS device as an SFTP client.

# Upload the server's certificate file **ssh-server-ecdsa384.p12** and the client's certificate file **ssh-client-ecdsa384.p12** to the SFTP client through FTP or TFTP. (Details not shown.)

# Create a PKI domain named **server384** for verifying the server's certificate and enter its view.

```
<DeviceA> system-view
[DeviceA] pki domain server384
```

# Disable CRL checking.

```
[DeviceA-pki-domain-server384] undo crl check enable
[DeviceA-pki-domain-server384] quit
```

# Import local certificate file **ssh-server-ecdsa384.p12** to PKI domain **server384**.

```
[DeviceA] pki import domain server384 p12 local filename ssh-server-ecdsa384.p12
The system is going to save the key pair. You must specify a key pair name, which is
a case-insensitive string of 1 to 64 characters. Valid characters include a to z, A
to Z, 0 to 9, and hyphens (-).
Please enter the key pair name[default name: server384]:
```

# Display information about local certificates in PKI domain **server384**.

```
[DeviceA] display pki certificate domain server384 local

5. Configure the SFTP server:

# Upload the server's certificate file **ssh-server-ecdsa384.p12** and the client's certificate file **ssh-client-ecdsa384.p12** to the SFTP server through FTP or TFTP. (Details not shown.)

# Create a PKI domain named **client384** for verifying the client's certificate and import the file of the client's certificate to this domain. (Details not shown.)

# Create a PKI domain named **server384** for the server's certificate and import the file of the server's certificate to this domain. (Details not shown.)

# Specify Suite B algorithms for algorithm negotiation.

```
[DeviceB] ssh2 algorithm key-exchange ecdh-sha2-nistp384
[DeviceB] ssh2 algorithm cipher aes256-gcm
[DeviceB] ssh2 algorithm public-key x509v3-ecdsa-sha2-nistp384
```

# Specify **server384** as the PKI domain of the server's certificate.

```
[DeviceB] ssh server pki-domain server384
```

# Enable the SFTP server.

```
[DeviceB] sftp server enable
```

# Set the authentication mode to AAA for user lines.

```
[DeviceB] line vty 0 63
[DeviceB-line-vty0-63] authentication-mode scheme
[DeviceB-line-vty0-63] quit
```

# Create a local device management user named **client001**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

```
[DeviceB] local-user client001 class manage
[DeviceB-luser-manage-client001] service-type ssh
[DeviceB-luser-manage-client001] authorization-attribute user-role network-admin
[DeviceB-luser-manage-client001] quit
```

# Create an SSH user named **client001**. Specify the **publickey** authentication method for the user and specify **client384** as the PKI domain for verifying the client's certificate.

```
[DeviceB] ssh user client001 service-type sftp authentication-type publickey assign
pki-domain client384
```

6. Establish an SFTP connection to the SFTP server based on the 192-bit Suite B algorithms:

# Establish an SFTP connection to the server at 192.168.0.1.

```
<DeviceA> sftp 192.168.0.1 suite-b 192-bit pki-domain client384 server-pki-domain
server384
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.0.1 port 22.
sftp>
```

SCP configuration examples

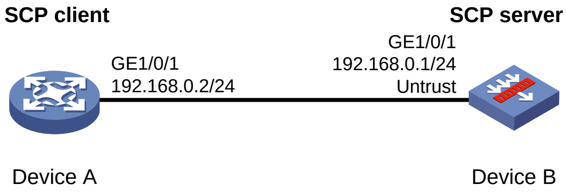
Example: Configuring SCP with password authentication

Network configuration

As shown in Figure 17:

- Device B acts as the SCP server and uses password authentication to authenticate the SCP client. The client's username and password are saved on Device B.
- Device A acts as the SCP client. After the user on Device A logs in to Device B through SCP, the user can transfer files between devices as a network administrator.

Figure 17 Network diagram



Procedure

1. Configure Device A:

   a. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip address 192.168.0.2 255.255.255.0
[DeviceA-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure Device B:

   a. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 192.168.0.1 255.255.255.0
[DeviceB-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

   b. Add interfaces to security zones.

```
[DeviceB] security-zone name Untrust
[DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
[DeviceB-security-zone-Untrust] quit
```

   c. In the IPv4 security policy, configure a rule to permit traffic between the **Untrust** and **Local** security zones, so Device A can send pacekts to Device B.

```
[DeviceB] security-policy ip
[DeviceB-security-policy-ip] rule name sshlocalin
[DeviceB-security-policy-ip-1-sshlocalin] source-zone untrust
[DeviceB-security-policy-ip-1-sshlocalin] destination-zone local
[DeviceB-security-policy-ip-1-sshlocalin] source-ip-host 192.168.0.2
[DeviceB-security-policy-ip-1-sshlocalin] destination-ip-host 192.168.0.1
[DeviceB-security-policy-ip-1-sshlocalin] action pass
[DeviceB-security-policy-ip-1-sshlocalin] quit
[DeviceA-security-policy-ip] quit
```

3. Configure the SCP server:

   # Generate RSA key pairs.

```
<DeviceB> system-view
[DeviceB] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
```

```
Input the modulus length [default = 1024]:
Generating Keys...
..
Create the key pair successfully.
```

# Generate a DSA key pair.

```
[DeviceB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..................
Create the key pair successfully.
```

# Generate an ECDSA key pair.

```
[DeviceB] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

# Configure the SCP server.

```
[DeviceB] scp server enable
[DeviceB] local-user client001 class manage
[DeviceB-luser-manage-client001] password simple aabbcc
[DeviceB-luser-manage-client001] service-type ssh
[DeviceB-luser-manage-client001] authorization-attribute user-role network-admin
[DeviceB-luser-manage-client001] quit
```

# Create an SSH user named **client001**. Specify the service type as **scp** and the authentication method as **password** for the user.

```
[DeviceB] ssh user client001 service-type scp authentication-type password
```

4. Connect to the SCP server, download file **remote.bin** from the server, and save it as a local file named **local.bin**.

```
<DeviceA> scp 192.168.0.1 get remote.bin local.bin
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.0.1 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
client001@192.168.0.1’s password:
remote.bin                                       100% 2875     2.8KB/s   00:00
```

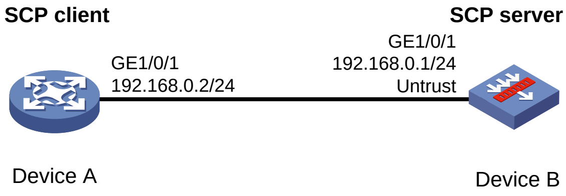
Example: Configuring SCP based on Suite B algorithms

Network configuration

As shown in Figure 18:

- Device B acts as the SCP Suite B server (SSH2), and it uses publickey authentication to authenticate the SCP client.
- Device A acts as an SCP Suite B client (SSH2). After the user on Device A logs in to Device B through SCP based on the SCP Suite B client software, the user can transfer files between devices as a network administrator.

Figure 18 Network diagram



Procedure

1. Generate the client's certificates and the server's certificates. (Details not shown.)

   You must first configure the certificates of the server and the client because they are required for identity authentication between the two parties.

   In this example, the server's certificate files are **ssh-server-ecdsa256.p12** and **ssh-server-ecdsa384.p12**. The client's certificate files are **ssh-client-ecdsa256.p12** and **ssh-client-ecdsa384.p12**.

2. Configure Device A:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 192.168.0.2 255.255.255.0
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

3. Configure Device B:

   a. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <DeviceB> system-view
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] ip address 192.168.0.1 255.255.255.0
   [DeviceB-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

   b. Add interfaces to security zones.

   ```
   [DeviceB] security-zone name Untrust
   [DeviceB-security-zone-Untrust] import interface gigabitethernet 1/0/1
   [DeviceB-security-zone-Untrust] quit
   ```

   c. In the IPv4 security policy, configure a rule to permit traffic between the **Untrust** and **Local** security zones, so Device A can send pacekts to Device B.

   ```
   [DeviceB] security-policy ip
   [DeviceB-security-policy-ip-1-sshlocalin] source-zone untrust
   [DeviceB-security-policy-ip-1-sshlocalin] destination-zone local
   [DeviceB-security-policy-ip-1-sshlocalin] source-ip-host 192.168.0.2
   [DeviceB-security-policy-ip-1-sshlocalin] destination-ip-host 192.168.0.1
   [DeviceB-security-policy-ip-1-sshlocalin] action pass
   [DeviceB-security-policy-ip-1-sshlocalin] quit
   [DeviceA-security-policy-ip] quit
   ```

4. Configure the SCP client:

   You can modify the pkix version of the client software OpenSSH to support Suite B. This example uses an NSFOCUS device as an SCP client.

# Upload the server's certificate files (**ssh-server-ecdsa256.p12** and **ssh-server-ecdsa384.p12**) and the client's certificate files (**ssh-client-ecdsa256.p12** and **ssh-client-ecdsa384.p12**) to the SCP client through FTP or TFTP. (Details not shown.)

# Create a PKI domain named **server256** for verifying the server's certificate **ecdsa256** and enter its view.

```
[DeviceA] pki domain server256
```

# Disable CRL checking.

```
[DeviceA-pki-domain-server256] undo crl check enable
[DeviceA-pki-domain-server256] quit
```

# Import local certificate file **ssh-server-ecdsa256.p12** to PKI domain **server256**.

```
[DeviceA] pki import domain server256 p12 local filename ssh-server-ecdsa256.p12
The system is going to save the key pair. You must specify a key pair name, which is
a case-insensitive string of 1 to 64 characters. Valid characters include a to z, A
to Z, 0 to 9, and hyphens (-).
Please enter the key pair name[default name: server256]:
```

# Display information about local certificates in PKI domain **server256**.

```
[DeviceA] display pki certificate domain server256 local

[DeviceA] quit
```

5. Configure the SCP server:

   # Upload the server's certificate files (**ssh-server-ecdsa256.p12** and **ssh-server-ecdsa384.p12**) and the client's certificate files (**ssh-client-ecdsa256.p12** and **ssh-client-ecdsa384.p12**) to the SCP server through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **client256** for verifying the client's certificate **ecdsa256** and import the file of this certificate to this domain. Create a PKI domain named **server256** for the server's certificate **ecdsa256** and import the file of this certificate to this domain. (Details not shown.)

   # Create a PKI domain named **client384** for verifying the client's certificate **ecdsa384** and import the file of this certificate to this domain. Create a PKI domain named **server384** for the server's certificate **ecdsa384** and import the file of this certificate to this domain. (Details not shown.)

   # Specify Suite B algorithms for algorithm negotiation.

   ```
   <DeviceB> system-view
   [DeviceB] ssh2 algorithm key-exchange ecdh-sha2-nistp256 ecdh-sha2-nistp384
   [DeviceB] ssh2 algorithm cipher aes128-gcm aes256-gcm
   [DeviceB] ssh2 algorithm public-key x509v3-ecdsa-sha2-nistp256
   x509v3-ecdsa-sha2-nistp384
   ```

   # Enable the SCP server.

   ```
   [DeviceB] scp server enable
   ```

   # Set the authentication mode to AAA for user lines.

   ```
   [DeviceB] line vty 0 63
   [DeviceB-line-vty0-63] authentication-mode scheme
   [DeviceB-line-vty0-63] quit
   ```

   # Create a local device management user named **client001**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

   ```
   [DeviceB] local-user client001 class manage
   [DeviceB-luser-manage-client001] service-type ssh
   ```

```
[DeviceB-luser-manage-client001] authorization-attribute user-role network-admin
[DeviceB-luser-manage-client001] quit
```

# Create a local device management user named **client002**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

```
[DeviceB] local-user client002 class manage
[DeviceB-luser-manage-client002] service-type ssh
[DeviceB-luser-manage-client002] authorization-attribute user-role network-admin
[DeviceB-luser-manage-client002] quit
```

6. Establish an SCP connection to the SCP server:

- Based on the 128-bit Suite B algorithms:

  # Specify **server256** as the PKI domain of the server's certificate.

  ```
  [DeviceB] ssh server pki-domain server256
  ```

  # Create an SSH user **client001**. Specify the authentication method **publickey** for the user and specify **client256** as the PKI domain for verifying the client's certificate.

  ```
  [DeviceB] ssh user client001 service-type scp authentication-type publickey assign
  pki-domain client256
  ```

  # Establish an SCP connection to the SCP server at 192.168.0.1 based on the 128-bit Suite B algorithms.

  ```
  <DeviceA> scp 192.168.0.1 get src.cfg suite-b 128-bit pki-domain client256
  server-pki-domain server256
  Username: client001
  Press CTRL+C to abort.
  Connecting to 192.168.0.1 port 22.
  src.cfg                                       100% 4814     4.7KB/s   00:00
  <DeviceA>
  ```

- Based on the 192-bit Suite B algorithms:

  # Specify **server384** as the PKI domain of the server's certificate.

  ```
  [DeviceB] ssh server pki-domain server384
  ```

  # Create an SSH user **client002**. Specify the **publickey** authentication method for the user and specify **client384** as the PKI domain for verifying the client's certificate.

  ```
  [DeviceB] ssh user client002 service-type scp authentication-type publickey assign
  pki-domain client384
  ```

  # Establish an SCP connection to the SCP server at 192.168.0.1 based on the 192-bit Suite B algorithms.

  ```
  <DeviceA> scp 192.168.0.1 get src.cfg suite-b 192-bit pki-domain client384
  server-pki-domain server384
  Username: client002
  Press CTRL+C to abort.
  Connecting to 192.168.0.1 port 22.
  src.cfg                                       100% 4814     4.7KB/s   00:00
  <DeviceA>
  ```

NETCONF over SSH configuration examples

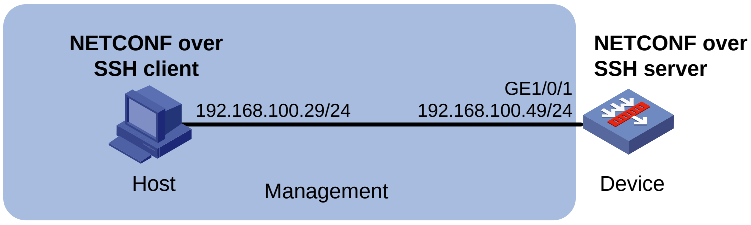
Example: Configuring NETCONF over SSH with password authentication

Network configuration

As shown in Figure 19:

- The device acts as the NETCONF-over-SSH server and uses password authentication to authenticate the client. The client's username and password are saved on the device.
- The host acts as the NETCONF-over-SSH client, using SSH2 client software. After the user on the host logs in to the device through NETCONF over SSH, the user can perform NETCONF operations on the device as a network administrator.

Figure 19 Network diagram



Procedure

# Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.100.49 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

# Add interfaces to security zones.

```
[Device] security-zone name management
[Device-security-zone-Management] import interface gigabitethernet 1/0/1
[Device-security-zone-Management] quit
```

# Generate RSA key pairs.

```
[Device] public-key local create rsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..................
Create the key pair successfully.
```

# Generate a DSA key pair.

```
[Device] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
```

```
Input the modulus length [default = 1024]:
Generating Keys...
.................
Create the key pair successfully.
```

# Generate an ECDSA key pair.

```
[Device] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

# Enable NETCONF over SSH.

```
[Device] netconf ssh server enable
```

# Set the authentication mode to AAA for user lines.

```
[Device] line vty 0 63
[Device-line-vty0-63] authentication-mode scheme
[Device-line-vty0-63] quit
```

# Create a local device management user named **client001**.

```
[Device] local-user client001 class manage
```

# Set the password to **aabbcc** in plain text for local user **client001**.

```
[Device-luser-manage-client001] password simple aabbcc
```

# Authorize local user **client001** to use the **SSH** service.

```
[Device-luser-manage-client001] service-type ssh
```

# Assign the **network-admin** user role to local user **client001**.

```
[Device-luser-manage-client001] authorization-attribute user-role network-admin
[Device-luser-manage-client001] quit
```

# Create an SSH user named **client001**. Specify the service type as **NETCONF** and the authentication method as **password** for the user.

```
[Device] ssh user client001 service-type netconf authentication-type password
```

Verifying the configuration

1. Launch a client that supports NETCONF over SSH.

   This example uses NetConf Browser 2015 (version 3.1).

2. Select **File** > **Connect…** from the menu.

   The **Connect** page opens, as shown in Figure 20.

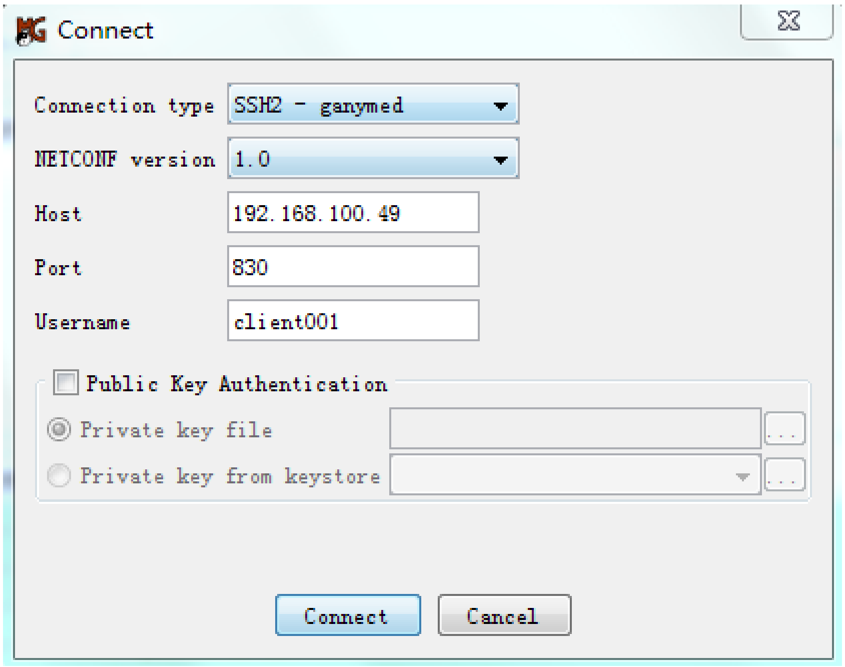
3. Configure connection parameters as follows:
   a. Select a connection type from the **Connection type** list.

      This example uses **SSH2-ganymed**.

   b. Select **1.0** from the **NETCONF version** list.
   c. Enter **192.168.100.49** in the **Host** field.
   d. Enter **830** in the **Port** field.
   e. Enter **client001** in the **Username** field.
   f. Use the default setting for the **Public Key Authentication** area.

4. Click **Connect**.

Figure 20 Connecting to the device



Connection type: SSH2 - ganymed

NETCONF version: 1.0

Host: 192.168.100.49

Port: 830

Username: client001

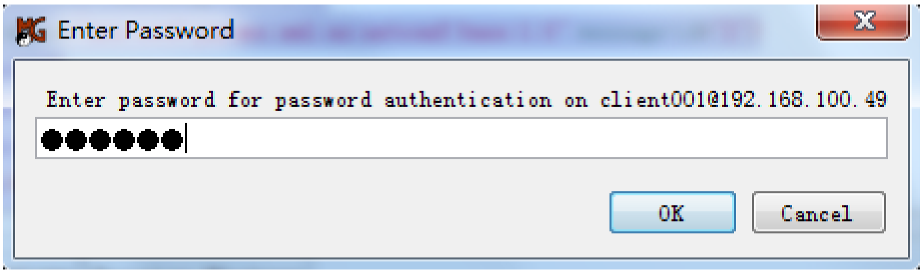
☐ Public Key Authentication

● Private key file

○ Private key from keystore

5. Enter password **aabbcc**, and then click **OK**, as shown in Figure 21.

Figure 21 Entering the password

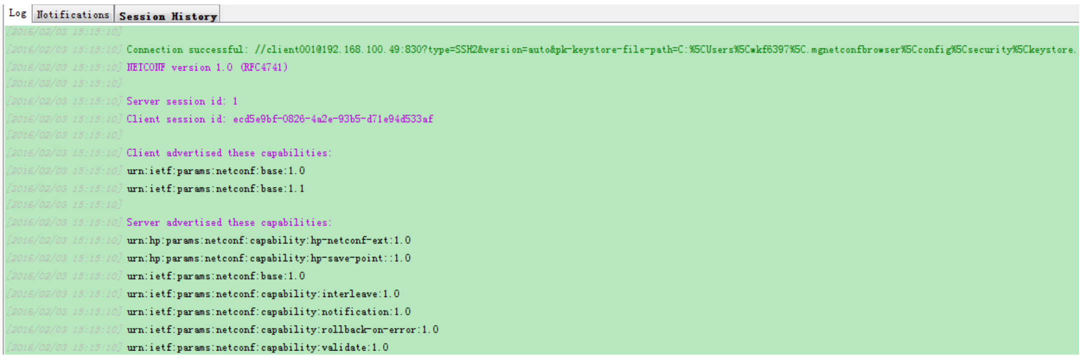


Enter password for password authentication on client001@192.168.100.49

●●●●●●

The NETCONF configuration interface opens when the client successfully establishes an NETCONF-over-SSH connection to the device. The **Log** tab of the interface displays the connection information, as shown in Figure 22.

Figure 22 Logging in to the device



```
[2016/02/03 15:15:10]
[2016/02/03 15:15:10] Connection successful: //client001@192.168.100.49:830?type=SSH2&version=auto&pk-keystore-file-path=C:%5CUsers%5Cwkf6397%5C.mgnetconfbrowser%5Cconfig%5Csecurity%5Ckeystore.
[2016/02/03 15:15:10] NETCONF version 1.0 (RFC4741)
[2016/02/03 15:15:10]

[2016/02/03 15:15:10] urn:ietf:params:netconf:capability:validate:1.0
```

6. Verify that you have obtained the permissions of the **network-admin** user role:

   In the **Command XML** area of the NETCONF configuration interface, enter **<get-sessions/>**, and then click **Send**.

The following message is displayed in the **Output XML** area.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="2">
  <get-sessions>
    <Session>
      <SessionID>1</SessionID>
      <Line>vty1</Line>
      <UserName>client001</UserName>
      <Since>2016-02-03T15:05:30</Since>
      <LockHeld>false</LockHeld>
    </Session>
  </get-sessions>
</rpc-reply>
```

Verifying the configuration

1. Launch a client that supports NETCONF over SSH.

   This example uses NetConf Browser 2015 (version 3.1).

2. Select **File** > **Connect…** from the menu.

   The **Connect** page appears, as shown in Figure 23.

3. Configure connection parameters as follows:

   a. Select a connection type from the **Connection type** list.

      This example uses **SSH2-ganymed**.

   b. Select **1.0** from the **NETCONF version** list.

   c. Enter **192.168.100.49** in the **Host** field.

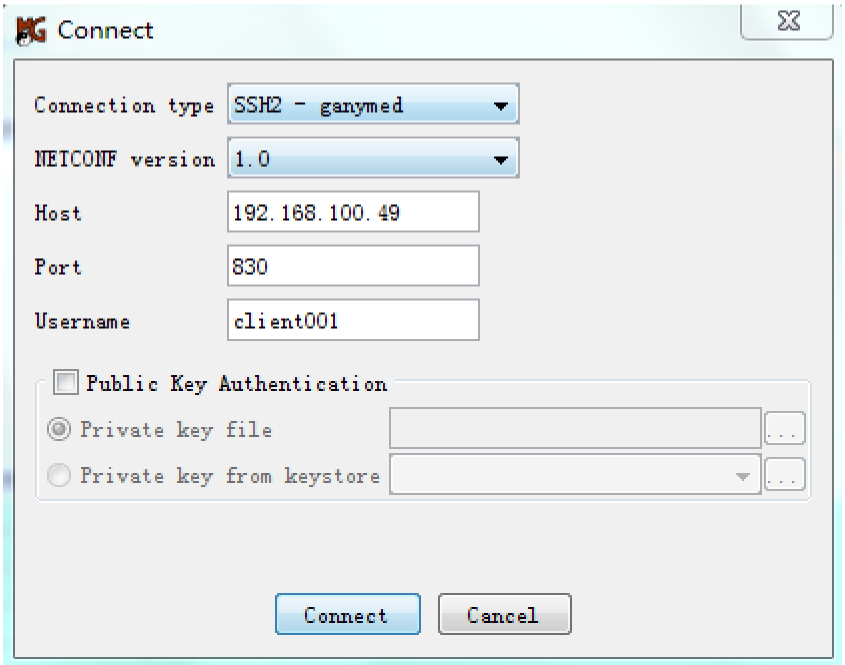
   d. Enter **830** in the **Port** field.

   e. Enter **client001** in the **Username** field.

   f. Use the default setting for the **Public Key Authentication** area.

4. Click **Connect**.

Figure 23 Connecting to the device



Connect

Connection type: SSH2 - ganymed

NETCONF version: 1.0

Host: 192.168.100.49

Port: 830

Username: client001

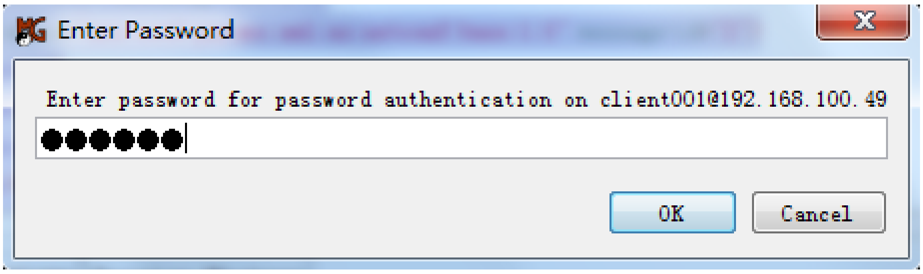
□ Public Key Authentication

● Private key file

○ Private key from keystore

5. Enter password **123456TESTplat&!**, and then click **OK**, as shown in Figure 24.

Figure 24 Entering the password



Enter Password
Enter password for password authentication on client001@192.168.100.49
●●●●●●
OK
Cancel

The NETCONF configuration interface appears when the client successfully establishes an NETCONF-over-SSH connection to the device. The **Log** tab of the interface displays the connection information, as shown in Figure 25.

Configuring SSL

About SSL

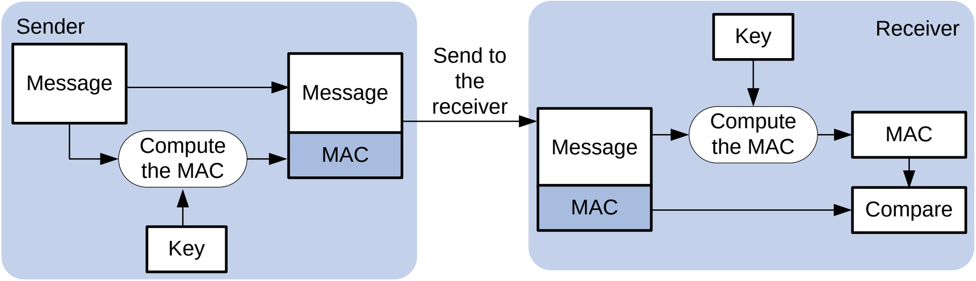
Secure Sockets Layer (SSL) is a cryptographic protocol that provides communication security for TCP-based application layer protocols such as HTTP. SSL has been widely used in applications such as e-business and online banking to provide secure data transmission over the Internet.

SSL security services

SSL provides the following security services:

- **Privacy**—SSL uses a symmetric encryption algorithm to encrypt data. It uses the asymmetric key algorithm of RSA to encrypt the key used by the symmetric encryption algorithm. For more information about RSA, see "Managing public keys."
- **Authentication**—SSL uses certificate-based digital signatures to authenticate the SSL server and client. The SSL server and client obtain digital certificates through PKI. For more information about PKI and digital certificates, see "Configuring PKI."
- **Integrity**—SSL uses the message authentication code (MAC) to verify message integrity. It uses a MAC algorithm and a key to transform a message of any length to a fixed-length message. Any change to the original message will result in a change to the calculated fixed-length message. As shown in Figure 1, the message integrity verification process is as follows:
  - **a.** The sender uses a MAC algorithm and a key to calculate a MAC value for a message. Then, it appends the MAC value to the message and sends the message to the receiver.
  - **b.** The receiver uses the same key and MAC algorithm to calculate a MAC value for the received message, and compares it with the MAC value appended to the message.
  - **c.** If the two MAC values match, the receiver considers the message intact. Otherwise, the receiver considers that the message was tampered with and it discards the message.

Figure 1 MAC algorithm diagram

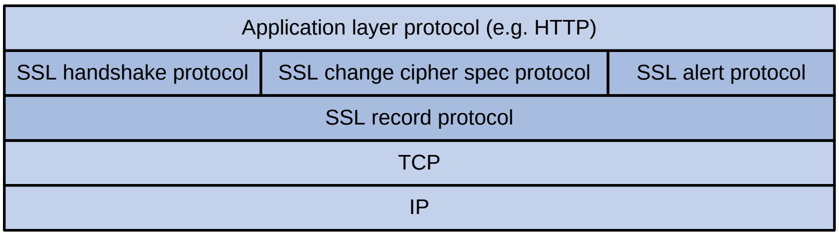


SSL protocol stack

The SSL protocol stack includes the following protocols:

- SSL record protocol at the lower layer.
- SSL handshake protocol, SSL change cipher spec protocol, and SSL alert protocol at the upper layer.

Figure 2 SSL protocol stack



Application layer protocol (e.g. HTTP)
SSL handshake protocol
SSL change cipher spec protocol
SSL alert protocol
SSL record protocol
TCP
IP

The following describes the major functions of SSL protocols:

- **SSL record protocol**—Fragments data received from the upper layer, computes and adds MAC to the data, and encrypts the data.
- **SSL handshake protocol**—Negotiates the cipher suite used for secure communication, authenticates the server and client, and securely exchanges the keys between the server and client. The cipher suite that needs to be negotiated includes the symmetric encryption algorithm, key exchange algorithm, and MAC algorithm.
- **SSL change cipher spec protocol**—Notifies the receiver that subsequent packets are to be protected based on the negotiated cipher suite and key.
- **SSL alert protocol**—Sends alert messages to the receiving party. An alert message contains the alert severity level and a description.

SSL protocol versions

SSL protocol versions include SSL 2.0, SSL 3.0, TLS 1.0 (or SSL 3.1), TLS 1.1, and TLS 1.2. Because SSL 3.0 is known to be insecure, you can disable SSL 3.0 for the SSL server to ensure security.

Restrictions and guidelines: SSL configuration

By default, the SSL server can communicate with clients running all SSL protocol versions. When the server receives an SSL 2.0 Client Hello message from a client, it notifies the client to use a later version for communication.

SSL tasks at a glance

Configuring the SSL server

- Configuring an SSL server policy
- (Optional.) Disabling SSL protocol versions for the SSL server
- (Optional.) Disabling SSL session renegotiation

Configuring the SSL client

Configuring an SSL client policy

Configuring an SSL server policy

About this task

An SSL server policy is a set of SSL parameters used by the device when the device acts as the SSL server. An SSL server policy takes effect only after it is associated with an application such as HTTPS.

Some services (such as SSL VPN, load balancing, and proxy policy) might require using two digital certificates on the server. To meet the requirement, you can use this command to specify two PKI domains in the SSL server policy at a time.

Procedure

1. Enter system view.

   system-view

2. Create an SSL server policy and enter its view.

   ssl server-policy *policy-name*

3. Specify a PKI domain for the SSL server policy.

   pki-domain *domain-name*&<1-2>

   By default, no PKI domain is specified for an SSL server policy.

   If SSL server authentication is required, you must specify a PKI domain and request a local certificate for the SSL server in the domain.

   For information about configuring a PKI domain, see "Configuring PKI."

4. Specify the cipher suites that the SSL server policy supports.

   ciphersuite { **dhe_rsa_aes_128_cbc_sha** | **dhe_rsa_aes_128_cbc_sha256** | **dhe_rsa_aes_256_cbc_sha** | **dhe_rsa_aes_256_cbc_sha256** | **ecc_sm2_sm1_sm3** | **ecc_sm2_sm4_sm3** | **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **ecdhe_sm2_sm1_sm3** | **ecdhe_sm2_sm4_sm3** | **exp_rsa_des_cbc_sha** | **rsa_3des_ede_cbc_sha** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_128_gcm_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_aes_256_gcm_sha384** | **rsa_des_cbc_sha** | **rsa_sm1_sha** | **rsa_sm1_sm3** | **rsa_sm4_sha** | **rsa_sm4_sm3** | **tls_aes_128_ccm_8_sha256** | **tls_aes_128_ccm_sha256** | **tls_aes_128_gcm_sha256** | **tls_aes_256_gcm_sha384** | **tls_chacha20_poly1305_sha256** } *<1-11>

   By default, an SSL server policy supports cipher suites ECC_SM2_SM1_SM3, ECC_SM2_SM4_SM3, ECDHE_SM2_SM1_SM3, ECDHE_SM2_SM4_SM3, RSA_SM1_SHA, RSA_SM1_SM3, RSA_SM4_SHA, RSA_SM4_SM3, RSA_AES_128_CBC_SHA, RSA_AES_256_CBC_SHA, DHE_RSA_AES_128_CBC_SHA, DHE_RSA_AES_256_CBC_SHA, RSA_AES_128_CBC_SHA256, RSA_AES_256_CBC_SHA256, DHE_RSA_AES_128_CBC_SHA256, DHE_RSA_AES_256_CBC_SHA256, ECDHE_RSA_AES_128_CBC_SHA256, ECDHE_RSA_AES_256_CBC_SHA384, ECDHE_RSA_AES_128_GCM_SHA256, ECDHE_RSA_AES_256_GCM_SHA384, ECDHE_ECDSA_AES_128_CBC_SHA256, ECDHE_ECDSA_AES_256_CBC_SHA384, ECDHE_ECDSA_AES_128_GCM_SHA256, ECDHE_ECDSA_AES_256_GCM_SHA384, RSA_AES_128_GCM_SHA256, RSA_AES_256_GCM_SHA384, TLS_AES_128_GCM_SHA256, TLS_AES_256_GCM_SHA384, TLS_CHACHA20_POLY1305_SHA256, TLS_AES_128_CCM_SHA256, and TLS_AES_128_CCM_8_SHA256.

5. (Optional.) Set the maximum number of sessions that the SSL server can cache and the session cache timeout time.

session { **cachesize** *size* | **timeout** *time* } *

By default, the SSL server can cache a maximum of 500 sessions, and the session cache timeout time is 3600 seconds.

6. Enable mandatory or optional SSL client authentication.

   client-verify { **enable** | **optional** }

   By default, SSL client authentication is disabled. The SSL server does not perform digital certificate-based authentication on SSL clients.

   When authenticating a client by using the digital certificate, the SSL server verifies the certificate chain presented by the client. It also verifies that the certificates in the certificate chain (except the root CA certificate) are not revoked.

7. (Optional.) Enable the SSL server to send the complete certificate chain to the client during SSL negotiation.

   certificate-chain-sending enable

   By default, the SSL server sends the server certificate rather than the complete certificate chain to the client during negotiation.

Configuring an SSL client policy

About this task

An SSL client policy is a set of SSL parameters used by the device when the device acts as the SSL client. The SSL client uses the settings in the client policy to establish a connection to the server. An SSL client policy takes effect only after it is associated with an application such as DDNS. For information about DDNS, see *Layer 3—IP Services Configuration Guide*.

Restrictions and guidelines

As a best practice to enhance system security, do not specify SSL 3.0 for the SSL client policy.

Procedure

1. Enter system view.

   system-view

2. Create an SSL client policy and enter its view.

   ssl client-policy *policy-name*

3. Specify a PKI domain for the SSL client policy.

   pki-domain *domain-name*

   By default, no PKI domain is specified for an SSL client policy.

   If SSL client authentication is required, you must specify a PKI domain and request a local certificate for the SSL client in the PKI domain.

   For information about configuring a PKI domain, see "Configuring PKI."

4. Specify the preferred cipher suite for the SSL client policy.

   prefer-cipher { **dhe_rsa_aes_128_cbc_sha** | **dhe_rsa_aes_128_cbc_sha256** | **dhe_rsa_aes_256_cbc_sha** | **dhe_rsa_aes_256_cbc_sha256** | **ecc_sm2_sm1_sm3** | **ecc_sm2_sm4_sm3** | **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **ecdhe_sm2_sm1_sm3** | **ecdhe_sm2_sm4_sm3** | **exp_rsa_des_cbc_sha** | **rsa_3des_ede_cbc_sha** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_128_gcm_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_aes_256_gcm_sha384** | **rsa_des_cbc_sha** | **rsa_sm1_sha** | **rsa_sm1_sm3**

| rsa_sm4_sha | rsa_sm4_sm3 | tls_aes_128_ccm_8_sha256 | tls_aes_128_ccm_sha256 | tls_aes_128_gcm_sha256 | tls_aes_256_gcm_sha384 | tls_chacha20_poly1305_sha256 } *<1-11>

By default, the preferred cipher suites of an SSL client policy are **dhe_rsa_aes_256_cbc_sha, rsa_aes_256_cbc_sha**, **dhe_rsa_aes_128_cbc_sha**, and **rsa_aes_128_cbc_sha**.

5. Specify the SSL protocol version for the SSL client policy.

   version { **gm-tls1.1** | **ssl3.0** | **tls1.0** | **tls1.1** | **tls1.2** | **tls1.3** }

   Support for the **gm-tls1.1** keyword depends on the device model. For more information, see the command reference.

   By default, an SSL client policy uses TLS 1.2.

6. Enable the SSL client to authenticate servers through digital certificates.

   server-verify enable

   By default, SSL server authentication is enabled.

Disabling SSL protocol versions for the SSL server

About this task

To enhance security, you can disable the SSL server from using specific SSL protocol versions for session negotiation.

You can disable an SSL protocol version for the SSL server in system view or in SSL server policy view. The SSL server can use an SSL protocol version for session negotiation only when the status of the SSL protocol version in the SSL server policy is **Enabled**. The status of an SSL protocol version in an SSL server policy is determined in the following sequence:

1. Configuration of the **version disable** command in SSL server policy view.
2. Configuration of the **ssl version disable** command in system view.
3. Default setting (**Enabled**).

Make sure the SSL server is allowed to use a minimum of one SSL protocol version for session negotiation.

Restrictions and guidelines

Disabling an SSL protocol version does not affect the availability of earlier SSL protocol versions. For example, if you execute the **ssl version tls1.1 disable** command, TLS 1.1 is disabled but TLS 1.0 is still available for the SSL server.

Procedure

1. Enter system view.

   system-view

2. Disable SSL protocol versions for the SSL server in system view.

   ssl version { **gm-tls1.1** | **ssl3.0** | **tls1.0** | **tls1.1** | **tls1.2** | **tls1.3** } * **disable**

   Support for the **gm-tls1.1** keyword depends on the device model. For more information, see the command reference.

   By default, the SSL server supports TLS 1.1 and TLS 1.2.

3. Enter SSL server policy view.

   ssl server-policy *policy-name*

4. Disable SSL protocol versions in the SSL server policy.

   version { **gm-tls1.1** | **ssl3.0** | **tls1.0** | **tls1.1** | **tls1.2** | **tls1.3** } * **disable**

   Support for the **gm-tls1.1** keyword depends on the device model. For more information, see the command reference.

   By default, an SSL protocol version is enabled in an SSL sever policy unless it is explicitly disabled in system view by using the **ssl version disable** command.

Disabling SSL session renegotiation

About this task

The SSL session renegotiation feature enables the SSL client and server to reuse a previously negotiated SSL session for an abbreviated handshake.

Disabling session renegotiation causes more computational overhead to the system but it can avoid potential risks.

Restrictions and guidelines

Disable SSL session renegotiation only when explicitly required.

Procedure

1. Enter system view.

   system-view

2. Disable SSL session renegotiation.

   ssl renegotiation disable

   By default, SSL session renegotiation is disabled.

Enabling the server-preferred order during cipher suite negotiation

About this task

During SSL connection negotiation, the key exchange algorithm, symmetric encryption algorithm, and MAC algorithm used for message exchange between the SSL server and the SSL client will be determined. By default, the SSL server uses the order of cipher suites presented by the client to negotiate the cipher suite. That is, the SSL server chooses the first cipher suite in the client's list that matches any one of the server's cipher suites. If no match is found, the negotiation fails.

This feature allows you to select the server-preferred order for cipher suite negotiation. That is, the SSL server chooses the first cipher suite in its list that matches any one of the client's cipher suites. If no match is found, the negotiation fails.

The earlier a cipher suite is configured, the higher priority it has during the cipher suite negotiation.

Procedure

1. Enter system view.

   system-view

2. Enter SSL server policy view.

   ssl server-policy *policy-name*

3. Enable the server-preferred order for choosing a cipher suite during the cipher suite negotiation between the SSL server and SSL client.

ciphersuite server-preferred enable

By default, the client-preferred order for choosing a cipher suite during the cipher suite negotiation between the SSL server and SSL client.

Display and maintenance commands for SSL

Execute **display** commands in any view.

Task	Command
Display SSL client policy information.	**display ssl client-policy** [*policy-name*]
Display SSL server policy information.	**display ssl server-policy** [*policy-name*]

Contents

Configuring connection limits

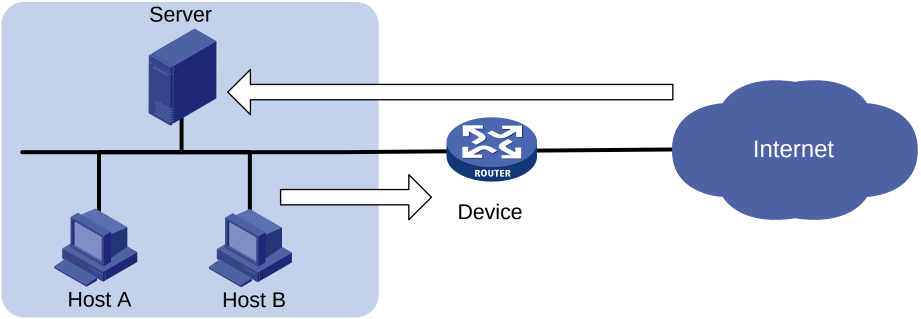
About connection limits

The connection limit feature enables the device to monitor and limit the number of established connections.

As shown in Figure 1, configure the connection limit feature to resolve the following issues:

- If Host B initiates a large number of connections in a short period of time, it might exhaust system resources and cause Host A to be unable to access the Internet.
- If the internal server receives a large number of connection requests in a short period of time, the server cannot process other requests.

Figure 1 Network diagram



Connection limit tasks at a glance

To configure connection limits, perform the following tasks:

1. Creating a connection limit policy
2. Configuring the connection limit policy
   - Configuring an IPv4 connection limit policy
   - Configuring an IPv6 connection limit policy
3. Applying the connection limit policy
   - Applying a connection limit policy to an interface
   - Applying a connection limit policy globally

Creating a connection limit policy

1. Enter system view.
   system-view
2. Create a connection limit policy and enter its view.
   connection-limit { **ipv6-policy** | **policy** } *policy-id*

Configuring the connection limit policy

About connection limit policies

To use a connection limit policy, you need to add limit rules to the policy. Each rule defines a range of connections and the criteria for limiting the connections. Connections in the range will be limited based on the criteria. The criteria include upper/lower connection limit and connection establishment rate limit. When the number of matching connections reaches the upper limit or connection rate limit, the device accepts or rejects new connections depending on the action you configured. If the action is to reject new connections, the device does not accept new connections until the number of connections drops below the lower limit or connection rate limit due to connection aging. The device will send logs when the number of connections exceeds the upper limit or connection rate limit. The device will send logs when the number of connections drops below the lower limit or connection rate limit only if the action is to reject new connections. The connections that do not match any connection limit rules are not limited.

In each connection limit rule, an ACL is used to define the connection range. In addition, the rule also uses the following filtering methods to further limit the connections:

- **per-destination**—Limits user connections by destination IP address.
- **per-service**—Limits user connections by service (transport layer protocol and service port).
- **per-source**—Limits user connections by source IP address.
- **per-dslite-b4**—Limits user connections by the B4 device on a DS-Lite tunnel. For information about DS-Lite tunnels, see *VPN Configuration Guide*.

You can select more than one filtering method, and the selected methods take effect at the same time. For example, if you specify both **per-destination** and **per-service**, the user connections using the same service and destined to the same IP address are limited. If you do not specify any filtering methods in a limit rule, all user connections in the range are limited.

Restrictions and guidelines for connection limit policy configuration

When a connection limit policy is applied, connections on the device match all limit rules in the policy in ascending order of rule IDs. As a best practice, specify a smaller range and more filtering methods in a rule with a smaller ID.

Configuring an IPv4 connection limit policy

1. Enter system view.

   system-view

2. Create an IPv4 connection limit policy and enter its view.

   connection-limit policy *policy-id*

3. Configure a connection limit rule.
   - Configure a connection limit rule based on destination IP address, service, or source IP address.

     limit *limit-id* **acl** { *acl-number* | **name** *acl-name* } [**per-destination** | **per-service** | **per-source**] * { **amount** *max-amount min-amount* | **rate** *rate* } * [**description** *text* | **permit-new**] *

   - Configure a connection limit rule based on DS-Lite tunnel.

limit *limit-id* **acl ipv6** { *acl-number* | **name** *acl-name* } **per-dslite-b4** { **amount** *max-amount min-amount* | **rate** *rate* } * [**description** *text* | **permit-new**] *

4. (Optional.) Configure a description for the connection limit policy.

   description *text*

   By default, an IPv4 connection limit policy does not have a description.

Configuring an IPv6 connection limit policy

1. Enter system view.

   system-view
2. Create an IPv6 connection limit policy and enter its view.

   connection-limit ipv6-policy *policy-id*
3. Configure a connection limit rule.

   limit *limit-id* **acl ipv6** { *acl-number* | **name** *acl-name* } [**per-destination** | **per-service** | **per-source**] * { **amount** *max-amount min-amount* | **rate** *rate* } * [**description** *text* | **permit-new**] *
4. (Optional.) Configure a description for the connection limit policy.

   description *text*

   By default, an IPv6 connection limit policy does not have a description.

Applying the connection limit policy

About connection limit application

To make a connection limit policy take effect, apply it globally or to an interface. The connection limit policy applied to an interface takes effect only on the specified connections on the interface. The connection limit policy applied globally takes effect on all the specified connections on the device.

Different connection limit policies can be applied to individual interfaces as well as globally on the device. In this case, the device matches connections against these policies in the order of the policy on the inbound interface, the global policy, and the policy on the outbound interface. It cannot accept new connections as long as the number of connections reaches the smallest upper connection limit defined by these policies.

Restrictions and guidelines for connection limit application

A connection limit policy or any modification to it takes effect only on new connections. It does not take effect on existing connections.

On an IRF fabric where session synchronization is enabled, connection limit policies applied to a subordinate device do not take effect on sessions switched from the master device.

On a DS-Lite tunnel network, if the AFTR device uses the Endpoint-Independent Mapping-based NAT configuration, you must limit connections from external IPv4 networks to access the internal IPv4 network. To implement B4 device-based connection limits, perform the following tasks:

- Add a rule that has the **per-dslite-b4** keyword to a connection limit policy.
- Apply the policy globally or on the DS-Lite tunnel interface.

Applying a connection limit policy to an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Apply a connection limit policy to the interface.

   connection-limit apply { **ipv6-policy** | **policy** } *policy-id*

   By default, no connection limit policy is applied to an interface.

   Only one IPv4 connection limit policy and one IPv6 connection limit policy can be applied to an interface. A new IPv4 or IPv6 connection limit policy overwrites the old policy.

Applying a connection limit policy globally

1. Enter system view.

   system-view

2. Apply a connection limit policy globally.

   connection-limit apply global { **ipv6-policy** | **policy** } *policy-id*

   By default, no connection limit policy is applied globally.

   Only one IPv4 connection limit policy and one IPv6 connection limit policy can be applied globally. A new IPv4 or IPv6 connection limit policy overwrites the old policy.

Display and maintenance commands for connection limits

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the connection limit policy information.	**display connection-limit** { **ipv6-policy** | **policy** } { **all** | *policy-id* }
Display the connection limit statistics globally or on an interface.	**display connection-limit statistics** { **global** | **interface** *interface-type interface-number* } [**slot** *slot-number*]
Display statistics about IPv4 connections matching connection limit rules globally or on an interface.	**display connection-limit stat-nodes** { **global** | **interface** *interface-type interface-number* } [**slot** *slot-number*] [{ **deny-new** | **permit-new** } | **destination** *destination-ip* | **service-port** *port-number* | **source** *source-ip*] * [**count**] **display connection-limit stat-nodes** { **global** | **interface** *interface-type interface-number* } [**slot** *slot-number*] **dslite-peer** *b4-address* [**count**]
Display statistics about IPv6 connections matching connection limit rules globally or on an interface.	**display connection-limit ipv6-stat-nodes** { **global** | **interface** *interface-type interface-number* } [**slot** *slot-number*]

Task	Command
	[{ **deny-new** | **permit-new** } | **destination** *destination-ip* | **service-port** *port-number* | **source** *source-ip*] * [**count**]
Clear the connection limit statistics globally or on an interface.	**reset connection-limit statistics** { **global** | **interface** *interface-type interface-number* } [**slot** *slot-number*]

Connection limit configuration examples

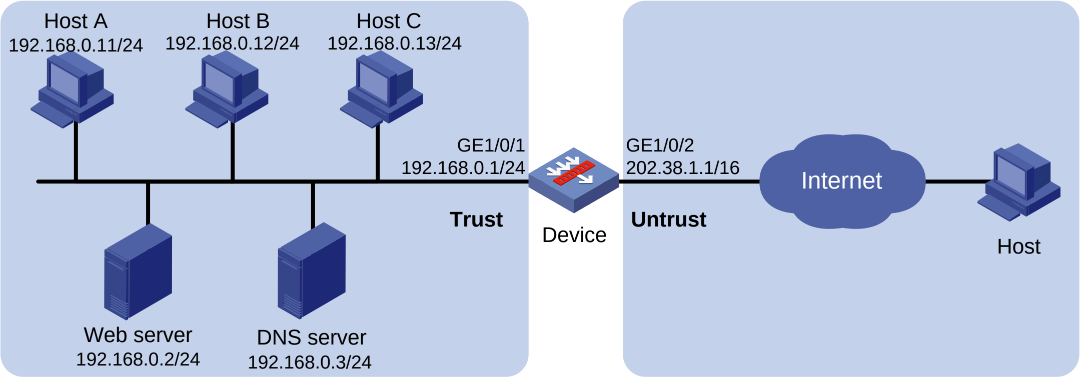
Example: Configuring connection limits

Network configuration

As shown in Figure 2, a company has five public IP addresses: 202.38.1.1/24 to 202.38.1.5/24. The internal network address is 192.168.0.0/16. Configure NAT so that the internal users can access the Internet and external users can access the internal servers. Configure connection limits to meet the following requirements:

- All hosts on segment 192.168.0.0/24 can establish a maximum of 100000 connections to the external network.
- Each host on segment 192.168.0.0/24 can establish a maximum of 100 connections to the external network.
- A maximum of 10000 query requests from DNS clients to the DNS server are allowed at the same time.
- A maximum of 10000 connection requests from Web clients to the Web server are allowed at the same time.

Figure 2 Network diagram



Procedure

The following example only describes how to configure connection limits. For information about NAT configuration and internal server configuration, see *Layer 3—IP Services Configuration Guide*.

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.0.1 255.255.255.0
```

```
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing.

   This example configures static routes, and the next hop in the routes is 202.38.1.254.

```
[Device] ip route-static 0.0.0.0 0 202.38.1.254
```

3. Add interfaces to security zones.

```
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/1
[Device-security-zone-Trust] quit
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
[Device-security-zone-Untrust] quit
```

4. Configure a security policy.

   # Configure a rule named **trust-untrust** to allow Host A to access the Internet.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name trust-untrust
[Device-security-policy-ip-1-trust-untrust] source-zone trust
[Device-security-policy-ip-1-trust-untrust] destination-zone untrust
[Device-security-policy-ip-1-trust-untrust] source-ip-subnet 192.168.0.0 24
[Device-security-policy-ip-1-trust-untrust] action pass
[Device-security-policy-ip-1-trust-untrust] quit
```

# Configure a rule named **untrust-trust** to allow the external host to access internal servers.

```
[Device-security-policy-ip] rule name untrust-trust
[Device-security-policy-ip-2-untrust-trust] source-zone untrust
[Device-security-policy-ip-2-untrust-trust] destination-zone trust
[Device-security-policy-ip-2-untrust-trust] destination-ip-subnet 192.168.0.0 24
[Device-security-policy-ip-2-untrust-trust] action pass
[Device-security-policy-ip-2-untrust-trust] quit
[Device-security-policy-ip] quit
```

5. Configure ACLs.

   # Create ACL 3000 to permit packets from all hosts on the internal network.

```
[Device] acl advanced 3000
[Device-acl-ipv4-adv-3000] rule permit ip source 192.168.0.0 0.0.0.255
[Device-acl-ipv4-adv-3000] quit
```

# Create ACL 3001 to permit packets to the Web server and the DNS server.

```
[Device] acl advanced 3001
[Device-acl-ipv4-adv-3001] rule permit ip destination 192.168.0.2 0
[Device-acl-ipv4-adv-3001] rule permit ip destination 192.168.0.3 0
[Device-acl-ipv4-adv-3001] quit
```

6. Configure connection limit policies.

   # Create connection limit policy 1.

```
[Device] connection-limit policy 1
```

# Configure connection limit rule 1 to permit a maximum of 100000 connections from all the hosts that match ACL 3000. When the number of connections exceeds 100000, new connections cannot be established until the number drops below 95000.

```
[Device-connlmt-policy-1] limit 1 acl 3000 amount 100000 95000
```

# Configure connection limit rule 2 to permit a maximum of 10000 connections to the servers that match ACL 3001. When the number of connections exceeds 10000, new connections cannot be established until the number drops below 9800.

```
[Device-connlmt-policy-1] limit 2 acl 3001 per-destination amount 10000 9800
[Device-connlmt-policy-1] quit
```

# Create connection limit policy 2.

```
[Device] connection-limit policy 2
```

# Configure connection limit rule 1 to permit a maximum of 100 connections from each host matching ACL 3000. When the number of connections exceeds 100, new connections cannot be established until the number drops below 90.

```
[Device-connlmt-policy-2] limit 1 acl 3000 per-source amount 100 90
[Device-connlmt-policy-2] quit
```

7. Apply connection limit policies.

# Apply connection limit policy 1 globally.

```
[Device] connection-limit apply global policy 1
```

# Apply connection limit policy 2 to inbound interface GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] connection-limit apply policy 2
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

# Display information about the connection limit policy.

```
[Device] display connection-limit policy 1
IPv4 connection limit policy 1 has been applied 1 times, and has 2 limit rules.
Limit rule list:
  Policy  Rule    StatType  HiThres  LoThres   rate    PermitNew   ACL
-------------------------------------------------------------------------------
       1     1          --   100000    95000      0           No   3000
             2         Dst    10000     9800      0           No   3001

 Applied list:
     Global
[Device] display connection-limit policy 2
IPv4 connection limit policy 2 has been applied 1 times, and has 1 limit rules.
Limit rule list:
  Policy  Rule    StatType  HiThres  LoThres   rate     PermitNew   ACL
--------------------------------------------------------------------------------
       2     1         Src      100       90      0            No   3000

 Applied list:
     GigabitEthernet1/0/1
```

Troubleshooting connection limits

ACLs in the connection limit rules with overlapping segments

Symptom

A connection limit policy has two rules. Rule 1 sets the upper limit to 10 for the connections from each host on segment 192.168.0.0/24. Rule 2 sets the upper limit to 100 for the connections from 192.168.0.100/24.

```
<Device> system-view
[Device] acl basic 2001
[Device-acl-ipv4-basic-2001] rule permit source 192.168.0.0 0.0.0.255
[Device-acl-ipv4-basic-2001] quit
[Device] acl basic 2002
[Device-acl-ipv4-basic-2002] rule permit source 192.168.0.100 0
[Device-acl-ipv4-basic-2002] quit
[Device] connection-limit policy 1
[Device-connlmt-policy-1] limit 1 acl 2001 per-destination amount 10 5
[Device-connlmt-policy-1] limit 2 acl 2002 per-destination amount 100 10
```

As a result, the host at 192.168.0.100 can only initiate a maximum of 10 connections to the external network.

Solution

To resolve the issue:

1. Rearrange the two connection limit rules by exchanging their rule IDs.
2. If the issue persists, contact NSFOCUS Support.

Contents

Configuring attack detection and prevention

About attack detection and prevention

Attack detection and prevention enables a device to detect attacks by inspecting arriving packets, and to take prevention actions to protect a private network. Prevention actions include logging, packet dropping, blacklisting, and client verification.

Attacks that the device can prevent

This section describes the attacks that the device can detect and prevent.

Single-packet attacks

Single-packet attacks are also known as malformed packet attacks. An attacker typically launches single-packet attacks by using the following methods:

- An attacker sends defective packets to a device, which causes the device to malfunction or crash.
- An attacker sends normal packets to a device, which interrupts connections or probes network topologies.
- An attacker sends a large number of forged packets to a target device, which consumes network bandwidth and causes denial of service (DoS).

Table 1 lists the single-packet attack types that the device can detect and prevent.

Table 1 Types of single-packet attacks

Single-packet attack	Description
ICMP redirect	An attacker sends ICMP redirect messages to modify the victim's routing table. The victim cannot forward packets correctly.
ICMP destination unreachable	An attacker sends ICMP destination unreachable messages to cut off the connections between the victim and its destinations.
ICMP type	A receiver responds to an ICMP packet according to its type. An attacker sends forged ICMP packets of a specific type to affect the packet processing of the victim.
ICMPv6 type	A receiver responds to an ICMPv6 packet according to its type. An attacker sends forged ICMPv6 packets of specific types to affect the packet processing of the victim.
Land	An attacker sends the victim a large number of TCP SYN packets, which contain the victim's IP address as the source and destination IP addresses. This attack exhausts the half-open connection resources on the victim, and locks the victim's system.
Large ICMP packet	An attacker sends large ICMP packets to crash the victim. Large ICMP packets can cause memory allocation error and crash the protocol stack.
Large ICMPv6 packet	An attacker sends large ICMPv6 packets to crash the victim. Large ICMPv6 packets can cause memory allocation error and crash the protocol stack.

Single-packet attack	Description
IP option	An attacker builds IP datagrams with certain option types and sends them to probe the network topology.
IP option abnormal	An attacker sends IP datagrams in which the IP options are abnormal. This attack intends to probe the network topology. The target system will break down if it is incapable of processing error packets.
IP fragment	An attacker sends the victim an IP datagram with an offset no larger than 5, which causes the victim to malfunction or crash.
IP impossible packet	An attacker sends IP packets whose source IP address is the same as the destination IP address, which causes the victim to malfunction.
Tiny fragment	An attacker makes the fragment size small enough to force Layer 4 header fields into the second fragment. These fragments can pass the packet filtering because they do not hit any match.
Smurf	An attacker sends an ICMP echo request to target networks. In these requests, the destination IP address is a network or broadcast address of a Class A, B, or C subnet, and the source IP address is the victim's IP address. Every receiver on the target networks will send an ICMP echo reply to the victim. The victim will be flooded with replies, and will be unable to provide services. Network congestion might occur.
TCP flag	An attacker sends packets with defective TCP flags to probe the operating system of the target host. Different operating systems process unconventional TCP flags differently. The target system will break down if it processes this type of packets incorrectly.
Traceroute	An attacker uses traceroute tools to probe the topology of the victim network.
WinNuke	An attacker sends Out-Of-Band (OOB) data to the TCP port 139 (NetBIOS) on the victim that runs Windows system. The malicious packets contain an illegal Urgent Pointer, which causes the victim's operating system to crash.
UDP bomb	An attacker sends a malformed UDP packet. The length value in the IP header is larger than the IP header length plus the length value in the UDP header. When the target system processes the packet, a buffer overflow can occur, which causes a system crash.
UDP Snork	An attacker sends a UDP packet with destination port 135 (the Microsoft location service) and source port 135, 7, or 19. This attack causes an NT system to exhaust its CPU.
UDP Fraggle	An attacker sends a large number of packets with source UDP port 7 and destination UDP port 19 (UDP chargen port) to a network. These packets use the victim's IP address as the source IP address. Replies will flood the victim, resulting in DoS.
Teardrop	An attacker sends a stream of overlapping fragments. The victim will crash when it tries to reassemble the overlapping fragments.
Ping of death	An attacker sends the victim an ICMP echo request larger than 65535 bytes that violates the IP protocol. When the victim reassembles the packet, a buffer overflow can occur, which causes a system crash.
IPv6 extension header	An attack sends the victim a packet with IPv6 extension headers.
IPv6 ext header abnormal	An attacker sends IPv6 packets with disordered or repeated IPv6 extension headers to the target.
IPv6 ext header exceed	An attacker sends IPv6 packets with IPv6 extension headers exceeding the upper limit to the target.

Scanning attacks

Scanning is a preintrusion activity used to prepare for intrusion into a network. The scanning allows the attacker to find a way into the target network and to disguise the attacker's identity.

Attackers use scanning tools to probe a network, find vulnerable hosts, and discover services that are running on the hosts. Attackers can use the information to launch attacks.

The device can detect and prevent the IP sweep and port scan attacks. If an attacker performs port scanning from multiple hosts to the target host, distributed port scan attacks occur.

Flood attacks

An attacker launches a flood attack by sending a large number of forged requests to the victim in a short period of time. The victim is too busy responding to these forged requests to provide services for legal users, and a DoS attack occurs.

The device can detect and prevent the following types of flood attacks.

SYN flood attack

A SYN flood attacker exploits the TCP three-way handshake characteristics and makes the victim unresponsive to legal users. An attacker sends a large number of SYN packets with forged source addresses to a server. This causes the server to open a large number of half-open connections and respond to the requests. However, the server will never receive the expected ACK packets. The server is unable to accept new incoming connection requests because all of its resources are bound to half-open connections.

ACK flood attack

An ACK packet is a TCP packet only with the ACK flag set. Upon receiving an ACK packet from a client, the server must search half-open connections for a match.

An ACK flood attacker sends a large number of ACK packets to the server. This causes the server to be busy searching for half-open connections, and the server is unable to process packets for normal services.

SYN-ACK flood attack

Upon receiving a SYN-ACK packet, the server must search for the matching SYN packet it has sent. A SYN-ACK flood attacker sends a large number of SYN-ACK packets to the server. This causes the server to be busy searching for SYN packets, and the server is unable to process packets for normal services.

FIN flood attack

FIN packets are used to shut down TCP connections.

A FIN flood attacker sends a large number of forged FIN packets to a server. The victim might shut down correct connections, or be unable to provide services because it is busy searching for matching connections.

RST flood attack

RST packets are used to abort TCP connections when TCP connection errors occur.

An RST flood attacker sends a large number of forged RST packets to a server. The victim might shut down correct connections, or be unable to provide services because it is busy searching for matching connections.

DNS flood attack

The DNS server processes and replies all DNS queries that it receives.

A DNS flood attacker sends a large number of forged DNS queries. This attack consumes the bandwidth and resources of the DNS server, which prevents the server from processing and replying legal DNS queries.

DNS response flood attack

The DNS client processes all DNS responses that it receives.

A DNS response flood attacker sends a large number of forged DNS responses. This attack consumes the bandwidth and resources of the DNS client, which prevents the client from processing legal DNS responses.

HTTP flood attack

Upon receiving an HTTP GET or POST request, the HTTP server performs complex operations, including character string searching, database traversal, data reassembly, and format switching. These operations consume a large amount of system resources.

An HTTP flood attacker sends a large number of HTTP GET or POST requests that exceed the processing capacity of the HTTP server, which causes the server to crash.

SIP flood attack

After receiving a SIP INVITE packet from a SIP client, the server must allocate resources to establish and trace the session with the SIP client.

A SIP flood attacker sends a large number of fake INVITE request packets at a rate exceeding the processing capacity of the SIP server, which causes the server to crash.

ICMP flood attack

An ICMP flood attacker sends ICMP request packets, such as ping packets, to a host at a fast rate. Because the target host is busy replying to these requests, it is unable to provide services.

ICMPv6 flood attack

An ICMPv6 flood attacker sends ICMPv6 request packets, such as ping packets, to a host at a fast rate. Because the target host is busy replying to these requests, it is unable to provide services.

UDP flood attack

A UDP flood attacker sends UDP packets to a host at a fast rate. These packets consume a large amount of the target host's bandwidth, so the host cannot provide other services.

Login DoS attack

In a login DoS attack, a malicious user can attempt to interfere with the normal operations of a device by flooding it with login requests. These requests consume the authentication resources, which makes the device unable to allow legal users to log in.

You can configure login attack prevention to prevent the login DoS attacks. This feature blocks user login attempts for a period of time after the user fails the maximum number of successive login attempts.

Login dictionary attack

The login dictionary attack is an automated process to attempt to log in by trying all possible passwords from a pre-arranged list of values (the dictionary). Multiple login attempts can occur in a short period of time.

You can configure the login delay feature to slow down the login dictionary attacks. This feature enables the device to delay accepting another login request after detecting a failed login attempt for a user.

HTTP slow attack

An attacker exploits the HTTP connection mechanism to establish a connection to an HTTP server and hold the connection for a long time in order to exhaust the server resources. The following types of HTTP slow attacks are commonly used:

- **Slow headers**—An attacker uses the HTTP GET or POST method to connect to the server. The HTTP header does not contain two CRLF sequences that mark the end of the header. In subsequent communication, the attacker sends packets to the server regularly with other HTTP header fields filled to keep the connection alive. The server is expecting the header end markers and maintains the connection for a long time.
- **Slow POST**—This type of attack occurs in one of the following conditions:
    - An attacker sends an HTTP POST request to submit data to the server and sets the **Content-Length** field to a greater value. In subsequent payload transisthmian, the attacker sends a small number of data each time to maintain the connection. The server keeps expecting the payload data from the attacker without releasing the connection.
    - An attacker sends an HTTP packet in chunked transfer encoding. If the HTTP packet is not ended with a zero-length chunk, the server is expecting the payload data from the attacker without releasing the connection.

To prevent HTTP slow attacks, configure HTTP slow attack detection and prevention. This feature detects such attacks and adds attacker addresses to the blacklist. Packets with source addresses on the blacklist are dropped.

Session creation attack

An attacker sends a large number of packets to create new sessions with the target to exhaust the target's resources and affect operation of its services.

To prevent session creation attacks, configure session creation rate limit to enable the device to limit the receiving rates of inbound packets for new sessions.

Blacklist feature

IP blacklist

The IP blacklist feature uses the source or destination IP addresses to filter packets.

- **Source IP blacklist**—Blocks packets if the source IP address of the packets matches a source IP blacklist entry.
- **Destination IP blacklist**—Blocks packets if the destination IP address of the packets matches a destination IP blacklist entry.

Compared with ACL-based packet filtering, IP blacklist filtering is simpler and provides effective screening at a faster speed.

User blacklist

The user blacklist feature is an attack prevention method that filters packets by source users in blacklist entries. Compared with IP blacklist filtering, user blacklist filtering performs access control on the user level and improves the filtering usability.

The user blacklist feature must be used together with the user identification feature. User identification provides the mappings between usernames and IP addresses for the user blacklist. For more information about user identification, see "Configuring user identification."

Address object group blacklist

The address object group blacklist feature is an attack prevention method that filters packets by address object group. The address object group blacklist feature must be used together with the address object group feature. An address object group is a set of IP address objects. For more information about address object groups, see "Configuring object groups." Compared with IP blacklist filtering, address object group blacklist filtering performs access control for subnets and improves the filtering usability.

Address object group whitelist

The address object group whitelist feature exempts packets from the whitelisted address object group from attack detection. Packets from the whitelisted address object group are directly forwarded whether they are attack packets or not. The address object group whitelist feature must be used together with the address object group feature. An address object group is a set of IP address objects. For more information about address object groups, see "Configuring object groups."

Client verification

TCP client verification

The TCP client verification feature protects TCP servers against the following flood attacks:

- SYN.
- ACK.
- SYN-ACK.
- FIN.
- RST.

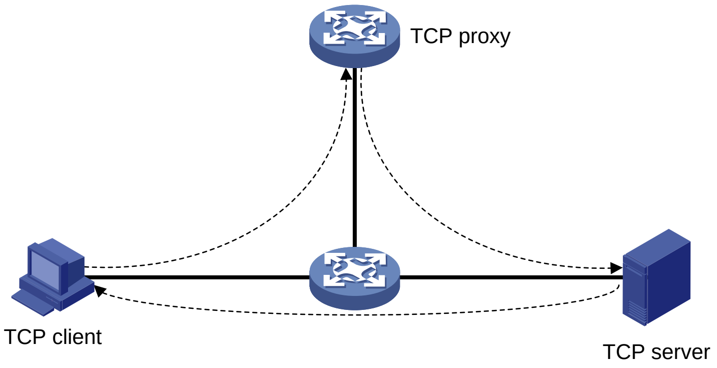
The TCP client verification feature enables a TCP proxy on the device.

TCP client verification can operate in the following modes:

- **Safe reset**—Enables unidirectional TCP proxy for packets only from TCP connection initiators. The unidirectional TCP proxy is sufficient for most scenarios because attacks are often seen from clients.

  As shown in Figure 1, if packets from TCP clients pass through the proxy device, but the packets from servers do not, only the safe reset mode can be used.

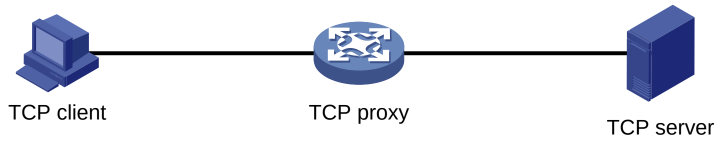
  Figure 1 Safe reset mode application



- **SYN cookie**—Enables bidirectional TCP proxy for TCP clients and servers.

As shown in Figure 2, if packets from clients and servers pass through the TCP proxy device, either safe reset or SYN cookie can be used.

Figure 2 Safe reset/SYN cookie mode application



TCP proxy in safe reset mode

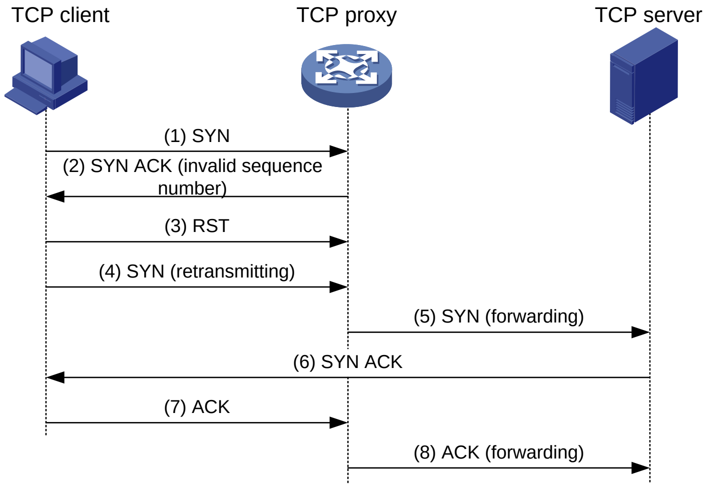
As shown in Figure 3, the safe reset mode functions as follows:

1. After receiving a SYN packet destined for a protected server, the TCP proxy sends back a SYN ACK packet with an invalid sequence number.
2. If the TCP proxy receives an RST packet from the client, the client is verified as legitimate.
3. The TCP proxy adds the client's IP address to the trusted IP list. The client initiates the connection again and the TCP proxy directly forwards the TCP packets to the server.

The safe reset mode requires that TCP clients comply with the TCP protocol suite. The TCP proxy will deny a legitimate client to access the server if the client does not comply with the TCP protocol suite.

With client verification, the TCP connection establishment takes more time than normal TCP connection establishment.

Figure 3 TCP proxy in safe reset mode



TCP proxy in SYN cookie mode

As shown in Figure 4, SYN cookie mode requires two TCP connections to be established as follows:

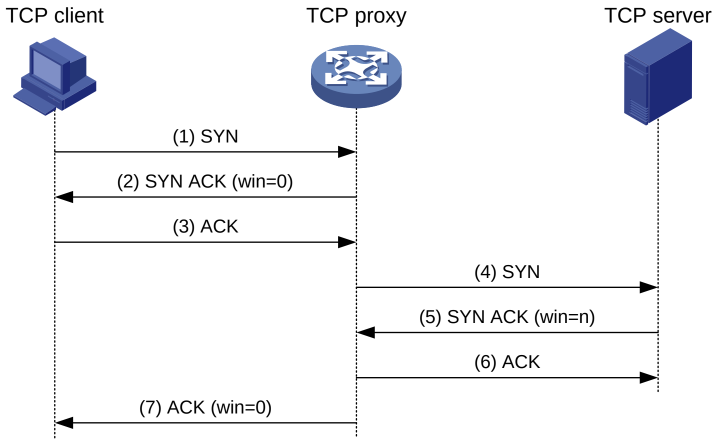
1. After receiving a SYN packet from a client to a protected server, the TCP proxy sends back a SYN ACK packet with the window size 0. If the client responds with an ACK packet, the client is verified as legitimate. The proxy device establishes a TCP connection with the client.
2. The TCP proxy device establishes a connection with the server through a new three-way handshake that has a different window size. This connection uses a different sequence number from the connection between the client and proxy device.

In SYN cookie mode, the TCP proxy is the server proxy that communicates with clients and the client proxy that communicates with server. Choose this mode when the following requirements are met:

- The TCP proxy device is deployed on the key path that passes through the ingress and egress of the protected server.

- All packets exchanged between clients and server pass through the TCP proxy device.

Figure 4 TCP proxy in SYN cookie mode



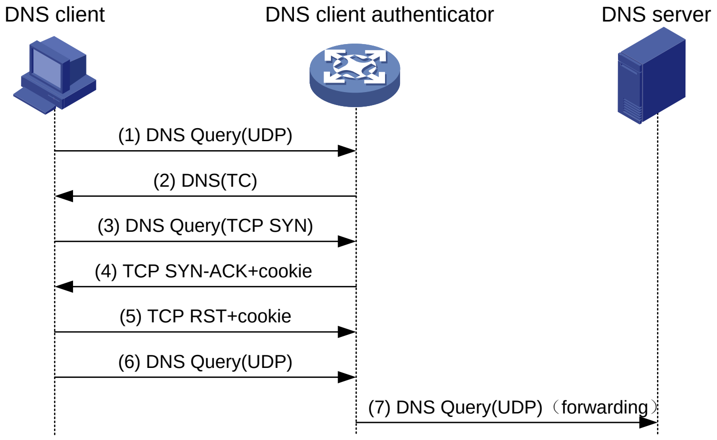
DNS client verification

The DNS client verification feature protects DNS servers against DNS flood attacks. It is configured on the device where packets from the DNS clients to the DNS servers pass through. The device with DNS client verification feature configured is called a DNS client authenticator.

As shown in Figure 5, the DNS client verification functions as follows:

1. Upon receiving a UDP DNS query destined for a protected server, the DNS client authenticator responds with a DNS truncate (TC) packet. The DNS truncate packet requires the client to initiate a query in a TCP packet.
2. When the authenticator receives a DNS query in a TCP SYN packet to port 53 from the client, the authenticator responds with a SYN-ACK packet that contains an incorrect sequence number.
3. When the authenticator receives a RST packet from the client, the authenticator verifies the client as legitimate.
4. The authenticator adds the client's IP address to the trusted IP list and forwards the trusted client's subsequent packets to the server.

Figure 5 DNS client verification process



The DNS client verification feature requires that clients use the standard TCP/IP protocol suite and DNS protocol. Legitimate clients that use non-standard protocols will be verified as illegitimate by the DNS client authenticator.

With client verification, the first DNS resolution takes more time than normal DNS resolution.

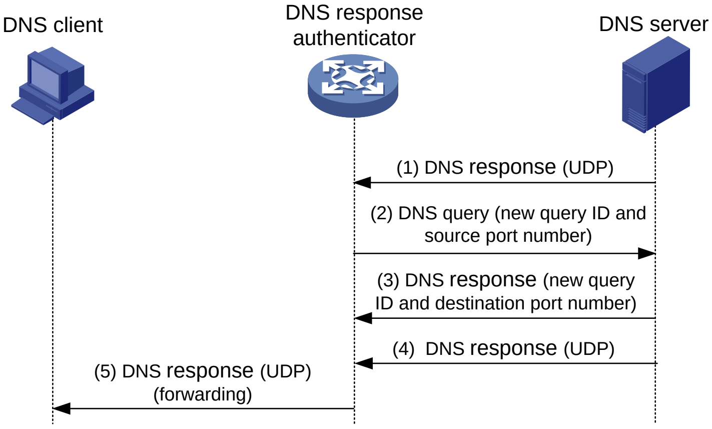
DNS response verification

The DNS response verification feature protects DNS clients against DNS response flood attacks. It is configured on the device where packets from the DNS servers to the DNS clients pass through. The device with DNS response verification feature configured is called a DNS response authenticator.

As shown in Figure 6, the DNS response verification functions as follows:

1. Upon receiving a UDP DNS response destined for a protected client, the DNS response authenticator sends back a DNS query packet with the locally generated query ID and port number.
2. After receiving the DNS query, a valid DNS server responds with a DNS response that contains a new query ID and destination port.
3. The DNS response authenticator verifies the query ID and destination port in the response. If the query ID and destination port are the same as the query ID and port number the authenticator has sent, the DNS server passes verification. The authenticator will forward subsequent packets from the server.

Figure 6 DNS response verification process



DNS client
DNS response authenticator
DNS server
(1) DNS response (UDP)
(2) DNS query (new query ID and source port number)
(3) DNS response (new query ID and destination port number)
(4) DNS response (UDP)
(5) DNS response (UDP) (forwarding)

HTTP client verification

The HTTP client verification feature protects HTTP servers against HTTP flood attacks. It is configured on the device where HTTP GET or POST request packets from the HTTP clients to the HTTP servers pass through. A device with HTTP client verification feature configured is called an HTTP client authenticator.

GET request-based verification

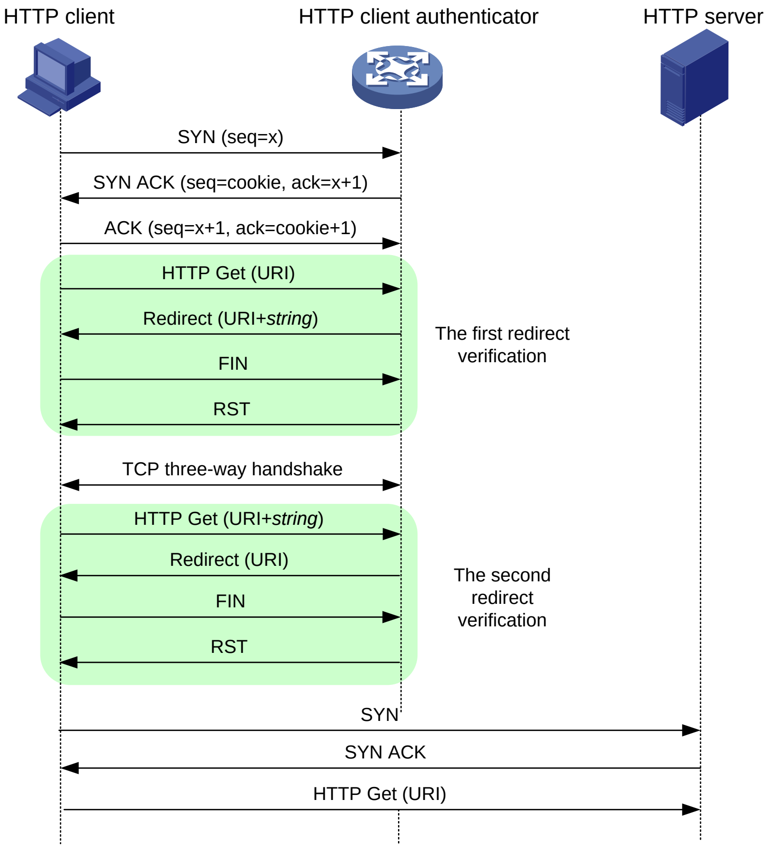
As shown in Figure 7, the HTTP client authenticator uses HTTP GET requests to verify the HTTP client as follows:

1. Upon receiving a SYN packet destined for a protected HTTP server, the HTTP client authenticator performs TCP client verification in SYN cookie mode. If the client passes the TCP client verification, a TCP connection is established between the client and the authenticator. For more information about TCP client verification, see "TCP client verification."
2. When the authenticator receives an HTTP GET packet from the client, it performs the first redirect verification. The authenticator records the client information and responds with an

HTTP Redirect packet. The HTTP Redirect packet contains a redirect URI and requires the client to terminate the TCP connection.

3. After receiving the HTTP Redirect packet, the client terminates the TCP connection and then establishes a new TCP connection with the authenticator.
4. When the authenticator receives the HTTP GET packet, it performs the second redirection verification. The authenticator verifies the following information:
   - The client has passed the first redirection verification.
   - The URI in the HTTP GET packet is the redirect URI.
5. If the client passes the second redirection verification, the authenticator adds its IP address to the trusted IP list, and responds a Redirect packet. The Redirect packet contains the URI that the client originally carried and requires the client to terminate the TCP connection.
6. The authenticator directly forwards the trusted client's subsequent packets to the server.

Figure 7 HTTP client verification process



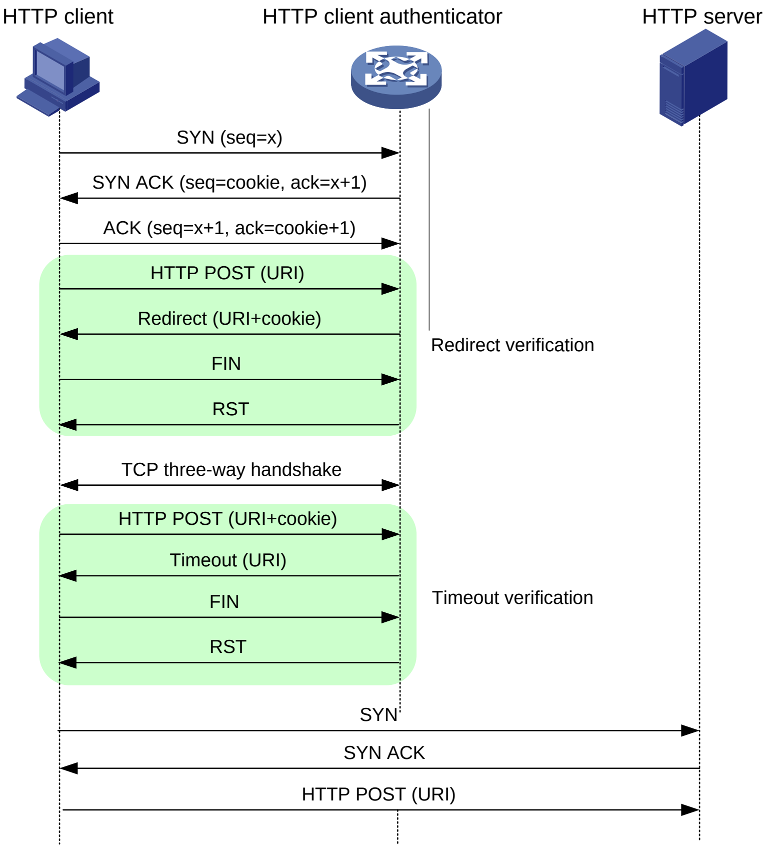
POST request-based verification

As shown in Figure 8, the HTTP client authenticator uses HTTP POST requests to verify the HTTP client as follows:

1. Upon receiving a SYN packet destined for a protected HTTP server, the HTTP client authenticator performs TCP client verification in SYN Cookie mode. If the client passes the TCP client verification, a TCP connection is established between the client and the authenticator. For more information about TCP client verification, see "TCP client verification."
2. When the authenticator receives an HTTP POST request from the client, it performs the redirect verification. The authenticator records the client information and responds with an HTTP Redirect packet. The HTTP Redirect packet contains a redirect URI and the Set-Cookie header, and requires the client to terminate the TCP connection.

3. After receiving the HTTP Redirect packet, the client terminates the TCP connection and then establishes a new TCP connection with the authenticator.
4. When the authenticator receives the HTTP POST request, it performs the timeout verification. The authenticator verifies the following information:
   - The client has passed the redirection verification.
   - The HTTP POST request contains a valid cookie.
5. If the client passes the timeout verification, the authenticator adds its IP address to the trusted IP list, and responds with an HTTP Timeout packet. The Timeout packet contains the URI that the client originally carried and requires the client to terminate the TCP connection.
6. The authenticator directly forwards the trusted client's subsequent packets to the server.

Figure 8 POST request-based verification process



SIP client verification

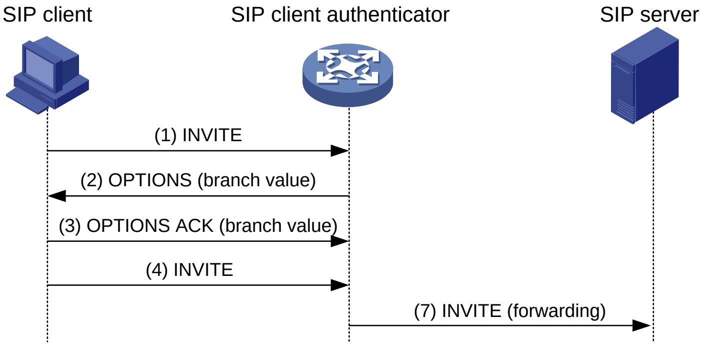
The SIP client verification feature protects SIP servers against SIP flood attacks. It is configured on the device where SIP INVITE request packets from the SIP clients to the SIP servers pass through. A device with the SIP client verification feature configured is called an SIP client authenticator.

As shown in Figure 9, the SIP client verification functions as follows:

1. Upon receiving a UDP INVITE packet destined for a protected server, the SIP client authenticator sends back an OPTIONS packet with a branch value.
2. After receiving the OPTIONS packet, the client sends an OPTIONS ACK to the SIP client authenticator.
3. When receiving the OPTIONS ACK, the SIP client authenticator verifies the branch value in the OPTIONS ACK.

- If the branch value in the OPTIONS ACK is the same as the branch value in the OPTIONS packet that the SIP client authenticator has sent, the client passes verification. The authenticator will forward subsequent packets from the client.
- If the branch value in the OPTIONS ACK is different from the branch value in the OPTIONS packet that the SIP client authenticator has sent, the client fails verification. The authenticator drops packets from the client.

Figure 9 SIP client verification process



Attack detection and prevention tasks at a glance

To configure attack detection and prevention, perform the following tasks:

1. Configuring and applying an attack defense policy
   a. Creating an attack defense policy
   b. Configuring an attack defense policy
      Choose the following tasks as needed:
      - Configuring a single-packet attack defense policy
      - Configuring a scanning attack defense policy
      - Configuring a flood attack defense policy
      - Configuring an HTTP slow attack defense policy
   c. (Optional.) Configuring attack detection exemption
   d. Applying an attack defense policy to a security zone
2. (Optional.) Configuring single-packet attack detection and prevention
3. (Optional.) Enabling log non-aggregation for single-packet attack events
4. (Optional.) Enabling the top attack statistics ranking feature
5. (Optional.) Configuring client verification
   Use this feature separately or jointly with a flood attack defense policy.
   - Configuring TCP client verification
   - Configuring DNS client verification
   - Configuring HTTP client verification
   - Configuring SIP client verification
6. (Optional.) Configuring the blacklist feature
   Use this feature separately or jointly with a scanning attack defense policy.
   - Configuring the IP blacklist feature
   - Configuring the user blacklist feature
   - Configuring the address object group blacklist

7. (Optional.) Configuring the address object group whitelist
8. (Optional.) Configuring the login attack prevention feature

   Typically, this feature is separately used.

   - Configuring login attack prevention
   - Enabling the login delay
9. (Optional.) Limiting the creation rate of new sessions

   Typically, this feature is separately used.
10. (Optional.) Configuring attack detection and prevention for a CPU core

Configuring and applying an attack defense policy

Creating an attack defense policy

About this task

An attack defense policy contains a set of attack detection and prevention configuration.

To configure attack defense configuration such as detection signatures and protection actions, you must first create an attack defense policy and enter its view.

Restrictions and guidelines

△ **CAUTION:**

The default thresholds for triggering attack prevention might not be appropriate for your network. Set appropriate thresholds according to the actual application scenarios. Small thresholds might affect the Internet or webpage access speed. Large thresholds might make your network vulnerable to attacks.

Procedure

1. Enter system view.

   `system-view`
2. Create an attack defense policy and enter its view.

   `attack-defense policy` *`policy-name`*

Configuring a single-packet attack defense policy

About this task

Apply the single-packet attack defense policy to the security zone that is connected to the external network.

Single-packet attack detection inspects incoming packets based on the packet signature. If an attack packet is detected, the device can take the following actions:

- Output logs (the default action).
- Drop attack packets.

You can also configure the device to not take any actions.

Restrictions and guidelines

The **`logging`** keyword enables the attack detection and prevention module to log single-packet attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output single-packet attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view single-packet attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Configure signature detection for specific single-packet attack types, and specify the actions against the attacks.

   - Configure signature detection for well-known single-packet attacks, and specify the actions against the attacks.

     signature detect { **fraggle** | **fragment** | **impossible** | **land** | **large-icmp** | **large-icmpv6** | **smurf** | **snork** | **tcp-all-flags** | **tcp-fin-only** | **tcp-invalid-flags** | **tcp-null-flag** | **tcp-syn-fin** | **tiny-fragment** | **traceroute** | **udp-bomb** | **winnuke** } [**action** { { **drop** | **logging** } * | **none** }]

     signature detect { **ip-option-abnormal** | **ping-of-death** | **teardrop** } **action** { **drop** | **logging** } *

   - Configure signature detection for ICMP packet attacks, and specify the actions against the attacks.

     signature detect icmp-type { *icmp-type-value* | **address-mask-reply** | **address-mask-request** | **destination-unreachable** | **echo-reply** | **echo-request** | **information-reply** | **information-request** | **parameter-problem** | **redirect** | **source-quench** | **time-exceeded** | **timestamp-reply** | **timestamp-request** } [**action** { { **drop** | **logging** } * | **none** }]

   - Configure signature detection for ICMPv6 packet attacks, and specify the actions against the attacks.

     signature detect icmpv6-type { *icmpv6-type-value* | **destination-unreachable** | **echo-reply** | **echo-request** | **group-query** | **group-reduction** | **group-report** | **packet-too-big** | **parameter-problem** | **time-exceeded** } [**action** { { **drop** | **logging** } * | **none** }]

   - Configure signature detection for IP option attacks, and specify the actions against the attacks.

     signature detect ip-option { *option-code* | **internet-timestamp** | **loose-source-routing** | **record-route** | **route-alert** | **security** | **stream-id** | **strict-source-routing** } [**action** { { **drop** | **logging** } * | **none** }]

   - Configure signature detection for IPv6 extension header attacks, and specify the actions against the attacks.

     signature detect ipv6-ext-header *ext-header-value* [**action** { { **drop** | **logging** } * | **none** }]

- Configure signature detection for abnormal IPv6 extension header attacks, and specify the actions against the attacks.

  signature detect ipv6-ext-header-abnormal [**action** { { **drop** | **logging** } * | **none** }]

- Configure signature detection for IPv6 extension header exceeded attacks, and specify the actions against the attacks.

  signature detect ipv6-ext-header-exceed [**limit** *limit-value*] [**action** { { **drop** | **logging** } * | **none** }]

By default, signature detection is not configured for single-packet attacks.

4. (Optional.) Set the maximum length of safe ICMP or ICMPv6 packets.

   signature { **large-icmp** | **large-icmpv6** } **max-length** *length*

   By default, the maximum length of safe ICMP or ICMPv6 packets is 4000 bytes.

5. (Optional.) Specify the actions against single-packet attacks of a specific level.

   signature level { **high** | **info** | **low** | **medium** } **action** { { **drop** | **logging** } * | **none** }

   The default action is **logging** for single-packet attacks of the informational and low levels.

   The default actions are **logging** and **drop** for single-packet attacks of the medium and high levels.

6. (Optional.) Enable signature detection for single-packet attacks of a specific level.

   signature level { **high** | **info** | **low** | **medium** } **detect**

   By default, signature detection is disabled for all levels of single-packet attacks.

Configuring a scanning attack defense policy

About this task

Apply a scanning attack defense policy to the security zone that is connected to the external network.

Scanning attack detection inspects the incoming packet rate of connections to the target system. If a source initiates connections at a rate equal to or exceeding the pre-defined threshold, the device can take the following actions:

- Output logs.
- Drop subsequent packets from the IP address of the attacker.
- Add the attacker's IP address to the IP blacklist.

If logging is specified for IP sweep and port scan attacks, the system outputs logs for only IP sweep attacks when both the IP sweep and port scan attack thresholds are reached.

Restrictions and guidelines

To blacklist the attackers, you must enable the blacklist feature globally or on the security zone where the defense policy is applied. For more information about the blacklist, see "Configuring the IP blacklist feature."

The **logging** keyword enables the attack detection and prevention module to log scanning attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output scanning attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view scanning attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Configure scanning attack detection.

   scan detect level { { **high** | **low** | **medium** } | **user-defined** { **port-scan-threshold** *threshold-value* | **ip-sweep-threshold** *threshold-value* } * [**period** *period-value*] } **action** { { **block-source** [**timeout** *minutes*] | **drop** } | **logging** } *

   By default, scanning attack detection is not configured.

Configuring a flood attack defense policy

About this task

Apply a flood attack defense policy to the security zone that is connected to the external network to protect internal servers.

Flood attack detection monitors the rate at which connections are initiated to the internal servers.

The device supports the following flood attack prevention types:

- **Source-based flood attack prevention**—Monitors the receiving rate of packets on a per-source IP basis. When the receiving rate of packets originating from an IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified defensive actions. Supported defensive actions include logging and dropping packets that originate from this IP address. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.
- **Destination-based flood attack prevention**—Monitors the receiving rate of packets on a per-destination IP basis. When the receiving rate of packets destined for an IP address keeps reaching or exceeding the threshold, the device enters prevention state and takes the specified actions. Supported defensive actions include logging, dropping subsequent packets destined for this IP address, and client verification. When the rate drops below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

An appropriate threshold can effectively prevent attacks. If the global threshold for triggering flood attack prevention is too low, false positives might occur, causing performance degradation or packet loss. If the global threshold is too high, false negatives might occur, making the network defenseless. Therefore, it is a good practice to enable the threshold learning feature for the device to automatically learn the global threshold. This feature allows the device to learn the global threshold based on the traffic flows in the network as follows:

1. Monitors the packet receiving rate in the network.
2. Calculates the global threshold based on the peak rate learned within the threshold learning duration.

You can choose to manually apply the learned threshold or configure the device to automatically apply the learned threshold.

The threshold learning feature includes the following modes:

- **One-time learning**—The device performs threshold learning only once.
- **Periodic learning**—The device performs threshold learning at intervals. The most recent learned threshold always takes effect.

Restrictions and guidelines for flood attack detection and prevention

If a device has multiple service cards, the global trigger threshold you set takes effect on each service card. The global trigger threshold of the device is the product of multiplying the value you set by the service card quantity.

You can configure flood attack detection and prevention for a specific IP address. Only destination-based flood attack prevention supports specifying IP addresses in the current software version. For non-specific IP addresses, the device uses the global attack prevention settings.

The **logging** keyword enables the attack detection and prevention module to log flood attack events and send log messages to the information center.

With the information center, you can set log message filtering and output rules, including output destinations.

The information center can output flood attack logs to any destinations except the console and the monitor terminal. If you configure the console or monitor terminal as an output destination, the output destination setting will not take effect.

To view flood attack logs stored on the device, use the **display logbuffer** command. Make sure you do not disable log output to the log buffer, which is enabled by default.

For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Configuring a SYN flood attack defense policy

1. Enter system view.
   system-view
2. Enter attack defense policy view.
   attack-defense policy *policy-name*
3. Enable global SYN flood attack detection.
   syn-flood detect non-specific
   By default, global SYN flood attack detection is disabled.
4. Set the global threshold for triggering source-based SYN flood attack prevention.
   syn-flood source-threshold *threshold-value*
   The default setting is 1000.
5. Set the global threshold for triggering destination-based SYN flood attack prevention.
   syn-flood threshold *threshold-value*
   The default setting is 10000.
6. Specify global actions against SYN flood attacks.
   syn-flood action { **client-verify** | **drop** | **logging** } *
   By default, no global action is specified for SYN flood attacks.
7. Configure IP address-specific SYN flood attack detection.
   syn-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **drop** | **logging** } * | **none** }]
   By default, IP address-specific SYN flood attack detection is not configured.

Configuring an ACK flood attack defense policy

1. Enter system view.
   system-view
2. Enter attack defense policy view.
   attack-defense policy *policy-name*

3. Enable global ACK flood attack detection.

   ack-flood detect non-specific

   By default, global ACK flood attack detection is disabled.

4. Set the global threshold for triggering source-based ACK flood attack prevention.

   ack-flood source-threshold *threshold-value*

   The default setting is 40000.

5. Set the global threshold for triggering destination-based ACK flood attack prevention.

   ack-flood threshold *threshold-value*

   The default setting is 40000.

6. Specify global actions against ACK flood attacks.

   ack-flood action { **client-verify** | **drop** | **logging** } *

   By default, no global action is specified for ACK flood attacks.

7. Configure IP address-specific ACK flood attack detection.

   ack-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **drop** | **logging** } * | **none** }]

   By default, IP address-specific ACK flood attack detection is not configured.

Configuring a SYN-ACK flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global SYN-ACK flood attack detection.

   syn-ack-flood detect non-specific

   By default, global SYN-ACK flood attack detection is disabled.

4. Set the global threshold for triggering source-based SYN-ACK flood attack prevention.

   syn-ack-flood source-threshold *threshold-value*

   The default setting is 10000.

5. Set the global threshold for triggering destination-based SYN-ACK flood attack prevention.

   syn-ack-flood threshold *threshold-value*

   The default setting is 10000.

6. Specify global actions against SYN-ACK flood attacks.

   syn-ack-flood action { **client-verify** | **drop** | **logging** }*

   By default, no global action is specified for SYN-ACK flood attacks.

7. Configure IP address-specific SYN-ACK flood attack detection.

   syn-ack-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **drop** | **logging** } * | **none** }]

   By default, IP address-specific SYN-ACK flood attack detection is not configured.

Configuring a FIN flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global FIN flood attack detection.

   fin-flood detect non-specific

   By default, global FIN flood attack detection is disabled.

4. Set the global threshold for triggering source-based FIN flood attack prevention.

   fin-flood source-threshold *threshold-value*

   The default setting is 10000.

5. Set the global threshold for triggering destination-based FIN flood attack prevention.

   fin-flood threshold *threshold-value*

   The default setting is 10000.

6. Specify global actions against FIN flood attacks.

   fin-flood action { **client-verify** | **drop** | **logging** } *

   By default, no global action is specified for FIN flood attacks.

7. Configure IP address-specific FIN flood attack detection.

   fin-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **drop** | **logging** } * | **none** }]

   By default, IP address-specific FIN flood attack detection is not configured.

Configuring an RST flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global RST flood attack detection.

   rst-flood detect non-specific

   By default, global RST flood attack detection is disabled.

4. Set the global threshold for triggering source-based RST flood attack prevention.

   rst-flood source-threshold *threshold-value*

   The default setting is 10000.

5. Set the global threshold for triggering destination-based RST flood attack prevention.

   rst-flood threshold *threshold-value*

   The default setting is 10000.

6. Specify global actions against RST flood attacks.

   rst-flood action { **client-verify** | **drop** | **logging** } *

   By default, no global action is specified for RST flood attacks.

7. Configure IP address-specific RST flood attack detection.

   rst-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **drop** | **logging** } * | **none** }]

   By default, IP address-specific RST flood attack detection is not configured.

Configuring an ICMP flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global ICMP flood attack detection.

   icmp-flood detect non-specific

   By default, global ICMP flood attack detection is disabled.

4. Set the global threshold for triggering source-based ICMP flood attack prevention.

   icmp-flood source-threshold *threshold-value*

   The default setting is 10000.

5. Set the global threshold for triggering destination-based ICMP flood attack prevention.

   icmp-flood threshold *threshold-value*

   The default setting is 10000.

6. Specify global actions against ICMP flood attacks.

   icmp-flood action { **drop** | **logging** } *

   By default, no global action is specified for ICMP flood attacks.

7. Configure IP address-specific ICMP flood attack detection.

   icmp-flood detect ip *ip-address* [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific ICMP flood attack detection is not configured.

Configuring an ICMPv6 flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global ICMPv6 flood attack detection.

   icmpv6-flood detect non-specific

   By default, global ICMPv6 flood attack detection is disabled.

4. Set the global threshold for triggering source-based ICMPv6 flood attack prevention.

   icmpv6-flood source-threshold *threshold-value*

   The default setting is 10000.

5. Set the global threshold for triggering destination-based ICMPv6 flood attack prevention.

   icmpv6-flood threshold *threshold-value*

   The default setting is 10000.

6. Specify global actions against ICMPv6 flood attacks.

   icmpv6-flood action { **drop** | **logging** } *

   By default, no global action is specified for ICMPv6 flood attacks.

7. Configure IP address-specific ICMPv6 flood attack detection.

   icmpv6-flood detect ipv6 *ipv6-address* [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific ICMPv6 flood attack detection is not configured.

Configuring a UDP flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global UDP flood attack detection.

udp-flood detect non-specific

By default, global UDP flood attack detection is disabled.

4. Set the global threshold for triggering source-based UDP flood attack prevention.

   udp-flood source-threshold *threshold-value*

   The default setting is 10000.

5. Set the global threshold for triggering destination-based UDP flood attack prevention.

   udp-flood threshold *threshold-value*

   The default setting is 10000.

6. Specify global actions against UDP flood attacks.

   udp-flood action { **drop** | **logging** } *

   By default, no global action is specified for UDP flood attacks.

7. Configure IP address-specific UDP flood attack detection.

   udp-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific UDP flood attack detection is not configured.

Configuring a DNS flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global DNS flood attack detection.

   dns-flood detect non-specific

   By default, global DNS flood attack detection is disabled.

4. Set the global threshold for triggering source-based DNS flood attack prevention.

   dns-flood source-threshold *threshold-value*

   The default setting is 10000.

5. Set the global threshold for triggering destination-based DNS flood attack prevention.

   dns-flood threshold *threshold-value*

   The default setting is 10000.

6. (Optional.) Specify the global ports to be protected against DNS flood attacks.

   dns-flood port *port-list*

   By default, DNS flood attack prevention protects port 53.

7. Specify global actions against DNS flood attacks.

   dns-flood action { **client-verify** | **drop** | **logging** } *

   By default, no global action is specified for DNS flood attacks.

8. Configure IP address-specific DNS flood attack detection.

   dns-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-list*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **drop** | **logging** } * | **none** }]

   By default, IP address-specific DNS flood attack detection is not configured.

Configuring a DNS response flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global DNS response flood attack detection.

   dns-reply-flood detect non-specific

   By default, global DNS response flood attack detection is disabled.

4. Set the global threshold for triggering source-based DNS response flood attack prevention.

   dns-reply-flood source-threshold *threshold-value*

   The default setting is 10000.

5. Set the global threshold for triggering destination-based DNS response flood attack prevention.

   dns-reply-flood threshold *threshold-value*

   The default setting is 10000.

6. (Optional.) Specify the global ports to be protected against DNS response flood attacks.

   dns-reply-flood port *port-list*

   By default, DNS response flood attack prevention protects port 53.

7. Specify global actions against DNS response flood attacks.

   dns-reply-flood action { **client-verify** | **drop** | **logging** } *

   By default, no global action is specified for DNS response flood attacks.

8. Configure IP address-specific DNS response flood attack detection.

   dns-reply-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-list*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **logging** } * | **none** }]

   By default, IP address-specific DNS response flood attack detection is not configured.

Configuring an HTTP flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global HTTP flood attack detection.

   http-flood detect non-specific

   By default, global HTTP flood attack detection is disabled.

4. Set the global threshold for triggering source-based HTTP flood attack prevention.

   http-flood source-threshold *threshold-value*

   The default setting is 10000.

5. Set the global threshold for triggering destination-based HTTP flood attack prevention.

   http-flood threshold *threshold-value*

   The default setting is 10000.

6. (Optional.) Specify the global ports to be protected against HTTP flood attacks.

   http-flood port *port-list*

   By default, HTTP flood attack prevention protects port 80.

7. Specify global actions against HTTP flood attacks.

   http-flood action { **client-verify** | **drop** | **logging** } *

   By default, no global action is specified for HTTP flood attacks.

8. Configure IP address-specific HTTP flood attack detection.

http-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-list*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **drop** | **logging** } * | **none** }]

By default, IP address-specific HTTP flood attack detection is not configured.

Configuring a SIP flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global SIP flood attack detection.

   sip-flood detect non-specific

   By default, global SIP flood attack detection is disabled.

4. Set the global threshold for triggering source-based SIP flood attack prevention.

   sip-flood source-threshold *threshold-value*

   The default setting is 10000.

5. Set the global threshold for triggering destination-based SIP flood attack prevention.

   sip-flood threshold *threshold-value*

   The default setting is 10000.

6. (Optional.) Specify the global ports to be protected against SIP flood attacks.

   sip-flood port *port-list*

   By default, SIP flood attack prevention protects port 5060.

7. Specify global actions against SIP flood attacks.

   sip-flood action { **client-verify** | **drop** | **logging** } *

   By default, no global action is specified for SIP flood attacks.

8. Configure IP address-specific SIP flood attack detection.

   sip-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-list*] [**threshold** *threshold-value*] [**action** { { **client-verify** | **drop** | **logging** } * | **none** }]

   By default, IP address-specific SIP flood attack detection is not configured.

Configuring threshold learning for flood attack prevention

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable the threshold learning feature for flood attack prevention.

   threshold-learn enable

   By default, the threshold learning feature for flood attack prevention is disabled.

4. (Optional.) Set the threshold learning mode.

   - To set the one-time learning mode:
     threshold-learn mode once
   - To set the periodic learning mode:
     threshold-learn mode periodic

   By default, the one-time learning mode is used.

5. (Optional.) Set the threshold learning duration.

threshold-learn duration *duration*

By default, the threshold learning duration is 1440 minutes.

6. (Optional.) Set the threshold learning interval.

   threshold-learn interval *interval*

   By default, the threshold learning interval is 1440 minutes.

   Skip this step for the one-time learning mode.

7. (Optional.) Set the threshold learning tolerance value.

   threshold-learn tolerance-value *tolerance-value*

   By default, the threshold learning tolerance is 50, in percentage.

   Skip this step if auto application of the learned threshold is disabled.

8. (Optional.) Enable auto application of the learned threshold.

   threshold-learn auto-apply enable

   By default, auto application of the learned threshold is disabled.

9. Apply the most recent threshold that the device has learned.

   threshold-learn apply

   This command does not take effect when auto application of the learned threshold is enabled.

Configuring an HTTP slow attack defense policy

About this task

The device enters HTTP slow attack detection state when the number of HTTP concurrent connections reaches the detection triggering threshold. If the device receives an HTTP slow attack packet later, an HTTP slow attack occurs. When the number of HTTP slow attack packets exceeds the threshold within the detection period, the device takes defensive actions.

HTTP slow attack defensive actions include logging the attack events and blacklisting IP addresses of attackers.

Restrictions and guidelines

To use blacklisting as a defensive action, enable the blacklist feature.

As a best practice, specify port 80 as the global port to be protected against HTTP slow attacks. If you specify other ports by using the **http-slow-attack port** command, make sure these ports are used for HTTP communication. If the specified ports are not used for HTTP communication, the device resources will be wasted in inspecting non-HTTP slow attack packets.

Procedure

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global HTTP slow attack detection.

   http-slow-attack detect non-specific

   By default, global HTTP slow attack detection is disabled.

4. Set the global thresholds for triggering HTTP slow attack prevention.

   http-slow-attack threshold [**alert-number** *alert-number* | **content-length** *content-length* | **payload-length** *payload-length* | **packet-number** *packet-number*]*

By default, thresholds for HTTP concurrent connections, the **Content-Length** field value, payload size, and abnormal packets are 5000, 10000, 50, and 10, respectively.

5. Set the global HTTP slow attack detection period.

   `http-slow-attack period` *`period`*

   By default, the global HTTP slow attack detection period is 60 seconds.

6. (Optional.) Specify the global ports to be protected against HTTP slow attacks.

   `http-slow-attack port` *`port-list`*

   By default, HTTP slow attack prevention protects port 80.

7. Specify global actions against HTTP slow attacks.

   `http-slow-attack action` { **`block-source`** [**`timeout`** *`minutes`*] | **`logging`** } *

   By default, no global action is specified for HTTP slow attacks.

8. Configure IP address-specific HTTP slow attack detection.

   `http-slow-attack detect` { **`ip`** *`ipv4-address`* | **`ipv6`** *`ipv6-address`* } [**`vpn-instance`** *`vpn-instance-name`*] [**`port`** *`port-list`*] [**`threshold`** { **`alert-number`** *`alert-number`* | **`content-length`** *`content-length`* | **`payload-length`** *`payload-length`* | **`packet-number`** *`packet-number`* }*] [**`period`** *`period`*] [**`action`** { **`block-source`** [**`timeout`** *`minutes`*] | **`logging`** }*]

   By default, IP address-specific HTTP slow attack detection is not configured.

Configuring attack detection exemption

About this task

The attack defense policy uses the ACL to identify exempted packets. The policy does not check the packets permitted by the ACL. You can configure the ACL to identify packets from trusted servers. The exemption feature reduces the false alarm rate and improves packet processing efficiency. For example, the attack defense policy identifies multicast packets with the same source addresses and different destination addresses as scanning attack packets (for example, OSPF or PIM packets). You can configure an ACL to exempt such packets from attack detection.

Restrictions and guidelines

If an ACL is used for attack detection exemption, only the following match criteria in the ACL permit rules take effect:

- Source IP address.
- Destination IP address.
- Source port.
- Destination port.
- Protocol.
- L3VPN instance.
- The **`fragment`** keyword for matching non-first fragments.

Procedure

1. Enter system view.

   `system-view`

2. Enter attack defense policy view.

   `attack-defense policy` *`policy-name`*

3. Configure attack detection exemption.

exempt acl [**ipv6**] { *acl-number* | **name** *acl-name* }

By default, attack detection exemption is not configured.

Applying an attack defense policy to a security zone

1. Enter system view.

   system-view

2. Enter security zone view.

   security-zone name *zone-name*

3. Apply an attack defense policy to the security zone.

   attack-defense apply policy *policy-name*

   By default, no attack defense policy is applied to the security zone.

Configuring single-packet attack detection and prevention globally

About this task

The global single-packet attack detection and prevention (also called the malformed packet attack detection and prevention) drops malformed packets of the following attacks on each interface:

- IP impossible packet attack.
- TCP packet attacks that use TCP packets with different flag settings (all flags set, only the FIN flag set, invalid flags, no flags set, and both SYN and FIN flags set).
- Land attack and WinNuke attack.
- UDP fraggle attack, UDP bomb attack, and UDP snork attack.

Restrictions and guidelines

The feature is more efficient than a single-packet attack defense policy in defend against malformed packet attacks. When this feature is enabled, you do not need to configure a single-packet attack defense policy to prevent attacks of the listed malformed packets.

Procedure

1. Enter system view.

   system-view

2. Enable malformed packet attack detection and prevention.

   attack-defense malformed-packet defend enable

   By default, malformed attack detection and prevention is enabled.

Enabling log non-aggregation for single-packet attack events

About this task

Log aggregation aggregates multiple logs generated during a period of time and sends one log. Logs that are aggregated must have the following attributes in common:

- Attacks are detected on the same security zone or are destined for the device.
- Attack type.

- Attack defense action.
- Source and destination IP addresses.
- VPN instance to which the victim IP address belongs.

Restrictions and guidelines

As a best practice, do not disable log aggregation. A large number of logs will consume the display resources of the console.

Procedure

1. Enter system view.
   `system-view`
2. Enable log non-aggregation for single-packet attack events.
   `attack-defense signature log non-aggregate`
   By default, log non-aggregation is disabled for single-packet attack events.

Enabling the top attack statistics ranking feature

About this task

This feature collects statistics about dropped attack packets based on attacker, victim, and attack type and ranks the top attack statistics by attacker and victim. To display the top attack statistics rankings, use the **`display attack-defense top-attack-statistics`** command.

Procedure

1. Enter system view.
   `system-view`
2. Enable the top attack statistics ranking feature.
   `attack-defense top-attack-statistics enable`
   By default, the top attack statistics ranking feature is disabled.

Configuring TCP client verification

About this task

Configure TCP client verification on the security zone that is connected to the external network. TCP client verification protects internal TCP servers against TCP flood attacks, including the following flood attacks:

- SYN.
- SYN-ACK.
- RST.
- FIN.
- ACK.

IP addresses protected by TCP client verification can be manually added or automatically learned:

- You can manually add protected IP addresses. The device performs client verification when it receives the first SYN packet destined for a protected IP address.
- The TCP client verification can automatically add victims' IP addresses to the protected IP list when collaborating with flood attack detection. Make sure **`client-verify`** is specified as the flood attack prevention action. For more information, see "Configuring a flood attack defense policy."

If a TCP client is verified legitimate in **safe reset** mode, the device adds the client's IP address to the trusted IP list. The device directly forwards TCP packets from trusted IP addresses.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Specify an IP address to be protected by the TCP client verification feature.

   client-verify tcp protected { **ip** *destination-ip-address* | **ipv6** *destination-ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-number*]

3. Enter security zone view.

   security-zone name *zone-name*

4. Enable TCP client verification.

   - Set the safe reset mode.

     client-verify tcp enable mode safe-reset

   - Set the SYN cookie mode.

     client-verify tcp enable [**mode syn-cookie**]

   By default, TCP client verification is disabled.

Configuring DNS client verification

About this task

Configure DNS client verification on the security zone that is connected to the external network. The DNS client verification protects internal DNS servers against DNS flood attacks.

IP addresses protected by DNS client verification can be manually added or automatically learned:

- You can manually add protected IP addresses. The device performs client verification when it receives the first DNS query destined for a protected IP address.
- The DNS client verification can automatically add victims' IP addresses to the protected IP list when collaborating with DNS flood attack detection. Make sure **client-verify** is specified as the DNS flood attack prevention action. For more information, see "Configuring a DNS flood attack defense policy."

If a DNS client is verified legitimate, the device adds the client's IP address to the trusted IP list. The device directly forwards DNS packets from trusted IP addresses.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Specify an IP address to be protected by the DNS client verification feature.

   client-verify dns protected { **ip** *destination-ip-address* | **ipv6** *destination-ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-number*]

3. Entersecurity zone view.

   security-zone name *zone-name*

4. Enable DNS client verification.

   client-verify dns enable

   By default, DNS client verification is disabled.

Configuring DNS response verification

About this task

Configure DNS response verification on the interface or security zone that is connected to the external network. The DNS response verification protects internal DNS clients against DNS response flood attacks.

IP addresses protected by DNS response verification can be manually added or automatically learned:

- You can manually add protected IP addresses. The device performs response verification when it receives the first DNS response destined for a protected IP address.
- The DNS response verification can automatically add victims' IP addresses to the protected IP list when collaborating with DNS response flood attack detection. Make sure **client-verify** is specified as the DNS response flood attack prevention action. For more information, see "Configuring a DNS response flood attack defense policy."

If a DNS server is verified legitimate, the device adds the client's IP address to the trusted IP list. The device directly forwards DNS responses from trusted IP addresses.

Restrictions and guidelines

The DNS response verification feature requires that servers use the standard TCP/IP protocol suite and DNS protocol. Legitimate servers that use non-standard protocols will be verified as illegitimate by the DNS response authenticator.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Specify an IP address to be protected by the DNS response verification feature.

   Client-verify dns-reply protected { **ip** *destination-ip-address* | **ipv6** *destination-ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-number*]

3. Enter interface/security zone view.

   interface *interface-type interface-number*

   security-zone name *zone-name*

4. Enable DNS response verification.

   client-verify dns-reply enable

   By default, DNS response verification is disabled.

Configuring HTTP client verification

About this task

Configure HTTP client verification on the security zone that is connected to the external network. The HTTP client verification protects internal HTTP servers against HTTP flood attacks.

IP addresses protected by HTTP client verification can be manually added or automatically learned:

- You can manually add protected IP addresses. The device performs client verification when it receives the first HTTP GET or POST packet destined for a protected IP address.
- The HTTP client verification can automatically add victims' IP addresses to the protected IP list when collaborating with HTTP flood attack detection. Make sure **client-verify** is specified as the HTTP flood attack prevention action. For more information, see "Configuring an HTTP flood attack defense policy."

If an HTTP client is verified legitimate, the device adds the client's IP address to the trusted IP list. The device directly forwards HTTP packets from trusted IP addresses.

Procedure

1. Enter system view.

   `system-view`

2. (Optional.) Specify an IP address to be protected by the HTTP client verification feature.

   `client-verify http protected` { **`ip`** *`destination-ip-address`* | **`ipv6`** *`destination-ipv6-address`* } [**`vpn-instance`** *`vpn-instance-name`*] [**`port`** *`port-number`*]

3. Enter security zone view.

   `security-zone name` *`zone-name`*

4. Enable HTTP client verification.

   `client-verify http enable`

   By default, HTTP client verification is disabled.

Configuring SIP client verification

About this task

Configure SIP client verification on the security zone that is connected to the external network. The SIP client verification protects internal SIP servers against SIP flood attacks.

IP addresses protected by SIP client verification can be manually added or automatically learned:

- You can manually add protected IP addresses. The device performs client verification when it receives the first INVITE packet destined for a protected IP address.
- The SIP client verification can automatically add victims' IP addresses to the protected IP list when collaborating with SIP flood attack detection. Make sure **client-verify** is specified as the SIP flood attack prevention action. For more information, see "Configuring a SIP flood attack defense policy."

If a SIP client is verified legitimate, the device adds the client's IP address to the trusted IP list. The device directly forwards SIP packets from trusted IP addresses.

Restrictions and guidelines

A legitimate SIP client might not pass the client verification if packets sent by the SIP client do not contain complete header information due to fragmentation.

Procedure

1. Enter system view.

   `system-view`

2. (Optional.) Specify an IP address to be protected by the SIP client verification feature.

   `client-verify sip protected` { **`ip`** *`destination-ip-address`* | **`ipv6`** *`destination-ipv6-address`* } [**`vpn-instance`** *`vpn-instance-name`*] [**`port`** *`port-number`*]

3. Enter security zone view.

   `security-zone name` *`zone-name`*

4. Enable SIP client verification.

   `client-verify sip enable`

   By default, SIP client verification is disabled.

Configuring the IP blacklist feature

About this task

The IP blacklist feature filters packets sourced from or destined for IP addresses in blacklist entries. If the global blacklist feature is enabled, the blacklist feature is enabled on all security zones.

You can manually add source or destination IP blacklist entries. When creating such an entry, you can set an aging time for it. Entries without the aging time do not age out unless you delete them manually.

The device can automatically add source IP blacklist entries when collaborating with scanning attack detection. Each dynamically learned source IP blacklist entry has an aging time, which is user configurable. Make sure the **block-source** keyword is specified as the scanning attack prevention action. For more information about the scanning attack detection and prevention, see "Configuring a scanning attack defense policy."

Procedure

1. Enter system view.

   system-view

2. (Optional.) Add an IP blacklist entry.
   - Add a source IPv4 blacklist entry.

     blacklist ip *source-ip-address* [**vpn-instance** *vpn-instance-name*] [**ds-lite-peer** *ds-lite-peer-address*] [**timeout** *minutes*]
   - Add a source IPv6 blacklist entry.

     blacklist ipv6 *source-ipv6-address* [**vpn-instance** *vpn-instance-name*] [**timeout** *minutes*]
   - Add a destination IPv4 blacklist entry.

     blacklist destination-ip *destination-ip-address* [**vpn-instance** *vpn-instance-name*] [**timeout** *minutes*]
   - Add a destination IPv6 blacklist entry.

     blacklist destination-ipv6 *destination -ipv6-address* [**vpn-instance** *vpn-instance-name*] [**timeout** *minutes*]

3. (Optional.) Enable logging for the blacklist feature.

   blacklist logging enable

   By default, logging is disabled for the blacklist feature.

4. Enable the blacklist feature. Choose one option as needed:
   - Enable the global blacklist feature.

     blacklist global enable

     By default, the global blacklist feature is disabled.
   - Execute the following commands in sequence to enable the blacklist feature on a security zone:

     security-zone name *zone-name*

     blacklist enable

     By default, the blacklist feature is disabled on the /security zone.

Configuring the user blacklist feature

About this task

The user blacklist feature filters packets sourced from users in blacklist entries.

A user blacklist entry can only be manually added by using the **`blacklist user`** command. When creating such an entry, you can set an aging time for it. Entries without the aging time do not age out unless you delete them manually.

Restrictions and guidelines

The user blacklist feature must be used together with the user identification feature. For more information about user identification, see "Configuring user identification."

Procedure

1. Enter system view.

   `system-view`

2. Enable the global blacklist feature.

   `blacklist global enable`

   By default, the global blacklist feature is disabled.

3. Add a user blacklist entry.

   `blacklist user` *`user-name`* `[` **`domain`** *`domain-name`* `] [` **`timeout`** *`minutes`* `]`

4. (Optional.) Enable logging for the blacklist feature.

   `blacklist logging enable`

   By default, logging is disabled for the blacklist feature.

Configuring the address object group blacklist

About this task

This feature filters packets sourced from the subnets specified in the blacklisted address object group.

Restrictions and guidelines

An address object group can only be manually added to or deleted from the blacklist.

The address object group blacklist feature must be used together with the address object group feature. For more information about address object groups, see "Configuring object groups."

Procedure

1. Enter system view.

   `system-view`

2. Add an address object group to the blacklist.

   `blacklist object-group` *`object-group-name`*

   By default, no address object group is on the blacklist.

3. Enable the blacklist feature. Choose one option as needed:

   - Enable the global blacklist feature.

     `blacklist global enable`

     By default, the global blacklist feature is disabled.

   - Enter security zone view and enable the blacklist feature on the security zone.

     `security-zone name` *`zone-name`*

blacklist enable

By default, the blacklist feature is disabled on the security zone.

Configuring the address object group whitelist

About this task

This feature exempts packets sourced from the subnets specified in the whitelisted address object group from attack detection.

Restrictions and guidelines

An address object group can only be manually added to or deleted from the whitelist.

The address object group whitelist feature must be used together with the address object group feature. For more information about address object groups, see "Configuring object groups."

Procedure

1. Enter system view.

   system-view

2. Add an address object group to the whitelist.

   whitelist object-group *object-group-name*

   By default, no address object group is added to the whitelist.

3. Enable the whitelist feature. Choose one option as needed:

   - Enable the global whitelist feature.

     whitelist global enable

     By default, the global whitelist feature is disabled.

   - Enter security zone view and enable the whitelist feature on the security zone.

     security-zone name *zone-name*

     whitelist enable

     By default, the whitelist feature is disabled on the security zone.

Configuring login attack prevention

About this task

The login attack prevention feature detects a login DoS attack if a user fails the maximum number of successive login attempts. The feature triggers the blacklist feature to add the user's IP to the blacklist. Following login attempts from the user is blocked for the block period. For login attack prevention to take effect, you must enable the global blacklist feature.

This feature can effectively prevent login DoS attacks.

Restrictions and guidelines

The login attack prevention feature takes effect on users logging in through HTTP/HTTPS (including Web, NETCONF, AND RESTful), Telnet, terminal, SSH, and FTP. It does not support SNMP logins.

The login attack prevention feature takes effect on logins using local authentication or remote AAA server authentication.

To ensure that this feature can add a user's IP address to the blacklist after the user fails the maximum number of successive login attempts, complete the following configuration:

- Make sure the user's username exists on the device if the device performs local authentication for the user.

- Make sure the AAA server is reachable and well configured if the device uses remote AAA authentication for the user.

Procedure

1. Enter system view.

   `system-view`

2. Enable login attack prevention.

   `attack-defense login enable`

   By default, login attack prevention is disabled.

3. Set the maximum number of successive login failures.

   `attack-defense login max-attempt` *`max-attempt`*

   The default value is three.

4. Set the block period during which a login attempt is blocked.

   `attack-defense login block-timeout` *`minutes`*

   The default value is 60 minutes.

5. Enable the global blacklist feature.

   `blacklist global enable`

   By default, the global blacklist feature is disabled.

Enabling the login delay

About this task

The login delay feature delays the device from accepting a login request from a user after the user fails a login attempt. This feature can slow down login dictionary attacks.

The login delay feature is independent of the login attack prevention feature.

Procedure

1. Enter system view.

   `system-view`

2. Enable the login delay feature.

   `attack-defense login reauthentication-delay` *`seconds`*

   By default, the login delay feature is disabled. The device does not delay accepting a login request from a user who has failed a login attempt.

Limiting the creation rate of new sessions

About this task

This feature limits the receiving rate of inbound packets for new sessions to a specific value. The device supports rate limiting session creation based on the following criteria:

- Source IPv4 addresses.
- Source IPv6 addresses.
- Destination IPv4 addresses.
- Destination IPv6 addresses.

After you enable rate limit and specify a criterion on an interface, the device monitors the receiving rate of inbound packets for the matching sessions on this interface. When the receiving rate reaches or exceeds the rate limit, the device takes defense actions.

Restrictions and guidelines

You cannot enable session creation rate limit based on both source and destination IP addresses on the same interface.

Procedure

1. Enter system view

   system-view

2. Set defense actions upon threshold violations for monitored sessions.

   attack-defense ipcar { **destination** | **source** } { **ip** | **ipv6** } [**threshold** *threshold*] **action** { { **drop** | **logging** } * | **none** }

   By default, the packet receiving rate threshold is 5000 pps for each monitored session, and no defense actions are set.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable session creation rate limit.

   attack-defense ipcar { **destination** | **source** } { **ip** | **ipv6** } **session-rate-limit enable**

   By default, session creation rate limit is disabled.

Configuring attack detection and prevention for a CPU core

About this task

After the usage of a CPU core reaches the specified threshold and the shared queue of the driver is full, the system determines that an attack risk is present on the CPU core. Then, it processes the subsequent packets sent to the CPU core as follows:

- **Drop**—The CPU core uses all its available processing capability to process packets. The driver drops the packets beyond the maximum processing capability to decrease the CPU core usage. This action affects normal service processing.
- **Per-packet balance**—The CPU core uses all its available processing capability to process packets. Packets exceeding the maximum processing capability are sent to other CPU cores for load sharing on a per-packet basis. This action ensures normal service processing to some extent, but leads to risk of attacks on other CPU cores.
- **Isolate**—The driver isolates the flow that uses the most CPU time to lower the flow's processing priority. It sends the isolated packets to the CPU core for processing after the shared queue has no packets to process. This action ensures normal service processing to some extent, but it cannot significantly decrease the CPU usage because the packets in the public queue are still sent to the CPU core for processing.
- **No attack prevention action**—The driver takes no attack prevention action and still sends subsequent packets to the CPU core.

To set the CPU usage threshold per CPU core, execute the **context-capability inbound unicast total** command. For more information about this command, see context commands in *Virtual Technologies Command Reference*.

Hardware and feature compatibility

Models	Feature compatibility
NFNX3-HDB3280, NFNX5-T6280, NFNX5-HD5280, NFNX5-HD6480	Yes

Models	Feature compatibility
NFNX3-HDB1180, NFNX3-HDB1480, NFNX3-HDB1780, NFNX3-HDB3080, NFNX3-HDB680, NFNX3-HDB1080	No

Procedure

1. Enter system view
   system-view
2. Specify an attack prevention action for CPU core protection.
   attack-defense cpu-core action { **drop** | **isolate** | **per-packet-balance** }
   By default, the attack prevention action for CPU core protection is **drop**.

Display and maintenance commands for attack detection and prevention

Use the **display** commands in any view and the **reset** commands in user view.

To display and maintain attack detection and prevention:

Task	Command
Display flood attack detection and prevention statistics for an IPv4 address.	**display attack-defense** { **ack-flood** | **dns-flood** | **dns-reply-flood** | **fin-flood** | **flood** | **http-flood** | **icmp-flood** | **rst-flood** | **sip-flood** | **syn-ack-flood** | **syn-flood** | **udp-flood** } **statistics ip** [*ip-address* [**vpn** *vpn-instance-name*]] [**count**] [**security-zone** *zone-name*] [**slot** *slot-number*] [**count**]
Display flood attack detection and prevention statistics for an IPv6 address.	**display attack-defense** { **ack-flood** | **dns-flood** | **dns-reply-flood** | **fin-flood** | **flood** | **http-flood** | **icmpv6-flood** | **rst-flood** | **sip-flood** | **syn-ack-flood** | **syn-flood** | **udp-flood** } **statistics ipv6** [*ipv6-address* [**vpn** *vpn-instance-name*]] [**security-zone** *zone-name*] [**slot** *slot-number*] [**count**]
Display statistics about IPv4 HTTP slow attack detection and prevention.	**display attack-defense http-slow-attack statistics ip** [*ip-address* [**vpn-instance** *vpn-instance-name*]] [**security-zone** *zone-name*] [**slot** *slot-number*] [**count**]
Display statistics about IPv6 HTTP slow attack detection and prevention.	**display attack-defense http-slow-attack statistics ipv6** [*ipv6-address* [**vpn-instance** *vpn-instance-name*]] [**security-zone** *zone-name*] [**slot** *slot-number*] [**count**]
Display statistics about malformed packets.	**display attack-defense malformed-packet statistics** [**slot** *slot-number*]
Display attack defense policy configuration.	**display attack-defense policy** [*policy-name*]
Display information about IPv4 addresses protected by flood attack	**display attack-defense policy** *policy-name* { **ack-flood** | **dns-flood** | **dns-reply-flood** |

Task	Command
detection and prevention.	**fin-flood** | **flood** | **http-flood** | **icmp-flood** | **rst-flood** | **sip-flood** | **syn-ack-flood** | **syn-flood** | **udp-flood** } **ip** [*ip-address* [**vpn** *vpn-instance-name*]] [**slot** *slot-number*] [**count**]
Display information about IPv6 addresses protected by flood attack detection and prevention.	**display attack-defense policy** *policy-name* { **ack-flood** | **dns-flood** | **dns-reply-flood** | **fin-flood** | **flood** | **http-flood** | **icmpv6-flood** | **rst-flood** | **sip-flood** | **syn-ack-flood** | **syn-flood** | **udp-flood** } **ipv6** [*ipv6-address* [**vpn** *vpn-instance-name*]] [**slot** *slot-number*] [**count**]
Display information about IPv4 scanning attackers.	**display attack-defense scan attacker ip** [**security-zone** *zone-name* [**slot** *slot-number*]] [**count**]
Display information about IPv6 scanning attackers.	**display attack-defense scan attacker ipv6** [**security-zone** *zone-name* [**slot** *slot-number*]] [**count**]
Display attack detection and prevention statistics on a security zone.	**display attack-defense statistics security-zone** *zone-name* [**slot** *slot-number*]
Display top 10 attack statistics.	**display attack-defense top-attack-statistics** { **last-1-hour** | **last-24-hours** | **last-30-days** } [**by-attacker** | **by-type** | **by-victim**]
Display destination IPv4 blacklist entries.	**display blacklist destination-ip** [*destination-ip-address* [**vpn-instance** *vpn-instance-name*]] [**slot** *slot-number*] [**count**]
Display destination IPv6 blacklist entries.	**display blacklist destination-ipv6** [*destination-ipv6-address* [**vpn-instance** *vpn-instance-name*]] [**slot** *slot-number*] [**count**]
Display source IPv4 blacklist entries.	**display blacklist ip** [*source-ip-address* [**vpn-instance** *vpn-instance-name*] [**ds-lite-peer** *ds-lite-peer-address*]] [**slot** *slot-number*] [**count**]
Display source IPv6 blacklist entries.	**display blacklist ipv6** [*source-ipv6-address* [**vpn-instance** *vpn-instance-name*]] [**slot** *slot-number*] [**count**]
Display user blacklist entries.	**display blacklist user** [*user-name*] [**domain** *domain-name*] [**count**]
Display protected IPv4 list entries for client verification.	**display client-verify** { **dns** | **dns-reply** | **http** | **sip** | **tcp** } **protected ip** [*ip-address* [**vpn** *vpn-instance-name*]] [**port** *port-number*] [**slot** *slot-number*] [**count**]
Display protected IPv6 addresses for client verification.	**display client-verify** { **dns** | **dns-reply** | **http** | **sip** | **tcp** } **protected ipv6** [*ipv6-address* [**vpn** *vpn-instance-name*]] [**port** *port-number*]

Task	Command
	[**slot** *slot-number*] [**count**]
Display trusted IPv4 addresses for client verification.	**display client-verify** { **dns** | **dns-reply** | **http** | **sip** | **tcp** } **trusted ip** [*ip-address* [**vpn** *vpn-instance-name*]] [**slot** *slot-number*] [**count**]
Display trusted IPv6 addresses for client verification.	**display client-verify** { **dns** | **dns-reply** | **http** | **sip** | **tcp** } **trusted ipv6** [*ipv6-address* [**vpn** *vpn-instance-name*]] [**slot** *slot-number*] [**count**]
Display statistics about packets that match the address object groups on the whitelist.	**display whitelist object-group** [*object-group-name*] [**slot** *slot-number*]
Clear statistics about malformed packets.	**reset attack-defense malformed-packet statistics**
Clear flood attack detection and prevention statistics.	**reset attack-defense policy** *policy-name* **flood protected** { **ip** | **ipv6** } **statistics**
Clear attack detection and prevention statistics for a security zone.	**reset attack-defense statistics security-zone** *zone-name*
Clear top 10 attack statistics.	**reset attack-defense top-attack-statistics**
Delete dynamic destination IPv4 blacklist entries.	**reset blacklist destination-ip** { *destination-ip-address* [**vpn-instance** *vpn-instance-name*] | **all** }
Delete dynamic destination IPv6 blacklist entries.	**reset blacklist destination-ipv6**{ *destination-ipv6-address* [**vpn-instance** *vpn-instance-name*] | **all** }
Delete dynamic source IPv4 blacklist entries.	**reset blacklist ip** { *source-ip-address* [**vpn-instance** *vpn-instance-name*] [**ds-lite-peer** *ds-lite-peer-address*] | **all** }
Delete dynamic source IPv6 blacklist entries.	**reset blacklist ipv6** { *source-ipv6-address* [**vpn-instance** *vpn-instance-name*] | **all** }
Clear blacklist statistics.	**reset blacklist statistics**
Clear protected IP statistics for client verification.	**reset client-verify** { **dns** | **dns-reply** | **http** | **sip** | **tcp** } **protected** { **ip** | **ipv6** } **statistics**
Clear the trusted IP list for client verification.	**reset client-verify** { **dns** | **dns-reply** | **http** | **sip** | **tcp** } **trusted** { **ip** | **ipv6** }
Clear statistics about packets that match the address object groups on the whitelist.	**reset whitelist statistics**

Attack detection and prevention configuration examples

Example: Configuring security zone-based attack detection and prevention

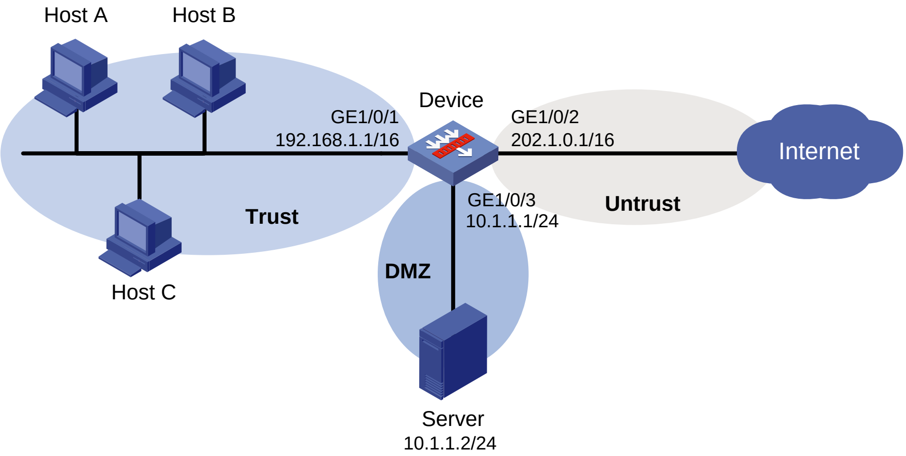
Network configuration

As shown in Figure 10, the device is the gateway for the internal network.

Configure an attack defense policy and apply the policy to security zone **Untrust** to meet the following requirements:

- Provide low-level scanning attack detection for the internal network. If a scanning attack is detected, log the attack and keep the attacker on the blacklist for 10 minutes.
- Protect internal hosts and servers against smurf attacks. If a smurf attack is detected, log the attack.
- Protect the internal server against SYN flood attacks. If the number of SYN packets sent to the server per second reaches or exceeds 5000, log the attack and drop subsequent packets.

Figure 10 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.0.0
[Device-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/1
[Device-security-zone-Trust] quit
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
```

```
[Device-security-zone-Untrust] quit
[Device] security-zone name dmz
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/3
[Device-security-zone-DMZ] quit
```

3. Configure a security policy:

   # Configure a rule named **trust-untrust** to allow hosts in security zone **trust** to access the Internet.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name trust-untrust
   [Device-security-policy-ip-1-trust-untrust] source-zone trust
   [Device-security-policy-ip-1-trust-untrust] destination-zone untrust
   [Device-security-policy-ip-1-trust-untrust] source-ip-subnet 192.168.0.0 16
   [Device-security-policy-ip-1-trust-untrust] action pass
   [Device-security-policy-ip-1-trust-untrust] quit
   ```

   # Configure a rule named **untrust-dmz** to allow hosts on the Internet to access the server.

   ```
   [Device-security-policy-ip] rule name untrust-dmz
   [Device-security-policy-ip-2-untrust-dmz] source-zone untrust
   [Device-security-policy-ip-2-untrust-dmz] destination-zone dmz
   [Device-security-policy-ip-2-untrust-dmz] destination-ip-host 10.1.1.2
   [Device-security-policy-ip-2-untrust-dmz] action pass
   [Device-security-policy-ip-2-untrust-dmz] quit
   [Device-security-policy-ip] quit
   ```

4. Configure an attack defense policy:

   # Create attack defense policy **a1**.

   ```
   [Device] attack-defense policy a1
   ```

   # Configure signature detection for smurf attacks, and specify **logging** as the prevention action.

   ```
   [Device-attack-defense-policy-a1] signature detect smurf action logging
   ```

   # Configure low-level scanning attack detection, specify **logging** and **block-source** as the prevention actions, and set the blacklist entry aging time to 10 minutes.

   ```
   [Device-attack-defense-policy-a1] scan detect level low action logging block-source
   timeout 10
   ```

   # Configure SYN flood attack detection for 10.1.1.2, set the attack prevention triggering threshold to 5000, and specify **logging** and **drop** as the prevention actions.

   ```
   [Device-attack-defense-policy-a1] syn-flood detect ip 10.1.1.2 threshold 5000 action
   logging drop
   [Device-attack-defense-policy-a1] quit
   ```

   # Apply attack defense policy **a1** to security zone **Untrust**.

   ```
   [Device] security-zone name untrust
   [Device-security-zone-Untrust] attack-defense apply policy a1
   [Device-security-zone-Untrust] quit
   ```

5. Enable the global blacklist feature.

   ```
   [Device] blacklist global enable
   ```

Verifying the configuration

# Verify that attack defense policy **a1** is successfully configured.

```
[Device] display attack-defense policy a1
          Attack-defense Policy Information
--------------------------------------------------------------------------
Policy name                        : a1
```

```

```

# Verify that the IPv4 blacklist collaborates with the scanning attack detection.

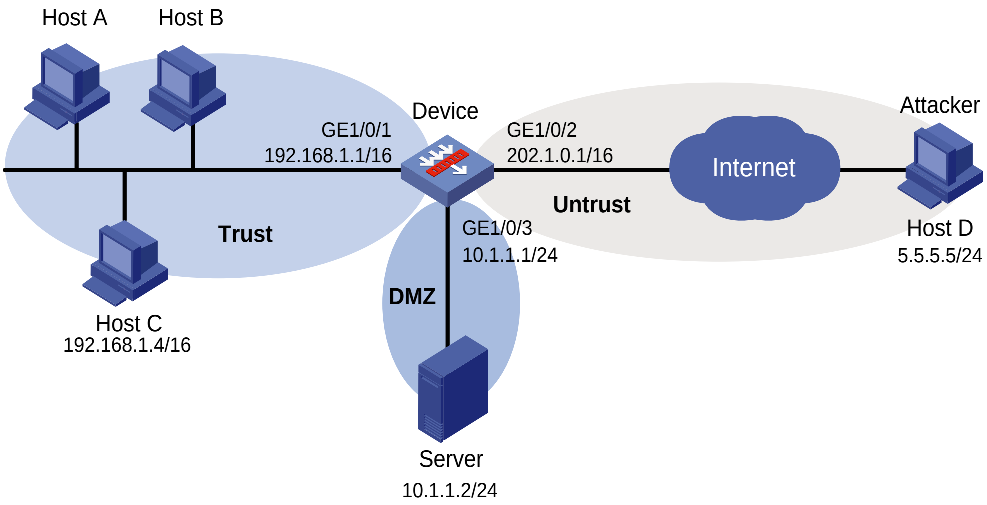
```
[Device] display blacklist ip
IP address      VPN instance   DS-Lite tunnel peer  Type    TTL(sec) Dropped
5.5.5.5         --             --                   Dynamic 600      353452
```

Example: Configuring the source IP blacklist

Network configuration

As shown in Figure 11, configure source IP blacklist entries on the device to block packets from the attacker Host D permanently and from Host C for 50 minutes.

Figure 11 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.0.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   ［Device］ security-zone name trust
   ［Device-security-zone-Trust］ import interface gigabitethernet 1/0/1
   ［Device-security-zone-Trust］ quit
   ［Device］ security-zone name untrust
   ［Device-security-zone-Untrust］ import interface gigabitethernet 1/0/2
   ［Device-security-zone-Untrust］ quit
   ［Device］ security-zone name dmz
   ```

```
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/3
[Device-security-zone-DMZ] quit
```

3. Configure a security policy:

   # Configure a rule named **trust-untrust** to allow hosts in security zone **trust** to access the Internet.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name trust-untrust
[Device-security-policy-ip-1-trust-untrust] source-zone trust
[Device-security-policy-ip-1-trust-untrust] destination-zone untrust
[Device-security-policy-ip-1-trust-untrust] source-ip-subnet 192.168.0.0 16
[Device-security-policy-ip-1-trust-untrust] action pass
[Device-security-policy-ip-1-trust-untrust] quit
```

   # Configure a rule named **untrust-dmz** to allow hosts on the Internet to access the server.

```
[Device-security-policy-ip] rule name untrust-dmz
[Device-security-policy-ip-2-untrust-dmz] source-zone untrust
[Device-security-policy-ip-2-untrust-dmz] destination-zone dmz
[Device-security-policy-ip-2-untrust-dmz] destination-ip-host 10.1.1.2
[Device-security-policy-ip-2-untrust-dmz] action pass
[Device-security-policy-ip-2-untrust-dmz] quit
[Device-security-policy-ip] quit
```

4. Configure the source IP blacklist:

   # Add a source IPv4 blacklist entry for Host D.

```
[Device] blacklist ip 5.5.5.5
```

   # Add a source IPv4 blacklist entry for Host C and set the blacklist entry aging time to 50 minutes.

```
[Device] blacklist ip 192.168.1.4 timeout 50
```

   # Enable the global blacklist feature.

```
[Device] blacklist global enable
```

Verifying the configuration

# Verify that the source IPv4 blacklist entries are successfully added.

```
<Device> display blacklist ip
IP address      VPN instance   DS-Lite tunnel peer  Type    TTL(sec) Dropped
5.5.5.5         --             --                   Manual  Never    0
192.168.1.4     --             --                   Manual  2989     0
```

# Verify that the device drops packets from Host D. (Details not shown.)

# Execute the **undo blacklist ip 5.5.5.5** command and verify that the device forwards packets from Host D. (Details not shown.)

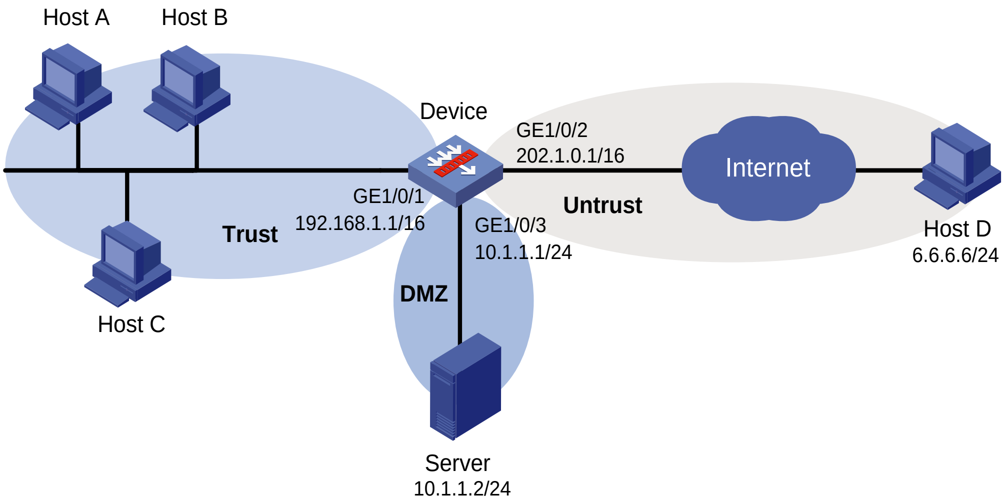
# Verify that the device drops packets from Host C for 50 minutes and forwards packets from Host C after 50 minutes. (Details not shown.)

Example: Configuring the destination IP blacklist

Network configuration

As shown in Figure 12, configure destination IP blacklist entries on the device to block packets destined for the server permanently and block packets destined for Host D for 50 minutes.

Figure 12 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.0.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/1
   [Device-security-zone-Trust] quit
   [Device] security-zone name untrust
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Untrust] quit
   [Device] security-zone name dmz
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/3
   [Device-security-zone-DMZ] quit
   ```

3. Configure a security policy:

   # Configure a rule named **trust-untrust** to allow hosts in security zone **trust** to access the Internet.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name trust-untrust
   [Device-security-policy-ip-1-trust-untrust] source-zone trust
   [Device-security-policy-ip-1-trust-untrust] destination-zone untrust
   [Device-security-policy-ip-1-trust-untrust] source-ip-subnet 192.168.0.0 16
   [Device-security-policy-ip-1-trust-untrust] action pass
   [Device-security-policy-ip-1-trust-untrust] quit
   ```

   # Configure a rule named **untrust-dmz** to allow hosts on the Internet to access the server.

   ```
   [Device-security-policy-ip] rule name untrust-dmz
   [Device-security-policy-ip-2-untrust-dmz] source-zone untrust
   ```

```
[Device-security-policy-ip-2-untrust-dmz] destination-zone dmz
[Device-security-policy-ip-2-untrust-dmz] destination-ip-host 10.1.1.2
[Device-security-policy-ip-2-untrust-dmz] action pass
[Device-security-policy-ip-2-untrust-dmz] quit
[Device-security-policy-ip] quit
```

4. Configure the destination IP blacklist:

   # Add a destination IPv4 blacklist entry for the server.

   ```
   [Device] blacklist destination-ip 10.1.1.2
   ```

   # Add a destination IPv4 blacklist entry for Host D and set the blacklist entry aging time to 50 minutes.

   ```
   [Device] blacklist destination-ip 6.6.6.6 timeout 50
   ```

   # Enable the global blacklist feature.

   ```
   [Device] blacklist global enable
   ```

Verifying the configuration

# Verify that the destination IPv4 blacklist entries are successfully added.

```
[Device] display blacklist destination-ip
IP address      VPN instance     Type    TTL(sec) Dropped
10.1.1.2        --               Manual  Never    0
6.6.6.6         --               Manual  2989     0
```

# Verify that the device drops packets destined for the server. (Details not shown.)

# Execute the **undo blacklist destination-ip 10.1.1.2** command and verify that the device forwards packets to the server. (Details not shown.)

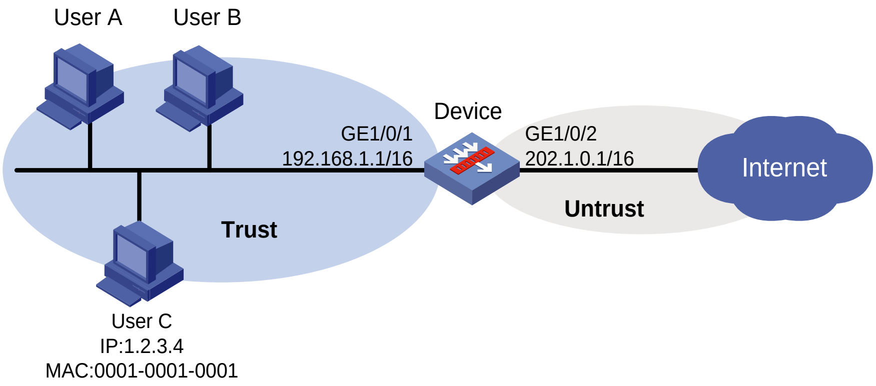
# Verify that the device drops packets destined for Host D for 50 minutes and forwards packets to Host B after 50 minutes. (Details not shown.)

Example: Configuring the user blacklist

Network configuration

As shown in Figure 13, configure the user blacklist feature on the device to block packets from User C for 50 minutes. The IP address of User C is 1.2.3.4 and the MAC address of User C is 0001-0001-0001.

Figure 13 Network diagram



Procedure

1. Assign IP addresses to interfaces:

Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.0.0
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/1
[Device-security-zone-Trust] quit
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
[Device-security-zone-Untrust] quit
```

3. Configure a security policy to allow hosts in security zone **trust** to access the Internet.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name trust-untrust
[Device-security-policy-ip-1-trust-untrust] source-zone trust
[Device-security-policy-ip-1-trust-untrust] destination-zone untrust
[Device-security-policy-ip-1-trust-untrust] source-ip-subnet 192.168.0.0 16
[Device-security-policy-ip-1-trust-untrust] action pass
[Device-security-policy-ip-1-trust-untrust] quit
[Device-security-policy-ip] quit
```

4. Configure the user blacklist:

# Add a network access user named **userc**.

```
[Device] local-user userc class network
[Device-luser-network-userc] quit
```

# Configure a static identity user with the username **userc**, IP address 1.2.3.4, and MAC address 0001-0001-0001.

```
[Device] user-identity static-user userc bind ipv4 1.2.3.4 mac 0001-0001-0001
```

# Add a user blacklist entry for user **userc** and set the blacklist entry aging time to 50 minutes.

```
[Device] blacklist user userc timeout 50
```

# Enable user identification.

```
[Device] user-identity enable
```

# Enable the global blacklist feature.

```
[Device] blacklist global enable
```

Verifying the configuration

# Verify that the user blacklist entry is successfully added.

```
[Device] display blacklist user
User name   Domain name   Type    TTL(sec) Dropped
userc                     Manual  2987     0
```

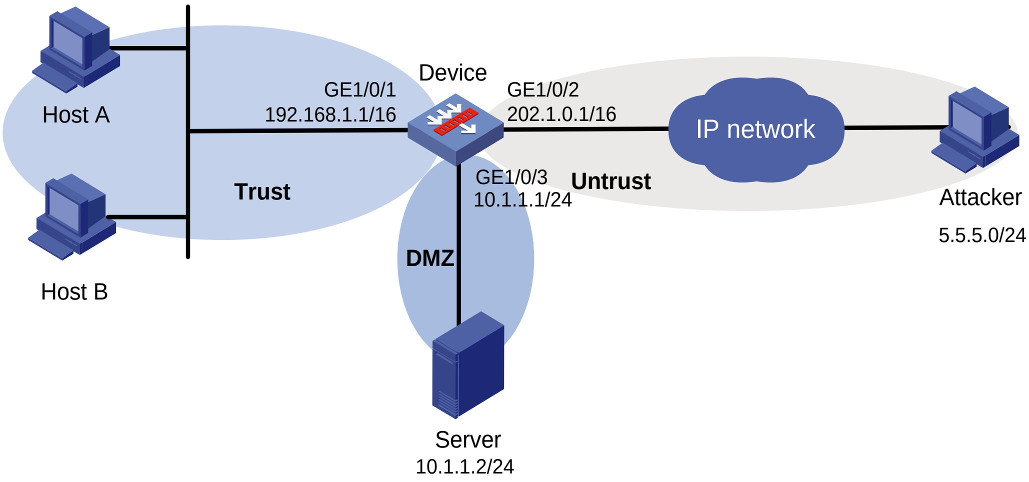
# Verify that the device drops packets from User C for 50 minutes and forwards packets from User C after 50 minutes. (Details not shown.)

Example: Configuring the address object group blacklist

Network configuration

As shown in Figure 14, configure the address object group blacklist feature on the device to block all packets from subnet 5.5.5.0/24 to prevent attacks from the subnet.

Figure 14 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.0.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/1
   [Device-security-zone-Trust] quit
   [Device] security-zone name untrust
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Untrust] quit
   [Device] security-zone name dmz
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/3
   [Device-security-zone-DMZ] quit
   ```

3. Configure a security policy:

   # Configure a rule named **trust-untrust** to allow hosts in security zone **trust** to access the Internet.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name trust-untrust
   [Device-security-policy-ip-1-trust-untrust] source-zone trust
   [Device-security-policy-ip-1-trust-untrust] destination-zone untrust
   [Device-security-policy-ip-1-trust-untrust] source-ip-subnet 192.168.0.0 16
   [Device-security-policy-ip-1-trust-untrust] action pass
   ```

```
[Device-security-policy-ip-1-trust-untrust] quit
```

# Configure a rule named **untrust-dmz** to allow hosts on the Internet to access the server.

```
[Device-security-policy-ip] rule name untrust-dmz
[Device-security-policy-ip-2-untrust-dmz] source-zone untrust
[Device-security-policy-ip-2-untrust-dmz] destination-zone dmz
[Device-security-policy-ip-2-untrust-dmz] destination-ip-host 10.1.1.2
[Device-security-policy-ip-2-untrust-dmz] action pass
[Device-security-policy-ip-2-untrust-dmz] quit
[Device-security-policy-ip] quit
```

4. Configure the address object group blacklist:

# Create IPv4 address object group **obj1**. Configure an IPv4 address object with subnet 5.5.5.0/24.

```
[Device] object-group ip address obj1
[Device-obj-grp-ip-obj1] network subnet 5.5.5.0 24
[Device-obj-grp-ip-obj1] quit
```

# Add IPv4 address object group **obj1** to the blacklist.

```
[Device] blacklist object-group obj1
```

# Enable the global blacklist feature.

```
[Device] blacklist global enable
```

Verifying the configuration

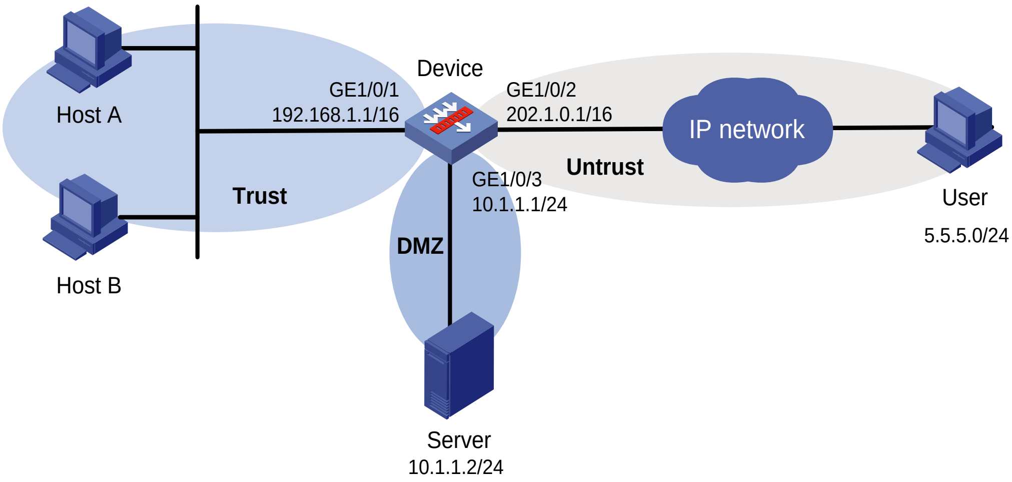
# Verify that the device drops all packets from subnet 5.5.5.0/24 unless you execute the **undo blacklist object-group** command on the device. (Details not shown.)

Example: Configuring the address object group whitelist

Network configuration

As shown in Figure 15, configure the address object group whitelist feature on the device to allow all packets from subnet 5.5.5.0/24 to pass through.

Figure 15 Network diagram



Procedure

1. Assign IP addresses to interfaces:

Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.0.0
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/1
[Device-security-zone-Trust] quit
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
[Device-security-zone-Untrust] quit
[Device] security-zone name dmz
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/3
[Device-security-zone-DMZ] quit
```

3. Configure a security policy:

# Configure a rule named **trust-untrust** to allow hosts in security zone **trust** to access the Internet.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name trust-untrust
[Device-security-policy-ip-1-trust-untrust] source-zone trust
[Device-security-policy-ip-1-trust-untrust] destination-zone untrust
[Device-security-policy-ip-1-trust-untrust] source-ip-subnet 192.168.0.0 16
[Device-security-policy-ip-1-trust-untrust] action pass
[Device-security-policy-ip-1-trust-untrust] quit
```

# Configure a rule named **untrust-dmz** to allow hosts on the Internet to access the server.

```
[Device-security-policy-ip] rule name untrust-dmz
[Device-security-policy-ip-2-untrust-dmz] source-zone untrust
[Device-security-policy-ip-2-untrust-dmz] destination-zone dmz
[Device-security-policy-ip-2-untrust-dmz] destination-ip-host 10.1.1.2
[Device-security-policy-ip-2-untrust-dmz] action pass
[Device-security-policy-ip-2-untrust-dmz] quit
[Device-security-policy-ip] quit
```

4. Configure the address object group whitelist:

# Create IPv4 address object group **obj1**. Configure an IPv4 address object with subnet 5.5.5.0/24.

```
[Device] object-group ip address obj1
[Device-obj-grp-ip-obj1] network subnet 5.5.5.0 24
[Device-obj-grp-ip-obj1] quit
```

# Add IPv4 address object group **obj1** to the whitelist.

```
[Device] whitelist object-group obj1
```

# Enable the global whitelist feature.

```
[Device] whitelist global enable
```

Verifying the configuration

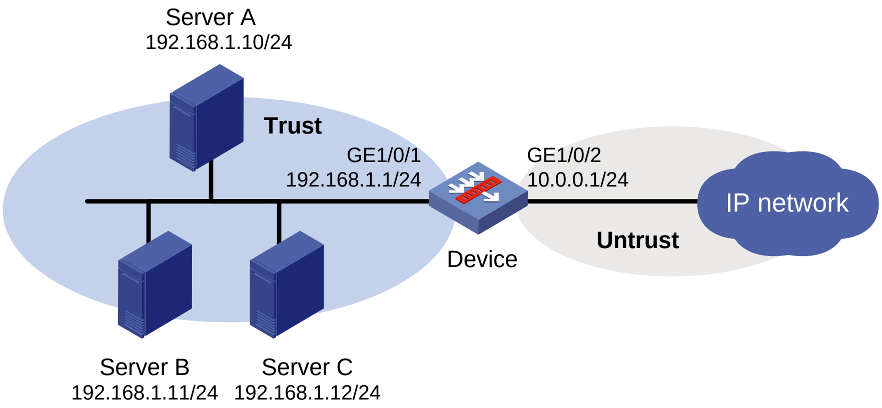
# Verify that the device allows all packets from subnet 5.5.5.0/24 to pass through unless you execute the **`undo whitelist object-group`** command on the device. (Details not shown.)

Example: Configuring security zone-based TCP client verification

Network configuration

As shown in Figure 16, configure TCP client verification in SYN cookie mode on the device to protect the internal servers against SYN flood attacks.

Figure 16 Network configuration



Procedure

1. Assign IP addresses to interfaces:

   Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/1
   [Device-security-zone-Trust] quit
   [Device] security-zone name untrust
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Untrust] quit
   ```

3. Configure a security policy to allow hosts in security zone **trust** to access the Internet.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name untrust-trust
   [Device-security-policy-ip-1-untrust-trust] source-zone untrust
   [Device-security-policy-ip-1-untrust-trust] destination-zone trust
   [Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.10
   [Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.11
   [Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.12
   [Device-security-policy-ip-1-untrust-trust] action pass
   [Device-security-policy-ip-1-untrust-trust] quit
   [Device-security-policy-ip] quit
   ```

4. Configure TCP client verification:

# Create attack defense policy **a1**.

```
[Device] attack-defense policy a1
```

# Enable global SYN flood attack detection.

```
[Device-attack-defense-policy-a1] syn-flood detect non-specific
```

# Set the global threshold for triggering SYN flood attack prevention to 10000.

```
[Device-attack-defense-policy-a1] syn-flood threshold 10000
```

# Specify **logging** and **client-verify** as the global actions against SYN flood attacks.

```
[Device-attack-defense-policy-a1] syn-flood action logging client-verify
[Device-attack-defense-policy-a1] quit
```

# Apply attack defense policy **a1** to security zone **Untrust**.

```
[Device] security-zone name untrust
[Device-security-zone-Untrust] attack-defense apply policy a1
```

# Enable TCP client verification in SYN cookie mode on security zone **Untrust**.

```
[Device-security-zone-Untrust] client-verify tcp enable mode syn-cookie
[Device-security-zone-Untrust] quit
```

Verifying the configuration

# Launch a SYN flood attack. (Details not shown.)

# Verify that the victim's IP address is added to the protected IP list for TCP client verification.

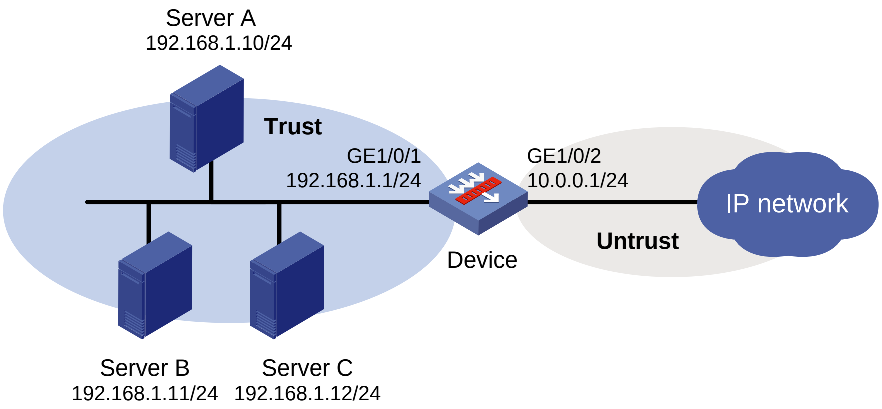
```
[Device] display client-verify tcp protected ip
IP address      VPN instance Port  Type     Requested  Trusted
192.168.1.10    --           any   Dynamic   20         12
```

Example: Configuring security zone-based DNS client verification

Network configuration

As shown in Figure 17, configure DNS client verification on the device to protect internal servers against DNS flood attacks.

Figure 17 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
```

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
［Device］ security-zone name trust
［Device-security-zone-Trust］ import interface gigabitethernet 1/0/1
［Device-security-zone-Trust］ quit
［Device］ security-zone name untrust
［Device-security-zone-Untrust］ import interface gigabitethernet 1/0/2
［Device-security-zone-Untrust］ quit
```

3. Configure a security policy to allow hosts in security zone **trust** to access the internal servers.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name untrust-trust
[Device-security-policy-ip-1-untrust-trust] source-zone untrust
[Device-security-policy-ip-1-untrust-trust] destination-zone trust
[Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.10
[Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.11
[Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.12
[Device-security-policy-ip-1-untrust-trust] action pass
[Device-security-policy-ip-1-untrust-trust] quit
[Device-security-policy-ip] quit
```

4. Configure DNS client verification:

# Create attack defense policy **a1**.

```
[Device] attack-defense policy a1
```

# Enable global DNS flood attack detection.

```
[Device-attack-defense-policy-a1] dns-flood detect non-specific
```

# Set the global threshold for triggering DNS flood attack prevention to 10000.

```
[Device-attack-defense-policy-a1] dns-flood threshold 10000
```

# Specify **logging** and **client-verify** as the global actions against DNS flood attacks.

```
[Device-attack-defense-policy-a1] dns-flood action logging client-verify
[Device-attack-defense-policy-a1] quit
```

# Apply attack defense policy **a1** to security zone **Untrust**.

```
[Device] security-zone name untrust
[Device-security-zone-Untrust] attack-defense apply policy a1
```

# Enable DNS client verification on security zone **Untrust**.

```
[Device-security-zone-untrust] client-verify dns enable
[Device-security-zone-Untrust] quit
```

Verifying the configuration

# Launch a DNS flood attack. (Details not shown.)

# Verify that the victim's IP address is added to the protected IP list for DNS client verification**.**

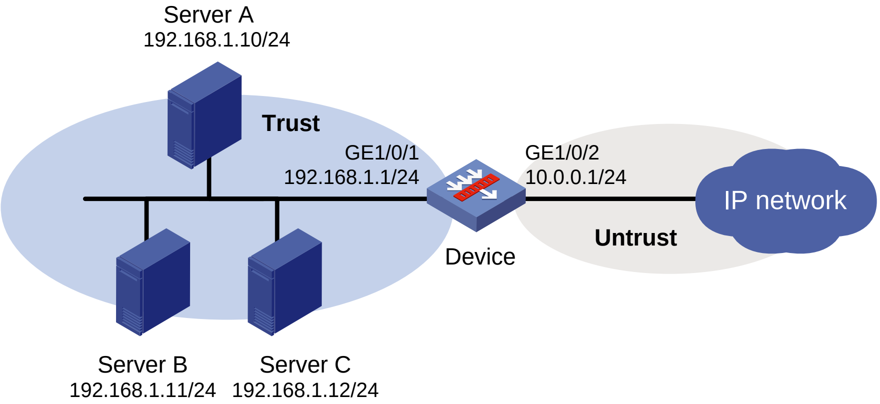
```
[Device] display client-verify dns protected ip
IP address      VPN instance Port  Type       Requested  Trusted
192.168.1.10    --           53    Dynamic    20         12
```

Example: Configuring security zone-based HTTP client verification

Network configuration

As shown in Figure 18, configure HTTP client verification on the device to protect internal servers against HTTP flood attacks.

Figure 18 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/1
   [Device-security-zone-Trust] quit
   [Device] security-zone name untrust
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Untrust] quit
   ```

3. Configure a security policy to allow hosts in security zone **trust** to access the internal servers.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name untrust-trust
   [Device-security-policy-ip-1-untrust-trust] source-zone untrust
   [Device-security-policy-ip-1-untrust-trust] destination-zone trust
   [Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.10
   [Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.11
   [Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.12
   [Device-security-policy-ip-1-untrust-trust] action pass
   [Device-security-policy-ip-1-untrust-trust] quit
   [Device-security-policy-ip] quit
   ```

4. Configure HTTP client verification:

# Create attack defense policy **a1**.

```
[Device] attack-defense policy a1
```

# Enable global HTTP flood attack detection.

```
[Device-attack-defense-policy-a1] http-flood detect non-specific
```

# Set the global threshold for triggering HTTP flood attack prevention to 10000.

```
[Device-attack-defense-policy-a1] http-flood threshold 10000
```

# Specify **logging** and **client-verify** as the global actions against HTTP flood attacks.

```
[Device-attack-defense-policy-a1] http-flood action logging client-verify
[Device-attack-defense-policy-a1] quit
```

# Apply attack defense policy **a1** to security zone **Untrust**.

```
[Device] security-zone name untrust
[Device-security-zone-Untrust] attack-defense apply policy a1
```

# Enable HTTP client verification on security zone **Untrust**.

```
[Device-security-zone-Untrust] client-verify http enable
[Device-security-zone-Untrust] quit
```

Verifying the configuration

# Launch an HTTP flood attack. (Details not shown.)

# Verify that the victim's IP address is added to the protected IP list for HTTP client verification**.**

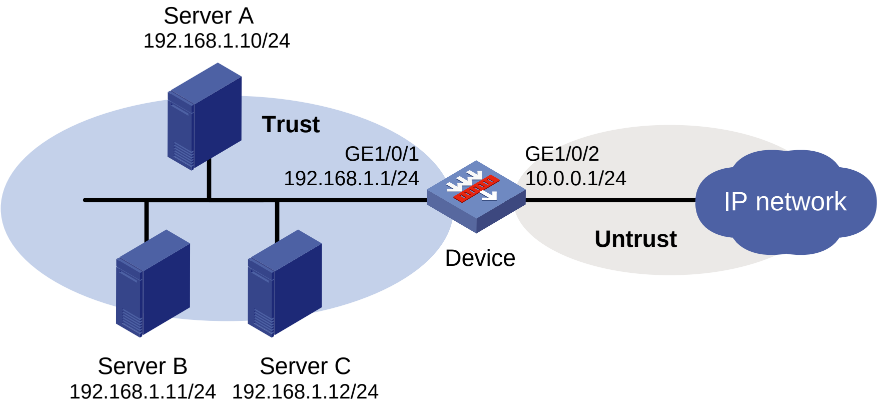
```
[Device] display client-verify http protected ip
IP address      VPN instance Port  Type       Requested  Trusted
192.168.1.10    --           8080  Dynamic    20         12
```

Example: Configuring security zone-based SIP client verification

Network configuration

As shown in Figure 19, configure SIP client verification on the device to protect internal servers against SIP flood attacks.

Figure 19 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
```

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

# Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/1
[Device-security-zone-Trust] quit
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
[Device-security-zone-Untrust] quit
```

3. Configure a security policy to allow hosts on the Internet to access the internal servers.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name untrust-trust
[Device-security-policy-ip-1-untrust-trust] source-zone untrust
[Device-security-policy-ip-1-untrust-trust] destination-zone trust
[Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.10
[Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.11
[Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.12
[Device-security-policy-ip-1-untrust-trust] action pass
[Device-security-policy-ip-1-untrust-trust] quit
[Device-security-policy-ip] quit
```

4. Configure SIP client verification:

# Create attack defense policy **a1**.

```
[Device] attack-defense policy a1
```

# Enable global SIP flood attack detection.

```
[Device-attack-defense-policy-a1] sip-flood detect non-specific
```

# Set the global threshold to 10000 for triggering SIP flood attack prevention.

```
[Device-attack-defense-policy-a1] sip-flood threshold 10000
```

# Specify **logging** and **client-verify** as the global actions against SIP flood attacks.

```
[Device-attack-defense-policy-a1] sip-flood action logging client-verify
[Device-attack-defense-policy-a1] quit
```

# Apply attack defense policy **a1** to security zone **Untrust**.

```
[Device] security-zone name untrust
[Device-security-zone-Untrust] attack-defense apply policy a1
```

# Enable SIP client verification on security zone **Untrust**.

```
[Device-security-zone-Untrust] client-verify sip enable
[Device-security-zone-Untrust] quit
```

Verifying the configuration

# Launch a SIP flood attack. (Details not shown.)

# Verify that the victim's IP address is added to the protected IP list for SIP client verification**.**

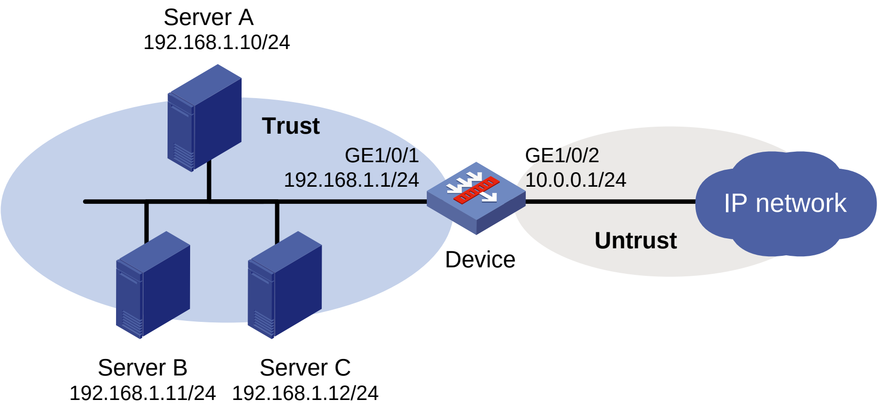
```
[Device] display client-verify sip protected ip
IP address      VPN instance Port  Type       Requested  Trusted
192.168.1.10    --           5060  Dynamic    20         12
```

Example: Configuring threshold learning for flood attack prevention

Network configuration

As shown in Figure 20, configure threshold learning for flood attack prevention on the device to protect internal servers against SYN flood attacks.

Figure 20 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

   ```
   [Device] security-zone name trust
   [Device-security-zone-Trust] import interface gigabitethernet 1/0/1
   [Device-security-zone-Trust] quit
   [Device] security-zone name untrust
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Untrust] quit
   ```

3. Configure a security policy to allow hosts on the Internet to access the internal servers.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name untrust-trust
   [Device-security-policy-ip-1-untrust-trust] source-zone untrust
   [Device-security-policy-ip-1-untrust-trust] destination-zone trust
   [Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.10
   [Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.11
   [Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.12
   [Device-security-policy-ip-1-untrust-trust] action pass
   [Device-security-policy-ip-1-untrust-trust] quit
   [Device-security-policy-ip] quit
   ```

4. Configure threshold learning for flood attack prevention:

# Create attack defense policy **a1**.

```
[Device] attack-defense policy a1
```

# Set the threshold learning duration to 60 minutes.

```
[Device-attack-defense-policy-a1] threshold-learn duration 60
```

# Set the periodic learning mode.

```
[Device-attack-defense-policy-a1] threshold-learn mode periodic
```

# Set the threshold learning interval to 120 minutes.

```
[Device-attack-defense-policy-a1] threshold-learn interval 120
```

# Enable auto application of the learned threshold.

```
[Device-attack-defense-policy-a1] threshold-learn auto-apply enable
```

# Set the threshold learning tolerance value to 100.

```
[Device-attack-defense-policy-a1] threshold-learn tolerance-value 100
```

# Enable the threshold learning feature.

```
[Device-attack-defense-policy-a1] threshold-learn enable
```

# Enable global SYN flood attack detection.

```
[Device-attack-defense-policy-a1] syn-flood detect non-specific
```

# Specify **logging** and **drop** as the global actions against SYN flood attacks.

```
[Device-attack-defense-policy-a1] syn-flood action drop logging
[Device-attack-defense-policy-a1] quit
```

# Apply attack defense policy **a1** to security zone **Untrust**.

```
[Device] security-zone name untrust
[Device-security-zone-Untrust] attack-defense apply policy a1
```

Verifying the configuration

# Verify that the device has learned a threshold for triggering SYN flood attack prevention in 180 minutes (one learning cycle) or later.

```
[Device]display attack-defense policy a1
          Attack-defense Policy Information
--------------------------------------------------------------------------

UDP flood        1000               -               -               Disabled
ICMP flood       1000               -               -               Disabled
ICMPv6 flood     1000               -               -               Disabled

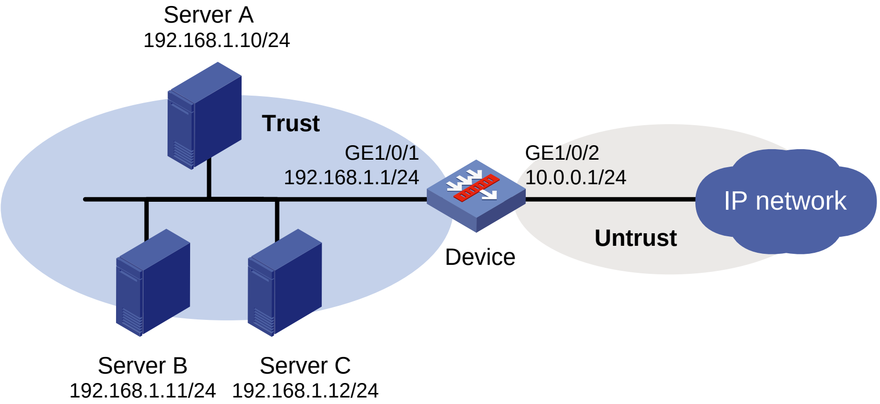
Flood attack defense for protected IP addresses:
 Address                  VPN instance Flood type    Thres(pps) Actions Ports
```

Example: Limiting the creation rate of new sessions

Network configuration

As shown in Figure 21, limit the creation rate of new sessions on the device to protect the internal servers against external DDoS attacks.

Figure 21 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/1
[Device-security-zone-Trust] quit
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
[Device-security-zone-Untrust] quit
```

3. Configure a security policy to allow hosts on the Internet to access internal servers.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name untrust-trust
[Device-security-policy-ip-1-untrust-trust] source-zone untrust
[Device-security-policy-ip-1-untrust-trust] destination-zone trust
[Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.10
[Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.11
[Device-security-policy-ip-1-untrust-trust] destination-ip-host 192.168.1.12
[Device-security-policy-ip-1-untrust-trust] action pass
[Device-security-policy-ip-1-untrust-trust] quit
[Device-security-policy-ip] quit
```

4. Limit the creation rate of new sessions:

# Limit sessions on a per-source IPv4 address, set the packet receiving rate threshold to 10 pps and set the **drop** action.

```
[Device] attack-defense ipcar source ip threshold 10 action logging drop
```

# Enable session creation rate limit based on source IPv4 addresses on GigabitEthernet 2/0/1.

```
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] attack-defense ipcar source ip session-rate-limit
enable
```

Configuring server connection detection

About server connection detection

Server connection detection (SCD) provides protections for internal servers. It enables the device to identify legal and illegal connections initiated by the protected servers. This helps you monitor internal servers and prevent them from becoming part of a botnet and launching attacks or performing internal network penetration.

SCD tasks at a glance

To configure SCD, perform the following tasks:

1. Configuring server connection learning
2. Configuring an SCD policy
3. Configuring SCD rules in an SCD policy

Configuring server connection learning

About this task

Server connection learning learns connections initiated by given servers. The learning results provide the basis for you to create SCD policies to monitor and log illegal connections initiated by the servers.

Restrictions and guidelines

You cannot edit any settings in server connection learning configuration view if server connection learning is in progress.

Procedure

1. Enter system view.
   system-view
2. Enter server connection learning configuration view.
   scd learning
3. Specify an IP address object group for server connection learning.
   source-ip *object-group-name*
   By default, no IP address object groups are specified for server connection learning.
4. Enable server connection learning for a learning period.
   auto-learn enable period { **one-day** | **one-hour** | **seven-day** | **twelve-hour** }
   By default, server connection learning is disabled.

Configuring an SCD policy

About this task

An SCD policy monitors the connections initiated by the specified protected server. You can configure the following settings in an SCD policy:

- Protected server IP address.
- SCD rules to identify legal connections initiated by the server.
- Logging for illegal connections initiated by the server.
- SCD policy enabling status.

Restrictions and guidelines

An SCD policy monitors only the connections initiated by the server specified by the **protected-server** command.

The protected server IP address must be unique for each SCD policy.

Procedure

1. Enter system view.
   system-view
2. Create an SCD policy and enter its view.
   scd policy name *policy-name*
3. Specify the IP address of the protected server.
   protected-server *ip-address*

   By default, no protected server IP address is specified.
4. (Optional.) Enable logging for illegal connections initiated by the protected server.
   logging enable

   By default, the device does not log illegal connections initiated by the protected server.
5. Enable the SCD policy.
   policy enable

   By default, an SCD policy is disabled.

Configuring SCD rules in an SCD policy

About this task

You can configure multiple SCD rules in an SCD policy. Each SCD rule contains the following criteria to identify legal connections initiated by the protected server:

- A destination IP address criterion, which specifies the destination IP address for server-initiated connections.
- One or more protocol criteria. Each protocol criterion specifies a protocol and optionally a set of destination port numbers.

A connection initiated by the protected server matches the SCD rule if the connection matches both the destination IP address criterion and a protocol criterion. Connections initiated by the server that do not match any SCD rules are considered illegal connections.

Restrictions and guidelines

If you do not configure any rules in an SCD policy, all connections initiated by the protected server of the policy are illegal connections.

An SCD rule must contain one destination IP address criterion and a minimum of one protocol criteria.

In one SCD policy, each SCD rule must use a unique destination IP address.

Procedure

1. Enter system view.

```
system-view
```

2. Enter the view of an SCD policy.

```
scd policy name policy-name
```

3. Create an SCD rule and enter its view.

```
rule rule-id
```

4. Configure the destination IP address criterion.

```
permit-dest-ip ip-address
```

By default, the destination IP address criterion is not configured.

5. Configure a protocol criterion.

```
protocol { icmp | tcp port port-list | udp port port-list }
```

By default, no protocol criterion is configured in an SCD rule.

Display and maintenance commands for server connection detection

Execute **display** commands in any view.

Execute **reset** commands in user view.

Task	Command
Display the server connection learning information.	**display scd auto-learn config**
Display the server connection learning results.	**display scd learning record** [**protected-server** *ip-address*] [**destination-ip** *ip-address*]
Display the SCD policy information.	**display scd policy** [**name** *policy-name*]
Clear the server connection learning results.	**reset scd learning record**

SCD configuration examples

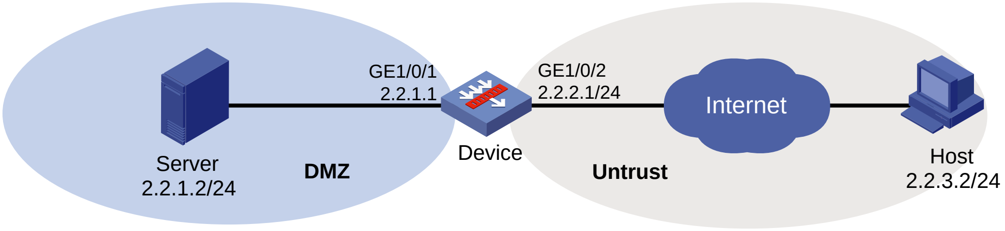
Example: Configuring SCD

Network configuration

As shown in Figure 1, configure SCD on the device to perform the following tasks:

- Monitor connections initiated by servers in subnet 2.2.1.0/24 for one day.
- Logs all connections initiated by the server except for TCP connections destined for TCP ports 80 and 443 on host 2.2.3.2/24.

Figure 1 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

   ```
   <Device> system-view
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip address 2.2.1.1 255.255.255.0
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Configure settings for routing.

   This example configures a static route, and the next hop in the route is 2.2.2.2.

   ```
   [Device] ip route-static 2.2.3.0 24 2.2.2.2
   ```

3. Add interfaces to security zones.

   ```
   [Device] security-zone name dmz
   [Device-security-zone-DMZ] import interface gigabitethernet 1/0/1
   [Device-security-zone-DMZ] quit
   [Device] security-zone name untrust
   [Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
   [Device-security-zone-Untrust] quit
   ```

4. Configure a security policy:

   # Configure a rule named **dmz-untrust** to permit the packets from the internal server to the Internet.

   ```
   [Device] security-policy ip
   [Device-security-policy-ip] rule name dmz-untrust
   [Device-security-policy-ip-1-dmz-untrust] source-zone dmz
   [Device-security-policy-ip-1-dmz-untrust] destination-zone untrust
   [Device-security-policy-ip-1-dmz-untrust] source-ip-host 2.2.1.2
   [Device-security-policy-ip-1-dmz-untrust] action pass
   [Device-security-policy-ip-1-dmz-untrust] quit
   [Device-security-policy-ip] quit
   ```

5. Create an IP address object group named **abc** and specify IPv4 address 2.2.1.0 and mask length 24 for the object group.

   ```
   [Device] object-group ip address abc
   [Device-obj-grp-ip-abc] network subnet 2.2.1.0 24
   [Device-obj-grp-ip-abc] quit
   ```

6. Specify IP address object group **abc** for server connection learning and enable server connection learning for one day.

   ```
   [Device] scd learning
   [Device-scd-learning] source-ip abc
   [Device-scd-learning] auto-learn enable period one-day
   ```

```
[Device-scd-learning] quit
```

7. Create an SCD policy named **policy1**.

```
[Device] scd policy name policy1
[Device-scd-policy-policy1] protected-server 2.2.1.2
[Device-scd-policy-policy1] logging enable
[Device-scd-policy-policy1] rule 1
[Device-scd-policy-policy1-1] permit-dest-ip 2.2.3.2
[Device-scd-policy-policy1-1] protocol tcp port 80 443
[Device-scd-policy-policy1-1] quit
[Device-scd-policy-policy1] policy enable
[Device-scd-policy-policy1] quit
```

Verifying the configuration

# After the server connection learning is complete, display the server connection learning results.

```
[Device] display scd learning record
Id      Protected server    Destination IPv4 address   Protocol    Port
1       2.2.1.2             2.2.3.2                    TCP         80
2       2.2.1.2             2.2.3.2                    TCP         443
3       2.2.1.2             2.2.3.2                    UDP         4433
4       2.2.1.2             2.2.3.2                    UDP         567
Total entries: 4
```

# Display information about SCD policy **policy1**.

```
<Sysname> display scd policy name policy1
SCD policy name: policy1
 Protected server IPv4: 2.2.1.2
 Logging: Enabled
 Policy status: Enabled
 Rule ID: 1
  Permitted dest IPv4: 2.2.3.2
  Protocol: TCP port 80,443
```

Contents

Configuring ARP attack protection

About ARP attack protection

The device can provide multiple features to detect and prevent ARP attacks and viruses in the LAN. An attacker can exploit ARP vulnerabilities to attack network devices in the following ways:

- Sends a large number of unresolvable IP packets to have the receiving device busy with resolving IP addresses until its CPU is overloaded. Unresolvable IP packets refer to IP packets for which ARP cannot find corresponding MAC addresses.
- Sends a large number of ARP packets to overload the CPU of the receiving device.
- Acts as a trusted user or gateway to send ARP packets so the receiving devices obtain incorrect ARP entries.

ARP attack protection tasks at a glance

All ARP attack protection tasks are optional.

- Preventing flood attacks
  - Configuring unresolvable IP attack protection
  - Configuring source MAC-based ARP attack detection
- Preventing user and gateway spoofing attacks
  - Configuring ARP packet source MAC consistency check
  - Configuring ARP active acknowledgement
  - Configuring authorized ARP
  - Configuring ARP attack detection
  - Configuring ARP scanning and fixed ARP
  - Configuring ARP gateway protection
  - Configuring ARP filtering

Configuring unresolvable IP attack protection

About unresolvable IP attack protection

If a device receives a large number of unresolvable IP packets from a host, the following situations can occur:

- The device sends a large number of ARP requests, overloading the target subnets.
- The device keeps trying to resolve the destination IP addresses, overloading its CPU.

To protect the device from such IP attacks, you can configure ARP source suppression. This feature stops resolving packets from an IP address if the number of unresolvable IP packets from the IP address exceeds the upper limit within 5 seconds. The device continues ARP resolution when the interval elapses. This feature is applicable if the attack packets have the same source addresses.

Configuring ARP source suppression

1. Enter system view.

```
system-view
```

2. Enable ARP source suppression.

```
arp source-suppression enable
```

By default, ARP source suppression is disabled.

3. Set the maximum number of unresolvable packets that the device can process per source IP address within 5 seconds.

```
arp source-suppression limit limit-value
```

By default, the maximum number is 10.

Display and maintenance commands for unresolvable IP attack protection

Execute **display** commands in any view.

Task	Command
Display ARP source suppression configuration information.	**display arp source-suppression**

Configuring source MAC-based ARP attack detection

About source MAC-based ARP attack detection

This feature checks the number of ARP packets delivered to the CPU. If the number of packets from the same MAC address within 5 seconds exceeds a threshold, the device generates an ARP attack entry for the MAC address. If the ARP logging feature is enabled, the device handles the attack by using either of the following methods before the ARP attack entry ages out:

- **Monitor**—Only generates log messages.
- **Filter**—Generates log messages and filters out subsequent ARP packets from the MAC address.

To enable the ARP logging feature, use the **arp check log enable** command. For information about the ARP logging feature, see ARP configuration in *Layer 3—IP Services Configuration Guide*.

When an ARP attack entry ages out, ARP packets sourced from the MAC address in the entry can be processed correctly.

Restrictions and guidelines

When you change the handling method from monitor to filter, the configuration takes effect immediately. When you change the handling method from filter to monitor, the device continues filtering packets that match existing attack entries.

You can exclude the MAC addresses of some gateways and servers from this detection. This feature does not inspect ARP packets from those devices even if they are attackers.

Procedure

1. Enter system view.

```
system-view
```

2. Enable source MAC-based ARP attack detection and specify the handling method.

   ```
   arp source-mac { filter | monitor }
   ```

   By default, this feature is disabled.

3. Set the threshold.

   ```
   arp source-mac threshold threshold-value
   ```

   By default, the threshold for source MAC-based ARP attack detection is 30.

4. Set the aging timer for ARP attack entries.

   ```
   arp source-mac aging-time time
   ```

   By default, the lifetime is 300 seconds.

5. (Optional.) Exclude specific MAC addresses from this detection.

   ```
   arp source-mac exclude-mac mac-address&<1-n>
   ```

   By default, no MAC address is excluded.

Display and maintenance commands for source MAC-based ARP attack detection

Execute **display** commands in any view.

Task	Command
Display ARP attack entries detected by source MAC-based ARP attack detection.	**display arp source-mac** { **interface** *interface-type interface-number* | **slot** *slot-number* }

Configuring ARP packet source MAC consistency check

About this task

This feature enables a gateway to filter out ARP packets whose source MAC address in the Ethernet header is different from the sender MAC address in the message body. This feature allows the gateway to learn correct ARP entries.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable ARP packet source MAC address consistency check.

   ```
   arp valid-check enable
   ```

   By default, ARP packet source MAC address consistency check is disabled.

Configuring ARP active acknowledgement

About this task

Use the ARP active acknowledgement feature on gateways to prevent user spoofing.

This feature enables the device to perform active acknowledgement before creating an ARP entry.

- Upon receiving an ARP request that requests the MAC address of the device, the device sends an ARP reply. Then, it sends an ARP request for the sender IP address in the received ARP request to determine whether to create an ARP entry for the sender IP address.
    - If the device receives an ARP reply within the probe interval, it creates the ARP entry.
    - If the device does not receive an ARP reply within the probe interval, it does not create the ARP entry.
- Upon receiving an ARP reply, the device examines whether it was the reply to the request that the device has sent.
    - If it was, the device creates an ARP entry for the sender IP address in the ARP reply.
    - If it was not, the device sends an ARP request for the sender IP address to determine whether to create an ARP entry for the sender IP address.
        - If the device receives an ARP reply within the probe interval, it creates the ARP entry.
        - If the device does not receive an ARP reply within the probe interval, it does not create the ARP entry.

To improve validity and reliability of ARP entries, you can enable ARP active acknowledgement in strict mode. In this mode, the device creates ARP entries only for the IP addresses that the device actively initiates the ARP resolution.

Procedure

1. Enter system view.

   `system-view`

2. Enable the ARP active acknowledgement feature.

   `arp active-ack enable`

   By default, this feature is disabled.

Configuring authorized ARP

About authorized ARP

Authorized ARP entries are generated based on the DHCP clients' address leases on the DHCP server or dynamic client entries on the DHCP relay agent. For more information about DHCP server and DHCP relay agent, see *Layer 3—IP Services Configuration Guide*.

Use this feature to prevent user spoofing and to allow only authorized clients to access network resources.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

   Supported interface types include Layer 3 Ethernet interface, Layer 3 Ethernet subinterface, Layer 3 aggregate interface, Layer 3 aggregate subinterface, and VLAN interface.

3. Enable authorized ARP on the interface.

   `arp authorized enable`

   By default, authorized ARP is disabled.

Configuring ARP attack detection

About ARP attack detection

ARP attack detection enables access devices to block ARP packets from unauthorized clients to prevent user spoofing and gateway spoofing attacks.

ARP attack detection provides the following features:

- User validity check.
- ARP packet validity check.
- ARP restricted forwarding.
- ARP attack detection logging.

If both ARP packet validity check and user validity check are enabled, the former one applies first, and then the latter applies.

Do not configure ARP attack detection together with ARP snooping. Otherwise, ARP snooping entries cannot be generated.

Configuring user validity check

About this task

User validity check does not check ARP packets received on ARP trusted interfaces. This feature compares the sender IP and sender MAC in the ARP packet received on an ARP untrusted interface with the matching criteria in the following order:

1. User validity check rules.
   - If a match is found, the device processes the ARP packet according to the rule.
   - If no match is found or no user validity check rule is configured, proceeds to step 2.
2. Static IPSG bindings.
   - If a match is found, the device determines that the ARP packet is valid. Then, the device forwards the packet by searching for an entry that contains the target IP address.
     - If a match is found and the receiving interface is different from the interface in the entry with a matching sender IP address, the device performs Layer 3 forwarding.
     - If a match is found but the receiving interface is the same as the interface in the entry with a matching sender IP address, the device performs Layer 2 forwarding.
     - If no match is found, the device performs Layer 2 forwarding.
   - If no match is found, the device discards the ARP packet.

Static IP source guard bindings are created by using the **`ip source binding`** command. For more information, see "Configuring IP source guard."

Restrictions and guidelines

When you configure user validity check, make sure one or more of the following items are configured:

- User validity check rules.
- Static IP source guard bindings.

If neither of the items is configured, all incoming ARP packets on ARP untrusted interfaces are discarded.

Specify an IP address, a MAC address, and a VLAN where ARP attack detection is enabled for an IP source guard binding. Otherwise, no ARP packets can match the IP source guard binding.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Configure a user validity check rule.

   arp detection rule *rule-id* { **deny** | **permit** } **ip** { *ip-address* [*mask*] | **any** } **mac** { *mac-address* [*mask*] | **any** } [**vlan** *vlan-id*]

   By default, no user validity check rules are configured.

3. Enter VLAN view.

   vlan *vlan-id*

4. Enable ARP attack detection.

   arp detection enable

   By default, ARP attack detection is disabled. The device does not perform user validity check.

5. (Optional.) Configure an interface that does not require ARP user validity check as a trusted interface.

   a. Return to system view.

      quit

   b. Enter interface view.

      interface *interface-type interface-number*

      Supported interface types include Layer 2 Ethernet interface and Layer 2 aggregate interface.

   c. Configure the interface as a trusted interface excluded from ARP attack detection.

      arp detection trust

      By default, an interface is untrusted.

Configuring ARP packet validity check

About this task

ARP packet validity check does not check ARP packets received on ARP trusted interfaces. To check ARP packets received on untrusted interfaces, you can specify the following objects to be checked:

- **src-mac**—Checks whether the sender MAC address in the message body is identical to the source MAC address in the Ethernet header. If they are identical, the packet is forwarded. Otherwise, the packet is discarded.
- **dst-mac**—Checks the target MAC address of ARP replies. If the target MAC address is all-zero, all-one, or inconsistent with the destination MAC address in the Ethernet header, the packet is considered invalid and discarded.
- **ip**—Checks the sender and target IP addresses of ARP replies, and the sender IP address of ARP requests. All-one or multicast IP addresses are considered invalid and the corresponding packets are discarded.

Prerequisites

Before you configure ARP packet validity check, you must first configure user validity check. For more information about user validity check configuration, see "Configuring user validity check."

Procedure

1. Enter system view.

   system-view

2. Enter VLAN view.

```
vlan vlan-id
```

3. Enable ARP attack detection.

   ```
   arp detection enable
   ```

   By default, ARP attack detection is disabled. The device does not perform ARP packet validity check.

4. Enable ARP packet validity check.
   a. Return to system view.

      ```
      quit
      ```

   b. Enable ARP packet validity check and specify the objects to be checked.

      ```
      arp detection validate { dst-mac | ip | src-mac } *
      ```

      By default, ARP packet validity check is disabled.

5. (Optional.) Configure the interface that does not require ARP packet validity check as a trusted interface.
   a. Enter interface view.

      ```
      interface interface-type interface-number
      ```

      Supported interface types include Layer 2 Ethernet interface and Layer 2 aggregate interface.

   b. Configure the interface as a trusted interface excluded from ARP attack detection.

      ```
      arp detection trust
      ```

      By default, an interface is untrusted.

Configuring ARP restricted forwarding

About this task

ARP restricted forwarding does not take effect on ARP packets received on ARP trusted interfaces and forwards the ARP packets correctly. This feature controls the forwarding of ARP packets that are received on untrusted interfaces and have passed user validity check as follows:

- If the packets are ARP requests, they are forwarded through the trusted interface.
- If the packets are ARP replies, they are forwarded according to their destination MAC address. If no match is found in the MAC address table, they are forwarded through the trusted interface.

Restrictions and guidelines

ARP restricted forwarding does not apply to ARP packets that use multiport destination MAC addresses.

Prerequisites

Configure user validity check before you configure ARP restricted forwarding. For information about user validity check configuration, see "Configuring user validity check."

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter VLAN view.

   ```
   vlan vlan-id
   ```

3. Enable ARP restricted forwarding.

   ```
   arp restricted-forwarding enable
   ```

   By default, ARP restricted forwarding is disabled.

Display and maintenance commands for ARP attack detection

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the VLANs enabled with ARP attack detection.	**display arp detection**
Display statistics for packets dropped by ARP attack detection.	**display arp detection statistics** [**interface** *interface-type interface-number*]
Clear statistics for packets dropped by ARP attack detection.	**reset arp detection statistics** [**interface** *interface-type interface-number*]

Configuring ARP scanning and fixed ARP

About this task

ARP scanning is typically used together with the fixed ARP feature in small-scale and stable networks.

ARP scanning automatically creates ARP entries for devices in an address range. The device performs ARP scanning in the following steps:

1. Sends ARP requests for each IP address in the address range.
2. Obtains their MAC addresses through received ARP replies.
3. Creates dynamic ARP entries.

Fixed ARP converts existing dynamic ARP entries (including those generated through ARP scanning) to static ARP entries. These static ARP entries are of the same attributes as the ARP entries that are manually configured. This feature prevents ARP entries from being modified by attackers.

Restrictions and guidelines

IP addresses in existing ARP entries are not scanned.

Due to the limit on the total number of static ARP entries, some dynamic ARP entries might fail the conversion.

The **arp fixup** command is a one-time operation. You can use this command again to convert the dynamic ARP entries learned later to static.

To delete a static ARP entry converted from a dynamic one, use the **undo arp** *ip-address* [*vpn-instance-name*] command. You can also use the **reset arp all** command to delete all ARP entries or the **reset arp static** command to delete all static ARP entries.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Trigger an ARP scanning.
   arp scan [*start-ip-address* **to** *end-ip-address*]

△ **CAUTION:**

ARP scanning will take some time and occupy a lot of system and network resources. To stop an ongoing scan, press **Ctrl** + **C**. Dynamic ARP entries are created based on ARP replies received before the scan is terminated.

4. Return to system view.
   `quit`
5. Convert existing dynamic ARP entries to static ARP entries.
   `arp fixup`

Configuring ARP gateway protection

About ARP gateway protection

Configure this feature on interfaces not connected with a gateway to prevent gateway spoofing attacks.

When such an interface receives an ARP packet, it checks whether the sender IP address in the packet is consistent with that of any protected gateway. If yes, it discards the packet. If not, it handles the packet correctly.

Restrictions and guidelines

You can enable ARP gateway protection for a maximum of eight gateways on an interface.

Do not configure both the **`arp filter source`** and **`arp filter binding`** commands on an interface.

If ARP gateway protection works with ARP attack detection and ARP snooping, ARP gateway protection applies first.

Procedure

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
   Supported interface types include Layer 2 Ethernet interface and Layer 2 aggregate interface.
3. Enable ARP gateway protection for the specified gateway.
   `arp filter source` *`ip-address`*
   By default, ARP gateway protection is disabled.

Configuring ARP filtering

ARP filtering

The ARP filtering feature can prevent gateway spoofing and user spoofing attacks.

An interface enabled with this feature checks the sender IP and MAC addresses in a received ARP packet against permitted entries. If a match is found, the packet is handled correctly. If not, the packet is discarded.

Restrictions and guidelines

You can configure a maximum of eight permitted entries on an interface.

Do not configure both the **`arp filter source`** and **`arp filter binding`** commands on an interface.

If ARP filtering works with ARP attack detection and ARP snooping, ARP filtering applies first.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

   Supported interface types include Ethernet interface and Layer 2 aggregate interface.

3. Enable ARP filtering and configure a permitted entry.

   `arp filter binding` *`ip-address mac-address`*

   By default, ARP filtering is disabled.

Contents

Configuring ND attack defense

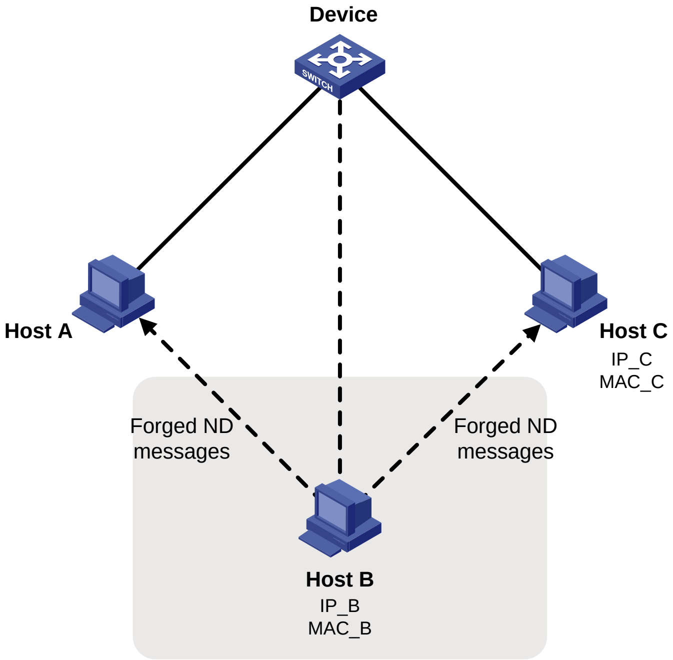
About ND attack defense

IPv6 Neighbor Discovery (ND) attack defense is able to identify forged ND messages to prevent ND attacks.

The IPv6 ND protocol does not provide any security mechanisms and is vulnerable to network attacks. As shown in Figure 1, an attacker can send the following forged ICMPv6 messages to perform ND attacks:

- Forged NS/NA/RS messages with an IPv6 address of a victim host. The gateway and other hosts update the ND entry for the victim with incorrect address information. As a result, all packets intended for the victim are sent to the attacking terminal.
- Forged RA messages with the IPv6 address of a victim gateway. As a result, all hosts attached to the victim gateway maintain incorrect IPv6 configuration parameters and ND entries.

Figure 1 ND attack diagram



Configuring source MAC-based ND attack detection

About source MAC-based ND attack detection

Source MAC-based ND attack detection checks the number of ND messages delivered to the CPU on a per source MAC basis. If the number of messages from the same MAC address within 5 seconds exceeds the threshold, the device generates an ND attack entry for the MAC address. The processing of the ND messages matching this entry depends on the detection mode. With ND logging enabled (by using the **`ipv6 nd check log enable`** command), source MAC-based ND attack detection processes the messages as follows:

- **Filter mode**—Filters out subsequent ND messages sent from the MAC address, and generates log messages.
- **Monitor mode**—Only generates log messages.

The device uses the entry aging time (fixed at 300 seconds) and the threshold to calculate a value:

The calculated value = (threshold/5) × 300

The device monitors the number of dropped packets for an entry. When the entry aging time is reached, it compares the number with the calculated value and takes actions accordingly:

- If the number of dropped packets is higher than or equal to the calculated value, the device resets the aging time for the entry.
- If the number of dropped packets is lower than the calculated value, the system deletes the entry and marks MAC address in the entry as a common MAC address.

Restrictions and guidelines

When you change the detection mode from monitor to filter, the filter mode takes effect immediately.

When you change the detection mode from filter to monitor, the device continues filtering messages that match existing attack entries.

Procedure

1. Enter system view.
   `system-view`
2. Enable source MAC-based ND attack detection and set the detection mode.
   `ipv6 nd source-mac { filter | monitor }`
   By default, source MAC-based ND attack detection is disabled.
3. Set the threshold for source MAC-based ND attack detection.
   `ipv6 nd source-mac threshold` *`threshold-value`*
   The default setting is 30.
4. Enable the ND logging feature.
   `ipv6 nd check log enable`
   By default, the ND logging feature is disabled.

Display and maintenance commands for source MAC-based ND attack detection

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display the configuration of source MAC-based ND attack detection.	**`display ipv6 nd source-mac configuration`**

Display source MAC-based ND attack detection entries.	**`display ipv6 nd source-mac interface`** *`interface-type interface-number`* `[` **`slot`** *`slot-number`* `] [` **`verbose`** `]`
	`display ipv6 nd source-mac` `{` **`mac`** *`mac-address`* `|` **`vlan`** *`vlan-id`* `}` **`slot`** *`slot-number`* `[` **`verbose`** `]`

Task	Command
	display ipv6 nd source-mac slot *slot-number* [**count** | **verbose**]
Delete source MAC-based ND attack detection entries.	**reset ipv6 nd source-mac** [**interface** *interface-type interface-number* | **mac** *mac-address* | **vlan** *vlan-id*] [**slot** *slot-number*]

Configuring interface-based ND attack suppression

About interface-based ND attack suppression

This feature rate limits ND request on each Layer 3 interface to prevent ND spoofing attacks. It monitors the number of ND requests that each Layer 3 interface received within 5 seconds. If the number on an interface exceeds the threshold, the device creates an ND attack suppression entry for the interface. During the suppression period (fixed at 300 seconds), the device drops ND messages received on this interface.

When the suppression time expires, the system examines the number of dropped ND messages on the interface within the suppression time:

- If the number is higher than or equal to the calculated value, the device resets the suppression time for the entry and continues ND suppression on the interface.

  The calculated value = (threshold/5) × 300
- If the number is lower than the calculated value, the device deletes the suppression entry.

Restrictions and guidelines

As a best practice, enable this feature on the gateway.

Procedure

1. Enter system view.

   system-view
2. Enable interface-based ND attack suppression.

   ipv6 nd attack-suppression enable per-interface

   By default, interface-based ND attack suppression is disabled.
3. Set the threshold for triggering ND attack suppression.

   ipv6 nd attack-suppression threshold *threshold-value*

   By default, the threshold for triggering ND attack suppression is 1000.

Display and maintenance commands for interface-based ND attack suppression

Execute **display** commands in any view.

Task	Command
Display the configuration of interface-based ND attack suppression.	**display ipv6 nd attack-suppression configuration**
Display interface-based ND attack suppression entries.	**display ipv6 nd attack-suppression per-interface slot** *slot-number* [**count** | **verbose**]
Display interface-based ND attack suppression entries on an interface.	**display ipv6 nd attack-suppression per-interface interface** *interface-type interface-number* [**verbose**]
Delete interface-based ND attack suppression entries.	**reset ipv6 nd attack-suppression per-interface** [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Clear statistics for ND messages dropped by interface-based ND attack suppression.	**reset ipv6 nd attack-suppression per-interface statistics** [**interface** *interface-type interface-number*] [**slot** *slot-number*]

Enabling source MAC consistency check for ND messages

About this task

The source MAC consistency check feature is typically configured on gateways to prevent ND attacks.

This feature checks the source MAC address and the source link-layer address for consistency for each arriving ND message.

- If the source MAC address and the source link-layer address are not the same, the device drops the packet.
- If the addresses are the same, the device continues learning ND entries.

The ND logging feature logs source MAC inconsistency events, and it sends the log messages to the information center. The information center can then output log messages from different source modules to different destinations. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

```
system-view
```

2. Enable source MAC consistency check for ND messages.

```
ipv6 nd mac-check enable
```

By default, source MAC consistency check is disabled for ND messages.

3. (Optional.) Enable the ND logging feature.

```
ipv6 nd check log enable
```

By default, the ND logging feature is disabled.

As a best practice, disable the ND logging feature to avoid excessive ND logs.

Configuring uRPF

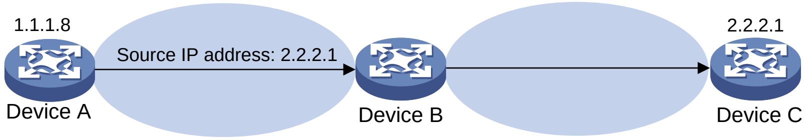
About uRPF

Unicast Reverse Path Forwarding (uRPF) protects a network against source address spoofing attacks, such as DoS and DDoS attacks.

uRPF application scenario

Attackers send packets with a forged source address to access a system that uses IPv4-based authentication, in the name of authorized users or even the administrator. Even if the attackers or other hosts cannot receive any response packets, the attacks are still disruptive to the attacked target.

Figure 1 Source address spoofing attack



As shown in Figure 1, an attacker on Device A sends the server (Device B) requests with a forged source IP address 2.2.2.1 at a high rate. Device B sends response packets to IP address 2.2.2.1 (Device C). Consequently, both Device B and Device C are attacked. If the administrator disconnects Device C by mistake, the network service is interrupted.

Attackers can also send packets with different forged source addresses or attack multiple servers simultaneously to block connections or even break down the network.

uRPF can prevent these source address spoofing attacks. It checks whether an interface that receives a packet is the output interface of the FIB entry that matches the source address of the packet. If not, uRPF considers it a spoofing attack and discards the packet.

uRPF check modes

uRPF supports strict and loose modes.

Strict uRPF check

To pass strict uRPF check, the source address of a packet and the receiving interface must match the destination address and output interface of a FIB entry. In some scenarios (for example, asymmetrical routing), strict uRPF might discard valid packets.

Strict uRPF is often deployed between a PE and a CE.

Loose uRPF check

To pass loose uRPF check, the source address of a packet must match the destination address of a FIB entry. Loose uRPF can avoid discarding valid packets, but might let go attack packets.

Loose uRPF is often deployed between ISPs, especially in asymmetrical routing.

uRPF extended functions

Link layer check

Strict uRPF check can further perform link layer check on a packet. It uses the next hop address in the matching FIB entry to look up the ARP table for a matching entry. If the source MAC address of the packet matches the MAC address in the matching ARP entry, the packet passes strict uRPF check. Link layer check is applicable to ISP devices where a Layer 3 Ethernet interface connects a large number of PCs.

Loose uRPF does not support link layer check.

Using the default route in uRPF check

When a default route exists, all packets that fail to match a specific FIB entry match the default route during uRPF check and thus are permitted to pass. To avoid this situation, you can disable uRPF from using any default route to discard such packets. If you allow using the default route (set by using **`allow-default-route`**), uRPF permits packets that only match the default route.

By default, uRPF discards packets that can only match a default route.

Typically, you do not need to configure the **`allow-default-route`** keyword on a PE device because it has no default route pointing to the CE. If you enable uRPF on a security zone where the CE interface resides and the security zone has a default route pointing to the PE, specify the **`allow-default-route`** keyword.

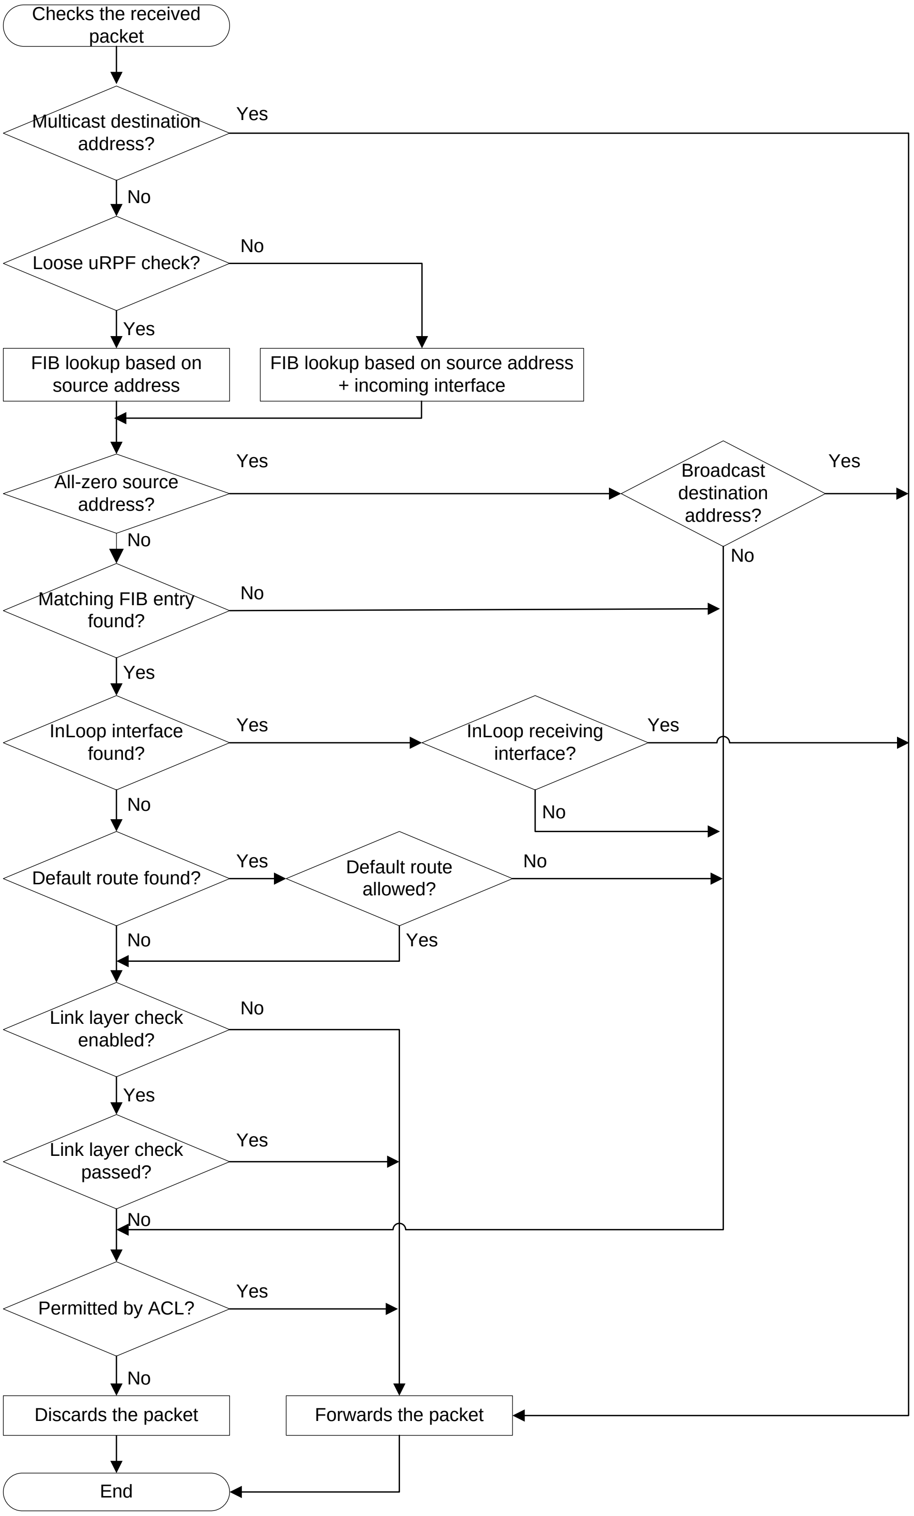
Using an ACL for uRPF check exemption

To identify specific packets as valid packets, you can use an ACL to match these packets. Even if the packets do not pass uRPF check, they are still forwarded.

uRPF operation

Figure 2 shows how uRPF works.

Figure 2 uRPF work flow



Checks the received packet

No
Discards the packet
Forwards the packet
End

1. uRPF checks whether the received packet carries a multicast destination address:
   - If yes, uRPF permits the packet.
   - If no, uRPF proceeds to step 2.
2. uRPF checks whether the uRPF check mode is loose:

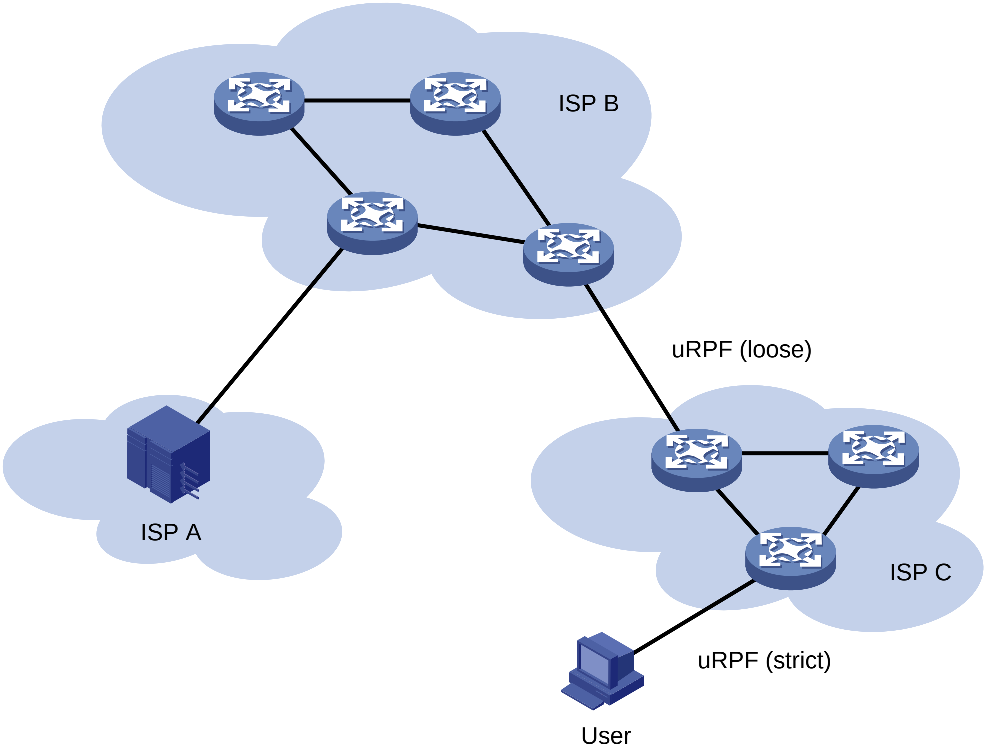
    - If yes, uRPF performs FIB lookup based on the source IP address and then proceeds to step 3.
    - If no, uRPF performs FIB lookup based on the source IP address and the receiving interface and then proceeds to step 3.
3. uRPF checks whether the source IP address is an all-zero address:
    - If yes, uRPF checks whether the destination address of the packet is a broadcast address.
        - If yes, uRPF permits the packet.
        - If no, uRPF proceeds to step 8.
    - If no, uRPF proceeds to step 4.
4. uRPF checks whether the source address matches a unicast route:
    - If yes, uRPF proceeds to step 5.
    - If no, uRPF proceeds to step 8.
5. uRPF checks whether the matching route is to the host itself (whether the output interface of the matching route is an InLoop interface):
    - If yes, uRPF checks whether the receiving interface of the packet is an InLoop interface.
        - If yes, uRPF permits the packet.
        - If no, uRPF proceeds to step 8.
    - If no, uRPF proceeds to step 6.
6. uRPF checks whether the matching route is a default route:
    - If yes, uRPF checks whether the **`allow-default-route`** keyword is configured to allow using the default route.
        - If yes, uPRF proceeds to step 7.
        - If no, uPRF proceeds to step 8.
    - If no, uRPF proceeds to step 7.
7. uRPF checks whether the **`link-check`** keyword is configured for link layer check:
    - If no, uRPF permits the packet.
    - If yes, uRPF uses the next-hop address of the FIB entry to look up the ARP table for a matching entry. Then it checks whether the MAC address of the matching ARP entry is identical with the source MAC address of the packet.
        - If yes, uRPF permits the packet.
        - If no, uRPF proceeds to step 8.
8. uRPF checks whether the packet is permitted by the ACL:
    - If yes, the packet is forwarded (such a packet is displayed in the uRPF information as a "suppressed drop").
    - If no, the packet is discarded.

Network application

As shown in Figure 3, strict uRPF check is configured between an ISP network and a customer network. Loose uRPF check is configured between ISPs.

For special packets or users, you can configure ACLs.

Figure 3 Network diagram



Restrictions and guidelines: uRPF configuration

Do not configure the **`allow-default-route`** keyword for loose uRPF check. Otherwise, uRPF might fail to work.

Do not use strict uRPF if ECMP routing is available in the network. Service packets that travel along ECMP routes cannot pass the strict uRPF check and will be dropped.

Enabling uRPF for a security zone

Restrictions and guidelines

uRPF enabled for a security zone takes effect on all interfaces in the security zone.

Procedure

1. Enter system view.

   `system-view`

2. Enter security zone view.

   `security-zone name` *`zone-name`*

3. Enable uRPF.

   `ip urpf` { **`loose`** [**`allow-default-route`**] [**`acl`** *`acl-number`*] | **`strict`** [**`allow-default-route`**] [**`acl`** *`acl-number`*] [**`link-check`**] }

   By default, uRPF is disabled.

Display and maintenance commands for uRPF

Execute **display** commands in any view.

Task	Command
Display uRPF configuration.	**display ip urpf** [**security-zone** *zone-name*] [**slot** *slot-number*]
Display uRPF statistics for a security zone.	**display ip urpf statistics security-zone** *zone-name* [**slot** *slot-number*]
Clear uRPF statistics for a security zone.	**reset ip urpf statistics security-zone** *zone-name*

Configuring IPv6 uRPF

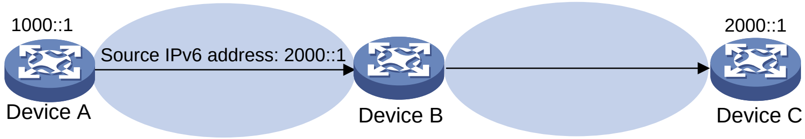
About IPv6 uRPF

IPv6 Unicast Reverse Path Forwarding (uRPF) protects a network against source address spoofing attacks, such as DoS and DDoS attacks.

IPv6 uRPF application scenario

Attackers send packets with a forged source address to access a system that uses IPv6-based authentication, in the name of authorized users or even the administrator. Even if the attackers or other hosts cannot receive any response packets, the attacks are still disruptive to the attacked target.

Figure 4 Source address spoofing attack



As shown in Figure 4, an attacker on Device A sends the server (Device B) requests with a forged source IPv6 address 2000::1 at a high rate. Device B sends response packets to IPv6 address 2000::1 (Device C). Consequently, both Device B and Device C are attacked. If the administrator disconnects Device C by mistake, the network service is interrupted.

Attackers can also send packets with different forged source addresses or attack multiple servers simultaneously to block connections or even break down the network.

IPv6 uRPF can prevent these source address spoofing attacks. It checks whether an interface that receives a packet is the output interface of the FIB entry that matches the source address of the packet. If not, IPv6 uRPF considers it a spoofing attack and discards the packet.

IPv6 uRPF check modes

IPv6 uRPF supports strict and loose check modes.

Strict IPv6 uRPF check

To pass strict IPv6 uRPF check, the source address of a packet and the receiving interface must match the destination address and output interface of an IPv6 FIB entry. In some scenarios (for example, asymmetrical routing), strict IPv6 uRPF might discard valid packets.

Strict IPv6 uRPF is often deployed between a PE and a CE.

Loose IPv6 uRPF check

To pass loose IPv6 uRPF check, the source address of a packet must match the destination address of an IPv6 FIB entry. Loose IPv6 uRPF can avoid discarding valid packets, but might let go attack packets.

Loose IPv6 uRPF is often deployed between ISPs, especially in asymmetrical routing.

IPv6 uRPF extended functions

Using the default route in IPv6 uRPF check

When a default route exists, all packets that fail to match a specific IPv6 FIB entry match the default route during IPv6 uRPF check and thus are permitted to pass. If you allow using the default route (by using **`allow-default-route`**), IPv6 uRPF permits packets that only match the default route.

By default, IPv6 uRPF discards packets that can only match a default route.

Typically, you do not need to configure the **`allow-default-route`** keyword on a PE device because it has no default route pointing to the CE device. If you enable uRPF on a security zone where the CE interface resides and the security zone has a default route pointing to the PE, specify the **`allow-default-route`** keyword.

Using an ACL for IPv6 uRPF check exemption

To identify specific packets as valid packets, you can use an IPv6 ACL to match these packets. Even if the packets do not pass IPv6 uRPF check, they are still forwarded.

IPv6 uRPF operation

Figure 5 shows how IPv6 uRPF works.

Figure 5 IPv6 uRPF work flow

Permits the packet
End

1. IPv6 uRPF checks whether the received packet carries a multicast destination address:
   - If yes, IPv6 uRPF permits the packet.
   - If no, IPv6 uRPF proceeds to step 2.
2. IPv6 uRPF checks whether the IPv6 uRPF check mode is loose:
   - If yes, IPv6 uRPF performs IPv6 FIB lookup based on the source IPv6 address and then proceeds to step 3.
   - If no, IPv6 uRPF performs IPv6 FIB lookup based on the source IPv6 address and the receiving interface and then proceeds to step 3.
3. IPv6 uRPF checks whether the source address is a link-local address:
   - If yes, IPv6 uRPF checks whether the receiving interface is a InLoop interface.

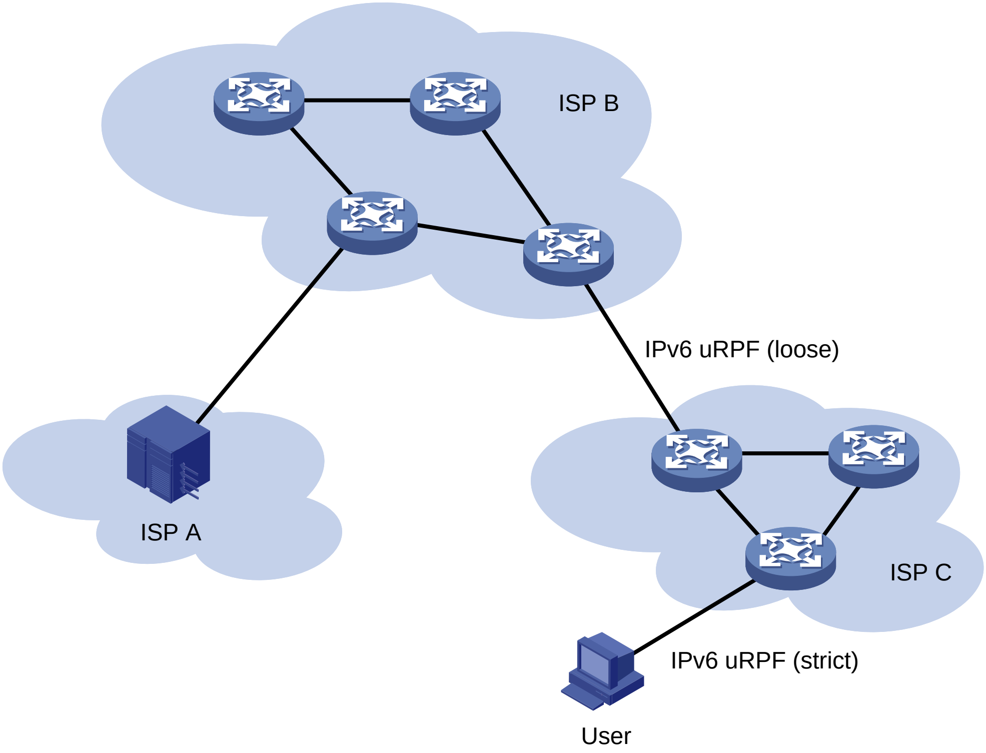
    - If yes, IPv6 uRPF permits the packet.
    - If not, IPv6 uRPF proceeds to step 4.
  - If no, IPv6 uRPF proceeds to step 8.
4. IPv6 uRPF checks whether the source address is an all-zero address:
   - If yes, IPv6 uRPF proceeds to step 8.
   - If no, IPv6 uRPF proceeds to step 5.
5. IPv6 uRPF checks whether the source address matches a unicast route:
   - If yes, IPv6 uRPF proceeds to step 6.
   - If no, IPv6 uRPF proceeds to step 8.
6. IPv6 uRPF checks whether the matching route is to the host itself (whether the output interface of the matching route is an InLoop interface):
   - If yes, IPv6 uRPF checks whether the receiving interface of the packet is an InLoop interface.
     - If yes, IPv6 uRPF permits the packet.
     - If no, IPv6 uRPF proceeds to step 8.
   - If no, IPv6 uRPF proceeds to step 7.
7. IPv6 uRPF checks whether the matching route is a default route:
   - If yes, IPv6 uRPF checks whether the **`allow-default-route`** keyword is configured to allow using the default route.
     - If yes, the packet is forwarded.
     - If no, IPv6 uRPF proceeds to step 8.
   - If no, the packet is forwarded.
8. IPv6 uRPF checks whether the packet is permitted by the IPv6 ACL:
   - If yes, the packet is forwarded (such a packet is displayed in the uRPF information as a "suppressed drop").
   - If no, the packet is discarded.

Network application

As shown in Figure 6, strict IPv6 uRPF check is configured between an ISP network and a customer network. Loose IPv6 uRPF check is configured between ISPs.

For special packets or users, you can configure IPv6 ACLs.

Figure 6 Network diagram



Restrictions and guidelines: IPv6 uRPF configuration

Do not configure the **`allow-default-route`** keyword for loose IPv6 uRPF check. Otherwise, IPv6 uRPF might fail to work.

Do not use strict IPv6 uRPF if ECMP routing is available in the network. Service packets that travel along ECMP routes cannot pass the strict uRPF check and will be dropped.

Enabling IPv6 uRPF for a security zone

Restrictions and guidelines

IPv6 uRPF enabled for a security zone takes effect on all interfaces in the security zone.

Procedure

1. Enter system view.
   `system-view`
2. Enter security zone view.
   `security-zone name` *`zone-name`*
3. Enable IPv6 uRPF.
   `ipv6 urpf` { **`loose`** | **`strict`** } [**`allow-default-route`**] [**`acl`** *`acl-number`*]
   By default, IPv6 uRPF is disabled.

Display and maintenance commands for IPv6 uRPF

Execute **display** commands in any view.

Task	Command
Display IPv6 uRPF configuration.	**display ipv6 urpf** [**security-zone** *zone-name*] [**slot** *slot-number*]
Display IPv6 uRPF statistics for a security zone.	**display ipv6 urpf statistics security-zone** *zone-name* [**slot** *slot-number*]
Clear IPv6 uRPF statistics for a security zone.	**reset ipv6 urpf statistics security-zone** *zone-name*

Contents

Configuring IP-MAC binding

About IP-MAC binding

The device prevents user spoofing attacks by using an IP-MAC binding table to filter out illegitimate packets with forged source IP addresses or MAC addresses.

Operating mechanism

The IP-MAC binding table contains binding entries that bind IP addresses and MAC addresses. The device uses the binding entries to match an incoming packet.

As shown in Figure 1, all hosts communicate with the IP network through the device. When the device receives a packet, it compares the source IP address and source MAC address in the packet with the IP-MAC binding entries. Table 1 describes the way the device processes the packet based on the match result.

Figure 1 IP-MAC binding application scenario

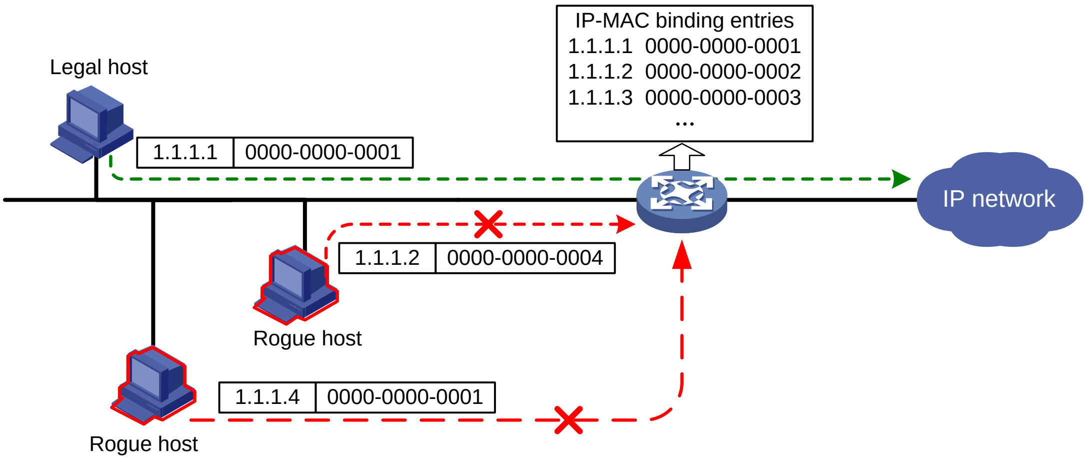


Table 1 Processing of a packet based on the match result

Match result	Processing of the packet
The packet source IP address and source MAC address match the same IP-MAC binding entry.	Permits the packet.
Only the source IP address or source MAC address matches a binding entry.	Drops the packet.
The source IP address and source MAC address match two different binding entries.	Drops the packet.
Both the source IP address and the source MAC address of a packet match no IP-MAC binding entry.	Processes the packet based on the default action. By default, the device permits all packets that do not match any binding entries. You can use the **`ip-mac binding no-match action deny`** command to set the default action to deny.

IP-MAC binding entry creation

An IP-MAC binding entry binds an IP address to a MAC address. You can manually create IP-MAC binding entries one by one or generate them in bulk. All binding entries are globally effective.

Manual creation of IP-MAC binding entries

This method is applicable only to networks that do not contain many hosts and in which the hosts are statically assigned IP addresses.

Bulk generation of IP-MAC binding entries

This method is applicable to networks that contain many hosts.

This method allows a device to generate IPv4-MAC binding entries based on ARP entries and create IPv6-MAC binding entries based on ND entries on an interface.

The device generates an IP-MAC binding entry based on an ARP or ND entry as follows:

- If neither the IP address nor the MAC address in the ARP/ND entry exists in the binding table, the device generates a new binding entry. In this situation, the IP address and the MAC address are uniquely bound to each other.
- If the MAC address in the ARP/ND entry exists in the binding table but the IP address does not, the device generates a new binding entry. In this situation, the MAC address is bound to multiple IP addresses.
- If the IP address in the ARP/ND entry exists in the binding table, the device will not generate a new binding entry. This is because an IP address can be bound to only one MAC address.

IP-MAC binding entries generated based on ARP and ND entries are static. Therefore, the binding entries are not updated when the relevant ARP or ND entries change.

Restrictions and guidelines: IP-MAC binding configuration

IP-MAC binding entries are static. Therefore, the IP-MAC binding feature is applicable only to networks where all users are statically assigned IP addresses. Using this feature in a network where all users' IP addresses are dynamically assigned through DHCP might cause communication failure.

A MAC address can be bound to multiple IP addresses. To bind a MAC address in a binding entry to another IP address, use the MAC address and new IP address to create a new binding entry. You can choose to delete the existing binding entry or retain it. An IP address can be bound to only one MAC address. To bind an IP address in a binding entry to another MAC address, you must delete the existing binding entry and then create the new one.

IP-MAC binding tasks at a glance

To configure IP-MAC binding, perform the following tasks:

1. Enabling the IP-MAC binding feature
2. Configuring IP-MAC binding entries

   Choose the options to configure as needed:

   - Manually creating an IP-MAC binding entry
   - Bulk generating IP-MAC binding entries
3. Setting the default action for packets that do not match any IP-MAC binding entries

Enabling the IP-MAC binding feature

About this task

With this feature enabled, the device compares the source IP address and source MAC address in packets with existing IP-MAC binding entries. Packets that do not exactly match any IP-MAC binding entries are dropped.

Procedure

1. Enter system view.

   `system-view`

2. Enable the IP-MAC binding feature.

   `ip-mac binding enable`

   By default, the IP-MAC binding feature is disabled.

Manually creating an IP-MAC binding entry

Creating an IP-MAC binding entry

1. Enter system view.

   `system-view`

2. Create an IP-MAC binding entry.

   IPv4:

   ip-mac binding ipv4 *ipv4-address* **mac-address** *mac-address* [**vlan** *vlan-id* | **vpn-instance** *vpn-instance-name*]

   IPv6:

   ip-mac binding ipv6 *ipv6-address* **mac-address** *mac-address* [**vlan** *vlan-id* | **vpn-instance** *vpn-instance-name*]

   By default, no IP-MAC binding entry is configured.

Bulk generating IP-MAC binding entries

About this task

This task allows the device to generate IP-MAC binding entries in bulk based on existing ARP and ND entries on an interface.

Procedure

1. Enter system view.

   `system-view`

2. Bulk generate IP-MAC binding entries.

   ip-mac binding interface *interface-type interface-number*

Setting the default action for packets that do not match any IP-MAC binding entries

About this task

By default, the device permits packets that do not match any IP-MAC binding entries to pass through. This task allows you to set the default action to deny for these packets.

Procedure

1. Enter system view.
   `system-view`
2. Set the default action to deny for packets that do not match any IP-MAC binding entries.
   `ip-mac binding no-match action deny`
   By default, the action for packets that do not match any IP-MAC binding entries is **permit**.

Display and maintenance commands for IP-MAC binding

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display IPv4-MAC binding entries.	**display ip-mac binding ipv4** [*ipv4-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id* | **vpn-instance** *vpn-instance-name*]
Display IPv6-MAC binding entries.	**display ip-mac binding ipv6** [*ipv6-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id* | **vpn-instance** *vpn-instance-name*]
Display statistics about packets dropped by the IP-MAC binding feature.	**display ip-mac binding statistics** [**slot** *slot-number*]
Display the status of the IP-MAC binding feature.	**display ip-mac binding status**
Clear statistics about packets dropped by the IP-MAC binding feature.	**reset ip-mac binding statistics** [**slot** *slot-number*]

IP-MAC binding configuration examples

Example: Configuring IPv4-MAC binding

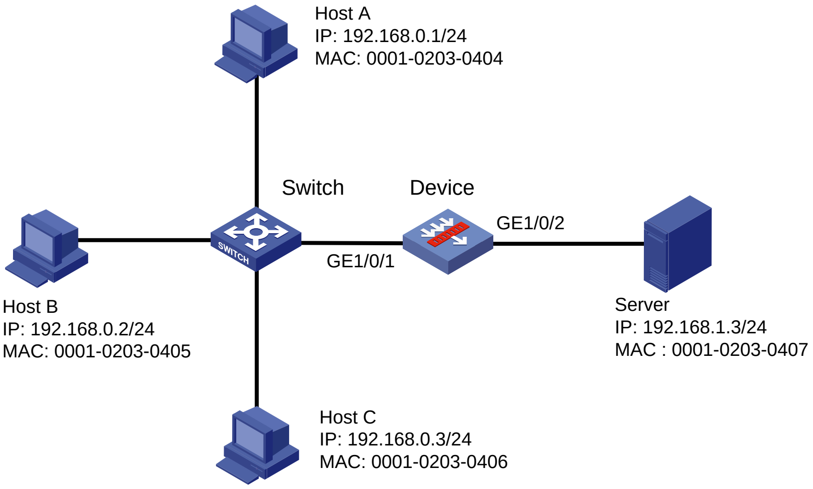
Network configuration

As shown in Figure 2, Host A, Host B, and the server are statically assigned IPv4 addresses. Host A and Host B communicate with the server through the gateway (the device).

Create the following IPv4-MAC binding entries on the device to permit packets only from Host A, Host B, and the server:

- Bind IPv4 address 192.168.0.1 to MAC address 0001-0203-0404 for Host A.
- Bind IPv4 address 192.168.0.2 to MAC address 0001-0203-0405 for Host B.
- Bind IPv4 address 192.168.1.3 to MAC address 0001-0203-0407 for the server.

Figure 2 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.0.254 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/1
[Device-security-zone-Trust] quit
[Device] security-zone name dmz
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/2
[Device-security-zone-DMZ] quit
```

3. Configure a security policy:

   # Configure a rule named **trust-dmz** to allow hosts in security zone **trust** to access the server.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name trust-dmz
[Device-security-policy-ip-1-trust-dmz] source-zone trust
[Device-security-policy-ip-1-trust-dmz] destination-zone dmz
[Device-security-policy-ip-1-trust-dmz] source-ip-subnet 192.168.0.0 24
[Device-security-policy-ip-1-trust-dmz] destination-ip-subnet 192.168.1.0 24
[Device-security-policy-ip-1-trust-dmz] action pass
[Device-security-policy-ip-1-trust-dmz] quit
```

   # Configure a rule named **dmz-trust** to allow the hosts to access the internal servers.

```
[Device-security-policy-ip] rule name untrust-dmz
[Device-security-policy-ip-2-untrust-dmz] source-zone untrust
```

```
[Device-security-policy-ip-2-untrust-dmz] destination-zone dmz
[Device-security-policy-ip-2-untrust-dmz] destination-ip-host 10.1.1.2
[Device-security-policy-ip-2-untrust-dmz] action pass
[Device-security-policy-ip-2-untrust-dmz] quit
[Device-security-policy-ip] quit
```

4. Configure the IP-MAC binding feature:

   # Enable the IP-MAC binding feature on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

   ```
   [Device] ip-mac binding enable
   ```

   # Create IPv4-MAC binding entries to permit packets only from Host A, Host B, and the server.

   ```
   [Device] ip-mac binding ip 192.168.0.1 mac-address 0001-0203-0404
   [Device] ip-mac binding ip 192.168.0.2 mac-address 0001-0203-0405
   [Device] ip-mac binding ip 192.168.1.3 mac-address 0001-0203-0407
   ```

   # Set the default action to deny for packets that do not match any IP-MAC binding entries.

   ```
   [Device] ip-mac binding no-match action deny
   ```

Verifying the configuration

# Display IPv4-MAC binding entries.

```
<Device> display ip-mac binding ipv4
Total entries: 1
IP address      MAC address         VPN instance         VLAN ID
192.168.0.1     0001-0203-0404      public               N/A
192.168.0.2     0001-0203-0405      public               N/A
192.168.1.3     0001-0203-0407      public               N/A
```

# Ping the server from Host C.

```
C:\> ping 192.168.1.3

Pinging 192.168.1.3 with 32 bytes of data:

Request timed out.
Request timed out.
Request timed out.
Request timed out.

Ping statistics for 192.168.1.3:
   Packets: Sent = 4, Received = 0, Lost = 4 (100% loss),
```

The ping requests timed out, which indicates that the requests are blocked by the device.

Example: Configuring IPv6-MAC binding

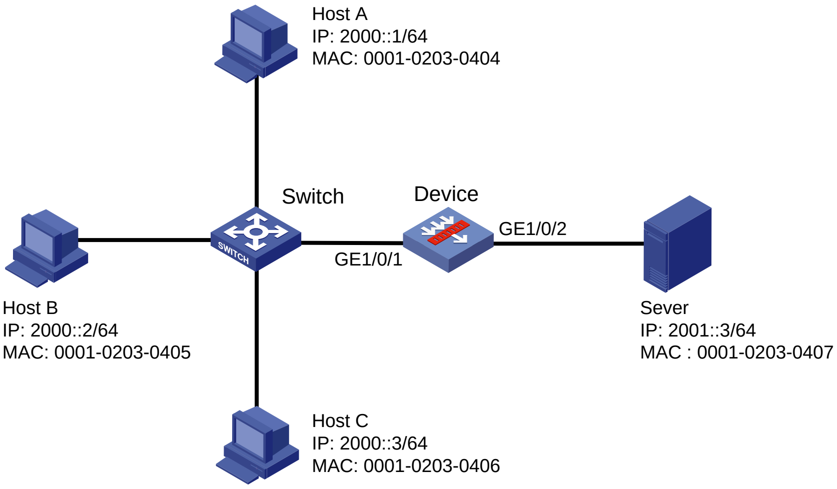
Network configuration

As shown in Figure 3, Host A, Host B, and the server are statically assigned IPv6 addresses. Host A and Host B communicate with the server through the gateway (the device).

Create the following IPv6-MAC binding entries on the device to permit packets only from Host A, Host B, and the server:

- Bind IPv6 address 2000::1/64 to MAC address 0001-0203-0404 for Host A.
- Bind IPv6 address 2000::2/64 to MAC address 0001-0203-0405 for Host B.
- Bind IPv6 address 2001::3/64 to MAC address 0001-0203-0407 for the server.

Figure 3 Network diagram



Procedure

1. Assign IP addresses to interfaces:

   Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ipv6 address 2000::4 64
[Device-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

2. Add interfaces to security zones.

```
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/1
[Device-security-zone-Trust] quit
[Device] security-zone name dmz
[Device-security-zone-DMZ] import interface gigabitethernet 1/0/2
[Device-security-zone-DMZ] quit
```

3. Configure a security policy:

   # Configure a rule named **trust-dmz** to allow hosts in security zone **trust** to access the server.

```
[Device] security-policy ipv6
[Device-security-policy-ipv6] rule name trust-dmz
[Device-security-policy-ipv6-1-trust-dmz] source-zone trust
[Device-security-policy-ipv6-1-trust-dmz] destination-zone dmz
[Device-security-policy-ipv6-1-trust-dmz] source-ip-subnet 2000::1 64
[Device-security-policy-ipv6-1-trust-dmz] destination-ip-subnet 2001::1 64
[Device-security-policy-ipv6-1-trust-dmz] action pass
[Device-security-policy-ipv6-1-trust-dmz] quit
```

   # Configure a rule named **dmz-trust** to allow the hosts to access the internal servers.

```
[Device-security-policy-ipv6] rule name dmz-trust
[Device-security-policy-ipv6-2-dmz-trust] source-zone dmz
[Device-security-policy-ipv6-2-dmz-trust] destination-zone trust
[Device-security-policy-ipv6-2-dmz-trust] source-ip-subnet 2001::1 64
[Device-security-policy-ipv6-2-dmz-trust] destination-ip-subnet 2000::1 64
[Device-security-policy-ipv6-2-dmz-trust] action pass
```

```
[Device-security-policy-ipv6-2-dmz-trust] quit
[Device-security-policy-ipv6] quit
```

4. Configure the IP-MAC binding feature:

   # Enable the IP-MAC binding feature on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

   ```
   [Device] ip-mac binding enable
   ```

   # Create IPv6-MAC binding entries to permit packets only from Host A, Host B, and the server.

   ```
   [Device] ip-mac binding ipv6 2000::1 mac-address 0001-0203-0404
   [Device] ip-mac binding ipv6 2000::2 mac-address 0001-0203-0405
   [Device] ip-mac binding ipv6 2001::3 mac-address 0001-0203-0407
   ```

   # Set the default action to deny for packets that do not match any IP-MAC binding entries.

   ```
   [Device] ip-mac binding no-match action deny
   ```

Verifying the configuration

# Display IPv6-MAC binding entries.

```
<Device> display ip-mac binding ipv6
Total entries: 1
IP address      MAC address         VPN instance         VLAN ID
2000::1         0001-0203-0404      public               N/A
2000::2         0001-0203-0405      public               N/A
2001::3         0001-0203-0407      public               N/A
```

# Ping the server from Host C.

```
C:\> ping 2001::3

Pinging 2001::3 with 32 bytes of data:

Request timed out.
Request timed out.
Request timed out.
Request timed out.

Ping statistics for 2001::3:
   Packets: Sent = 4, Received = 0, Lost = 4 (100% loss),
```

The ping requests timed out, which indicates that the requests are blocked by the device.

Contents

Configuring APR

About APR

The application recognition (APR) feature recognizes application protocols of packets for features such as QoS, ASPF, and bandwidth management.

APR uses the following methods to recognize an application protocol:

- Port-based application recognition (PBAR).
- Network-based application recognition (NBAR).

PBAR

PBAR maps a port to an application protocol and recognizes packets of the application protocol according to the port-protocol mapping.

PBAR supports the following port-protocol mappings:

- **Predefined**—An application protocol uses the port defined by the system. You can modify the predefined mappings as needed.
- **User-defined**—An application protocol uses the port defined by the user.

PBAR offers the following mappings to maintain and apply user-defined port configuration:

- **General port mapping**—Maps a user-defined port to an application protocol. All packets destined for that port are regarded as packets of the application protocol. For example, if port 2121 is mapped to FTP, all packets destined for that port are regarded as FTP packets.
- **Host-port mapping**—Maps a user-defined port to an application protocol for packets to or from some specific hosts. For example, you can establish a host-port mapping so that all packets destined for the network segment 10.110.0.0/16 on port 2121 are regarded as FTP packets. To define the range of the hosts, you can specify the ACL, the host IP address range, or the subnet.

  Host-port mapping can be further divided into the following categories:

  - **ACL-based host-port mapping**—Maps a port to an application protocol for the packets matching the specified ACL.
  - **Subnet-based host-port mapping**—Maps a port to an application protocol for the packets sent to the specified subnet.
  - **IP address-based host-port mapping**—Maps a port to an application protocol for the packets destined for the specified IP addresses.

APR selects a port mapping to recognize the application protocol of a packet in the following order:

- IP address-based port mapping.
- Subnet-based port mapping.
- ACL-based host-port mapping.
- General port mapping.

For the same type of mappings, the port mapping with a transport layer protocol has higher priority than the mapping without a transport layer protocol.

NBAR

NBAR uses predefined or user-defined NBAR rules to match packet contents to recognize the application protocols of packets that match the applied object policy.

NBAR can recognize the following application types:

- **Predefined**—Defined by NBAR rules in the APR signature library.
- **User-defined**—Defined by user-configured NBAR rules.

Application group

You can add application protocols that have similar signatures or restrictions to an application group. APR recognizes packets of the application protocols by matching the packet contents with the signatures or restrictions. If a packet is recognized as the packet of an application protocol in the application group, the packet is considered to be the packet of the application group. Features such as ASPF and bandwidth management can handle packets belonging to the same group in batch.

You can add application protocols to an application group by using the following methods:

- Add application protocols one by one to the application group.
- Copy application protocols from another application group to the application group.

APR signature library management

APR signature library

APR signature library is a resource library of character string signatures for application recognition. It includes PBAR and NBAR signatures. To meet the changing requirements for application recognition, you must update the APR signature library in a timely manner and roll back the APR signature library as needed.

APR signature library update

You can update the APR signature library by using one of the following methods:

- Automatic update.

  The device automatically downloads the most up-to-date APR signature file to update its local signature library periodically.
- Triggered update.

  The device downloads the most up-to-date APR signature file to update its local signature library immediately after you trigger the update operation.
- Manual update.

  Use this method when the device cannot obtain the APR signature file automatically.

  You must first download the most up-to-date APR signature file manually. The device then obtains the downloaded file to update its local signature library.

APR signature library rollback

You can perform the rollback operation if high error rate or abnormality occurs when the device uses the current APR signature library for application recognition.

You can roll back the current APR signature library to the last version or to the factory version.

Restrictions: Licensing requirements for APR

To update the APR signature library, you must purchase and install the appropriate license. After the license expires, APR can still use the existing signature library but cannot update the signature library. For information about licenses, see license management in *Fundamentals Configuration Guide*.

APR tasks at a glance

To configure APR, perform the following tasks:

1. Configuring PBAR
2. Configuring a user-defined NBAR rule
3. Configuring a risk type for a user-defined application
4. Configuring application groups
5. Enabling application statistics on an interface
6. Configuring detection thresholds for categorizing an application as type other
7. Managing the APR signature library

Configuring PBAR

1. Enter system view.

   system-view

2. Configure a port mapping.

   Choose the options to configure as needed:

   - Configure a general port mapping:

     port-mapping application *application-name* **port** *port-number* [**protocol** *protocol-name*]

   - Configure an ACL-based host-port mapping:

     port-mapping application *application-name* **port** *port-number* [**protocol** *protocol-name*] **acl** [**ipv6**] *acl-number*

   - Configure a subnet-based host-port mapping:

     port-mapping application *application-name* **port** *port-number* [**protocol** *protocol-name*] **subnet** { **ip** *ipv4-address* { *mask-length* | *mask* } | **ipv6** *ipv6-address prefix-length* } [**vpn-instance** *vpn-instance-name*]

   - Configure an IP address-based host-port mapping:

     port-mapping application *application-name* **port** *port-number* [**protocol** *protocol-name*] **host** { **ip** | **ipv6** } *start-ip-address* [*end-ip-address*] [**vpn-instance** *vpn-instance-name*]

   By default, all application protocols are mapped to well-known ports.

   If the specified application protocol does not exist, the system first creates the protocol.

Configuring a user-defined NBAR rule

About this task

You can configure user-defined NBAR rules if predefined NBAR rules cannot meet user needs. The predefined NBAR rules cannot be deleted or modified.

A user-defined NBAR rule can contain the following match criteria:

- Signatures.
- Destination IP subnet.
- Source IP subnet.
- Direction at which the application is recognized.

- Port number.

You can configure more than one match criterion for the NBAR rule. To match the NBAR rule, packets must match all the configured match criteria in the rule. If multiple signatures are configured, packets must match a minimum of one signature.

Procedure

1. Enter system view.

   system-view

2. Create a user-defined NBAR rule and enter its view.

   nbar application *application-name* **protocol** { **http** | **tcp** | **udp** }

3. (Optional.) Configure the description of the NBAR rule.

   description *text*

   By default, the user-defined NBAR rule is described as **User defined application**.

4. Configure a signature and enter NBAR rule signature view.

   signature [*signature-id*] [**field** *field-name*] [**offset** *offset-value*] { **hex** *hex-vector* | **regex** *regex-pattern* | **string** *string* }

   By default, no signatures are configured for an NBAR rule.

5. (Optional.) Configure a detection item for the signature.

   detection *detection-id* **field** *field-name* **match-type** { **exclude** | **include** } { **hex** *hex-vector* | **regex** *regex-pattern* | **text** *text-string* } [**offset** *offset-value* [**depth** *depth-value*] | **relative-offset** *relative-offset-value* [**relative-depth** *relative-depth-value*]]

   By default, no detection items are configured for a signature.

6. Return to user-defined NBAR rule view.

   quit

7. (Optional.) Specify a destination IP subnet.

   destination ip *ipv4-address* [*mask-length*]

   By default, an NBAR rule matches packets with any destination IP address.

8. (Optional.) Specify a source IP subnet.

   source ip *ipv4-address* [*mask-length*]

   By default, an NBAR rule matches packets with any source IP address.

9. (Optional.) Specify a direction.

   direction { **to-client** | **to-server** }

   By default, an NBAR rule matches packets in both directions.

10. (Optional.) Specify a port number or port range.

    service-port { *port-num* | **range** *start-port end-port* }

    By default, an NBAR rule matches packets of all port numbers.

11. (Optional.) Set the maximum detected length.

    apr set detectlen *bytes*

    By default, the maximum detected length is not set for an NBAR rule.

12. (Optional.) Disable the user-defined NBAR rule.

    disable

    By default, a user-defined NBAR rule is enabled.

13. Activate the user-defined NBAR rule.

    inspect activate

For information about this command, see DPI engine commands in *DPI Command Reference*.

Configuring a risk type for a user-defined application

About this task

A user-defined application can have multiple or no risk types.

The more risk types a user-defined application has, the higher risk level the application has. You can configure security policies according to the risk level.

The risk types for predefined applications are automatically generated by the APR signature library.

Restrictions and guidelines

Before configuring risk types, you must update the APR signature library to the latest version.

The user-defined application must already exist.

Procedure

1. Enter system view.

   `system-view`

2. Enter user-defined application view.

   `user-defined-application` *`application-name`*

3. Configure a risk type for the user-defined application.

   `risk type` *`risk-type`*

   By default, a user-defined application does not have any risk type.

Configuring application groups

1. Enter system view.

   `system-view`

2. Create an application group and enter its view.

   `app-group` *`group-name`*

3. (Optional.) Configure the description of the application group.

   `description` *`text`*

   By default, the description is **"User-defined application group"**.

4. Add application protocols to the group.

   Choose the options to configure as needed:

   - Copy all application protocols from another group to the group.

     `copy app-group` *`group-name`*

     Execute this command multiple times to copy application protocols from multiple groups to the current group.

   - Add an application protocol to the group.

     `include application` *`application-name`*

     By default, an application group does not contain any application protocols.

Enabling application statistics on an interface

About this task

When the application statistics feature is enabled on an interface, the device separately counts the number of packets or bytes that the interface has received or sent for each application protocol. It also calculates the transmission rates of the interface for these protocols.

To display application statistics, use the **display application statistics** command.

Restrictions and guidelines

The application statistics feature consumes a large amount of system memory. When the system generates an alarm for lack of memory, disable the application statistics feature on all interfaces.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Enable application statistics on the interface.

   application statistics enable [**inbound** | **outbound**]

   By default, this feature is disabled.

   If you do not specify the **inbound** or **outbound** keyword, this command enables the application statistics feature in both the inbound and outbound directions of the interface.

Configuring detection thresholds for categorizing an application as type other

About this task

If the device cannot identify the application to which the packets of a protocol belongs after detection thresholds are reached, it categorizes the packets as belonging to type **other**.

Restrictions and guidelines

You can configure both the packet count threshold and the payload length threshold for the same protocol.

Procedure

1. Enter system view.

   system-view

2. Configure detection thresholds for categorizing an application as type **other**.

   apr protocol *protocol-name* **detect-threshold** { **packet-count** *count* | **payload-length** *length* } **application-other**

   By default, the device uses predefined detection thresholds in the signature library for categorizing an application as type **other**.

Managing the APR signature library

Restrictions and guidelines for APR signature library management

For a successful APR signature library update or rollback, do not delete the **/dpi/** folder in the root directory on the device storage media.

Do not update or roll back the APR signature library when the remaining system memory reaches any alarm threshold. Insufficient memory causes update or rollback failure and affects the operation of NBAR. For information about memory alarm thresholds, see device management in *Fundamentals Configuration Guide*.

You can update only one APR signature library at a time. If an APR signature library is being updated, please wait for the update to complete before updating another APR signature library.

Scheduling an automatic update for the APR signature library

About this task

If the device can access the signature library services on the official website, you can schedule an automatic update. The automatic update enables the device to automatically update the local APR signature library at the scheduled update time.

Restrictions and guidelines

For a successful automatic update, make sure the following requirements are met:

- The device can obtain the IP address of the official website through static or dynamic domain name resolution.
- The device can access the signature library services on the official website.

For information about DNS, see *Layer 3—IP Services Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable the automatic update feature and enter auto-update configuration view.

   apr signature auto-update

   By default, the automatic update feature is disabled.

3. Configure the update schedule.

   update schedule { **daily** | **weekly** { **fri** | **mon** | **sat** | **sun** | **thu** | **tue** | **wed** } } **start-time** *time* **tingle** *minutes*

   By default, the device automatically updates the APR signature library between 02:01:00 to 04:01:00 every day.

4. (Optional.) Overwrite the current signature file.

   override-current

   By default, the current APR signature file is not overwritten for an update operation. Instead, the device will back up the current APR signature file.

Triggering an automatic update for the APR signature library

About this task

Anytime you find a release of new signature version on the official website, you can trigger the device to immediately update the local APR signature library.

Restrictions and guidelines

For a successful triggered update, make sure the following requirements are met:

- The device can obtain the IP address of the official website through static or dynamic domain name resolution.
- The device can access the signature library services on the official website.

For information about DNS, see *Layer 3—IP Services Configuration Guide.*

Procedure

1. Enter system view.
   `system-view`
2. Trigger an automatic update for the APR signature library.
   `apr signature auto-update-now`

Performing a manual update for the APR signature library

About this task

If the device cannot access the signature library services on the official website, use one of the following methods to manually update the APR signature library on the device:

- **Local update**—By using the locally stored APR signature file.

  The APR signature file must be stored on the mater device for a successful update.
- **FTP/TFTP update**—By using the APR signature file stored on the FTP or TFTP server.

Procedure

1. Enter system view.
   `system-view`
2. Manually update the APR signature library.
   `apr signature update` [**`override-current`**] *`file-path`*

Rolling back the APR signature library

About this task

Each time a rollback operation is performed, the device backs up the APR signature library of the current version. If you repeat the rollback to the last version operation multiple times, the APR signature library will repeatedly switch between the current version and the last version.

Restrictions and guidelines

To ensure that the APR signature library can be successfully rolled back to the last version, back up the current APR signature library each time you update the library.

Procedure

1. Enter system view.
   `system-view`

2. Roll back the APR signature library.
   apr signature rollback { **factory** | **last** }

Display and maintenance commands for APR

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about application groups.	**display app-group** [**name** *group-name*]
Display information about application protocols.	**display application** [**name** *application-name* | **pre-defined** | **user-defined**]
Display statistics for application protocols.	**display application statistics** [**direction** { **inbound** | **outbound** } | **interface** *interface-type interface-number* [**slot** *slot-number*] | **name** *application-name*] *
Display statistics for application protocols on an interface in descending order based on the specified criteria.	**display application statistics top** *number* { **bps** | **bytes** | **packets** | **pps** } **interface** *interface-type interface-number* [**slot** *slot-number*]
Display detection threshold settings for applications categorized as type **other**.	**display apr protocol** [*protocol-name*] **detection-threshold-other**
Display APR signature library information.	**display apr signature library**
Display information about predefined port mappings.	**display port-mapping pre-defined**
Display information about user-defined port mappings.	**display port-mapping user-defined** [**application** *application-name* | **port** *port-number*]
Clear application statistics for interfaces.	**reset application statistics** [**interface** *interface-type interface-number*]

Contents

Configuring keychains

About keychains

A keychain, a sequence of keys, provides dynamic authentication to ensure secure communication by periodically changing the key and authentication algorithm without service interruption.

Operating mechanism

Each key in a keychain has a key string, authentication algorithm, sending lifetime, and receiving lifetime. When the system time is within the lifetime of a key in a keychain, an application uses the key to authenticate incoming and outgoing packets. The keys in the keychain take effect one by one according to the sequence of the configured lifetimes. In this way, the authentication algorithms and keys are dynamically changed to implement dynamic authentication.

Time modes

A keychain operates in absolute time mode or periodic time mode. The lifetime for a key varies by time mode.

- **Absolute time mode**—Each time point in a key's lifetime is in UTC and is not affected by the system's time zone or daylight saving time.
- **Periodic time mode**—A key's lifetime is calculated based on the local time and is affected by the system's time zone and daylight saving time.
  - **daily**—The lifetime for a key is from the specified start time to the specified end time of each day.
  - **weekly**—The lifetime for a key is from the specified start day to the specified end day of each week.
  - **monthly**—The lifetime for a key is from the specified start date to the specified end date of each month.
  - **yearly**—The lifetime for a key is from the specified start month to the specified end month of each year.

Restrictions and guidelines: Keychain configuration

To make sure only one key in a keychain is used at a time to authenticate packets to a peer, set non-overlapping sending lifetimes for the keys in the keychain.

The keys used by the local device and the peer device must have the same authentication algorithm and key string.

Configuring a keychain in absolute time mode

1. Enter system view.

   ```
   system-view
   ```

2. Create a keychain and enter keychain view.

   ```
   keychain keychain-name mode absolute
   ```

3. (Optional.) Configure TCP authentication.
   - Set the kind value in the TCP Enhanced Authentication Option.

     tcp-kind *kind-value*

     By default, the kind value is 254.
   - Set an algorithm ID for a TCP authentication algorithm.

     tcp-algorithm-id { **hmac-md5** | **hmac-sha-256** | **hmac-sm3** | **md5** | **sm3** } *algorithm-id*

     By default, the algorithm ID is 3 for the MD5 authentication algorithm, 5 for the HMAC-MD5 authentication algorithm, 7 for the HMAC-SHA-256 authentication algorithm, 51 for the SM3 authentication algorithm, and 52 for the HMAC-SM3 authentication algorithm.

   When the local device uses TCP to communicate with a peer device from another vendor, make sure both devices have the same kind value and algorithm ID settings. If they do not, modify the settings on the local device.
4. (Optional.) Set a tolerance time for accept keys in the keychain.

   accept-tolerance { *value* | **infinite** }

   By default, no tolerance time is configured for accept keys in a keychain.

   If authentication information is changed, information mismatch occurs on the local and peer devices, and the service might be interrupted. Use this command to ensure continuous packet authentication.
5. Create a key and enter key view.

   key *key-id*
6. Configure the key.
   - Specify an authentication algorithm for the key.

     authentication-algorithm { **hmac-md5** | **hmac-sha-1** | **hmac-sha-256** | **hmac-sm3** | **md5** | **sm3** }

     By default, no authentication algorithm is specified for a key.
   - Configure a key string for the key.

     key-string { **cipher** | **plain** } *string*

     By default, no key string is configured.
   - Set the sending lifetime in UTC mode for the key.

     send-lifetime utc *start-time start-date* { **duration** { *duration-value* | **infinite** } | **to** *end-time end-date* }

     By default, the sending lifetime is not configured for a key.
   - Set the receiving lifetime in UTC mode for the key.

     accept-lifetime utc *start-time start-date* { **duration** { *duration-value* | **infinite** } | **to** *end-time end-date* }

     By default, the receiving lifetime is not configured for a key.
   - (Optional.) Specify the key as the default send key.

     default-send-key

     By default, a keychain does not have a default send key.

     You can specify only one key as the default send key in a keychain.

Configuring a keychain in periodic time mode

1. Enter system view.

   system-view

2. Create a keychain and enter keychain view.

   keychain *keychain-name* **mode periodic** { **daily** | **monthly** | **weekly** | **yearly** }

3. (Optional.) Configure TCP authentication.

   - Set the kind value in the TCP Enhanced Authentication Option.

     tcp-kind *kind-value*

     By default, the kind value is 254.

   - Set an algorithm ID for a TCP authentication algorithm.

     tcp-algorithm-id { **hmac-md5** | **hmac-sha-256** | **hmac-sm3** | **md5** | **sm3** } *algorithm-id*

     By default, the algorithm ID is 3 for the MD5 authentication algorithm, 5 for the HMAC-MD5 authentication algorithm, 7 for the HMAC-SHA-256 authentication algorithm, 51 for the SM3 authentication algorithm, and 52 for the HMAC-SM3 authentication algorithm.

   When the local device uses TCP to communicate with a peer device from another vendor, make sure both devices have the same kind value and algorithm ID settings. If they do not, modify the settings on the local device.

4. (Optional.) Set a tolerance time for accept keys in the keychain.

   accept-tolerance { *value* | **infinite** }

   By default, no tolerance time is configured for accept keys in a keychain.

   If authentication information is changed, information mismatch occurs on the local and peer devices, and the service might be interrupted. Use this command to ensure continuous packet authentication.

5. Create a key and enter key view.

   key *key-id*

6. Configure the key.

   - Specify an authentication algorithm for the key.

     authentication-algorithm { **hmac-md5** | **hmac-sha-1** | **hmac-sha-256** | **hmac-sm3** | **md5** | **sm3** }

     By default, no authentication algorithm is specified for a key.

   - Configure a key string for the key.

     key-string { **cipher** | **plain** } *string*

     By default, no key string is configured.

   - Set the daily, weekly, monthly, or yearly sending lifetime in periodic time mode for the key.

     send-lifetime daily *start-day-time* **to** *end-day-time*

     send-lifetime date { *month-day*&<1-31> | *start-month-day* **to** *end-month-day* }

     send-lifetime day { *week-day* | *start-week-day* **to** *end-week-day* }

     send-lifetime month { *month* | *start-month* **to** *end-month* }

     By default, the sending lifetime is not configured for a key.

   - Set the daily, weekly, monthly, or yearly receiving lifetime in periodic time mode for the key.

     accept-lifetime daily *start-day-time* **to** *end-day-time*

     accept-lifetime date { *month-day*&<1-31> | *start-month-day* **to** *end-month-day* }

     accept-lifetime day { *week-day* | *start-week-day* **to** *end-week-day* }

     accept-lifetime month { *month* | *start-month* **to** *end-month* }

     By default, the receiving lifetime is not configured for a key.

- (Optional.) Specify the key as the default send key.

  default-send-key

  By default, a keychain does not have a default send key.

  You can specify only one key as the default send key in a keychain.

Display and maintenance commands for keychain

Execute **display** commands in any view.

Task	Command
Display keychain information.	**display keychain** [**name** *keychain-name* [**key** *key-id*]]

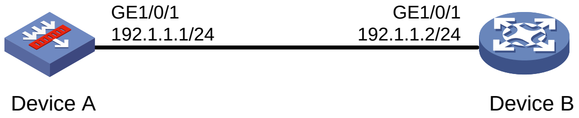
Keychain configuration examples

Example: Configuring keychains

Network configuration

As shown in Figure 1, establish an OSPF neighbor relationship between Device A and Device B, and use a keychain to authenticate packets between the devices. Configure key 1 and key 2 for the keychain and make sure key 2 is used immediately when key 1 expires.

Figure 1 Network diagram



Procedure

1. Assign IP addresses to interfaces and configure routes, security zones, zone pairs, and interzone policies. Make sure the network connections are available. (Details not shown.)
2. Configure Device A:

   # Configure OSPF.

   ```
   <DeviceA> system-view
   [DeviceA] ospf 1 router-id 1.1.1.1
   [DeviceA-ospf-1] area 0
   [DeviceA-ospf-1-area-0.0.0.0] network 192.1.1.0 0.0.0.255
   [DeviceA-ospf-1-area-0.0.0.0] quit
   [DeviceA-ospf-1] quit
   ```

   # Create a keychain named **abc**, and specify the absolute time mode for it.

   ```
   [DeviceA] keychain abc mode absolute
   ```

   # Create key **1** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

   ```
   [DeviceA-keychain-abc] key 1
   [DeviceA-keychain-abc-key-1] authentication-algorithm md5
   [DeviceA-keychain-abc-key-1] key-string plain 123456
   ```

```
[DeviceA-keychain-abc-key-1] send-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[DeviceA-keychain-abc-key-1] accept-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[DeviceA-keychain-abc-key-1] quit
```

# Create key **2** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[DeviceA-keychain-abc] key 2
[DeviceA-keychain-abc-key-2] authentication-algorithm hmac-md5
[DeviceA-keychain-abc-key-2] key-string plain pwd123
[DeviceA-keychain-abc-key-2] send-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[DeviceA-keychain-abc-key-2] accept-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[DeviceA-keychain-abc-key-2] quit
[DeviceA-keychain-abc] quit
```

# Configure GigabitEthernet 1/0/1 to use keychain **abc** for authentication.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ospf authentication-mode keychain abc
[DeviceA-GigabitEthernet1/0/1] quit
```

3. Configure Device B:

# Configure OSPF.

```
<DeviceB> system-view
[DeviceB] ospf 1 router-id 2.2.2.2
[DeviceB-ospf-1] area 0
[DeviceB-ospf-1-area-0.0.0.0] network 192.1.1.0 0.0.0.255
[DeviceB-ospf-1-area-0.0.0.0] quit
[DeviceB-ospf-1] quit
```

# Create a keychain named **abc**, and specify the absolute time mode for it.

```
[DeviceB] keychain abc mode absolute
```

# Create key **1** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[DeviceB-keychain-abc] key 1
[DeviceB-keychain-abc-key-1] authentication-algorithm md5
[DeviceB-keychain-abc-key-1] key-string plain 123456
[DeviceB-keychain-abc-key-1] send-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[DeviceB-keychain-abc-key-1] accept-lifetime utc 10:00:00 2015/02/06 to 11:10:00
2015/02/06
[DeviceB-keychain-abc-key-1] quit
```

# Create key **2** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[DeviceB-keychain-abc] key 2
[DeviceB-keychain-abc-key-2] key-string plain pwd123
[DeviceB-keychain-abc-key-2] authentication-algorithm hmac-md5
[DeviceB-keychain-abc-key-2] send-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[DeviceB-keychain-abc-key-2] accept-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
```

```
[DeviceB-keychain-abc-key-2] quit
[DeviceB-keychain-abc] quit
```

# Configure GigabitEthernet 1/0/1 to use keychain **abc** for authentication.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ospf authentication-mode keychain abc
[DeviceB-GigabitEthernet1/0/1] quit
```

Verifying the configuration

1. When the system time is within the lifetime from 10:00:00 to 11:00:00 on the day 2015/02/06, verify the status of the keys in keychain **abc**.

   # Display keychain information on Device A. The output shows that key 1 is the valid key.

```
[DeviceA] display keychain

 Keychain name          : abc

Configuring crypto engines

About crypto engines

Crypto engines encrypt and decrypt data for service modules.

Crypto engine types

Crypto engines include the following types:

- **Hardware crypto engines**—A hardware crypto engine is a coprocessor integrated on a CPU or hardware crypto card. Hardware crypto engines can accelerate encryption/decryption speed, which improves device processing efficiency. You can enable or disable hardware crypto engines globally as needed. By default, hardware crypto engines are enabled.
- **Software crypto engines**—A software crypto engine is a set of software encryption algorithms. The device uses software crypto engines to encrypt and decrypt data for service modules. They are always enabled. You cannot enable or disable software crypto engines.

Crypto engine processing mechanism

If you disable hardware crypto engines, the device uses only software crypto engines for data encryption/decryption. If you enable hardware crypto engines, the device preferentially uses hardware crypto engines. If the device does not support hardware crypto engines, or if the hardware crypto engines do not support the required encryption algorithm, the device uses software crypto engines for data encryption/decryption.

Crypto engines provide encryption/decryption services for service modules, for example, the IPsec module. When a service module requires data encryption/decryption, it sends the desired data to a crypto engine. After the crypto engine completes data encryption/decryption, it sends the data back to the service module.

Display and maintenance commands for crypto engines

Execute **display** commands in any view and **reset** commands in user view.

Task	**Command**
Display crypto engine information.	**display crypto-engine**
Display crypto engine statistics.	**display crypto-engine statistics** [**engine-id** *engine-id* **slot** *slot-number*]
Clear crypto engine statistics.	**reset crypto-engine statistics** [**engine-id** *engine-id* **slot** *slot-number*]

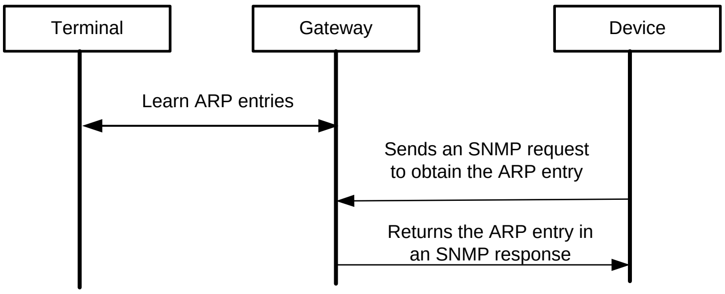
Configuring MAC address learning through a Layer 3 device

About MAC address learning through a Layer 3 device

This feature enables the device to learn the MAC address of a terminal (a PC for example) when a Layer 3 device exists between the device and the terminal through SNMP for network traffic control.

Working mechanism

Figure 1 MAC address learning through a Layer device workflow



Terminal
Gateway
Device
Learn ARP entries
Sends an SNMP request to obtain the ARP entry
Returns the ARP entry in an SNMP response

As shown in Figure 1, MAC address learning through a Layer 3 device proceeds as follows:

1. The gateway learns the IP-MAC binding of the terminal, and then generates an ARP entry.
2. The device sends SNMP requests to the gateway at the specified intervals to request the ARP entry.
3. The gateway sends a response that contains the ARP entry to the device.
4. Upon receiving the response, the device saves the ARP entry in the memory. Then it can learn the MAC address of the terminal.

Entry aging

ARP entries learned through a Layer 3 device will be automatically deleted when the aging timer expires, or can be cleared using the **`reset snmp-server arp-sync table`** command.

Restrictions and guidelines: MAC address learning through a Layer 3 device configuration

- MAC addresses learned using this feature can be used for policy packet filtering and packet information recording in the IPS logs.
- Only MAC addresses mapped from IPv4 addresses can be learned.
- Make sure no NAT devices exist between the device and the Layer 3 device.
- This feature is not applicable to a VRF network.

Prerequistes

Make sure SNMP agent has been enabled and a community name has been configured on the Layer 3 device. For information about SNMP, see SNMP configuration in *Network Management and Monitoring*.

MAC address learning through a Layer 3 device configuration tasks at a glance

To configure MAC address learning through a Layer 3 device, perform the following tasks:

1. Enabling ARP entry synchronization through SNMP
2. Configuring the target Layer 3 device
3. (Optional.) Setting the parameters for ARP entry synchronization

Enabling ARP entry synchronization through SNMP

About this task

With this feature enabled, the device acts as an NMS to learn all ARP entries on a Layer 3 device (agent) to obtain the MAC address of the Layer 3 device.

Procedure

1. Enter system view.

   system-view

2. Enable ARP entry synchronization through SNMP.

   snmp-server arp-sync enable

   By default, ARP entry synchronization through SNMP is disabled.

Configuring the target Layer 3 device

1. Enter system view.

   system-view

2. Configure the target Layer 3 device for ARP entry synchronization through SNMP.

   SNMP v2c:

   snmp-server arp-sync target-host address *ip-address* **community** { **simple** | **cipher** } *community-name* **v2c**

   SNMP v3:

   snmp-server arp-sync target-host address *ip-address* **usm-user v3** *user-name* [{ **simple** | **cipher** } **authentication-mode** { **md5** | **sha** } *auth-password* [**privacy-mode** { **aes128** | **des56** } *pri-password*]]

   By default, no target Layer 3 device is configured for ARP entry synchronization through SNMP.

Setting the parameters for ARP entry synchronization

About this task

With this feature configured, the device sends SNMP requests for ARP entry synchronization to the target Layer 3 device at the specified intervals. If the device does not receive an SNMP response before the timeout expires within the specified interval, the device re-sends SNMP requests.

Procedure

1. Enter system view.

   `system-view`

2. Set the parameters for ARP entry synchronization.

   `snmp-server arp-sync` { **`interval`** *`interval`* | **`timeout`** *`time`* } *

   By default, the interval for sending SNMP requests is 5 seconds and the timeout for SNMP responses is 3 seconds.

Display and maintenance commands for

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display the ARP entries synchronized through SNMP.	**`display snmp-server arp-sync table`**
Clear the ARP entries synchronized through SNMP.	**`reset snmp-server arp-sync table`**

MAC address learning through a Layer 3 device configuration examples

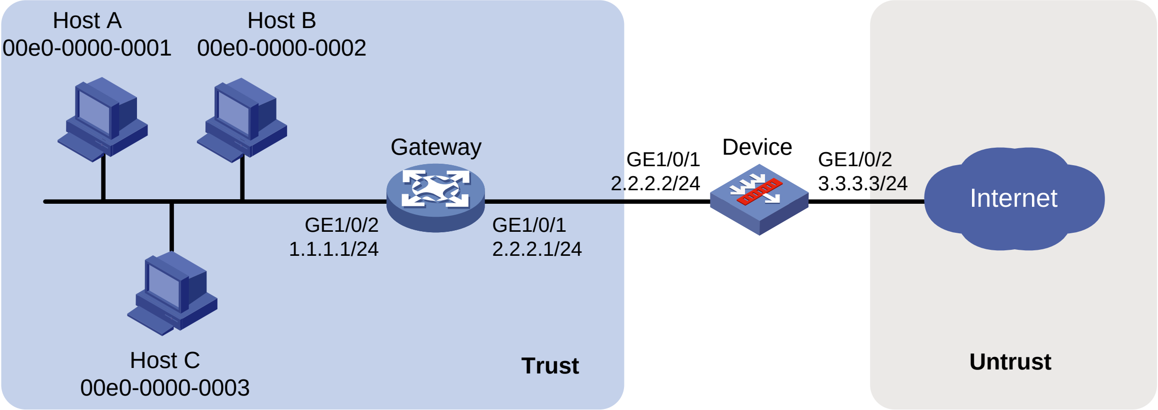
Example: Configuring MAC address learning through a Layer 3 device

Network configuration

As shown in Figure 2, hosts in an internal network are connected to the device through a Layer 3 gateway and the device is connected to the Internet.

- Configure MAC address learning through a Layer 3 device to ensure that the device can learn the MAC addresses of the hosts through the gateway.
- Configure security policies by using the learned MAC addresses to allow only Host A and Host B to access the Internet.

Figure 2 Network diagram



Procedure

1. Configure the gateway:

   # Specify an IP address for each interface and configure routing features to ensure network reachability. (Details not shown.)

   # Configure SNMPv2c, and create the read-only community with the plaintext form name **public**.

```
<Gateway> system-view
[Gateway] snmp-agent sys-info version v2c
[Gateway] snmp-agent community read simple public
```

2. Configure the device:

   a. Assign IP addresses to interfaces:

   # Assign an IP address to interface GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 2.2.2.2 255.255.255.0
[Device-GigabitEthernet1/0/1] quit
```

   # Assign IP addresses to other interfaces in the same way. (Details not shown.)

   b. Configure settings for routing.

   This example configures static routes, and the next hop in the route to the Internet is 3.3.3.1.

```
[Device] ip route-static 1.1.1.0 24 2.2.2.1
[Device] ip route-static 0.0.0.0 0 3.3.3.1
```

   c. Add interfaces to security zones.

```
[Device] security-zone name trust
[Device-security-zone-Trust] import interface gigabitethernet 1/0/1
[Device-security-zone-Trust] quit
[Device] security-zone name untrust
[Device-security-zone-Untrust] import interface gigabitethernet 1/0/2
[Device-security-zone-Untrust] quit
```

   d. Configure a security policy.

   # Configure a rule named **rule1** to allow the device to access the gateway.

```
[Device] security-policy ip
[Device-security-policy-ip] rule name rule1
[Device-security-policy-ip-0-rule1] source-zone local
[Device-security-policy-ip-0-rule1] destination-zone trust
```

```
[Device-security-policy-ip-0-rule1] source-ip-host 2.2.2.2
[Device-security-policy-ip-0-rule1] destination-ip-host 2.2.2.1
[Device-security-policy-ip-0-rule1] action pass
[Device-security-policy-ip-0-rule1] quit
```

# Configure a rule named **rule2** to permit traffic only from MAC object group **groupmac** to the Internet.

```
[Device-security-policy-ip] rule name rule2
[Device-security-policy-ip-1-rule2] source-zone trust
[Device-security-policy-ip-1-rule2] destination-zone untrust
[Device-security-policy-ip-1-rule2] source-mac groupmac
[Device-security-policy-ip-1-rule2] action pass
